Method 320 QA Data

Quality control measures for the FTIR measurements included calibrations, bias checks, and system and instrument leak checks as well as verification and documentation of instrument performance. The FTIR system was challenged with direct and system calibration checks for several components. A CTS (calibration transfer standard) containing ethylene (C_2H_4, nominally 10 ppm) was used for local and system calibration checks and to verify the system pathlength. Nitrogen gas from a nitrogen cylinder was used for local and system zero checks. Four gas standards hydrogen chloride (HCl)/sulfur hexafluoride (SF6), hydrogen fluoride (HF)/SF6, hydrogen cyanide (HCN)/SF6, and formaldehyde /SF6) were used for direct, system, and dynamic matrix spiking calibrations.

Testing was conducted on the HRSG Main Stack during normal conditions using one MKS FTIR analyzer and a heated, extractive sampling system.

Measurement Equipment Leak Checks, Detector Linearity Check

The sampling system was checked for leaks after assembly on-site and allowing all heated equipment to stabilize. The sampling system was leak-checked by capping the end of the sample probe and observing the sampling system flow rate as measured by an inline rotameter. The rotameters indicated zero flow, showing the sampling system was leak free.

A detector linearity check was performed by verifying that detector response in a region with no response had no detectable signal.

CTS Calibration Check

Direct and system CTS calibration measurements were made each day prior to the test runs and upon completion of testing. The 10.07 ppm ethylene (C_2H_4) gas standard (cylinder CC282663) was used to demonstrate instrument performance. The repeatability (% RPD) of each measurement is reported that is a calculation comparing two successive measurements of the CTS gas. The % RPD is a measure of the difference between two consecutive measurements and indicates the calibration gas had stabilized. The CTS gas calibrations met method requirements.

FTIR CTS Response Summary

The sampling system response time was determined using the System CTS calibration. The CTS was measured in a system calibration immediately after a system zero calibration. A response time of 2 minutes was measured based on measuring 95% of the CTS cylinder concentration.

Direct and System Zero Calibration Check

The FTIR system was challenged with nitrogen gas (AirGas Cylinder CC313009) flowed directly to the analyzer as well as through the sampling system at the start and end of each test day. There is no method requirement for the zero-calibration check, but TRC has established a quality assurance standard requiring an acceptable zero calibration be demonstrated by detection of analytes (except H_2O and CO_2) below 1 ppm. The table below shows the zero measurement for selected analytes; acceptable zero calibration values were obtained for all measured compounds. The background concentrations were well below stack levels.

Analysis Confirmation by Manual Subtraction

In order to confirm the accuracy of the computer analysis, a separate manual analysis was conducted by subtracting the scaled reference spectra of the analyzed compounds from a representative spectrum from the testing. The results from this scaled subtraction are compared with the computer analysis to verify accuracy. One spectral file from the HRSG Main Stack test location was used to confirm the computer CLS (Classical Least Squares) analysis. The spectra used were:

- HRSG STACK_000418.LAB, collected 2/6/2023 at 12:30 at the HRSG Main Stack Location during Run 3 and analyzed using MKS Method file "Cement-Coal-EGU Method 191C". This spectrum is representative of the measured emissions.

The reference spectra for the compounds identified in this spectrum were sequentially subtracted, and the subtraction factor (the ratio between the spectrum measured at the source and reference spectrum) was used to calculate the measured concentration. The table below compares the calculated and manually subtracted concentrations. In some cases, the percent difference between the two analyses is relatively large, but the absolute concentration difference is small. "ND" indicates the compound was not detected in the computerized analysis, and this was confirmed by manual subtraction. This comparison confirms the spectral analysis accuracy and verifies that additional compounds are not present in the matrix that could be interferents from the analytes of interest.

Dynamic Matrix Spiking Calibration

Dynamic matrix spiking calibrations were conducted at the HRSG Main Stack test location using the gas standards listed in Table 5; the direct measured cylinder concentrations were used to calculate spike recoveries. A mass flow meter and needle valve were used to control the spike gas flow rate. The spiking results are summarized in the tables below. The acceptable limits for spike recovery in the EPA Method 320 are 70-130% recovery. The dilution ratio is calculated using the tracer gas measurement, and in turn the expected spike value is calculated from the dilution ratio. The spiking met all method requirements.

Dynamic Matrix Example Calculation for HCl

The example calculations demonstrate how spike recovery for HCl was calculated. First the Dilution Ratio for the spike flow rate that was used is calculated from the measured SF_6 tracer concentration and the SF_6 unspiked and spiked measurements:

Dilution Ratio

DILUTION RATIO = TRACER GAS (SPIKED) - TRACER GAS (UNSPIKED) / TRACER GAS MEASURED CONCENTRATION

Tracer Spiked =	0.305	ppm
Tracer Unspiked Spiked =	-0.004	ppm
Tracer Measured Concentration =	5.060	ppm
Dilution Ratio =	**0.060**	**or 16.61 : 1**

The total measured spike is the difference between the spiked and unspiked concentrations, but first the unspiked level must be corrected for dilution by the spike. In other words, when the spike is added to the gas stream, the original gas concentration is diluted by the presence of the spike, and so is less than the measured unspiked concentration. The unspiked concentration is corrected using the average unspiked measurement and the Dilution Ratios:

Unspiked Concentration (Dilution Correction)

CORRECTED UNSPIKED CONCENTRATION = UNSPIKED CONCENTRATION X (1- DILUTION RATIO)

Unspiked Concentration =	2.81	ppm
Dilution Ratio =	0.060	
Corrected Unspiked Concentration =	**2.64**	**ppm**

The expected spike concentration is calculated from the direct measured concentration and the dilution ratio:

Expected Spike Concentration

EXPECTED CONCENTRATION = SPIKE GAS MEASURED CONCENTRATION X DILUTION RATIO

Spike Measured Concentration =	23.88	ppm
Dilution Ratio =	0.060	
Expected Spike Concentration =	**1.44**	**ppm**

The measured spike concentration is the difference between the spiked and corrected unspiked concentrations:

Measured Spike Concentration

MEASURED SPIKE CONCENTRATION = SPIKED - UNSPIKED CONCENTRATION (DILUTION CORRECTED)

Spiked Concentration =	3.77	ppm
Unspiked Concentration	2.64	ppm
Measured Spike Concentration =	**1.14**	**ppm**

The Spike Recovery is then calculated from the ratio of the expected and measured spike concentrations:

Percent Spike Recovery

$$\% \text{ SPIKE RECOVERY} = 1 - \frac{(\text{EXPECTED SPIKE} - \text{MEASURED SPIKE})}{\text{EXPECTED SPIKE}} \times 100$$

Expected Spike =	1.44	ppm
Measured Spike =	1.14	ppm
Percent Spike Recovery =	**79.0%**

EPA Protocol Calculations

The EPA FTIR protocol defines two measures of FTIR data quality, the Minimum Analytical Uncertainty (MAU) and the Fractional Model Uncertainty (FMU). These are analogous to the Instrumental Detection Limit and Percent Measurement Uncertainty used in other analytical measurements. The MAU is a measure of the noise limited detection limit and does not take into account the interferences encountered in measuring a complex gas matrix. The FMU is a more true detection limit taking into account the interferences in the gas matrix.

The noise-limited detection is defined in EPA Reference Method 320 as Minimum Analytical Uncertainty defined as:

$$\mathbf{MAU} = \frac{RMS_{noise} * [\nu_u - \nu_l]}{\frac{\mathbf{A}_i}{\mathbf{C}_i * \mathbf{L}_i}}$$

In this equation RMS_{noise} is the RMS (root mean square) noise in the analysis region between ν_u and ν_l, A_i the area of the ith reference spectrum in this analysis region, while C_i, L_i are the concentration and path length of the reference spectrum. MAU has the units of ppm*m and represents the lowest detection possible with the system as limited by system noise. If the system has a path length of L the ppm limit is (1/L) time this value.

The true detection of an FTIR system is usually limited not by noise but by interference from other compounds. The FMU attempts to model this by looking at the spectral residual resulting after analysis (what is left over that the analysis routines have not accounted for) and comparing this to the reference spectra. FMU is defined as:

$$\mathbf{FMU} = \frac{RMS_{resid} * (\nu_u - \nu_l)}{\frac{\mathbf{A}_i}{(\mathbf{C}_i * \mathbf{L}_i)} * C_i^{cls}}$$

Here RMS_{resid} is the RMS of the spectral residual in the analysis region from ν_u to ν_l, A_i is (as above) the area of the ith reference spectrum normalized to its concentration (C_i) and path length (L_i), and C_i^{cls} is the (ppm*m) concentration provided by the CLS-routine (classical least squares) for the ith analyte. The FMU is a percentage representing the percent-uncertainty of the analysis system near detection limit. The CLS error bar provided by most CLS routines is very similar to this value as it is derived from the spectral residual and the references as well.

An equivalent extractive FTIR test method has been published by ASTM (ASTM D6348 12, Standard Test Method for Determination of Gaseous Compounds by Extractive Direct Interface Fourier Transform Infrared (FTIR) Spectroscopy). This test method includes additional equations

to calculate the MDC (minimum detectable concentration). For example, the MDC #1 and MDC#3 are defined as:

$$\boldsymbol{MDC\#1} = \frac{RMS_{noise}}{RMS_{ref}} \times \frac{C_i \times L_i}{L_{cell}}$$

$$\boldsymbol{MDC\#3} = \frac{RMS_{resid}}{RMS_{ref}} \times \frac{C_i \times L_i}{L_{cell}}$$

These equations are shown in a different format than the ASTM method so that the factors defined above can be expressed in the same fashion. The RMS_{ref} is the RMS of the reference spectrum in the analysis region from v_u to v_l and L_{cell} is the pathlength of the gas cell used in the test program. The ASTM Method also states that the spectral residual returned by the CLS analysis program of the FTIR analyzer can be used as MDC#3.

The figure below summarizes the FTIR Protocol and ASTM calculations for this test program. A single spectrum from the HRSG Main Stack test location (file name HRSG STACK_000418.LAB, collected 2/6/2023 at 12:30 during Run 3) was selected as representative of the test runs and used for the calculations. The table lists the measured concentration and residual from the CLS analysis and the calculated MAU and FMU for the analytes of interest. The different calculations yield a wide range of concentrations. The absorbance features are plainly visible (and can be analyzed) to concentrations below 0.1 ppm. The spectral residuals indicate that the measurements were performed with sufficient accuracy to quantify the analyte concentrations. Please note the HF analysis wave number range is not compatible with the support spectra and therefore calculations were not performed for HF.

EPA Method 301 Validations

TRC performed a Method 301 validation for HCl at the HRSG Main Stack. One sampling system (heated probe, umbilical, pump, and manifold) was used to spike with an HCl/SF_6 calibration gas (cylinder CC481144, 25.22 ppm HCl/5.104 ppm SF_6) and for unspiked sampling. The FTIR system alternated sampling between the spiked and unspiked gas streams to collect the required 12 paired samples.

The Table below summarizes the Validation measurements and calculations. Because the Relative Bias was <10%, the calculated correction factor of 1.05 did not have to be applied. The Plot below shows the spiked and unspiked measurements for HCl and SF_6.

TRC also performed a Method 301 validation for HF at the HRSG Main Stack. Two identical sampling systems (heated probe, umbilical, pump, and manifold) were assembled. One sampling system was spiked with an HF/SF_6 calibration gas (cylinder CC752703, 25.9 ppm HF/5.47 ppm SF_6) and the second sampling system was unspiked. The FTIR alternated sampling between the spiked and unspiked gas streams to collect the required 12 paired samples. Separate sampling systems were used for the spiked and unspiked samples in order to achieve faster time response. HF is slow to equilibrate in the sampling system, and by continuously sampling the spiked stream the time response was improved. An "overspiking" technique was employed to improve response time. The spike flow was increased while the unspiked gas stream was measured, and then the spike flow was reduced to measure the spiked concentration.

The Table below summarizes the Validation measurements and calculations. Because the Relative Bias was <10%, the calculated correction factor of 1.08 did not have to be applied. The Plot below shows the spiked and unspiked measurements for HF and SF_6.

Bias $B = S_m - CS = 6.17 - 6.48 = -0.31$

Bias Test using t-statistic $t = \frac{|B|}{SDM} = \frac{0.31}{0.512} = 0.61$

IF t>2.201 Bias is statistically significant and correction can be applied

Pre-Test Thermocouple Calibration Checks

Analyst:	Dave Wells
Date:	2/2/2023
Project Number:	508369
Client:	Primary Energy
Test Location:	HRSG Main Stack

(See SOP AM-CAL-005 for instructions)

Console/Meter Box ID #	E-31
Probe ID#	797
Test Location/Measurement Point Info:	Main Stack
NIST Thermometer ID #	CL23A

Procedure 1: Calibrate thermocouple against a reference thermometer.

After each test run series, check the accuracy (and, hence, the calibration) of each thermocouple system at ambient temperature, or any other temperature, within the range specified by the manufacturer, using a reference thermometer.

Procedure 2: Check the response of the thermocouple to a change in temperature.

Check the "continuity" of the thermocouple by subjecting it to a change in temperature (e.g., removing it from the stack or touching an ice cube). This step will also check for loose connections and reversed connections.

Grade of Product: EPA PROTOCOL STANDARD

Part Number:	E02AI99E15W0021	Reference Number:	54-402163057-1
Cylinder Number:	CC500607	Cylinder Volume:	146.2 Cubic Feet
Laboratory:	124 - Chicago (SAP) - IL	Cylinder Pressure:	2015 PSIG
PGVP Number:	B12021	Valve Outlet:	660
Gas Code:	NO2,BALA	Certification Date:	Jul 15, 2021

Expiration Date: Jul 15, 2024

Certification performed in accordance with "EPA Traceability Protocol for Assay and Certification of Gaseous Calibration Standards (May 2012)" document EPA 600/R-12/531, using the assay procedures listed. Analytical Methodology does not require correction for analytical interference. This cylinder has a total analytical uncertainty as stated below with a confidence level of 95%. There are no significant impurities which affect the use of this calibration mixture. All concentrations are on a mole/mole basis unless otherwise noted. The results relate only to the items tested. The report shall not be reproduced except in full without approval of the laboratory. Do Not Use This Cylinder below 100 psig, i.e. 0.7 megapascals.

Target Response is 95% of the Pre 1 System Response from the Upscale Bias Test

Start time is the time at which gas is introduced upstream of the probe.

Time at target is the time at which the required target response is achieved.

Response time is the difference between the two.

PGVP Number:	B12021	Valve Outlet:	660
Gas Code:	CO,CO2,NO,NOX,SO2,BALN	Certification Date:	Oct 09, 2021

Expiration Date: Oct 09, 2024

Certification performed in accordance with "EPA Traceability Protocol for Assay and Certification of Gaseous Calibration Standards (May 2012)" document EPA 600/R-12/531, using the assay procedures listed. Analytical Methodology does not require correction for analytical interference. This cylinder has a total analytical uncertainty as stated below with a confidence level of 95%. There are no significant impurities which affect the use of this calibration mixture. All concentrations are on a mole/mole basis unless otherwise noted. The results relate only to the items tested. The report shall not be reproduced except in full without approval of the laboratory. Do Not Use This Cylinder below 100 psig, i.e. 0.7 megapascals.
