Increase Walking Survey from a 5- to 3-Year Basis

Technology/Practice Overview

Description
Methane emissions from valves, flanges, and connectors on gas service connections can be significant, as well as a safety hazard. One partner has reported successfully reducing these emissions through an improvement in their inspection program.

By decreasing the time between fugitive emissions surveys on their gas service connections, from five to three years, methane leaks were discovered earlier. Those pieces of equipment that are found to be emitting gas are tightened, if applicable, or scheduled for maintenance.

Operating Requirements
Additional personnel and fugitive emissions detectors may be necessary.

Applicability
Gas delivery facilities for which leak surveys are being performed at the minimum regulatory frequency may be good candidates for this practice.

Methane Emissions
Methane emissions result from leaks at flanges, valves, and connectors throughout the gas delivery network. With early detection, methane leaks can be mitigated more promptly, therefore avoiding gas losses and reducing methane emissions. One partner reported finding and repairing one leaking service connection per 100 service connections inspected. A program that inspects all services in three years rather than five years will find about 15 percent of the leaks a year earlier. The partner reported methane savings ranging from 1,400 Mcf to 1,665 Mcf for one year.

Economic Analysis

**Basis for Costs and Emissions Savings**

Methane emissions reductions of 1,500 Mcf per year were estimated for a distribution system with 250,000 service connections and one leak repair per 100 service connections inspected, saving 0.5 scf per hour per repair.

One partner reported an incremental cost of $11,000 when increasing walking survey frequency from a 5– to 3– year basis for a pipeline system of 2,900 miles in length. It is estimated that about $1,000 of the $11,000 corresponds to additional equipment and repair materials, while the remaining $10,000 correspond to labor costs. The same partner reported emissions savings of approximately 1,400 Mcf.

**Discussion**

This practice can provide a payback in less than three years. To implement more frequent surveys, additional costs may include new fugitive emissions detectors, extra personnel to perform surveys and repair the leaks, and new/replacement parts. These costs should be largely offset by the incremental benefits of detecting leaks earlier and preventing future methane losses in the service connections.

---

**Methane Content of Natural Gas**

The average methane content of natural gas varies by natural gas industry sector. The Natural Gas STAR Program assumes the following methane content of natural gas when estimating methane savings for Partner Reported Opportunities.

EPA provides the suggested methane emissions estimating methods contained in this document as a tool to develop basic methane emissions estimates only. As regulatory reporting demands a higher-level of accuracy, the methane emission estimating methods and terminology contained in this document may not conform to the Greenhouse Gas Reporting Rule, 40 CFR Part 98, Subpart W methods or those in other EPA regulations.
