ACKNOWLEDGMENTS

The Office of Air and Waste Management of the Environmental Protection Agency would like to thank the Regional Offices and the many state and local agencies that have contributed to air quality data. Thanks also are extended to the Environmental Monitoring and Support Laboratory, RTP, for providing air quality data from the National Air Surveillance Network.

This report has been reviewed by the Monitoring and Data Analysis Division, Office of Air Quality Planning and Standards, Office of Air and Waste Management, Environmental Protection Agency, and approved for publication. Mention of trade names or commercial products does not constitute endorsement or recommendation for use. Copies are available free of charge to Federal employees, current contractors and grantees, and nonprofit organizations - as supplies permit - from the Air Pollution Technical Information Center, Environmental Protection Agency, Research Triangle Park, North Carolina 27711; or copies may be purchased from the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20460.

LIST OF FIGURES

LIST OF TABLES

ABSTRACT

This report presents a comprehensive tabulation of the nation's air quality and monitoring activities for 1974. These summaries are based on data acquired through extensive monitoring activities conducted by Federal, state and local air pollution control agencies, and compiled according to the nation's 247 Air Quality Control Regions. Information is provided on the five pollutants for which National Ambient Air Quality Standards have been set (suspended particulate matter, sulfur dioxide, carbon monoxide, oxidants, and nitrogen dioxide). Analyses of pollutant trends are presented for the period 1970-1974, plus a discussion of non-urban ozone and estimates of nationwide emissions for the period 1970-1974.

LIST OF ABBREVIATIONS

AQCR	Air Quality Control Region

SMSA	Standard Metropolitan Statistical Area
SO_2	Sulfur dioxide
SO_x	Sulfur oxides
TSP	Total suspended particulates

MONITORING AND AIR QUALITY TRENDS REPORT, 1974

1. INTRODUCTION

1.1 GENERAL DESCRIPTION

Progress toward achieving compliance with the National Ambient Air Quality Standards (NAAQS) is measured through the collection and analysis of air quality data. These data are obtained by state and local control agencies through their monitoring activities, and are forwarded to the U.S. Environmental Protection Agency (EPA). This report, the fourth in a series issued by EPA[1-3], summarizes (1) the air quality data collected in 1974 and (2) the scope of monitoring activities for that year. Trends in air quality over recent years are discussed at length in two sections of this report. Other sections treat selected aspects of data interpretation.

Data are included in this report on five of the six pollutants for which NAAQS have been set: total suspended particulate matter (TSP), sulfur dioxide (SO_2), carbon monoxide (CO), oxidants (O_x), and nitrogen dioxide (NO_2). As yet, no reference method has been designated by EPA for NO_2; the data presented in this report were obtained by one or more of eight methods that are regarded as candidates for the reference method or as possible equivalent methods.

The nonmethane hydrocarbons guide (NMHC) is used for meeting oxidant standards because of the relationship between emission of hydrocarbons and the production of oxidants; but monitoring of hydrocarbons is not currently required. Thus, no information is given in this report for this group of pollutants.

The principal sources of air quality data in 1974 were the many monitoring networks operated by or responsible to the state air pollution control agencies. Data acquired through these state-supervised monitoring networks must be submitted quarterly to EPA's National Aerometric Data Bank (NADB). This schedule is designed to facilitate periodic appraisal, nationwide, of progress in implementing the monitoring networks themselves and progress toward achieving the air quality standards. According to this schedule, data for a calendar quarter are to be submitted through one of EPA's ten Regional Offices, entered in the data bank, and made accessible for summarization within 120 days after the close of that quarter.

The summaries in this report reflect all 1974 data received by September 1, 1975.

Reporting stations have been included in the data tables in the Appendices if they have submitted at least three sample values from monitors which collect an integrated sample over a 24-hour period or at least 400 hourly values from a continuous monitor.

Annual means of pollutants have been calculated only if four valid quarters of data have been collected and reported. A tentative annual mean (followed by a question mark) is calculated if at least two but fewer than four valid quarters of data are present.

Extraordinarily high maximum values have been flagged (#) in the Appendices of this report. Some may be the consequence of measurement or data processing errors; some may be legitimate values. This is the only publication in which such values will be flagged as being suspect. Because it is the responsibility of the agencies submitting the data to check suspect values and delete erroneous ones, routine data retrievals from EPA's National Air Data Bank will not identify these potentially anomalous values.

The monitoring results reported here are by no means comprehensive. For example, diffusion modeling of emissions from large point sources of SO_2 indicates areas in which violations of NAAQS have probably occurred, even though no actual monitoring data have been reported. Also, data from some short-term or sporadic monitoring for such purposes as special studies and complaint investigations are usually not submitted to the National Air Data Bank because the data are not extensive enough to provide equitable comparisons with routine data from permanent monitoring sites.

The special topics section of this report contains a review of urban-nonurban oxidant investigations and a summary of estimated nationwide emissions for 1970 through 1974.

2. SUMMARY

Air quality in the United States in 1974 was in many respects similar to that reported for 1973. Air Quality Standards were exceeded at approximately the same percentage of reporting stations, with one exception: there was an evident decline in the proportion of stations at which the 8-hour carbon monoxide standard was exceeded.

The dicussion that follows is presented in condensed form in Table 2-1.

The primary annual standard for total suspended particulates (TSP) was exceeded at 23 percent of the high-volume air sampler (high-vol) stations reporting a valid year's data (467 out of 2004) in 1974. (A valid year of data is defined as a data record containing at least five 24-hour samples in each quarter or 75 percent of the possible hourly values from a continuous monitor.) These 467 stations represent 111 Air Quality Control Regions (AQCRs) in which the annual particulate standard was exceeded. This is 56 percent of the 198 AQCRs reporting at least one station with valid yearly data. All 247 AQCRs, however should be reporting at least one such station.

The primary 24-hour standard for TSP was exceeded at less than one-tenth of all high-vol stations reporting—326 out of 3788, including stations reporting minimal* data; however, these 326 stations represent some 40 percent of the AQCRs reporting such data (99 out of 236).

The annual sulfur dioxide (SO_2) standard was exceeded at only 3 percent of the stations** reporting valid annual means (31 out of 1030); these stations represent 11 out of 155 AQCRs reporting a full

---

*At least three 24-hour high-vol or bubbler samples, or 400 hourly values from continuous monitors.

**These figures on SO_2 violations may be subject to reevaluation if they were based on measurements taken with 24-hour bubbler samplers. Preliminary results from a current review of this sampler's chemistry indicate that elevated temperatures inside the sampler box may result in the underestimation of ambient concentrations.

Table 2-1. SUMMARY OF 1974 AIR QUALITY TRENDS FOR THE FIVE CRITERIA POLLUTANTS: TSP, SO_2, CO, Ox, AND NO_2

Pollutant	NAAQS exceeded	Reporting stations at which NAAQS were exceeded		AQCRs in which reporting stations showed NAAQS violations	
		No.	%	No.	%
TSP	primary annual	467 of 2004	23	111 of 198[a]	56
TSP	primary 24-hr	326 of 3788[b]	8.6	99 of 236[a]	42
SO_2	primary annual	31 of 1030	3.0	11 of 155[a]	7.0
SO_2	primary 24-hr	99 of 2241[b]	4.4	22 of 210[a]	10
CO	primary 1-hr	27 of 377[b]	7.0	13 of 92	14
CO	primary 8-hr	211 of 377[b]	56	58 of 92	63
Ox/O_3	primary 1-hr	273 of 343[b]	80	76 of 86	88
NO_2	primary annual	18 of 582	3.0	4 of 101	4.0

[a] Each of the 247 AQCRs should have at least one station for TSP and SO_2.

[b] Total number of reporting stations given includes those stations reporting minimal data for 1-hour, 8-hour, or 24-hour measurements.

year's data for at least one station. As with particulates, all 247 AQCRs should be operating at least one sulfur dioxide monitoring station full-time.

The 24-hour SO_2 standard was exceeded at less than 5 percent of all reporting stations—99 out of 2241, including stations reporting minimal data. These 99 stations represent 22 of the 210 AQCRs reporting such data.

Carbon monoxide (CO) data were reported from 377 stations in 92 AQCRs. The 1-hour CO standard was exceeded at 27 stations, or 7 percent, in 13 AQCRs; the 8-hour CO standard was exceeded at 211 stations, or 56 percent, in 58 AQCRs.

Oxidant/ozone (Ox/O_3) data were reported from 343 stations in 86 AQCRs; the 1-hour standard was exceeded at 273 of those stations, 80 percent, representing 76 AQCRs.

Nitrogen dioxide (NO_2) measurement methods are still being reviewed for the purpose of redesignating a Federal reference method. Valid annual data for NO_2 are reported for 582 stations. The method used by these stations are deemed candidates for the status of reference or equivalent methods. These stations represent 101 AQCRs. The currently defined annual standard for NO_2 was exceeded at only 18 stations in 4 AQCRs.

Difficulty by many monitoring stations in acquiring or reporting a full year's data continues to handicap the evaluation of the nation's air quality. From the preceding paragraphs it can be deduced that of the 3788 TSP monitoring stations and 2241 SO_2 monitoring stations reporting minimal data in 1974, only 53 percent and 46 percent, respectively, reported data sufficiently complete to permit calculation of a valid annual mean. Not only can the annual standards for these pollutants be evaluated at only about half the existing stations, but the incidence of 24-hour standard violations remains indeterminate wherever the data record is incomplete. Thus, expediting the flow of data from the state and local monitoring agencies to EPA's national data bank is being given increased emphasis.

Historical trends in air quality levels afford a convenient guide to determining progress in the control of air pollution. For some pollutants, lack of historical data on a national basis limits the inferences that may be made. The recent expansion, however, of air pollution monitoring networks is resulting in data that will serve as a baseline for future trend assessment. Currently, a good historical data base on the national level is available for total suspended particulates and sulfur dioxide primarily in urbanized areas. For oxidants, carbon monoxide, and nitrogen dioxide, historical data are limited and their geographical distribution is very sparse. Therefore, trends for these three pollutants are considered as a series of special cases. The present status of historical data reflects the evolution of air pollution monitoring efforts. For the most part, initial efforts were concentrated on the assessment of total suspended particulates and sulfur dioxide in center-city areas.

Based on composite averages from 1096 sites, total suspended particulate levels have improved from 1970 to 1974. During this period, the composite annual average declined from 80 $\mu g/m^3$ to 66 $\mu g/m^3$. This is an overall decrease of 17 percent, or slightly less than 5 percent per year. This improvement was generally reflected throughout the nation, but specific localities are still experiencing TSP levels in excess of the national ambient air quality standards. The principal sources of the problem are (1) fugitive particulate emissions from various industrial processes; (2) wind-blown dusts from barren terrain, plowed fields, dirt roads, etc., primarily a problem in western states; and (3) the miscellaneous detritus more typical of eastern cities, a sort of urban background that includes salt and grit from the treatment of snowy streets, secondary particulates formed in reactions among gaseous pollutants, and re-entrained particulates from paved areas and roof tops. In spite of continued NAAQS violations, particulate emissions are estimated to have declined 29 percent from 1970 to 1974.

Sulfur dioxide levels have declined from an annual composite average of 38 $\mu g/m^3$ in 1970 to 26 $\mu g/m^3$ in 1974, according to data from 258 sites. This represents an overall decrease of 32 percent or approximately 9 percent per year. Over 90 percent of these sites, however, are located in urbanized areas and caution must be used in generalizing these results. During this time period, estimated emissions decreased 8 percent. The much greater reduction in ambient SO_2 levels may reflect a shift in SO_x emissions away from center-city areas, where monitoring sites are concentrated. Thus, the overall decline in SO_2 levels may be the combined result of emission reductions and redistribution of emissions. The data for 1975 are expected to show additional decline in SO_2 emissions in response to The Clean Air Act's mid-1975 compliance deadline for meeting air quality standards.

Carbon monoxide trends in the few cities for which there are historical data suggest general improvement. This is consistent with the estimated emission reduction for this period. Although peak concentrations have shown little or no decrease in the majority of urban areas, the 8-hour standard has been the more serious problem and there is clear evidence of a reduction in the incidence of violations of that standard. Data from the states of California, New Jersey, New York, and Washington show improvement in the percentage of the time the 8-hour standard is exceeded. Data from Los Angeles and New Jersey indicate that the percentage of time the 8-hour CO standard was exceeded was reduced by approximately one-half from 1970 through 1974, going from about 12 percent to 6 percent. The state of Washington showed consistent progress during the 1971 through 1973 period, and New York State and San Francisco data showed that less than 0.5 percent of the 8-hour values were in excess of the standard. Nationally, the number of CO monitoring sites increased consistently from 1970 through 1974, having grown more than 400 percent between 1970 and 1974 and 25 percent from 1973 to 1974.

California is still the primary source of good historical data on oxidants. Oxidant trends in California continue to show long-term improvement in both peak values and in the incidence of violations. Data from the Los Angeles and San Francisco areas show decreases of 20 to 50 percent in the number of times the 1-hour oxidant standard was exceeded. Recent studies have shown that high oxidant levels are widely distributed, extending even into rural areas. This spatial distribution is an important aspect of the oxidant problem. One of the special topics in Section 5 of this report deals with a study of photochemical oxidant concentrations in rural versus urban areas. In the future, broader interpretations of ambient oxidant levels should be possible because of the expansion of oxidant montitoring networks. The number of oxidant or ozone monitoring stations increased almost 600 percent nationally between 1970 and 1974.

Nitrogen dioxide emissions have increased nationally about 10 percent since 1970. Upward trends of approximately 30 percent in ambient concentrations of NO_2 have been reported in two specific urban areas, Los Angeles and Philadelphia since the mid-sixties. Because of recent changes in measurement methodology for monitoring nitrogen dioxide, few areas have sufficient historical data with which to assess NO_2 trends for 1970 through 1974. Between 1973 and 1974, however, the number of stations reporting a complete year of acceptable NO_2 data increased by almost 800 percent, so that future reports should be able to assess more accurately the national trends in NO_2 levels.

One of the special topics included in this year's report is a discussion of air pollutant emissions. Nationwide estimates of pollutant emissions from 1970 through 1974 show steady declines in the tonnage of particulates and carbon monoxide being dumped into our air. The two principal categories of particulate emissions—stationary-source fuel combustion and industrial processes—showed reductions of some 30 percent for this 5-year period. Carbon monoxide emissions from motor vehicles, which are responsible for three-fourths of the total CO emissions, were reduced by 10 percent.

Emissions of sulfur oxides fluctuated, but ended the 5-year period with a 10 percent decrease in emissions from the dominant category, stationary-source fuel combustion.

Hydrocarbon emissions showed a small overall decline, the combined result of a more than 10 percent decrease in the principal category, motor vehicles, and increases of smaller magnitude in other categories.

Nitrogen oxides showed an increase of about 10 percent. The majority of the increase came from motor vehicles, although the other principal category of NO_x emissions, stationary-source fuel combustion, also showed an increase.

3. STATUS OF AIR QUALITY AND MONITORING ACTIVITY

The majority of the summaries in this report deal with data for the calendar year 1974. Most of the data summarized are the product of measurements of pollutant concentrations in the ambient air taken by state and local monitoring networks. These data are submitted to EPA's National Aerometric Data Bank (NADB) for assessments of nationwide progress in achieving and maintaining air quality standards (Table 3-1). The assessments presented here are based on data incorporated in the NADB as of September 1, 1975. Since these assessments are

Table 3-1. NATIONAL AMBIENT AIR QUALITY STANDARDS

Pollutant	Time period/standard	Maximum permissible concentration
Suspended particulate matter	Annual, secondary	60 μg/m³
(Total suspended particulates)	Annual, primary[a]	75 μg/m³
(TSP)	24-hr, secondary[b]	150 μg/m³[c]
	24-hr, primary	260 μg/m³[c]
Sulfur dioxide	Annual, primary	80 μg/m³
(SO_2)	24-hr, primary	365 μg/m³[c]
	3-hr, secondary	1300 μg/m³[c]
Carbon monoxide	1-hr, primary	40 mg/m³
(CO)	8-hr, primary	10 mg/m³
Oxidants/ozone	1-hr, primary	160 μg/m³[c]
(O_x + Oz or O_3)		
Nitrogen dioxide	Annual, primary	100 μg/m³[c]
(NO_2)		

[a] Primary: to protect public health.

[b] Secondary: to protect public welfare.

[c] These values are not to be exceeded more than once per year.

based only on air quality data reported to EPA, fewer ACQRs will be shown in violation here than in "attainment/non-attainment" evaluations, because the latter also draw upon diffusion modeling of source emissions and other information to estimate ambient pollutant levels where monitoring data are unavailable.

The nationwide status of air quality in 1974 is presented in two principal ways: (1) a summary of data from all reporting stations and (2) a summary of data from the 247 Air Quality Control Regions that encompass the 50 states, 4 territories, and the District of Columbia covered by the Clean Air Act. Detailed summaries of 1974 data reported from individual stations within each AQCR are presented in the appendices.

Two tables, 3-2 and 3-3, presenting a 5-year perspective (1970 - 1974), show some increases in the numbers of stations now on record for prior years compared with the number shown in previous reports; the numbers in these tables, therefore, supercede the numbers in previous annual reports. Some of the increase results from additional submitted data; some increase results from a change in the criterion for including a station in the total. Previous publications listed only stations reporting at least one quarter's valid data* in a calendar year. The new criterion accepts any station reporting at least three 24-hour values from a manual method (high volume or bubbler) or 400 hourly values from an automated (continuous) monitor in a calendar year. The choice of three 24-hour values virtually eliminates the scattering of miscoded samples that show up as spurious sites having usually one, sometimes, two samples. Three such samples, if collected consecutively on the "every sixth day" schedule prescribed by the reference methods, would encompass a 13-day period. In very round numbers, 400 hourly values represent a similar period of time. This change arises from the recognition that if even such a limited data record contains values that exceed a short-term standard, this constitutes information, albeit limited, on the existence of a problem area. Obviously, the absence of violations in such partial data warrants no conclusive claim for compliance with a standard.

---

* At least 5 values from a manual-method, 24-hour monitor, equitably distributed in the quarter; or at least 75 percent of the possible hourly values from a continuous monitor.

Table 3-2. NATIONAL SUMMARY OF TOTAL STATIONS REPORTING DATA AND NUMBER REPORTING VIOLATIONS OF AIR QUALITY STANDARDS, 1970-1974

Pollutant	Data record and standard exceeded	Number of stations					
						1974	
		1970	1971	1972	1973	Total	Std. Exceeded by 50%
TSP	Valid annual data[a]	763	1032	1889	2024	2004	
	Annual sec. (guide only)	550	704	1060	996	906	217
	Annual primary	385	462	626	521	467	88
	At least minimal data[b]	1283	2044	2975	3762	3788	
	24-Hour secondary	668	1001	1275	1458	1332	410
	24-Hour primary	212	283	311	355	326	111
SO_2	Valid annual data	184	257	588	716	1030	
	Annual primary	29	21	20	24	31	14
	At least minimal data	403	729	1311	2008	2241	
	24-Hour primary	33	32	42	103	99	28
	3-Hour secondary	13	24	26	52	71	
CO	At least minimal data	73	133	191	299	377	
	1-Hour primary	14	24	16	33	27	3
	8-Hour primary	60	102	114	192	211	104
Ox/O_3	At least minimal data	51	82	162	265	343	
	1-Hour primary	45	66	115	217	273	205
NO_2	Valid annual data	28	32	47	67	582	
	Annual primary	9	10	8	10	18	0

[a]Valid annual data record must contain at least five of the scheduled 24-hour samples or 75% of possible values in all 4 quarters.

[b]Minimal data consist of at least three 24-hour samples or 400 hourly values.

The nationwide status of monitoring activity is summarized in the last part of this section. A minimum number of monitors is required in the Air Quality Control Regions of each state[2]. An accounting of these AQCR requirements versus the number of monitors actually reporting data is summarized for each state, for the 10 EPA Regions, and for the nation as a whole in Section 3.6.

3.1 NATIONAL SUMMARY OF AIR QUALITY BY STATION

A general picture of national air quality is obtained from the number of reporting sites at which ambient pollutant concentrations exceeded the standards (Table 3-2). In addition to the totals for 1974, Table 3-2 includes figures for the previous 4 years, 1970 through 1973. This conveys some essential historical perspective on the increase in the number of monitors in recent years as well as the number of monitors at which air pollution exceeds standards.

It is important to keep in mind, when reflecting on the changing percentage of stations where standards were exceeded each year, that the number of monitoring stations has increased substantially in this 5-year period. Changes in the percentage of stations that reported values exceeding the standards could be largely a consequence of a shifting balance in the types of stations reporting. Also, administrative changes occasionally result in mid-year transfers of stations to a different identification code, which causes such stations to be counted twice, thus inflating annual totals. Of course, when a station is physically moved, a new site code is essential. To separate these effects from true changes in air quality requires the examination of a subset of stations that have reported data throughout the period, as is done in Section 4 of this report.

In 1974, the primary annual standard for suspended particulates was exceeded at some 23 percent of all hi-vol stations reporting valid annual data (467 of 2004 stations). This is a decrease from 1970, when approximately 50 percent of the stations reporting at that time (385 of 763) recorded values that exceeded the annual standard. The 24-hour primary TSP standard has characteristically been exceeded at substantially fewer stations than has the annual primary standard. Of the total number of stations reporting at least minimal data (3 or more samples per year), TSP stations at which the 24-hour primary standard was exceeded have declined from about 16 percent in 1970 (212 of 1283) to less than 9 percent (326 of 3788) in 1974.

Among sulfur dioxide monitoring stations reporting a valid year's data, concentrations at approximately 3 percent (31 of 1030) exceeded the annual SO_2 standard in 1974. The percentage of stations at which the annual standard was violated decreased from 16 percent in 1970 to its present plateau in 1972. At about 5 percent (99 of 2241) of all SO_2 stations reporting at least minimal data (3 or more bubbler samples or 400 hourly values), the 24-hour SO_2 standard was exceeded in 1974. This percentage has changed little since 1971, declining from 11 percent in 1970.

These figures on SO_2 violations may be subject to reevaluation where they are based on measurements taken with 24-hour bubbler samplers. Preliminary results from a current review of the bubbler's chemistry indicate that elevated temperatures inside the sampler box can convert some portion of the collected SO_2 into an insoluble compound. The resulting decrease in the apparent SO_2 concentration is variable, depending on both temperature and the time the collected sample remains in the box.

The carbon monoxide standard most frequently exceeded is the 8-hour standard—at 56 percent of CO monitoring stations reporting in 1974 this standard was violated.* The 1-hour CO standard was exceeded at only 7 percent of these stations.

The 1-hour oxidant standard was exceeded at 80 percent of the stations reporting in 1974, and the rate has fluctuated around this value since 1970.

Nitrogen dioxide monitoring technology has been in a state of flux since revocation of the initially designated reference method (Jacobs-Hochheiser Method). The presently defined annual standard for NO_2 was exceeded at 5 percent of the stations using methods which are candidates for reference or equivalent methods and reporting a full year's data.

*See Section 3.4 for a description of the "different-day, second-high value" interpretation of the 8-hour CO standard used in this report.

3.2 POPULATION-ORIENTED AND SOURCE-ORIENTED MONITORING STATIONS

The TSP and SO_2 monitoring stations are sufficiently numerous to afford a broad comparison between population-oriented stations and source-oriented stations. (The last two digits in a station's SAROAD code identify a station's project function: 01 = population-oriented, 02 = source oriented). Although some sites are in complex neighborhoods where the balance between population and source influence requires some subjective judgment in the choice of a station's designation, the national composites reveal some interesting contrasts.

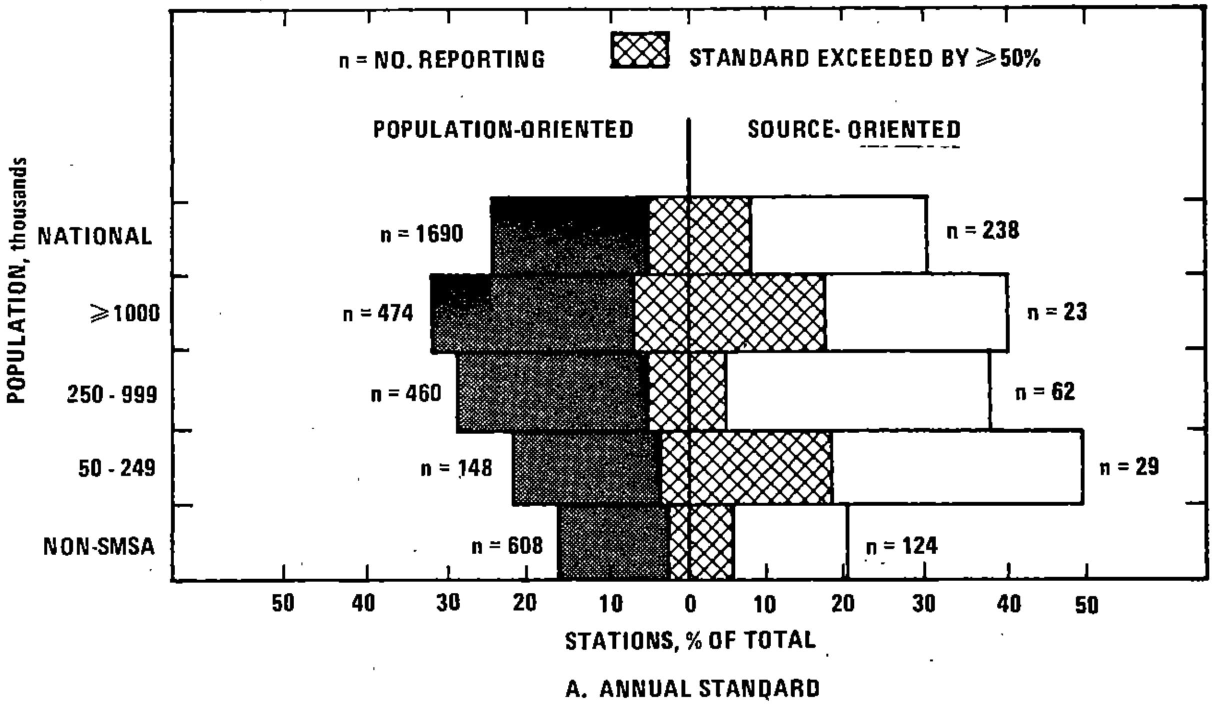
Figure 3-1 presents the percentage of population- and of source-oriented particulate stations at which primary standards were exceeded. In addition to the national composites, the two groups of stations within Standard Metropolitan Statistical Areas (SMSAs)* are in turn grouped into three population categories in this figure. The population-oriented stations show an increasing percentage of annual standard violations with increasing SMSA population. A consistently higher percentage of the source-oriented TSP monitoring stations reported violations of both the annual and the 24-hour primary standards.

Data from sulfur dioxide monitors exhibit patterns (Figure 3-2) that differ from those of TSP data. First, the percentage of stations at which the annual or the 24-hour primary SO_2 standard was exceeded is substantially smaller than for the particulate standards. Further, in contrast to TSP, it is the 24-hour SO_2 standard that is more often exceeded. As might be expected, the 24-hour standard is exceeded by a higher percentage of source-oriented SO_2 stations than population-oriented stations. The opposite is true for the annual SO_2 standard—it was exceeded by a larger percentage of the population-oriented groups.

Table 3-3 further subdivides the SO_2 stations according to their use of 24-hour bubblers or continuous instruments. Understandably, a larger proportion of violations of the 24-hour standard are recorded by the continuous instruments. The continuous instruments are, by intent at least, in operation every day, while the periodic sampling

---

*An SMSA is, basically, a county or group of contiguous counties that meets certain criteria of population size, metropolitan character, and economic and social integration with the central city. In New England, towns and cities are used to define SMSAs.



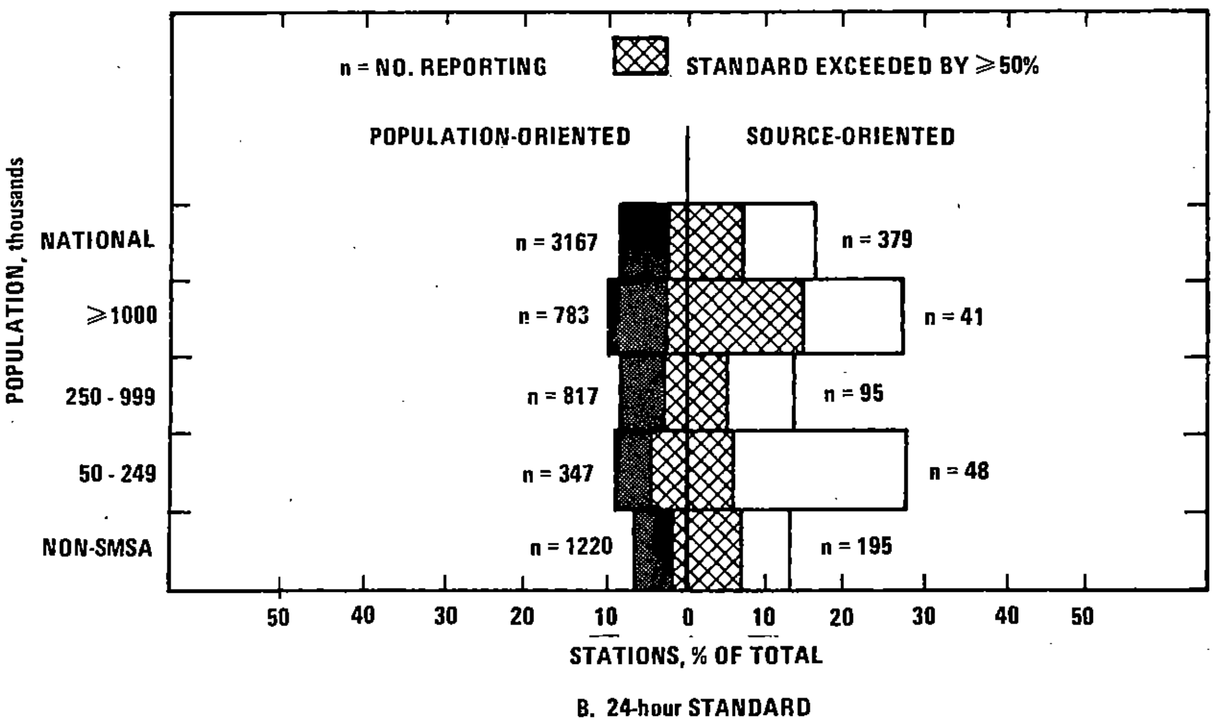


Figure 3-1. Percentage of population-oriented and source-oriented particulate monitoring stations at which (a) annual and (b) 24-hour standards were exceeded in 1974, given by SMSA population group.

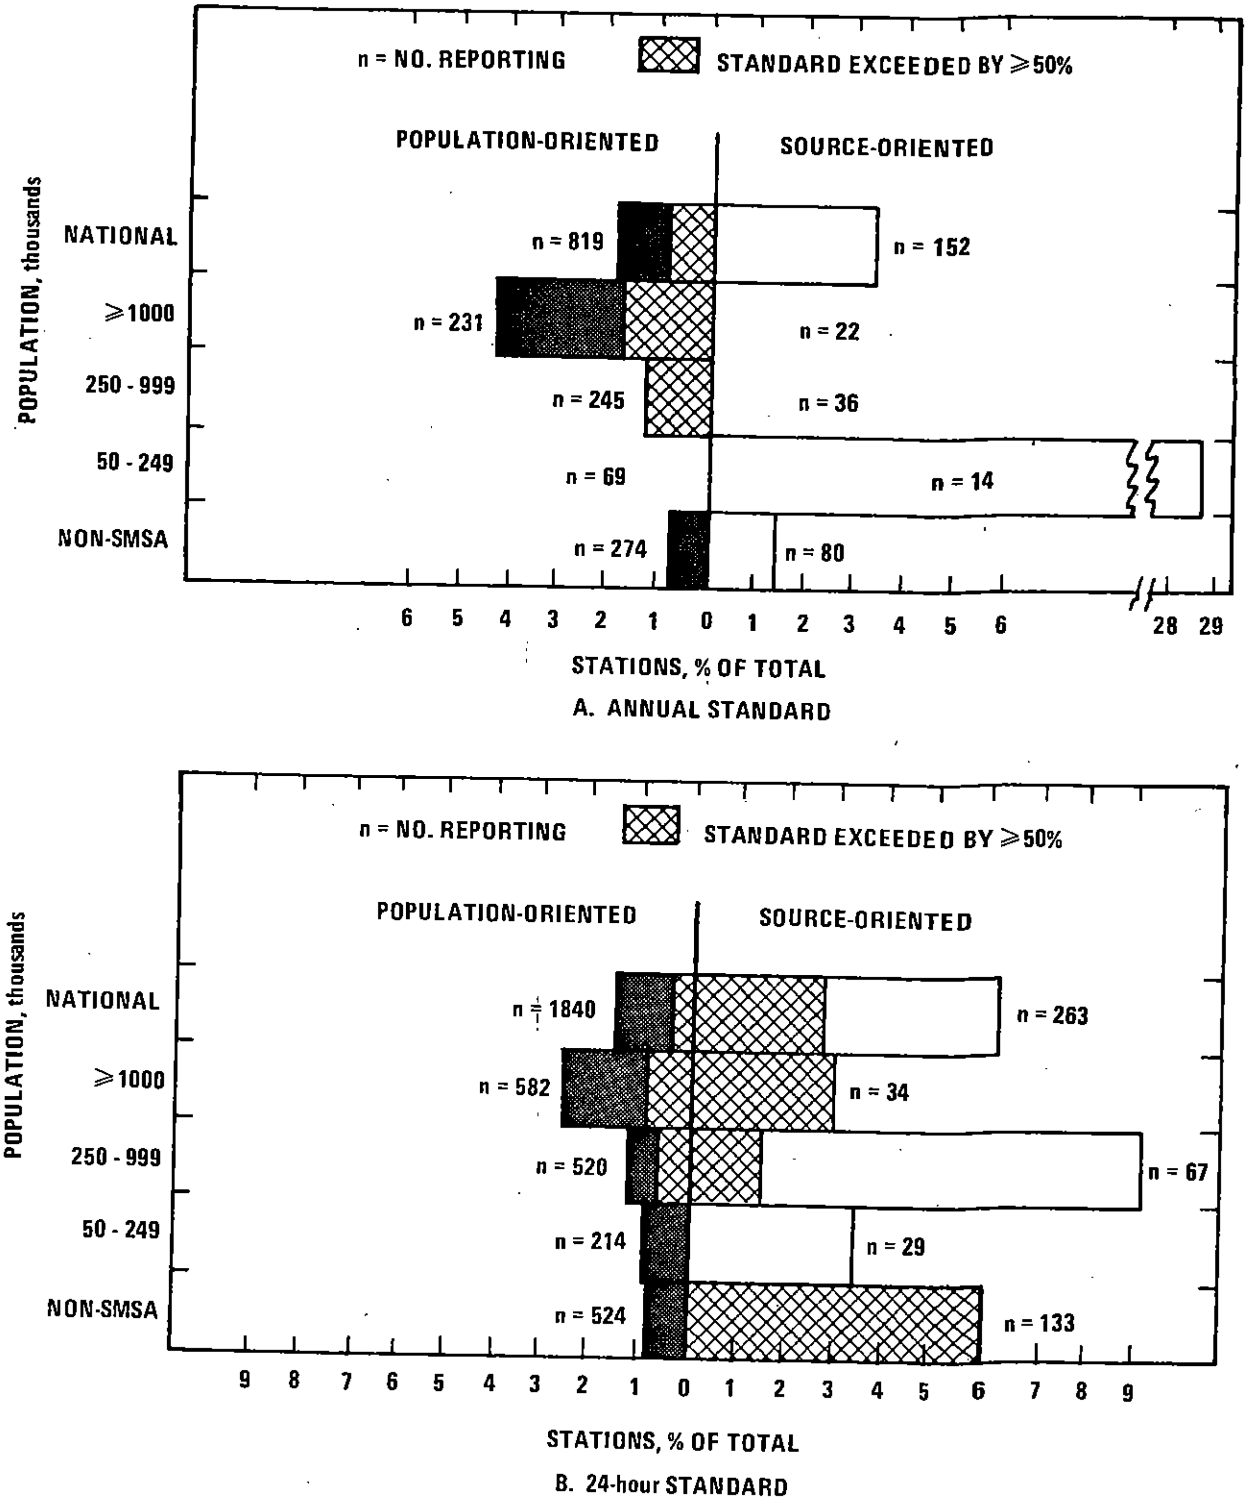

Figure 3-2. Percentage of population-oriented and source-oriented sulfur dioxide monitoring stations at which (a) annual and (b) 24-hour standards were exceeded in 1974, given by SMSA population group.

schedule of most bubbler stations (every 6th day or every 3rd day) has a corresponding probability of missing some of the days with high concentrations.

Table 3-3. NUMBERS OF POPULATION- AND SOURCE-ORIENTED SULFUR DIOXIDE MONITORING STATIONS OPERATING 24-hour BUBBLERS OR CONTINUOUS MONITORS

Data reported and standard exceeded	Number of stations			
	Population-oriented		Source-oriented	
	Bubbler	Continuous	Bubbler	Continuous
Valid annual data[a]	694	125	131	21
Annual standard exceeded	8	7	5	0
Exceeded by 50% or more	4	3	0	0
At least minimal data[b]	1361	479	202	61
24-hour standard exceeded	8	19	4	12
Exceeded by 50% or more	0	8	2	5

[a]Four valid quarters are required to qualify as a valid annual record.

[b]At least three 24-hour samples or 400 hourly values.

3.3 NATIONAL SUMMARY OF AIR QUALITY BY AQCR

The status of the nation's 247 Air Quality Control Regions (AQCRs) with respect to National Ambient Air Quality Standards is summarized in Table 3-4 for 1970 through 1974. The increasing number in recent years of AQCRs with stations at which certain standards were exceeded (24-hour primary TSP and SO_2 standards, for example) may appear to contradict reports of improving air quality. In fact, examination of trends later in this report confirm downward trends at stations with a good historical record of measurements. The contributing effect seen in Table 3-4 is the result of expansion of monitoring activity over this 5-year period, which adds previously unmonitored areas to the list of AQCRs in violation. While the number of AQCRs having violations of standards is beginning to show some decreases in 1974, it should be kept in mind that a single high station can keep an AQCR in the violation category even though substantial portions of the AQCR may have achieved significant improvements.

Table 3-4. NATIONAL SUMMARY OF AIR QUALITY CONTROL REGIONS AND NUMBER IN WHICH AIR QUALITY STANDARDS WERE EXCEEDED, 1970-1974

	1970	1971	1972	1973	1974
Suspended particulates					
AQCRs reporting at least 1 station-yr	148	159	205	202	198
Annual secondary guide exceeded	124	132	169	168	160
Annual primary standard exceeded	102	108	131	128	111
AQCRs reporting at least minimal data[a]	182	199	228	235	236
24-Hour secondary standard exceeded	121	150	185	201	197
24-Hour primary standard exceeded	74	87	106	125	99
Either sec. std. or guide exceeded	146	167	199	206	198
Either primary standard exceeded	112	121	148	159	136
AQCRs reporting insufficient data to assess any standard.	65	48	19	12	11
Sulfur dioxide					
AQCRs reporting at least 1 station-year	73	74	124	130	155
Annual primary standard exceeded	9	7	6	17	11
AQCRs reporting at least minimal data[a]	122	138	169	203	210
24-Hour primary standard exceeded	8	18	26	29	22
3-Hour secondary standard exceeded	8	12	17	20	33
Either primary standard exceeded	11	20	26	33	25
AQCRs reporting insufficient data to assess any standard	125	109	78	44	37
Carbon monoxide[b]					
AQCRs reporting at least minimal data[a]	16	48	66	82	92
1-Hour standard exceeded	7	12	9	14	13
8-Hour standard exceeded[e]	16	39	47	63	58
Oxidants[c]					
AQCRs reporting at least minimal data[a]	17	30	51	77	86
1-Hour standard exceeded	14	24	31	65	76
Nitrogen dioxide[d]					
AQCRs reporting at least 1 station-yr	11	12	15	28	101
Annual standard exceeded	2	3	2	4	4[f]

[a] Minimal data consist of at least three 24-hour samples or 400 hourly values.

[b] Only 30 AQCRs required to have monitors.

[c] Only 55 AQCRs required to have monitors.

[d] No monitoring required since reference method was rescinded. Once a new reference method is designated, monitoring requirements will be promulgated.

[e] Running averages, 2nd high on different day.

[f] A detailed examination of all NO_2 data indicates a total of 16 AQCRs have an NO_2 problem (015, 024, 029, 030, 036, 042, 043, 045, 056, 067, 115, 119, 123, 174, 220, 225).

3.4 DISTRIBUTION OF AQCRs WITH RESPECT TO STANDARDS

To be included in the analysis for short-term standards (1-hour, 8-hour, or 24-hour), an AQCR must report at least one station with at least three 24-hour values from a manual method (hi-vol or bubbler), or at least 400 hourly values from an automated (continuous) monitor, as appropriate. The station with the largest "second-high" value determines an AQCR's position in the distribution. Stations with flagged (#) values (see Appendices) are not used.*

To be included in the analysis for annual standards, an AQCR must report at least one station with a complete year's data (4 valid quarters). The station with the highest annual mean determines an AQCR's position in the distribution. AQCRs lacking sufficient data in either of the above groups are relegated to the "no data" category.

Such an analysis potentially masks some substantive distinctions between AQCRs. For example, two AQCRs with ten monitors each may rank equally, on the basis of maximum values reported; yet the other nine reporting stations in each network may reveal quite contrasting conditions in the remainder of the two regions. The question of how to comprehensively yet succinctly characterize AQCRs with diverse network sizes, situated in diverse topography and operating in neighborhoods of diverse complexion under the influence of diverse meteorology, remains unreconciled. Nevertheless, as long as one reporting station in an AQCR registers values in excess of a standard, that AQCR will be grouped in the violation category. Therefore, this presentation uses the station reporting the highest values in an AQCR to show the AQCR standing with respect to a standard, but it does not convey the extent of the area in which the standard is exceeded.

The TSP data show contrasting profiles for the AQCRs having TSP concentrations above and below the 24-hour and annual primary standards (Figure 3-3a). The majority of AQCRs are reporting second-high 24-hour values within the standard, yet a significant group of 15 have reported values in excess of the standard by a factor of three or more. On the other hand, over half the AQCRs with complete annual stations are reporting annual means above the primary annual standard, yet only one ranges as high as three times that standard.

---

*Flagged values are only tentatively suspect. Responsibility lies with the submitting agency to review and delete where appropriate. Subsequent retrievals will not include the flag.

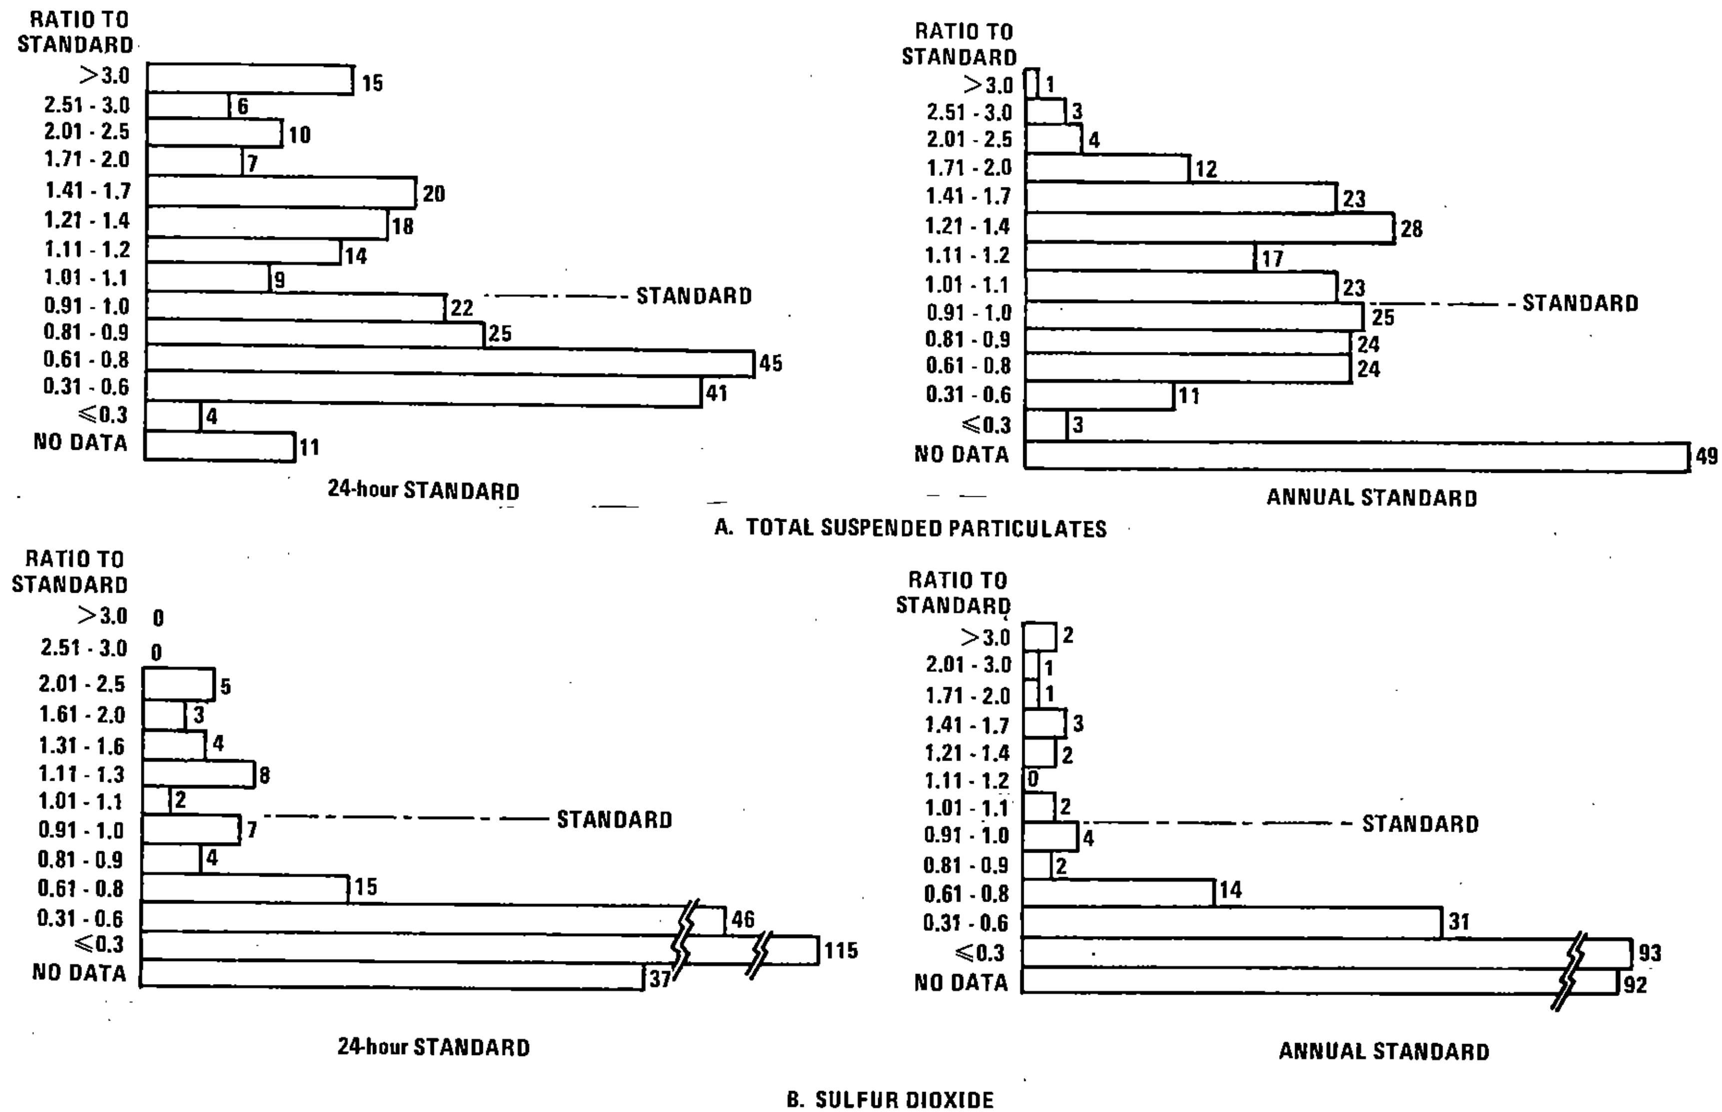

Figure 3-3. Distribution of AQCRs according to reported values exceeding National Ambient Air Quality Standards, 1974 (based on maximum values reported).

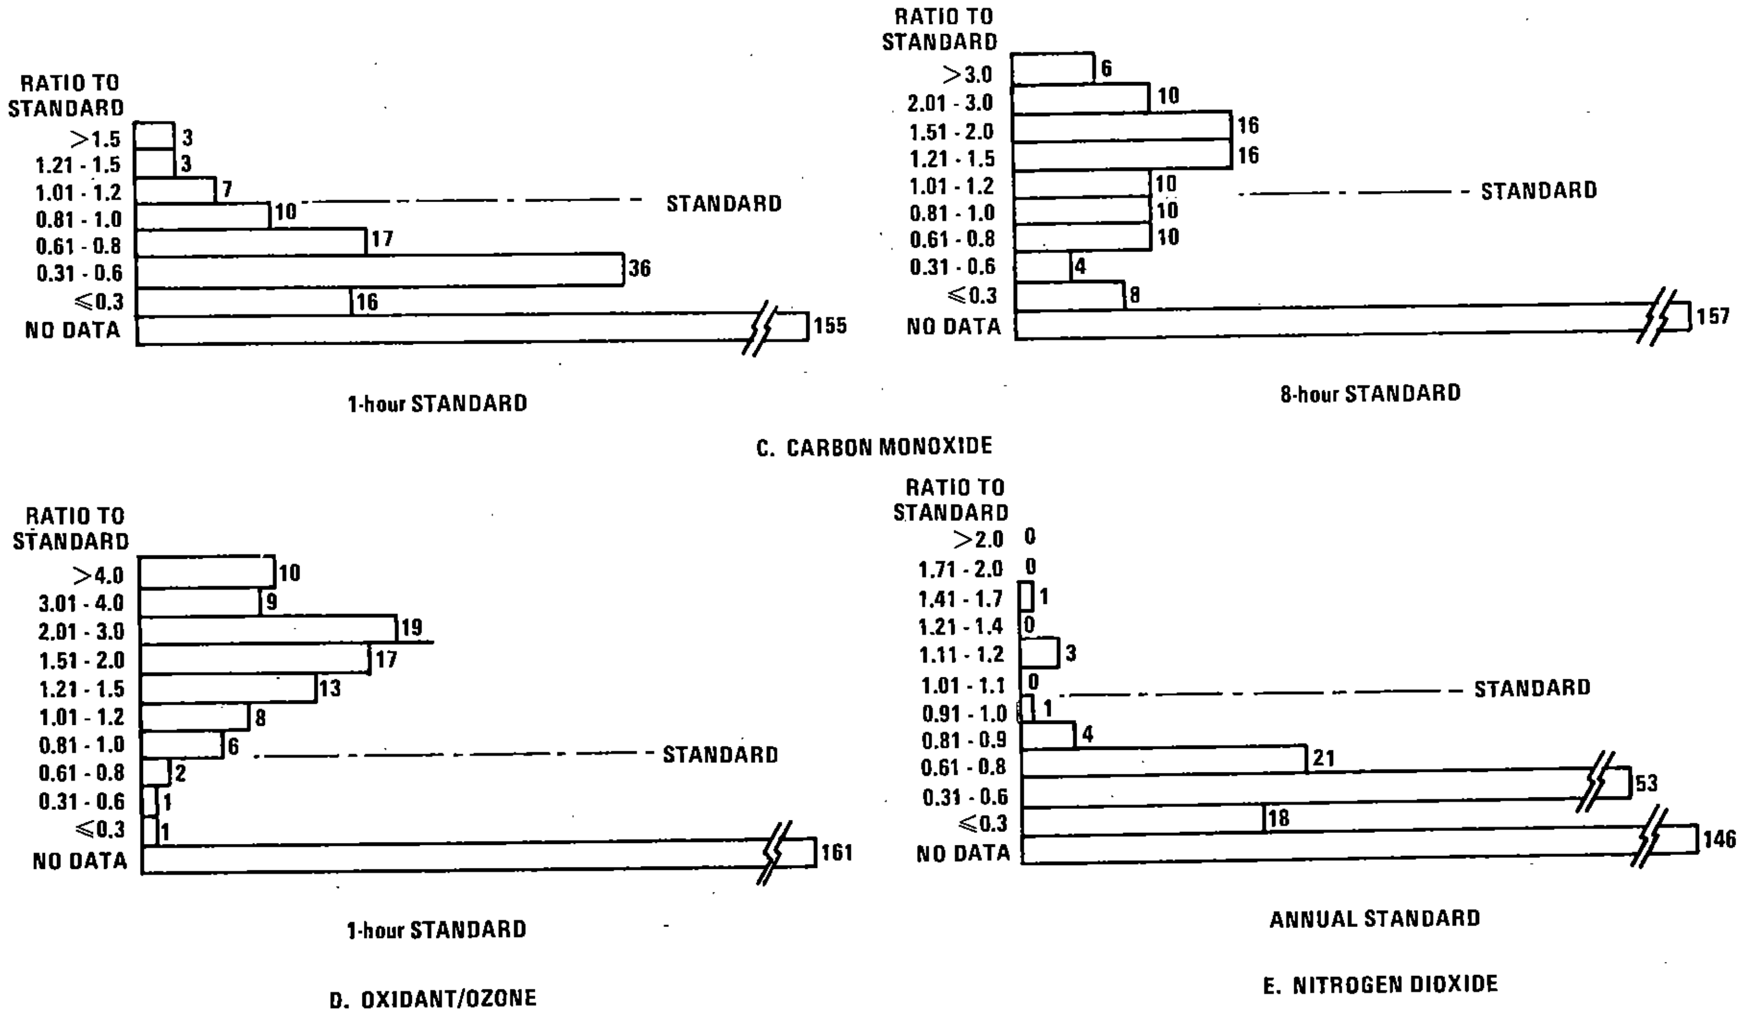

Figure 3-3 (continued). Distribution of AQCRs according to reported values exceeding National Ambient Air Quality Standards, 1974 (based on maximum values reported).

Most AQCRs reported sulfur dioxide data, Figure 3-3b, within both the 24-hour and the annual standards. Among the AQCRs in which SO_2 standards were exceeded, the 24-hour standard was exceeded in more AQCRs than the annual standard.

These comparisons of AQCR distributions for 24-hour versus annual standards for TSP and SO_2 are not as useful as they might be since the numbers of AQCRs in each group are unequal. Because of incomplete TSP data, only 84 percent of the AQCRs appraised for the 24-hour standard can also be appraised for the annual standard; for SO_2, only 74 percent have annual as well as minimal 24-hour data. Some apparent differences may thus be at least a partial artifact of different group sizes and composition.

For carbon monoxide (Figure 3-3c) even minimal data can provide a comparable appraisal of both the 1-hour and the 8-hour standards. Therefore, the same AQCRs are included in both distributions* and the validity of the contrast is unqualified. Violations of the 8-hour standard for cumulative exposure clearly occur more widely than violations of the higher 1-hour standard for acute exposure. The 8-hour standard is also likely to be exceeded by a larger factor.

Notice should be taken of the manner in which the 8-hour CO averages are interpreted in this report. First, running 8-hour averages are calculated for each station and the number of these averages exceeding the standard is reported as a measure of cumulative exposure potential (see Appendix C). Then, a station's second-highest 8-hour average, as reported in Appendix C, is drawn from a different day than the maximum value. This "different-day" second-highest value has been used here to determine whether a station is in violation and to assign an AQCR's position in Figure 3-3c. The results of this simple procedure appear to approximate closely those that would be obtained from the more elaborate proposal for searching out a non-overlapping second-highest 8-hour value.

The 1-hour oxidant standard was exceeded in 1974 in most of the AQCRs where measurements were taken—76 of 86 (Figure 3-3d). The second-highest value ranged over the standard by a factor of four in 10 AQCRs.

Nitrogen dioxide monitors with valid annual means were reported from 101 AQCRs; of these, only 4 AQCRs reported violations of the NO_2 annual standard. The majority of the reporting AQCRs had NO_2 concentrations below the standard by the comfortable margin of 40 percent or more.

*With the exception of two AQCRs in Michigan, where data problems thwarted calculation of 8-hour averages.

3.5 FIVE-YEAR SUMMARY OF AQCR STATUS

Table 3-5 presents a 5-year summary (1970-1974) of the number of stations reporting data for each pollutant from each of the 247 AQCRs, and the number of stations at which respective standards were exceeded.

On the same line with each AQCR number and name, under each pollutant, the figure in parentheses is the minimum number of monitoring stations required for that pollutant as specified in the Federal Register[2].

Two different station counts are used in Table 3-5: the columns headed "# STA(1)" contain the number of stations reporting a valid year's data (at least five 24-hour values each quarter, representatively distributed; or 75 percent of the possible hourly values in each quarter); the columns headed "#STA(2)" contain the number of stations reporting at least minimal data (at least three 24-hour values or 400 hourly values). In previous publications, this second category was defined as including stations with at least one valid quarter's data. This new criterion means that more stations are being included.

Only values reported from stations with a full year's data can be judged against an annual standard. All valid annual data plus partial data can be judged against a short-term standard, although obviously, when incomplete data show no violations of a short-term standard, this result must be regarded as inconclusive. Further, the status of an AQCR must be considered inconclusive if the number of stations reporting a valid year's data is less than the minimum number required.

Occasionally, a question mark will appear in a column for the number of stations at which an annual standard is exceeded. This indicates that only tentative means rather than validated means are above the annual standard in that AQCR. Tentative means have been calculated for the first time in this report and are based on two or three valid quarters. In the appendix tabulations of individual stations, these tentative means are identified with a question mark. These stations are not counted in the number of stations reporting valid annual means, nor are tentative annual means above the standard counted as confirmed violations.

The remaining columns in Table 3-5 list the number of stations where standards are exceeded with respect to each pollutant, as explained in Figure 3-4. The values of those standards are included in the headings, in both micrograms per cubic meter (μg/cu.m.)--

Table 3-5. NUMBER OF STATIONS REPORTING AND NUMBER OF STATIONS AT WHICH STANDARDS WERE EXCEEDED, BY AQCR, 1970-1974

Column heading	Explanation
NITROGEN DIOXIDE: # >AN STD 100	Number of NO_2 stations at which annual standard was exceeded.
NITROGEN DIOXIDE: # STA (1)	Number of NO_2 stations reporting a valid year's data.
OXIDANTS 1-HR: # > STD 160 .08	Number of oxidant stations at which 1-hr standard was exceeded.
OXIDANTS: # STA (2)	Number of oxidant stations reporting at least minimal data.
CARBON MONOXIDE 8-HR: #> STD 10* 9	Number of CO stations at which 8-hr standard was exceeded.
CARBON MONOXIDE 1-HR: #> STD 40* 35	Number of CO stations at which 1-hr standard was exceeded.
CARBON MONOXIDE: # STA (2)	Number of CO stations reporting at least minimal data.
SULFUR DIOXIDE 3-HR: #> STD 1300 .50	Number of SO_2 stations at which 3-hr standard was exceeded.
SULFUR DIOXIDE 24-HR: #> STD 365 .14	Number of SO_2 stations at which 24-hr standard was exceeded.
SULFUR DIOXIDE 24-HR: # STA (2)	Number of SO_2 stations reporting at least minimal data.
SULFUR DIOXIDE ANNUAL: #> STD 80 .03	Number of SO_2 stations at which annual standard was exceeded.
SULFUR DIOXIDE ANNUAL: # STA (1)	Number of SO_2 stations reporting a valid year's data.
SUSPENDED PARTICULATES 24-HOUR: #> PRI 260 -	Number of particulate stations at which primary 24-hr standard was exceeded.
SUSPENDED PARTICULATES 24-HOUR: #> SEC 150 -	Number of particulate stations at which secondary 24-hr standard was exceeded.
SUSPENDED PARTICULATES 24-HOUR: # STA (2)	Number of particulate stations reporting at least minimal data.
SUSPENDED PARTICULATES ANNUAL: #> PRI 75 -	Number of particulate stations at which primary annual standard was exceeded.
SUSPENDED PARTICULATES ANNUAL: #> SEC 60 -	Number of particulate stations at which secondary annual standard was exceeded.
SUSPENDED PARTICULATES ANNUAL: # STA (1)	Number of particulate stations reporting a valid year's data.
YR (UG/CU.M: P.P.M:)	Year.
AIR QUALITY CONTROL REGION	Number and name of Air Quality Control Region. Numbers in parentheses in each pollutant column give the Federally required minimum number of monitors. The two numbers for SO_2 are for bubblers and continuous instruments, respectively.

(1) NUMBER OF STATIONS REPORTING A FULL YEAR'S VALID DATA
(2) NUMBER OF STATIONS REPORTING AT LEAST 3 24-HR VALUES OR 400 HOURLY VALUES
? STATIONS WITH INCOMPLETE DATA MAY BE EXCEEDING THE ANNUAL STANDARD; SEE APPENDICES
* CO STANDARDS ARE IN MILLIGRAMS PER CUBIC METER

milligrams per cubic meter for CO (mg/cu.m.)-- and in parts per million (ppm).

Diligent scrutiny will reveal that a few stations are counted in violation of a standard, yet the appendix table will show the determining value just equal to the standard. The comparison with the standard is made with values containing decimal places that are not printed; thus, the violation consists of only a fraction of a microgram. For example, a hi-vol station may show an annual mean of 75, yet be counted technically in violation because that mean is actually some value like 75.3.

3.6 STATUS OF MONITORING ACTIVITY BY STATE AND BY EPA REGION

As in the other sections of this report, monitoring stations are counted if they have reported "minimal" data; that is, at least three values from manual-method, 24-hour monitors (hi-vols and bubblers) or at least 400 hours from automated or continuous monitors. Station totals for prior years will not necessarily match previously published figures both because of these revised criteria and because some additional data have been belatedly submitted since the completion of the last annual report.

Table 3-6 lists the number of TSP, SO_2, CO, oxidant, and NO_2 monitors reporting in each state. Sulfur dioxide monitors are subdivided into bubbler (24-hour) and continuous (hourly) monitors.

The four columns under each pollutant heading show (1) the number of monitors required to satisfy minimum Federal requirements; (2) the number of monitors actually reporting at least minimal data; (3) the number of required monitors actually reporting to EPA; and (4) the percentage of the required monitors actually reporting. Note that there are separate requirements for SO_2 bubblers and for SO_2 continuous instruments. Bubblers are specified where the annual standard is of principal interest; continuous monitors are specified where short-term standards are the principal interest. In some instances, agencies have chosen to install continuous instruments in place of bubblers. A separate column under "SO_2 Bubblers" shows the percentage of required monitors reporting when these continuous monitors are credited toward bubbler requirements.

In some instances, the number of monitors reporting equals or exceeds the minimum number required for a state; yet the completion

[a]Column headings: REQ = minimum required number of monitors; RPT = total number of monitors reporting at least minimal data; RQ RP = sub-total of required monitors actually reporting; % = percent of required monitors actually reporting

*NOTE: Second percentage figure under SO_2 bubblers indicates States where continuous monitors can be credited toward bubbler requirements.

status appears in the table as less than 100 percent. This simply indicates that at least one AQCR within that state still does not have the minimum required number of monitors.

The minimum required number of monitors for each AQCR is included in Table 3-5. In interstate AQCRs, the total required stations are apportioned among the component states according to the population in each state portion of the AQCR.

Table 3-7 summarizes the total stations reporting compared with the number of stations required and with the required stations actually reporting for each of the 10 EPA Regions.

Table 3-8 identifies the number of stations monitoring each pollutant according to the method or principle being used. The preponderance of air monitoring is being conducted with reference methods or with methods based on reference-method principles. These are the sole members of the "approved" category at present. Other methods that are not reference methods but are considered reasonable candidates for passing equivalency tests are listed as "unapproved." The "Unacceptable" category includes those methods or measurement principles that are generally acknowledged to be inaccurate and obsolete.

4. TRENDS IN CRITERIA POLLUTANTS

This section discusses trends in the criteria pollutants: total suspended particulates, sulfur dioxide, oxidants, carbon monoxide, and nitrogen dioxide. The previous section covered nationwide air quality with respect to the National Ambient Air Quality Standards (NAAQS) and examined the available data on a calendar-year basis. For the discussion of trends, however, only those sites having data with historical continuity are considered. Therefore, this analysis uses data from fewer sites than given in the previous section and, as a consequence, gives a less detailed picture of the current status of air pollution with respect to standards. The pollutant trends are presented on a national basis and also on a regional basis. The data base used for the analysis is discussed, with particular attention given to how well the data sample represents the nation. In addition, possible meteorological influences on air quality trends are briefly discussed. Although there are many ways of looking at trends in air quality, the primary emphasis in this section is to discuss trends with respect to the National Ambient Air Quality Standards since the passage of the Clean Air Act of 1970.

4.1 NATIONAL OVERVIEW

In a discussion of air quality trends, it is reasonable first to summarize the information on a national level. The purpose of this section is to give a general overview; later sections will present more detailed information concerning the nature of the data base and regional trends. As mentioned earlier, the time period of interest for this report is 1970-1974. The selection of 1970 as the base year was influenced by the amount of data available and the fact that the Clean Air Act of 1970 provides a convenient frame of reference for discussion of trends in the 1970's. It should be noted, however, that while 1970 represents a convenient reference point for considering recent trends, many localities showed considerable improvement in air quality prior to this date. The progress made in the late 1960's has been discussed in previous editions of this report[1-3].

Sufficient data by which to determine trends on the national level are available only for TSP and SO_2. Historical data for CO, oxidant, and NO_2 are available only for limited geographical areas and, therefore, trends in these pollutants are examined only on a regional basis.

Figure 4-1 displays the median and the 10th and 90th percentiles of the quarterly means and maximums for TSP and SO_2 data on a national level. Running four-quarter averages of the percentile values are also shown to smooth out the seasonal variation that occurs in pollutant concentrations. These graphs are based upon data from 1096 sites for TSP and 258 sites for SO_2, these sites having been chosen from the National Aerometric Data Bank on the basis of availability of historical data. The selection criteria employed are discussed in the next section. As shown in these graphs, the general trend in air pollution for the 1970-1974 period has been downward. In all cases, the 10th percentile indicates a fairly stable pattern for the lower values while the decrease in 90th percentiles shows improvement at the sites with higher values. The median values for TSP show improvement in both mean and maximum values over the 5-year period. For SO_2, the median is fairly stable but is well below the standard. The graphs suggest that although there has been overall improvement for both these pollutants since 1970, little or no change has occurred in the past 2 years.

While the graphs of Figure 4-1 give a convenient summary of the general trends in the nation, an alternative approach is to compare the 1970-1971 period with the 1972-1974 period and to tabulate how many sites show improved air quality. This is done in Figure 4-2, which shows the percentage of sites at which TSP and SO_2 concentrations increased or decreased by more than 10 percent between these two time periods. In this computation, interpolated values were substituted for missing quarters, according to the scheme discussed in Section 4.3, in order to assure balanced seasonability. Here again, the results indicate the general improvement that has occurred on the national scale. For both TSP and SO_2, considerable progress has clearly been made with respect to mean levels. Although the net effect indicates overall improvement in maximum values, there appears to be much more fluctuation, which is not surprising for extreme values. For the purposes of this report, trends in maximum values will not be treated in further detail. One reason for this is that in the past few years many sites have increased their sampling frequency from biweekly to every sixth or every third day.

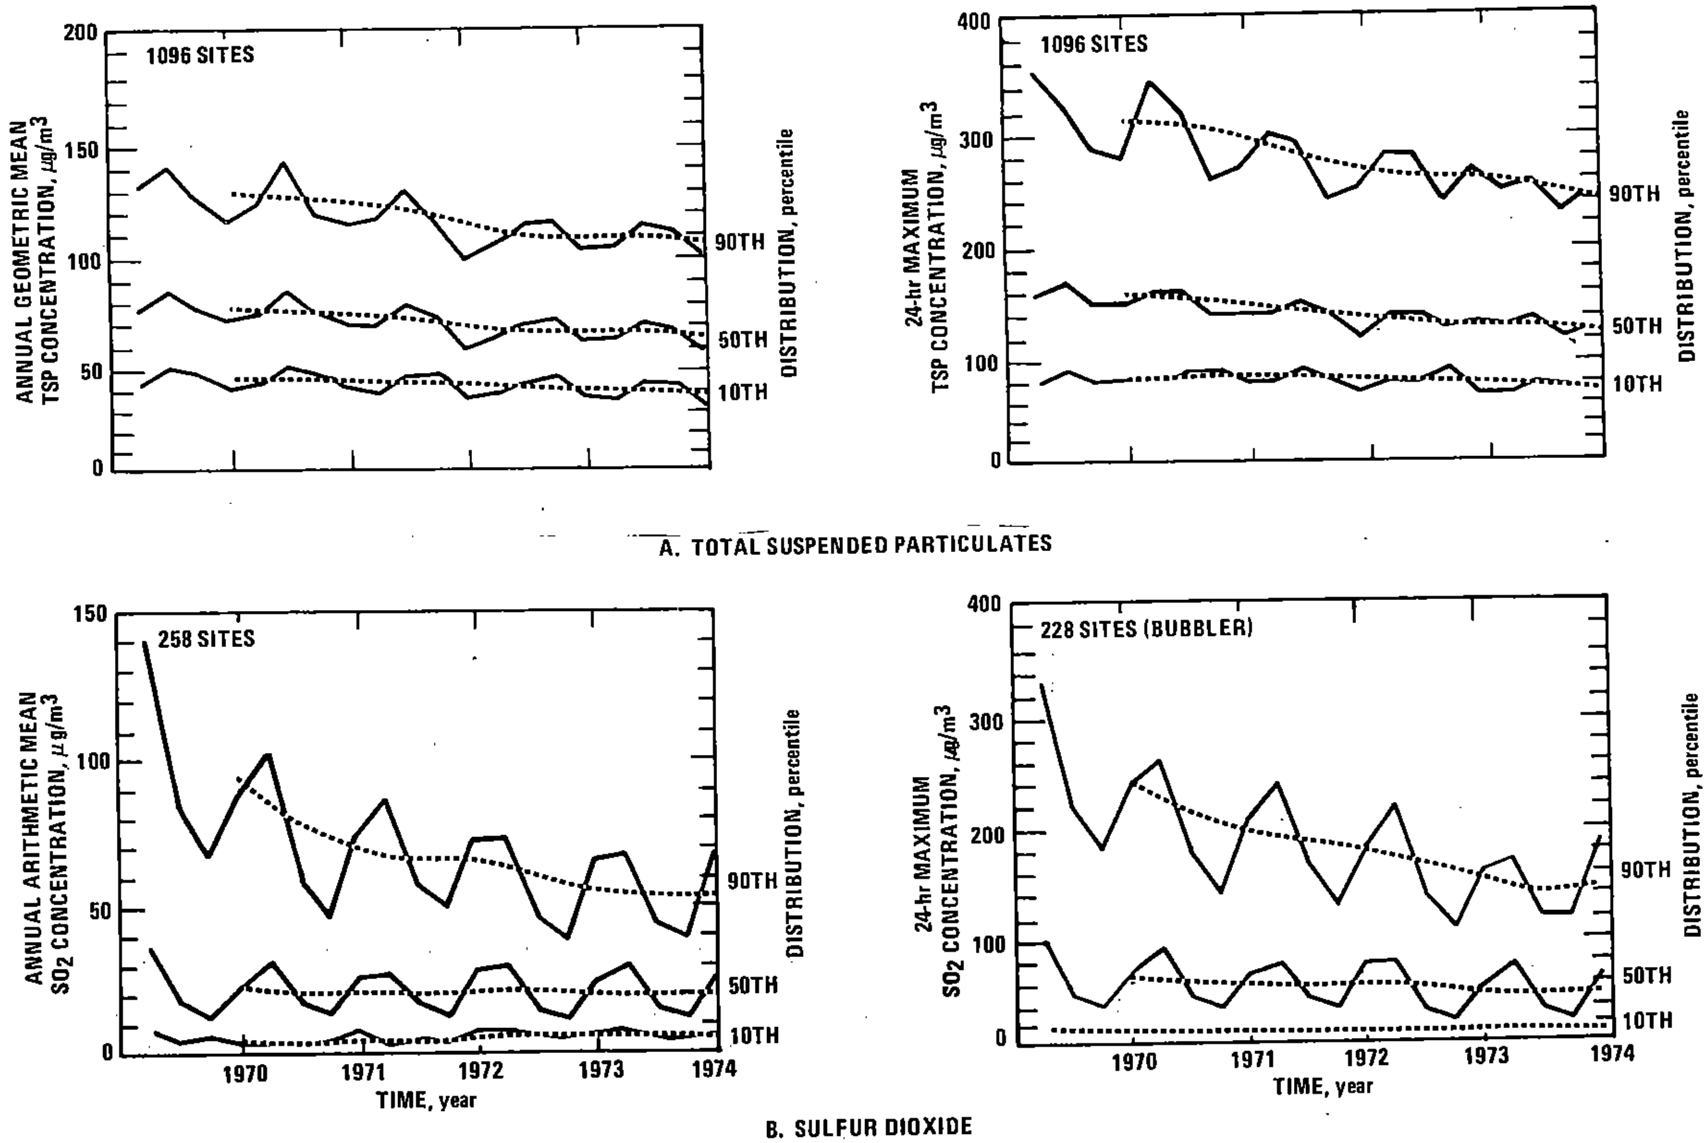

Figure 4-1. National (a) total suspended particulate and (b) sulfur dioxide trends: 10th, 50th, and 90th percentiles for the annual mean and 24-hour maximum values.

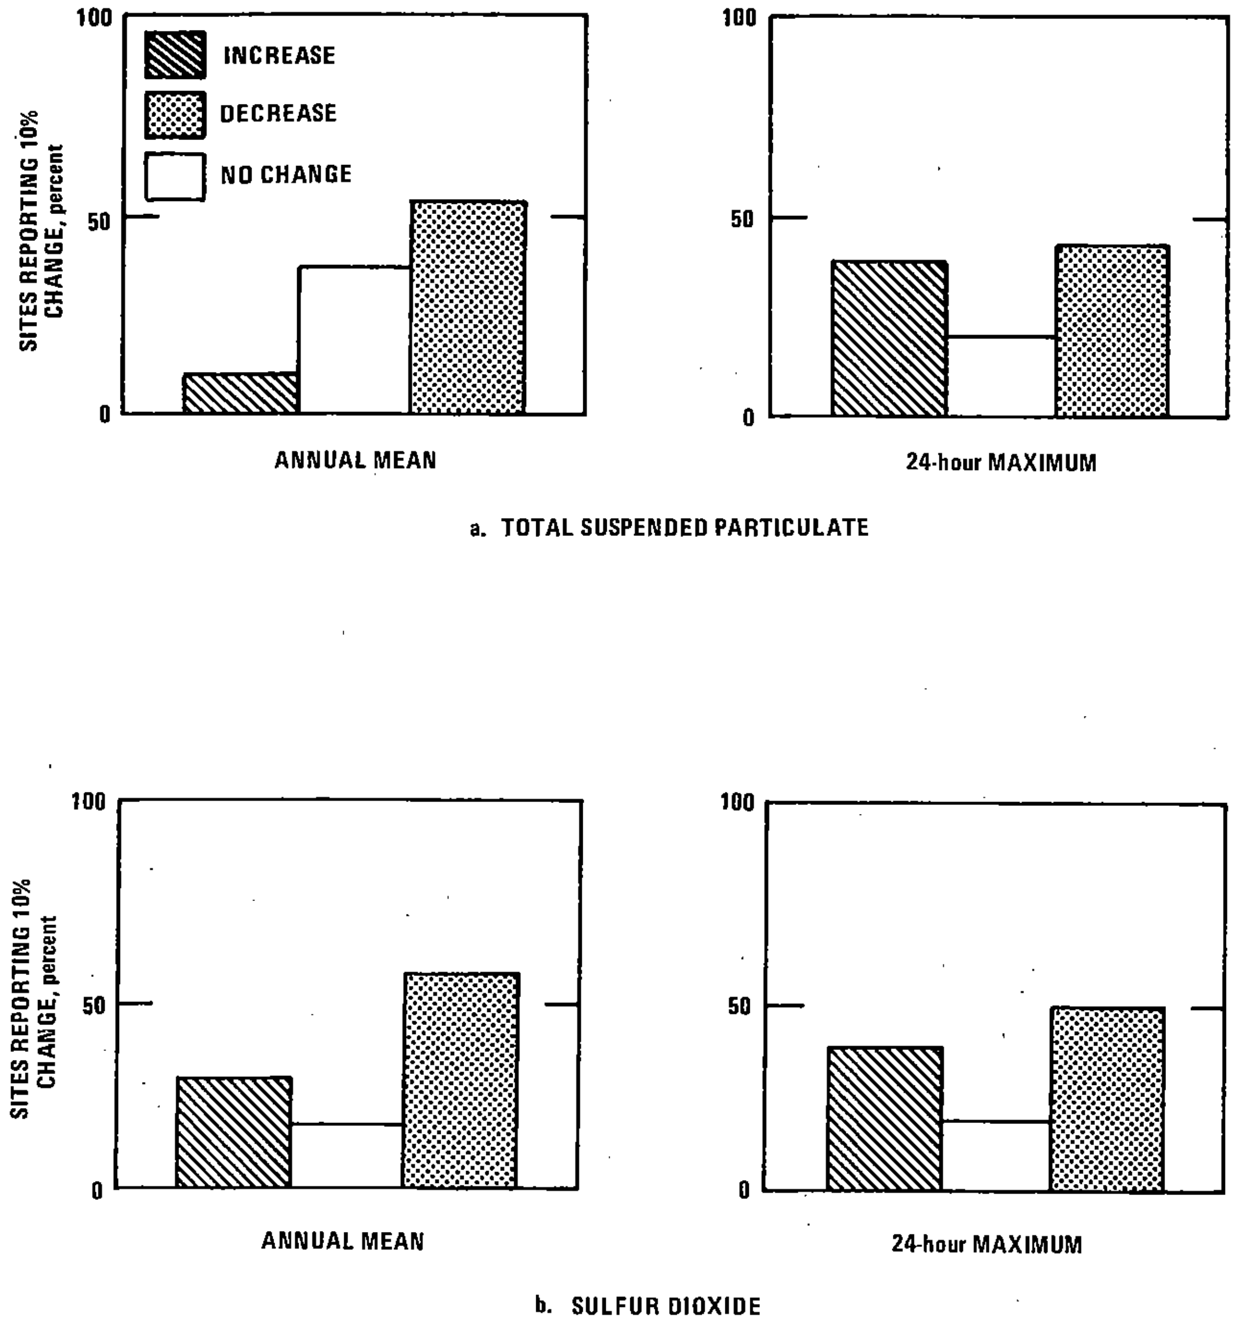

Figure 4-2. Percentage of (a) total suspended particulate and (b) sulfur dioxide sites reporting a greater than 10 percent change in annual mean and 24-hour maximum values between 1970-1971 and 1972-1974.

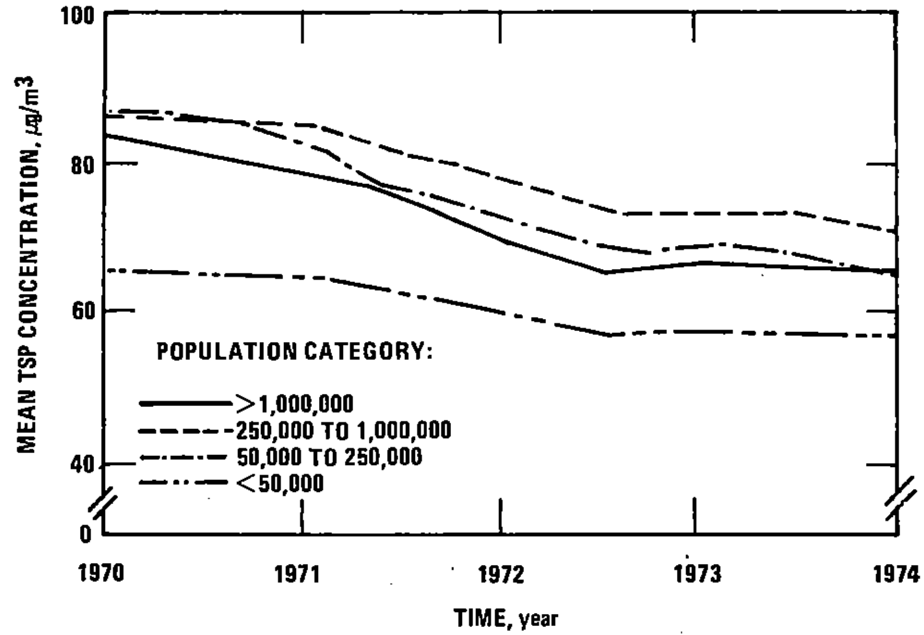
This increase in sampling frequency would be expected to complicate an analysis of maximum values by increasing the probability of detecting the highest values. Any apparent trend would include an indeterminate component resulting from the more comprehensive sampling schedule, confounding the effect of any real environmental change.

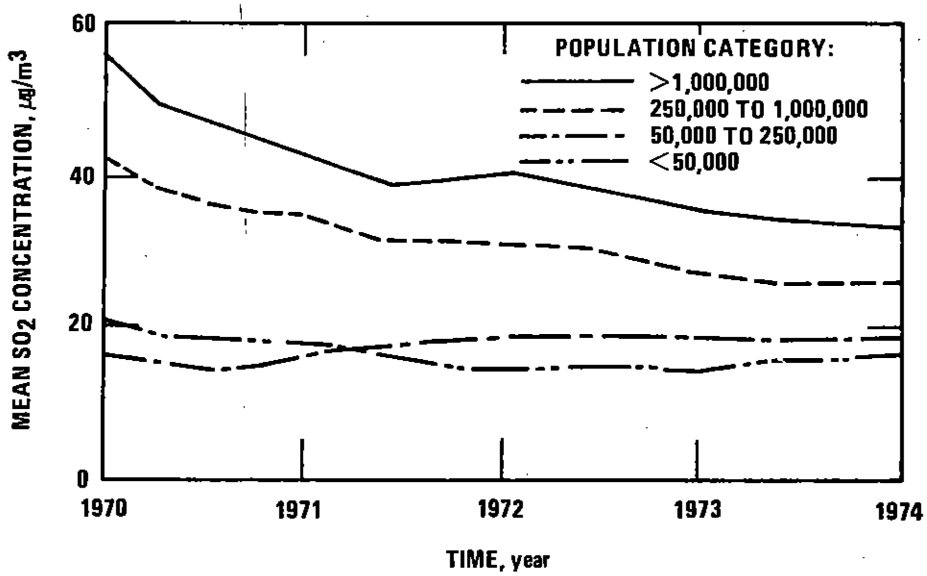
In considering a national overview for TSP and SO_2 trends, the previous figures have combined data from various types of sites. Figure 4-3 displays the composite averages for the same data, stratified by population. The population figures were taken from the Standard Metropolitan Statistical Areas (SMSA) in which the sites are located. These SMSAs are used by the U.S. Bureau of the Census and provide a convenient means for summarizing data by population category. As these graphs indicate, air quality is improving across all population categories for TSP; however, for SO_2, while the overall trend is down, the smaller-sized cities show a slight increase. Although many of these sites were in the North Central and Midwest, there does not appear to be any specific geographical grouping. At most of these sites, means are well below the annual standards despite these increases. Later sections will present further stratifications of the data to examine the major components of national trends.

4.2 METEOROLOGICAL FACTORS AFFECTING AIR QUALITY TRENDS

In considering air quality trends, the effect of meteorology is important. One reason for examining air quality trends is to see if genuine improvement is being made because meteorological phenomena over a given time period may mask actual trends. A study was conducted, therefore, to examine seasonal patterns and trends in meteorological parameters on a scale comparable to that of air quality parameters. To accomplish this, meteorological data for 1970 through 1974 were selected from National Weather Service observation stations most representative of the dominant SMSAs within each of 5 major geographic regions of the U.S. (as discussed in sections 4.4 and 4.5). Wind speed, rainfall, and temperature were selected for analysis because of their generally accepted relationships with ambient air quality and their amenability to large-scale regional analysis. Quarterly and annual averages were computed for the meteorological parameters in the same manner as for the air quality data.



A. TOTAL SUSPENDED PARTICULATES



B. SULFUR DIOXIDE

Figure 4-3. Comparison of trends in mean values for (a) total suspended particulates and (b) sulfur dioxide for 1970 through 1974, according to population categories: (1) < 50,000; (2) 50,000 to 250,000; (3) 250,000 to 1,000,000; and (4) > 1,000,000.

4.2.1 Regional Meteorological Trends

In general, dispersion is enhanced and pollutant levels are lower at higher wind speeds. Conversely, dispersion is limited and pollutant levels tend to be greater at low wind speed. Examination of the data indicates that wind-speed conditions that enhance dispersion tended to occur during the winter and spring seasons; whereas those conditions limiting dispersion were experienced mostly during the summer and fall. In addition, the higher maximum and minimum quarterly average wind speeds observed in the Northeast, Midwest, and Central Plains indicate that these areas had the most favorable wind-speed conditions for dispersion; whereas the Southeast experienced the least favorable.

The seasonality of rainfall was most distinct in the western half of the nation; in the East, however, no distinct seasonal patterns were observed. Rainfall is important in relation to air quality because it can remove particulates from the atmosphere. In general, the eastern half of the nation received more rainfall annually than the western half did during the 1970-1974 period. This, together with the observed seasonal patterns in the West, suggests that rainfall may more favorably influence annual air quality in the East, but may be more significant to variability in pollutant levels in the West.

The importance of these effects becomes clear when the seasonality of rainfall is examined together with that of wind speed. For example, the greater amounts of rainfall in the Southeast may partially have negated the unfavorable effects on dispersion of the observed low wind speeds. More significantly, in the Southwest and plains region, high wind speeds had a tendency to occur during the same seasons as low rainfall. This combination may have increased the amount of fugitive dust in the atmosphere and thereby unfavorably influenced air quality.

The distribution of quarterly average temperatures followed established summer maximum and winter minimum seasonal patterns with no unusual or dissimilar variations. Seasonality in temperature may be important with respect to seasonal and regional variations in air quality. For example, a well-defined seasonality in temperature-related pollutants would more likely be expected in the eastern two-thirds of the nation where summer and winter temperature differences generally are about 20 degrees greater and where the seasonability in wind speed is more distinct than in the West. In addition, the seasonality of sulfur dioxide may be related to temperature patterns in the eastern states since the major sources of this pollutant are linked with the seasonal consumption of fossil fuel.

It would be advantageous to separate the variability due to meteorology from that due to changes in emissions. While this would be the ideal approach, it is difficult to quantify the specific contribution of each component to the overall trend. For long-term air quality trends, the effect of meteorology may average out because of the cyclical nature of variation in meteorological variables; however, for short-term trends the change in air quality from one year to the next may be influenced by meteorologocal factors. Table 4-1 summarizes the short-term trends in the three meteorological parameters for the period 1970-1974 and qualitatively relates these to variations in air quality that might be expected from the effects previously discussed. To relate meteorological phenomena more quantitatively to air quality parameters, it is necessary to reduce the spatial scale of analysis because of the variability that exists on the regional level. As the scale of the meteorological data base approaches that of air quality, the interpretability of quantitative relationships would be expected to improve. The following section, therefore, examines the relationship between air quality and meteorological data on an SMSA basis.

4.2.2 Effect of Meteorology on Air Quality in Los Angeles: An Example

In order to help identify the effect of emissions on air qualtiy, it is desirable to remove the effect of meteorology. As an illustration of meteorological adjustment of air quality levels, a simple model* was entertained to relate quarterly air quality levels as a linear function of trend and the selected meteorological variables discussed in section 4.2.1. Because of the complicating influence of seasonality on an analysis using quarterly data, all regression analyses were performed upon seasonally adjusted measurements. In effect, an examination was made on departures from typical quarterly values during the 5-year period. A discussion of the results of this type of analysis for the Los Angeles SMSA is presented below.

---

*The model was of the form: $P=\mu + \alpha Y + \beta_1 W + \beta_2 T + \beta_3 R$, where Y represents year and P, W, T, and R are seasonally adjusted values of pollutant, inverse wind speed, temperature, and rainfall, respectively.

Table 4-1. SUMMARY OF METEOROLOGICAL TRENDS, 1970-1974

Regions[a]	Meteorological parameters			
	Wind speed	Rainfall	Temperature	Combined effect[b]
Northeast	No distinct trend.	Increased approximately 1.5 inches from 1970 to 1972; then decreased through 1974.	No distinct trend.	Favorable for improving air quality in the first of period, but unfavorable in the second.
Southeast	Increased slightly in the latter half of the 5-year period.	Increased steadily. Average climbed nearly 1 inch during the period.	Increased approximately 1 degree between mid-1970 and mid-1973.	Inconclusive effect in the first half, but favorable for improving air quality in the second half.
Midwest	Decreased from 1970 to mid-1972; then increased slightly.	Fluctuated between 1970 and 1971; increased to a peak value in early 1973; then remained relatively unchanged through 1974.	Decreased from 1970 through 1972; rose to above 1970 levels in 1973; then decreased again in 1974.	Unfavorable for improving air quality in the first half, but favorable in the second.
Central States	Decreased slightly in the southern part, but increased in the western portion of the region.	Increased between late 1971 and mid-1974; then decreased in late 1974.	Decreased throughout the period in the southern and central portions, but increased in the western part of the region.	Unfavorable for improving air quality in the first half, but favorable in the second

Table 4-1. (Cont)

Regions	Meteorological parameters			
	Wind speed	Rainfall	Temperature	Combined effect
West Coast	Decreased through the period.	Increased in late 1972; then decreased slowly through 1973 in southern sections; but increased through mid-1973 and increased again into mid-1974 in the northern sections of the region.	Increased slightly from mid-1973 through 1974.	Unfavorable for improving air quality throughout the period.

[a]Geographical regions were defined by combining EPA Regions as follows: Northeast includes EPA Regions I, II, and III; Southeast includes EPA Region IV; Midwest includes EPA Region V; Central states includes EPA Regions VI, VII, and VIII; and West Coast includes EPA Regions XI and X.

[b]Combined effect of meteorological variability of TSP and SO_2.

In the Los Angeles SMSA, during the period 1970-1974, average wind speed displayed a consistent downward trend; rainfall remained constant from 1970 until mid-1972, and then increased through 1974; and temperature remained fairly constant. These trends are depicted graphically in Figure 4-4.

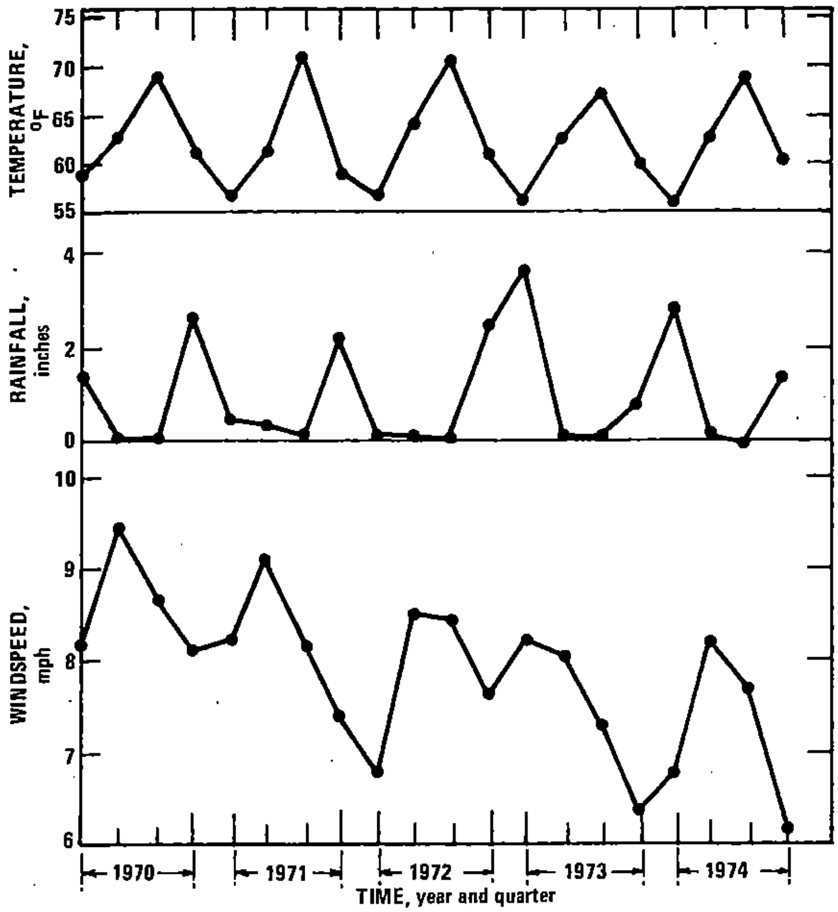


Figure 4-4. Comparison of trends in quarterly average temperature, rainfall, and windspeed in the Los Angeles Basin, 1970 through 1974.

SO_2 levels in the Long Beach-Los Angeles SMSA displayed a slight increase during the period 1970-1975. Composite average concentrations at nine sites increased from 34 $\mu g/m^3$ in 1970 to 37 $\mu g/m^3$ in 1974. Seasonally adjusted levels of SO_2 are highly correlated with those of TSP, suggesting that both pollutant concentrations were affected by similar influences, whether emissions or meteorology.

Seasonally adjusted average wind speed was found to be significantly correlated with seasonally adjusted SO_2. The decline in average wind speed may perhaps be partly responsible for the increase in SO_2 levels during this period. Although the characteristic periodicity of quarterly average temperature corresponded to the average seasonal behavior of SO_2, their seasonally adjusted values were not related. Rainfall was also not related to variations in SO_2 levels.

Each of the three meteorological variables was included in the model. Only inverse wind speed was found to be significant. The observed quarterly levels of SO_2 were normalized to the average meteorological conditions observed in each calendar quarter. Both before and after meteorological adjustment, the trend in SO_2 was not statistically significant, but the adjusted values indicate less variation and a marginal decrease. This comparison is displayed in Figure 4-5.

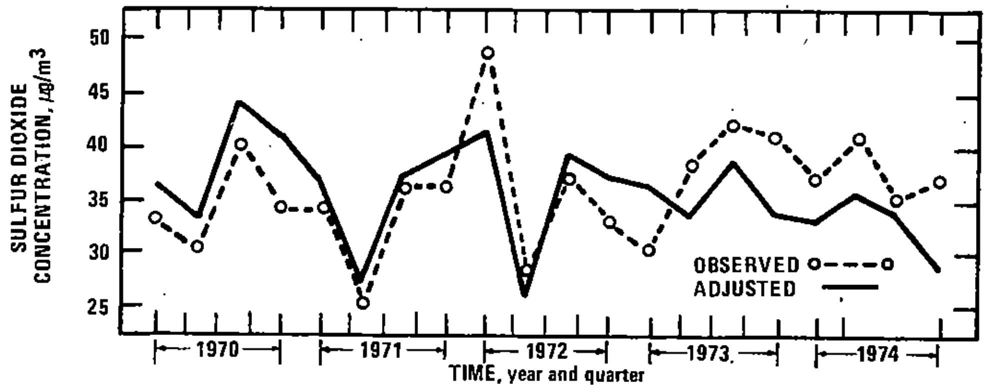

Figure 4-5. Comparison of observed and meteorologically adjusted quarterly average sulfur dioxide concentrations in the Los Angeles SMSA, 1970 through 1974.

The major impact of the meteorological adjustment occurred in the first quarter of 1972 and generally throughout the latter part of the 5-year period when wind speed averaged slightly below the 24-year normal of 7.4 miles per hour.

Total suspended particulates in Los Angeles declined moderately during the 5-year period. Of the three meteorological variables considered, only rainfall was correlated with TSP. Although the dry season during the second and third quarters coincided with the period of high TSP concentrations, seasonally adjusted rainfall was also negatively correlated with seasonally adjusted TSP. When all three meteorological parameters were examined jointly in combination with the assumed presence of a linear trend, the effects of wind speed, and rainfall were found to be statistically significant. After the effect of these meteorological parameters was taken into account, the slight downward trend in TSP was intensified and became statistically significant.

The impact of meteorology can best be viewed by comparing the observed TSP with TSP levels adjusted to reflect average meteorological conditions. This is presented in Figure 4-6.

The impact of meteorology on TSP levels was essentially the same as that on SO_2 levels. The major downward adjustment came in the first quarter of 1972, second, third and fourth quarters of 1973, and during all of 1974, when generally lower wind speeds occurred.

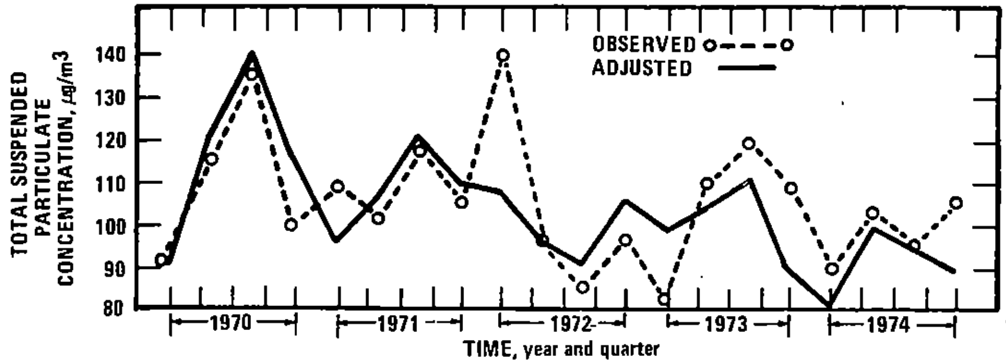

Figure 4-6. Comparison of observed and meteorologically adjusted quarterly average total suspended particulate concentrations in the Los Angeles SMSA, 1970 through 1974.

Although it is admittedly highly simplified, the statistical model employed for this analysis proved to be effective even with quarterly data. The model did not take into account interdependence among the various meteorological parameters and was based on composite measures of air quality and quarterly aggregates of meteorology. Nevertheless, it illustrates the importance of considering the impact of meteorology on air quality levels and trends.

4.3 AIR QUALITY DATA BASE CHARACTERISTICS

Any presentation of trends in air quality levels requires some discussion of the data base employed. In this section are given the general characteristics of the data base employed in the trends analyses, as well as the techniques used to summarize this information. As mentioned in the national overview, there are considerable differences in the sizes of the data bases for different pollutants. Reasons for differences in numbers of monitors range from economic considerations to improved knowledge of measurement techniques that has revealed some methods to be imprecise and their historical data consequently unreliable.

Definite differences exist between the data bases employed in section 3, which deals with status, and this section, section 4, which deals with trends. While in both cases data obtained from the National Aerometric Data Bank (NADB) were used in the analyses, different criteria were used in selecting the data for the analyses, based upon their respective purposes. The section dealing with status incorporates as many stations as possible from a given year in order to give a complete picture of current status with respect to the National Ambient Air Quality Standards (NAAQS). For trend analyses, however, historical continuity of data is required. Such continuity is needed to ensure that any apparent trend is actually the result of changes in measured air quality at a specific location rather than the result of a change in site location.

The requirement for historical continuity has certain consequences in terms of the sites that qualify for trend analysis. This is perhaps best understood by briefly considering the history of air quality monitoring. Efforts by Federal government to monitor air pollution have been historically concentrated in the National Air Surveillance Network (NASN) and the Continuous Air Monitoring Program (CAMP). With the expansion of non-Federal networks, the NASN and CAMP networks have been decentralized and are diminishing in scope. Although there are other Federal monitoring efforts for special study projects, these two networks have provided, until the last few years, the major data base for national trends. Although the NASN program at one time included some 30 background sites, the vast majority of the sites were in the center-city locations of urbanized areas. The original six CAMP stations were also located in center-city areas. As would be expected, the non-Federal monitoring activities are also initially concentrated in high population areas as individual cities develop their monitoring networks. In view of this evolution, it is not surprising that the selection of trend sites based upon historical continuity results in a sample that is dominated by population-oriented sites in urban areas. A detailed breakdown of these sites is given in Tables 4-2 and 4-3.

For this particular analysis, the TSP and SO_2 sites were selected on the basis of having four consecutive quarters of data in the 1970-1971 period and four consecutive quarters in the 1972-1974 period. The restriction on four consecutive quarters was employed to provide balanced seasonality. The 1970-1971 requirement was used to ensure that these sites would have data from the early 1970's, which was an important time period in the implementation of control measures in many areas. A site was considered to have a quarter of data if it satisfied the SAROAD validity criteria as discussed in section 3. Once these sites were selected, missing values were computed using linear interpolation between corresponding quarters of adjacent years. Missing end points were extrapolated assuming no change from the corresponding quarter of the adjacent year.

While this procedure results in a data base with the same number of values in each quarter, it is useful to consider whether the results

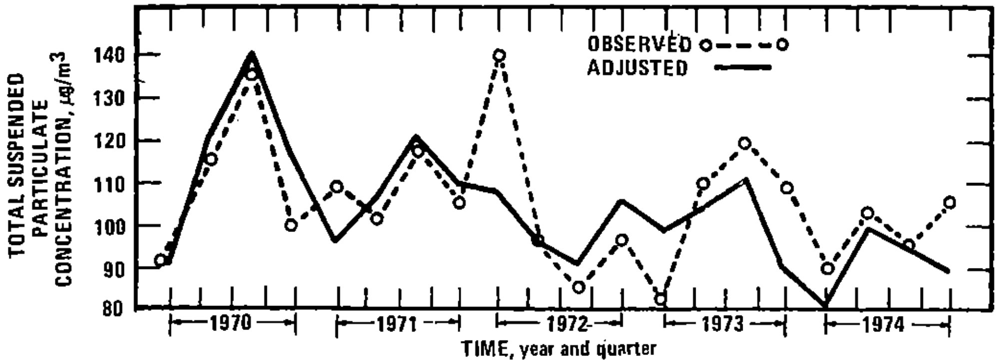

Figure 4-6. Comparison of observed and meteorologically adjusted quarterly average total suspended particulate concentrations in the Los Angeles SMSA, 1970 through 1974.

Although it is admittedly highly simplified, the statistical model employed for this analysis proved to be effective even with quarterly data. The model did not take into account interdependence among the various meteorological parameters and was based on composite measures of air quality and quarterly aggregates of meteorology. Nevertheless, it illustrates the importance of considering the impact of meteorology on air quality levels and trends.

4.3 AIR QUALITY DATA BASE CHARACTERISTICS

Any presentation of trends in air quality levels requires some discussion of the data base employed. In this section are given the general characteristics of the data base employed in the trends analyses, as well as the techniques used to summarize this information. As mentioned in the national overview, there are considerable differences in the sizes of the data bases for different pollutants. Reasons for differences in numbers of monitors range from economic considerations to improved knowledge of measurement techniques that has revealed some methods to be imprecise and their historical data consequently unreliable.

Definite differences exist between the data bases employed in section 3, which deals with status, and this section, section 4, which deals with trends. While in both cases data obtained from the National Aerometric Data Bank (NADB) were used in the analyses, different criteria were used in selecting the data for the analyses, based upon their respective purposes. The section dealing with status incorporates as many stations as possible from a given year in order to give a complete picture of current status with respect to the National Ambient Air Quality Standards (NAAQS). For trend analyses, however, historical continuity of data is required. Such continuity is needed to ensure that any apparent trend is actually the result of changes in measured air quality at a specific location rather than the result of a change in site location.

The requirement for historical continuity has certain consequences in terms of the sites that qualify for trend analysis. This is perhaps best understood by briefly considering the history of air quality monitoring. Efforts by Federal government to monitor air pollution have been historically concentrated in the National Air Surveillance Network (NASN) and the Continuous Air Monitoring Program (CAMP). With the expansion of non-Federal networks, the NASN and CAMP networks have been decentralized and are diminishing in scope. Although there are other Federal monitoring efforts for special study projects, these two networks have provided, until the last few years, the major data base for national trends. Although the NASN program at one time included some 30 background sites, the vast majority of the sites were in the center-city locations of urbanized areas. The original six CAMP stations were also located in center-city areas. As would be expected, the non-Federal monitoring activities are also initially concentrated in high population areas as individual cities develop their monitoring networks. In view of this evolution, it is not surprising that the selection of trend sites based upon historical continuity results in a sample that is dominated by population-oriented sites in urban areas. A detailed breakdown of these sites is given in Tables 4-2 and 4-3.

For this particular analysis, the TSP and SO_2 sites were selected on the basis of having four consecutive quarters of data in the 1970-1971 period and four consecutive quarters in the 1972-1974 period. The restriction on four consecutive quarters was employed to provide balanced seasonality. The 1970-1971 requirement was used to ensure that these sites would have data from the early 1970's, which was an important time period in the implementation of control measures in many areas. A site was considered to have a quarter of data if it satisfied the SAROAD validity criteria as discussed in section 3. Once these sites were selected, missing values were computed using linear interpolation between corresponding quarters of adjacent years. Missing end points were extrapolated assuming no change from the corresponding quarter of the adjacent year.

While this procedure results in a data base with the same number of values in each quarter, it is useful to consider whether the results

Table 4-2. TSP TREND SITES BY MONITORING CATEGORY WITHIN EPA REGIONS.

EPA Region	Surveillance category			
	Population-oriented	Source-oriented	Background	Total
I	91	1	5	97
II	200	0	0	200
III	59	11	3	73
IV	104	3	3	110
V	204	11	7	222
VI	130	3	5	138

IX	46	2	2	50
X	42	6	5	53
Total	1019	39	38	1096

would change if different site selection criteria had been employed. For comparative purposes, the general trends obtained by restricting station selection ("trend" sites) according to the above criteria are shown in Figure 4-7, along with the trends obtained by using all available data for this time period. The all-data medians are derived from TSP data from 4927 sites and SO_2 data from 2565 sites. For both pollutants the general agreement in the medians from the two data bases seems reasonable. In each case, the difference in medians is minimal

Table 4.3. SO_2 TREND SITES BY MONITORING CATEGORY WITHIN EPA REGIONS

EPA Region	Surveillance category			
	Population-oriented	Source-oriented	Background	Total
I	21	0	1	22
II	45	0	1	46
III	13	1	2	16
IV	22	1	3	26

VII	8	0	1	9
VIII	4	1	1	6
IX	20	0	0	20
X	3	0	0	3
Total	235	10	13	258

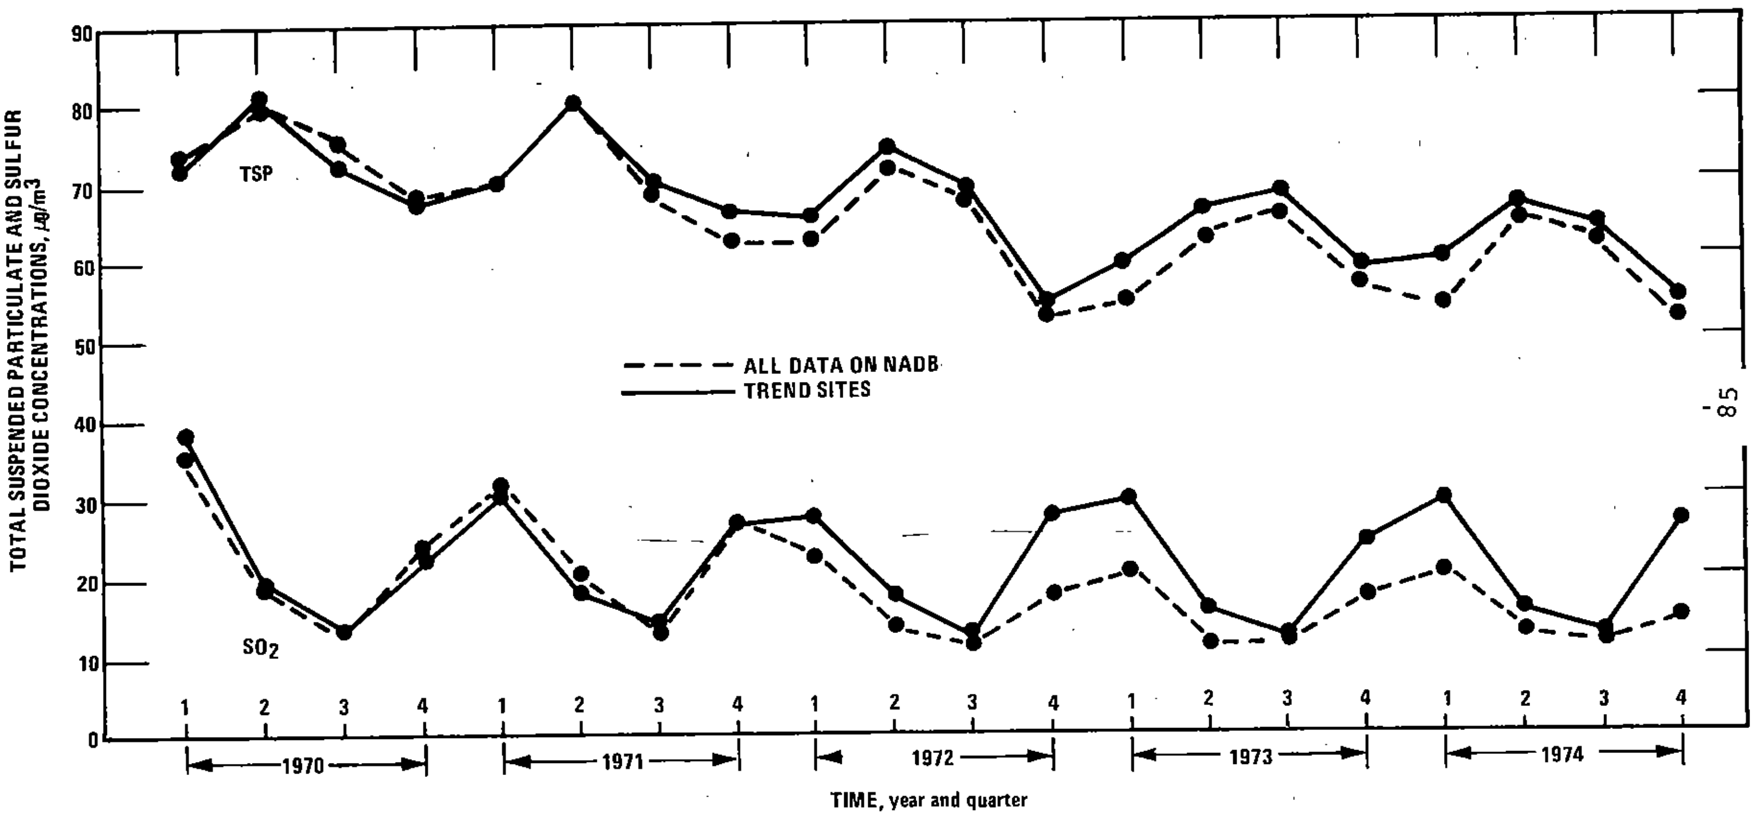

Figure 4-7. Comparison of median quarterly average of data from national trend sites with median quarterly averages of all data on the NADB for total suspended particulates and sulfur dioxide.

in the initial year but in the late time periods the trend-site subset of data is slightly higher than the all-data set. This pattern is consistent with what would be expected as new sites are added in the cleaner areas. Because problem areas with higher concentrations would more likely be the first locations monitored, trends based upon an expanding data base could be influenced merely by the addition of new monitoring sites in cleaner areas. Therefore, the data set constructed on the bases of historical continuity has the advantage of adequately describing the general trends while minimizing the possible effects of a shifting data base.

4.4 REGIONAL TRENDS IN TOTAL SUSPENDED PARTICULATES

As indicated in the national overview section, a reduction in TSP levels has been achieved. The purpose of this section is to examine the data in terms of geographical regions and the specific cities that dominate the regional trends. Despite the general improvement in TSP levels, many localities are having difficulty attaining the NAAQS for TSP. These difficulties fall mainly into two categories: fugitive dust emissions and urban background levels.[4] Fugitive dust refers to TSP levels that are attributable to factors such as natural sources, tilled farm lands, unpaved roads, or to activities such as construction. The fugitive dust problem occurs generally in the western half of the nation but can also be a contributing factor in the east. The control of such dust emissions is quite difficult and in some western states it is estimated that TSP levels resulting from fugitive dust alone are sufficient to violate the NAAQS.[5,6] The urban background problem refers to TSP levels in major urban areas that come from numerous miscellaneous sources, such as tire fragments, salt and sand particles from snow control, or re-entrainment of street dust caused by wind and traffic flow. These problems are currently under study in many cities, but it appears that reduction of urban background will require long-term control strategies.[4] These two factors may contribute to the leveling off observed in the national TSP trends.

The regional trends for TSP are examined by EPA Regions rather than more general geographical regions. Figure 4-8 shows the geographical boundaries of the EPA Regions. Table 4-4 shows the SMSAs that contain at least 10 percent of the total number of trend sites within a region.

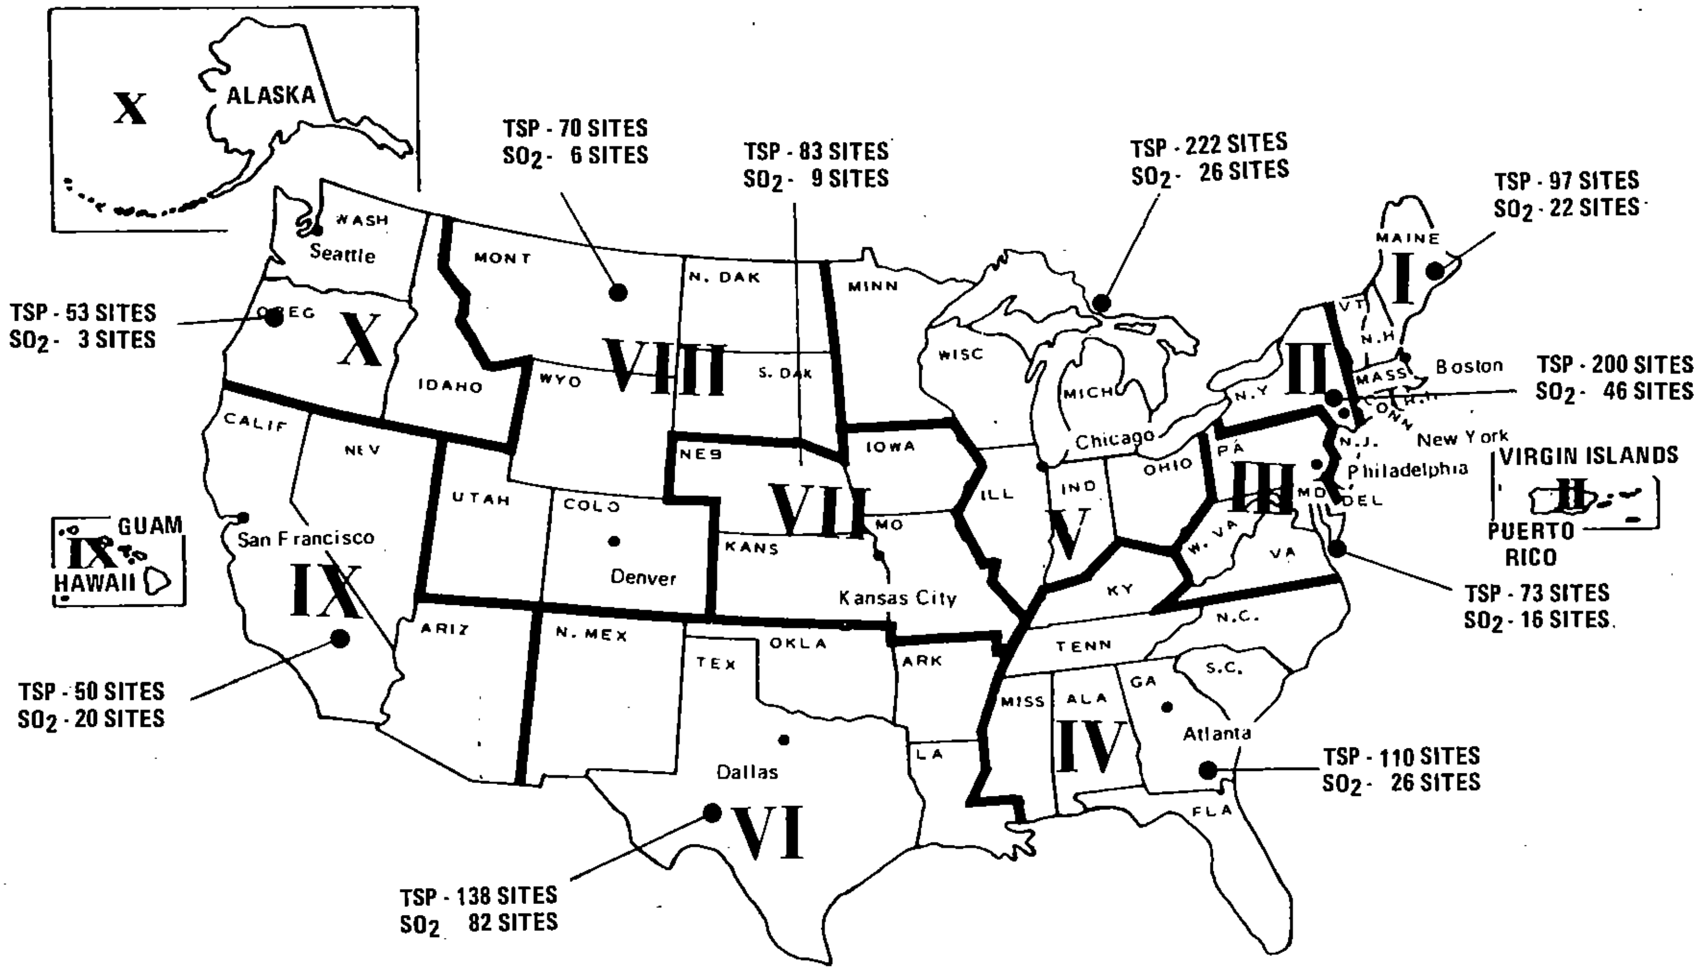

Figure 4-8. Distribution by EPA Region of monitoring sites meeting criteria for selection as "trend" sites, 1970 through 1974.

Table 4-4. SMSAs WHOSE TREND SITES COMPRISE MORE THAN 10 PERCENT OF TSP TREND SITES IN RESPECTIVE REGIONS

Region	Major city in SMSA	Sites, no.
I	Providence	12
II	Buffalo	31
	New York	34
	Syracuse	21
III	Washington, D.C.	18
	Wilmington	12
IV	Louisville	11
	Nashville	14
V	Chicago	22
VI	Houston	17
	Lubbock	17
VII	St. Louis	11
VIII	Denver	21
IX	Los Angeles	5
	Phoenix	5
	San Francisco	5
X	Seattle	11
	Tacoma	7

As would be expected from the overall improvement shown on the national level, most of these regions have downward trends in mean TSP levels. Figure 4-9 categorizes the upward and downward changes during this period on a regional basis. This is complemented by the graphs in Figure 4-10, which show the composite average for each region and for selected SMSAs that are major components of the regional data base and that had data continuity through 1974. Because of this selection criterion, it would be expected that the regional trends and the SMSA trends would be congruent or at least parallel, and, in most cases, this is true. In Region I, Providence shows a downward trend that is consistent with the overall regional trend. TSP levels in New York and Buffalo show more improvement than in Region II overall. In Region III, the trend in Wilmington, Delaware, is consistent with the regional improvement. In contrast, Washington, D.C., shows an upward trend in the late 1973-1974 period. These higher TSP values in Washington may have been caused by the subway construction activity in this city.[7] The downward trend in Region IV is linear, while the trends in Louisville and Nashville are downward but appear to have occurred more recently. In Cleveland and Chicago, TSP levels decreased, followed by a leveling off, which agrees with the overall Region V trend. Average TSP concentrations in Region VI show a downward trend as they do in Dallas; while in Houston, TSP levels are fairly stable. The TSP trend in St. Louis is consistent with the overall improvement in Region VII.

While TSP levels in Regions I through VII show general improvement, levels in Regions VIII, IX, and X show mixed and upward trends. Denver accounts for 30 percent of the sites in Region VIII and is the dominant factor in the increase in the regional composite average. It has been suggested that a major contributing factor to the TSP problem in Denver is the sand and salt used for snow control.[8] In Region IX, TSP levels in San Francisco have been relatively stable in the 1970's while those in Los Angeles have shown a slight decrease. Particulate levels in Los Angeles have remained relatively high despite the implementation of the usual particulate control strategies, such as reduction of open burning and use of emission controls on major sources.[4] Part of this difficulty is caused by the formation of secondary particulates from gaseous precursors that are frequently unaffected by the usual particulate control strategies. This is particularly true in the Los Angeles area, where it has been estimated that approximately 40 percent of the TSP pollution is caused by these secondary particulates. In Region X,

	Tacoma	2

of the sites in Region IX, and it shows increasing SO_2 levels. This is discussed in more detail later in this section.

Because of the potential impact on SO_2 levels of the use of higher-sulfur fuels, it is useful to examine changes between the 1972-1973 winter and the 1973-1974 winter. This was done on the basis of quarterly SO_2 averages for the fourth quarter of 1972 and the first quarter of 1973 versus the fourth quarter of 1973 and the first quarter of 1974. In order to utilize data from as many sites as possible, the general trends criteria were dropped and all sites having data in the National Aerometric Data Bank for these two winter seasons were used. This resulted in the use of data from 1922 sites rather than from just the 258 trends sites. Figure 4-12 summarizes these results for each EPA Region and for the nation. From these results it appears that the general improvement in SO_2 levels seen during the early 1970's has ended and that the current pattern is quite mixed. Ambient levels of SO_2 in Regions II and III seem to have experienced a definite reversal during this period. This suggests that the energy crisis during this period may have contributed to increases in SO_2 levels. Because of the variety of factors that influence air quality levels, a more detailed analysis on a case-by-case basis, such as was done in last year's report,[3] is necessary to establish definitely the exact cause of this increase. Reports, however, by the New York State Department of Environmental Conservation[10] and the Philadelphia Department of Environmental Health[11] indicate that the energy crisis had an adverse effect in those areas.

Among the possible reasons for present trends in SO_2 levels, temperature is an important factor because of the emissions associated with fuel combustion for heating. As discussed in section 4.2, various meteorological factors, including temperature, were examined for comparisons with air quality trends. Seven out of the ten EPA regions had warmer winters in the 1972-1974 period than in the 1970-1971 period. Only Regions VI, VII, and VIII departed from this pattern. Therefore, a portion of the improvement in SO_2 levels could be attributable to the warmer winters. All ten regions were warmer in the winter of 1973-1974 than in the winter of 1972-73. Despite the milder winters, many sites showed increased SO_2 levels, which reinforces the possibility that the energy crisis contributed to the increase.

As discussed in section 4.2, in only one case did these meteorological parameters appear to account for a major portion of the apparent trend. This occurred in Los Angeles, where the upward trend in SO_2 levels coincided with decreasing wind speeds, particularly in the forth quarter

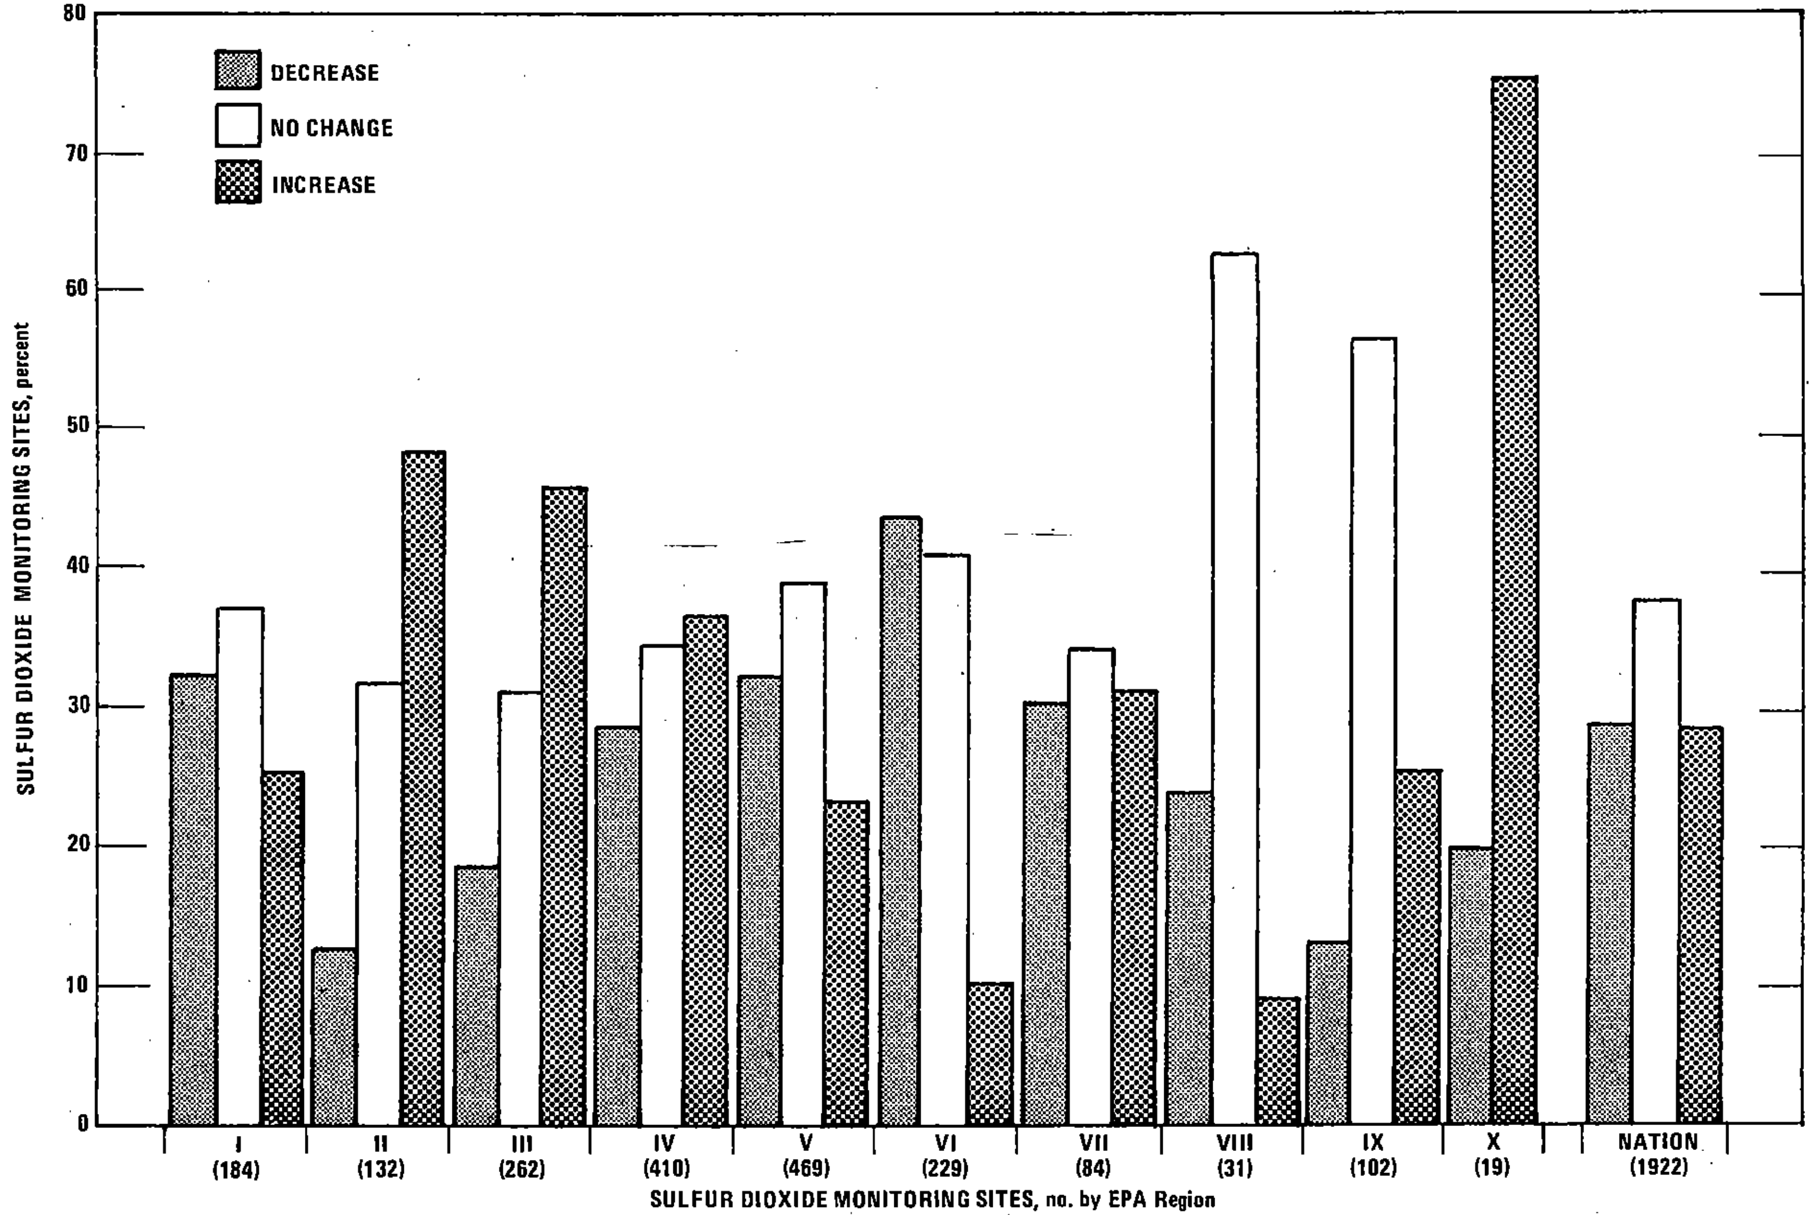

Figure 4-12. Percentage distribution of monitoring sites, by EPA Region, with respect to changes in sulfur dioxide levels for winter 1973-1974 versus winter 1972-1973.

of 1974. At the present time it is anticipated that SO_2 levels in this area will increase because of fuel switching associated with natural gas shortages. This possibility also exists in the San Francisco and San Diego areas. Consequently, though SO_2 increases caused by clean-fuel shortages have been primarily confined to the east so far, such shortages may also result in SO_2 increases on the west coast.

In summary, it appears that the general improvement in SO_2 levels has leveled off. The current pattern is now mixed, and future trends will be determined by actual changes in emission levels. This is much more apparent for SO_2 than for TSP. Because natural SO_2 background is essentially zero for urban areas, ambient SO_2 levels are much more sensitive to changes in emission levels. This was seen in the decreases in SO_2 levels effected by controls in the late 1960s and early 1970s. It is apparent from recent patterns that future SO_2 levels will be influenced primarily by the types of fuels available and the emission controls associated with fuel combustion.

4.6 REGION-SPECIFIC TRENDS IN CARBON MONOXIDE, OXIDANTS, HYDROCARBONS, AND NITROGEN DIOXIDE

Carbon monoxide, oxidant, hydrocarbon, and nitrogen dioxide trends for specific areas of the country will be discussed in this section because there are insufficient historical data from which to derive national trends. The specific area analyses are based on data from the National Aerometric Data Bank (NADB), as well as on summaries of trends taken from several state and local reports. While separate trend criteria were used for the NADB, state, and local analyses, in all cases the data covered a 3-year period at a minimum. The areas examined include several cities in California, as well as Philadelphia and the states of New York, New Jersey, and Washington. Historically, California has had the most extensive monitoring network, and this is reflected in the trend analyses that follow. In 1970 and 1971 a majority of the sites that were monitoring oxidant, nitrogen dioxide, and carbon monoxide in the nation and reporting to the NADB were in that state. California had 38 out of 45 sites (85 percent) monitoring oxidant, 50 out of 77 sites (65 percent) monitoring nitrogen dioxide, and 28 out of 45 sites (58 percent) monitoring carbon monoxide. In 1974, California was still dominant, reporting data from 26 percent of all oxidant sites

(87 out of 330) to the NADB, from 20 percent of the carbon monoxide sites (62 out of 316), and from 8 percent of the nitrogen dioxide sites (98 out of 1217).

4.6.1 Carbon Monoxide Trends

4.6.1.1 California

Using data from the NADB, carbon monoxide trends are examined here for the Los Angeles and the San Francisco areas. Table 4-7 indicates that the Los Angeles area has made progress toward meeting the 8-hour standard inasmuch as the percentage of values above the 8-hour standard has declined; and in the San Francisco area data show less than 0.5 percent violations of the 8-hour standard. With respect to the annual second-highest 1-hour average CO concentrations, Los Angeles has shown some progress, while San Francisco has basically shown no change.

Carbon monoxide trends are also shown in Figures 4-13 and 4-14 for San Diego[12] and Sacramento,[13] respectively. The CO levels in San Diego have been fairly stable between 1963 and 1973, while Sacramento has shown improvement.

4.6.1.2 Philadelphia

Based on a report by the Philadelphia Department of Public Health,[14] carbon monoxide in Philadelphia does not show a clear trend (Figure 4-15) in spite of the use of air pollution control devices on automobiles and the achievement of reductions in emissions from stationary sources. The downward trend over recent months is attributed primarily to the effects of the 1973-1974 winter fuel shortage and its consequent reduction in use of automobiles. This trend may also show the early effects of emission controls on new cars.

4.6.1.3 New Jersey, New York, and Washington

Carbon monoxide trends based on data in the NADB, are summarized in Table 4-8 for the states of New Jersey, New York, and Washington.

Composite averages of the second-highest annual maximum 1-hour concentration and the average percentage of measured values exceeding the 8-hour National Ambient Air Quality Standard (NAAQS) for CO are presented for each of the three states for the period 1970-1973.

Table 4-7. ANNUAL SECOND-HIGHEST 1-HOUR AVERAGE CARBON MONOXIDE CONCENTRATIONS AND PERCENTAGE OF ANNUAL VALUES ABOVE 8-HOUR STANDARD FOR COMPOSITE GROUPS OF SITES IN CALIFORNIA, 1970 THROUGH 1974

Period, yr.	Avg. second-highest annual 1-hr CO concentration, mg/m^3		Avg. annual values >8-hr standard, %	
	Los Angeles (10 sites)	San Francisco Bay area (7 sites)	Los Angeles (10 sites)	San Francisco Bay area (7 sites)
1970	32	15	14	< 0.5
1971	32	16	11	< 0.5
1972	31	16	8	< 0.5
1973	26	14	6	< 0.5
1974	28	17	8	< 0.5

Table 4-8. ANNUAL SECOND-HIGHEST 1-HOUR AVERAGE CARBON MONOXIDE CONCENTRATIONS AND PERCENTAGE OF ANNUAL VALUES ABOVE 8-HOUR STANDARD FOR COMPOSITE GROUPS OF SITES IN NEW JERSEY, NEW YORK, AND WASHINGTON STATE, 1970 THROUGH 1974

Period, yr.	Avg. second-highest annual CO concentration, mg/m^3			Avg. annual values 8-hr standard, %		
	New Jersey (15 sites)	New York (8 sites)	Washington (7 sites)	New Jersey (15 sites)	New York (8 sites)	Washington (7 sites)
1970	29	--	--	16	--	--
1971	30	20	21	9	1	5
1972	28	16	20	10	< 0.5	4
1973	30	18	23	7	1	3
1974	26	14	--	3	< 0.5	--

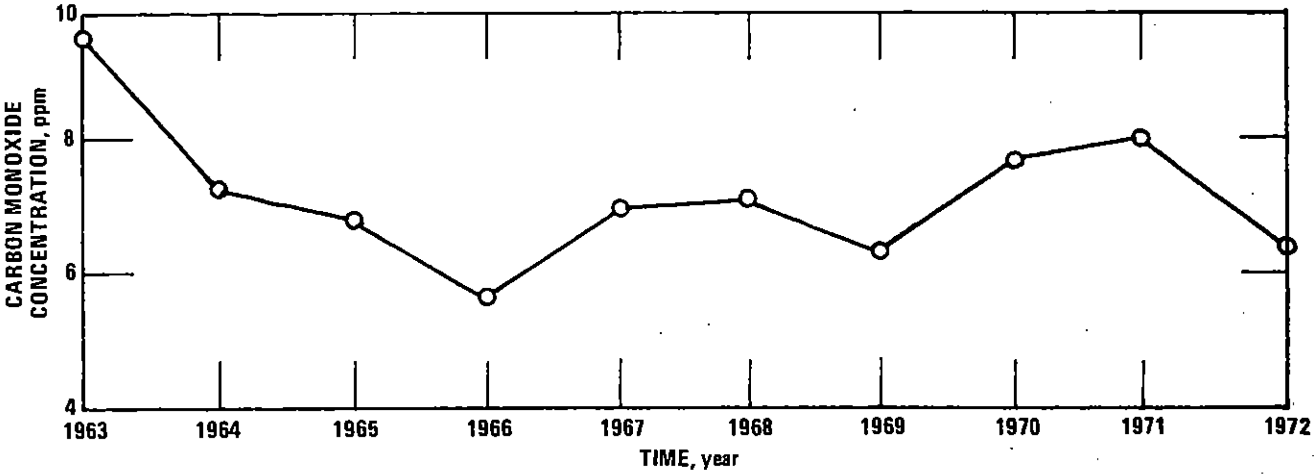

Figure 4-13. Carbon monoxide trends at San Diego monitoring stations; annual averages of daily maximum 1-hour concentrations.[12]

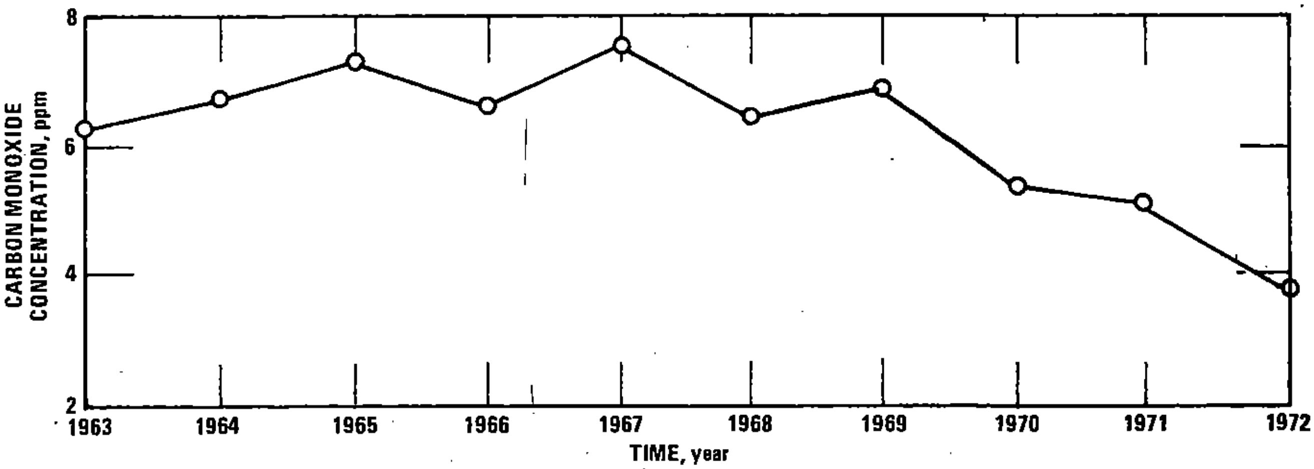

Figure 4-14. Carbon monoxide trends at Sacramento monitoring station; annual averages of daily maximum 1-hour concentrations.[13]

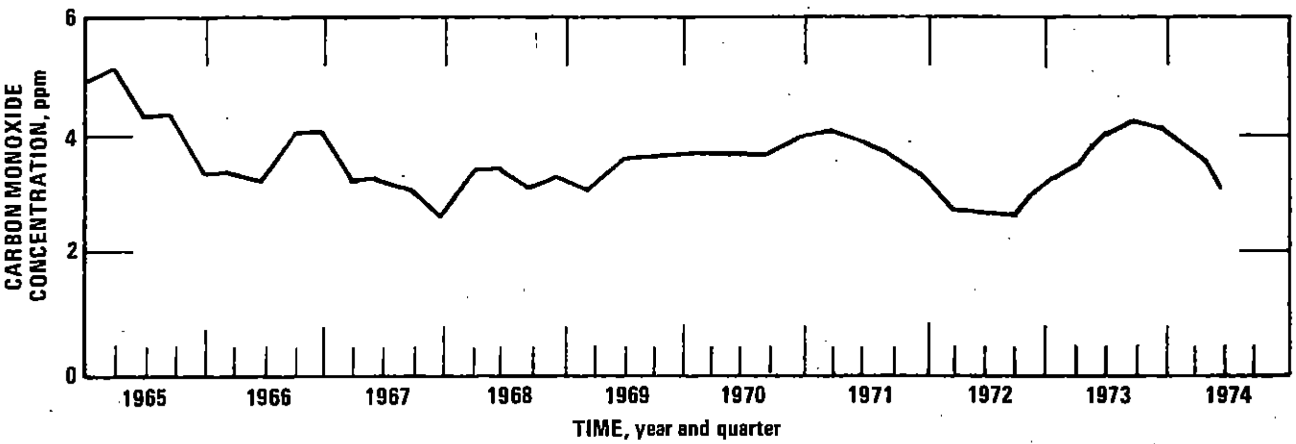

Figure 4-15. Carbon monoxide trends at Philadelphia monitoring station; four-quarter moving arithmetic average.[14]

Carbon monoxide levels declined in each of the states as evidenced by a downward trend in the percentage of annual values greater than the 8-hour standard. This progress is noteworthy because it is the 8-hour CO standard that is most frequently violated.

There appears to be some progress in reducing the annual second-highest 1-hour average CO concentrations for New Jersey and New York. In the state of Washington, the apparent discrepancy between the downward trend in the percentage of annual values greater than the 8-hour NAAQS and the lack of sustained change in the second-highest 1-hour concentrations is not too surprising. Short-term statistics, such as the 1-hour maximum, are notoriously influenced by irregular conditions, such as high CO levels caused by an extraordinary traffic tie-up. Consequently, the high variability of the 1-hour maximum may cause it to be an unreliable indicator of real, long-term change; however, because of its relationship to the NAAQS, its information content should not be ignored. The percentage of values above a particular threshold, such as the 8-hour NAAQS, is derived from the average of an entire year of data, so that CO levels arising from a variety of conditions have been averaged out; it is, therefore, a more stable indicator of real change.

The decrease in the percentage of values above the 8-hour NAAQS seen in Table 4-8 can be explained, in part, by the success of the Federal Motor Vehicle Emissions Control Program, which has resulted in reducing CO emissions.

4.6.2 Oxidant and Hydrocarbon Trends in California

California oxidant data from the NADB were examined according to three groupings: Coastal Los Angeles, Noncoastal Los Angeles, and the San Francisco Bay Area. In general, oxidant levels found in 1974 from the three groups of California sites confirm a continuation of the longer-term downward oxidant trends previously reported.[15,16] This improvement can be seen in both the magnitude of the peak hourly oxidant concentrations (Figure 4-16) as well as in the number of values exceeding the 1-hour NAAQS (Table 4-9).

Air quality at the group of sites within the Los Angeles area at which some of the historical oxidant problems have occurred continues to show improvement. A notable deviation from the general pattern

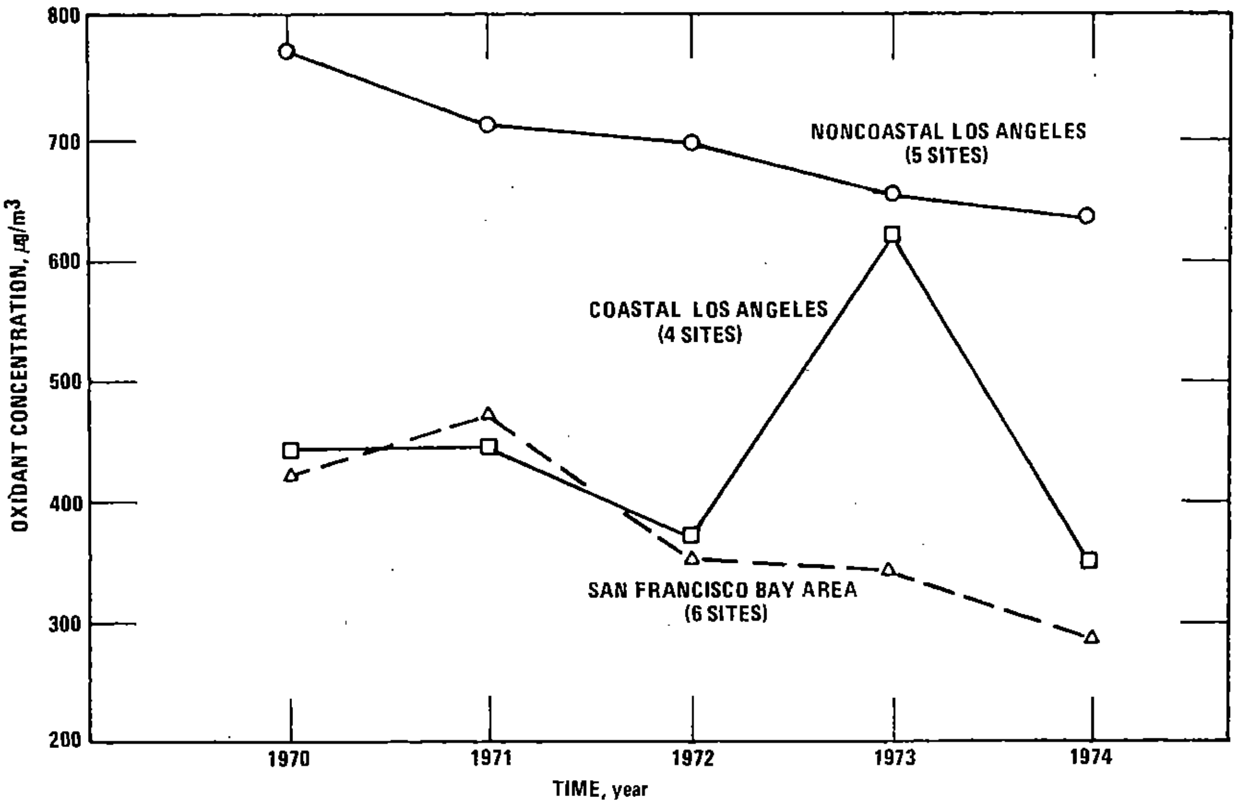

Figure 4-16. Composite averages of second-highest annual 1-hour oxidant values for various areas within California.

Table 4-9. AVERAGE ANNUAL NUMBER OF VALUES ABOVE 1-HOUR OXIDANT STANDARDS[a] AT GROUPS OF SITES IN LOS ANGELES AND SAN FRANCISCO BAY REGIONS

Sites	Stations, no.	Time, yr				
		1970	1971	1972	1973	1974
Coastal Los Angeles	4	309	202	188	205	152
Noncoastal Los Angeles	5	886	768	698	703	614
Bay Area	6	110	77	80	49	50

[a]The 1-hour National Ambient Air Quality Standard for oxidant is 600 μg/m^3.

of decline in concentrations did occur, however, in some areas of the Los Angeles Basin, as indicated by the trend found at four coastal sites in Los Angeles in 1973. The California Air Resources Board attributes the high oxidant concentrations recorded during 1973 to extranormal meteorological conditions,[17] which emphasizes the potential impact on air quality of adverse meteorological conditions. These conditions contributed to the slight increase in the number of annual violations of the 1-hour NAAQS that occurred within the Los Angeles Basin during 1973. It is interesting to note that the composite average of the second-highest annual 1-hour oxidant values in 1974 returned to the 1972 low at the four coastal sites.

At the sites selected from the San Francisco Bay area, the second-highest annual maximum value and the number of values exceeding the NAAQS have shown improvement. A Bay Area Air Pollution Control District report, however, indicates that the downward trend in oxidant concentration has leveled off somewhat since 1974.[18]

Overall, the general pattern seems to be one of the modest improvements in peak oxidant levels and in the frequency with which the NAAQS are exceeded. The improvements are consistent with scheduled reductions of hydrocarbon emissions, which are known to cause oxidant formation.

Paskind and Kinosian[19] examined long-term trends in oxidants and nonmethane hydrocarbons for the South Coast Air Basin of California (Los Angeles) for the period 1963-1973. They found an overall decrease in emissions and ambient levels of hydrocarbons; and a decline in oxidant concentrations in the western portion of the Basin and an increase in the eastern portion (Figure 4-17). They concluded that emissions of hydrocarbons must be further reduced to achieve lower oxidant concentrations in all areas of the South Coast Air Basin.

Long-term oxidant and hydrocarbon trends at the San Diego site are shown in Figures 4-18 and 4-19, respectively, for the San Diego Air Basin for the period 1963-1972. The statistic examined is the annual average of the daily maximum 1-hour oxidant concentrations. At this station, as at five other stations in San Diego,[12] oxidants decreased several parts per hundred million (pphm) from the maximum (in 1963) to the minimum year.[12]

The average of maximum 1-hour hydrocarbon concentrations, shown in Figure 4-19, generally remained constant from 1965 to 1973.[12] Since there was an increase in automobiles and other hydrocarbon sources, this decrease may be attributed to control of hydrocarbon emissions from automobiles and stationary sources. In California, motor vehicle crankcase emission control began in 1963 and exhaust control began with 1966 model-year cars.

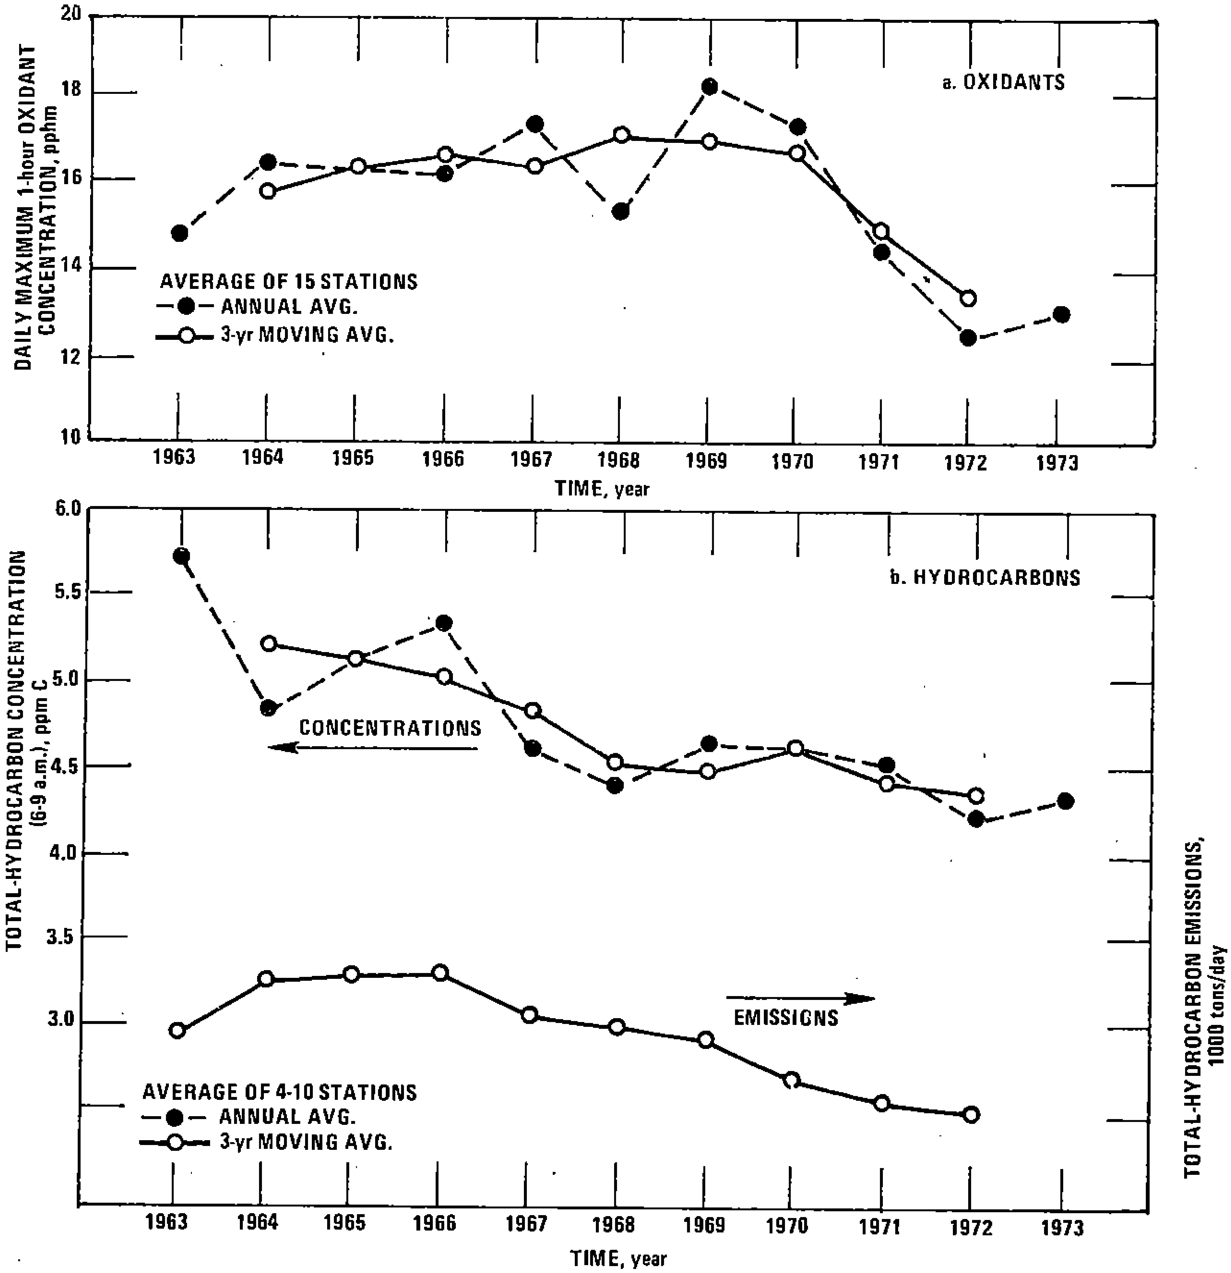

Figure 4-17. Ambient (a) oxidant and (b) hydrocarbon levels and hydrocarbon emission trends in the South Coast Air Basin (Los Angeles), July through September, 1963 through 1973.[19]

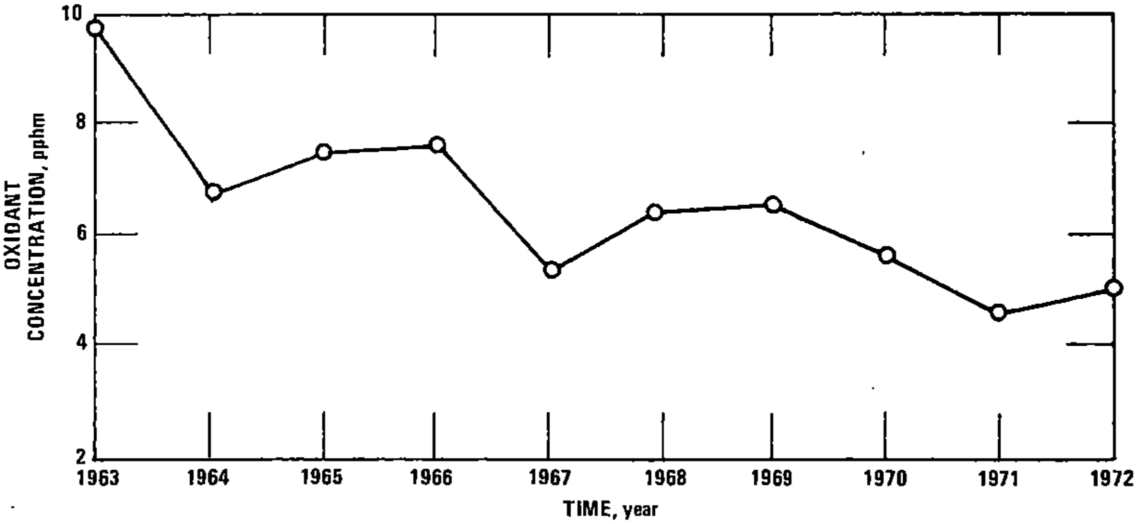

Figure 4-18. Oxidant trends at San Diego monitoring station; annual averages of daily maximum 1-hour concentrations.[12]

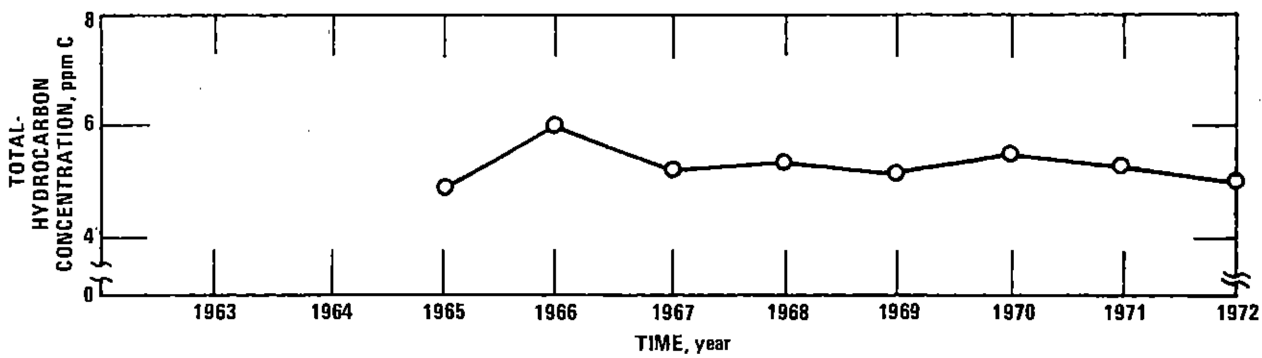

Figure 4-19. Hydrocarbon trends at San Diego monitoring station; annual averages of daily maximum 1-hour concentrations.[12]

4.6.3 Nitrogen Dioxide Trends

4.6.3.1 California

Emissions and ambient levels of oxides of nitrogen show an upward trend in the South Coast Air Basin (Los Angeles) for the period 1963-1973, according to a paper by Paskind and Kinosian[19] (Figure 4-20). These authors concluded in their paper that the oxides of nitrogen emissions must be reduced, along with hydrocarbon emissions, if lower oxidant concentrations are to be achieved in all areas of the South Coast Air Basin.

The maximum 1-hour nitrogen dioxide levels in San Diego, shown in Figure 4-21, have generally remained unchanged with some random fluctuations.[12] Exhaust control systems for hydrocarbon and carbon monoxide emissions from 1966-1970 model automobiles caused increased emissions of oxides of nitrogen from these automobiles. Control of oxides of nitrogen emissions in California began with the 1971 model year.

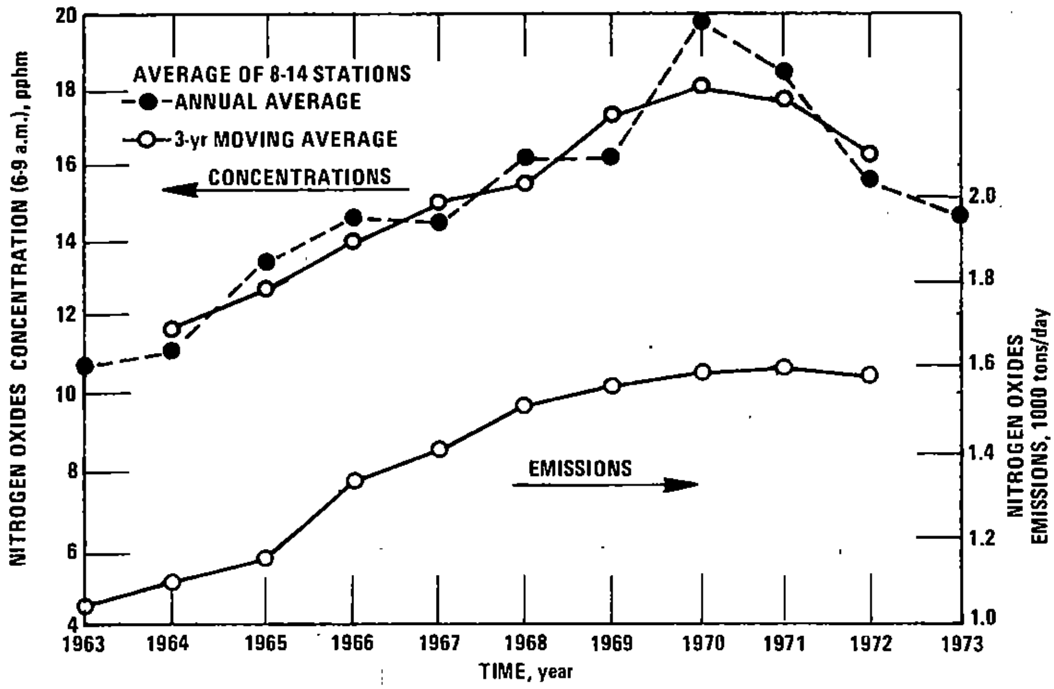

Figure 4-20. Trends in ambient levels and emissions of nitrogen oxides in the South Coast Basin.[19]

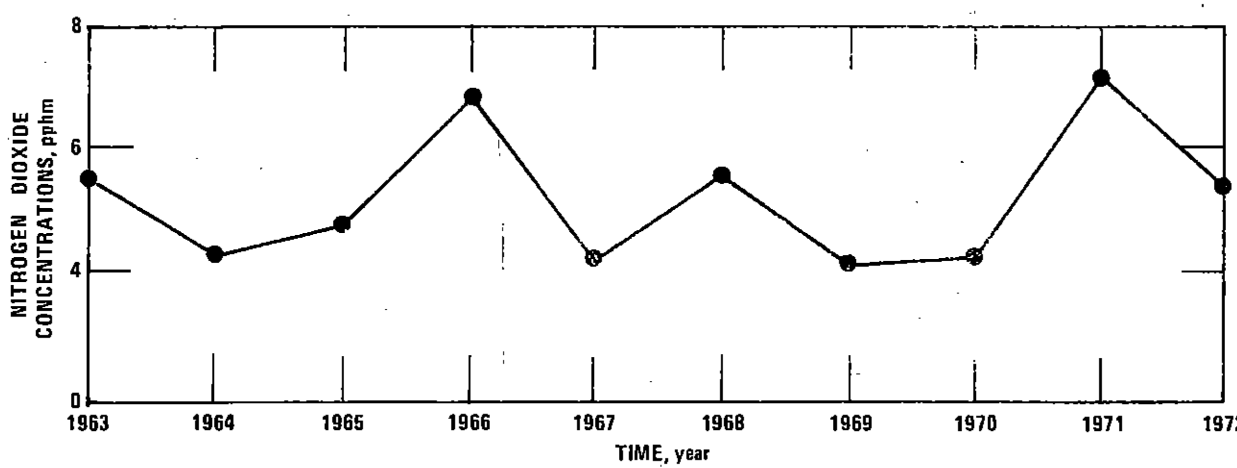

Figure 4-21. Trends in ambient levels of nitrogen dioxide at San Diego monitoring station; annual averages of daily maximum 1-hour concentrations.[12]

4.6.3.2 Philadelphia

An increase in nitrogen dioxide concentrations was the trend in Philadelphia from 1972 through 1974, possibly reflecting a temporary increase in nitrogen oxide emissions associated with the 1970-1973 model cars (Figure 4-22), according to a report from the Philadelphia Department of Public Health.[14] Future reductions in automotive emissions of NO_x should result in lower NO_2 concentrations.

4.6.4 Summary

In summary, progress is being made in achieving the NAAQS for oxidants and carbon monoxide in the Los Angeles Air Basin, the San Diego Air Basin, the San Francisco Air Basin, and in Sacramento. While there is no clear trend in carbon monoxide concentrations in Philadelphia, progress is being made in achieving the 8-hour CO NAAQS in New Jersey New York, and Washington State.

Hydrocarbon levels are decreasing in the Los Angeles Air Basin and are unchanged in San Diego. The trend is an increase in NO_2 concentrations in the Los Angeles Air Basin and in Philadelphia, but relatively no change in San Diego.

As more monitoring stations accumulate at least 3 or more years of data, long-term air quality trends can be determined for more areas of the country.

5. SPECIAL TOPICS

5.1 URBAN-RURAL OXIDANT STUDIES

Over the past few years, EPA has been engaged in a program of field monitoring studies to assess the extent and causes of the high ozone concentrations (above the NAAQS for photochemical oxidants measured as ozone) that have been observed in rural areas of the United States, particularly in the Eastern portion. Because of EPA's interest in improving the technical basis for oxidant control strategies, the studies have focused on the contribution to ambient ozone concentrations of urban ozone precursor emissions and on the relative roles of local ozone formation and of long-range transport.

A large-scale study was conducted during the summer of 1974 that covered an extensive area of the Midwest and East. The final report on the findings and results of the study was published in March 1975.[1] The study included both ground-based and airborne monitoring of ozone, ozone precursors, and meteorological variables. Overall direction for the study was provided by the Monitoring and Data Analysis Division (MDAD) of OAQPS. Major contributions to the study were made by the Research Triangle Institute (RTI), the principal MDAD contractor; and by the Chemistry and Physics Laboratory, NERC-RTP, and its contractors. Sampling was performed from June 15 through August 31, 1974. The area covered by the ground monitoring network is shown in Figure 5-1. Table 5-1 presents data on maximum hourly ozone concentrations observed and frequency of occurrence of concentrations above the NAAQS of 0.08 ppm (160 micrograms/cubic meter). It should be noted that at DuBois, a small town in rural Pennsylvania, the oxidant standard was exceeded for 341 hours during the measurement period. During the same period, Pittsburgh, approximately 100 miles southwest of the station, had only 106 hours during which the standard level was exceeded. The maximum hourly concentration at DuBois was 0.20 ppm; at Pittsburgh, it was 0.14 ppm. Oxidant levels in urban areas may be suppressed by reactions of ozone with nitric oxide, a product of automotive exhaust. Oxidant

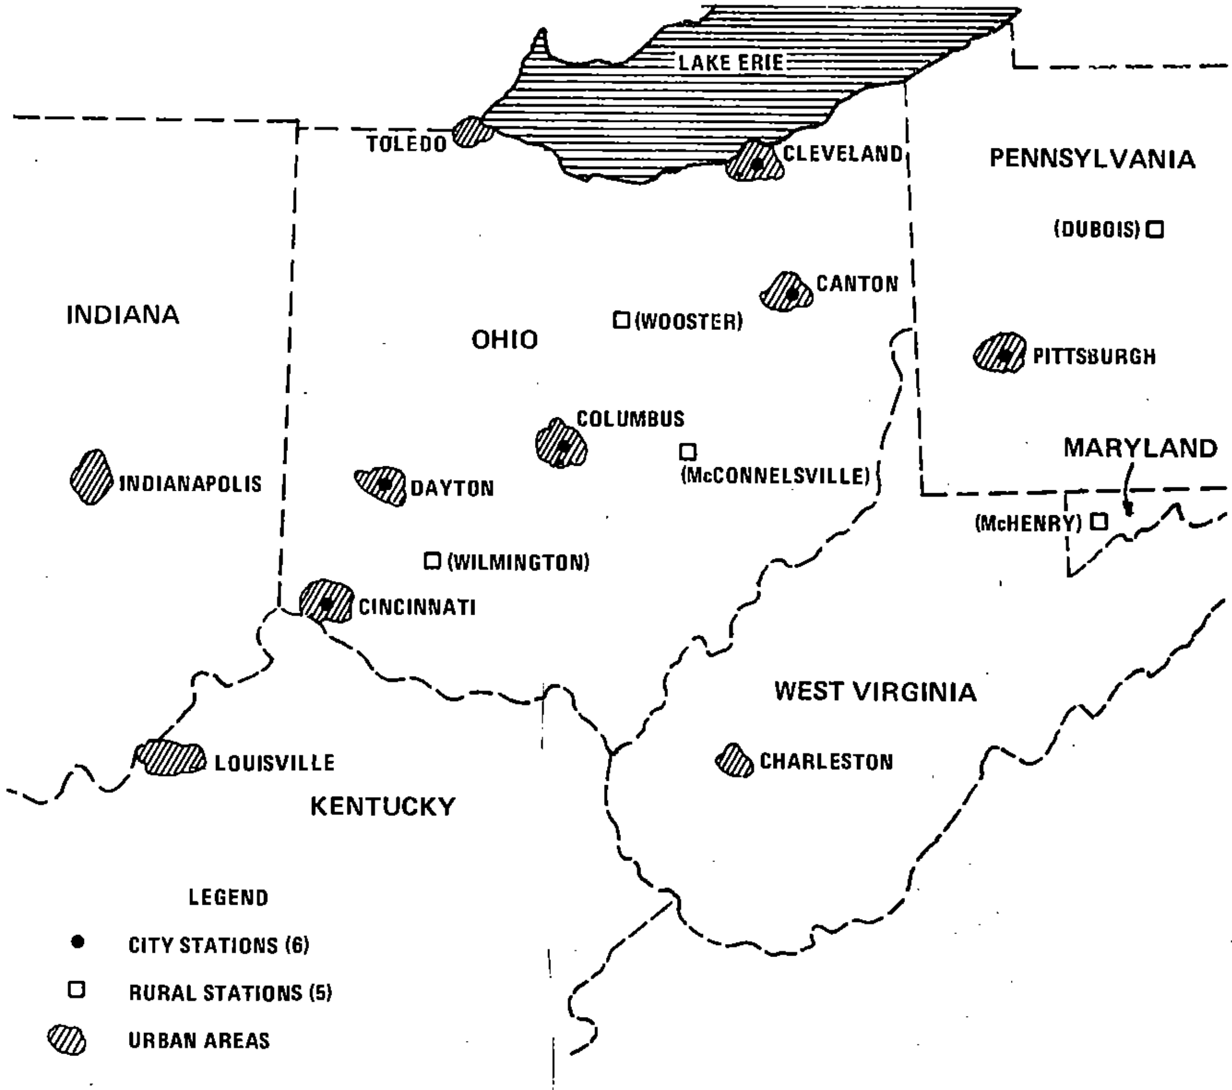

Figure 5-1. Location of fixed ground stations for 1974 oxidant study.

values of similar magnitude to those observed in rural areas in the 1974 field study have been observed in other areas. Results of studies in other areas and EPA studies in the same general area in 1972 and 1973 were presented in the previous trends report.[2]

Recent measurements downwind of urban centers (Houston, Phoenix, several Ohio cities, and Philadelphia)[1,3,4] demonstrate that an identifiable urban plume of oxidants and oxidant precursors can be found as far as 30 to 50 miles from the urban center. In Los Angeles, where the magnitude of oxidant generation is greater, the distance extends perhaps 75 miles or more downwind.[5] Beyond these distances, the contribution

of pollutants (from one city) becomes so well mixed with other urban and nonurban contributions that the individual urban effect is difficult to distinguish.

Data collected in the 1974 EPA oxidant study have been correlated with meteorological parameters. The data analysis suggests that beyond the shorter range of 50 to 75 miles, pollutants become rather well mixed in the prevailing pressure systems. High-pressure systems have been found to be associated with the highest ozone concentrations. A relationship between average ozone concentrations for the eastern midwest, using 1973 study data, and average pressure for the area (with a 9-day smoothing function applied) is shown in Figure 5-2.[1] The central portions of high-pressure systems in the mideastern portion of the

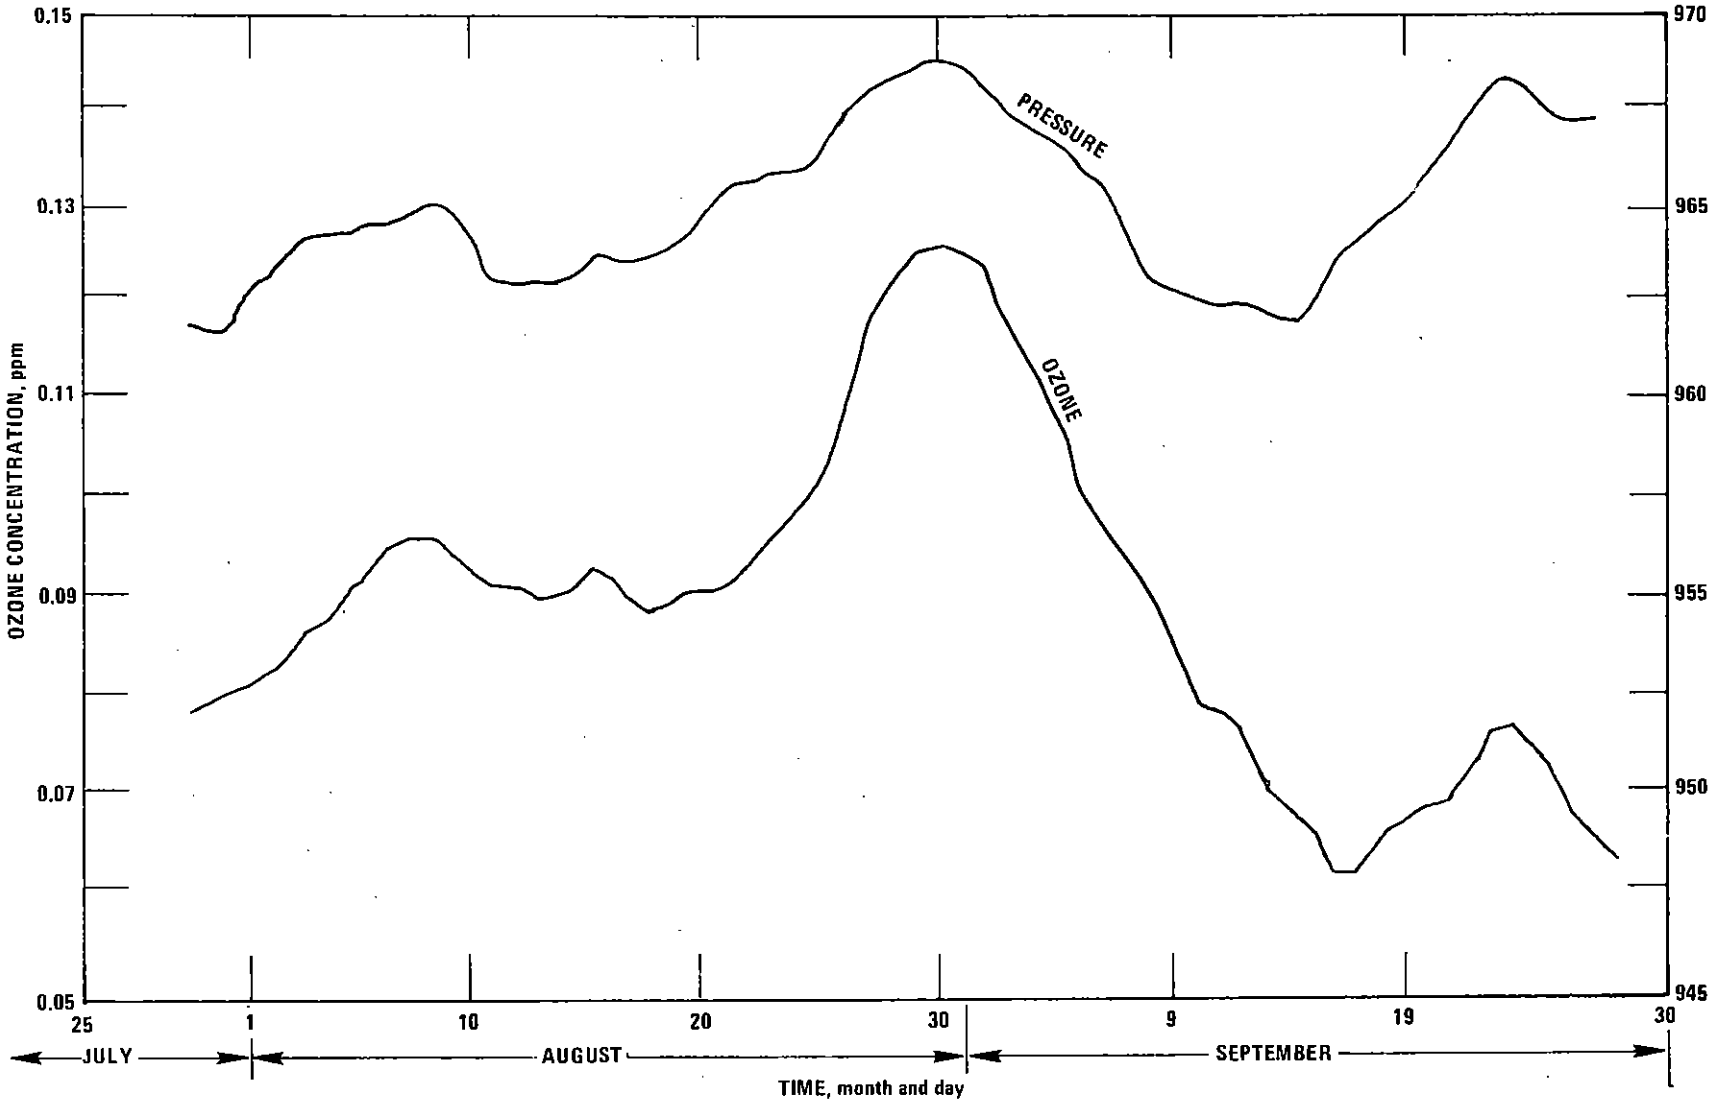

Figure 5-2. Smoothed variations in average daily ozone concentration versus average surface pressure for July 25 through September 30, 1973.

country have been found usually to contain the highest rural ozone concentrations. Areas within central portions of high-pressure systems are often favored for light winds, high solar intensity, and higher temperatures. Therefore, the conditions associated with central portions of high-pressure systems are considered more important than the existence of high pressure itself. A sequence of 2 days of data showing ozone, weather, and emission density values during the passage of a high-pressure weather system during the 1974 Midwest Study is shown in Figures 5-3 and 5-4.[6]

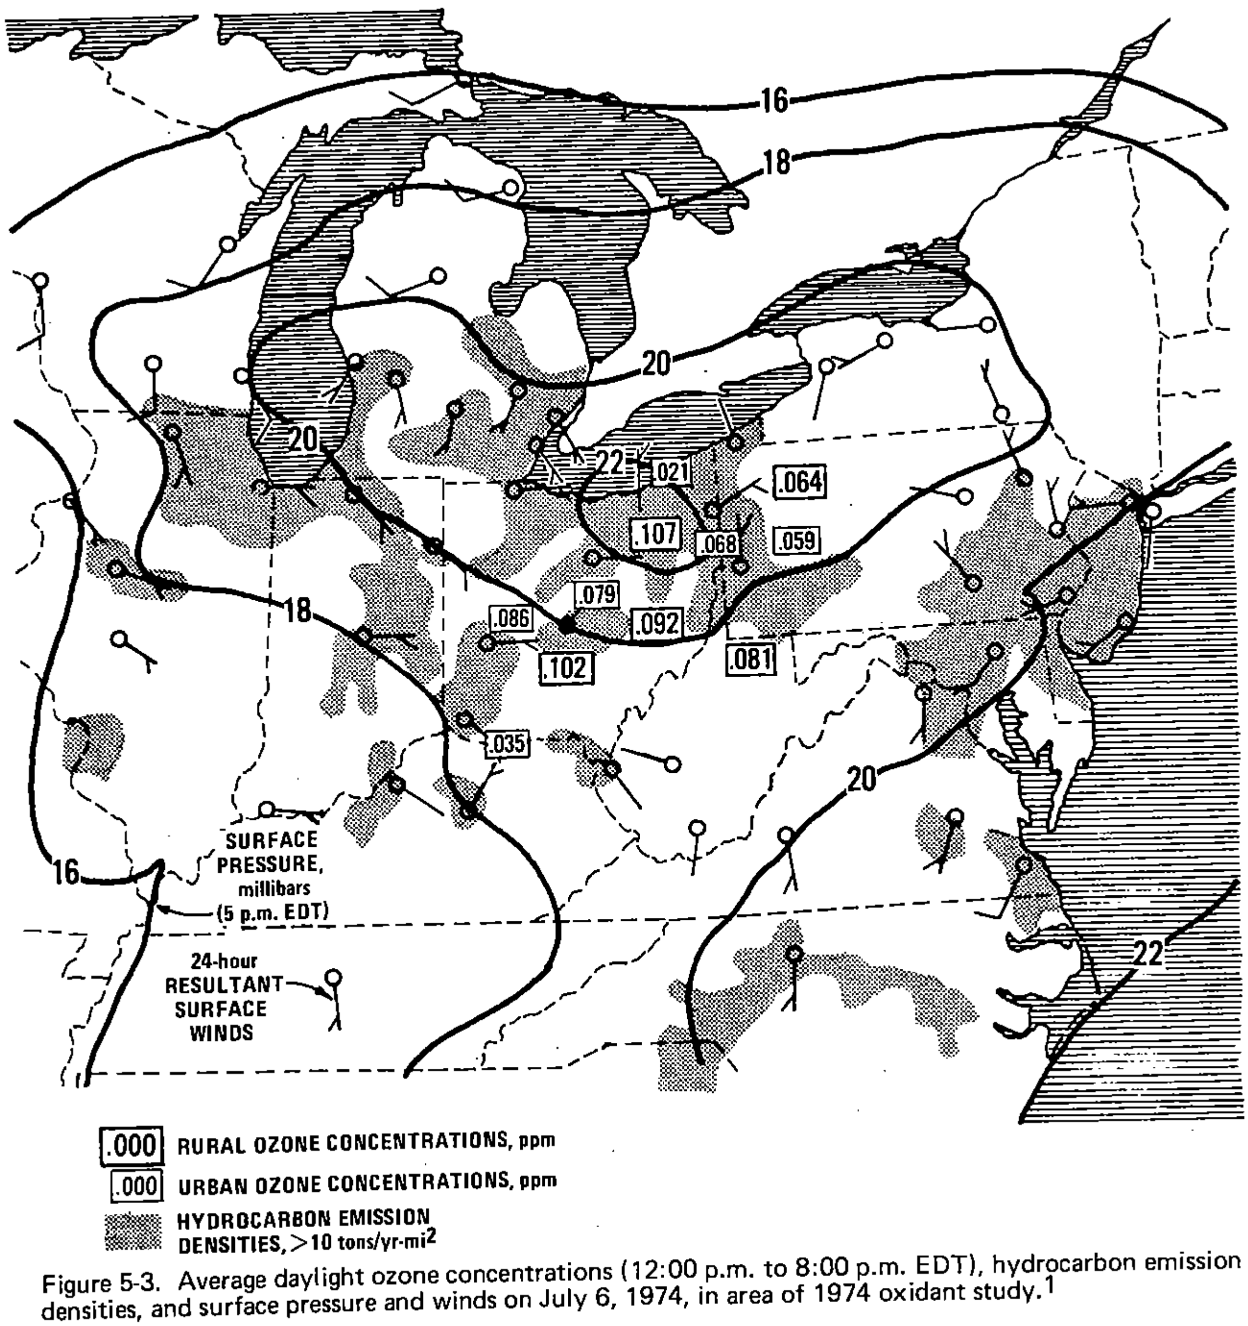

Figure 5-3. Average daylight ozone concentrations (12:00 p.m. to 8:00 p.m. EDT), hydrocarbon emission densities, and surface pressure and winds on July 6, 1974, in area of 1974 oxidant study.[1]

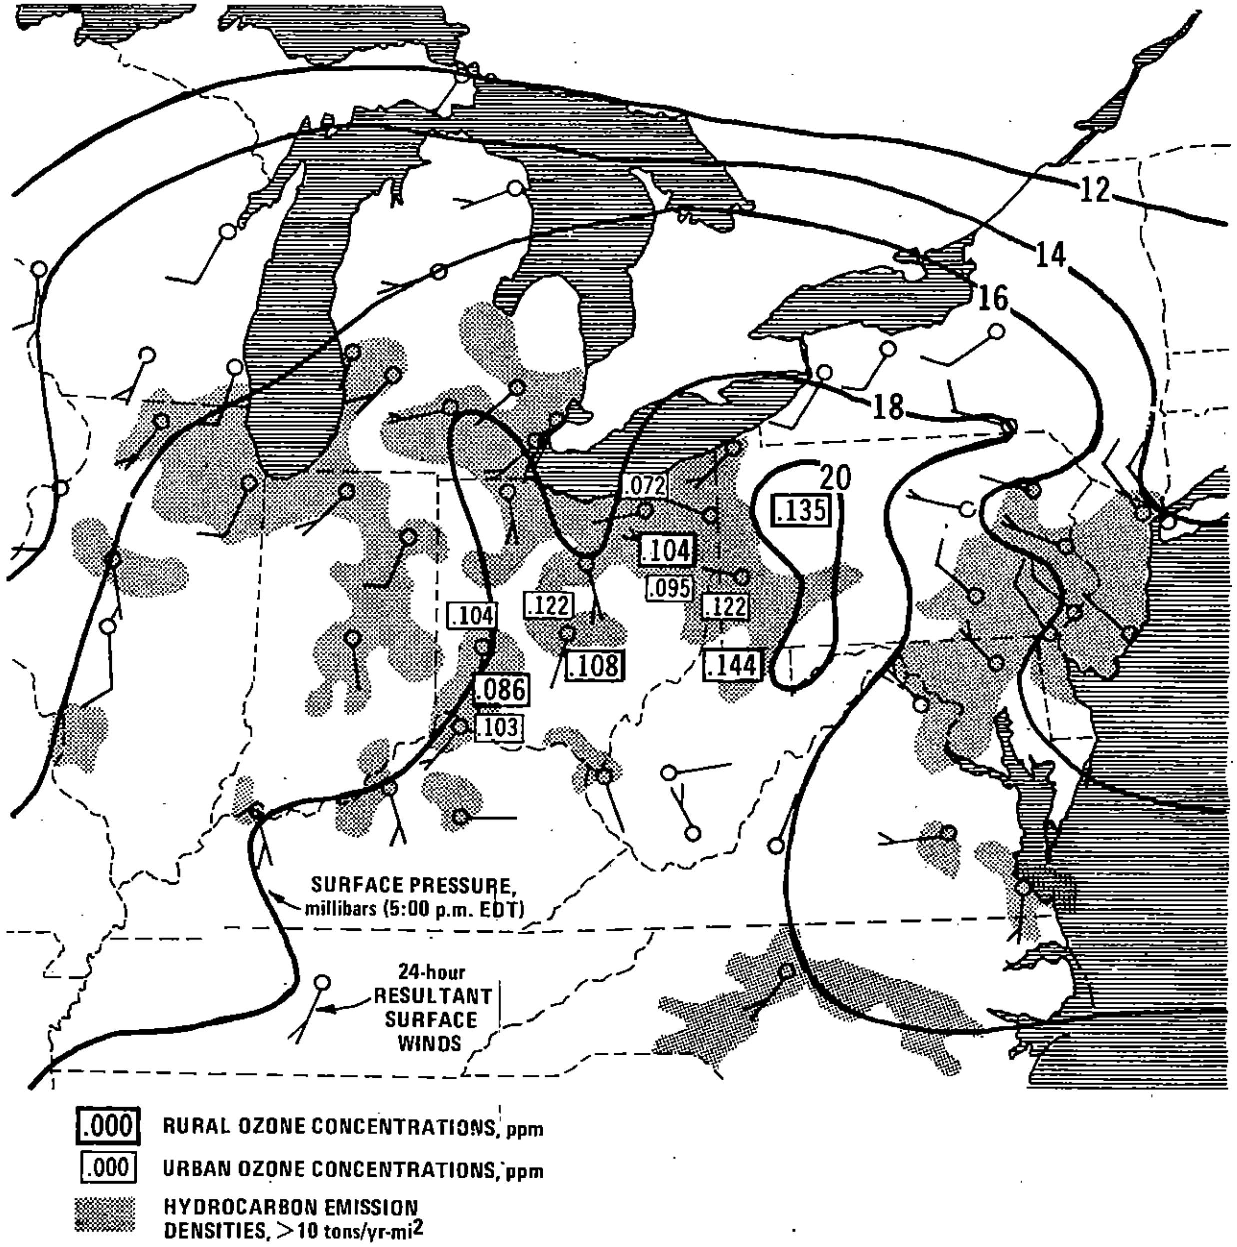

Figure 5-4. Average daylight ozone concentrations (12:00 p.m. to 8:00 p.m. EDT), hydrocarbon emission densities, and surface pressure and winds on July 8, 1974, in area of 1974 oxidant study.[1]

The following briefly summarizes the findings and conclusions of the 1974 summer oxidant study.

1. Both maximum concentrations of photochemical oxidants and the frequency with which the standard was exceeded were generally higher at rural than at urban sites. The NAAQS was exceeded approximately twice as frequently at the rural stations. Mean diurnal ozone concentration curves for the rural and urban stations were similar, varying mainly in magnitude of hourly ozone concentration and time of

maxima. Nocturnal concentrations of ozone were, on the average, three to five times higher at the rural sites relative to the urban sites.

2. Nitrogen dioxide concentrations observed at the rural stations were consistently at or near the minimum detectable level for the measurement method (i.e., approximately 10 $\mu g/m^3$).

3. There were periods (at times 5 days or more) during which the surface and near surface concentrations of ozone measured by aircraft equaled or exceeded the standard of 160 $\mu g/m^3$ (0.08 ppm) hourly average over large areas (2.3×10^5 square kilometers or more). That the air contained anthropogenic air pollutants was demonstrated by the presence of acetylene in all hydrocarbon samples and the presence in a preponderance of samples of carbon monoxide in concentrations two to six times the usually quoted geochemical background of 91 to 137 $\mu g/m^3$ (0.08 to 0.12 ppm).

4. An area-wide system [with a radius of 240 kilometers (150 miles) or more] of high ozone concentrations can exist in which most features that suggest precursor origin are no longer apparent; but a short-range urban influence on both hydrocarbon and ozone concentrations can be observed. The data showed a discernible urban influence extending about 48 to 80 kilometers (30 to 50 miles) downwind of a city.

5. When the central region of a synoptic high-pressure system—a region characterized by relatively clear skies and weak, disorganized flow near the surface--moved into the area being studied, high concentrations of ozone generally occurred at all stations. In this context, high concentrations of ozone are defined as levels in excess of 160 ug/m^3 for 8 hours each day. This condition persisted as long as the high-pressure center remained in the immediate vicinity.

6. Pertinent data from the 1974 summer study show that the high concentrations of ozone observed at rural sites were generated in the lower troposphere.

7. The observed high ozone concentrations cannot be explained in terms of air flow from a specific point source or from a single urban-industrial area source.

8. The results of this investigation provide substantial evidence for the transport of ozone precursors from urban to rural areas under appropriate meteorological conditions. During transport in the presence of sunlight, ozone is synthesized.

9. The results of this investigation indicate that the control of hydrocarbon emissions in any individual city will reduce but will not necessarily prevent the occurrence of high rural ozone concentrations in excess of the ambient air standard at any given rural site. The indication is that the release of hydrocarbons and oxides of nitrogen from anthropogenic or biogenic sources, located in either an urban or rural area, all combine to generate appreciable quantities of ozone over wide areas.

Additional large-scale field studies took place during the summer of 1975. These studies attempted to answer relevant questions not previously resolved by field studies or research. The two studies were conducted concurrently: one from the Upper Great Plains eastward to the Appalachians, and the other along the Western Gulf Coast (between Corpus Christi, Little Rock, and Mobile). Ground and airborne sampling were included in these studies. The main purpose of the Great Plains Study was to follow the development of high ozone concentrations in high-pressure systems as they entered "clean" from areas of origin in West-Central Canada into the United States and moved eastward. The analysis is incomplete, but concerted efforts are being made to assess the relative contributions of natural and man-made sources to the development of high oxidant concentrations. The Gulf Coast Study was mainly exploratory, its main purpose being to examine the distribution and probable causes of ozone concentrations over a wide area characterized by the presence of large petrochemical sources. Few monitoring data have heretofore been available for areas surrounding major cities in the Gulf Coast area in which some of the highest ambient oxidant values outside of Los Angeles have been observed. Figure 5-5 shows a map of the general areas covered by the two 1975 studies and the locations that have been selected for ground-based monitoring. Airborne monitoring off-shore and inland were included to assess the role of large-scale as opposed to smaller-scale circulation of air (such as the sea breeze), and thus distant versus local generation of the ozone that contributes to locally observed ozone levels.

Another regional-scale oxidant study was also conducted in the southeastern New England area during the summer of 1975. Its purpose was to assess the factors contributing to high concentration levels in the corridor dominated by New York City and Boston. Results for this study as for the other two large-scale studies are expected by mid-1976.

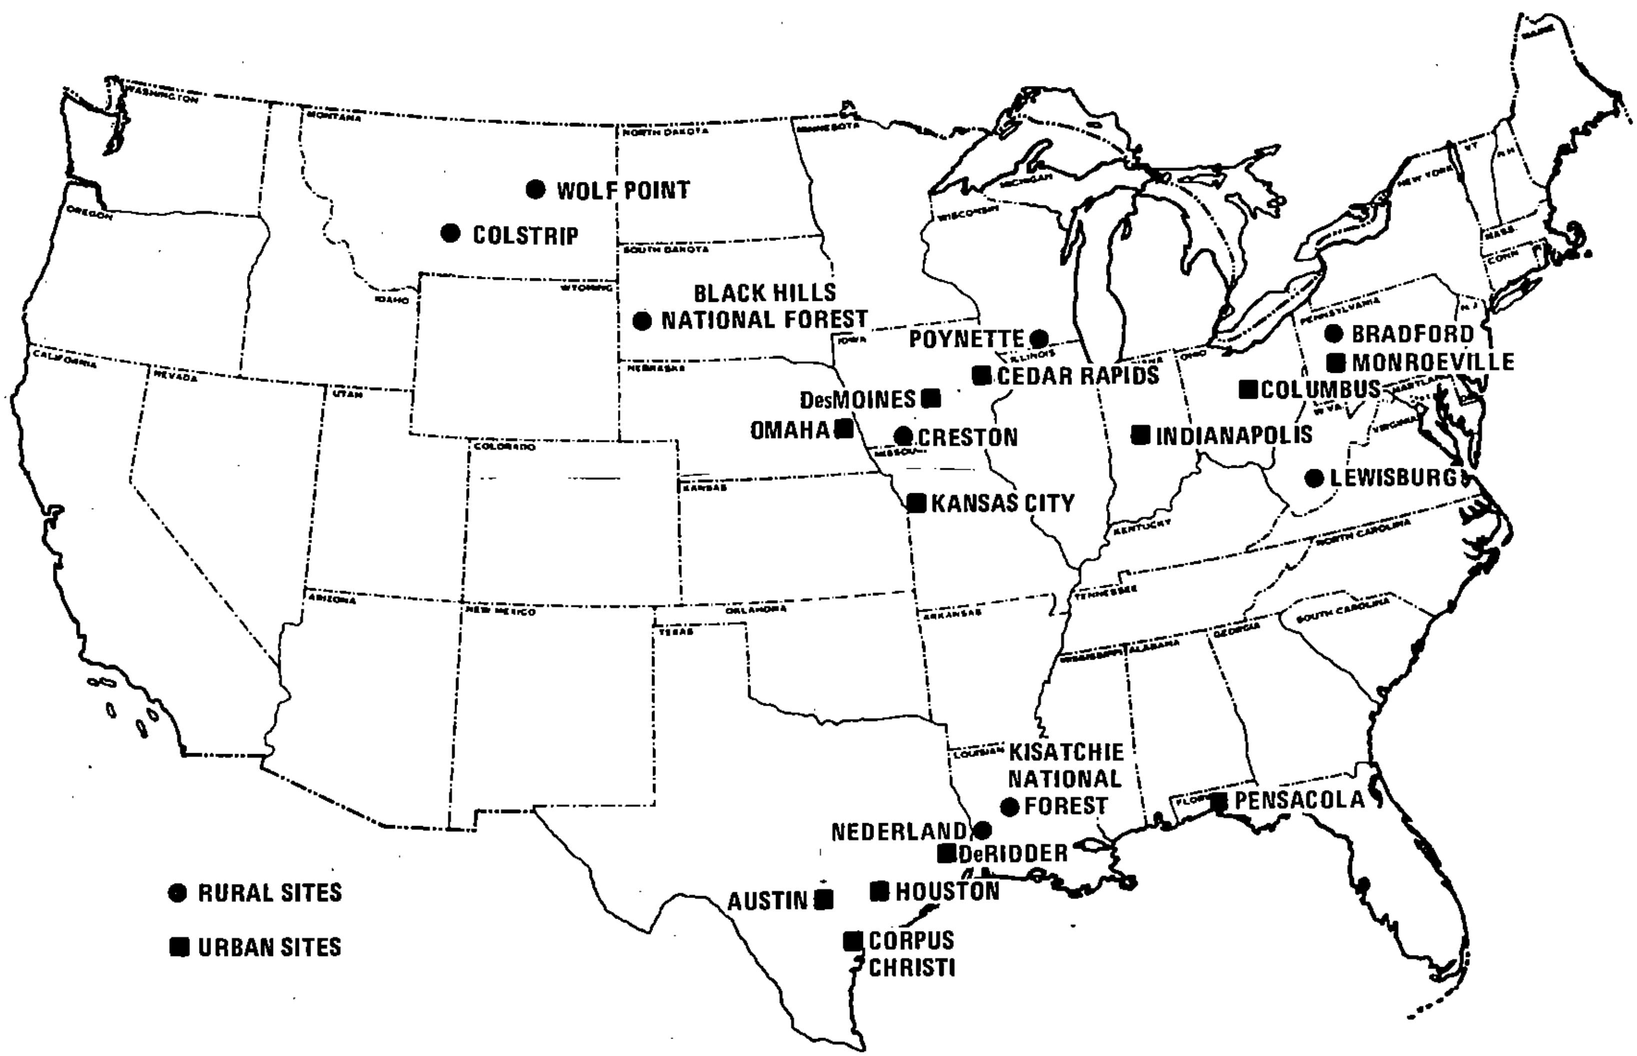

Figure 5-5. Site locations for ground station network (1975 oxidant study).[1]

5.2 NATIONWIDE EMISSION ESTIMATES

These estimates of nationwide emissions for 1970 through 1974 compris newly calculated, internally consistent sets of figures based on the most current emission factors and on a more inclusive list of source categories than previously used. Consequently, the emission estimates presented here supercede any previously published estimates for the years since 1970. Obviously, previously published estimates of emissions for years prior to 1970 will also lack strict continuity with these figures for the 1970 through 1974 period.

Appendix Tables F-1 through F-5 list the estimates of yearly total emissions for 1970 through 1974, respectively, for particulates (Part), sulfur oxides (SO_x), nitrogen oxides (NO_x), hydrocarbons (HC), and carbon monoxide (CO). Sources of these pollutants are divided into the major categories and several subcategories responsible for significant contributions to the national totals.

Two distinctions between these emission estimates and ambient pollutant measurements should be noted. First, the emission estimates for particulates, sulfur oxides, and nitrogen oxides embrace a broader range of substances than are measured by routine ambient air monitoring equipment. The high-volume air sampler collects only the particulates suspended in air that range from approximately 0.3 to 100 micrometers in diameter, while emission inventories include all man-made particulates, suspended and settled. Sulfur dioxide and nitrogen dioxide ambient air monitors measure only those two specific compounds, not all the oxides of sulfur and nitrogen included in the emission estimates. In each case, however, the compound actually measured is the most prevalent constituent of its pollutant class or is acknowledged to be its most representative indicator.

Second, the tables of estimated emissions include hydrocarbons but not oxidants, and the tables of ambient data include oxidants but not hydrocarbons. Obviously, oxidant emissions would not be meaningful because the overwhelming majority of oxidants are so-called secondary pollutants generated by photochemical reactions in the atmosphere. Emissions of hydrocarbons are important because hydrocarbons are a major ingredient for those oxidant-producing reactions; yet ambient measurements of hydrocarbons are not reported because a reliable method has not yet been developed for the continuous monitoring of this large and diverse class of compounds. Consequently, monitoring is not required.

Figure 5-6 portrays the 1970 through 1974 trends in estimated emissions of the five pollutant classes for the five major source categories given in the appendix tables. Particulate emissions have

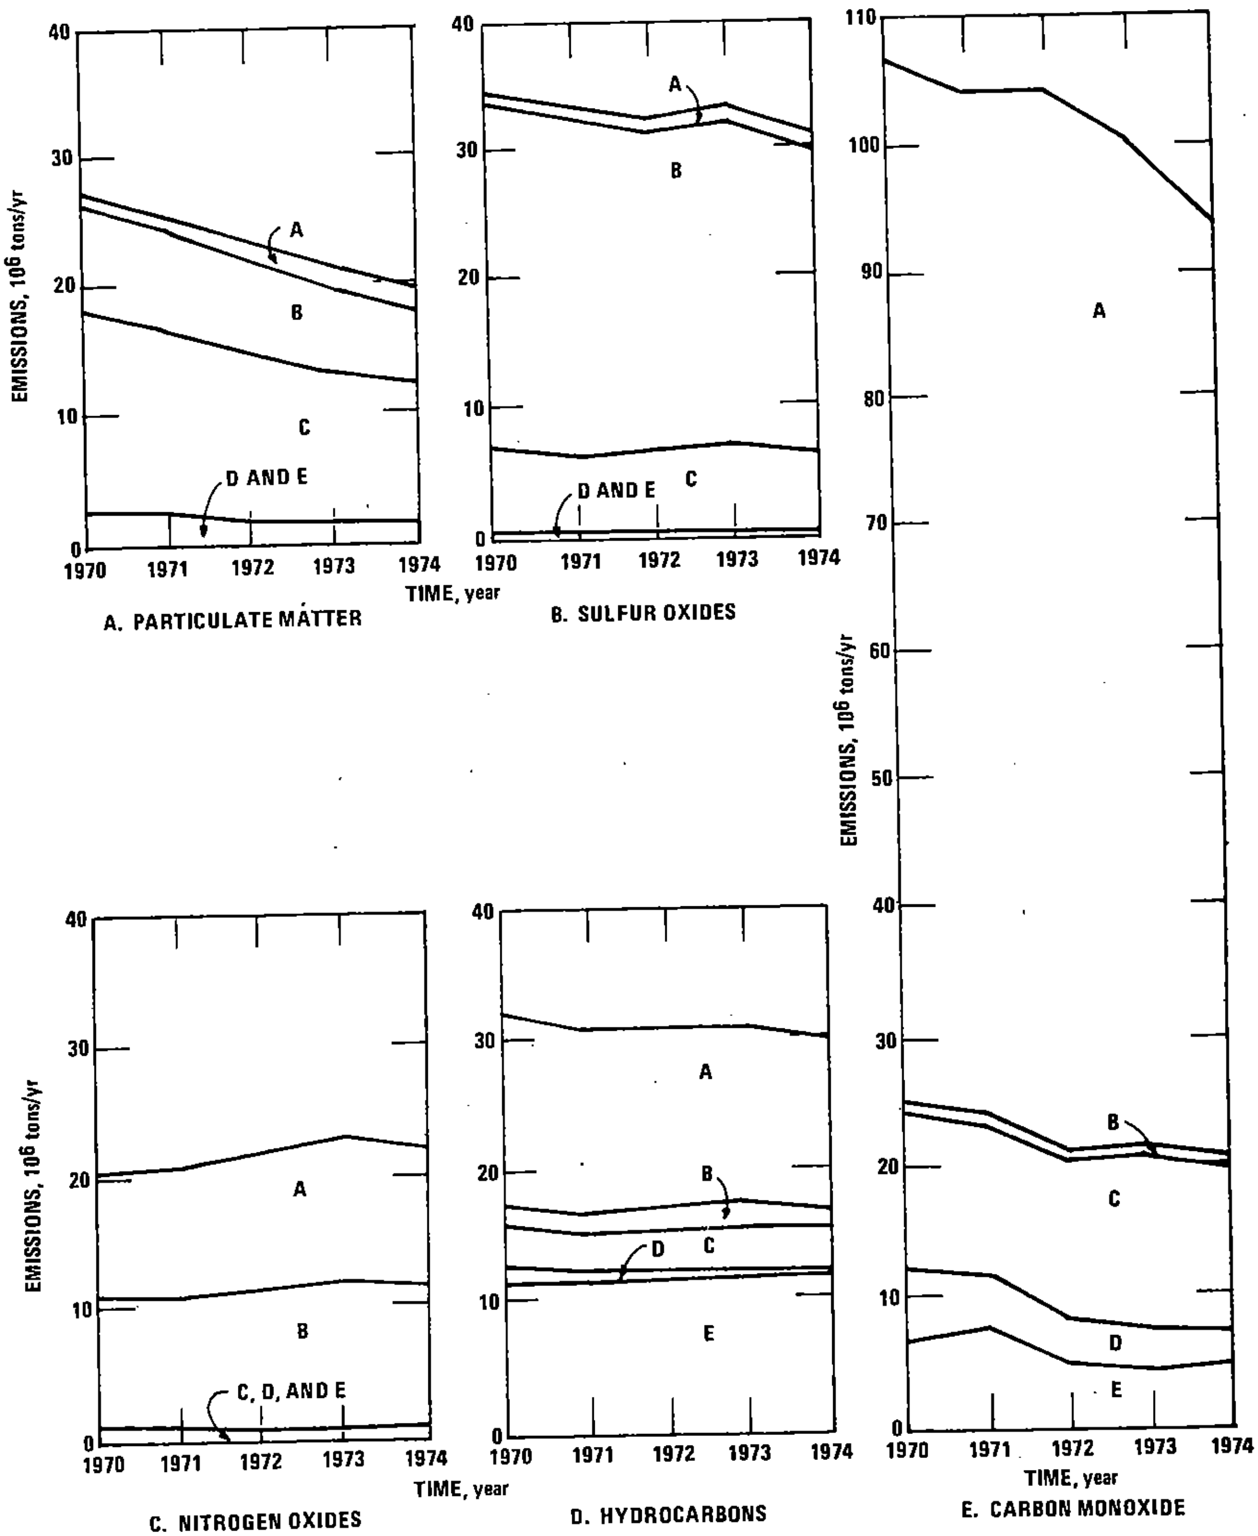

Figure 5-6. Calculated total emissions of criteria pollutants by source category, 1970 through 1974 (A-Transportation; B-Stationary source fuel combustion; C-Industrial processes; D-Solid waste; and E-Miscellaneous).

been declining rather steadily, a decline mainly attributable to emission controls and process changes in two emission categories, stationary-source fuel combustion and industrial processes. As a consequence, a significant number of monitoring stations have reported decreases in average levels of total suspended particulates (see section 4).

Total emissions of sulfur oxides are estimated to have declined slightly. Monitoring results show that ambient levels in the relatively well-monitored urban areas have declined markedly in recent years (see section 4), which suggests a significant shift in the use of higher-sulfur fuels by urban sources to their use by a growing number of sources in relatively sparsely monitored areas. It has also been estimated[7] that SO_x emissions from electric-power-generating plants increased through at least 1973. These plants contribute some 70 percent of the SO_x emissions in the stationary-source category.

Nitrogen oxide emissions are up slightly, primarily in the transportation category. This can be attributed in part to growth in the number of vehicular and stationary sources and in part to a slight increase in NO_x emissions from the 1968 through 1972 model-year vehicles as a consequence of modification designed to reduce CO and hydrocarbons.

Hydrocarbon emissions have decreased slightly in the transportation and solid-waste-disposal categories. The decrease in the transportation category takes on more significance if one remembers that the vehicle population was still increasing at a fairly steady rate through 1974. (The installation of closed systems for handling volatile liquids and the addition of controls on evaporative gasoline losses from automobiles are examples of actions that will both reduce emissions and conserve resources.)

Carbon monoxide emissions show the most dramatic decrease, principally in the transportation category, and, again, in spite of a rising number of vehicles.

In addition to the trends shown in Figure 5-6, a prominent feature of the graphs is the relative contribution from the five source categories. The transportation category (A) dominates CO emissions and contributes a substantial portion of the NO_x and HC emissions; transportation is a minor contributor, however, to particulate and SO_x emissions. The stationary sources group (B) contributes a significant portion to the totals for particulates, SO_x, and NO_x; but a minor portion to the HC and CO totals. Industrial processes (C) are the major source of particulates, contributing smaller yet significant percentages to SO_x

and CO totals. Solid waste disposal (D) only really shows up as a source of CO. The miscellaneous category (E) is significant only for its HC and CO emissions.

APPENDIX A.
SUSPENDED PARTICULATE MATTER

At present, only one method is generally accepted for the measurement of suspended particulate matter (the reference method); that is, the gravimetric determination of the net weight of material collected on a 20- by 25-centimeter 8- by 10-inch) glass fiber filter through which approximately 2200 cubic meters of air have been drawn over a 24-hour period. The high-volume sampler used to collect such samples is familiarly known as a high-vol.

In Table A-1, the hi-vol stations are listed by AQCR. Stations in interstate AQCRs are sorted according to their respective states.

The body of the table (refer to Figure A-1) contains a line for each reporting station, starting with the state name, site code, station name, and year - 1974. The next three columns show the number of valid values reported, and the number of those values exceeding the secondary (150 $\mu g/m^3$) and primary (260 $\mu g/m^3$) 24-hour standards. The next two columns list the first- and second-highest values, in micrograms per cubic meter. From these values, one can judge either the degree to which the 24-hour standard has been exceeded or the margin by which it has been met.

The final three columns pertain to the annual geometric mean, showing its ratio to the secondary (60 $\mu g/m^3$) and primary (75 $\mu g/m^3$) annual standards and the annual geometric mean itself, if four valid quarters of data have been reported. If only two or three valid quarters have been reported, a tentative annual mean is shown, followed by a question mark. Because these tentative means are not used in appraising standards, no ratios are given.

Stations appearing in this listing, but showing no entries in the last three columns have reported at least three samples for the year, but fewer than two valid quarters of data.

Table A-1. SUSPENDED PARTICULATE DATA

METHOD: GRAVIMETRIC, 24-HOUR HI-VOLUME FILTER SAMPLE-91

ANNUAL GEOM. MEAN UG/CU.M.	Valid annual means are based on 4 valid quarters. " ? " indicates a tentative mean based on 2 or 3 valid quarters.
ANNUAL RATIOS TO ANN. STDS SEC. / PRI.	Ratios to annual secondary guide (60 $\mu g/m^3$) and primary standard (75 $\mu g/m^3$) are shown only if annual mean is valid.
HIGHEST 24-HR VALUES UG/CU.M. 1ST / 2ND	Two highest 24-hour values reported. " # " symbol indicates a suspect value greater than 1500 $\mu g/m^3$.
NO. OF DAILY VALUES EXC'D'G 24-HR STDS. SEC. / PRI.	Number of 24-hour values exceeding secondary (150 $\mu g/m^3$) and primary (260 $\mu g/m^3$) 24-hour standards.
NO. OF VALID VALUES	Number of 24-hour measurements reported.
YEAR 19--	All data in this table are for 1974.
AIR QUALITY CONTROL REGION	Following each AQCR number and name is a line for each reporting station in the AQCR showing its state, the site code number, and the city or country in which it is located. (Note: only one method, the reference method.)

APPENDIX B.
SULFUR DIOXIDE

Data from 24-hour bubbler monitors, the reference method, and from continuous SO_2 monitors are summarized in Table B (refer to Figure B-1). The right-hand column identifies the instrumental method used at each station. All of the continuous instrumental methods are candidate methods pending Federal approval.

Stations are grouped by AQCR in Table B-1. Stations in interstate AQCRs are grouped according to their respective states. In the body of the table, each line represents a station, beginning with its state, station code, station name and year - 1974. The next column, number of valid values, represents the number of 24-hour samples for bubblers or hourly measurements for continuous instruments. The next column reports the number of values (or 24-hour averages, midnight to midnight, for continuous instruments) exceeding the 24-hour standard (365 $\mu g/m^3$). The first- and second-highest 24-hour values (or averages) are reported in the next two columns.

The next column pertains only to continuous instruments, reporting the number of times the running 3-hour average of the hourly SO_2 measurements exceeded the 3-hour standard (1300 $\mu g/m^3$).

The remaining two columns present the ratio of the annual arithmetic mean to the annual standard (80 $\mu g/m^3$) and the annual arithmetic mean itself, if four valid quarters have been reported. If only two or three valid quarters have been reported, a tentative annual mean is shown, followed by a question mark. Because these tentative means are not used in appraising standards, so no ratios are given.

Stations appearing in these tables, but showing no entries in the annual summary columns, have reported at least three bubbler values or 400 hourly values, but fewer than two valid quarters of data.

Table B-1. SULFUR DIOXIDE DATA

Method codes (see heading); 91 is Federal Reference Method.

Valid annual means are based on 4 valid quarters; " ? " indicates a tentative mean based on 2 or 3 valid quarters.

Ratio to annual standard (80 $\mu g/m^3$) is shown only if annual mean is valid.

Number of 3-hour running average values exceeding the 3-hour standard (1300 $\mu g/m^3$). Applies to continuous instruments only.

Two highest 24-hour concentrations (midnight-to-midnight average for continuous monitors); " # " symbol indicates a suspect value greater than 1000 $\mu g/m^3$.

Number of 24-hour values exceeding the 24-hour standard (365 $\mu g/m^3$). Midnight-to-midnight averages used for continuous monitors.

Number of 24-hour bubbler samples (365 possible), or number of hourly values from continuous monitors (8760 possible).

All data in this table are for 1974.

Following each AQCR number and name is a line for each station reporting in the AQCR showing its state, the site code number, and the city or county in which it is located.

Figure B-1. Elaboration of column headings on Table B-1.

APPENDIX C.
CARBON MONOXIDE

Stations are grouped by AQCR in Table C-1. Stations in interstate AQCRs are grouped according to their respective states. In the body of the table (refer to Figure C-1), each line represents a station, showing its state, station code, station name, and year - 1974. The next two columns list the number of valid hourly values reported and the number of those values exceeding the 1-hour standard (40 mg/m^3). The next column reports the number of times the moving 8-hour average exceeded the 8-hour standard (10 mg/m^3).

The next column lists the 99th percentile in the frequency distribution of 1-hour values; that is, the concentration that 99 percent of the values are equal to or less than. This statistic gives perspective on the upper range of values in addition to the first- and second-highest 1-hour values shown in the next two columns.

The next two columns show the first and second highest moving 8-hour averages (the second-highest value is from a different day than the maximum value).

The final column lists annual means, if 75 percent of the possible hourly values for four quarters have been reported. A tentative annual mean, followed by a question mark, is shown if only two or three valid quarters of data have been reported. Stations showing no annual statistics reported at least 400 hourly values but fewer than two valid quarters of data.

Table C-1. CARBON MONOXIDE DATA

METHOD: NONDISPERSIVE INFRARED (NDIR) CONTINUOUS, HOURLY VALUES-11, FLAME IONIZATION-21 (*)

Column heading	Elaboration
AIR QUALITY CONTROL REGION	Following each AQCR number and name is a line for each reporting station in the AQCR showing its state, the site code number, and the city or country in which it is located. No method column; NDIR - 11 is reference method and flame ionization - 21* is candidate for equivalent method (values tagged with * in table were determined by flame ionization - 21).
YEAR 19--	All data in this table are for 1974.
NO. OF VALID VALUES	Number of 1-hour values reported (8760 possible).
NO. OF VALUES EXCEEDING STANDARDS 1-HR	Number of 1-hour values exceeding the 1-hour standard (40 mg/m^3).
NO. OF VALUES EXCEEDING STANDARDS 8-HR	Number of 8-hour running averages exceeding the 8-hour standard (10 mg/m^3).
99TH PCTL OF 1-HR VALUES, MG/CU.M.	An indicator of the upper range of concentrations.
HIGHEST 1-HR VALUES MG/CU.M. 1ST | 2ND	Two highest 1-hour values; " # " symbol indicates a suspect value greater than 100 mg/m^3.
HIGHEST 8-HR AVGS MG/CU.M. 1ST | 2ND	Two highest 8-hour running averages, occurring on different days.
ANNUAL ARITH. MEAN MG/CU.M.	Annual average included for relative comparisons; no standard applicable. Valid means based on 4 valid quarters; " ? " indicates a tentative mean based on 2 or 3 valid quarters.

Figure C-1. Elaboration of column headings on Table C-1.

APPENDIX D.
OXIDANT/OZONE

Table D-1 presents results obtained from five different methods, only one of which - chemiluminescence, No. 44201 11 - is the reference method. The remaining methods are candidates for equivalency to the reference method.

Stations are listed by AQCR. Stations in interstate AQCRs are sorted according to their respective states.

The body of the table (refer to Figure D-1) contains a line for each reporting station, starting with the state name, the station code, the station name, and the year - 1974. The next two columns list the number of valid 1-hour standard (160 $\mu g/m^3$). The next two columns list the first- and second-highest 1-hour values, giving a measure of the degree to which the standard has been exceeded or the margin by which it has been met. The next columns, 99th percentile, gives an additional measure of the upper range of concentrations.

The final column identifies the instrumental methods used at each station by code numbers, which are elaborated in the table heading Stations appearing in this listing have reported at least 400 hourly values.

Table D-1. OXIDANT AND OZONE DATA

Method codes are identified in the heading; 44201 is the Federal Reference Method.

An indicator of the upper range of concentrations.

The two highest 1-hour values reported from each station; " # " symbol indicates a suspect value greater than 1500 $\mu g/m^3$.

Number of 1-hour values exceeding the standard (160 $\mu g/m^3$).

Number of 1-hour values reported (8760 possible).

All data in this table are for 1974.

Following each AQCR number and name is a line for each reporting station in the AQCR showing its State, the site code number, and the city or county in which it is located.

Figure D-1. Elaboration of column headings on Table D-1.

APPENDIX E.
NITROGEN DIOXIDE

At this writing, there is no approved reference method for the measurement of nitrogen dioxide. Eight candidate methods are reported in Table E.

The NO_2 monitoring stations are listed by AQCR in Table E-1. The body of the table (refer to Figure E-1) contains a line for each station reporting at least three bubbler values or 400 hourly values. Each line contains the state name, station code, station name, and the year--1974. The next column records the number of valid values reported. For 24-hour methods, the reported values will be small--usually less than 60. For continuous methods, the number of 1-hour values will be 400 or more.

The next column lists the highest 24-hour value or 24-hour average (based on bubbler or continuous instrument, respectively).

The next two columns show the ratio of the annual mean to the annual mean standard (100 $\mu g/m^3$) and the annual arithmetic mean itself if four valid quarters of data have been reported. If only two or three valid quarters have been reported, a tentative annual mean is shown, followed by a question mark. These tentative means are not used in appraising standards; so no ratios are given.

Table E-1. NITROGEN DIOXIDE DATA

METHODS: SALTZMAN COLORIMETRIC-11 AND 12, COULOMETRIC-13, CHEMILUMINESCENCE-14, NASN SODIUM ARSENITE-ORIFICE-84, NASN SODIUM ARSENITE-FRIT-94, TEA METHOD-95, TGS METHOD-76

Column heading	Explanation
METH	Method codes are identified in the heading; 84 and greater are 24-hour bubblers; others are continuous monitors.
ANNUAL ARITH. MEAN UG/CU.M.	Valid annual means are calculated from 4 valid quarters; " ? " indicates a tentative mean based 2 or more valid quarters; blank indicates fewer than 2 quarters of data.
ANNUAL RATIO TO ANN. STD	Ratio to annual standard (100 $\mu g/m^3$) is shown only if annual mean is valid (4 quarters).
HIGHEST 24-HR VALUE UG/CU.M.	Maximum 24-hour concentration (midnight-to-midnight average for continuous monitors).
NO. OF VALID VALUES	Number of 24-hour bubbler samples (365 possible), or number of hourly values from continuous monitors (8760 possible).
YEAR 19--	All data in this table are for 1974.
AIR QUALITY CONTROL REGION	Following each AQCR number and name is a line for each reporting station in the AQCR showing its state, the site code number, and the city or county in which it is located.
