**Number: P-18-0233** 

**TSCA Section 5(a)(3) Determination**: The chemical substance is not likely to present an unreasonable risk (5(a)(3)(C))

#### **Chemical Name:**

Generic: Alkyl Alkenoic acid, alkyl ester, telomer with alkylthiol, substituted carbomonocycle, substituted alkyl alkyl alkenoate and hydroxyalkyl alkenoate, tert-butyl alkyl peroxoate-initiated

# Conditions of Use (intended, known, or reasonably foreseen)<sup>1</sup>:

Intended conditions of use (generic): Imported in solution for processing for use and use as a coating agent, consistent with the manufacturing, processing, use, distribution, and disposal information described in the PMN.

Known conditions of use: Known conditions of use: Applying such factors as described in footnote 1, EPA evaluated whether there are known conditions of use and found none. Reasonably foreseen conditions of use: Applying such factors as described in footnote 1 EPA evaluated whether there reasonably foreseen condition of use and found none.

**Summary:** The chemical substance is not likely to present an unreasonable risk of injury to health or the environment, without consideration of costs or other nonrisk factors, including an unreasonable risk to a potentially exposed or susceptible subpopulation identified as relevant by the Administrator under the conditions of use, based on the risk assessment presented below. Although EPA estimated that the new chemical substance could be very persistent, the new chemical substance has low potential for bioaccumulation, such that repeated exposures are not expected to be cumulative. Based on EPA's TSCA New Chemicals Program Chemical Category for Polycationic Polymers<sup>2</sup> and test data on potential metabolites, EPA estimates that the chemical substance has low environmental hazard and potential for the following human health

<sup>&</sup>lt;sup>1</sup> Under TSCA § 3(4), the term "conditions of use" means "the circumstances, as determined by the Administrator, under which a chemical substance is intended, known, or reasonably foreseen to be manufactured, processed, distributed in commerce, used, or disposed of." In general, EPA considers the intended conditions of use of a new chemical substance to be those identified in the section 5(a) notification. Known conditions of use include activities within the United States that result from manufacture that is exempt from PMN submission requirements. Reasonably foreseen conditions of use are future circumstances, distinct from known or intended conditions of use, under which the Administrator expects the chemical substance to be manufactured, processed, distributed, used, or disposed of. The identification of "reasonably foreseen" conditions of use will necessarily be a case-by-case determination and will be highly fact-specific. Reasonably foreseen conditions of use will not be based on hypotheticals or conjecture. EPA's identification of conditions of use includes the expectation of compliance with federal and state laws, such as worker protection standards or disposal restrictions, unless case-specific facts indicate otherwise. Accordingly, EPA will apply its professional judgment, experience, and discretion when considering such factors as evidence of current use of the new chemical substance outside the United States, evidence that the PMN substance is sufficiently likely to be used for the same purposes as existing chemical substances that are structurally analogous to the new chemical substance, and conditions of use identified in an initial PMN submission that the submitter omits in a revised PMN. The sources EPA uses to identify reasonably foreseen conditions of use include searches of internal confidential EPA PMN databases (containing use information on analogue chemicals), other U.S. government public sources, the National Library of Medicine's Hazardous Substances Data Bank (HSDB), the Chemical Abstract Service STN Platform, REACH Dossiers, technical encyclopedias (e.g., Kirk-Othmer and Ullmann), and Internet searches.

## TSCA Section 5(a)(3) Determination for Premanufacture Notice (PMN) P-18-0233

hazards: lung effects based on cationic binding, and systemic, reproductive, and developmental toxicity. EPA concludes that the new chemical substance is not likely to present an unreasonable risk under the conditions of use.

Fate: Environmental fate is the determination of which environmental compartment(s) a chemical moves to, the expected residence time in the environmental compartment(s) and removal and degradation processes. Environmental fate is an important factor in determining exposure and thus in determining whether a chemical may present an unreasonable risk. EPA estimated physical/chemical and fate properties of this new chemical substance data for analogous polymers. The chemical substance is estimated to be removed during wastewater treatment with an efficiency of 90% via sorption. Removal by biodegradation is estimated to be negligible. Sorption to sludge is estimated to be strong, and sorption to soil and sediment is estimated to be very strong, resulting in negligible migration to groundwater for the new chemical substance. Volatilization to air is estimated to be negligible because of the high molecular volume. Overall, these estimates are indicative of low potential for this chemical substance to volatilize into the air and a low potential for this chemical substance to migrate into groundwater.

**Persistence**<sup>3</sup>: Persistence is relevant to whether a new chemical substance is likely to present an unreasonable risk because chemicals that are not degraded in the environment at rates that prevent substantial buildup in the environment, and thus increase potential for exposure, may present a risk if the substance presents a hazard to human health or the environment. Based on data for analogous polymers, EPA estimated the anaerobic and aerobic biodegradation half-lives to be greater than six months. These estimates for biodegradation indicate that the new chemical substance may be very persistent in aerobic environments (e.g., surface water) and anaerobic environments (e.g., sediment).

**Bioaccumulation<sup>4</sup>:** Bioaccumulation is relevant to whether a new chemical substance is likely to present an unreasonable risk because substances that bioaccumulate in aquatic and/or terrestrial species pose the potential for elevated exposures to humans and other organisms via food chains. The new chemical substance has low bioaccumulation potential based on the large predicted molecular volume and low water solubility, which limit bioavailability and bioaccumulation. Although EPA estimated that the new chemical substance could be very persistent, it has low potential for bioaccumulation, such that repeated exposures are not expected to cause food chain effects via accumulation in exposed organisms.

<sup>&</sup>lt;sup>3</sup> Persistence: A chemical substance is considered to have limited persistence if it has a half-life in water, soil or sediment of less than 2 months or there are equivalent or analogous data. A chemical substance is considered to be persistent if it has a half-life in water, soil or sediments of greater than 2 months but less than or equal to 6 months or if there are equivalent or analogous data. A chemical substance is considered to be very persistent if it has a half-life in water, soil or sediments of greater than 6 months or there are equivalent or analogous data. (64 FR 60194; November 4, 1999)

<sup>&</sup>lt;sup>4</sup> Bioaccumulation: A chemical substance is considered to have a low potential for bioaccumulation if there are bioconcentration factors (BCF) or bioaccumulation factors (BAF) of less than 1,000 or there are equivalent or analogous data. A chemical substance is considered to be bioaccumulative if there are BCFs or BAFs of 1,000 or greater and less than or equal to 5,000 or there are equivalent or analogous data. A chemical substance is considered to be very bioaccumulative if there are BCFs or BAFs of 5,000 or greater or there are equivalent or analogous data. (64 FR 60194; November 4 1999)

Human Health Hazard<sup>5</sup>: Human health hazard is relevant to whether a new chemical substance is likely to present an unreasonable risk because the significance of the risk is dependent upon both the hazard (or toxicity) of the chemical substance and the extent of exposure to the substance. EPA estimated the human health hazard of this chemical substance based on data on potential metabolites and other structural information. Absorption of the new chemical substance is expected to be nil through all routes, and, if in solution, absorption of the low molecular weight fraction is expected to be poor through all routes based on physical/chemical properties. EPA identified lung effects based on cationic binding, and systemic, reproductive, and developmental toxicity as human health hazards based on potential release of [claimed CBI] from the absorbed low molecular weight fraction ([claimed CBI]). The concern for lung effects due to cationic binding is estimated to be low, due to the high functional group equivalent weight (FGEW) for [claimed CBI], which indicates there are only 2 [claimed CBI] groups per molecule. EPA quantitatively assessed risk using test data for two potential metabolites of the new chemical substance (i.e., [claimed CBI]). For [claimed CBI], EPA identified a NOAEL of 1000 mg/kg-day for developmental toxicity (OECD SIDS Initial Assessment Profile<sup>6</sup>), but it was not used for the quantitative risk assessment as the oral LOAEL for developmental toxicity based on the other metabolite [claimed CBI] was lower and therefore more sensitive. For [claimed CBI], EPA identified a NOAEC of 36.4 mg/m<sup>3</sup> (10 ppm) for maternal toxicity from a 90-day developmental toxicity inhalation study and a LOAEL of 300 mg/kg-day for systemic toxicity and developmental toxicity in a combined Prenatal Developmental Toxicity Study and Reproductive/Developmental Toxicity Screening Test (OECD TG 414/421). These data were used to derive exposure route- and population-specific points of departure for quantitative risk assessment, described below. Benchmark MOE = 100 for inhalation exposure and = 1000 for dermal and oral exposure.

**Environmental Hazard**<sup>7</sup>: Environmental hazard is relevant to whether a new chemical substance is likely to present unreasonable risk because the significance of the risk is dependent

<sup>&</sup>lt;sup>5</sup> A chemical substance is considered to have low human health hazard if effects are observed in animal studies with a No Observed Adverse Effect Level (NOAEL) equal to or greater than 1,000 mg/kg/day or if there are equivalent data on analogous chemical substances; a chemical substance is considered to have moderate human health hazard if effects are observed in animal studies with a NOAEL less than 1,000 mg/kg/day or if there are equivalent data on analogous chemical substances; a chemical substance is considered to have high human health hazard if there is evidence of adverse effects in humans or conclusive evidence of severe effects in animal studies with a NOAEL of less than or equal to 10 mg/kg/day or if there are equivalent data on analogous chemical substances. EPA may also use Benchmark Dose Levels (BMDL) derived from benchmark dose (BMD) modeling as points of departure for toxic effects. See https://www.epa.gov/bmds/what-benchmark-dose-software-bmds. Using this approach, a BMDL is associated with a benchmark response, for example a 5 or 10 % incidence of effect. The aforementioned characterizations of hazard (low, medium, high) would also apply to BMDLs. In the absence of animal data on a chemical or analogous chemical substance, EPA may use other data or information such as from in vitro assays, chemical categories (e.g., Organization for Economic Co-operation and Development, 2014 Guidance on Grouping of Chemicals, Second Edition. ENV/JM/MONO(2014)4. Series on Testing & Assessment No. 194. Environment Directorate, Organization for Economic Co-operation and Development, Paris, France. (http://www.oecd.org/officialdocuments/publicdisplaydocumentpdf/?cote=env/jm/mono(2014)4&doclanguage=en)), structure-activity relationships, and/or structural alerts to support characterizing human health hazards.

<sup>&</sup>lt;sup>6</sup> OECD SIDS document for [claimed CBI].

<sup>7</sup> A chemical substance is considered to have low ecotoxicity hazard if the Fish, Daphnid and Algae LC50 values are greater than 100 mg/L, or if the Fish and Daphnid chronic values (ChVs) are greater than 10.0 mg/L, or there are not

## TSCA Section 5(a)(3) Determination for Premanufacture Notice (PMN) P-18-0233

upon both the hazard (or toxicity) of the chemical substance and the extent of exposure to the substance. EPA estimated environmental hazard of this new chemical substance using predictions based on the negligible water solubility (insoluble polymers cationic - [claimed CBI]). This new chemical substance falls within the TSCA New Chemicals Category of Polycationic Polymers. Acute and chronic toxicity values estimated for fish, aquatic invertebrates, and algae are no effects at saturation. These toxicity values indicate that the new chemical substance is expected to have low environmental hazard. Because hazards are not expected up to the water solubility limit, acute and chronic concentrations of concern are not identified.

**Exposure:** The exposure to a new chemical substance is potentially relevant to whether a new chemical substance is likely to present unreasonable risks because the significance of the risk is dependent upon both the hazard (or toxicity) of the chemical substance and the extent of exposure to the substance.

EPA estimates occupational exposure and environmental release of the new chemical substance under the intended conditions of use described in the PMN using ChemSTEER (Chemical Screening Tool for Exposures and Environmental Releases <a href="https://www.epa.gov/tsca-screening-tools/chemsteer-chemical-screening-tool-exposures-and-environmental-releases">https://www.epa.gov/tsca-screening-tools/chemsteer-chemical-screening-tool-exposures-and-environmental-releases</a>). EPA uses EFAST (the Exposure and Fate Assessment Screening Tool; <a href="https://www.epa.gov/tsca-screening-tools/e-fast-exposure-and-fate-assessment-screening-tool-version-2014">https://www.epa.gov/tsca-screening-tools/e-fast-exposure-and-fate-assessment-screening-tool-version-2014</a>) to estimate general population, consumer, and environmental exposures.

EPA considers workers to be a potentially exposed or susceptible subpopulation (PESS) on the basis of greater exposure potential compared to the general population. EPA also considers PESS in conducting general population drinking water exposures by evaluating risks associated with water intake rates for multiple age groups, ranging from infants to adults. EPA considers consumers of specific products to be a potentially exposed or susceptible subpopulation on the basis of greater exposure potential compared to the general population who do not use specific products.

For this new chemical assessment, EPA assessed exposure to workers via the dermal and inhalation routes to a liquid formulation containing the new chemical substance. Releases to water and air were estimated and used to assess exposure to the general population. Exposure to the general population was assessed via drinking water. Exposure to the general population via inhalation was not quantitatively assessed but is expected to be negligible, as the estimated releases were below modeling thresholds. Although consumer use was not identified as an intended, known, or reasonably foreseen condition of use, potential consumer exposures were

effects at saturation (occurs when water solubility of a chemical substance is lower than an effect concentration), or the log Kow value exceeds QSAR cut-offs. A chemical substance is considered to have moderate ecotoxicity hazard if the lowest of the Fish, Daphnid or Algae LC50s is greater than 1 mg/L and less than 100 mg/L, or where the Fish or Daphnid ChVs are greater than 0.1 mg/L and less than 10.0 mg/L. A chemical substance is considered to have high ecotoxicity hazard, or if either the Fish, Daphnid or Algae LC50s are less than 1 mg/L, or any Fish or Daphnid ChVs is less than 0.1 mg/L (Sustainable Futures <a href="https://www.epa.gov/sustainable-futures/sustainable-futures-p2-framework-manual">https://www.epa.gov/sustainable-futures/sustainable-futures-p2-framework-manual</a>).

#### TSCA Section 5(a)(3) Determination for Premanufacture Notice (PMN) P-18-0233

assessed as a hypothetical scenario using a model for coatings. Exposure to aquatic organisms was not quantitatively assessed because environmental hazards are not expected for the new chemical substance up to the water solubility limit.

**Risk Characterization:** EPA applies a margin of exposure approach to calculate potential human health risks of new chemicals. A benchmark (acceptable) margin of exposure is derived by applying uncertainty factors for the following types of extrapolations: intra-species extrapolation ( $UF_H = 10$  to account for variation in sensitivity among the human population), inter-species extrapolation ( $UF_A = 10$  to account for extrapolating from experimental animals to humans) and LOAEL-to-NOAEL extrapolation (UF<sub>L</sub> = 10 to account for using a LOAEL when a NOAEL is not available). Hence, in the New Chemicals Program, a benchmark MOE is typically 100 and 1000 when NOAELs and LOAELs, respectively, are used to identify hazard. When allometric scaling or pharmacokinetic modeling is used to derive an effect level, the UF<sub>H</sub> may be reduced to 3, for a benchmark MOE of 30. The benchmark MOE is used to compare to the MOE calculated by comparing the toxicity NOAEL or LOAEL to the estimated exposure concentrations. When the calculated MOE is equal to or exceeds the benchmark MOE, the new chemical substance is not likely to present an unreasonable risk. EPA assesses risks to workers considering engineering controls described in the PMN but in the absence of personal protective equipment (PPE) such as gloves and respirators. If risks are preliminarily identified, EPA then considers whether the risks would be mitigated by the use of PPE (e.g., impervious gloves, respirator).

Risks to human health for the new chemical substance were evaluated using the route-specific effect levels (i.e., NOAEC and LOAEL) for a low molecular weight metabolite of the new chemical substance described above. Risks were not identified for workers for systemic or developmental toxicity via dermal exposure, as limited bioavailability is expected via this route (MOE = 200,000; benchmark MOE = 1,000). Risks were identified for maternal toxicity for workers from inhalation exposure to the new chemical substance in liquid form (MOE = 89; benchmark MOE = 100). Risks will be mitigated if exposures are controlled by the use of appropriate PPE, including a respirator with an APF of at least 10. EPA expects that workers will use appropriate personal protective equipment (i.e., a respirator with an APF of at least 10), consistent with the Safety Data Sheet prepared by the PMN submitter, in a manner adequate to protect them.

Risks were not identified for systemic or developmental toxicity for the general population from oral exposure to drinking water because the estimated MOEs (MOE<sub>Adult</sub> = 330,000; MOE<sub>Infant</sub> = 79,000) exceed the benchmark MOE of 1,000. Risks were not identified for consumers for dermal exposure (MOE = 140,000; benchmark MOE = 1,000) or inhalation exposure (MOE = 270,000; benchmark MOE = 100).

Due to low environmental hazard, EPA believes that this chemical substance is not likely to present an unreasonable risk to the environment even if potential exposures were high.

Because worker exposures can be controlled by PPE, and no unreasonable risks to the general population, consumers, or environment were identified, EPA has determined that the new chemical substance is not likely to present unreasonable risk to human health or the environment under the conditions of use.
