4. Environmental Siting Criteria Considerations

4.1. Overview

School location plays an integral role in creating healthy, safe schools that support high quality education and promote sustainable and healthy communities. In order to reach these goals, the local education agency (LEA) (see Section 10), in concert with the school siting committee (SSC) (see Section 3.3) and with meaningful public involvement (see Section 3), should identify criteria that will be used to evaluate both the present characteristics and possible future characteristics of all locations being considered for the school. Characteristics of surrounding properties and current and planned zoning and land uses near the location should be evaluated. Careful assessment takes time, but the importance of school siting decisions justifies the attention and the need for sustained public involvement to ensure that the location meets the needs of the community and has community support.

This section includes information on the following general areas of consideration for deciding where to locate a school:

- Whether a new school is needed (see Section 4.2.2);
- Whether the new school will be a high performance/green school (see Section 4.2.3);
- Whether some candidate locations increase environmental health or safety risks (see Section 4.3.1);
- Implications of the school location for transportation options (see Section 4.3.3);
- Options for developing Safe Routes to School Programs that can support alternative modes of transportation (see Section 4.3.4); and
- The potential use of the school as an emergency shelter (see Section 4.3.5).

Balancing the many criteria and potentially conflicting characteristics of candidate locations can be very complex. For example, in most urban areas, potential school locations that are accessible to the community may have been previously used for other purposes that may present environmental hazards. Further, they may be located in proximity to sources of potential environmental health and safety concerns, such as highways, rail yards, a wide range of light and heavy industries and other facilities that, under ideal circumstances, would not be located near a school or other facilities used for children's care. Sites that have not previously been developed—often called greenfields (see Section 10)—are often not ideally located in terms of environmental impact and transportation options. Integrating community centered schools into existing residential neighborhoods often allows for better environmental, community, economic, educational and public health outcomes. These community centered schools allow children, faculty and staff to walk or bike to and from the school and use public transportation options, when available. These schools also often take advantage of previous investments in infrastructure and add to the vibrancy and vitality of a community.
Some candidate school locations may have real or perceived environmental challenges. While the prior uses and potential for onsite contamination and impacts from nearby sources for some candidate locations may be known, in other cases, determining these issues at candidate sites requires investigation. The challenges of potential environmental hazards associated with sites can be overcome in many, although not all instances. Technical assistance and oversight from state, tribal and local environmental, public health and planning agencies can help communities evaluate potential environmental and public health concerns at specific sites. A thorough evaluation of such concerns will help communities, LEAs, and local, tribal and state leaders choose locations that can achieve multiple objectives from school facility investments while minimizing potentially adverse environmental and health issues.

Assessing and balancing multiple potential risks and benefits while considering renovation or expansion of an existing facility or prospective new sites is not a simple task, and there is no single tool available to accomplish it. The following sections, Identify Desirable School Location Attributes (see Section 4.3), and Consider Environmental Hazards (see Section 4.4), highlight considerations that should be taken into account as local communities establish their own school siting criteria, and the Environmental Review Process section (see Section 5) of the guidelines describes a process for identifying and assessing environmental hazards.

### 4.2. Before the Siting Process Begins

**4.2.1. Develop a Long-range School Facilities Plan**

School siting decisions should be integrated with broader community planning efforts, including transportation, health care, libraries, parks and historic districts, to name a few. Many communities across the country use data-driven, community-based processes to create and implement comprehensive plans that set forward strategies and policies that support future growth and development. Development of a long-range school facilities plan can help LEAs to identify important projections of long-term school and community needs such as student enrollment, operational costs and infrastructure to use in making school siting decisions. LEAs should engage with planning commissions, boards of supervisors and/or city councils from the outset to develop long-range school facilities plans that link to and complement comprehensive community plans. Through this linkage, the long-range school facilities plan would incorporate community growth and the school district at large in the school siting process, rather than considering the potential school locations in isolation from other important community planning issues.

EPA encourages LEAs to prepare a long-range school facilities plan that does the following:

- **Projects school district enrollments** for the foreseeable future (e.g., 5 – 20 years);
- **Identifies existing school infrastructure that may need to be improved or replaced**;
- **Establishes the need for additional instructional or multiuse space**, if any, based on projections;
- **Works with local authorities** to consider broader community needs such as emergency shelters, community meeting space, sports and recreation;
- **Develops a plan for meeting new space needs** that includes various approaches such as renovating or reconstructing school facilities on existing school grounds, constructing school buildings on newly acquired sites and leasing space in existing buildings;
- **Includes approximate dates** for opening new school facilities;

---

35 San Diego Unified School District, “Long-Range Facility Master Plan.” Available at: http://www.sandi.net/cms/lib/CA01001235/Centricity/Doma...
- **Targets enrollment size by type of facility;**
  and

- **Factors in other local and regional planning cycles and potential funding or resource streams,** such as connections with existing or new street, park, residential or commercial infrastructure.

The LEA’s long-range plan should be reviewed and commented on by the public, including other local public entities (e.g., municipalities, planning departments). Finally, the long-range plan should be approved by the LEA.

### 4.2.2. Consider Whether a New School Is Needed

The first criterion to consider is whether a new school is needed. Communities should consider renovation, repair and/or expansion options before deciding to build a new school. The terms “old” and “obsolete” are not synonymous. Many existing schools can be retrofitted with new technologies to expand their useful life, possibly at a lower cost and with fewer environmental impacts (e.g., energy savings, less impact on open space) than new construction. A school that is too small for an existing population may be expanded or may serve a narrower grade configuration or a special program. Using existing facilities offers other benefits that new construction often cannot. For example, many older school facilities were built at a time when schools were planned to serve as the focal point in a neighborhood not only for education but also for community events, libraries and open play fields. Continued use of existing schools can encourage physical activity because they are often located in the most walkable and bikeable parts of a community. Renovating existing neighborhood school facilities can provide an impetus for community revitalization, have an impact on neighboring property values, encourage investment in schools by community members, and preserve irreplaceable community assets.

It is important to consider both direct and indirect costs associated with building in a new location, such as the cost of site acquisition, transportation, traffic congestion, operation and maintenance, environmental cleanup, necessary infrastructure improvements and long-term monitoring and maintenance costs. In addition, renovation and/or expansion of an existing building can be part of a community revitalization effort or serve as an impetus for starting a broader revitalization effort. Siting policies that discourage renovation or expansion of existing schools and favor building larger new schools can contribute to disinvestment in existing neighborhoods. This disinvestment further contributes to the physical, social and economic decline seen in many neighborhoods where a large percentage of low-income, African-American and Hispanic or Latino students live.36

Consider taking the following actions to decide whether a new school is needed:

- **Evaluate the existing school’s current facilities and potential facilities** (through renovation/rehabilitation) and the full costs of alternatives, including educational, fiscal, environmental and public health impacts.

- **Evaluate the school for health, environmental and safety risks** from both onsite and offsite sources of potential contamination.

NOTE: The Environmental Protection Agency (EPA) recommends that districts periodically inspect existing schools for potential environmental health and safety risks using tools designed for that purpose such as EPA’s Healthy School Environments Assessment Tool (HealthySEAT; [www.epa.gov/schools/healthyseat/](http://www.epa.gov/schools/healthyseat/)) or the NIOSH Safety Checklist Program for Schools ([www.cdc.gov/niosh/docs/2004-101/](http://www.cdc.gov/niosh/docs/2004-101/)). Where deficiencies are found, EPA recommends identifying and implementing steps to reduce student and staff exposure to potential

hazards, to the maximum extent practical (see Section 9.14).

- **Evaluate the physical characteristics of existing schools** for their potential to meet changing community needs. Is the school ideally located to serve residents of the community, including senior citizens?

- **Evaluate the effect on the educational and social development of the students in the community** of constructing a new building, renovating or expanding an existing facility or closing a school.

- **Evaluate the ongoing value of a school building as a public asset** and identify how the community in the immediate vicinity of the school will be affected by renovating the school, building a new school or closing the school. Is the school a treasured part of the town? Is the building a landmark that defines the neighborhood?

- **Conduct an analysis of school system operation savings and costs** that would be anticipated from renovating, building or closing a school.

- **Consider potential increases in transportation costs** that would come from moving the school to a new, more distant location, including infrastructure (additional buses, bus stops, street improvements, traffic signals, etc.), fuel, increased air pollutant emissions from buses and privately owned vehicles and traffic congestion.

- **Determine if the school is accessible to students, faculty and other employees with disabilities** (i.e., Americans with Disabilities Act (ADA) and Section 504 compliant). If not, what would be the cost of retrofitting an older inaccessible building so that it meets ADA and Section 504 requirements?

- **Evaluate stated preferences, goals and alternatives** within a community's comprehensive plan, projected capital investments in infrastructure and other strategic investment commitments.

- **Evaluate the capacity of existing infrastructure**. If you build a new school, will the facility be on public water and sewer? If the LEA expands an existing school on a well and septic system, can the septic field be expanded?

- **Consider opportunities to partner with other government services** (e.g., parks, health clinics and libraries) that can help promote wellness and active transportation choices.

- **Plan how to ensure the safety of the children in the existing school during renovation and construction**. If major renovation is undertaken or a new building is built on an existing site, there is the potential for significant disruption of construction and demolition materials. It is important that best management practices are used during renovation and construction to prevent exposure to these materials.

More information on renovating older and historic buildings, environmental cleanup and community planning can be found on the Resources page of the guidelines website. (www.epa.gov/schools/siting/resources.html#LINKS_community_planning)

### 4.2.3. Consider Whether the New School Will Be a High Performance/Green School

More than ever, technology, expertise and public support exist to allow communities to build superior learning environments that can support higher achievement and provide healthier learning environments while also saving energy, resources and significant amounts of money. Often referred to as healthy high performance schools or green schools (see Section 10), these are facilities that integrate all aspects of the design process starting with selection of the design team and the school location to design schools that meet multiple educational, environmental and community goals. The environmental goals of such facilities include energy and water efficiency, healthy indoor air, safer materials selection (including life-cycle cost consideration), and reduced environmental impact from the school. The technologies and practices used to achieve these goals are often integrated into the curriculum and other student learning opportunities.
LEAs can use elements from green rating systems, such as the U.S. Green Building Council’s Leadership in Energy and Environmental Design (LEED; www.usgbc.org/DisplayPage.aspx?CategoryID=19) for Schools Rating System and the Collaborative for High Performance Schools (CHPS; www.chps.net/dev/Drupal/node). Both LEED and CHPS rate schools based on sustainable site selection and development, indoor environmental quality, materials and resources, energy atmosphere, water efficiency and innovation. Because high performance/green schools are based on the principle of integrated design, in which all aspects of the school are designed with a clear understanding of how the various systems and decisions affect each other, the decision to build a green school or renovate an existing school to meet green standards should be made before establishing siting criteria.

To ensure that a new school is energy efficient, LEAs can design it to earn the ENERGY STAR (see www.energystar.gov/newbuildingdesign). Building orientation and shading strategies and renewable energy technologies, such as geothermal heat pumps, wind turbines and solar panels, can help increase energy efficiency and reduce greenhouse gas emissions. EPA encourages local governments and communities to investigate and, where appropriate, integrate healthy high performance school or green school principles into their location selection and school planning and operation processes. Links to more information on green building (www.epa.gov/greenbuilding) are available on the Resources page of the guidelines website (www.epa.gov/schools/siting/resources).

The focus of these guidelines is on school siting, but there are many tools and resources available to ensure that school environments are healthy throughout the lifecycle of the school building. EPA has a considerable body of guidance and regulations that are specifically geared toward existing schools, which is available at www.epa.gov/schools. EPA recommends that districts periodically inspect existing schools for potential environmental health and safety risks from both onsite and nearby hazards using tools designed for that purpose. These include EPA’s Healthy School Environments Assessment Tool (HealthySEAT; www.epa.gov/schools/healthysseat/) or the NIOSH Safety Checklist Program for Schools (www.cdc.gov/niosh/docs/2004-101/). Where deficiencies are found, EPA recommends identifying and implementing steps to reduce student and staff exposure to potential hazards (see Section 9.14), to the maximum extent practical. In some cases, school specific improvements can reduce potential hazards; in other cases, such as widespread air pollution or water quality issues, a community wide approach may be called for.

4.3. Identify Desirable School Location Attributes

State and local policies and practices should support school locations that promote healthy people and healthy behaviors, including physical activity, healthy environments, and healthy communities. School siting decisions influence growth and development patterns and are influenced by these patterns. Many communities across the country are increasingly interested in ensuring that growth and development meet multiple community goals, including improving public health; supporting revitalization efforts; strengthening fiscal responsibility; increasing transportation choices; providing opportunities to live, work, play and attend school in convenient locations; and limiting emissions of greenhouse gases, criteria air pollutants and air toxics.

Selecting healthy, safe school locations in the neighborhoods of the students the schools serve helps meet many of these goals (see Exhibit 4: Desirable Attributes of Candidate Locations). Community centered schools encourage students to walk and bike between home, school and centers of community activity. In addition, locations that allow community access to school playgrounds and facilities encourage physical activity outside of school time. The location of schools in neighborhoods may allow more children to participate in after-school activities such as clubs, intramural and physical activity
clubs, interscholastic sports or activities sponsored by the community at local libraries, parks and community centers. As discussed in Principle 3 (see Section 1.4.3) in the About the Guidelines section (see Section 1), schools located within neighborhoods can also increase access to public transportation for students, faculty and staff in the neighborhood and in surrounding communities.\textsuperscript{37,38}

4.3.1. Select Locations That Do Not Increase Environmental Health or Safety Risks

During the initial screen of candidate locations, the LEA and SSC should seek to avoid locations that are either on or are in close proximity to land uses that may be incompatible with schools, if acceptable alternative sites exist within the neighborhood(s) being served by the new school. These incompatible land uses may include contaminated sites that have not been remediated (i.e., cleaned up) to at least a residential use standard, clusters of industrial facilities, or other potential hazards identified in Exhibit 6: Screening Potential Environmental, Public Health and Safety. The section, Consider Environmental Hazards (see Section 4.4), describes some principles used to define environmental criteria and the typical environmental and safety issues that the school siting process should consider and address to ensure that the location chosen does not pose unacceptable environmental and public health risks.

If no alternative locations exist, it is critically important that the LEA and SSC fully explain the absence of alternatives in a transparent manner and fully engage the public in identifying and implementing both site-specific and community-wide exposure and risk reduction strategies to protect the health and safety of students and staff. The LEA and SSC should consult with regional planning authorities to be cognizant of future plans for development or facilities that may result in environmental or health threats to the school location (e.g., large industrial facilities). Exhibit 5: Factors Influencing Exposures and Potential Risks, introduces some potential mitigation options for potential environmental, safety and health hazards.

4.3.2. Locate Schools Near Populations and Infrastructure

Consider establishing clear goals and criteria to give preference to locations near existing populations and close to facilities and infrastructure that support school programs to minimize transportation and infrastructure costs and their related environmental, economic, public health and sustainability impacts. Additional school capacity and the location of new schools often influence the location of residential development.\textsuperscript{39} School location is a critical aspect of quality community planning. Schools built on the fringes of communities can contribute to outward migration from city centers, which can cause disinvestment in existing neighborhoods and can hurt local economies. This phenomenon is particularly common when new school sites require the extension of infrastructure, making undeveloped areas more attractive for residential and commercial development.

Flexibility with respect to school size and site size allows communities to retain and upgrade (or replace on the same site, when necessary) existing schools. Smaller schools tend to be easier to locate near population centers, minimizing transportation needs and commuting exposures to traffic-related air pollution. Goals and criteria to

\textsuperscript{37} Ariel H. Bierbaum, Jeffrey M. Vincent and Deborah L. McKoy, “Putting Schools on the Map: Linking Transit-Oriented Development, Families, and Schools in the San Francisco Bay Area,” Center for Cities and Schools, Institute of Urban and Regional Development, University of California Berkeley (June 2010). Available at: http://citiesandschools.berkeley.edu/reports/Putting%20Schools%20on%20the%20Map_Final_Jul10_appendices.pdf.

give preference to locations near existing populations include:

- **Avoiding building schools in remote locations** that are not accessible by walking, biking and public transportation;
- **Maximizing proximity to program support facilities** such as community museums, theaters, libraries, program centers, recreational and enrichment activities and downtown commercial areas;
- **Developing joint use agreements** (see Section 10) to facilitate school access to community facilities and to allow community access to school facilities;
- **Considering proximity to other schools.** There may be local reasons to minimize or maximize distance between schools, such as the desire to promote diversity or reduce isolation in the LEA's schools; and
- **Avoiding locations that will require new infrastructure** such as roads, water/sewer or utilities.

Locating a school in the community it serves may result in proximity to pollution sources. Such situations should be addressed by considering information on associated hazards and the availability and effectiveness of mitigation options for addressing the environmental hazards, as well as the potential additional cost and time involved. Similar analyses for alternative options for locating the school should be made. With that information, communities should seek to balance the benefits of a community centered school with any potential environmental and public health risks.

### 4.3.3. Consider Implications of the School Location on Transportation Options

Transportation is a major factor in a school's overall environmental impact. Schools that offer more transportation choices can reduce the amount of land that is paved, reduce automobile and bus traffic and pollution and encourage walking or biking to school. Scientific literature on school travel shows clearly that the farther a school is from a child's residence, the less likely it is that the child will walk or bike to school, and that virtually no children walk over two miles to school.\(^{40,41}\) Connecting a school to a network of sidewalks, bike paths and other infrastructure encourages physical activity by making walking or biking safe and enjoyable. It is also important to provide walking and biking routes that do not bring children close to large roads, highways and other major pollution sources (for both health and safety concerns). Site size, location and design all play a role in determining whether walking or biking will be an option for students. Locations that provide access for students and staff via public transit will also reduce vehicle use as well as potentially promote increased physical activity in getting to the transit stops from both home and school.

Transportation costs, either to the school district or to the families it serves, are also important to consider. For example, transportation costs to the district can include the cost to purchase, maintain and store buses; the cost of fuel and personnel; and the cost associated with an increase in school bus mileage. The costs to families may be direct (e.g., a fee for students to ride the bus) or indirect (e.g., transportation-related taxes and fuel costs associated with personally transporting their children to school). The siting process should also account for transportation cost externalities, such as the health implications of exposure to exhaust while riding the school bus or from idling vehicles. Low-income and minority families can be especially impacted by transportation costs since children may not have the option of being driven to school and often need to walk, bike, use the school bus or take public transportation. This reinforces the need to locate schools within reasonable distance and provide a safe biking and

walking environment for these populations. LEAs should also consider how these costs may change over the life of the school.

Communities should consider establishing goals and criteria to give preference to locations that will promote alternative modes of transportation, including walking or biking. Minimum acreage requirements, school funding formulas and building codes often favor construction of new schools over the renovation of existing neighborhood schools; however, giving preference to locations that will promote the use of public transportation, walking or biking or that require shorter driving distances will reduce transportation costs for local government, as well as parents and caregivers.\(^\text{42}\) School consolidation policies should be carefully examined for their impact on school transportation and students' physical activity.

In new locations, schools can be designed to encourage integration with future developments by establishing street patterns, sidewalks and trail networks that support walking and biking as surrounding developments are constructed. This can happen both as part of the design and construction of the school campus and as a result of subdivision regulations guiding development within potential walking and biking distance from a school’s boundary.

The SSC should assess walkability and bikeability of the area surrounding each school location under consideration and evaluate the potential long-term health effects of candidate locations on the students and staff.\(^\text{43}\) A detailed example of how to assess the bikeability/walkability of candidate locations can be found in the "Active School Neighborhood Checklist" (www.epa.gov/schools/siting/resources.html#LNKS_cleanup_regulations_and_processes) developed in Arizona. The aim of the checklist is to provide decision makers with a quantitative tool for evaluating the potential long-term health impacts of candidate school locations on the children who will attend them. LEAs may also wish to consider conducting a health impact assessment that seeks to balance the health impacts of planning project alternatives, for example changes of transportation on air pollution and health risks. Information about health impact assessments can be found on the Resources page of the guidelines website. (www.epa.gov/schools/siting/resources.html#LNKS_health_impact_assesments)

By completing an assessment for proposed or existing school locations and comparing them, LEAs may find that one location is clearly preferable to others with regard to biking and walking potential and/or health impacts. LEAs should take the results of such assessments into consideration when selecting school locations or deciding whether to move from an existing location. If there is only one candidate location, it is still recommended that an assessment of walkability/bikeability be conducted.

If walking routes for a location are unsatisfactory, the school district should consider another location or work with the city or county to have safe walking routes installed before opening the school. New or renovated schools can act as an impetus for retrofitting or repairing sidewalk and bike trail networks in existing communities. Some localities may use different metrics and rules for determining walking/biking boundaries, and some may prioritize completion or repair of sidewalks and trail networks near school locations. Streets within realistic walking or biking distance of the location should include clear pedestrian pathways, bicycle routes, and speed control measures (e.g., traffic calming, design speeds).

Commonly accepted maximum walking/biking distances are:

- Elementary schools: ½-mile radius around school;
- Middle schools: 1-mile radius around school; and
- High schools: 1½-mile radius around school.

The example in Exhibit 3, adapted from the “Active School Neighborhood Checklist” created by the Arizona Department of Transportation (www.adotenhancement.com/SafeRoutes/PDF/Documents_Active_School_Neighborhood_Checklist.pdf), shows a middle school enrollment area that exceeds one mile in radius and creates a prohibitively long walking/biking trip for students who live in the shaded areas.

4.3.4. Plan for and Develop Safe Routes to School Programs that Can Support Alternative Modes of Transportation

A growing number of communities are implementing measures to improve the safety of walking and biking to school. Many schools participate in a program funded by the U.S. Department of Transportation (DOT) called Safe Routes to School (www.nhtsa.gov/People/Injury/Pedbimot/Bike/Safe-Routes-2004/Index), which encourages both infrastructure improvements and education programs to help more children safely walk or bike to and from school. In addition to the federally funded program, many schools offer similar programs (also called safe passages or walk to school programs) that facilitate and encourage safe walking and biking to school. These programs often educate community members, families, students, administrators, faculty and staff on the benefits of walking and biking to school and on approaches to make walking and biking to school a safe alternative. Related efforts include improvements to existing infrastructure that

Exhibit 3: Example Enrollment Area that Creates a Prohibitively Long Walking/Biking Trip for Some Students
make routes to school safer and more convenient for walking and biking. More information about Safe Routes to Schools Programs can be found on the Resources page of the guidelines website. (www.epa.gov/schools/siting/resources.html#LI NKS_Community_planning)

When planning for a new school location, the LEA and the SSC should consider ensuring that safe routes to school exist for children to bike and walk. In addition, transit connections near walking and biking routes may facilitate their use outside of the immediate school neighborhood. Factors related to walking and biking that should be considered include:

- The likelihood that bike lanes and paths, adequate sidewalks and crosswalks will be developed;
- Access to building entrances for pedestrians and bikers without crossing bus zones, parking entrances, or student drop-off and pick-up areas;
- Connectivity to transit lines for students outside the immediate neighborhood of a school;
- Bus flow plans that ensure pedestrian and bike safety;
- Accessibility for parents, students, teachers and staff with disabilities; and
- Walking and biking routes that do not cross or run adjacent to highways, other large roadways and transportation facilities (e.g., rail lines), and other large pollution sources.

Relevance of Childhood Obesity to School Locations

Today, nearly one in every three (or more than 23 million) children in the United States is overweight or obese, and physical inactivity contributes to this. Children who carry their obesity into adolescence have up to an 80-percent chance of developing an associated chronic disease (e.g., high blood pressure, high cholesterol and diabetes). This childhood obesity epidemic is the result of the interaction of three identified factors: genetics, behavior and environment. Two of these factors are associated with an ever-decreasing amount of physical activity in the lives of our children due, in part, to how our communities are built. For example, a lack of sidewalks, safe bike paths and parks in neighborhoods can discourage children from walking or biking to school as well as from participating in physical activity. While childhood obesity does not discriminate across race and ethnicity, studies show that a disproportionate number of minority children are overweight and obese; while 30.7 percent of white children ages 2 to 19 are considered obese or overweight, 34.9 percent of African-American children and 38 percent of Mexican-American children are considered so. Physical activity is especially important for youth not only because of its immediate health and academic benefits, but also because participation in physical activity tracks from youth into adulthood. See Principle 3 (see Section 1.4.3) in the About the Guidelines section for further discussion (see Section 1).
4.3.5. Consider the Potential Use of the School as an Emergency Shelter

Although schools are built with a primary mission of providing education services to youth, schools can, and often do, serve multiple purposes for their communities. Schools located and designed to withstand natural disasters and terrorist attacks not only protect students, faculty and staff from harm, but can also serve as emergency shelters in the immediate aftermath of a disaster, particularly when proper emergency preparedness plans are coordinated among school officials, local emergency management authorities and voluntary relief organizations (such as the American Red Cross). In some jurisdictions, it may be required or encouraged for certain school facilities to be designed or available to serve as an emergency shelter for the community.

For some communities, schools may be the best suited structure to serve as a post-disaster shelter. Schools frequently contain gymnasiums or other large multipurpose spaces that can shelter large numbers of residents and frequently have food preparation and storage capacity. Further, school building locations tend to be well-known among residents and sited within the communities they serve. Because schools are public property, the financial costs of using school facilities temporarily are often minimal. Thus, choosing a school location that is central to the community and easily accessible to residents can aid in disaster preparedness, planning and recovery.

The Federal Emergency Management Agency, the Department of Health and Human Services, the Red Cross and other governmental and non-governmental entities have translated the lessons learned from Hurricane Katrina and subsequent disasters into better planning and operational considerations for both emergency and longer term community shelters. Links to these resources are available in the emergency planning section of the Resources page of the guidelines website. (www.epa.gov/schools/siting/resources.html#LI NKS_emergency_planning_and_response)

4.3.6. Summary

Exhibit 4: Desirable Attributes of Candidate Locations is intended to summarize some of the important attributes for communities to consider in identifying candidate sites for school.

4.4. Consider Environmental Hazards

The primary purpose of establishing environmental criteria for school siting is to guide the screening and evaluation of candidate school locations for natural, safety and environmental hazards to identify the location that poses the least potential health and safety risk to students and staff and financial risk to the community. While the typical steps and procedures that should be included in an effective environmental review are described in the Environmental Review Process section (see Section 5), this section describes some principles used to define environmental criteria and the typical environmental and safety issues that the school siting process should consider and address to ensure that the location chosen does not pose unacceptable environmental and public health risks. EPA strongly recommends identifying and evaluating hazards associated with a location prior to taking title or ownership of that property, or in the case of leased space, prior to executing the lease.

4.4.1. Potential Onsite Hazards

Current or prior site uses

A large number of properties in the United States have been contaminated by past uses or naturally occurring hazards, such as high levels of arsenic in ground water or radon in rock formations. Some of these properties fall under the oversight of EPA, in which case EPA works together with state, tribal and local authorities to assess and remediate the site. Other known contaminated properties may be under the jurisdiction of the Department of Defense, the Department of Energy or other federal land managers, such as the Bureau of Land Management or the Bureau of Indian Affairs in the Department of Interior, while others may be dealt with directly by state, tribal and local authorities. There is also an unknown number of sites that may be contaminated but have not yet been identified by federal, state, local or tribal authorities.

Applicability of the Guidelines

The school siting guidelines are NOT designed for retroactive application to previous school siting decisions. They are designed to inform and improve the school siting decision-making process from this point forward. In developing these guidelines, EPA seeks to strengthen information exchange and cooperation between LEAs, state and tribal education agencies and their environmental counterparts to better serve school children, parents, staff and their communities in providing safe school environments.

EPA recommends that districts periodically inspect existing schools for potential environmental health and safety risks using tools designed for that purpose such as EPA’s Healthy School Environments Assessment Tool (HealthySEAT; www.epa.gov/schools/healthyseat/) or the NIOSH Safety Checklist Program for Schools. (www.cdc.gov/niosh/docs/2004-101/) Where deficiencies are found, steps to reduce student and staff exposure to potential hazards should be identified and implemented (see Section 9.13).
employees. The public should be engaged to help establish historical uses of potential school sites and adjacent sites and to assess the likelihood and possible presence of contamination. Because these groups may also have frequent contact with the site, they can significantly contribute to efforts to ensure compliance with site use restrictions as part of long-term site management plans. The Meaningful Public Involvement section provides more information on engaging the public in the school siting process (see Section 3).

**Existing structures**

While there are economic, social and environmental benefits to renovating/reusing an existing structure for a school, it is important for the LEA and the SSC to be aware that a number of products used historically in building construction (e.g., asbestos, lead, PCBs) are now recognized to be potentially hazardous to the health of children and adults in certain situations, such as when disturbed or managed unsafely by improperly trained staff or contractors. LEAs considering renovating existing schools or structures for school use or adapting other existing structures for educational purposes should weigh the hazards and the costs of the safe removal or management of these hazardous materials compared to the steps and costs associated with evaluating and acquiring sites to construct new school facilities. Links to more information on considerations related to existing buildings are provided in the Resources page of the guidelines website. (www.epa.gov/schools/siting/resources.html#LINKS_natural_hazards)

**Natural hazards**

The potential for natural hazards should be explored in decisions to renovate existing schools, as well as all potential new school locations. The natural hazards may be common or unique to the area and may include the site’s geology (naturally occurring hazards such as elevated levels of radon, arsenic or other naturally occurring toxic materials), areas of seismic activity, flooding or frequent wildfires, or areas prone to extreme weather events. Additional consideration may need to be given to natural hazards where school facilities are also planned or renovated to serve as temporary or longer term emergency shelters. Links to more information on natural hazards are provided in the Resources page of the guidelines website. (www.epa.gov/schools/siting/resources.html#LINKS_natural_hazards)

4.4.2. Potential Nearby Hazards

There is a wide range of potential environmental and safety hazards that may be located in close proximity to a prospective school location. The offsite hazards may change over time as areas are developed for industrial, transportation or other new uses; existing facilities change production processes, activity or configuration; or unforeseen events, such as spills, occur. Identifying, evaluating and planning for potential hazards from nearby sources is a critical component of successful school siting. Characterizing potential risks from nearby hazards is challenging because of the wide range of variables that influence whether there is an actual exposure to a potential hazard that may pose a risk. Additional factors to consider are whether physical, engineering or other controls can reduce or remove exposures, thus reducing risk, if such measures are properly maintained.

Exhibit 5: Factors Influencing Exposures and Potential Risks, presents some of the environmental hazards that may be on or located near candidate sites, the variables that influence the potential for exposure and risk, and mitigation options for each hazard. In some cases, the mitigation options differ if there will be a new school facility constructed (N) or if there is an existing structure that is being renovated (E). These differences are designated in the table.
### Exhibit 5: Factors Influencing Exposures and Potential Risks

4.4.3. Screening Locations for Potential Environmental Hazards

The initial screening process of identifying and narrowing potential school location choices takes into account a wide range of school siting considerations and challenges. Among the most important of these is to identify potential environmental and public health concerns as early in the process as possible to fully understand the potential costs and benefits of candidate locations before deciding to pursue a particular site. Unanticipated environmental issues can be extremely costly in terms of cleanup costs, time delays, community concern and potential loss of support for siting choices. A full understanding of the potential risks of candidate sites to ensure that a prospective school site does not pose unacceptable health and safety risks to students and staff is very important but can be costly and time-consuming. For this reason, it may be desirable to try to avoid sites that have onsite contamination or are in very close proximity to pollution generating land uses at the initial stage of identifying candidate sites if other acceptable locations exist in the community that may pose fewer environmental challenges.

Exhibit 6: Screening Potential Environmental, Public Health and Safety Hazards, below, contains a list of potential environmental and safety hazards that should be identified, evaluated and weighed, along with other factors, in choosing a school location. In general, the closer a potential hazard is to a candidate location for a school, the more important it is to gain an early understanding of the potential risks that may be associated with that hazard. Exhibit 6 is intended to be used in conjunction with the example Environmental Review Process (see Section 5) and with Evaluating Impacts of Nearby Sources of Air Pollution (see Section 6).

Screening perimeters can help the LEA and SSC quickly identify activities or features on or in the area surrounding a prospective school location that have the potential to pose a hazard to students and staff and warrant further evaluation. These include a wide range of potential ongoing sources of air, water and land contamination as well as features or activities that may pose safety risks from accidental releases. For potential school locations identified within the "screening perimeter" of an environmental feature, further study is warranted to ensure that the potential risks associated with that feature are not significant.

Screening perimeters are intended to facilitate:

- Rapid identification of land uses near candidate school locations that could potentially pose health and safety hazards to students and staff;
- Consultation with appropriate state, tribal, local and other authorities, local stakeholders and the public to assist with the evaluation; and
- Consideration of appropriate mitigation or separation strategies to reduce potential risks within the context of the broader school siting decision-making process.

Determining screening distances for various hazards is, to a large degree, a matter of best professional judgment. Several jurisdictions have adopted screening distances based primarily on existing state or local rules, law, ordinance, policy or guidance. Links to this information are provided on the Resources page of the guidelines website (www.epa.gov/schools/siting/resources). In the following table, EPA has included recommended screening distances based on existing approaches at the state and local level as approximate distances within which EPA recommends that potential hazards should be identified and considered for additional study.

**NOTE:** Screening distances are intended to identify potential land uses near candidate school locations that warrant further consideration rather than to identify land uses that may be incompatible with the location of schools. Screening distances, alone, may not be predictive of the actual potential for a source located within that distance to present an environmental or health hazard. Potential hazards associated with candidate school locations should be evaluated as part of the site screening and evaluation process.
Exhibit 6: Screening Potential Environmental, Public Health and Safety Hazards

**IMPORTANT:** This table is intended to assist with the initial screening of candidate locations but is NOT a substitute for case- and site-specific evaluation of potential risks and hazards. It is intended to be used in conjunction with the example Environmental Review Process (see Section 5) and Evaluating Impacts of Nearby Sources of Air Pollution (see Section 6). For more information on typical environmental hazards that may be encountered during the school siting process, see the Quick Guide to Environmental Issues in Section 8). Existing applicable federal, state, tribal or local statutes, ordinances, codes or regulations take precedence over the recommendations contained in this table. Users should check with state, tribal and local authorities for applicable requirements or other recommendations.
