Comment: The definition of tune-up in proposed §63.7575 describes "adjustments made ... to optimize combustion efficiency." While we believe that is an appropriate definition, it does not match the requirements specified in proposed §63.7540(a)(10). That paragraph specifies six tune-up requirements that require specific inspections, that CO production is optimized, and that specific records be maintained and submitted on request. This problem was noted in the finalization of the March 21, 2011 BPH NESHAP and the proposed definition of tune-up was not finalized in order to remove this conflict. EPA stated in the final rule preamble "The definition of "Tune-up" was removed from 40 CFR 63.7575 because all of the requirements for a tune-up are provided in the rule language at 40 CFR 63.7540(a)(10), making the definition unnecessary." 15 We recommend the same action here. EPA should not finalize the proposed definition of "tune-up". Should the Agency opt to finalize a tune-up definition 1) a specific reference to the required §63.7540(a)(10) elements should be added, 2) the reference to optimizing combustion should be removed, since that is not an element in the (a)(10) requirements and 3) the following 2 items should be addressed. [Footnote 15: 76 Fed. Reg. 15620 (March 21, 2011)]

Response: See the responses to comments EPA-HQ-OAR-2002-0058-3677-A2, excerpt 53 and excerpt 54.

Comment Excerpt Number: 2

Comment: Westlake seeks clarification that the proposed definition of *distillate oil*¹ is the same as the one in 40 CFR 60, Subpart Db.

[Footnote]

(1) See 40 CFR §60.41b - *Distillate oil* means fuel oils that contain 0.05 weight percent nitrogen or less and comply with the specifications for fuel oil numbers 1 and 2, as defined by the American Society of Testing and Materials in ASTM D396 (incorporated by reference, see § 60.17) or diesel fuel oil numbers 1 and 2, as defined by the American Society for Testing and Materials in ASTM D975 (incorporated by reference, see § 60.17).

Response: In order to maintain consistency for boilers and process heaters that may be subject to various subparts under 40 CFR part 60, 61, 63, and 65, we have revised the definition of

distillate oil to be consistent with 40 CFR 60, Subpart Db, Standards of Performance for Industrial-Commercial-Institutional Steam Generating Units.

Comment Excerpt Number: 176

Comment: The definition of "residual oil" includes #4 fuel oil. In other EPA rules (e.g., GHG reporting rule), #4 fuel oil was defined as a distillate fuel. In order to maintain some consistency, we recommend striking "#4" from the residual oil definition. Doing so would still allow #4 to be considered a "heavy fuel," but eliminate the inconsistency between rules.

Response: The EPA acknowledges the commenter's concerns but disagrees with the proposed changes. The GHG Reporting Rule requires reporting of greenhouse gas data to inform future regulatory decisions, but does not provide emission standards for boilers and process heaters. In order to maintain consistency for boilers and process heaters that may be subject to emission standards under various subparts under 40 CFR part 60, 61, 63, and 65, we have revised the definition of residual oil to be consistent with 40 CFR 60, Subpart Dc, Standards of Performance for Small Industrial-Commercial-Institutional Steam Generating Units. The definition has been revised as follows:

Residual oil means crude oil, fuel oil numbers 1 and 2 that have a nitrogen content greater than 0.05 weight percent, and all fuel oil numbers 4, 5, and 6, as defined by the American Society of Testing and Materials in ASTM D396–10 (incorporated by reference, see §63.14(b)).

Commenter Name: Kevin Bloomer

Commenter Affiliation: Westlake Chemical Corporation

Document Control Number: EPA-HQ-OAR-2002-0058-3535-A2

Comment Excerpt Number: 3

Comment: Westlake requests EPA to make the definition of the term *residual oil*² be the same as the definition in 40 CFR 60, Subpart Db in order to make these two rules impacting ICI boilers consistent with one another.

[Footnote]

(2) See 40 CFR §60.41b - *Residual oil* means crude oil, fuel oil numbers 1 and 2 that have a nitrogen content greater than 0.05 weight percent, and all fuel oil numbers 4, 5, and 6, as defined by the American Society of Testing and Materials in ASTM D396 (incorporated by reference, see § 60.17).

Response: In order to maintain consistency for boilers and process heaters that may be subject to various subparts under 40 CFR part 60, 61, 63, and 65, we have revised the definition of residual oil to be consistent with 40 CFR 60, Subpart Db, Standards of Performance for Industrial-Commercial-Institutional Steam Generating Units.

Comment: The requirements in proposed §63.7550 are very unclear because of use of the term "affected source" to mean different things and all instances should be replaced with use of clear and specific defined terms.

Inconsistent use of the term "affected source" is a serious problem throughout this proposal. It is a particular problem in §63.7550, because the term appears to have been used in this section to refer to 1) individual boilers and process heaters (e.g., ones where there has been a deviation), 2) collections of boilers and process heaters (e.g., ones subject to emission limits), and 3) entire facilities (e.g., ones with Title V operating permits). Understanding is further blurred because new and reconstructed affect sources are defined in the proposal as individual boilers and process heaters, while existing affected sources are the collection of all boilers and process heaters at a facility in a particular subcategory that are not new or reconstructed. There are several places in §63.7550 where it is unclear whether reports are required for only specific boilers and process heaters meeting the indicated criterion or whether reports are required for all boilers and process heaters at the facility if any meets the indicated criterion. Every use of the term affected source should be replaced with either "individual boiler or process heater," "collection of boilers and process heaters," or "facility" as appropriate.

Response: The EPA acknowledges the commenter's concern and has clarified the requirements of §63.7550 to specify when the requirements apply to individual boilers and process heaters, collections of boilers and process heaters, or entire facilities.

Comment: The definition of "benchmarking" is inconsistent with the use of the term "benchmark" in the emission averaging portion of the rule. "Benchmark" should be the defined term, not "benchmarking", since "benchmarking" is not used anywhere in the rule and "benchmark" should be defined consistent with its use in the rule. We suggest the following.

Benchmark means the fuel use for a boiler or process heater for the one-year period before the date that an energy demand reduction occurs, unless it can be demonstrated that a different time period is more representative of historical operations.

Response: The EPA agrees with the commenter. The terminology and definition for "benchmark" have been updated accordingly.

Commenter Affiliation: The Aluminum Association

Document Control Number: EPA-HQ-OAR-2002-0058-3509-A1

Comment Excerpt Number: 1

Comment: The Aluminum Association has concerns that the current definition for *Metal Process Furnace* may lead to incorrect interpretations with regard to direct-fired equipment. The current definition of a process heater is:

"*Process heater* means an enclosed device using controlled flame, that is not a boiler, and the unit's primary purpose is to transfer heat indirectly to a process material ..."[i.e., indirect-fired units].

Only sources meeting the definition of "Process Heaters" are supposed to be affected sources under the Boiler MACT. The current definition of *Metal Process Furnace* is:

"*Metal process furnaces* include natural gas-fired annealing furnaces, preheat furnaces, reheat furnaces, aging furnaces, heat treat furnaces, and homogenizing furnaces."

To clarify that only indirect-fired furnaces are included within this definition, the Aluminum Association requests EPA to revise the definition to say:

"*Metal process furnaces* are a subcategory of *Process Heaters* which include natural gas-fired annealing furnaces, preheat furnaces, reheat furnaces, aging furnaces, heat treat furnaces, and homogenizing furnaces."

Response: The EPA acknowledges the commenter's concerns and has revised the definition of Metal process furnances as follows, "Metal process furnaces are a subcategory of Process heaters, as defined in this subpart, which include natural gas-fired annealing furnaces, preheat furnaces, reheat furnaces, aging furnaces, heat treat furnaces, and homogenizing furnaces."

Comment Excerpt Number: 50

Comment: E. The Proposed Revisions to the Definition of "Process Heater": Including Units Heating Hot Water as a Process Heat Transfer Medium Creates Unnecessary Confusion.

In the table of proposed technical corrections in the Boiler MACT Reconsideration Proposal, EPA indicates that it proposes to "[r]evise the definition of 'process heater' to include 'units heating hot water as a process heat transfer medium.'" *Id.* at 80,620. The following underlined portion reflects the proposed additions to the definition:

Process heater means an enclosed device using controlled flame, and the unit's primary purpose is to transfer heat indirectly to a process material (liquid, gas, or solid) or to a heat transfer material for use in a process unit, instead of generating steam. Process heaters include units heating hot water as a process heat transfer medium. Process heaters are devices in which the combustion gases do not come into direct contact with process materials. A device combusting solid waste, as defined in §241.3, is not a process heater unless the device is exempt from the definition of a solid waste incineration unit as provided in section 129(g)(1) of the Clean Air Act. Process heaters do not include units used for comfort heat or space heat, food preparation for on-site consumption, or autoclaves. Waste heat process heaters that use only natural gas, refinery gas, or other gas 1 fuels for supplemental fuel are excluded from this definition.

Id. at 80,653 (underline added). The absence of a rational basis or explanation of any kind as to the proposed revision is troubling in light of the substantive changes to the definition of "process

heater” that EPA seeks to effectuate. The proposed revision is likely to lead to confusion for affected sources, including those owned and/or operated by AIF members.

In bringing “units heating hot water as a process heat transfer medium” into the definition of “process heater,” EPA’s proposal creates the confusing circumstance whereby the regulations could classify a hot water heater as both a boiler *and* a process heater. Traditional, centralized boilers, for example, serve to heat facility buildings both for comfort *and* for some processes. Even though the majority of the annual heat load is related to comfort heat and *not* process heat, and the definition of “process heater” otherwise endeavors to exclude from its ambit those “units used for comfort heat,” the proposed, revised regulations would identify those units as both a boiler *and* a process heater. The confusion – and additional regulation – that would flow from EPA’s proposed revision is unnecessary and lacks any rational basis. It would be simpler to keep all hot water heaters classified first as boilers, regardless of whether they heat a process, *see, e.g., id.* at 80,650 (“Boiler means an enclosed device using controlled flame combustion and having the primary purpose of recovering thermal energy in the form of steam or hot water”), and then exclude from regulation under the Boiler MACT those units that meet § 63.7575’s definition of “hot water heater,” *see, e.g., id.* at 80,641 (including a hot water heater as defined at § 63.7575 as one of the types of boilers and process heaters that is not subject to the Boiler MACT). EPA should rescind this proposed revision.

Response: We agree that the addition would cause confusion. In terms of the regulation, the unit would be subject to the same requirements regardless of whether it is classified as a boiler or process heater.

10B. Rule Language: Definitions (New)

Commenter Name: David A. Buff, Golder Associates Inc.

Commenter Affiliation: Florida Sugar Industry (FSI)

Document Control Number: EPA-HQ-OAR-2002-0058-3504-A1

Comment Excerpt Number: 61

Comment: EPA has set forth a definition of 30-day rolling average as "the arithmetic mean of all valid data from 30 successive operating days that is calculated for each operating day using the data from that operating day and the previous 29 operating days." EPA has not defined "10-day rolling average" in the Proposed Boiler MACT Rule, although the CO CEMS-based emission limit is based on a 10-day rolling average. However, in Table 8, Item 10, Carbon Monoxide Emissions, the Proposed Boiler MACT Rule states "Correcting the data to 3 percent oxygen, and reducing the data to one-hour and daily block averages...", and "Reducing the data from the daily averages to 10- day rolling averages...". Thus, a 10-day rolling average would be comprised of ten (10) daily averages that are averaged together. The problem with this accounting method is that each day will count as 1/10th of the total 10-day average, even if a boiler only operates briefly on one of the days. For example, the 10 day average could be skewed upward, in an inappropriate and disproportionate manner, if the boiler has elevated emissions on a day in which the boiler only operates for one hour. To eliminate this problem, the EPA should define 10-day rolling average (or any rolling average) in the same manner as the 30-day rolling average (i.e., the arithmetic average of all valid data occurring over the 10-day period). With this

approach, an operating day with very little operating data would not have a disproportionate affect on the rolling average.

Response: The EPA agrees with the commenter and has revised the definitions of 10-day rolling average and 30-day rolling average accordingly. The definition of 10-day rolling average has been clarified as follows:

10-day rolling average means the arithmetic mean of the previous 240 hours of valid operating data. Valid data excludes hours during startup and shutdown, data collected during periods when the monitoring system is out of control as specified in your site-specific monitoring plan, while conducting repairs associated with periods when the monitoring system is out of control, or while conducting required monitoring system quality assurance or quality control activities, and periods when this unit is not operating. The 240 hours should be consecutive, but not necessarily continuous if operations were intermittent.

The definition of 30-day rolling average has been clarified as follows:

30-day rolling average means the arithmetic mean of the previous 720 hours of valid operating data. Valid data excludes hours during startup and shutdown, data collected during periods when the monitoring system is out of control as specified in your site-specific monitoring plan, while conducting repairs associated with periods when the monitoring system is out of control, or while conducting required monitoring system quality assurance or quality control activities, and periods when this unit is not operating. The 720 hours should be consecutive, but not necessarily continuous if operations were intermittent.

Comment Excerpt Number: 29

Comment: Item #4.f. of Table 3 lists the requirements for a one-time energy assessment. This element requires the assessment include:

(f) A list of major energy conservation measures.

There is no definition for what constitutes a *major* energy conservation measure. However, the proposed rule provides the following definition

Cost-effective energy conservation measure means a measure that is implemented to improve the energy efficiency of the boiler or facility that has a payback (return of investment) period of 2 years or less. The preamble twice refers to "cost-effective energy conservation measures" with respect to the energy assessment (pp. 80602 and 80603 of the Federal Register). It appears the intent of EPA is that the energy-assessment list *cost-effective* energy conservation measures rather than *major* energy conservation measures. Therefore, we recommend that Table 3, item 4, element (f) be reworded as:

(f) A list of ~~major~~ cost-effective energy conservation measures.

Response: The EPA acknowledges the commenter's concern. It was the EPA's intent in the development of the proposed rule to require a list of cost-effective energy conservation measures as part of the one-time energy assessment, for which a definition was provided. Table 3 of the final rule has been revised accordingly for consistency.

Document Control Number: EPA-HQ-OAR-2002-0058-3667-A2

Comment Excerpt Number: 13

Comment: Some small BPH are standard units that are purchased as a complete unit and come with manufacturer's recommendations. However, many boilers and most process heaters are custom designs and usually are not single units provided by one manufacturer. Typically, burners come from one manufacturer, the tubes from another, and controls, the structure, and the firebox are field fabricated from components purchased from many sources. In these cases, there are no manufacturer's recommendations that deal with the entire unit. Thus, the burner manufacturer's recommendations do not deal with the needs to assure the integrity of the firebox or the refractory or consider instrumentation setup or response times. The owner/operator considers the manufacturer's recommendations, but must be free to adjust for the overall construction and condition of the unit and to fill in gaps where no manufacturer's recommendation exists or where the manufacturer did not consider other unit equipment needs or situations. Furthermore, as a unit ages, startup and shutdown needs can change and original manufacturer's recommendation may no longer be applicable. For instance, changing burners to low-NOx configurations, installing a different refractory, or changing firebox operating temperature, can require alteration to original manufacturer's recommendations or the original operating plan developed by the operator for a particular boiler or process heater. Finally, at very low firing in multi-burner process heaters, oxygen control is lost since only a few burners are operating and procedures have to deal with that situation. Thus, the phrase "as specified by the boiler manufacturer" should be deleted from the first sentence of Item 5 in Table 3.

Response: The final rule has been revised to delete the phrase "as specified by the boiler manufacturer" from the first sentence of Item 5 in Table 3. We agree with the commenter that there will be many instances where the original boiler manufacturer's specifications will not be available or where optimizing to them would not be appropriate.

Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1

Comment Excerpt Number: 160

Comment: Table 1, Item 5.a. specifies that a span value of 600 ppmv is to be used for Method 10. This appears to be an error since the CO limit for that subcategory is 590 ppmv. For comparison, other Table 1 and 2 CO M10 span requirements are in the range of 2 times the emission limit. Therefore, it is recommended to change the required span for Table 1, Item 5.a to be 1000 ppm.

Response: The final span values have been deleted from Table 1 because 63.7525(a)(6) specifies that the span value of a CO CEMS must be two times the applicable emission limit.

Document Control Number: EPA-HQ-OAR-2002-0058-3453-A1

Comment Excerpt Number: 6

Comment: *COCEMS-Based Alternative Emission Limits and Monitoring*

Table 2 in the summary lists the alternate CO CEMS limit for the 'Coal-Burning Pulverized Coal' subcategory as 35 ppm @ 3% oxygen; this is in conflict with Table 2 in the rule itself which indicates 28 ppm @ 3% oxygen. FMC requests EPA to correct this discrepancy.

Response: The final CO CEMS limit in the rule and preamble summary tables have been updated to reflect the revised CO CEMS analysis, as discussed in the preamble and in Chapter 4 of the RTC document.

Commenter Name: David A. Buff, Golder Associates Inc.

Commenter Affiliation: Florida Sugar Industry (FSI)

Document Control Number: EPA-HQ-OAR-2002-0058-3504-A1

Comment Excerpt Number: 13

Comment: It appears that Table 4 and Table 8 of the Proposed Boiler MACT Rule establish inconsistent requirements. In Table 4 ("Operating Limits For Boilers and Process Heaters"), item 9, indicates that the oxygen level must be maintained at all times so that it never drops "below the lowest hourly average oxygen concentration measured during the most recent CO performance test." 76 F.R. 80665, However, in Table 8 ("Demonstrating Continuous Compliance"), item 9 indicates that the "30-day rolling average oxygen content [must be maintained] at or above the lowest hourly average oxygen level measured during the most recent carbon monoxide performance test." 76 F.R. 80670. The FSI believes EPA should revise Table 4 to make it consistent with Table 8, because "EPA has determined that a 30- day rolling average for parameter monitoring and demonstration of continuous compliance with operating limits is appropriate for this rule." 76 F.R. 80610.

Response: The EPA thanks the commenter for their input. As noted by the commenter, it was the EPA's intent in the proposed rule to require the 30-day rolling average of the oxygen content for parameter monitoring and demonstration of continuous compliance, as discussed in Section V.D.6 of the proposal preamble and Table 8 of the proposed rule. Therefore, item 9 of Table 4 has been updated as follows, "For boilers and process heaters subject to a carbon monoxide emission limit that demonstrate compliance with an O₂ analyzer system as specified in §63.7525(a), maintain the 30-day rolling average oxygen content at or above the lowest hourly average oxygen concentration measured during the most recent CO performance test."

Comment: Table 4 contains requirements for operating limits, but it is unclear that these operating limits only apply if you are complying with a Table 1 or 2 numerical emission limit and, then only, while that limit is applicable (e.g., not during periods of startup and shutdown). The Table 4 first column header should be revised to make this clear. We recommend the Table 4 first column header be revised to "When complying with a Table 1 or 2 numerical limit, using".

Response: The EPA agrees with this clarification and has revised Table 4 accordingly.

Commenter Name: Richard D. Garber

Commenter Affiliation: Boise Inc.

Document Control Number: EPA-HQ-OAR-2002-0058-3686-A2

Comment Excerpt Number: 21

Comment: EPA should amend 02-trim monitoring and reporting requirements for units that will demonstrate compliance using an annual stack test.

40 CFR 63.7525(a) states that boilers subject to a carbon monoxide emissions limit must install either an oxygen analyzer or CO CEMS. For boilers that select use of the oxygen analyzer, 40 CFR 63.7525(a)(2) requires that the operator use the analyzer as part of an oxygen trim system and that the oxygen level be set at the minimum percent oxygen by volume established as the operating limit for oxygen according to Table 4 in the subpart. In Table 4, item 9, (FR page 80665) EPA states that the system "*maintain* the oxygen level such that it is not below the lowest hourly average oxygen concentration measured during the most recent CO performance test." In this section, EPA has failed to acknowledge the 30-day averaging time specified in Table 8, item 9 (FR page 80670).

Response: See the response to comment EPA-HQ-OAR-2002-0058-3504-A1, excerpt 13.

Comment: The language in Table 4 and Table 9 should be consistent- each with the other and accurately reference the 30-day averaging period specified in Table 9. This is necessary so that Table 4 cannot be incorrectly interpreted or be suggested to require that the 02 level be used as some sort of hourly *limit* for the boiler. Should EPA continue to use the 30-day average for oxygen monitoring, Boise requests that EPA clarify that the calculation of the 30-day average be based on the most recent 720 hours of valid operating data to allow for the appropriate exclusion of outage data from the average.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3504-A1, excerpt 13.

Comment Excerpt Number: 28

Comment: The proposed rule at §63.7520 and in Table 5 requires the use of the F-Factor methodology and equations as contained in EPA Method 19 for the calculation of particulate matter, hydrogen chloride, mercury, and total selected metals emissions on a pound per million BTU basis. The original technical documents for this method as contained in EPA-450/2-78-042a, Stack Sampling Technical Information, A Collection of Monographs and Papers, Volume I, however, make it clear that this method is envisioned as an alternative to the use of measured volumetric flows and heat inputs. Many sources subject to the proposed rule already measure and keep records of fuel heat inputs as part of their normal operations, therefore, to mandate the use of calculated data from secondary measurements as opposed to direct data from primary measurements would seem to increase the potential for error in the resulting emissions values. For multi-fuel sources, Method 19 itself requires that the fraction of heat input from each type of fuel be determined in order to prorate the applicable F-Factors. Since direct measurement of heat input for all fuels for a given multi-fuel boiler is often not possible, proration of the applicable F-Factors will necessarily require a combination of direct measurement and back-calculation using steam flow and boiler efficiency data. Once data adequate to calculate an appropriate prorated F-Factor is available, requiring its further use to calculate total heat input via F-Factor methodology would seem redundant. The use of approaches other than Method 19 could be accomplished via a request to EPA for approval of alternative monitoring, however, amendment of the proposed rule to explicitly allow for the use of a broader range of options would be a far more efficient resolution.

GP urges EPA to: Amend §63.7520 and Table 5 to provide for the use of Method 19 or some other technically appropriate method(s) for determining heat input data.

Response: We disagree with the commenter that 63.7520 and Table 5 should be amended to allow other undefined method and the commenter does not provide information on how to determine if another methods is technically appropriate.

Comment Excerpt Number: 13

Comment: Table 5 of the proposed rule does not describe the stack test method requirements for boilers which elect to use the alternative TSM limit. FMC requests EPA to include the appropriate stack test method in Table 5.

Response: The EPA acknowledges the commenter's concerns. As discussed in Section III.F of the proposed rule, we intended to require initial and annual stack tests using EPA Method 29 at 40 CFR part 60, appendix A-8 to determine compliance with the alternate TSM emission limits. Table 5 of the final rule has been updated to include EPA Method 29 and other applicable stack test requirements for boilers electing to use the alternative TSM emission limits.

Comment: As found in Table 7 of the proposed rule, boilers and process heaters who use sorbent injection are required to develop a site-specific minimum sorbent injection rate based on HCI performance testing. MSU is requesting U.S. EPA to provide clarification as to what is meant by sorbent injection.

In the electrical generation industry, limestone is commonly referred to as sorbent. As discussed previously, MSU operates a CFB boiler who's bed is composed of limestone, coal, and ash. During startup, the limestone is incorporated into the combustion chamber with the other components to build the bed and begin heat transfer. Limestone continues to be incorporated on an as-needed basis during operation, but not at a rate that could be considered linear.

As such, MSU would like to clarify what U.S. EPA intends for this requirement to be applicable to sorbent injections systems that are used as a control device, such as a dry scrubber, and did not mean to include the incorporation of limestone into a CFB bed.

Response: It was the EPA's intent in the proposed rule to require facilities using dry scrubbers as an add-on control device to establish a site-specific minimum sorbent injection rate and conduct monitoring of the sorbent injection rate to demonstrate compliance. The definition of Dry scrubber in the proposed rule included "an add-on air pollution control system that injects dry alkaline sorbent (dry injection) or sprays an alkaline sorbent (spray dryer) to react with and neutralize acid gas in the exhaust stream forming a dry powder material". Sorbent injection systems in fluidized bed boilers and process heaters were included in this definition. For clarification, the EPA has revised the definition of "Minimum sorbent injection rate" to clarify that not only add-on sorbent injection systems used as pollution control systems are included in this definition. The definition of "Minimum sorbent injection rate" has been revised as follows: Minimum sorbent injection rate means:

The load fraction multiplied by the lowest hourly average sorbent injection rate for each sorbent measured according to Table 7 to this subpart during the most recent performance test demonstrating compliance with the applicable emission limits; or

For fluidized bed combustion, the lowest average ratio of sorbent to sulfur measured during the most recent performance test.

Comment Excerpt Number: 27

Comment: We note that Table 8, item 11 does not state that a 30-day rolling average is used for boiler or process heater operating load. EPA needs to clarify this requirement in the final rule.

Response: The maximum operating load is an absolute value that should not be exceeded and it is not appropriate for this value to be changed to a 30-day rolling average. In EPA's stack test policy (L. Lund EPA/OECA Issuance of the Clean Air Act National Stack Testing Guidance April 27, 2009; Available on-line at: <http://www.epa.gov/compliance/resources/policies/monitoring/caa/stacktesting.pdf>), the EPA recommends that performance tests be performed under those representative (normal) conditions that:

- represent the range of combined process and control measure conditions under which the facility expects to operate (regardless of the frequency of the conditions); and
- are likely to most challenge the emissions control measures of the facility with regard to meeting the applicable emission standards, but without creating an unsafe condition.
- If operating at maximum capacity would result in the highest levels of emissions, operating at this level would not create an unsafe condition, and the facility expects to operate at that level at least some of the time, EPA recommends that the facility should conduct a stack test at maximum capacity or the allowable/permitted capacity.
- An affected source should conduct its performance test at an operating load that the source is not expected to exceed (with the exception of a 10% allowance). The EPA has provided a cushion of 10 percent to provide for some flexibility in operating loads. Operating load is a

different type of parameter than the other operating parameters which are based on 30-day rolling averages; these parameters are designed to give information on how well the source is being controlled, while the operating load gives information on if the compliance test was performed under representative emissions loading conditions.

- Item 11 of Table 8 and item 8 of Table 4, however, have been revised to clarify that the maximum operating limit is 110% of the highest hourly average operating load recorded during the performance test in order to be consistent with the other operating limit which are based on hourly averages.

Document Control Number: EPA-HQ-OAR-2002-0058-3427

Comment Excerpt Number: 13

Comment: DoD supports EPA's clarification that compliance extensions can be requested under §63.6(i) of the General Provision when additional time is needed to install control devices, combined heat and power, or waste heat recovery to comply with the rule. However, the statement added to Table 10 to Subpart DDDDD should be clarified to ensure it is clear that the statement is understood to expand and not limit the provisions of §63.6(i).

Recommendation

Clarify the sentence added to the comment corresponding to §63.6(i) in the third column of Table 10 to subpart DDDDD as follows:

*Yes. **Note:** Facilities may also request extensions of compliance for the installation of combined heat and power or waste heat recovery as a means of complying with this subpart."*

Response: EPA agrees with the commenter that the provisions of 40 CFR 63.6(i) are not intended to be limited. We have modified Table 10 accordingly.

10D. Rule Language Excluding Definitions and Tables 1 through 10

Commenter Name: Lee Zeugin and Lauren Freeman

Commenter Affiliation: Utility Air Regulatory Group (UARG)

Document Control Number: EPA-HQ-OAR-2002-0058-3500-A1

Comment Excerpt Number: 43

Comment: EPA proposes to remove the reporting provision specific to PM CEMS and to replace the more general reporting provision with three separate provisions. The first provision would require reporting of the "results of performance tests" within 60 days. Proposed § 63.7550(h). The second provision would require reporting of "relative accuracy test audit data" within 60 days of each CO and Hg CEMS "performance evaluation test." Proposed § 63.7550(i). The third provision would require quarterly reporting of "all the calculated 30 day rolling average values based on the daily CEMS (CO and Hg) and CPMS (PM CPMS output, scrubber pH, scrubber liquid flow rate, scrubber pressure drop) data." Proposed § 63.7550(j).

Proposed §§ 63.7550(h) would require reporting to WebFIRE using ERT and something called the “Compliance and Emissions Data Reporting Interface (CEDRI) that is accessed through [CDX].” Proposed §§ 63.7550(i) would require reporting to CDX using only ERT. Proposed §§ 63.7550(j) would require reporting to WebFIRE using only CEDRI. In support of its proposal, EPA again offers general assertions of reduced burden and emission factor improvements. With respect to the substantive content of the reports, EPA states that “[a]nother advantage is that ERT clearly states what testing information would be required.” 76 Fed. Reg. at 80,605. EPA did not respond to any of UARG’s prior comments related to the burden of this electronic reporting and the proposed benefits for the development of emission factors.

Response: We agree with comment from the 2009 ANPR that the template is not yet available and the process for transmitting the quarterly reports of the type required by this rule are not yet available for review at the time of the proposal. In response to this comment, we have changed the rule to reduce the reporting from quarterly to semi-annually and clarify that implementation of the requirement to electronic submit semi-annual reports will commence only when the electronic reporting tools (e.g., data submittal templates) and the data submission process are operative. Because the reporting template and data submission process for stack test reports are completed and operational, the requirement to submit stack test reports electronically will be effective on the compliance date. We also agree with the 2009 ANPR comment that EPA should limit its requirement for a reporting template to a specific format so as to allow facilities to procure or develop their own software to comply with that format and the associated reporting elements. The EPA plans to revise the electronic reporting requirements to provide an XML schema to allow facilities to obtain their own software that meets the XML schema specifications.

The EPA disagrees with the commenter’s 2009 ANPR comment that the ERT, as currently designed, requires the reporting of vast amounts of information that are not otherwise required to be reported under the applicable EPA test methods or EPA’s proposed rule. The commenter also adds that “the EPA must comply with the Paperwork Reduction Act and specify each piece of information it seeks to have reported, explain how those data have practical utility, and estimate the costs of collection and EPA review of those data. EPA has done none of that.” The ERT does not require vast amounts of data that are not otherwise required to be reported by a rule or method. The ERT was designed using the performance test report reporting requirements in the parts 60 and 63 General Provisions and the Emissions Measurement Center’s Guidance Document (GD-43) entitled “Preparation and Review of Emission Test Reports”. See <http://www.epa.gov/ttn/emc/guidlnd/gd-043.pdf>. There are a few data fields that aren’t mentioned in the general provisions and the guidance document, but these are facility and unit identification designations, such as the Federal Reference Number, fields that State and Local Air Pollution Control Agencies may require, and/or data fields that are not mandatory for performance test report submission.

The EPA agrees with the comment by the commenters that the EPA has not explained how the requirements of the Cross-Media Electronic Reporting Rule (CROMERR) have been met. Working closely with the EPA’s Office of Environmental Information, the EPA’s Office of Air Quality Planning and Analysis has established an electronic reporting process that meets the CROMERR requirements. The EPA has established a portal for electronic submission of the ERT data through the Central Data Exchange (CDX), where all electronic data submitted to EPA must be submitted. All users who want to submit ERT data must register for use of the CDX

which meets the signatory requirements of CROMERR. The EPA has developed the Compliance and Emissions Data Reporting Interface (CEDRI) that provides the user with the mechanism to submit ERT data through the CDX to the EPA's data repository, WebFIRE. Together, this system meets the CROMERR requirements and the requirements mentioned by UARG in 40 CFR section 3.2000(b)(5). The EPA agrees with the commenters assertion that the EPA has not explained how the information required to be submitted under the ERT to WebFIRE will be used to develop emissions factors. The EPA has a draft version of the Emissions Factors Development Procedures on the AP-42 website (see <http://www.epa.gov/ttn/chief/ap42/>) now. Although the EPA will not change the basic procedure of using the average of available and appropriate performance test data to develop emissions factors, the final specific procedures are not available in the procedures document have not been published.

Comment Excerpt Number: 162

Comment: Proposed §63.7550(d) and (e) identify the required content of the periodic report where deviations are reported. Because of the use of the term affected source, it is unclear whether the subparagraphs require reporting of information only for the boiler or process heater where the deviation occurred, for all boilers and process heaters at the facility, or for all boilers and process heaters in the same subcategory as the boiler or process heater where the deviation occurred (i.e., the existing source affected source). It should be made clear that the information in the §63.7550(d) and (e) subparagraphs is only required for the boiler or process heater for which there was a deviation by replacing "affected source" throughout these sections with "boiler or process heater where the deviation occurred".

Response: The EPA has clarified 40 CFR 63.7550(d) and (e) in the final rule to specify that the requirements apply only to individual boilers and process heaters where a deviation has occurred.

Comment: 40 CFR 63.7515(g) allows 90 days to report the results of a performance test or fuel analysis (following the test date). Should this be changed to 60 days?

40 CFR 63.7550(h) requires performance test results to be submitted to the WebFire database within 60 days following the performance test.

Response: We agree that 40 CFR 63.7515(g), now 63.7515(f), should be changed to 60 days. It is the EPA's intent that the timeframe for reporting the performance test results is 90 days. This timeframe is also consistent with the timeframe on the final Mercury and Air Toxics Standards (MATS). 40 CFR 63.7515(g) has been modified to reflect a 60 day timeframe, accordingly.

Commenter Name: Cheryl Suttman

Document Control Number: EPA-HQ-OAR-2002-0058-3795-A1

Comment Excerpt Number: 4

Comment: Can boilers and process heaters burning the same fuel (only oils, solids are well defined) be averaged in the same averaging group? They would be considered “units” designed to burn the same fuel and would share the same limit, but a boiler and a process heater are designed so differently. It seems a little unusual that a heater and boiler would be able to average their emissions for compliance, especially if the boiler had controls and the heater did not; and/or one was used for heating and the other was used for a production process.

Response: Units within the same subcategory can be averaged whether they are all boilers, process heaters, or both.

Comment: Under the revised 40CFR63.7505(d)(1), EPA states that the requirement for a facility to develop and submit a site specific monitoring plan does not apply to affected sources with existing monitoring plans that apply to CEMS and COMS prepared under Appendix B to part 60 and that meet the requirements of 40CFR63.7525. However, Appendix B to Part 60 only provides the performance specifications to be used for the design, performance, and installation of a COMS/CEMS. Please clarify which Part 60 monitoring plans EPA is referring to in this section of the rule.

Response: The EPA agrees with the commenter and has revised the exception under 40 CFR 63.7505(d)(1) to read as follows: "This requirement to develop and submit a site specific monitoring plan does not apply to affected sources with existing CEMS or COMS operated according to the performance specifications under appendix B to part 60 of this chapter and that meet the requirements of §63.7525."

Document Control Number: EPA-HQ-OAR-2002-0058-3504-A1
Comment Excerpt Number: 58

Comment: In the Proposed Boiler MACT Rule, EPA states "Another important proposed benefit of submitting these data to the EPA at the time that the source test is conducted is that it should substantially reduce the effort involved in data collection activities in the future". 76 F.R. 80605. This statement should be clarified to provide that the performance test report should be submitted to EPA within 60 days of completion of the performance test. This clarification would make the text consistent with standard state requirements. It should also be clarified that only the information required in a performance test report must be submitted to the WebFIRE database.

Response: 63.7550(h) of the final rule reflects a 60 day timeframe for submittal of performance test results and in keeping with the requirements outlined in 40 CFR 63.7515(g). See the response to comment EPA-HQ-OAR-2002-0058-3795-A1, excerpt 2. As previously specified in 40 CFR 63.7550(h), only data collected using test methods on the ERT website are subject to the requirement to submit reports electronically to WebFIRE.

Commenter Name: Douglas A. McWilliams
Commenter Affiliation: American Municipal Power
Document Control Number: EPA-HQ-OAR-2002-0058-3685-A2
Comment Excerpt Number: 39

Comment: EPA Should Clarify that Emission limits, Operating limits, and Monitoring Requirements Apply Only During Periods of Source Operation

The language of the Proposed Rule states that emission limits, operating limits, and work practice standards apply "at all times" except for periods of startup and shutdown. We do not believe it was EPA's intent to imply that the source remains subject to these limits even when the emission unit is not operating and is not producing emissions. EPA acknowledged that it did not intend for CPMS and opacity limits to apply during periods of startup and shutdown, because the unit is not subject to a numeric emission limit during these times. It would be nonsensical (and impossible as a practical matter) to require sources to establish compliance with these standards while the source and its associated control equipment are down. EPA should simply clarify in the text of the final rule that the emission limits, work practice standards, and operating limits apply "at all times the affected unit is operating" rather than "at all times."

Response: The EPA agrees with the commenter and has revised the final rule accordingly.

Commenter Name: Matthew Todd
Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)
Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2
Comment Excerpt Number: 5

Comment: Many requirements require that something be "minimized" (e.g., minimize the effects of swirling flow or abnormal velocity distributions on flow measurements). This term is unclear and nebulous. Experience shows that over the years it will be interpreted differently by affected facilities and regulators. Some regulators and citizens will interpret "minimize" to mean "eliminate." In order to avoid technologically infeasible and cost ineffective interpretations, every use of the term "minimize" in this regulation, where it is not currently qualified, should be qualified by adding the phrase "to the extent practicable" or "consistent with good engineering practice."

Response: The EPA agrees with the commenter and has updated the final rule accordingly.

Commenter Name: Matthew Todd

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 6

Comment: The term "affected source" is used frequently throughout the proposal when the intent is clearly to mean each individual boiler and process heater. Since the existing affected source is a collection of boilers and process heaters and not each individual one (as the new and reconstructed affected source is defined), most uses of the term "affected source" in the proposal are incorrect and confusing. Wherever it is intended that a requirement apply to each individual boiler and process heater the term "affected source" should be replaced with the phrase "each boiler and process heater." Similarly, the term "affected source" is sometimes used to mean facility, even though that is not how it is defined in proposed §63.7490(a). Wherever it is intended that a requirement apply to the facility the term "affected source" should be replaced with the word "facility." See Comment II.10.C for a specific example.

Response: The EPA agrees with the commenter and has clarified the requirements of the final rule accordingly.

Commenter Name: Matthew Todd

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 7

Comment: In general, the proposed language (including the preamble discussion and the requirements in the Tables) is inconsistent in the terminology used when referring to particular subcategories. This is confusing, leads to misunderstanding, and could lead to misinterpretation. For instance, proposed §63.7540(a)(10) begins "If your boiler or process heater is either in the natural gas, refinery gas, other gas 1, or metal process furnace subcategories ..." However, there is no natural gas subcategory, no refinery gas subcategory and no other gas 1 subcategory. Those are three fuels that if burned in a boiler or process heater would qualify that boiler or process heater to be in the "unit designed to burn gas 1" subcategory, if the other criterion in the subcategory definition is met. If the other criterion is not met, the boiler or process heater would be in a different subcategory even if it primarily fired natural gas, refinery gas, and/or other gas

1. This same mistaken terminology is used throughout the rule to refer to the gas 1 subcategory. By not using the proper subcategory names §63.7540(a)(10) could be misinterpreted and at a minimum is confusing. We recommend all references to subcategories be changed to use the defined subcategory name or a consistent short name that is set out in the subcategory definition.

Response: The EPA agrees with the commenter's concerns and has revised the final rule accordingly.

Commenter Name: Matthew Todd

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 8

Comment: Liquid and solid fired BPH are each in two subcategories (for instance a liquid fired unit is in the liquids subcategory and either the light liquids or heavy liquids subcategory.) However, rule requirements are all written as if a unit can only be in one source category. A general clean-up of rule language to change "subcategory" to "subcategories" where appropriate would improve rule clarity.

Response: The EPA agrees with the commenter and has revised the final rule accordingly.

Commenter Name: Matthew Todd

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 36

Comment: The use of fuel type terminology is inconsistent throughout the rule and should be reviewed and corrected where necessary. Of particular concern, "residual oil" is used in many places where "heavy liquid" may have been intended.

Response: The EPA appreciates the commenter's input. The fuel type terminology has been updated in the final rule (see 40 CFR 63.7510(d), 40 CFR 63.7525(b), and the definition of "liquid fuel" in 40 CFR 63.7575) to reflect "heavy liquid" and "light liquid" for clarification and consistency.

Document Control Number: EPA-HQ-OAR-2002-0058-3523-A1

Comment Excerpt Number: 15

Comment: There are a multitude of requirements for performance testing, continuous emissions monitoring systems (CEMS), continuous parameters monitoring systems (CPMS), operating parameters, instrument calibration and other quality assurance requirements embedded in the 2011 final rule and with a number of changes proposed in the December 2011 re-proposal. EPA should streamline the requirements where possible, correct discrepancies identified in comments submitted by the trade groups and respond to opportunities to minimize the monitoring burdens these extensive and complex provisions carry with them.

Response: We have streamline the requirements, where appropriate, have corrected discrepancies, when identified, and made changes to minimize the testing and monitoring burden.

Commenter Name: John V. Corra, Director

Commenter Affiliation: State of Wyoming Department of Environmental Quality

Document Control Number: EPA-HQ-OAR-2002-0058-3435-A1

Comment Excerpt Number: 1

Comment: The State has concerns regarding the overlap of requirements in the rules with those in the general provisions, particularly recordkeeping and reporting. Complying with both the general provisions and the requirements in the rule causes confusion for both the State and industry. This confusion often results in small companies, with limited resources, having to hire a third party contractor to ensure compliance. Wyoming recommends that EPA add language that waives the recordkeeping and reporting general provisions when there are very specific, detailed requirements for recordkeeping and reporting within the rule, and has provided some examples below that illustrate areas of compliance confusion. These examples are not inclusive of all problem areas within the rule.

The general provisions for the notification of compliance status in § 63.9(g)(2)(ii) states: "The notification must be sent before the close of business on the 60th day following the completion of the relevant compliance demonstration activity specified in the relevant standard".

In regard to the boiler rules, it is unclear what qualifies as a "relevant compliance demonstration activity". It is also unclear whether or not the activities are to be reported through both the notification of compliance status and the compliance reports described in § 63.7550.

It is stated in § 63.7515(g) that performance tests shall be submitted within 90 days.

The State requests clarification on whether that submission should follow the general provision requirements for a "notification of compliance status" or whether it is considered a "report".

Also, § 63.7530(h) requires a statement that good combustion practices were used and oxygen concentrations were maintained for each startup and shutdown event, as part of the notification of compliance status.

Clarification is needed regarding whether or not this is a onetime report required under the initial notification of compliance status, or whether the report should be submitted on a regularly scheduled basis.

Response: The requirement in 63.7515 for reporting the results of the performance tests has been changed to 60 days to be consistent with the General Provisions. 63.7530(h) pertains to the requirements for demonstrating initial compliance. These same requirements are in 63.7550 for reporting on a regularly scheduled basis in order to demonstrate continuous compliance.

Comment: The compliance timing for BPH that stop burning solid waste must be clarified and it should be clarified that only when it is intended to permanently cease burning solid waste does the CISWI unit become subject to the appropriate BPH NESHAP.

1. Proposed §§60.2145(a)(2) and (3), and 60.2710(a)(2) and (3) and the proposed definition of CISWI unit specify that a unit that has been subject to CISWI remains subject for 6 months after ceasing to combust solid waste. On the other hand, §63.7495(e) of this proposal states:

(e) If you own or operate an industrial, commercial, or institutional boiler or process heater and would be subject to this subpart except for the exemption in §63.7491(l) for commercial and industrial solid waste incineration units covered by part 60, subpart CCCC or subpart DDDD, and you cease combusting solid waste, you must be in compliance with this subpart on the effective date of the switch from waste to fuel.

"Effective date" is unclear in this context and should be clarified by specifically referencing the provisions of the CISWI rules that identify this effective date as being the date identified by the source for the transition from the CISWI rule to the BPH major source rule and not the date the source ceases to burn solid waste or the effective date of the BPH major source rule.

2. Proposed §63.7495(e) deals with compliance timing for BPH that have been subject to the CISWI rule, but stop firing solid waste and thus become subject to this major source rule instead. As currently worded, a temporary stoppage (which happens frequently at CISWI units) would appear to make the BPH rule applicable rather than CISWI. The language of §63.7495(e) needs to be clear that this transition only occurs if the unit is stopping solid waste burning permanently.

3. Proposed §63.7495(e) should also be clarified to confirm that the requirements of the CISWI rule no longer apply after the effective date of the transition.

4. To address these issues (1, 2 and 3) we suggest the following revision to §63.7495(e).

(e) If you own or operate an industrial, commercial, or institutional boiler or process heater and would be subject to this subpart except for the exemption in §63.7491(l) for commercial and industrial solid waste incineration units covered by part 60, subpart CCCC or subpart DDDD, and you permanently cease combusting solid waste, you must be in compliance with this subpart and are no longer subject to part 60, subparts CCCC or DDDD beginning on the effective date of the switch from waste to fuels identified under the provisions of §§60.2145(a)(2) and (3) or §§60.2710(a)(2) and (3).

Response: We agree with the commenter and have made the suggested revision to §63.7495(e). (e) If you own or operate an industrial, commercial, or institutional boiler or process heater and would be subject to this subpart except for the exemption in §63.7491(l) for commercial and industrial solid waste incineration units covered by part 60, subpart CCCC or subpart DDDD, and you cease combusting solid waste, you must be in compliance with this subpart and are no longer subject to part 60, subparts CCCC or DDDD beginning on the effective date of the switch as identified under the provisions of §§60.2145(a)(2) and (3) or §§60.2710(a)(2) and (3).

Comment: Since some process heaters produce steam as a waste heat recovery step, though not necessarily using a "waste heat boiler or process heater" we suggest proposed §63.7500(a)(1) be revised as follows:

...The output-based emission limits are not applicable to process heaters **that do not generate steam**.

Response: The EPA acknowledges the commenter's concern and recognizes that some process heaters may produce steam. 40 CFR 63.7500(a)(1) has been revised to specify that the output-based emission limits are applicable to process heaters that generate steam.

Comment: Approval of alternative monitoring and work practices to those specified in Tables 3 and 4 should be delegated.

Proposed §63.7500(a)(2) provides:

(2) You must meet each operating limit in Table 4 to this subpart that applies to your boiler or process heater. If you use a control device or combination of control devices not covered in Table 4 to this subpart, or you wish to establish and monitor an alternative operating limit and

alternative monitoring parameters, you must apply to the EPA Administrator for approval of alternative monitoring under § 63.8(f).

Similarly, proposed §63.7500(b) provides:

(b) As provided in § 63.6(g), EPA may approve use of an alternative to the work practice standards in this section.

Use of §63.8(f) and (g) to obtain approval of monitoring or work practices that deviate from that specified in a regulation is generally unworkable if that authority is not delegated, because EPA has demonstrated its inability to respond to such requests in a timely manner. This always puts sources at risk, but particularly so in this case, since sources may be unable to comply if Table 4 is not applicable to their control configuration or needs to be adjusted to make it applicable. Because of the large number and wide variety of BPH operations, the need for alternate monitoring and revisions to the work practice requirements is likely to be much more common than in typical rules, thus amplifying the problem. We therefore strongly recommend that EPA delegate this authority.

Should EPA opt to retain this authority, to avoid violations due to EPA inaction, the Agency should add language to the final BPH NESHAP rule that provides that any §63.8(f) or (g) request on which EPA does not act within 90 days is considered approved.

Response: We disagree with the suggestion to delegate authority to a state regulatory authority for approval of alternative work practice standards. The work practice standards are developed under section 112(h) of the Clean Air Act instead of MACT emission limits but are considered MACT-based standards. It is EPA who is mandated to develop the MACT-based standards and, thus, the authority to approve any alternative MACT standards.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 115

Comment: In addition, §63.7510(a)(2)(iii) appears to require mercury fuel analysis for natural gas:

"You are not required to conduct a chlorine fuel analysis for any gaseous fuels. You must still conduct a fuel analysis for mercury on gaseous fuels unless the fuel is exempted in paragraphs (a)(2)(i) through (iii) of this section."

EPA should clarify this paragraph to indicate that mercury analysis is also not required for natural gas or refinery gas.

Response: The EPA disagrees and believes that the intent of the rule is clear. 40 CFR 63.7510(a) applies to boilers or process heaters that "demonstrate compliance with any of the applicable emission limits in Tables 1 or 2 of this subpart". Emission limits are not provided for the units designed to burn gas 1 subcategory in these tables, therefore, the requirements of 40 CFR 7510(a) do not apply to the units burning natural gas, refinery gas, or other gas 1 fuels.

Furthermore, 40 CFR 7510(a)(2)(ii) specifically exempts natural gas, refinery gas, and other gas 1 fuels co-fired with fuels in other subcategories, affirming the EPA's intent that fuel analyses are not required for fuels from the gas 1 category.

40 CFR 63.7510(a)(2) also requires that the fuel analysis be conducted according to the requirements of 40 CFR 63.7521 and Table 6. The EPA's intent is clear in 40 CFR 63.7521(a), which states, "For gas 2 (other) fuels, you must conduct fuel analyses for mercury according to the procedures in paragraphs (b) through (e) of this section and Table 6 to this subpart, as applicable....You are required to conduct fuel analyses only for fuels and units that are subject to emission limits for mercury, hydrogen chloride, or total selected metals in Tables 1 and 2 to this subpart."

The EPA believes that 40 CFR 7510(a)(2)(iii) is clear in that it specifically applies to gaseous fuels that are subject to the emission limits in Tables 1 and 2 of the final rule, and not to units in the gas 1 category. Therefore, no changes have been made to the final rule.

Comment: Proposed §63.7510(a)(2)(iii) specifies in the second sentence that "You must still conduct a fuel analysis for mercury on gaseous fuels unless the fuel is exempted in paragraphs (a)(2)(i) through (iii) of this section" but the reference should only be to (a)(2)(i) and (ii), since (iii) exempts fuels from the chloride analysis requirement, not the mercury analysis requirement.

Response: The EPA thanks the commenter for the correction and has revised 40 CFR 63.7510(a)(2)(iii) to correct the reference.

Commenter Name: Paul Noe

Commenter Affiliation: American Forest & Paper Association (AF&PA) et al.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 114

Comment: We agree with EPA's determination that no fuel analysis for chloride is required for gases and that operators are not required to conduct the mercury fuel specification analyses for gaseous fuels that are natural gas, refinery gas, or otherwise subject to another subpart of part 63. EPA also should exempt those sources using process gases that otherwise are regulated under Parts 60 and 61 from conducting a fuel specification analysis. Specifically, §63.7510(a)(2)(ii) and §63.7521(f)(2) should be amended with the addition of the bold language noted to read:

*§63.7510(a)(2)(ii) When natural gas, refinery gas, other gas 1 fuels are co-fired with other fuels, you are not required to conduct a fuel analysis of those fuels according to § 63.7521 and Table 6 to this subpart. If gaseous fuels other than natural gas, refinery gas, or other gas 1 fuels are cofired with other fuels and those gaseous fuels are subject to another subpart of this part, **part 60, or part 61**, you are not required to conduct a fuel analysis of those fuels according to § 63.7521 and Table 6 to this subpart.*

*§63.7521(f)(2) You are not required to conduct the fuel specification analyses in paragraphs (g) through (i) of this section for gaseous fuels for units that are subject to another subpart of this part, **part 60, or part 61**.*

EPA has already extended the exemption for boilers serving as control devices to those controlling gaseous streams subject to Parts 60 and 61.

Response: The EPA agrees with the commenter and has incorporated the suggested revisions to §63.7510(a)(2)(ii) and §63.7521(f)(2). Additionally, we have incorporated an exemption for units subject to regulation under 40 CFR part 65. 40 CFR 65.7510(a)(2)(ii) reads as follows: "If gaseous fuels other than natural gas, refinery gas, or other gas 1 fuels are co-fired with other fuels and those gaseous fuels are subject to another subpart of this part, part 60, part 61, or part 65, you are not required to conduct a fuel analysis of those fuels according to §63.7521 and Table 6 to this subpart." 40 CFR 65.7521(f)(2) has also been revised accordingly.

Document Control Number: EPA-HQ-OAR-2002-0058-3427

Comment Excerpt Number: 2

Comment: The text at §63.7510 does not clearly identify that the requirements (e.g., emissions limits, operating limits, performance testing, fuel analysis, establishing operating limits, and demonstrating continuous compliance) in the other tables do not apply to gas 1 units, there is opportunity for confusion and differences in interpretation. Clarification that the requirements in the other tables do not apply to gas 1 units would eliminate any confusion regarding applicability and allow the regulated community to consistently achieve compliance. For example, Table 6 to Subpart DDDDD does not specifically state that gas 1 units are exempt from its requirements.

However, the rule clearly exempts gas 1 units from the requirements in Table 6 to Subpart DDDDD in §63.7521(a) [page 77 FR 80632] which states: "... *Gaseous and liquid fuels are exempt from the sampling requirements in paragraphs (c) and (d) of this section and Table 6 of this subpart.*" As such, gas 1 units are not subject to Table 6 requirements.

In the preamble to the proposed rule revision, the first paragraph under *III. Summary of This Proposed Rule, D. What emission limits and work practice standards must I meet?* [Page 77 FR 80600] states: "*You must meet the emission limits presented in Table 1 of this preamble for each subcategory of units listed in the table. This proposed rule includes 17 subcategories, which are based on unit design. New and existing units in 3 of the subcategories would be subject to work practices standards in lieu of emission limits for all pollutants. Numeric emission limits are being proposed for new and existing sources in each of 14 subcategories, which are shown in Table 1 of this preamble.*" Tables 1 and 2 do not address new or existing boilers or process heaters designed to burn natural gas, refinery gas or other gas 1 fuels. As such, gas 1 units are not subject to Tables 1 and 2 emission limits, but are instead subject to work practice standards in lieu of emission limits for all pollutants.

Additionally in the preamble, the second paragraph under *III. Summary of This Proposed Rule, D. What emission limits and work practice standards must I meet?* [Pages 77 FR 80600-80601] goes on to state: "... *If your unit is a metal process furnace, limited-use unit, or Gas 1 unit (that is, it combusts only natural gas, refinery gas, or other clean gas that meets the fuel specification, with limited exceptions for gas curtailments and emergencies), your unit is subject to a work practice standard that requires an annual tune-up in lieu of emission limits.*" Thus, Tables 1 and 2 emission limits do not apply to gas 1 units.

The rule at §63.7510 [Page 80630] states that "*(a) For affected sources that are required to or elect to demonstrate compliance with any of the applicable emission limits in Tables 1 or 2 of this subpart through performance testing, your initial compliance requirements include all the following: ...*" However, as stated above, the preamble identifies that Tables 1 and 2 do not apply to gas 1 units.

Regarding the operating limits, testing, and initial compliance requirements in the preamble to the proposed rule revision, the second paragraph under item (9) [Page 76 FR 80603] states: "*These operating limits do not apply to owners or operators of boilers or process heaters having a heat input capacity of less than 10 MMBtu/hr or boilers or process heaters of any size which combust natural gas or other clean gas, metal process furnaces, or limited-use units. Instead, if requested, owners or operators of such boilers and process heaters shall submit to the delegated authority or the EPA, as appropriate, documentation that a tune-up meeting the requirements of this final rule was conducted. ...*" As such, the operating limits do not apply to gas 1 units.

Clarify that the emission limits, operating limits, and requirements for performance testing, fuel analysis, establishing operating limits, and demonstrating continuous compliance as identified in the tables to this subpart do not apply to gas 1 units by adding IP (a)(6) to §63.7510 as follows:

§63.7510 What are my initial compliance requirements and by what date must I conduct them?

(1) Gas 1 units (e.g., those meeting the definition of unit designed to gas 1 subcategory) are exempt from the emission limits, testing, fuel analyses, and initial compliance requirements of Tables 1, 2, 4, 5, 6, 7, and 8 of this subpart.

Response: The EPA disagrees with the commenter. First, it is the EPA's intent that the requirements referenced in Tables 1 and 2 (and new Table 11) apply only to the unit categories identified in each table. The header for Table 4 has been revised to clarify that it applies only to units complying with numerical emission limits in Tables 1 and 2 (and new Table 11), which are only required for the unit categories identified in Tables 1 and 2 (and 11). The performance testing, fuel analysis, operating limits, and continuous compliance requirements of Tables 5 through 8 only apply to units subject to emission limits as outlined under 40 CFR 63.7510.

40 CFR 63.7510(a) specifically applies to "affected sources that are required to or elect to demonstrate compliance with any of the applicable emission limits in Tables 1 or 2 of this subpart through performance testing". Furthermore, 40 CFR 63.7510(b), (c), and (d) also specifically identify affected sources that demonstrate compliance with the applicable emission limits in Tables 1 and 2, including carbon monoxide and PM limits. Finally, 40 CFR 63.7510(e) and (g) specify the initial compliance requirements for existing and new or reconstructed sources not subject to the emissions limits in Tables 1 and 2.

Therefore, the EPA believes that it is clear that the emission limits, performance testing, fuel analysis, operating limits, and performance evaluation requirements of 40 CFR 7510(a), (b), (c), and (d), including the referenced requirements of Tables 1, 2, 4, 5, 6, 7, and 8, do not apply to gas 1 units.

Comment Excerpt Number: 1

Comment: There is Confusing language with respect to single type of fuel, co-fired with natural gas. Proposed regulation 63.7510 (a)(2)(i) specifies that, for sources that burn a single type of fuel, a fuel analysis is not required. This proposed regulation further specifies that units that use supplemental fuels only for startup, shutdown, or transient flame stability purposes still qualify as affected sources that use a single *type* of fuel if the supplemental fuel is not subject to the fuel analysis requirements under § 63.7521 and Table 6 to this subpart. Natural gas is not subject to the fuel analysis requirements of § 63.7521. Since that is the case. EPA seems to have recognized that natural gas is a fuel that is not expected to contribute to halogen or heavy metal emissions.

Alcoa-Warrick occasionally co-fires natural gas with coal. Since natural gas is not subject to the fuel analysis requirements of § 63.7521~ the single type of fuel burned exemption should not be restricted to start-up, shutdown, or transient flame stability maintenance purposes.

Accordingly, Alcoa-Warrick requests that §63.7510 (a)(2)(i) be amended, as follows:

"For affected sources that burn a single type of fuel, you are not required to conduct a fuel analysis for each type of fuel burned in your boiler or process heater according to § 63.7521 and

Table 6 to this subpart. For purposes of this subpart, units that use a supplemental fuel ~~only for startup, unit shutdown, and transient flame stability purposes~~, still qualify as affected sources that burn a single type of fuel, ~~if and~~ the supplemental fuel is not subject to the fuel analysis requirements under § 63.7521 and Table 6 to this subpart.

Response: We disagree with the commenter to exempt all uses of supplemental fuels and not just for startup, shutdown, or transient flame stability purposes.

Comment Excerpt Number: 129

Comment: Proposed §63.7515(f) calls for monthly fuel analyses, where fuel analysis is being used to demonstrate compliance. It is unclear what "monthly" means and this should be clarified. We suggest the language relative to "monthly" from the proposed §65.280(b) part 65 subpart H (Uniform Standard General Provisions)⁵¹ be added to §63.7515(f), including the revisions we suggested in Comment II.9.E.2 above, as follows.

(f) If you demonstrate compliance with the mercury, hydrogen chloride, or total selected metals based on fuel analysis, you must conduct a monthly fuel analysis according to § 63.7521 for each type of fuel burned that is subject to an emission limit in Table 1 or 2 to this subpart. You may comply with this monthly requirement by completing the fuel analysis any time within the

calendar month as long as the analysis is separated from the previous analysis by at least 14 calendar days. If you burn a new type of fuel, you must conduct a fuel analysis before burning the new type of fuel in your boiler or process heater. You must still meet all applicable continuous compliance requirements in § 63.7540. If 12 consecutive monthly fuel analyses demonstrate 75% or less of the compliance level, you may decrease the fuel analysis frequency to quarterly for that specie. If any quarterly sample exceeds 75% of the compliance level or you begin burning a new type of fuel, you must return to monthly monitoring for that specie, until 12 months of fuel analyses again are less than 75 % of the compliance level. ~~If 12 consecutive monthly fuel analyses demonstrate compliance, you may request decreased fuel analysis frequency by applying to the EPA Administrator for approval of alternative monitoring under § 63.8(f).~~

Response: The EPA agrees with the clarifications suggested by the commenter and has revised 40 CFR 63.7515(f), now (e), as follows:

"If you demonstrate compliance with the mercury, hydrogen chloride, or total selected metals based on fuel analysis, you must conduct a monthly fuel analysis according to §63.7521 for each type of fuel burned that is subject to an emission limit in Table 1, 2, or 11 to this subpart. You may comply with this monthly requirement by completing the fuel analysis any time within the calendar month as long as the analysis is separated from the previous analysis by at least 14 calendar days. If you burn a new type of fuel, you must conduct a fuel analysis before burning the new type of fuel in your boiler or process heater. You must still meet all applicable continuous compliance requirements in §63.7540. If 12 consecutive monthly fuel analyses demonstrate 75% or less of the compliance level, you may decrease the fuel analysis frequency to quarterly for that fuel. If any quarterly sample exceeds 75% of the compliance level or you begin burning a new type of fuel, you must return to monthly monitoring for that fuel, until 12 months of fuel analyses again are less than 75 % of the compliance level."

Comment: Proposed §63.7515(g) requires that after the initial testing you report "the results of performance tests and the associated initial fuel analyses within 90 days after the completion of the performance tests." However, this section deals with subsequent testing, not initial, so §63.7515(g) should be revised by removing the word "initial". Furthermore, as discussed in Comment II.10.B.4 above, subsequent performance test reporting should be required on the same schedule as the periodic reports.

Response: The EPA agrees with the commenter and has revised 40 CFR 63.7515(g) accordingly.

Commenter Name: Samuel H. Bruntz

Commenter Affiliation: Alcoa Power Generating, Inc.

Document Control Number: EPA-HQ-OAR-2002-0058-3755-A1

Comment Excerpt Number: 2

Comment: There is conflicting language with respect to fuel analysis requirements.

§63.7510 (a)(2)(i) as presently proposed seems to conflict with 63.7520 (c), which requires that fuels with the highest chlorine and mercury content must be burned during the performance tests. To eliminate this conflict in both regulations, Alcoa-Warrick suggests that 63.7520 (c) be amended as follows:

“You must conduct performance tests at representative operating load conditions while burning the type of fuel or mixture of fuels that has the highest content of chlorine and mercury , and you must demonstrate initial compliance and establish your operating limits based on these performance tests. These requirements could result in the need to conduct more than one performance test. *The requirement to conduct performance tests while burning fuels with the maximum amount of chlorine and mercury is not applicable for units that burn a single type of fuel, as specified by 63.7510(a)(2)(i), provided the performance tests are conducted at representative operating loads for the single type of fuel burned in the unit.*”

Response: We disagree that 63.7520(c) needs to be revised. §63.7520(c) states "while burning the type of fuel ... that has the highest content of ...". It does not state that a unit burning a single fuel type must conduct the test with the maximum content for that fuel type.

Comment: Proposed §63.7520(e) specifies how to convert performance test values to pounds per million BTU. However, the proposed language only makes the procedure applicable to the initial performance test. The word "initial" should be deleted from §63.7520(e) as the procedure applies for all performance tests.

Response: The EPA thanks the commenter for their input and has revised 40 CFR 63.7520(e) accordingly.

Comment Excerpt Number: 16

Comment: Sources Using Process Gases subject to Parts 60, 61, and 63 should be exempt from conducting the gas 1 fuel specification analysis.

The Boiler MACT currently provides that operators are not required to conduct the mercury fuel specification analyses for gaseous fuels that are natural gas, refinery gas, or otherwise subject to another subpart of part 63. EPA also should exempt those sources using process gases that

otherwise are regulated under Parts 60 and 61 from conducting a fuel specification analysis. Specifically, section 63.7521(f)(2) should be amended to read:

You are not required to conduct the fuel specification analyses in paragraphs (g) through (i) of this section for gaseous fuels for units that are subject to another subpart of this part, part 60, or part 61.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3521-A1, excerpt 114.

Comment Excerpt Number: 2

Comment: We do, however, have some concerns in regards to timing in needing EPA "approval" of the fuel analysis plan as specified in 63.7521(g). This "approval" authority should be delegated to the local authority (e.g. Title V permit writer) to help ensure that it can be obtained in a timely manner.

Alternatively, the "approval" section could be taken out altogether to read as follows:

(g) You must develop and submit a site-specific fuel analysis plan for other gas 1 fuels to the EPA Administrator/or for review ~~and approval~~ according to procedures and requirements in paragraphs (g)(1) and (2) of this section.

Response: 63.7521(g) has been revised in the final to be consistent with the revision to 63.7521(b) to remove the requirement for EPA approval unless an alternative method other than those in Table 6 is requested. 63.7521(g) is revised to read:

(g) You must develop a site-specific fuel analysis plan for other gas 1 fuels according to the following procedures and requirements in paragraphs (g)(1) and (2) of this section.

(1) If you intend to use an alternative analytical method other than those required by Table 6 to this subpart, you must submit the fuel analysis plan to the Administrator for review and approval no later than 60 days before the date that you intend to conduct the initial compliance demonstration described in §63.7510.

Comment Excerpt Number: 17

Comment: The rule calls for conducting performance tests and fuel sampling but does not describe how the fuel sampling results are to be correlated to performance test results. The rule is very prescriptive in determining maximum input levels for mercury, chlorine, and total selected metals, but does not explain how these levels relate to the performance test results. Please clarify.

Response: We disagree that the rule does not explain how these fuel sampling results relate to the performance test results. §63.7540(a)(4) and (a)(6) both states "If you demonstrate compliance with an applicable hydrogen chloride (or mercury) emission limit through performance testing and you plan to burn a new type of fuel or a new mixture of fuels, you must recalculate the maximum chlorine (mercury) input using Equation 7 of §63.7530. If the results of recalculating the maximum chlorine input using Equation 7 of §63.7530 are greater than the maximum chlorine input level established during the previous performance test, then you must conduct a new performance test.." The maximum chlorine and mercury input levels are what determines if a performance test is needed if the fuel type or mixture is changed.

Comment Excerpt Number: 90

Comment: Emissions averaging should be allowed for units complying with TSM emission limits. Section 63.7522 does not allow emissions averaging for TSM, but as the compliance provisions (either stack testing or fuel sampling and analysis) are essentially the same as those for HCl and Hg, there is no reason why it should not be allowed. EPA allows emissions averaging for TSM in the final MATS rule (see §63.10009).

Response: We agree with the commenter that emission averaging be allowed for demonstrating compliance with the TSM emission limit. Because PM is used as a surrogate for TSM and TSM limits were proposed as an alternate to the PM limits, §63.7522 has been revised in the final rule to include TSM to be consistent with the requirements for PM.

Commenter Name: Steve Gossett

Commenter Affiliation: Eastman Chemical Company

Document Control Number: EPA-HQ-OAR-2002-0058-3669-A2

Comment Excerpt Number: 49

Comment: Emissions averaging should be allowed for compliance with the optional TSM limit.

With no justification for doing so, EPA has proposed to exclude use of the emissions averaging option to comply with the proposed total selected metals (TSM) emission limits. EPA included TSM in the emissions averaging provisions for the Utility MACT (§63.10009) and Eastman is aware of no difference that would justify treating industrial and institutional boilers differently. Accordingly, Eastman requests that EPA allow the emissions averaging option for industrial and institutional facilities to comply with the proposed total selected metals (TSM) emission limits.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3521-A1, excerpt 90.

Commenter Affiliation: American Forest & Paper Association (AF&PA) et al.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 78

Comment: At §63.7522(b)(1), EPA has added a new provision stating "You may not include in an average units using a CEMS or PM CPMS for demonstrating compliance, even if the use of a CEMS or PM CPMS is optional." This restriction on use of CEMS for emissions averaging has been proposed with no explanation as to EPA's logic for this restriction. It is in direct conflict with the emissions averaging provisions in the recently finalized MATS rule (See §63.10009). EPA should provide industrial facilities with at least the same flexibility it provides electric utilities. This restriction would discourage the use of CEMS (where they are optional) in cases where a source elects to utilize emissions averaging. It also restricts emissions averaging among fossil fuel-fired units to those less than 250 MMBtu/hr, due to the PM CPMS restriction. EPA should not discourage use of CEMS as a compliance option or limit emissions averaging to small sources using stack testing and parameter monitoring to comply with the rule. To the contrary, EPA should provide sources that use a continuous direct measure of emissions with more flexibility, not less, than sources using periodic stack testing and parameter monitoring.

Response: The EPA acknowledges the commenter's concerns. The EPA believes that emissions averaging subject to certain unit eligibility criteria in the rule, including existing units within the same subcategory, can provide a cost-effective, flexible, environmentally-friendly means of demonstrating compliance. The rule has been revised to allow units that rely on CEMS for compliance demonstrations to be able to participate in emissions averaging. The EPA believes that the data certainty provided by units that use CEMS would be ideal for emissions averaging and the flexibility and cost-effectiveness it offers. We have removed the emissions averaging exclusion for units using a CEMS or PM CPMS in 40 CFR 63.7522(b)(1) in the final rule.

Commenter Affiliation: Texas Commission on Environmental Quality (TCEQ)

Document Control Number: EPA-HQ-OAR-2002-0058-3594-A3

Comment Excerpt Number: 7

Comment: The use of the term "delegated authority" in the emissions averaging provisions in §63.7522 and in the emissions credit provisions in §63.7533 may create confusion within the regulated community. It is unnecessary for the EPA to use a separate term within these sections of the rule. If a state accepts delegation of the final version of the proposed new Subpart DDDDD, using the term "administrator" would apply equally to §63.7522 and §63.7533 as it

does to the other provisions of the rule. If a state has not received delegation for the NESHAP rule, not only would the state have no authority to issue an approval under §63.7522 and §63.7533, the state is under no obligation to review the plans on the EPA's behalf. In the recently finalized 40 CFR 63 Subpart 63 NESHAP rule for utilities, the EPA made similar changes in response to the TCEQ's comments.

Response: The EPA agrees with the commenter and has replaced "delegated authority" with "administrator." The part 63 General Provisions definitions in part 63.2 defines "Administrator" to mean the Administrator or authorized representative (e.g. delegated state).

Commenter Name: Tangelia Niemann

Commenter Affiliation: Texas Commission on Environmental Quality (TCEQ)

Document Control Number: EPA-HQ-OAR-2002-0058-3594-A3

Comment Excerpt Number: 8

Comment: The EPA revised the emissions averaging approach for the utility NESHAP rule to only require the emissions averaging implementation plans to be submitted for review and approval upon request by the administrator. The TCEQ supports this change and requests that the EPA make the same change to §63.7522 and §63.7533. This option will help streamline the review process for the implementation plans and the administrator, or the delegated authority if a state receives delegation, and allow for the review process to prioritize review of the plans rather than require review and approval of all plans. As discussed elsewhere in these TCEQ comments, the TCEQ also suggests the EPA review §63.7522 and §63.7533 to determine if revisions to the rule are necessary to eliminate the need for case-by-case review and approval of the implementation plans.

Response: The EPA agrees with the commenter and has revised 40 CFR 63.7522 and 40 CFR 63.7533 to only require the emissions averaging implementation plans to be submitted for review and approval upon request by the administrator.

Comment: *The CEMS Location Requirement Should be Clarified*

Proposed § 63.7525(a)(1) requires that a CO CEMS monitor the CO level at the "outlet" of the boiler or process heater. Such CO monitors are also required to satisfy the requirements of PS 4, 4A or 4B. It is not possible to certify any gas monitor according to applicable Performance Specifications if the monitor is located at the outlet to the boiler. This inability to certify is caused by stratification of gases at the boiler/process heater outlet. In addition, for units equipped with add-on controls or flue gas recirculation systems the "outlet" could be construed to be either before or after these controls. Since these systems may impact the CO level, the measurement must be after any controls or recirculation (i.e., just before the gas is released to the atmosphere. EPA should revise the last sentence of § 63.7525(a)(1) as follows:

If a CO CEMS is used, the carbon monoxide level shall be monitored at the outlet of the boiler or process heater, after any add-on controls or flue gas recirculation system and before release to the atmosphere.

The installation of the monitor in the stack or breeching leading to the stack would not have any impact on determining the compliance status of the source since the CO data will have to be corrected to 3% O₂, thus negating the impact of any dilution of the stack gas due to leaks in the system.

Response: The EPA thanks the commenter for their input and has revised 40 CFR 63.7525(a)(1) accordingly to clarify the CO CEMS monitoring location is after any add-on controls or recirculation and before release to atmosphere.

Document Control Number: EPA-HQ-OAR-2002-0058-3504-A1

Comment Excerpt Number: 27

Comment: EPA should also specify how a 30-day rolling average for the operating parameter limits is calculated, indicating that the 30-day rolling average includes the previous 720 hours of valid operating data. EPA should make clear that valid data exclude hours during startup and shutdown as well as unit down time. This clarification will be helpful with the implementation of the final rule. For example, when a unit is down for an outage, the 30-day calculation would not include the outage. Specification of the minimum number of readings assures that the 30-day average concept is not undermined.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3504-A1, excerpt 27.

Commenter Name: Samuel H. Bruntz

Commenter Affiliation: Alcoa Power Generating, Inc.

Document Control Number: EPA-HQ-OAR-2002-0058-3755-A1

Comment Excerpt Number: 3

Comment: Proposed regulation 63.7510 (a)(3) requires that operating limits must be established, according to 63.7530 and Table 7 to *this* subpart. 63.7530(a) also conflicts with 63.7510 (a)(2)(i), in that it requires that .. You must demonstrate initial compliance with each emission limit that applies to you by conducting initial performance tests and fuel analyses ... "

Alcoa- Warrick suggests that this conflicting language be corrected, as follows:

63.7530(a) "You must demonstrate initial compliance with each emission limit that applies to you by conducting initial performance tests and fuel analyses and establishing operating limits,

as applicable. according to § 63.7520, paragraphs (b) and (c) of this section, and Tables 5 and 7 to this subpart. *The requirement to conduct a fuel analysis is not applicable for units that burn a single type of fuel, as specified by 63.7510(a)(2)(i).* If applicable, you must also install..."

Response: The EPA thanks the commenter for their input and has revised 40 CFR 63.7530(a) accordingly.

Commenter Name: Matthew Todd

Commenter Affiliation: Texas Commission on Environmental Quality (TCEQ)

Document Control Number: EPA-HQ-OAR-2002-0058-3594-A3

Comment Excerpt Number: 11

Comment: The EPA should use the term *efficiency credit* in §63.7533 rather than refer to the credit as an *emission credit*. The approach in §63.7533 prorates emission test results based on implemented efficiency measures that result from energy input savings before the results are compared to the emission standards, which is similar to approaches used for combined heat and power applications. *Efficiency credit* is a more accurate terminology for the approach the EPA has proposed. Additionally, use of the term *emission credits* may create confusion with terminology used in emissions banking and trading programs, such as *emission reduction credit*.

Response: The EPA agrees with the commenter that the term "efficiency credit" is more accurate. We have changed the term "emission credit" to "efficiency credit" in §63.7533.

Comment Excerpt Number: 154

Comment: The NCS filing criteria need to be clarified. The Notification of Compliance Status filing requirement in §63.7545(e) appears to only apply if you are required to conduct an initial compliance demonstration by §63.7530(a). However, the NCS is the only place that requires certification of compliance for the initial tune-up and for the energy assessment, which are not "compliance demonstrations" under the proposal. Thus, if no compliance demonstrations are required, no certification of the initial tune-ups or of the energy assessment appears to be required by the proposed language. §63.7545(e) should be revised to require filing of an NCS, but only require tune-up and energy assessment certifications if there are no initial performance tests or compliance demonstrations.

Response: The EPA agrees with the commenter and has revised the 40 CFR 63.7545(e) introductory text to add, "If you are not required to conduct an initial compliance demonstration as specified in §63.7530(a), the Notification of Compliance Status must only contain the information specified in paragraphs (e)(1) and (e)(8)."

Comment: Proposed §63.7545(e)(1) requires reporting in the NCS for each BPH a "description of the fuel(s) burned, including whether the fuel(s) were determined by you or EPA through a petition process to be a non-waste under § 241.3, whether the fuel(s) were processed from discarded nonhazardous secondary materials within the meaning of § 241.3." This wording presumes all fuels are secondary materials or processed from nonhazardous secondary materials. As discussed above, gases, the most common fuel type, are almost never secondary materials. Thus, for gases only a description of the fuel should be required. Additionally, for general clarity this phrase should be revised to require reporting of their 241.3 status only if the material being combusted is a secondary material.

Response: §63.7545(e)(1) has been revised to clarify that reporting of 241.3 status is only required if the material being combusted is a secondary material.

Comment: Proposed §63.7545(e)(7) requires reporting of deviation information in the NCS. This requirement is duplicative, since these same deviations must be reported in the initial periodic report. Since the periodic report is the appropriate and normal place for reporting deviations, §63.7545(e)(7) should not be finalized.

Response: We disagree that 63.7545(e)(7) is a duplicative requirement. §63.7545(e)(7) deals with the initial Notification of Compliance Status. Affected units are to be in compliance by the compliance date but have 180 days after to demonstrate compliance and another 60 days after the performance test to submit the Notification. Thus, there may be 240 days in which deviations could happen.

Comment: Proposed §63.7545(e)(8)(i) requires that the NCS contain a certification that the facility "complies with the requirements in §63.7540(a)(10), (11), or (12) to conduct an annual, biennial, or 5-year tune-up as applicable, of each unit." Sources cannot certify compliance with this statement since annual, biennial, or 5-year tune-ups cannot have been completed, since the NCS is required before those tune-ups are due. All a source can certify is that they have completed the required initial tune-up. Thus, proposed §63.7545(e)(8)(i) cannot be finalized.

Response: The EPA acknowledges the commenter's concern. The intent in the proposed rule was to provide a certification statement to specify that the facility following the initial tune-up procedures provided in 63.7540(a)(1). The rule has been revised at 40 CFR 63.7545(e)(8)(i) for clarification as follows, "This facility complies with the required initial tune-up according to the procedures in §63.7540(a)(10)(i) through (a)(10)(vi)."

Comment: Proposed §63.7550(e)(2) requires reporting "the date and time that each CMS was inoperative, except for zero (low level) and high level checks." However, the rule requires CMS to be out of service for other reasons, such as quality assurance checks and preventive maintenance, as detailed in the monitoring plan. Thus, there will be much wasteful reporting of outages that are not deviations or deviation related. We recommend this requirement be revised to exclude reporting of outages needed for compliance with the applicable monitoring plan.

Response: The EPA agrees with the commenter and has revised 40 CFR 63.7550(e)(2) to exclude reporting outages needed for compliance with applicable monitoring plan.

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 164

Comment: Proposed §63.7550(e)(8) requires identification of each parameter that was monitored at the affected source for which there was a deviation. It is unclear what this is requesting. Is it asking for identification of the parameter that had the deviation or is it asking for a list of all parameters monitored for that boiler or process heater where the deviation occurred? In either case, it would seem that information is already required in earlier paragraphs and it is unclear (e)(8) serves any purpose. Thus, §63.7550(e)(8) should be deleted as duplicative. If it is not deleted it must be clarified as to what it is requiring. There certainly is no justification for gathering information on anything other than the parameter for which there was a deviation.

Response: The EPA thanks the commenter for their input and has removed the redundant text from 40 CFR 63.7550(e) accordingly.

Comment Excerpt Number: 12

Comment: Section 63.7550(h) requires performance test reports and CEMS RATA tests to be submitted electronically to EPA's WebFIRE database. Since it is likely that many states eventually will be delegated authority, this requirement is overly burdensome and costly for facilities with limited resources. States like Maine already specify that performance test results be submitted in an electronic format. EPA should remove its reporting format requirement from the rule and work more closely with states to develop a universal reporting system that is not costly, does not require redundant, different electronic reporting formats, and that is not problematic and labor-intensive for data entry. As proposed, the rule's requirement is an extra, excessive burden for mills and stack testing vendors. EPA needs to defer any electronic collection of data until the CDX and WebFIRE systems are fully functional, user-friendly, and streamlined with States.

Response: We disagree with the commenter that electronic reporting is overly burdensome because many states will be the delegated authority. States are already delegated the authority to implement EPA rules and the shift from paper to electronic reporting to delegated authorities is not overly burdensome for a number of reasons. First, the tool that sources are required to use for electronically reporting results of stack tests (i.e., the Electronic Reporting Tool (ERT)) has an option to print a report after the required data and information are entered. Thus, a facility will be able to simply print a performance test report from the ERT in order to fulfill any requirement imposed by a delegated authority to submit reports in hard copy. Second, many sources and stack testing companies are already familiar with the ERT and have used the ERT in previously submitting stack test data to the Agency. Furthermore, many facilities are already experienced in electronically submitting reports as a result of the requirements of the Toxic Release Inventory and Greenhouse Gas Reporting Program.

The EPA disagrees with the commenter that the State of Maine already requires electronic reporting which makes the EPA electronic reporting of performance test reports redundant. The State of Maine does not require facilities to submit stack test reports electronically. First, the provision to submit test reports electronically is optional, and second, the optional requirement allows facilities to simply submit a pdf file. This approach allows facilities to fulfill the optional requirement by submitting their information via e-mail. This hardly compares to the electronic reporting system that the Agency has implemented and any suggestion that our approach is redundant with the e-mail approach that is allowed by the State of Maine is incorrect. Our approach is much more robust and provides for easy and quick access to submitted information, thereby making performance test data available for data analyses for regulation development and other analyses. The EPA agrees with the commenter that the EPA should defer any electronic reporting until the CDX and WebFIRE systems are fully functional, user-friendly, and stream-lined with States. However, such systems are currently fully functional and the time is right for implementing electronic reporting. In fact, we have previously incorporated electronic reporting requirements into numerous regulations and affected facilities are successfully submitting the required information to WebFIRE using the CDX data portal. All performance test reports that have been submitted are available to State Air Pollution Control Agencies at all times. Thus, the EPA believes that the electronic reporting is not adversely impacting any State reporting systems, so deferring any electronic collection is not warranted.

Commenter Affiliation: Utility Air Regulatory Group (UARG)

Document Control Number: EPA-HQ-OAR-2002-0058-3500-A1

Comment Excerpt Number: 42

Comment: The 2011 final rule includes two provisions for electronic reporting. The first requires reporting of “relative accuracy test audit” or “performance test” data for PM CEMS within 60 days to EPA’s Central Data Exchange (“CDX”) using EPA’s Electronic Reporting Tool (“ERT”). 40 C.F.R. § 63.7540(a)(9)(iv). The second requires reporting of “relative accuracy test audit (*i.e.*, reference method) data” and “performance test (*i.e.*, compliance test) data, except opacity data” to CDX using ERT with 60 days of “each performance test.” 40 C.F.R. § 63.7550(h). Both provisions differ from EPA’s proposed rule, which required submission of “test data” within 60 days of each “performance evaluation.” 75 Fed. Reg. 32,0006, 32,059, 32,062.

Response: The EPA has clarified the electronic reporting requirements contained in the 2011 final rule. However, the commenter is mistaken that the electronic reporting provisions in the proposed rule differ from the final rule. Section 63.7550(h) of the final rule specified that both relative accuracy test audit (RATA) data and performance test data were required to be submitted electronically within 60 days after completion of each performance test. EPA believes the reference to relative accuracy test audit data in this paragraph was redundant with the requirement contained in Section 63.750(a)(9)(iv) of the final rule which also required the submission of RATA data within 60 days of completing each CEMS RATA. As a result, we have proposed language in Section 63.7550(h) of the December 23, 2011 proposal to clarify that sources must submit performance test results within 60 days after the date of completing each performance test. The proposed requirement in Section 63.7550(i) to submit relative test audit data within 60 days of completing each performance evaluation remains the same as the requirement contained in Section 63.7540(a)(9)(iv) of the final rule. We believe the proposed

language is consistent with the electronic reporting requirements that were contained in the final rule but add a level of clarity that was absent from the final rule.

Commenter Name: Lee Zeugin and Lauren Freeman

Commenter Affiliation: Utility Air Regulatory Group (UARG)

Document Control Number: EPA-HQ-OAR-2002-0058-3500-A1

Comment Excerpt Number: 45

Comment: UARG appreciates EPA's attempts to revise these provisions. As promulgated, the provision aimed at PM CEMS is not implementable. PM CEMS testing involves neither a "performance test" nor a "relative accuracy test audit." UARG also appreciates the increased specificity regarding reporting of each category of data. For example, UARG agrees that it makes no sense to report relative accuracy test audit data to WebFIRE. However, the new proposed provisions remain flawed. EPA still has not sufficiently explained the need for each category of data, established the consistency of ERT with the applicable substantive reporting requirements, or ensured compliance with CROMERR.

Response: The reporting forms or templates, that would allow the PM CEMS data summaries to be submitted electronically through the CDX (using CEDRI) to WebFIRE, have not been developed. In response to this comment, we have changed the rule to clarify that implementation of the requirement to electronic report semi-annual reports will commence only when the electronic reporting tools (e.g., data submittal templates) and the data submission process are operative. Because the reporting template and data submission process for stack test reports are completed and operational, the requirement to submit stack test reports electronically will be effective on the compliance date.

The EPA disagrees with the commenters that the EPA has not sufficiently explained the need for each category of data. The preamble (76 Fed. Reg. at 80,605) to the proposed revisions explains the use of the data collected by electronic reporting. Additionally, the EPA believes it is important to require the submissions of the 30 day rolling average data in the semi-annual reports because these data serve multiple useful purposes and are important in: Ensuring continued compliance performance of process and control device operations and providing sources with data to support compliance certifications, providing the sources and the agency with data representing variability of control measures for support of future (e.g., 8 year) regulatory reviews and updates, and identifying the best performing units and control approaches making more manageable and less burdensome future information data collection projects. Thus, the EPA will retain the electronic reporting of 30-day rolling averages' requirements in the rule.

We disagree that with commenter's assertion that the EPA "still has not sufficiently established the consistency of ERT with the applicable substantive reporting requirements". To the contrary, the proposed rule clearly states that only source test data collected using test methods supported by ERT are required to be reported electronically. In this manner we have ensured that only reporting requirements supported by ERT are subject to the requirement to report such information electronically. In addition, the EPA has worked closely with stack testing companies to develop and improve the ERT to ensure that that data elements required in ERT are compatible with the data that is typically collected during a stack test and reported as part of the stack test report.

The EPA also disagrees with the statement that these electronic reporting provisions are not in compliance with CROMERR. The ERT, in conjunction with the Central Data Exchange (CDX) (which is the EPA portal for reporting electronic data), the requirement to register as a user of the CDX, and the requirement to use the reporting interface (Compliance and Emissions Data Retrieval Interface (CEDRI)). In order to submit ERT files through CDX/CEDRI, one must be a registered user of CDX. The CDX registration process ensures compliance with CROMERR through use of an identity validation process that meets the CROMERR requirements. As a result, submitting ERT files through CDX is fully compliant with CROMERR.

Document Control Number: EPA-HQ-OAR-2002-0058-3755-A1

Comment Excerpt Number: 17

Comment: 63.7550 (h),(i) and (j) requires submittal of test data and CPMS data using EPA's Webfire database. Alcoa -Warrick understands that the Webfire database is slightly more user friendly than the Electronic Reporting Tool. However, stack test contractors Alcoa Warrick uses have indicated that the Webfire database is still difficult to learn and tedious to complete. Alcoa" Warrick understands that EPA is working on improvements to this database, and will be discussing those improvements in the March SES conference. APGJ thus recommends that, until EPA revises the Webfire database in a manner that makes it more user friendly, proposed regulation 63.7550 (h) (i) and G) be amended by allowing data submittal in hard copy form.

Response: Under the EPA's proposed electronic data reporting process, facilities do not need to "learn and complete" WebFIRE. WebFIRE is an EPA maintained Oracle data base in which data that has been submitted electronically is automatically stored. Facilities simply need to upload ERT files using the user friendly data portal called CEDRI. While it is true that the EPA continues to make improvements to the ERT to address issues that users have identified, the ERT has been required to be used in previous data collection activities and is currently required in recent rulemakings. Our experience is that stack testing companies are finding that ERT is user friendly and that it provides a workable and reasonable format by which to document the results of stack tests. This is supported by the fact that facilities are currently using ERT and the CEDRI data reporting portal to successfully upload ERT files to WebFIRE. As such, the EPA believes that the electronic submittal of performance test reports do not need to be deferred and that paragraphs (h), (i), and (j) of section 63.7550 do not need to be revised.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 139

Comment: EPA has included a new requirement in the December 2011 proposed Boiler MACT that will be excessively burdensome to industry. This requirement is not justified, and is not discussed in the preamble. New section 63.7550 (j) states:

"Within 60 days after the reporting periods ending on March 31, June 30, September 30, and December 31, you must transmit quarterly reports to EPA's WebFIRE database by using the

Compliance and Emissions Data Reporting Interface (CEDRI) that is accessed through EPA's Central Data Exchange (CDX) (www.epa.gov/cdx). For each reporting period, the quarterly reports must include all of the calculated 30 day rolling average values based on the daily CEMS (CO and Hg) and CPMS (PM CPMS output, scrubber pH, scrubber liquid flow rate, scrubber pressure drop) data."

EPA has not yet built this interface, so industry has had no opportunity to provide comment on its usability or the burden it will impose. This addition to the rule was incorrectly characterized as a technical correction in Table 3 of the Preamble. We have had no opportunity to evaluate the compatibility of existing data acquisition systems with this new EPA system. There is no reason for EPA to require the submittal of all of a facility's monitoring data. EPA has provided no justification for this new requirement. Facilities will provide certifications on their semi-annual compliance reports that they have performed the required monitoring and will provide information on any deviations from monitoring requirements or established parameter ranges. Additional parametric monitoring reports provide no useful purpose, environmental or otherwise, to anyone and are an additional administrative burden on operating facilities. EPA has already increased reporting burden by requiring all test data to be submitted electronically through the ERT, which continues to be revised and updated due to various flaws. We expect that this CEDRI interface would suffer from the same issues and may not even be available when facilities must submit their first of these quarterly reports. It is unreasonable to put sources at risk of violations (late reporting) because of EPA reporting tool issues or availability.

Response: We agree with commenter that we mischaracterized the proposed addition of requirements to submit data electronically in the proposed rule. The proposed electronic reporting provisions are not technical corrections but are amendments to the rule on which we solicited comments. Commenters raised concerns about the proposed requirements relevant to the effects of those provisions and we have developed responses to those comments as summarized below.

We agree with commenters that the template and the process for transmitting the quarterly reports of the type required by this rule are not yet available for review at the time of the proposal, let alone for implementing the regulatory requirements. In response to this comment, we have changed the rule to clarify that implementation of the requirement to electronic report quarterly reports will commence only when the electronic reporting tools (e.g., data submittal templates) and the data submission process are operative. (Note: Because the reporting template and data submission process for stack test reports are completed and operational, the requirement to submit stack test reports electronically will be effective on the compliance date).

We also believe that the templates and data submission process to be used for submitting the quarterly reports are similar to other on line electronic reporting systems with which commenters are very likely familiar. We will continue to communicate to stakeholders information about the structure of the data templates and data flow but we also believe that the submissions of compliance data through CEDRI will present no new or extraordinary data submittal skills over those required for other online reporting programs such as the Toxic Release Inventory Tier II forms since 2002 (<http://www.epa.gov/tri/tridata/index.html>) and the Greenhouse Gas Reporting Program (<http://www.epa.gov/climatechange/emissions/ghgrulemaking.html>). We will make known the availability of the electronic reporting tools and data submission process to be used to comply with the rule through multiple venues (e.g., the EPA's industrial boiler website,

<http://www.epa.gov/ttn/atw/boiler/boilerpg.html>, and the Technology Transfer Network CHIEF website, <http://www.epa.gov/ttn/chief/>). To inform affected sources of the concept of the reporting templates for the quarterly reports, we will also prepare and submit to the docket screenshots of a proposed template to accompany these responses to comments.

The EPA does not require the submission of all monitoring data as suggested by the commenters. Rather, the proposed rule only requires the submission of 30 day rolling averages. The EPA believes it is important to require the submissions of the 30 day rolling average data in the quarterly reports because these data serve multiple useful purposes and are important in:

Ensuring continued compliance performance of process and control device operations and providing sources with data to support compliance certifications,

Providing the sources and the agency with data representing variability of control measures for support of future (e.g., 8 year) regulatory reviews and updates, and

Identifying the best performing units and control approaches making more manageable and less burdensome future information data collection projects.

Accordingly, the final rule will stipulate that sources will submit hard copies of the compliance monitoring reports to the Administrator until the electronic reporting tools are in place. There will be no consequence relative to compliance should the electronic reporting tools not yet be ready when sources are required to report monitoring data. We believe that once the electronic data reporting tools are in use, sources will experience a reduced reporting and record keeping burden. Once sources submit data electronically, there will no need to store on site hard copies of reports and monitoring records that have been submitted electronically to WebFIRE. We agree with commenters that there are some other measures we can take to reduce reporting burden. For example, the final rule reduces reporting frequency to semiannually from the quarterly schedule in the proposal. We will make more clear in the final rule that the only data to be reported will be the 30-day averages required by the rule (e.g., ≤ 180 values for 30-operating day averaging periods per semiannual reporting period).

Document Control Number: EPA-HQ-OAR-2002-0058-3530-A1

Comment Excerpt Number: 5

Comment: EPA should not require quarterly reporting of data that is based on a system that does not exist and that have little likelihood of being used. EPA has included a new requirement in the December 2011 proposed Boiler MACT that will be excessively burdensome to industry. This requirement is not justified, and is not discussed in the preamble. New section 63.7550 (j) states:

“Within 60 days after the reporting periods ending on March 31, June 30, September 30, and December 31, you must transmit quarterly reports to EPA’s WebFIRE database by using the Compliance and Emissions Data Reporting Interface (CEDRI) that is accessed through EPA’s Central Data Exchange (CDX) (www.epa.gov/cdx). For each reporting period, the quarterly reports must include all of the calculated 30 day rolling average

values based on the daily CEMS (CO and Hg) and CPMS (PM CPMS output, scrubber pH, scrubber liquid flow rate, scrubber pressure drop) data.”

There is no reason for EPA to require the submittal of all of a facility’s monitoring data. EPA has provided no justification for this new requirement. Facilities will provide certifications on their semi-annual compliance reports that they have performed the required monitoring and will provide information on any deviations from monitoring requirements or established parameter ranges. Additional parametric monitoring reports provide no useful purpose, environmental or otherwise, to anyone and are an additional administrative burden on operating facilities. EPA has already increased reporting burden by requiring all test data to be submitted electronically through the ERT, which continues to be revised and updated due to various flaws. We expect that this CEDRI interface would suffer from the same issues and may not even be available when facilities must submit their first of these quarterly reports. EPA has not yet built this interface, so industry has had no opportunity to provide comment on its usability or the burden it will impose. This addition to the rule was incorrectly characterized as a technical correction in Table 3 of the Preamble. The public has had no opportunity to evaluate the compatibility of existing data acquisition systems with this new EPA system. It is unreasonable to put sources at risk of violations (late reporting) because of EPA reporting tool issues or availability.

Comment: QUARTERLY REPORTING OF ALL PARAMETER MONITORING DATA

EPA has included a new requirement in the Reconsideration Proposal that will be excessively burdensome to industry. This requirement is not discussed in the preamble and is not justified.

EPA has not yet built this interface, so industry has had no opportunity to provide comment on its usability or the burden it will impose. This addition to the rule was incorrectly characterized as a technical correction in Table 3 of the preamble.

More importantly, the regulated community has had no opportunity to evaluate the compatibility of existing data acquisition systems with this new EPA system. There is no reason for EPA to require the submittal of all of a facility’s monitoring data. EPA has provided no justification for this new requirement. Facilities will provide certifications on their semi-annual compliance reports that they have performed the required monitoring and will provide information on any deviations from monitoring requirements or established parameter ranges.

Additional parametric monitoring reports provide no useful purpose, environmental or otherwise, to anyone and are an additional administrative burden on operating facilities. EPA has already increased reporting burden by requiring all test data to be submitted electronically through the ERT, which continues to be revised and updated due to various flaws. ACC expects that this CEDRI interface would suffer from the same issues and may not even be available when facilities must submit their first of these quarterly reports. It is unreasonable to put sources at risk

of violations (late reporting) because of EPA reporting tool issues or availability. In order to simplify the rule requirements, EPA should not require submittal of these additional data at this time, and instead should keep this as a recordkeeping requirement against which any deviations will be reported under a site's Title V Operating Permit.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3521-A1, excerpt 139.

Commenter Name: Russell A. Wozniak

Commenter Affiliation: The Dow Chemical Company

Document Control Number: EPA-HQ-OAR-2002-0058-3449-A1

Comment Excerpt Number: 28

Comment: EPA should delete the proposed 40 CFR 63.7550(j) regarding the reporting of quarterly data to EPA's web-fire system.

Section 63.7550(j) of EPA's proposed rule requires that the owner/operator transmit quarterly reports to EPA's Web FIRE database that include all of the calculated 30 day rolling average values based on the daily CEMS (CO and Hg) and CPMS (PM CPMS output, scrubber pH, scrubber liquid flowrate, scrubber pressure drop) data.

EPA has explained the subject change as a technical correction to the rule. However, this type of reporting requirement creates a new applicable requirement that a facility must implement and abide by, and is in our opinion more than a technical correction. We also question whether EPA needs this level of data transmission in order to conduct work such as improving emission factors and whether the agency has resources to review and evaluate all of these additional data for existing boilers and process heaters.

In order to simplify the rule requirements, EPA should not require submittal of these additional data at this time, and instead should keep this as a recordkeeping requirement against which any deviations will be reported under a site's Title V Operating Permit.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3521-A1, excerpt 139.

Commenter Affiliation: Verso Paper Corp.

Document Control Number: EPA-HQ-OAR-2002-0058-3537-A2

Comment Excerpt Number: 6

Comment: Section 63.7550 (j) requires facilities to transmit quarterly reports to EPA's WebFIRE database by using the Compliance and Emissions Data Reporting Interface (CEDRI) accessed through EPA's Central Data Exchange (CDX) (www.epa.gov/cdx). For each reporting period, the quarterly reports must include all of the calculated 30 day rolling average values based on the daily CEMS (CO and Hg) and CPMS (PM CPMS output, scrubber pH, scrubber liquid flow rate, scrubber pressure drop) data. Inputting data into WebFIRE is not an easy and efficient method of data submittal for the regulated community. Data acquisition and reporting systems designed to collect, format, and upload data into EPA's electronic collection system are costly and extremely time consuming. Yet EPA has not described any meaningful purpose for

collecting all these data. Each boiler and control equipment configuration is unique; the data will not be comparable between boilers. Since EPA has proposed this new requirement with no justification, the requirement is unreasonable and unnecessary.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3521-A1, excerpt 139.

Comment Excerpt Number: 29

Comment: The new and unprecedented proposal to require quarterly reporting of not only deviations but all data for all monitoring parameters is extremely burdensome and time consuming. And, it is contrary to all prior reporting framework in the CAA and Title V permitting, which requires periodic deviation reporting and rigorous annual compliance certification by each facility. EPA should eliminate the overly burdensome quarterly reporting of parametric monitoring data through EPA's CEDRI and CDX. This data is of little to no value to EPA and places an unnecessary burden on facilities.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3521-A1, excerpt 139.

Comment: Quarterly reporting of daily operating parameter averages serves no purpose and, consistent with the requirements of Executive Orders 12866 and 13563, should not be finalized.

Proposed §63.7550(j) requires the following.

Within 60 days after the reporting periods ending on March 31, June 30, September 30, and December 31, you must transmit quarterly reports to EPA's WebFIRE database by using the Compliance and Emissions Data Reporting Interface (CEDRI) that is accessed through EPA's Central Data Exchange (CDX) (www.epa.gov/cdx). For each reporting period, the quarterly reports must include all of the calculated 30 day rolling average values based on the daily CEMS (CO and Hg) and CPMS (PM CPMS output, scrubber pH, scrubber liquid flow rate, scrubber pressure drop) data.

We see no purpose for this requirement, since any daily average deviation will be reported in the normal periodic report and likely through Title V. Thus, it is a waste of facility and EPA time to gather the individual daily average data. If there is a concern about accurate deviation reporting, the daily averages will be available as records. Requiring such a large volume of information for no reason clearly violates Executive Orders 12866 and 13563.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3521-A1, excerpt 139.

Comment Excerpt Number: 10

Comment: U.S. EPA is proposing quarterly reporting requirements for emissions and operating parameters into the WebFIRE database. Under this reporting requirement, all sources would be obligated to report 30-day rolling average values based on the daily CEMS (CO and Hg) and CPMS (PM output, scrubber liquid flow and pressure drop) data within 60 days of the end of each quarter.

MSU believes that quarterly reporting to WebFIRE is unnecessary. As part of this requirement, data entry would be done through U.S. EPA's Central Data Exchange (CDX) and entered into the Compliance and Emissions Data Reporting Interface (CEDRI). Entry into CEDRI is a burdensome and time consuming process. Additionally, the amount of data that would be generated in these quarterly reports would exceed any amount of information that U.S. EPA would be of such a magnitude that it would in turn be burdensome for U.S. EPA to review. Furthermore, MSU will already be required to certify and submit semiannual compliance reports which will include emissions and operating information and an indication of deviations from emission limitations and monitor downtime.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3521-A1, excerpt 139.

Comment Excerpt Number: 105

Comment: The Proposed rule requires sources, within 60 days after the reporting periods ending on March 31, June 30, September 30, and December 31, to transmit quarterly reports to EPA's WebFIRE database by using the Compliance and Emissions Data Reporting Interface

(CEDRI) that is accessed through EPA's Central Data Exchange (CDX) (www.epa.gov/cdx). 40 CFR sec. 7550 (j)(proposed); 76 Fed. Reg. 32015. For each reporting period, the quarterly reports must include all of the calculated 30-day rolling average values based on the daily CEMS (CO and Hg) and CPMS (PM CPMS output, scrubber pH, scrubber liquid flow rate, scrubber pressure drop) data. 40 CFR §§63.7750(b) and 63.7550 (j).

EPA offers multiple unavailing reasons for imposing this never-before required submission of data. This quarterly requirement of data submission is not reasonable given the increased burden on sources and its lack of utility in ensuring compliance with the standards in this rule or improving environmental protection. EPA does not even attempt to assess the burden on sources, and the benefits it describes relate to the usefulness to EPA for future rulemaking efforts.

Among the reasons EPA propounds for this new reporting requirement is that by collecting performance test data now, the agency may not need to issue as many or as substantial CAA Section 114 information requests to obtain this data in the future. 75 Fed. Reg. 32,016. By mandating the perpetual submission of vast amounts of data to EPA, EPA subverts the intent of Congress in the Paperwork Reduction Act (PRA), which requires EPA and other agencies to obtain advance approval from the Office of Management and Budget (OMB) before imposing information production burdens on regulated sources. This information collection request approval process ensures that the burdens on regulated sources are assessed in advance and minimized whenever possible. EPA cannot avoid this requirement by requiring the piecemeal submission of "test data already collected for other purposes" on a perpetual basis.

Before mandating such a requirement, EPA must assess the additional burden that EPA thereby shifts to sources. Sources already must submit in many cases multiple MACT semi-annual compliance reports . With each report, a corporate officer or designee must certify the authenticity and accuracy of the submission. There is no rational need for sources to undertake another time-consuming reporting procedure, four times per year, and assume the additional substantial compliance risk that comes with this new requirement. EPA does not even attempt to assess the substantial additional burden of this requirement. Instead, with absolutely no record support, EPA claims that imposing this requirement will help EPA develop future regulations and thereby "save industry, State/local/Tribal agencies, and EPA time and money and work. . ." 76 Fed. Reg. 32016.

EPA describes as "easy" the use of its electronic reporting tool (ERT) and enhanced data management tools. 76 Fed. Reg. 32016. Yet data submission via the ERT will take a substantial amount of time and requires that multiple judgments be made by personnel entering and editing the data, and will require review and clearance by officers who are ultimately responsible for its accuracy. The aggregated number of labor hours across all the thousands of covered sources is absent from the record and would not be justified by EPA's rationales.

Response: Despite comments presented by the commenter, the EPA continues to believe it is important to require the submissions of the 30-day rolling average data in the semi-annual reports because these data serve multiple useful purposes and are important in: Ensuring continued compliance performance of process and control device operations and providing sources with data to support compliance certifications, providing the sources and the agency with data representing variability of control measures for support of future (e.g., 8 year) regulatory

reviews and updates, and identifying the best performing units and control approaches making more manageable and less burdensome future information data collection projects.

The Information Collection Requests, referred to by the commenter, for each rulemaking are updated every three years. Because the compliance date is 3 years from the publication of the rule, the EPA did not assess the burden of the reporting of the 30-day rolling average in this rulemaking. When the next ICR is due, the EPA plans to include the costs of the reporting of the requirements of section 63.7550(j). However, the EPA believes the commenter is correct in stating that semi-annual reporting of the 30-day rolling averages is burdensome. Thus, the EPA is revising the final rule to add this reporting requirement to the semi-annual compliance report, thus cutting this reporting burden by fifty percent .

The commenter states the Electronic Reporting Tool (ERT) will require “data submissions (that) will take a substantial amount of time and requires that multiple judgments be made by personnel entering and editing the data, and will require review and clearance by officers who are ultimately responsible for its accuracy.” Because the ERT has been in use for several years and for several ICRs, the EPA believes that most users have figured out the ERT in a reasonable amount of time. The commenter states that the ERT will require review and clearance by officers who are responsible for the accuracy (of the report). This is not a change from any routine reporting of performance test reports in any other NESHAP and has been a standard requirement in most EPA rules for many years. All performance test reports reported to EPA or the delegated State, Local, or Tribal Air Pollution Control Agency must be reviewed and signed by a “responsible official” that verifies the truth and accuracy of the report. Thus, the EPA disagrees that there is no rationale for the review and clearance by responsible officials and will not change the ERT electronic reporting requirements at this time..

Comment Excerpt Number: 106

Comment: EPA should assess thoroughly the volume of data it will receive each quarter vis-à-vis the functionality and dependability of its computer server. The tremendous volumes of electronic data that EPA will receive on the same day, four times per year, has not been quantified, nor has EPA apparently thought out how much of its computer server this will consume, the cost of the data management and storage, and potential risk to system stability.

In addition, to make use of this data, EPA staff must be prepared to sort through the volumes of information, ensuring the data has been properly quality assured in order to make the submissions useful to the Agency. The information collection and quality assurance associated with development of the Boiler MACT itself is an excellent example of the effort required to ensure reliable data goes into a database. The alternative to manually quality assuring data is to develop data checking software. This has been done in EPA’s Part 75 reporting program, but the effort on the part of sources to ensure data is uploaded in an acceptable format with the monitoring associated plans is costly and an unnecessary burden on sources. One CIBO member having four units in the NOx Budget Trading program spends \$25,000/year just to support the data QA and submission requirement of this Part 75 program.

Response: The EPA appreciates the comment regarding the volume of data expected from the electronic reporting requirements. The EPA is designing and choosing data storage media to adequately store the projected data and reports expected in this rulemaking. The EPA believes that the electronic reporting of these data will take up much less space than the paper copies that now reside in filing cabinets. The EPA agrees that quality assurance of the data is important, but wants to stress that the data will be quality assured when they are used. The EPA will store the data and reports received in the form they are received; these data and reports are enforceable documents and will be treated as such.

Comment: By imposing this data submission requirement on sources that have a State regulator, EPA illegally supersedes the authority of the States. Once a State has adopted the boiler MACT into its SIP, sources have no ongoing data submission requirements to EPA, and EPA does not thereafter oversee their compliance with the standards. To impose this requirement on sources in States with delegated programs defeats the structure of the Clean Air Act and makes sources responsible not only to the State regulator but also to EPA in a manner not contemplated by the Act.

Response: The EPA disagrees with the commenter regarding EPA illegally superseding the authority of State, Local, and Tribal Air Pollution Control Agency's (S/L/Ts) to implement and enforce this regulation. Section 112(l) of the Clean Air Act Amendments of 1990 speaks and allows the delegation of authorities to implement and enforce section 112 provisions. Section 112(l)(7) states "[n]othing in this subsection shall prohibit the Administrator from enforcing any applicable emission standard or requirement under this section" In other words, the EPA always retains the right to enforce whether a subpart has been delegated to an S/L/T or not and is required by Section 112(l) to provide oversight of S/L/T programs.

Comment: The Proposed rule requires sources to transmit quarterly reports to EPA's WebFIRE database by using the Compliance and Emissions Data Reporting Interface (CEDRI) that is accessed through EPA's Central Data Exchange (CDX). This quarterly requirement of data submission is not reasonable given the increased burden on sources and its lack of utility in ensuring compliance with the standards in this rule or improving environmental protection. EPA does not even attempt to assess the burden on sources, and the benefits it describes relate to the usefulness to EPA for future rulemaking efforts.

EPA describes as "easy" the use of its electronic reporting tool (ERT) and enhanced data management tools. Yet data submission via the ERT will take a substantial amount of time and requires that multiple judgments be made by personnel entering and editing the data, and will

require review and clearance by officers who are ultimately responsible for its accuracy. The aggregated number of labor hours across all the thousands of covered sources is absent from the record and would not be justified by EPA's rationales.

In addition to burden, EPA should also assess thoroughly the volume of data it will receive each quarter vis-a-vis the functionality and dependability of its computer server. The tremendous volumes of electronic data that EPA will receive on the same day, four times per year, has not been quantified, nor has EPA apparently thought out how much of its computer server this will consume, the cost of the data management and storage, and potential risk to system stability.

Once a State has adopted the boiler MACT into its SIP, sources have no ongoing data submission requirements to EPA, and EPA does not thereafter oversee their compliance with the standards. The state agencies are largely severely pressed for human and financial resources at present. This massive data submission will potentially swamp state resources and increase program costs unnecessarily.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3521-A1, excerpt 139 for accepting quarterly data through the WebFIRE database. See the response to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 106 for the volume of data handled by EPA. See response to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 107 for the impact on state resources.

Comment Excerpt Number: 2

Comment: EPA is proposing additional quarterly reporting requirements beyond semi-annual reporting of various performance related issues. In addition to recent requirements for many performance tests and CEM RATA related tests to be reported to EPA via the Electronic Reporting Tool (ERT) through the Central Data Exchange (CDX), the EPA has proposed that various data streams (CEM data, various CPMS and operating data) be reported to EPA on a quarterly basis.^[11]

NC DAQ Comment

Although EPA did not discuss this proposal in the preamble, they did request comment on this issue. Given there is no clarification for this requirement in the preamble, many questions come up about its use, access, and limitations. The NC DAQ understands the desire for better and more contemporaneous data for EPA's standard setting processes and emission factor development and has previously commented on this issue. However, this electronic reporting of various data raises several concerns for the NC DAQ.

First, no electronic data tool appears to be ready for review for the data that EPA is requiring to be submitted by affected residual oil and coal-fired units. The proposed changes require the data to be reduced to a series of arithmetic averages to produce hourly, daily and 30-day average values, but the proposed regulation is unclear about what data must be submitted as part of this quarterly reporting.

Second and more broadly, the proposed regulations require this data, as well as performance tests and CEM performance testing (via the ERT, if the test procedures are included in the ERT tool) to be submitted directly to EPA. It is silent on how and whether state agencies would access the data. Unless these tests and data showed deviation from a standard, only summaries of these performance tests and data would be included as part of the semi-annual report submitted to NC DAQ. As the delegated authority, this raises questions about accessibility for NC DAQ to the data and required testing in this proposed rule, and how that information might flow from the affected facility to NC DAQ.

[Footnote 1: Federal Register, Vol. 76, No. 247, December 23, 2011, page 80649-50.]

Response: The EPA disagrees with the comment that the proposed regulation is unclear. Section 63.7550(j) states “[f]or each reporting period, the semi-annual reports must include all of the calculated 30 day rolling average values based on the daily CEMS (CO and Hg) and CPMS (PM CPMS output, scrubber, pH, scrubber liquid flow rate, scrubber pressure drop) data.” The EPA believes that this paragraph clearly requires the facility to calculate a 30-day rolling average for each CEMS and CPMS daily and provide that value semi-annually. Thus, a semi-annual submittal for this requirement will be about 120 daily values for each CEMS or CPMS. The EPA does plan to develop a reporting template or tool for submittal of these data, but we expect it to be simple and straightforward because there are not any additional data needed or required for this report.

Regarding access to the data summary, performance test, excess emissions, and summary data required to be submitted electronically to the EPA’s WebFIRE database, the EPA is designing WebFIRE so that the State, Local, and Tribal Air Pollution Control Agency (S/L/Ts) and all users will have full access to these data in WebFIRE at all times. This proposal requires performance tests (section 63.7550(h)), data summaries (section 63.7550(j)), and relative accuracy test audit data (section 63.7550(i)) to be submitted electronically to the EPA’s WebFIRE database. The EPA had also intended to include the compliance reports, required in section 63.7550(b), to be submitted electronically to the EPA’s WebFIRE database. This will be clarified in the promulgation of this rulemaking. The EPA had also intended to add the sentence at the end of the paragraph in section 63.7550(h), “[a]t the discretion of the delegated authority, you must also submit these reports, including the confidential business information, to the

Administrator in the format specified by the Administrator” to sections 63.7550(i) and (j). This sentence allows the S/L/Ts to receive copies of these reports if S/L/Ts choose and in the manner S/L/Ts choose. Thus, S/L/Ts can continue to receive these reports in written or electronic forms and can continue to access the reports in the manner the S/L/Ts choose. However, the EPA is hopeful that S/L/Ts will choose to begin using the electronic reports, when possible, for review and compliance purposes..

Commenter Name: David A. Buff, Golder Associates Inc.

Commenter Affiliation: Florida Sugar Industry (FSI)

Document Control Number: EPA-HQ-OAR-2002-0058-3504-A1

Comment Excerpt Number: 60

Comment: Section 63.7550(j) of the March 2011 Final Boiler MACT Rule contained a new requirement -- all parametric monitoring data (i.e., scrubber pH, scrubber liquid flow rate, scrubber pressure drop, ESP power, etc.) must be reported to EPA on a quarterly basis. The quarterly report also must contain the calculated 30-day rolling averages based on the daily average data. FSI respectfully requests EPA to revise these reporting requirements. The FSI believes the data should be reported in the same manner as the Compliance Assurance Monitoring (CAM) data that are already reported under Title V operating permits. Under EPA’s Title V program, only deviations from the parametric ranges must be reported, and the reports are submitted on a semi-annual basis. It would be appropriate to make the reporting requirements for these two federal programs consistent. Making the reporting requirements consistent also would reduce the significant reporting burden that will be created if the regulated community must submit all of the parametric monitoring data for each boiler.

Response: The EPA intends to use the data summaries required in section 63.7550(j) for regulation development and rule effectiveness studies. The EPA believes that requiring the daily average for a 30-day rolling average will provide a more representative record of how well units and control devices are working which will enable the EPA to better develop and/or assess federal regulations. Further, the EPA believes it is important to require the submissions of the 30-day rolling average data in the semi-annual reports because these data serve multiple useful purposes and are important in:

Ensuring continued compliance performance of process and control device operations and providing sources with data to support compliance certifications,

Providing the sources and the agency with data representing variability of control measures for support of future (e.g., 8 year) regulatory reviews and updates, and

Identifying the best performing units and control approaches making more manageable and less burdensome future information data collection projects.

Accordingly, the final rule will stipulate that sources will submit the compliance monitoring reports to the Administrator electronically; although, the requirement will be contingent upon whether the EPA has the electronic reporting tools operational and in place. There will be no consequence relative to compliance should the electronic reporting tools not yet be ready when sources are required to report monitoring data. We believe that once the electronic data reporting tools are in use, sources will experience a reduced reporting and record keeping burden. Once

sources submit data electronically, there will no need to store on site hard copies of reports and monitoring records that have been submitted electronically to WebFIRE.

Comment Excerpt Number: 141

Comment: Proposed §63.7550(j) requires quarterly periodic reports of operating parameter daily averages. Although daily averages are reviewed immediately to determine if a deviation has occurred, having to gather and tabulate this information quarterly adds unnecessary burden, since this information would normally be gathered and tabulated semi-annually for use in preparing the normal periodic reports. As we discuss in Comment A of this section, EPA has no use for this information since deviations are reported in the semi-annual report and thus, if it is not deleted, there is no reason to require submitting this data more frequently than semi-annually. Thus, we recommend the requirement for submitting all daily averages be deleted and if not deleted that it only be required as part of the semi-annual report.

Response: We have reduced the frequency of reporting to Webfire to semi-annually. We have clarified in the final rule that the only data to be reported will be the 30-day averages required by the rule. See the response to comment EPA-HQ-OAR-2002-0058-3521-A1, excerpt 139.

Comment: Reporting and recordkeeping requirements for secondary material fuels are unclear relative to gases and should be clarified.

The majority of BPH subject to this proposal are gas-fired. Gases are not secondary materials unless they are combusted along with a container. Since gaseous fuels are so prevalent and will

almost never be secondary materials we request gases be specifically excluded from the secondary materials recordkeeping and reporting requirements.

Proposed §63.7555(d)(2) requires records if you combust non-hazardous secondary materials. From the definition in §241.2 it is unclear relative to gaseous fuels used in refineries, what fuels are non-hazardous secondary materials and thus what fuels require such records. It would save considerable effort and confusion if this is clarified in §63.7555(d)(2) by specifically excluding all gases that are not combusted along with the container in which they are contained. If that general exclusion is not acceptable, we request that natural gas, refinery gas and other gas 1 fuels be specifically exempted.

Response: We disagree that §63.7555(d)(2) needs to be revised. 63.7555(d)(2) only requires that a source keep the documents that show how the secondary material is not a solid waste.

Comment: It is also critical that adequate time be allotted to crafting clear regulatory language for the final rules. As indicated by our many editorial comments on the major source proposal, much of the proposed language is unclear, inconsistent, and confusing. In some cases, it is not even consistent with the apparent intent indicated in the preamble or in other portions of the rule. Similarly, there are significant differences in rule language for the same requirement between the major source and area source rules.

Response: The EPA thanks the commenter for their support.

Testing and Monitoring

11A. Minimum Data Availability for CEMS/CPMS

Commenter Name: Lee Zeugin and Lauren Freeman

Commenter Affiliation: Utility Air Regulatory Group (UARG)

Document Control Number: EPA-HQ-OAR-2002-0058-3500-A1

Comment Excerpt Number: 32

Comment: On reconsideration, EPA defends its final rule as reasonable. EPA explains its view that maintenance performed as normal scheduled quality control events under a site-specific quality control program required under § 63.8(d)(2)(iii) would be exceptions to the data collection requirements. 76 Fed. Reg. at 80610/2. EPA also proposes to add a reference to “scheduled CMS maintenance as defined in your site-specific monitoring plan” to § 63.7535(b). UARG appreciates and supports EPA’s explanation and proposed rule revision regarding maintenance periods. For consistency, UARG requests that EPA add similar language regarding maintenance to § 63.7535(d).

Unfortunately, EPA does not discuss or explain its position with respect to out-of-control periods. 76 Fed. Reg. at 80610/2. Moreover, EPA has not proposed to remove from § 63.7525(c)(6) language requiring identification of COMS out-of-control periods as deviations, and has proposed adding a similar provision regarding PM CPMS. Proposed § 63.7525(d)(3). EPA also has proposed to remove out-of-control periods from the exceptions to what constitute a deviation under § 63.7535(d). Accordingly, the rule is still internally inconsistent with respect to out-of-control periods. UARG requests that EPA remove the references to out-of-control periods from §§ 63.7525(c)(6) and (d)(3), and that EPA not finalize its proposed removal of out-of-control periods from the list of exceptions to monitoring deviations in § 63.7525(d). UARG notes that EPA included out-of-control periods in such a list in § 63.10020(d) of the recently promulgated EGU MACT rule. 77 Fed. Reg. 9304, 9479 (Feb. 16, 2012).

Response: The EPA thanks the commenter for their support on the explanation regarding maintenance periods. In the final rule, we have revised §63.7535(d) to be consistent with §63.7535(b).

Additionally, we have revised the language in the final rule to be more consistent with the language in the EGU MACT rule.

Comment Excerpt Number: 110

Comment: It is unprecedented to make every Continuous Monitoring System (CMS) out-of-control occurrence a deviation. As is typical of other rules, a data availability criterion should be established instead. Following rule quality assurance and maintenance requirements and normal instrument drift should not result in rule or Title V deviations, much less a multitude of deviations. Proposed §63.7525(c)(6) and (d)(3) should not be finalized. Proposed §63.7525(c)(6) specifies that any 6-minute period for which a Continuous Opacity Monitoring System (COMS) is out-of-control and data are not available for a required calculation is a deviation. Since the criteria for being out-of-control are specified either from daily to annual, each such event creates 240 to 87,600 deviations. Similarly, proposed §63.7525(d)(3) specifies that any 15-minute period for which a Continuous Parameter Monitoring System (CPMS) is out-of-control and data are not available constitutes a deviation. Since the criterion for out-of-control is a daily check, each out-of-control occurrence results in 96 deviations. Since many quality assurance and maintenance activities take more than 6 minutes or 15 minutes, many required quality assurance and maintenance activities will be deviations.

Making these occurrences deviations, and presumably violations, discourages obtaining quality data because of the potential penalty for doing so and because you are punished for undertaking preventive steps. Since it is impossible to not have a deviation, and very good performance is not recognized, there is no incentive to do more than the minimum the rule requires. Furthermore, these requirements contradict proposed §63.7535 and violate the requirements in the rule to develop and follow a site specific monitoring plan that addresses quality assurance and monitor maintenance and to perform certain performance evaluations (e.g., as required in §63.7525(e)(4) for flow monitors). How can it be a deviation to do activities that are required under other portions of the rule? Allowed monitor data outages are appropriately addressed in proposed §63.7535 and thus §63.7525(c)(6) and (d)(3) should not be finalized.

Response: We believe that making these occurrences deviations encourages, rather than discourages, obtaining quality data. As all periods where data is not collected is a deviation, we believe that this will encourage people to collect as much data as possible, instead of trying to meet an arbitrary data availability limit. The final rule allows for periods of monitoring deviations in order to perform scheduled CMS maintenance and quality assurance activities, as described in §63.7535(b). Additionally, §63.7535(d) has been revised to be consistent with §63.7535(b).

Comment: EPA should add minimum monitoring system data availability requirements. There will be times, even with a well maintained continuous monitoring system, when the system will be out of operation. Lengthening averaging periods to 30 days is not adequate to address this issue.⁴⁶ Even the final CISWI rule provided minimum data availability requirements for PM CEMS of 85 percent of the hours per day, 90 percent of the hours per calendar quarter, and 95 percent of the hours per calendar year that the affected facility is operated.⁴⁷ The final Large Municipal Waste Combustor rule also has data availability requirements: valid continuous monitoring system hourly averages shall be obtained at least 90 percent of the operating hours per calendar quarter and 95 percent of the operating hours per calendar year.⁴⁸ The Petroleum Refinery MACT, Subpart UUU, states that each continuous parameter monitoring system must have valid hourly average data from at least 75 percent of the hours during which the process operated.⁴⁹ EPA is not persuasive in its response that the need for minimum data availability provisions such as those in NSPS Subpart Da no longer exists due to EPA's better understanding of the need for continuous data collection and the dramatic improvement in CEMS data availability (citing Acid Rain Program). SO₂ CEMS used under the Acid Rain Program would differ starkly from some of the other CEMS (Hg, HCl, PM) that might be used under the Boiler MACT. SO₂ CEMS are a mature technology in widespread use, but even mature CEMS technologies such as SO₂, NO_x, and CO should be provided some reasonable amount of downtime. The Acid Rain rules recognize that NO_x and SO₂ monitors have downtime by including missing data procedures in Appendix C to 40 CFR 75. All equipment will malfunction at some point in time, and EPA should acknowledge this fact by providing a minimum data availability requirement in the Boiler MACT for continuous monitoring systems.

[Footnote 46: EPA responded that, "[r]egarding comments on PM CEMS, we have modified the language from the proposed 24-hour block to a 30-day rolling average. We disagree with the commenter about applying the data availability used in Da to the PM CEMS data collection. The Agency has developed a better understanding of the need for continuous data collection since Da was published and the equipment and software have dramatically improved as shown by the acid rain program CEMS data availability success. The monitoring system must operate at all times the process is operating." Response to Comments, EPAHQ-OAR-2002-0058-2908.1, excerpt number 31.]

[Footnote 47: See 40 CFR 60.2730(n)(14).]

[Footnote 48: See 40 CFR 60.58b(c)(10)(viii).]

[Footnote 49: See 40 CFR 63.1572(c)(3).]

Response: We have not included any specific minimum data availability requirement for CEMS or other monitoring in this final rule nor do we provide a specific tool for data substitution. We believe that there are other provisions in the final rule to provide incentives to conduct monitoring in a manner consistent with good air pollution control practices and to provide data

sufficient to demonstrate compliance with a relatively long-term emissions rate limit. Data quality certainty associated with any calculated value decreases with the collection of fewer data such as would occur with extended periods of monitoring system downtime. We believe that it is necessary and critical to compliance with the regulation that a source uses all measured data collected during an averaging period to assess compliance regardless of any periods of missing data. Sources should not disqualify any data otherwise meeting required data quality requirements simply because there were data missing for other hours or days of the averaging period. Instead of a minimum data availability threshold that would invalidate data collected for some averaging periods because one did not collect enough data to validate data collected, sources must report as deviations to the rule failures to collect data during required periods and that are not covered by exceptions allowed in the final rule. We believe that enforcement authorities have the discretion to determine the severity of the missing data and what action must be taken in response to the deviation. Should the source or the enforcement authority be concerned about the representativeness of data such as during periods of missing data, either may consider collecting information through other means (e.g., supplemental emissions testing) to fill data gaps not only because such gaps are deviations from the rule but such gaps can lead to uncertainty about compliance status.

We further believe that the final rule provides sufficient means to ensure CMS performance and ongoing compliance without specifying an arbitrary numerical minimum data availability. We believe that specifying that failure to collect required or otherwise excepted data is a deviation from the rule will provide the necessary incentive to collect data sufficient to demonstrate compliance with the limits in the final rule.

Comment: *MINIMUM DATA AVAILABILITY*

ACC requests EPA reconsider its response to the requests to add minimum CEMS data availability requirements. At least two commenters, Dominion and the Industrial Minerals Association, noted that the requirement to have valid CEMS data for all operating hours is not realistic.¹⁸ There will be times, even with a well maintained CEMS, when the system will be out of operation. EPA's response that, somehow, lengthening the averaging period for PM CEMS from 24 hours to 30 days addresses these comments is inadequate.¹⁹ ACC notes that the final Commercial/Industrial Solid Waste Incinerator (CISWI) rule provides minimum data availability requirements for PM CEMS. *See* 40 C.F.R. 60.2730(n)(14). EPA's response that the need for minimum data availability provisions such as those in NSPS Subpart Da no longer exists due to EPA's better understanding of the need for continuous data collection and the dramatic improvement in CEMS data availability (citing Acid Rain Program) is also not persuasive. SO₂ CEMS used under the Acid Rain Program differ starkly from some of the other CEMS (Hg, HCl, PM) discussed above. SO₂ CEMS are a mature technology in widespread use. Even mature CEMS technology such as SO₂, NO_x, and CO should be provided some reasonable amount of downtime. Therefore, ACC respectfully requests that EPA reconsider its decision to not include

minimum data availability requirements, and to propose for comment a reasonable allowance for equipment downtime in 40 C.F.R. 63.7525(a)(6).

[Footnote 18: See Response to Comments, EPA-HQ-OAR-2002-0058-2908.1, excerpt number 31; EPA-HQ-OAR-2002-0058-2740.2, excerpt number 14.]

[Footnote 19: EPA responded that, “[r]egarding comments on PM CEMS, we have modified the language from the proposed 24-hour block to a 30-day rolling average. Comment: Proposed §63.7535 should be the basis for rule data handling. However, it should clarify how to handle data collected during startup and shutdown periods.

Proposed §63.7535 is entitled “Is there a minimum amount of monitoring data I must obtain?” While this section lays out reasonable requirements for what data should be included in compliance demonstrations and what data should not be included, it never really answers the question in the title. Furthermore, there are conflicts between this section and requirements elsewhere in the proposal. We have tried to identify as many of those conflicts as possible in these comments and recommend those places in the proposal that conflict with §63.7535 should be deleted or revised.

Additionally, this section essentially requires all valid data to be used to “assess compliance.” We believe, it must be specifically clarified that in assessing compliance with numerical emission limits data collected during periods of startup and shutdown are excluded from emission averages as provided in §63.7500(e).

Response: §63.7525(d)(1) states: "The continuous parameter monitoring system must complete a minimum of one cycle of operation every 15-minutes. You must have a minimum of four successive cycles of operation, one representing each of the four 15-minute periods in an hour, to have a valid hour of data." The definitions of "10-day rolling average" and "30-day rolling average" have been revised and include the phrase "hours of valid operating data" and both definitions include "Valid data excludes hours during startup and shutdown, data collected during periods when the monitoring system is out of control as specified in your site-specific monitoring plan, while conducting repairs associated with periods when the monitoring system is

out of control, or while conducting required monitoring system quality assurance or quality control activities, and periods when this unit is not operating."

Comment Excerpt Number: 133

Comment: Proposed §63.7525(d)(1) specifies that you must have four successive cycles of operation to have a valid hour of data for a continuous parameter monitoring system. Since most such systems collect many data points per second, this seems to say a fraction of a second's data provides a valid hour of data. We assume the actual intent was to require some data from each 15 minute period and, if so, this wording needs to be revised. Furthermore, it is common practice for a valid hour of data to be any hour where at least two 15 minute periods are represented and we recommend that be incorporated into the rule, so all the hours during which brief quality assurance checks are performed (e.g., daily drift check of the PM CPMS required by the rule for some BPH) won't be lost due to one 15 minute period missing data. We recommend the language from proposed §63.7525(l)(6) be used as a model for a revised §63.7525(d)(1).

Response: We have made revisions to §63.7525(d)(1) to indicate that our intent is for the source to collect at least one data point for each of the 15-minute periods in an hour.

Comment Excerpt Number: 12

Comment: EPA is proposing to the use of "oxygen trim" systems to optimize air fuel ratios and optimize combustion in place of installing separate oxygen monitoring systems on the stack in order to meet parametric monitoring requirements for the carbon monoxide emission limitation. Many sources already have an oxygen trim system in place and EPA is determining that it is a better way to achieve good combustion versus only monitoring oxygen with no trim system.

The Department supports EPA's approach to using oxygen trim systems as a better means for parametric monitoring and ensuring good continuous combustion. Our support is based on a similar requirement in place here in Wisconsin since 2002 for certain sources operating in our ozone non-attainment area. The affected source categories subject to this good combustion

requirement include stoker boilers, glass furnaces, and lime kilns. Under this requirement, the sources must continually monitor both O₂ and CO flue gas concentrations and trim the system to optimize combustion and reduce NO_x emissions – basically minimize excess combustion air while ensuring complete combustion.

Response: The EPA thanks the commenter for their support.

Comment: OXYGEN MONITORING

a. The Change from O2 CEMS to O2 Trim is Appropriate and Supportable

In the Final Boiler Rule, EPA included continuous oxygen (O₂) monitoring as the compliance method for sources with a CO limit, instead of mandating the use of CO continuous emissions monitoring system (CEMS). EPA now proposes to amend the O₂ monitoring requirements to allow for the use of continuous oxygen trim analyzer systems instead of oxygen CEMS. (76 Fed. Reg. 80609) EPA also proposes to remove the requirement that the oxygen monitor be located at the outlet of the boiler, so that it can be located either within the combustion zone or at the outlet as a flue gas oxygen monitor. ACC supports EPA's proposal to add flexibility and reduce the cost and burden of the continuous oxygen monitoring requirements, as these changes allow facilities to utilize existing oxygen trim systems rather than installing CEMS.

Response: The EPA thanks the commenter for their support.

Commenter Name: Paul Noe

Comment: Appropriate numerical limits must be paired with an appropriate testing period and methodology to constitute an achievable MACT limit where compliance can be ensured on a continuous basis. For some proposed limits EPA has accomplished this workable structure and for others they have not. For example, CO limits as a surrogate for organic HAP to assure good combustion practices, established as a 3-hour maximum load stack test requirement accompanied thereafter by maintenance of 30-day average oxygen levels (reflective of excess air) at or above levels measured during the performance test is a comprehensive standard for many boiler operators to meet that achieves both environmental objectives and operational needs. We support this testing and monitoring paradigm as an alternative in the rules for a wide range of operators.

Response: The EPA thanks the commenter for their support.

Commenter Name: Robert D. Bessette
Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)
Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1
Comment Excerpt Number: 66

Comment: In the Final Boiler MACT Rule, EPA required continuous oxygen monitoring for boilers subject to CO numeric emission limits. 76 Fed. Reg. 15,671-73. (2011 Final Rule). EPA finalized this approach as an alternative to requiring the use of CO CEMS. While EPA maintained this approach in the 2012 Reconsidered Boiler MACT Rule, EPA did modify the rule

to provide more flexibility. EPA's oxygen monitoring approach and decision to increase flexibility is appropriate, however additional clarification is needed.

EPA concluded that, instead of requiring monitoring of oxygen levels in the stack, "a better way to ensure good combustion is by requiring the installation, calibration, monitoring and use of oxygen trim systems to optimize air to fuel ratio and combustion efficiency." 76 Fed. Reg. 80,609. (2012 Reconsidered Boiler MACT Rule). EPA reasoned that "the data from such devices is not only an appropriate control for efficient combustion and a less burdensome alternative to monitoring stack oxygen concentration but also is a better system for many types of units that experience significant load swings and operate with high levels of excess air." 76 Fed. Reg. 80,609. (2012 Reconsidered Boiler MACT Rule). As set forth in comments CIBO's Petition for Reconsideration of the Final Boiler MACT Rule, EPA's proposed oxygen monitoring requirements are appropriate and the EPA was justified in increasing the flexibility.

Response: The EPA thanks the commenter for their support.

Comment: AMP Supports Replacing the O₂ CEM Requirement with an O₂ Trim System Requirement

In the 2011 Boiler MACT rule, EPA imposed an O₂ CEM requirement on sources subject to CO limits that required sources to continuously monitor and maintain O₂ levels above the operating limit established during stack testing. An O₂ CEM measures oxygen concentrations in the stack gas. As many commenters noted, O₂ measurements in the stack gas are not a proper measure of good combustion. Furthermore, many existing boilers and process heaters already utilize flue gas oxygen analyzers for indication, alarm, and O₂ trim control, where the fuel/air ratio is automatically controlled for optimum combustion conditions. To the extent EPA retains CO emissions limits and/or operating limits, AMP supports the use of an O₂ trim analyzer in lieu of an O₂ CEM for purposes of demonstrating continuous compliance.

Response: The EPA thanks the commenter for their support.

Document Control Number: EPA-HQ-OAR-2002-0058-3449-A1
Comment Excerpt Number: 17

Comment: Element 9.a. of Table 8 states that if using Oxygen content as the operating limit then continuous compliance is demonstrated by “continuously monitoring the oxygen content using an oxygen trim system according to § 63.7525(a).” The owner/operator may have multiple oxygen analyzers installed on the boiler or process heater. The oxygen analyzer used for demonstrating compliance should not be required to be the oxygen analyzer used in the oxygen trim system. The key element is that the oxygen analyzer located where oxygen was measured during the CO Performance Test be the same location used for demonstrating continuous compliance. Table 8(9)(a) should be revised as follows:

a. ~~Continuously monitor the oxygen content using an oxygen trim system according to § 63.7525(a) the same oxygen analyzer location as used in the performance test of Table 5(4)(b).~~

Response: The EPA disagrees with the commenter in that we allow for the use of an O₂ monitor or O₂ trim system to be used for compliance with the rule. The source operator may choose the system of their preference and select that path for compliance. The source operator may not change their monitoring scheme and switch to another analyzer or O₂ trim system without conducting another performance test to set the operating parameter correlation. If an aggregate average of several analyzers is used to meet compliance with this section of the rule, that aggregate average then represents a single O₂ monitoring system and changes to such a system (such as removing or adding monitors from the scheme) would require another performance test to set the operating parameter correlation.

Comment Excerpt Number: 30

Comment: As proposed, regulated Boilers are required to complete and annual stack test and establish a minimum oxygen level for compliance monitoring purposes. The minimum oxygen requirement is then paired with the requirement to have an oxygen analyzer system and trim system to maintain the oxygen above this minimum established level. This approach is advantageous from a compliance demonstration perspective in that it eliminates the need to have costly CO-CEMS on all boilers. While oxygen is a reasonable surrogate, there are times when the CO and oxygen concentrations may diverge. These discrepancies may be particularly apparent during boiler swings or other intermittent transitory periods. Therefore, to provide the regulated community with an appropriate level of compliance assurance, EPA should make it clear that the oxygen limits are the only applicable compliance demonstration for CO in the periods between the annual tests. In other words, oxygen is a true surrogate and EPA has no expectation that short term CO will comply with the prescribed 3-hour CO limits during every 3-hour period over the course of an operating year.

Response: The EPA has set two distinct compliance paths in this rule. Sources using certified CO CEMS will comply with a ten day rolling average limit, while sources without certified CO CEMS systems comply by conducting an annual stack test and correlating O₂ CEMS or O₂ trim readings to the lowest O₂ reading obtained during the stack test, based on a three hour average.

Commenter Affiliation: American Forest & Paper Association (AF&PA) et al.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 102

Comment: Many existing boilers and process heaters utilize flue gas oxygen analyzers for indication, alarm, and O₂ trim control, where the air-to-fuel ratio is automatically controlled for optimum combustion conditions. For many types of combustion units, O₂ monitoring occurs upstream of potential air inleakage points like preheaters, thus minimizing the potential for erroneous measurements. For these units already equipped with existing O₂ analyzer systems and/or O₂ trim systems, monitoring data from these locations are currently being used both for boiler tuning and combustion control. Therefore, if O₂ monitoring is provided as an alternative to demonstrate continuous compliance with CO limits under the Boiler MACT rule, it would be logical and technically feasible for these facilities to continue monitoring O₂ at that current location. These O₂ analyzers are not compliance CEMS and therefore do not meet PS-3 requirements. However, they are calibrated and maintained to provide reliable and safe service for combustion unit operation. Proper maintenance and calibration routines are the only available option, given the inability to certify these monitors, according to applicable Performance Specifications, when located at the outlet to the boiler. This inability to certify is caused by stratification of gases at the boiler/process heater outlet.

Therefore, the most cost effective and technically feasible approach for utilization of O₂ analyzer systems would be to:

- Allow the continued use of existing O₂ analyzers

- Allow the installation of new O₂ analyzers of appropriate design at optimal locations, and
- Allow periodic sensor calibration as an alternative to certification and as a way to ensure accurate O₂ monitoring.

Boiler combustion and optimization experts indicate that most O₂ trim systems rely on O₂ measurements at the outlet of the boiler combustion chamber. These analyzers are not certified, but are employed successfully to implement control strategies. The monitoring strategy proposed above is therefore viable even if it is not connected to an automated trim system.

Response: The EPA agrees with the commenter and verifies that certified O₂ CEMS, O₂ monitors, and O₂ trim systems are permissible compliance systems for the short term compliance option in this rule.

Commenter Name: David A. Buff, Golder Associates Inc.

Commenter Affiliation: Florida Sugar Industry (FSI)

Document Control Number: EPA-HQ-OAR-2002-0058-3504-A1

Comment Excerpt Number: 18

Comment: Many existing boilers and process heaters already utilize flue gas oxygen analyzers for indication, alarm, and O₂ trim control where the fuel-to-air ratio is automatically controlled for optimum combustion conditions. For many types of combustion units, O₂ monitoring occurs upstream of any potential air in-leakage points, thus minimizing the potential for erroneous measurements. For those units already equipped with existing O₂ sensors and/or O₂ trim control systems, monitoring data from these locations are currently being used both for boiler tuning and combustion control. Therefore, if O₂ monitoring is provided as an alternative to demonstrate continuous compliance under the Boiler MACT Rule, it would be logical and technically feasible for these facilities to continue monitoring O₂ at that current location.

However, O₂ analyzers utilized for these existing purposes do not comply with Performance Specification 3 (PS-3) requirements regarding their positioning or other QA/QC standards. They are calibrated and maintained to provide reliable and safe service for combustion unit operation. Proper maintenance and calibration routines are the only available option, given the inability to certify these monitors according to applicable Performance Specifications, when the monitors are located at the outlet to the boiler. This inability to certify is caused by stratification of gases at the boiler/process heater outlet.

Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1

Comment Excerpt Number: 37

Comment: Many existing boilers already utilize flue gas oxygen analyzers for indication, alarm, and O₂ trim control, where the fuel/air ratio is automatically controlled for optimum combustion conditions. The sensing location for existing O₂ monitors is typically in the optimum location to sense flue gas composition as reliably as possible, because sensing of oxygen in these

cases maintains proper excess air levels and helps prevent unsafe operating conditions. For many types of combustion units, that location is near the boiler furnace outlet in a position upstream of any potential air leakage points to avoid erroneous excess air indications which would drive controls in an erroneous direction. This location is also upstream of air preheaters, thus avoiding the erroneous (high O₂) indications due to inherent leakage across regenerative air preheater seals or potential tube leakage in recuperative air preheaters. For those units equipped with existing O₂ sensors and O₂ trim control systems, flue gas composition at those locations would already be used for combustion tuning and control characterization. Therefore, if O₂ monitoring is desired for continuous compliance under the Boiler MACT rule, sensing O₂ at that current location would be logical and proper from a technical perspective.

Comment: In the March 21, 2011 final rule, EPA included continuous oxygen monitoring as the compliance method for sources with a CO limit, instead of mandating the use of CO CEMS. EPA now proposes to amend the oxygen monitoring requirements (76 FR 80609, Dec. 23, 2011) to allow for the use of continuous oxygen trim analyzer systems instead of oxygen CEMS. EPA is also removing the requirement that the oxygen monitor be located at the outlet of the boiler, so that it can be located either within the combustion zone or at the outlet as a flue gas oxygen monitor. We support EPA's proposal to add flexibility and reduce the cost and burden of the continuous oxygen monitoring requirements, as these changes allow facilities to utilize existing oxygen trim systems rather than installing CEMS.

Many existing boilers already utilize flue gas oxygen analyzers for indication, alarm, and O₂ trim control, where the fuel/air ratio is automatically controlled for optimum combustion conditions. The sensing location for existing O₂ monitors is typically in the optimum location to sense flue gas composition as reliably as possible, because sensing of oxygen in these cases maintains proper excess air levels and helps prevent unsafe operating conditions. For many types of combustion units, that location is near the boiler furnace outlet in a position upstream of any potential air inleakage points to avoid erroneous excess air indications which would drive controls in an erroneous direction. This location is also upstream of air preheaters where utilized, thus avoiding the erroneous (high O₂) indications due to inherent leakage across regenerative air preheater seals or potential tube leakage in recuperative air preheaters. For those units equipped with existing O₂ sensors and O₂ trim control systems, flue gas composition at those locations would already be used for combustion tuning and control characterization. Therefore, if O₂ monitoring is desired for continuous compliance under the Boiler MACT rule, sensing O₂ at that current location would be logical and proper from a technical perspective.

Comment: Oxygen monitoring corrections are necessary. The rule's proposal requiring that the oxygen trim control be used to maintain CO emissions compromises safe boiler operation. Instead of oxygen trim control, the Agency should allow the use of existing (or new) O₂ probes or analyzers situated at the boiler outlet as a surrogate CO compliance assurance monitoring strategy.

Response: For a response to the request that pre-existing or new oxygen probes situated at the boiler outlet to be allowed to demonstrate compliance in lieu of the oxygen trim system, please see comment EPA-HQ-OAR-2002-0058-3521-A1, excerpt 102.

Comment: While O₂ trim systems are viable for combustion control, there are limitations to its applicability that are especially pertinent for multi-fuel and biomass boilers.

- O₂ trim systems are best suited when the boiler predominantly burns only one type of fuel.
- Feedback control loops in O₂ trim systems are generally developed only for the predominant fuel. This limits the applicability of O₂ trim systems for multi-fuel units.
- O₂ trim systems are used as a means of "fine" control and are sometimes ineffective when there are frequent changes in fuel quality and mix. This limitation would apply to combination boilers co-firing biomass fuels.

While it is theoretically possible to develop control systems for each individual fuel used in a multi-fuel boiler, this approach is often expensive and may be ineffective.

Given these factors, it is our recommendation that facilities be given the option to use either the O₂ monitoring approach (install, calibrate, and monitor O₂ without the requirement to certify) or an O₂ trim system.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3521-A1, excerpt 102.

Comment: Oxygen sensing location

The Oxygen analyzer system is defined in §63.7575 in part as follows:

Oxygen analyzer system means all equipment required to determine the oxygen content of a gas stream and used to monitor oxygen in the boiler flue gas or firebox.

The optimum location of the sensor or sampling point is dependent on the specific boiler design. In different applications, that location might be at the furnace exit, in the convection pass, at the boiler outlet, or at another downstream location. We recommend that this language be modified as follows to allow latitude in the exact location of the sensing point:

Oxygen analyzer system means all equipment required to determine the oxygen content of a gas stream and used to monitor oxygen in the boiler or process heater flue gas, boiler/process heater ~~or~~ firebox, or other appropriate intermediate location.

Response: The EPA agrees with the commenter and has modified the rule language to read “Oxygen analyzer system means all equipment required to determine the oxygen content of a gas stream and used to monitor oxygen in the boiler or process heater flue gas, boiler/process heater, firebox, or other appropriate location.”

Document Control Number: EPA-HQ-OAR-2002-0058-3507-A1

Comment Excerpt Number: 7

Comment: The final rule required oxygen monitoring at the outlet of the boiler combustion chamber to ensure good combustion. Instead of this requirement, the proposed reconsideration requires the installation, calibration and use of oxygen trim systems to optimize air-to-fuel ratio and combustion efficiency.

The DEP agrees with the EPA that the use of oxygen trim systems is an appropriate control for efficient combustion and a less burdensome alternative to monitoring stack oxygen concentration. Additionally, the EPA should also provide for case-by-case approval of alternative systems that can be demonstrated to meet the intent of this requirement.

Response: The EPA thanks the commenter for their support of the use of oxygen trim systems as a control for efficient combustion.

For response to alternate O₂ monitoring systems, see comment EPA-HQ-OAR-2002-0058-3521-A1, excerpt 102.

The EPA agrees with the commenter and notes that 40 CFR 63.8(f) presents the procedure for submitting a request to the Administrator to use alternative monitoring.

Comment Excerpt Number: 1

Comment: As a variation on EPA's compliance method for the stack test-based CO limits, for units that experience significant operational variability, EPA could establish a performance standard (e.g., a work practice approach where good combustion was monitored by some indicator and fluctuations outside the range observed during the stack test triggered corrective action) that would apply during the periods between stack tests, rather than a strict compliance monitoring approach. Such a standard could consist of a numeric value indicative of good combustion, such as oxygen or CO levels in the furnace or stack, but values outside of the range observed during a performance test (or in the case of a continuous CO monitor, above the stack test-based standard) would not constitute a violation of the underlying stack test-based CO standard, as long as appropriate corrective action were taken within a reasonable time after the exceedance was measured or documentation was made for non-correctable conditions (e.g., a load swing or start-up condition). The source could determine if it wanted to comply using a three-hour stack test and the oxygen monitoring approach already included in the rule, or, due to the influence of variable conditions highlighted above, opt for a periodic three-hour stack test with a performance standard in between stack tests.

In concept, such an approach would be analogous to bag leak detection systems on fabric filters, which EPA routinely requires in its standards. When a leaking bag is detected, EPA's rules

typically do not define such an event as a violation. Instead, the affected source is required to replace the leaking bag and only might be found in violation if this corrective action is not taken within a specified period. So, there is clear precedent for applying this concept to the Industrial Boiler MACT stack test CO standards.

EPA has ample justification to adopt this approach as a work practice under § 112(h). Among other things, EPA is authorized to adopt work practices under § 112(h) when "the application of measurement methodology to a class of sources is not practicable due to technological and economic limitations." That is the case with the Boiler MACT stack-test-based CO emissions limitations for sources that experience significant operational variability. While it is true that certain relevant constituents such as oxygen and CO can be measured, the "application" of such methods may not be technologically practicable in some cases, because the data that are collected cannot reasonably be used to show compliance with a stack test-based CO limit. For sources using this approach, the performance data largely would be taken during periods when the affected source was not operating under the same steady state, high-load conditions as existed during the stack tests used to set the standards. Thus, EPA has authority and justification to set performance standards for the periods between stack tests.

Response: The EPA disagrees with the commenter in that CO and O₂ monitoring of affected sources are not sufficiently impracticable to trigger work practice standards as allowed by § 112(h); The EPA has a long history of using parametric monitoring in rules.

Comment Excerpt Number: 101

Comment: However, we would like to highlight the following inconsistency between preamble language and rule requirements as it pertains to O₂ monitoring requirements: • Preamble language (section G (9)) indicates that boilers and process heaters need to install, calibrate, and operate an oxygen trim system in order to ensure efficient combustion and compliance with the CO standards.

By comparison, as per the requirements under § 63.7525(a), if your boiler or process heater is subject to a carbon monoxide emission, you must install, operate, and maintain an oxygen analyzer system as defined in § 63.7575. By definition, *an oxygen analyzer system* "means all equipment required to determine the oxygen content of a gas stream and used to monitor oxygen in the boiler flue gas or firebox. This definition includes oxygen trim systems."

It is our understanding from the rule language that facilities can utilize an oxygen analyzer system (with one of the options being the use of an automated oxygen trim system) to demonstrate compliance with the metrics identified during the performance test. EPA should clarify the rule language to this effect.

The language related to parameter monitoring provided in § 63.7525(a)(2) and Table 4 seems to further clarify issue 1 above – Under the requirements under §63.7525 (a)(2), oxygen trim systems should be operated *with the oxygen level "set"* at the minimum percent oxygen by volume that is established as the operating limit for oxygen. By contrast, as indicated in Table 4,

facilities using oxygen analyzer systems as monitoring devices, as specified in § 63.7525(a), *should maintain the oxygen level* such that it is not below the lowest hourly average oxygen concentration measured during the most recent CO performance tests (use that as the set-point when using O₂ trim whereas maintain it at or above that level when using O₂ monitoring.)

Response: For response to alternate O₂ monitoring systems, see comment EPA-HQ-OAR-2002-0058-3521-A1, excerpt 102.

In response to oxygen monitoring limits, the EPA agrees with the commenter that the rule language was inconsistent and has modified the rule to align the requirements of §63.7525 (a)(2), with those indicated in Table 4.

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 93

Comment: Paragraph 63.7525(a)(2) references Table 4 (Operating Limits Table), which in turn, establishes the oxygen operating limit as an hourly average. However, Table 8, which establishes continuous compliance parameters, specifies the oxygen operating limit as a 30-day rolling average. Thus, the oxygen compliance requirements in §63.7525(a)(2), Table 4 and Table 8 are all inconsistent. BPH require operation with some excess air (higher oxygen) at lower operating rates simply due to lower fuel and air velocities, degraded mixing of fuel and air as those flow rates decrease, and lower furnace temperatures. Therefore, it is necessary for the actual oxygen trim system set point to vary over load, with the lowest set point typically occurring at or near full load operation. The Table 8 language accommodates this operating variability and is consistent with the 30 day rolling average used for most operating parameters in the rule. Therefore, we recommend Table 4 and §63.7525(a)(2) be changed to the Table 8 requirement (i.e., "Maintain the 30-day rolling average oxygen content at or above the lowest hourly average oxygen level measured during the most recent carbon monoxide performance test.")

Response: See the response to comment EPA-HQ-OAR-2002-0058-3521-A1, excerpt 101.

Comment Excerpt Number: 94

Comment: Proposed §63.7525(a)(2) requires that the oxygen trim system for CO monitoring be operated "with the oxygen level set at the minimum percent oxygen by volume that is established as the operating limit." However, this operating limit is a minimum and not a fixed value, thus, if §63.7525(a)(2) is not changed as recommended in the previous paragraph, §63.7525(a)(2) needs to be revised to require the oxygen trim system be operated "with the oxygen level set no lower than the minimum percent oxygen." This change will also make (a)(2) consistent with the referenced Table 4 wording of this requirement.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3521-A1, excerpt 101.

Commenter Name: Lorraine Gershman

Commenter Affiliation: American Chemistry Council (ACC)

Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1

Comment Excerpt Number: 40

Comment: The wording of § 63.7525(a)(2) above is more restrictive than the wording in Table 8, item 9 (c) as shown below:

"Maintain the 30-day rolling average oxygen content at or above the lowest hourly average oxygen level measured during the most recent carbon monoxide performance test."

The Table 8 language allows operation with the 30-day rolling average oxygen level at or above (no lower than) the lowest 1-hour average oxygen level measured in the most recent performance test whereas the § 63.7525(a)(2) wording requires continuous operation at the minimum oxygen percent established during the prior test. Inherent boiler operating characteristics require operation with higher excess air (higher oxygen) at lower operating rates simply due to lower fuel and air velocities, degraded mixing of fuel and air as those flow rates decrease, and lower furnace temperatures. Therefore, it is necessary for the actual oxygen trim system set point to vary over load, with the lowest set point typically occurring at or near full load operation. The Table 8 language accommodates this operating requirement, and ACC believes Table 4 and § 63.7525(a)(2) need to be revised to provide similar operating latitude.

Response: For issues with inconsistency between the rule language and wording in Table 4 regarding operating limits for oxygen levels, please see comment EPA-HQ-OAR-2002-0058-3521, excerpt 101. For a response to issues with inconsistency between the rule language and the wording in Table 8, please see comment EPA-HQ-OAR-2002-0058-3677-A2, excerpt 93.

Comment Excerpt Number: 1

Comment: Demonstrating compliance: EPA has proposed to use CO limits as a surrogate for organic HAPs. In its floor-setting work, EPA had access to results from thousands of CO emission tests, in addition to a much smaller amount of continuous CO CEM data. The emission test data was mostly made up of standard three-run emission test results. When EPA evaluated this data, it produced floor limits far stricter than the current proposed rule. Industry protested (and EPA apparently agreed) that these three-run test results are not representative of real operation, even though for decades these same industrial interests have submitted test results to state and federal agencies without pointing out that the test results weren't representative of real operation. To the contrary, industrial sites have often used these very three-run test results as the basis for certifying continuous compliance with Title V permit conditions that limit CO emissions.

EPA is now proposing relatively lenient CO limits (compared to the initial rule), and allowing sites to demonstrate compliance with the same three-run tests that industry, only a few months ago, said weren't representative of long-term operation. CO CEMS are inexpensive, reliable and proven technology. CO CEMS should be required for every boiler larger than 10 MMBtu/hr heat input. EPA and industry cannot in one moment say that three-run test data is inaccurate/non-representative for purposes of establishing limits, then a moment later say that three-run annual tests are appropriate for showing continuous compliance. It's no secret among agencies, industry, and emission testers that for decades, many industrial sites have "prepped" their boilers prior to compliance tests specifically for the purpose of passing three runs of CO emission tests. For the other 8700+ hours of the year, these sites had no reason to manage or monitor CO emissions.

EPA's proposal to require an oxygen trim system to assure continuous compliance is inadequate. EPA's proposed rule doesn't require these systems to be calibrated to any objective standards, instead referring only to manufacturer's recommendations. Thus, an off-the-shelf O2 trim system whose manufacturer does not include specific calibration standards will not be required to carry out systematic calibrations. These facilities can decide for themselves what calibration is appropriate. If O2 trim systems are used to assure continuous compliance with the CO standards, then there must be specific calibration requirements that the public can know are being implemented.

Since very few industrial sites have ever had to manage CO emissions, very few sites really know what their boilers are capable of with respect to CO emissions. It shouldn't surprise permittees that MACT standards may take some effort to meet. Yet industry comments consistently say the CO standards can't be met, even though they don't say what levels they can achieve (and even though there are thousands of emission test results in EPA's own records that

show compliance with these standards, results which industry has never discredited until this rule action). Combustion experts all say that far better CO performance can be readily and cost-effectively achieved by improved combustion management-related efforts, whether this be work practices, new software, or modifications to the combustion air systems.

Response: The EPA disagrees with the commenter that the use of O₂ trim systems constitutes inadequate monitoring, or that specific calibration requirements are necessary to ensure compliance with the CO standards in the rule. The O₂ trim system or O₂ monitor required by the rule will be correlated to a calibrated CO instrument during annual performance testing. The EPA recognizes that operating an O₂ trim system benefits the source through lower fuel costs by increasing combustion efficiency, simultaneously lowering CO emissions. In this respect the source is incentivized to operate the O₂ trim system calibrated according to manufacturer's specification, and maintain optimal combustion.

Comment Excerpt Number: 91

Comment: The definition of oxygen trim system in proposed §63.7575 suggests that the oxygen trim system must automatically adjust excess air, by identifying an automatic system as the "typical" example. For many smaller BPH, limited use BPH, BPH that normally operate at a fixed load, and process heaters where computer control systems are unavailable, automatic systems are not always in place, not always justified, and would be costly to install. The cost for installing and maintaining such automatic systems has not been included in the analyses supporting this rulemaking. Furthermore, even where automatic systems are in place, during startups and shutdowns and other special operations, it is often necessary to operate the automatic system manually to assure the firebox is not starved for air. While we support the change to an oxygen trim system from an oxygen CEMS, we do not believe such a system should be required to be automatic or that the costs of such a requirement have been considered. Therefore, the wording of the example in the oxygen trim system definition should be changed by deleting the word "automatically".

Response: The EPA thanks the commenter for their support of oxygen trim systems as a compliance alternative to oxygen CEMS.

We understand that the commenter is referring to an oxygen monitoring system, and not an oxygen trim system. A source operator may comply with the rule through the use of either system.

Comment Excerpt Number: 92

Comment: Not all boilers and process heaters are equipped with oxygen or CO monitors. Small units, in particular, may simply have a manual draft control. The oxygen trim requirement applies to all BPH of <10 MMBTU/hr and thus applies to some units that do not have such monitors. Use of manual draft control should be specifically allowed, where a boiler or process heater is not equipped with an oxygen or CO monitor.

Response: Small units, those with heat input capacity below 10 million Btu per hour, are not subject to emission limits and, thus, are not required to monitor oxygen or CO.

Comment: If the oxygen analyzer option is selected, two further requirements apply. A minimum oxygen level operating limit (oxygen set point) applies (40 CFR Part 63, Table 4, Item 9), as does a requirement to continuously monitor the oxygen content using an oxygen trim system. A 30-day rolling average limit is then imposed on the oxygen trim system.

A 30-day rolling average limit for oxygen content is redundant with the oxygen level operating limit. The oxygen level operating limit should adequately demonstrate continuous compliance. We Energies requests that EPA remove the requirement in 40 CFR Part 63, Table 8, Item 9 to continuously monitor oxygen content on a 30-day rolling average.

Response: In response to oxygen monitoring limits, the EPA agrees with the commenter that the rule language was inconsistent and has modified the rule to align the requirements of §63.7525 (a)(2), with those indicated in Table 4. As such we feel that a 30-day rolling average limit is appropriate for demonstration of compliance with the rule.

Comment: The appropriateness of using an oxygen trim system for continuous monitoring of all periods between source tests should be further examined. While the minimum oxygen level established during the performance test, using maximum range steaming rate and fuel feed rates, may be appropriate for boilers with a single fuel source, its appropriateness for boilers with multiple fuel sources may be questionable. Boise has been directly involved with discussions pertaining to this issue with boiler vendors and consultants. Multiple fuel boilers will likely have several different excess air and combustion profiles depending on the mix of the various fuels. Boise suggests that use of the oxygen analyzer system for establishing a "set point" for monitoring purposes may be technically more appropriate. Use of oxygen trim systems for feed-forward combustion control purposes with the requirement to *maintain* the minimum oxygen level as a 30-day average would seem to us to be reaching beyond the technical capability of many of these systems.

Response: The EPA has included language in the rule that may require more than one stack test to determine pollutant concentrations from multiple fuels. It may be advisable for a source operator to determine their minimum O₂ level from the various fuels they normally combust. We have included three different O₂ measurement approaches in the rule to accommodate the varied compliance needs of different facilities.

Comment: We also support the option to install oxygen trim systems as a less costly and less burdensome alternative to oxygen CEMS for units subject to CO limits. However, we have concerns with the requirement (specified in Table 4 to 40 CFR 63 Subpart DDDDD) to maintain an oxygen level based on the lowest hourly average oxygen concentration measured during the most recent CO performance test. The limit derived from a performance test period does not include the complete mix of fuels and range of fuel characteristics that may be encountered over the course of an operating year and would restrict operational flexibility to deal with fuel variations. This is of particular concern for biomass units which combust fuels of varying heating value and moisture content.

Response: The EPA thanks the commenter for their support of oxygen trim systems as a compliance alternative. For a response to issues with multi-fuel boilers maintaining an oxygen level based on the lowest hourly average oxygen concentration measured from the most recent performance test, please see comment EPA-HQ-OAR-2002-0058-3686-A2, excerpt 23.

Document Control Number: EPA-HQ-OAR-2002-0058-3504-A1

Comment Excerpt Number: 17

Comment: Hawaii Commercial & Sugar Company ("HC&S") in Hawaii has three multi-fuel hybrid suspension grate boilers that fire bagasse, coal, fuel oil and blends of these fuels. For multi-fueled boilers, like the ones at HC&S, the optimum air-to-fuel ratios will vary depending upon the fuel or fuel mixture being fired. The Proposed Boiler MACT Rule does not clearly explain how such boilers should determine the minimum O₂ level. The FSI believes such boilers should be allowed to develop minimum O₂ levels for each fuel and then comply with the minimum O₂ level that is appropriate for the fuel that is being fired.

Response: We disagree that the rule needs to be revised to address the commenter's issue of multi-fuel boilers maintaining an oxygen level based on the lowest hourly average oxygen concentration measured from the most recent performance test. See the response to comment EPA-HQ-OAR-2002-0058-3686-A2, excerpt 23.

Comment Excerpt Number: 16

Comment: The FSI also has examined the O₂ data that were measured during the EPA reference method relative accuracy testing for CO for U.S. Sugar Boiler No. 8 during each of the 3 years (2009-2011). The relative accuracy CO data were used to determine what the O₂ levels were during stack testing, because under the Proposed Boiler MACT Rule stack testing would set the operating limit each year for the boiler. The O₂ levels during these CO tests are shown in Table B-1 of Appendix B. [See submittal for Appendix B] The data show that the O₂ levels can vary during the testing, which is helpful in establishing a minimum O₂ level. In this case, all testing was performed during the same time of the season (December).

Given these data, it appears that a hybrid suspension grate bagasse-fired boiler could be tested relatively early in the crop season, because there is sufficient variability to set a reasonable minimum O₂ level for the remainder of the year. The final Boiler MACT Rule should allow multiple CO tests during a year, if necessary, to provide a source the flexibility to determine the minimum O₂ level that meets the CO limit.

Response: The EPA thanks the commenter for their support of O₂ monitoring in the rule. The rule allows for testing while firing various fuel configurations to determine the best compliance options, and places no stipulations on time of year such tests are performed. We recommend that source operators with varying fuels carefully consider each fuel condition they wish to test.

Comment Excerpt Number: 19

Comment: The most cost effective and technically feasible approach for utilization of O₂ analyzer systems would be to:

- Allow the continued use of existing O₂ analyzers
- Allow the installation of new O₂ analyzers of appropriate design at optimal locations, and
- Allow periodic sensor calibration as an alternative to certification and as a way to ensure accurate O₂ monitoring.

Boiler combustion and optimization experts indicate that most O₂ trim systems rely on O₂ measurements at the outlet of the boiler combustion chamber. These analyzers are not certified, but are employed successfully to implement control strategies. The monitoring strategy proposed above is therefore viable, even if the O₂ analyzer is not connected to an automated trim system.

Response: The EPA agrees with the commenter and has modified the rule language to allow flexibility and use of existing and new O₂ monitors and trim systems of various types.

Comment Excerpt Number: 105

Comment: We believe §63.7525(a)(2) should reference Table 7, not Table 4, since that is the table with the requirements for establishing operating limits. Second, the wording of above is more restrictive than the wording in Table 8, item 9 (c).

The Table 8 language allows operation with the 30-day rolling average oxygen level at or above (no lower than) the lowest 1-hour average oxygen level measured in the most recent performance test whereas the §63.7525(a)(2) wording requires continuous operation at the minimum oxygen percent established during the prior test. Inherent boiler operating characteristics require operation with higher excess air (higher oxygen) at lower operating rates simply due to lower fuel and air velocities, degraded mixing of fuel and air as those flow rates decrease, and lower furnace temperatures. Therefore, it is necessary for the actual oxygen trim system set point to vary over load, with the lowest set point typically occurring at or near full load operation. The Table 8 language accommodates this operating requirement and Table 4 and §63.7525(a)(2) need to be revised to provide similar operating latitude.

Response: For a response to issues with inconsistencies between the rule language and Table 8, please see comment EPA-HQ-OAR-2002-0058-3677-A2, excerpt 93 under the chapter Oxygen Monitors - Appropriateness and Location of.

Table 7 provides instruction on how to establish operating limits, while Table 4 provides instruction on how the limits are applied in the rule.

Commenter Name: Robert D. Bessette

Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 71

Comment: In addition, solid or liquid fuel fired boilers and process heaters subject to the CO limits in this rule may also be equipped to fire other liquid or gas fuels that may be able to allow the unit to operate at lower oxygen levels for improved boiler efficiency. Alternatively, they may also fire biomass or other traditional fuels that require higher excess air for improved combustion. Operators may also need to modify the oxygen setpoint or trim system to accommodate boiler or fuel quality issues. EPA needs to recognize that oxygen trim systems not only provide a means for energy efficiency, but they also are integral to furnace combustion control and furnace safety. While use of a 30-day rolling average does provide some operating latitude, this rule should not needlessly restrict operator latitude relative to safety or operating efficiency. The real value for operations is to have an indication of excess oxygen available to operators, along with appropriate alarms so that corrective actions can be taken in a timely manner. Therefore, considering all of the above, it is recommended that the paragraph 63.7525(a)(2) wording be revised to read as follows (suggested inserts in italics):

(2) You must operate the oxygen analyzer *and trim* system with the oxygen level set at *or above* the minimum percent oxygen by volume that is established as the operating limit for oxygen according to Table 7 to this subpart *when firing the fuel or fuel mixture utilized during the most recent CO performance stack test. Operation of oxygen trim control systems to meet these requirements shall not be done in a manner which compromises furnace safety.*

Response: For a response to different oxygen settings and varied fuels, see comment EPA-HQ-OAR-2002-0058-3504-A1, excerpt 16.

While The EPA does not expect or intend for source operators to compromise the safety of their operations we do feel that the requirements of the rule are flexible enough to allow sources to determine and meet compliance levels without jeopardizing the safety of their employees or facilities. The affirmative defense section in the rule provides for extenuating operational circumstances that necessitate deviations from compliance limits.

Commenter Name: Bart Sponsellar

Commenter Affiliation: Wisconsin Department of Natural Resources

Document Control Number: EPA-HQ-OAR-2002-0058-3527-A2

Comment Excerpt Number: 13

Comment: The Department believes that monitoring both CO and O₂ with a combustion analyzer system (non-CEM) is the best option for achieving complete and efficient combustion on a continuous basis. Sources under the state requirement have indicated that combustion efficiency is more sensitive to CO than to O₂ concentrations in the flue gas. Basically, monitoring O₂ levels help a source target combustion efficiency on the gross level while monitoring CO is used to fine tune pollutant levels and combustion efficiency. This finding is simply supported by looking at the magnitude of changes in concentration used in performing the trimming. Oxygen analyzer and trim systems are responding to changes on the order of 1% excess air or approximately 10,000 ppm O₂. Comparatively changes in CO are being monitored for combustion purposes between 10 to 500 ppm. Therefore a combustion efficiency system with both O₂ and CO monitoring will be able to achieve better performance than a system which monitors only O₂. The Department believes this approach to combustion trim systems ensures continuous and overall better control for all organic HAP emissions including dioxins and furans.

Therefore the Department supports EPA's approach to using an oxygen trim system for parametric monitoring along with annual stack testing. However, the Department believes that sources using a continuous automated combustion trim system with both CO and O₂ combustion analyzer monitoring should be allowed stack testing no more frequent than every two years. Similar to EPA's proposed PM continuous monitoring system (CMS), a CO and O₂ CMS can be maintained as a parametric monitoring system without the burden or expense of certification. A longer period between stack testing can potentially be allowed with a plan that ensures proper CO monitor calibration and operation of the trim system over time.

Response: The EPA thanks the commenter for their support of oxygen trim systems and annual stack testing.

The EPA makes no allowance other than annual stack testing requirements in the final rule.

Commenter Name: Bart Sponsellar

Commenter Affiliation: Wisconsin Department of Natural Resources

Document Control Number: EPA-HQ-OAR-2002-0058-3527-A2

Comment Excerpt Number: 27

Comment: For source categories that do not have emission limitations, such as oil and gas boilers or boilers smaller than 10 mmBtu/hr, the MACT rule requires that tune-ups be performed every two years. These sources should have the alternative to install and operate a CO/O₂ CMS trim system with tune-ups conducted on a four year schedule. This provides the same alternative as proposed for the larger sources subject to emission limitations.

Response: For a response to request for an alternative joint O₂ and CO monitoring option for all sources, please see comment EPA-HQ-OAR-2002-0058-3527-A2, excerpt 13.

The EPA disagrees with the commenter in that a unit less than 10 Mmbtu/hr may employ an O₂ trim system, but is still subject to the biennial tune-up requirement of the rule.

Comment: We strongly support removal of continuous emission monitors (CEMs) for particulate matter for biomass. Our continuous opacity monitors and proper operation of our control equipment assures very low particulate emissions.

Response: The EPA thanks the commenter for their support.

Commenter Name: Lee Zeugin and Lauren Freeman

Commenter Affiliation: Utility Air Regulatory Group (UARG)

Document Control Number: EPA-HQ-OAR-2002-0058-3500-A1

Comment Excerpt Number: 25

Comment: Under the 2011 final rule, units with a heat input rate greater than 250 MMBtu/hr from solid fuel and/or residual oil must install a particulate matter (“PM”) continuous emissions monitoring system (“CEMS”) to demonstrate compliance. 40 C.F.R. §§ 63.7510(d), 63.7525(b). In comments on the 2010 proposed rule, UARG objected to this requirement, pointing to EPA’s failure to consider the ability of PM CEMS to meet the required Performance Specification 11 (“PS 11”) criteria, or to accurately measure PM, at the levels of the proposed standards. EPAHQ-OAR-2002-0058-2880.1 at 51-54. Because EPA did not fully address or respond to UARG’s comments, UARG included the issue in its reconsideration petition. EPA-HQ-OAR-2002-0058-3324 at 16-17.

On reconsideration, EPA acknowledges commenters’ concerns regarding application of PM CEMS technology to various types of IBs, and concludes that for coal- and oil-fired IBs PM CEMS would best be employed as parametric monitors (*i.e.*, as a PM continuous parameter monitoring system or “PM CPMS”).¹⁴ 76 Fed. Reg. at 80,610/1. Under EPA’s new proposal, sources would be required to install and operate a PM CEMS, but would not be required to meet PS 11. Instead, sources would be required to establish during initial and periodic performance tests a site-specific operating limit in terms of the PM CPMS output, and to meet that operating limit on a 30-day rolling average basis. Proposed §§ 63.7510(d), 63.7525(b), and Table 8.

UARG appreciates EPA’s acknowledgment of the issues using PM CEMS under the final rule and supports EPA’s proposal to use the monitors as PM CPMS rather than to demonstrate compliance with an emission limit.

[Footnote]

(14) EPA also proposes to add an alternative total selected metals limit, which could be met using performance stack tests and operating parameters rather than PM CEMS. UARG supports addition of this option.

Response: The EPA thanks the commenter for their support.

Commenter Name: Stephen E. Woock

Commenter Affiliation: Weyerhaeuser Company

Document Control Number: EPA-HQ-OAR-2002-0058-3523-A1

Comment Excerpt Number: 17

Comment: We support EPA's decision to propose removing use of PM CEMS where previously required for solid fuel units with >250 mmBtu/hour heat input in the March 2011 final rule. EPA has recognized PM CEMS are not proven for the uses it was assigning them. In particular, the quality of biomass fuels can change from day to day and even hour to hour, depending on market source and availability. Mills often burn a mixture of fuels (green versus dry, top of the pile versus bottom of the pile, hardwood residuals versus softwood residuals, bark versus wood, etc.), and most often the fuels are not blended. In some cases, biomass is co-fired with fossil fuels. The reliability of PM CEMS and the ability to establish appropriate correlation curves across fuel types for these CEMS under constantly changing fuel conditions has not been demonstrated, thus EPA's requirement was unreasonable.

Response: The EPA thanks the commenter for their support.

Commenter Name: Heather Parent

Commenter Affiliation: Maine Department of Environmental Protection

Commenter Name: Lorraine Gershman

Commenter Affiliation: American Chemistry Council (ACC)

Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1

Comment Excerpt Number: 46

Comment: Beyond the objection to the practicality and cost of PM CPMS on these types of boilers, ACC is concerned about the requirement to limit the 30-day rolling average PM CPMS output data (milliamperes) to less than the operating limit established during the performance test (see Table 8, item 2c). As discussed below, ACC believes this requirement is unreasonable and would reduce operating flexibility of these boilers to an untenable level.

First, it imposes a much tighter operating envelope than even the final rule, which only required the 30-day rolling average to remain less than the emission standard (see § 63.7525(b)(3) of the Final Boiler Rule). At the very least, if EPA were to require these monitoring systems, they should allow the operating limit to be increased by the ratio of the allowable PM emission rate to the actual PM emission rate during the performance test.

Second, it does not account for variation in the measurement device output that is likely to occur during long-term operation. The fact that the measurement system is not held to some defined reference method will add to the uncertainty of the data. Even if it were held to PS-11, those specifications include a correlation coefficient of 0.85 between measured and predicted stack gas PM concentrations and the systems will have a high error band compared to the actual PM emission levels and indicate non-compliance when that is often not the case.

Response: The EPA recognizes that a source operating in continuous compliance is operating below their emissions limit at all times, and we therefore disagree with the commenter that use of PM CPMS reduces operating flexibility under this rule. The source operating parameter is tied to the average hourly output during a compliance test. This number is then used as a 30 day rolling average to allow for operational variability and flexibility as well as variation in the measurement device. While this operating level is, by definition, below the emissions limit of the rule, it is source specific and is expected to allow a well operated source the necessary flexibility to conduct normal operations and maintain compliance with the rule at all times. Allowing sources to exceed this value consistent with a ratio of allowable PM emissions is not technically possible as the instrument is not calibrated along a scale of PM emissions. Values

above and below the established operating limit are not measurements of PM concentration values, per se, but rather an indicator of PM concentration change. The rule does allow flexibility to use PM CEMS for continuous PM compliance should a source wish to measure PM continuously and use the full range of their PM emissions limit.

Commenter Name: Lee Zeugin and Lauren Freeman
Commenter Affiliation: Utility Air Regulatory Group (UARG)
Document Control Number: EPA-HQ-OAR-2002-0058-3500-A1
Comment Excerpt Number: 26

Comment: EPA's proposal to impose an enforceable site-specific operating limit based on output during a single short-term stack test remains flawed. A three-run performance test will not capture the variability in PM CPMS output that may occur during operations consistent with the PM limit, and setting a limit based on such a test will put sources at an unreasonable risk of noncompliance without any evidence that the PM limit has been exceeded. Although the proposed 30-day averaging period will add some flexibility, UARG is concerned it will not be sufficient and EPA has provided no data to suggest that it will be.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3510-A1, excerpt 46.

Commenter Name: David A. Buff, Golder Associates Inc.
Commenter Affiliation: Florida Sugar Industry (FSI)
Document Control Number: EPA-HQ-OAR-2002-0058-3504-A1
Comment Excerpt Number: 24

Comment: While the FSI supports EPA's proposal to give an affected source the option of using PM monitoring technology as a parametric monitor, which could be used to demonstrate compliance with operating limits, rather than emission limits, the FSI has some concerns over this approach. See 76 F.R. 80610; see also Section 63.7525(b) at 76 F.R. 80637. If a source must use, or chooses the option of using, a PM continuous parameter monitoring system (CPMS), the operating limit should be set at a level that is equivalent to the PM limit for the boiler, not at the PM emission rate experienced during the 3-run performance testing. The output of the PM CPMS must be expressed in milliamps, stack concentration, or other raw data signal. However, this raw data signal can be calibrated and/or correlated to the PM emissions during the testing. If the operating limit is set at the emission rate experienced during the performance testing, this is essentially setting a lower PM standard for that boiler.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3510-A1, excerpt 46.

Commenter Name: Melvin E. Keener
Commenter Affiliation: Coalition for Responsible Waste Incineration (CRWI)
Document Control Number: EPA-HQ-OAR-2002-0058-3454-A1
Comment Excerpt Number: 16

Comment: It is also unreasonable to limit the 30-day rolling average PM CPMS output data (milliamps) to less than the operating limit established during the performance test (see Table 8,

item 2c). This requirement would reduce operating flexibility of these boilers to an unacceptable level. It imposes a much tighter operating envelope than even the final rule, which only required the 30 day rolling average to remain less than the emission standard (see §63.7525(b)(3) of the March 21, 2011 final rule). At the very least, EPA should allow the operating limit to be increased by the ratio of the allowable PM emission rate to the actual PM emission rate during the performance test.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3510-A1, excerpt 46.

Commenter Affiliation: American Forest & Paper Association (AF&PA) et al.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 98

Comment: Beyond an overall objection to the practicality and cost of using PM CPMS on these types of boilers is the unreasonable requirement to limit the 30-day rolling average PM CPMS output data (milliamps) to less than the operating limit established during the performance test (see Table 8, item 2c). This requirement would reduce the operating flexibility of these boilers to an untenable level. First, it imposes a much tighter operating envelope than even the final rule, which only required the average PM CEMS output in lb/MMBtu to remain less than the emission standard (see §63.7525(b)(3) of the March 21, 2011 final rule). Second, it does not account for variation in the measurement device output that is likely to occur during long-term operation, especially with changes in fuel characteristics/fuel mix.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3510-A1, excerpt 46.

Comment Excerpt Number: 99

Comment: Even if an installed PM monitor were held to PS-11, those specifications include a correlation coefficient of 0.85 between measured and predicted stack gas PM concentrations and the systems will have a high error band compared to the actual PM emission levels and indicate non-compliance when that is often not the case. If these monitors are retained as parametric monitors in the final rule, EPA should not require sources to "certify" them and should allow operation at a signal level that is adjusted according to the unit's compliance margin with the applicable PM limit.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3510-A1, excerpt 46.

Comment: Beyond this overall objection to the practicality and cost of PM CPMS on these types of boilers is the unreasonable requirement to limit the 30-day rolling average PM CPMS output data (milliamps) to less than the operating limit established during the performance test (*see* Table 8, item 2c). This requirement would reduce operating flexibility of these boilers to an untenable level. First, it imposes a much tighter operating envelope than even the final rule, which only required the 30 day rolling average to remain less than the emission standard (*see* §63.7525(b)(3) of the March 21, 2011 final rule). At the very least, if EPA were to require these monitoring systems, they should allow the operating limit to be increased by the ratio of the allowable PM emission rate to the actual PM emission rate during the performance test. Second, it does not account for variation in the measurement device output that is likely to occur during long-term operation. The fact that the measurement system is not held to some defined reference method will add to the uncertainty of the data. Even if it were held to PS-11, those specifications include a correlation coefficient of 0.85 between measured and predicted stack gas PM concentrations and the systems will have a high error band compared to the actual PM emission levels and indicate non-compliance when that is often not the case.

Comment Excerpt Number: 28

Comment: Rather than use the PM CPMS output to set a not be exceeded limit, EPA should rely on the approach taken in the Compliance Assurance Monitoring (“CAM”) rule under Part 64 and require sources to establish a site-specific operating parameter baseline above which the owner or operator must investigate and, if necessary, take corrective action. This approach already has been upheld as sufficient to satisfy the CAA’s requirements for demonstrating continuous compliance. *See NRDC v. EPA*, 194 F.3d 130, 135-37 (D.C. Cir. 1999) (rejecting NRDC’s argument that the CAM rule’s “reasonable assurance of compliance” is not sufficient to assure continuous compliance as required by the CAA). EPA has taken a similar approach in at least one New Sources Performance Standard (“NSPS”) where the combination of controls makes monitoring compliance using traditional methods unreasonable. *See, e.g.*, 40 C.F.R.

§ 60.48Da(o)(2) (requiring establishment of a 24-hour average opacity baseline above which appropriate action is required). Such an approach would ensure that controls are operated consistent with the applicable PM limit without imposing unnecessary and unreasonable risk of noncompliance.

Response: The EPA agrees with the commenter and has revised the rule language to reflect this approach.

Comment Excerpt Number: 56

Comment: EPA has proposed to delete the requirement that compliance monitors for PM limits conduct annual RATA testing to demonstrate the accuracy of the results. NACAA opposes this proposal as it will diminish the protectiveness of the standards and potentially render the standard unenforceable.

Response: The EPA disagrees with the commenter in that we have retained PM CEMS compliance options that use PS-11 RATA testing in the rule. We have also included continuous PM compliance with PM CPMS monitoring using reference method stack testing to prove compliance with the rule and establish 30-day rolling average operating limits. We consider that both of these approaches will provide equivalent protection and compliance with the standard under the rule.

Document Control Number: EPA-HQ-OAR-2002-0058-3527-A2

Comment Excerpt Number: 14

Comment: Under the MACT rule certain sources were required to continuously monitor particulate emissions using a certified continuous emissions monitoring system (CEMs). EPA is now proposing that this requirement be replaced by a continuous particulate monitoring which is calibrated according to accurately measure emissions but which is not subject to the rigorous CEMs certification requirements and cost. Basically, the particulate monitoring is implemented as a parametric monitoring system. The Department supports EPA's approach to minimizing continuous monitoring requirements from a PM CEMS to a non-certified PM continuous monitoring system (PM CMS). The Department further believes that with direct PM CMS a source should only be required to stack test particulate every two years. This is especially true if the source is performing parametric monitoring of an activated carbon injection system which positively controls both mercury and non-mercury metals. In place of PM CMS monitoring we believe it is sufficient for a source to stack test annually then we believe parametric monitoring of ESP or fabric filter systems is sufficient. We believe a source should be provided the alternative of a PM CMS with biennial stack testing or parametric monitoring of particulate control devices along with annual stack testing. The Department believes that a source should be subject to biennial stack testing instead of annual stack testing when the pollutant is continuously monitored by a CMS or parametric monitoring of control equipment which positively reduces emissions of the pollutant in question (metals, mercury, CO) for a pollutant which has been demonstrated by the source to correlate with the pollutant in question.

Response: The EPA thanks the commenter for their support of using PM CPMS, but disagrees with the commenter that biannual testing is sufficient for setting and validating the operating parameter. An annual compliance test is necessary to update the parametric monitor with new information about the PM emissions as related to differences in fuel and control device operations over time.

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 85

Comment: PM CEMS have not been demonstrated for use on biomass or on other installations where fuel type, production rate or other characteristics of the emissions are changing. CIBO appreciates the fact that EPA recognizes that PM CEMS cannot effectively be used to measure particulate emissions accurately. However, EPA is proposing use of this instrument as a PM CPMS. However, for the same reasons that a PM CEMS is not practical for use in measuring PM, the PM CPMS will not provide any meaningful correlation to emissions or control device effectiveness and therefore is a technically inappropriate choice. In addition to the fact that a PM CPMS will not correlate with emissions and cannot be used effectively in a PM CPMS, it is much more costly than devices that can perform the same function. Thus, EPA must abandon its proposal to require PM CEMS technology for a PM CPMS.

Response: The EPA disagrees with the commenter that PM CPMS cannot be used effectively to monitor emissions continuously. The EPA has a long history of using continuous parametric monitoring in a wide variety of rules and has found the use of such monitoring to be effective in reducing source emissions through improving operational control monitoring..

Commenter Name: Robert D. Bessette

Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 91

Comment: For the same reasons that it is not feasible to develop a meaningful correlation between the emissions being monitored by the PM CEMS instrument and particulate emissions in the stack, using the PM CEMS instrument technology as a PM CPMS will produce no repeatable and no meaningful results in situations where the characteristics of the stack emissions change due to changes in fuel mixtures, production rates and instrument correlation issues.

The output from a PM CPMS based on a PM CEMS instrument will simply be meaningless. Any time the fuel mixture changes, the instrument will go out of range even with no change to control device effectiveness or any meaningful change to emissions. This means that requiring use of a PM CPMS would be a very expensive waste of capital resources and would send both the regulated industry and the regulatory agencies on meaningless goose chases. Put quite simply, this technology will not work for its intended purposes.

Commenter Name: Robert D. Bessette

Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 87

Comment: In the proposed Reconsidered Rule, PM CPMS has replaced the requirement of a PM CEMS. CPMS is not optional for sources >250 MMBtu. Although EPA altered the monitoring requirement, it is still onerous and not necessary to demonstrate compliance. The CPMS equipment is the same as the prior CEMS requirement, which is a major capital installation not justified by any additional environmental or compliance benefit beyond other PM monitoring systems.

The PM limits for solid fuel boilers range from 0.028 lbs/mmbtu for stoker boilers to 0.088 lbs/mmbtu for fluidized bed boilers. Almost all fluidized bed boilers in the country have been permitted since the effective date of the 40 CFR Part 60 Subpart Db NSPS and will have allowable limits for PM no higher than 0.05 lbs/mmbtu. Also, since most new solid fuel boilers would also have been permitted under PSD or non-attainment NSR, their allowable limits are likely more in the range of 0.02 – 0.03 lbs/mmbtu. As such, COMs supplemented with bag leak detectors and pressure drop monitoring are perfectly adequate to prevent any exceedance of the existing allowable standards much less, the 0.088 lbs/mmbtu proposed for the MACT. The addition of a CPMS will be a needless expense and will offer no benefit. Likewise, stoker and PC boilers can be, and are in practice, adequately monitored by COMs and parametric monitoring.

Response: The EPA believes a PM CPMS can produce data indicative of trends and changes in emissions, as well as be effective in monitoring control device performance. Additionally, the final rule now allows most boilers options when measuring PM. For instance, boilers with an average heat input greater than 250 MMBtu/hr, that burn coal or liquid/gas for fuel, have the option of using either PM CEMS or PM CPMS. Boilers with an average heat input of less than or equal to 250 MMBtu/hr have the option to measure PM with a PM CEMS, a PM CPMS, or to conduct periodic testing, regardless of fuel. If a source feels that one option is not suitable or practical for their unit, then the source is encouraged to select the option most applicable to their specific site. COMS and other CPMS are optional for units below 250 MMBtu.

Commenter Name: Robert D. Bessette
Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)
Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1
Comment Excerpt Number: 92

Comment: PM CEMS are not technically effective across a range of conditions as discussed above and are a very expensive method for achieving EPA's objective of assuring ongoing compliance with Boiler MACT and CISWI requirements. Costs¹⁸ for the light scattering PM CEMS, which is lower operating and maintenance costs vs the Beta Attenuation technology was estimated by EPA contractor data to cost between \$103,000 to 133,000 in 2004, with substantial annual operating costs as shown below. [See submittal for Table 3]

The above costs are high in and of itself. However, these costs do not include what might be required to establish correlation curves for multiple fuel and work to try to find a way to make this technology work effectively in scenarios it has never been successfully applied. Given the range of fuels, production rates and other variables in a given installation that would have to be accounted for, this cost is believed to be a small fraction of the true cost for applying this technology.

There are much more effective tried and true technologies that are currently used for assuring compliance that have been demonstrated to be effective in a variety of situations. For example, bag leak detection systems, baghouse pressure drop and many other technologies which EPA has included in their Compliance Assurance Monitoring Guidance would be much more effective and accurate indicators of problems with control technology. These tried and true and less costly approaches should be adopted to assure compliance. EPA should not force industry to use an unproven technology which is unlikely to be effective in a variety of situations when a simpler more elegant technological solution is already at hand.

For the above reasons, EPA must abandon its proposal to use PM CPMS as an indicator of effective operation.

Commenter Name: Robert D. Bessette
Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)
Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1
Comment Excerpt Number: 93

Comment: As an alternative to the extremely expensive particulate matter CEMS installation EPA proposes, EPA should allow the installation and operation of bag leak detection systems in accordance with the proposed rule's §63.7525(j)(1) through (8) in addition to the existing opacity monitors and pressure drop monitoring. The bag leak detection system provides ongoing

monitoring of the bag house component performance and provides for continuous compliance demonstration.

Method 5 stack testing is performed at the rated capacity of the boiler. At this rated capacity, all systems for particulate control are maximized as well (e.g., the air/cloth ratio in the baghouse, the ID fan output, ductwork losses, etc.). Hence, for particulate matter, stack testing conditions are the worst case operating conditions. At lower loads, the basic design parameters for the particulate collection system and for the combustion air management are not as taxed so it would be reasonable to expect that at lower loads, particulate emissions on a lb/MMBTU basis would be lower than the stack test. If all systems that were operating during the stack test continue to operate properly during normal operation, continuous compliance with the stack test can be determined due to the nature of particulate matter emissions behavior. One CIBO member already operates and maintains PS1 certified opacity monitors on all three units as well as monitoring baghouse pressure drop.

Commenter Name: Steve Gossett

Commenter Affiliation: Eastman Chemical Company

Document Control Number: EPA-HQ-OAR-2002-0058-3669-A2

Comment Excerpt Number: 18

Comment: Eastman has seven coal fired boilers at its Tennessee Operations (TNO) that are larger than 250 MMBtu/hr. These seven units, which range in size from 65 MWe to 88 MWe (electrical equivalent basis), are significantly smaller than a typical EGU and would have a commensurately smaller impact on the environment and human health. Eastman's 2011 engineering analysis of MACT control technologies for its fleet at TNO included estimating the cost of installing PM CEMS on its larger coal fired boilers. Based on budgetary quotations for SICK Maihak FWE 200 monitors and the estimated cost to install them on these seven units, the total installed cost was estimated at \$2.25 million. In addition to the capital cost, Eastman further estimated that the labor to maintain the instruments, provide quality assurance of the data, and coordinate stack testing would exceed \$100,000 per year. Eastman believes the state of Tennessee would, in absence of any guidance from EPA to the contrary, refer to PS-11 for certification given that this test method is the only accepted reference method. The cost of mobilizing a third-party testing firm to conduct a certification test would easily exceed \$30,000 per event, in addition to the internal labor required to support such testing. Given these significant capital and ongoing costs, and considering how much smaller Eastman's seven units are compared to a typical EGU, Eastman believes the requirement to install a PM CPMS to be unreasonably burdensome.

Commenter Name: Steve Gossett

Commenter Affiliation: Eastman Chemical Company

Document Control Number: EPA-HQ-OAR-2002-0058-3669-A2

Comment Excerpt Number: 20

Comment: Finally, if EPA is concerned that some method of parametric monitoring is necessary to ensure that sources adopt good practices to operate and maintain their particulate collectors, any number of lower cost alternatives exist to mandating the use of expensive particulate monitors. Most obviously, sources can use opacity monitoring systems, as has been the practice across many industries for decades. Units equipped with precipitators can monitor total power (e.g. based on secondary voltage and current), limits for which could be established during a performance test where the source successfully complies with the PM standard applicable for the unit. Units with fabric filters should be offered the flexibility to use bag leak detection systems, monitoring of cleaning cycles, or compartment pressure drop in lieu of a PM CPMS, which would provide real-time feedback of the performance of the FF at a fraction of the cost. Given that alternative methods to produce real-time monitoring and feedback of the PM collector efficiency exist, and at dramatically lower costs than PM CPMS or PM CEMS, EPA should give sources the flexibility to comply using less expensive and burdensome technologies.

Commenter Name: Douglas A. McWilliams

Commenter Affiliation: American Municipal Power

Document Control Number: EPA-HQ-OAR-2002-0058-3685-A2

Comment Excerpt Number: 43

Comment: This arbitrary decision to require PM CPMS for coal- and oil-fired units >250 mmBtu/hr is particularly problematic considering that these units already employ continuous monitoring devices to comply with the Compliance Assurance Monitoring ("CAM") provisions of 40 C.F.R. § 64. AMP's municipal utilities are also required to have continuous opacity monitoring ("COM") systems that monitor PM control device performance. COMs monitor particulate matter in flue gas streams by sending a beam of light through the flue gas and

measuring the attenuation caused by particles in the flue gas. Certain PM CEMs use a similar light absorption technique, or other optical techniques, to generate PM readings.⁴³ PM CPMS also use principles of light scatter to monitor PM emissions.⁴⁴ EPA has relied on COMs readings, combined with periodic stack testing, to monitor compliance with PM limits for decades. EPA also proposes to rely on these readings to ensure continuous compliance with the Boiler MACT requirements for units not subject to the PM CPMS requirement. Regulated units have already installed this equipment and are familiar with its maintenance and operation. Requiring a PM CPMS, in addition to COMs that are already installed and relied upon by the Agency, in addition to annual PM stack testing, is arbitrary and unreasonable and places an unnecessary burden on municipal utilities without any environmental benefit.

Document Control Number: EPA-HQ-OAR-2002-0058-3451-A1

Comment Excerpt Number: 14

Comment: The elimination of PM CEMS as a direct measure of compliance is appropriate and necessary. As stated in our prior comments, the PM CEMS is an unproven technology for use on industrial boilers. It is particularly unsuited to biomass boilers and multifuel boilers, and we support EPA's recognition of these facts. However, as noted above, the proposed use of PM CEMS for parametric monitoring is also inappropriate for industrial boilers and is unjustifiably burdensome and costly. The reasons such data are unreliable and inappropriate for use as a direct measure are the same reasons it is unreliable and inappropriate for parametric monitoring.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 87.

Commenter Name: Douglas A. McWilliams

Commenter Affiliation: American Municipal Power

Document Control Number: EPA-HQ-OAR-2002-0058-3685-A2

Comment Excerpt Number: 42

Comment: However, AMP does not support EPA's replacement of the PM CEM obligation with a PM CPMS obligation for coal- and oil-fired units of this size. Requiring a PM CPMS in lieu of a PM CEM does not resolve any of the issues pointed out by petitioners in prior comments.

EPA has offered no justification for requiring any type of additional PM monitoring for coal- and oil-fired units greater than 250 mmBtu/hr. All other units are subject to less burdensome operating limits (such as opacity limits, bag leak detection requirements, and primary and secondary voltage requirements), and have the option to use PM CPMS in lieu of these other

monitors. EPA has determined that these other monitoring parameters are sufficient to ensure continuous compliance with the emission limits. There is no justification for requiring the installation of an additional, expensive monitor for coal - and oil-fired units >250 mmBtu/hr when there is no evidence that the monitoring requirements applicable to other units are insufficient for units of this size. Because EPA can articulate no rationale for making PM CPMS optional for some units and mandatory for others, this requirement is arbitrary and should be eliminated. Instead, installation of a PM CPMS should be optional for all units in the final rule.

Response: The EPA agrees and has modified the rule to allow PM CPMS for continuous PM emissions compliance for all affected units.

Commenter Name: Robin Mills Ridgway

Commenter Affiliation: Purdue University

Document Control Number: EPA-HQ-OAR-2002-0058-3668-A2

Comment Excerpt Number: 2

Comment: Purdue asks EPA to confirm that only boilers having an average annual heat input of greater than 250 MMTU/hr need to install a PM CPMS for particulate throughout the repropose rule (e.g., §63.7510(d)). In §63.7575, EPA defines average annual heat input as the annual heat input divided by the number of operating hours for the year preceding the compliance determination. Purdue suggests that this value be determined not from the preceding year, but by using three consecutive years beginning **after** the compliance date to determine average annual heat input. As Purdue experienced during construction work for Boiler MACT I (2004), operating hours in the years preceding the compliance date may not be typical of normal operations due to MACT compliance construction activities.

Response: The final rule requires units combusting solid fossil fuel or heavy liquid with heat input capacities of 250 MMBtu/hr or greater to install, certify, maintain, and operate particulate matter (PM) continuous parameter monitoring systems (CPMS). Moreover, owners or operators of units combusting solid fossil fuel or heavy liquid with heat input capacities of 250 MMBtu/hr or greater are allowed to install, certify, maintain, and operate PM CEMS as an alternative to the use of PM CPMS, since similarly-sized commercial and industrial solid waste incinerators (CISWI) units and electrical generating units (EGUs) subject to the mercury air toxics standards (MATS) are able to use PM CEMS as an alternative to PM CPMS. Just as units using PM CPMS will not be required to conduct parameter monitoring for PM, units using PM CEMS will not be required to conduct parameter monitoring for PM.

Commenter Affiliation: Eastman Chemical Company

Document Control Number: EPA-HQ-OAR-2002-0058-3669-A2

Comment Excerpt Number: 47

Comment: Issue #2: EPA is clarifying that emissions averaging cannot include units using a CEMS or PM CPMS.

Comment Summary: Units using CEMS for compliance should be allowed to utilize the emissions averaging provisions for compliance with no discount factor applied.

In Section 63.7522(b)(1), EPA added and is taking comment on a new provision stating "You may not include in an average units using a CEMS or PM CEMS for demonstrating compliance, even if the use of a CEMS or PM CEMS is optional."

EPA is proposing this restriction on use of CEMS for emissions averaging without explaining the basis for the restriction. Moreover, this restriction is in direct conflict with the emissions averaging provisions in the Utility MACT (§63.10009). EPA should provide industrial and institutional facilities at least the same flexibility it provides electric utilities. This restriction would discourage the use of CEMS (where they are optional) in cases where a source elects to utilize emissions averaging. EPA should encourage use of CEMS, which provide a much more accurate estimate of actual emissions than periodic emissions tests. We see no valid reason for such restriction and request that the emissions averaging provisions be revised similar to the Utility MACT, to accommodate use of CEMS or sorbent traps.

Response: The EPA agrees with the commenter and has revised the rule to allow emissions averaging for facilities using CEMS to demonstrate compliance.

Commenter Name: Cheryl Suttman

Comment Excerpt Number: 5

Comment: PM CEMS were removed from the previous version of the boiler MACT. Can PM CEMS and Performance Specification 11 (e.g. a method of compliance in NSPS Subparts Da and Db) still be used to demonstrate compliance with the PM standards in Subpart DDDDD? Losing the option or requirement to use PM CEMS and Performance Specification 11 (PS 11) for certification was unexpected.

Or are PM CEMS simply a type of PM CPMS and the proposed amendment is allowing for other types of PM monitoring devices?

Response: The EPA is including PM CEMS calibrated and certified with PS-11 as a compliance option in the final rule.

Commenter Name: Lorraine Gershman

Commenter Affiliation: American Chemistry Council (ACC)

Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1

Comment Excerpt Number: 44

Comment: *PM CEMS*

EPA is proposing to employ PM CPMS rather than emissions compliance monitoring (CEMS). This proposal places sources in an untenable position if they are required to install, certify, and operate these monitoring systems. While EPA states these monitors do not have to comply with Performance Specification 11, presumably to reduce compliance burden, , EPA's proposed rule language requires the same host of requirements in a site-specific monitoring plan as any other continuous monitoring system (see § 63.7540(a)(9) and § 63.7505(d)).

ACC is not clear on how a source should "certify" their PM CPMS other than through the use of PS-11. EPA apparently recognizes that the burden of complying with PS-11 is unreasonable for coal-fired ICI boilers as it states in the 2010 Proposed Boiler Rule preamble at p. 80610. While EPA has required PM CEMS in the final MATS, those boilers are many times larger than ICI boilers with commensurately larger PM emissions and associated impact. They also operate at relatively steady loads compared to ICI boilers that have to respond to frequent load swings. ACC requests EPA remove from the final rule the requirement to install PM CPMS monitoring for boilers larger than 250 MMBtu/hr. Before requiring such a substantial monitoring burden on ICI sources, EPA should further evaluate these systems via field studies to determine the real-world performance.

Response: The final rule requires the source to develop a site specific monitoring plan (SSMP) for all continuous monitoring systems, including a PM CPMS. In the case of a PM CPMS, the monitor is used as a parametric monitor and not an emissions monitor and the source is allowed to determine the performance acceptance criteria and performance evaluation procedures that are appropriate for their specific stack conditions and process operations. Then the source conducts the performance evaluation as per the site specific monitoring plan. The SSMP does not require that PS 11 be used for the performance evaluation. Other methods to evaluate the performance of CPMS are available. For example, audit materials, vendor laboratory testing, etc. could be reasonable methods. Operation, maintenance, and QA/QC procedures are also developed specifically for each site. All of these requirements may be less rigorous than those for PM CEMS and are custom designed to be appropriate and practical for the site's own conditions.

The EPA has recently issued a memo on the capabilities of PM CEMS. That memo from Connie Oldham to Bob Schell, dated June 13, 2012, states that developing an acceptable PM CEMS correlation on a unit with very low emissions, or that burns multiple fuels, is possible but requires special care. For instance, one must select the best technology available for the job. The EPA has reviewed the study conducted by Georgia-Pacific and NCASI and would like to point out that the GP testing was done using only light scattering, or "backscattering" technology. If a source owner is concerned about the ability of a light based PM CEMS to meet the requirements of PS 11 because of variable physical characteristics of particles in the stack, there is at least one other PM CEMS technology based more directly on mass measurement rather than on the light scatter or "backscattering" technology.

Technical limitations of PM CEMS for a specific site do not mean that the technology cannot be used to monitor for compliance. The EPA believes a PM CPMS can produce data indicative of trends and changes in emissions, as well as be effective in monitoring control device performance. Additionally, the final rule now allows most boilers options when measuring PM. For instance, ERUs with an average heat input greater than 250 MMBtu/hr, that burn coal or liquid/gas for fuel, have the option of using either PM CEMS or PM CPMS. (However, large boilers that burn biomass are required to install PM CPMS.) Boilers with an average heat input of less than or equal to 250 MMBtu/hr have the option to measure PM with a PM CEMS, a PM CPMS, or to conduct periodic testing, regardless of fuel. If a source feels that one option is not suitable or practical for their unit, then the source is encouraged to select the option most applicable to their specific site.

Comment: How are PM CPMS certified? §63.7525(b)(1) requires the PM CPMS to be installed, certified, operated, and maintained in accordance with the site-specific monitoring plan, required per §63.7505(d), which in turn identifies §63.8(d). [And §63.8(e) for performance evaluations of CMS says the same, i.e., follow the plan.]

40 CFR 63.8(d) does not specify the individual Performance Specifications; but in §63.8(c)(6) it states that CPMS must be “calibrated prior to use” and “checked daily...”.

Do PM CPMS only need to be calibrated according to the manufacturer’s instructions, and if they are not technically certified, could “certified” be changed to “calibrated” in §63.7525(b)(1)?

Response: See the response to comment EPA-HQ-OAR-2002-0058-3510-A1, excerpt 44.

Comment: The PM CPMS provisions should be modified.

EPA is proposing to remove the requirement to install PM CEMs on biomass boilers and to modify the particulate matter (PM) continuous monitoring requirements for coal-fired boilers so they can be used as parametric monitors rather than emissions compliance monitors (76 Fed. Reg. at 80,609). EPA’s logic for removing the PM CEMs requirement for biomass boilers is based on the inability to calibrate these instruments. EPA logic for changing the requirements for coal-fired boilers is based on commenter’s concerns over the readiness of current PM CEMs technology and the technical effort and cost for recertification. EPA’s proposal places coal-fired boilers in a difficult position. On the one hand, EPA states these monitors do not have to comply with Performance Specification (PS) 11, while on the other hand, EPA’s proposed rule language requires the same host of requirements in a site-specific monitoring plan as any other continuous monitoring system (see §63.7540(a)(9) and §63.7505(d)). Without an EPA-approved

performance specification, how can a source possible "certify" a monitoring system? EPA apparently recognizes that the burden of complying with PS-11 is unreasonable for industrial boilers. However, the proposed rule has created a second problem of how to certify an instrument without a performance specification.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3510-A1, excerpt 44.

Comment Excerpt Number: 17

Comment: D.2. PM CEMS Comment Summary: PM CPMS should be removed from the rule. It is unworkable for EPA to require certification of these systems with no agreed performance specification. Despite these points, if EPA maintains this requirement, it must allow for an adjustment of the operating limit demonstrated during the performance test.

EPA's proposal places sources in an untenable position if they are required to install, certify, and operate these monitoring systems. While on the one hand, EPA states these monitors do not have to comply with Performance Specification 11, presumably to reduce compliance burden, on the other hand, EPA's proposed rule language requires the same host of requirements in a site-specific monitoring plan as any other continuous monitoring system (*see* §63.7540(a)(9) and §63.7505(d)). Without an EPA-approved performance specification, how can a source possible "certify" a monitoring system? EPA apparently recognizes that the burden of complying with PS-11 is unreasonable for coal-fired industrial and institutional boilers as it states in the preamble. Although EPA has required PM CEMS in the Utility MACT, those boilers are many times larger than ICI boilers with commensurately larger PM emissions and associated impact. They also operate at relatively steady loads compared to industrial and institutional boilers that have to respond to frequent load swings. We request EPA remove from the final rule the requirement to install PM CPMS monitoring for coal-fired boilers larger than 250 mmBtu/hr. We are aware of only one facility in the country other than an electric utility that operate PM CEMS on coal-fired boilers. This facility is more akin to an electric utility as the four boilers range in size from 165 MW to 320 MW, the facility sells electricity, and the boilers are base-loaded without load swings. Before requiring such substantial monitoring burden on industrial and institutional sources, EPA should further evaluate these systems via field studies to determine the real-world practicality.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3510-A1, excerpt 44.

11C02. PM CPMS: Applicability

Commenter Name: Ashok K. Jain

Commenter Affiliation: National Council for Air and Stream Improvement, Inc. (NCASI)

Document Control Number: EPA-HQ-OAR-2002-0058-3505-A1

Comment Excerpt Number: 3

Comment: Removing PM CPMS requirements for biomass and multi-fuel units are based on the findings of a recent study carried out by Georgia-Pacific and NCASI [See submittal for Attachment 1]. This study consisted of installing PM CEMS, operating on the light scattering principle, on multi-fuel boilers at two different facilities. During this study, calibration testing was performed for both PM CEMS, and a follow-up Relative Response Audit (RRA) was also carried out on both PM CEMS. Two different fuel mixtures were burned during the calibration testing for each PM CEMS, and fuel mixtures burned during the RRA were slightly different than those combusted during the calibration testing. Although the two monitoring systems worked reasonably well and required minimal routine maintenance, the study identified two major problems with the backscattering monitoring system:

1. The relationship between stack gas PM concentration as measured by the PM CEMS and the manual reference method varied when the fuel mixtures were changed. This resulted in several different calibration equations for different fuel combinations. 2. The PM monitoring system also failed to meet EPA's relative response audit criteria when the monitoring system was tested three months after the initial installation and calibration. In addition to the PM monitoring instrument calibration issue, the study also identified significant challenges associated with (a) calibrating stack PM monitors when a source is operating at very low stack gas PM concentrations, and (b) reporting stack PM emissions as lb/MMBtu heat input. These challenges include:

- High variability in EPA Method 5 measured values observed during tests when dual sampling trains are used simultaneously on a stack with low PM concentrations.
- Difficulty associated with determining instantaneous flow rates of individual fuels in multi-fuel boilers due to the time delay between monitoring fuel flow rate and its firing in the boiler.
- Integrating, maintaining, and calibrating ancillary monitoring equipment required for determination of PM emission rates.
- Complexity of converting stack gas PM concentration to the PM mass emission rate in lb/MMBtu when burning multiple fuels at varying rates.

The findings of this study support EPA's conclusion that the currently available stack gas PM monitors are not capable of being used as compliance monitors on biomass boilers. The study results also show that because the relationship between stack gas PM concentration and instrument response varies with fuel mix, in order to develop a parameter which would indicate that the source was in compliance with the PM standards, the facility would have to carry out PM CPMS calibration tests using every possible fuel combination and fuel ratio. This would require months of testing with varying fuel mixes and would be very expensive and disruptive to a facility's operation. Even after carrying out such a study, the facility would not be able to establish a parameter not to be exceeded during routine operations to ensure compliance with the PM emission standards, thus eliminating the feasibility of using such monitors as CPM devices.

The results of the G-P/NCASI study also raise significant doubts regarding the feasibility of installing and calibrating a PM CPMS on coal-fired boilers which burn other fuels such as petroleum coke, sludge, OCC rejects, TDF, and biomass.

We therefore recommend that EPA should modify the requirement to install PM CPMS and make it applicable only to fossil fuel boilers burning only one kind of fossil fuel. The

requirements should not apply to biomass boilers or multi-fuel fossil-fuel boilers due to the difficulty in developing a stack parameter which could be used as the threshold for maintaining compliance with the standard.

Response: The EPA acknowledges the potential limitations of the light backscatter technology with respect to multiple fuels. The EPA believes that no other technologies commercially available would have been better suited for the application of multiple fuel boilers. It should also be noted that when the low concentrations were measured co-located versus just time synced that the variability between paired trains was greatly reduced. The EPA disagrees that PM CPMS is not viable technology to use as a parametric monitor for sources burning multiple fossil fuels.

Commenter Name: Randall D. Quintrell

Commenter Affiliation: Georgia Paper & Forest Products Association

Document Control Number: EPA-HQ-OAR-2002-0058-3451-A1

Comment Excerpt Number: 5

Comment: The proposed requirement to use PM CEMS as parametric monitoring for larger units burning fossil fuel also is unwarranted. The use of total power for electrostatic precipitators, scrubber operating parameters, and/or opacity as a means of demonstrating good operation of control devices is sufficient and proven for parametric monitoring, and these provide the compliance assurance required. The installation, operation and maintenance of PM CEMS, even without certification, is extremely burdensome, expensive and unnecessary. The reasons such data are unreliable and inappropriate for use as a direct measure are the same reasons it is unreliable and inappropriate for parametric monitoring. Bad data is bad data, no matter what the end use.

Response: The EPA disagrees with the commenter that PM CEMS as parametric monitors would not be indicative of trends and changes in emissions in addition to being effective as a control monitoring device.

Commenter Name: Melvin E. Keener

Commenter Affiliation: Coalition for Responsible Waste Incineration (CRWI)

Document Control Number: EPA-HQ-OAR-2002-0058-3454-A1

Comment Excerpt Number: 17

Comment: All of this seems to point out the uncertainty over the use of PM CEMS for this source category. CRWI suggests that until all this uncertainty can be worked out, EPA should remove the PM CEMS requirement for both biomass boilers and coal-fired boilers. The Agency should conduct field studies on these instruments to determine their real-world practicability. After further evaluation of these systems, the Agency may be able to clear up these uncertainties associated with these instruments on these sources and create clear methods for certifying and operating these types of instruments.

Response: For a response to general opposition to PM CEMS requirements, please see comment EPA-HQ-OAR-2002-0058-3451-A1, excerpt 5.

Commenter Affiliation: American Municipal Power

Document Control Number: EPA-HQ-OAR-2002-0058-3685-A2

Comment Excerpt Number: 45

Comment: Units Employing CEMS or PM CPMS Should Not Be Excluded From Emissions Averaging

In the Proposed Rule, EPA established a new provision excluding units employing a CEMS or PM CPMS from participating in emissions averaging. EPA offered no explanation for this exclusion. Sources using the stack testing option have the ability to extrapolate their test results over a 30-day period using operating data, and establish 30-day averages that can be compared to the data for units operating continuous monitoring systems. Furthermore, EPA allowed units with CEMS to participate in emissions averaging in the recently finalized Utility MACT rule .48 EPA should provide the smaller municipal utilities operated by AMP members subject to Boiler MACT with at least the same flexibility it provides the much larger electric generating units subject to the Utility MACT rule. EPA should not discourage the use of CEMS (where they are optional) in cases where a source elects to utilize emissions averaging. It also unnecessarily restricts emissions averaging among fossil fuel fired units to those of 250 MMBtu/hr or less, due to the PM CPMS restriction. EPA should not discourage use of CEMS as a compliance option or limit emissions averaging to smaller sources. On the contrary, EPA should provide sources that use a continuous direct measure of emissions with more flexibility, not less, than sources using periodic stack testing and parameter monitoring.

[Footnote 48: *See* 40 C.F.R. §63. 10009 (not yet published).]

Response: The EPA agrees with the commenter and has revised the rule to allow emissions averaging for facilities using CEMs to demonstrate compliance.

Commenter Name: Eric Guelker, Alliant Energy Corporate Services, Inc.

Commenter Affiliation: Interstate Power and Light Company (IPL) and Wisconsin Power and Light Company (WPL), Alliant Energy Corp.

Document Control Number: EPA-HQ-OAR-2002-0058-3492-A1

Comment Excerpt Number: 6

Comment: Alliant Energy appreciates that the EPA has considered the PM CPMS as an alternative to the PM CEM requirement. However, we still believe that this requirement is too restrictive and that EPA should provide sources the flexibility to determine the most appropriate continuous compliance method (CEM, CPMS fuel analysis or stack testing). Therefore, we request that the EPA should allow performance stack testing as another additional compliance option in this rule, similar to what is in the final MATS.

Response: The EPA thanks the commenter for their support of PM CPMS as an alternative to PM CEMS. For a response to the request that the EPA should allow sources more flexibility in determining the most appropriate compliance method, please see comment EPA-HQ-OAR-2002-0058-3685-A2, excerpt 45.

Commenter Name: Dirk J. Krouskop

Commenter Affiliation: MeadWestvaco Corporation (MWV)

Document Control Number: EPA-HQ-OAR-2002-0058-3493-A1

Comment Excerpt Number: 15

Comment: MWV supports EPA's decision to not require PM CEMs monitoring for biomass units. MWV does not believe there is enough proven application of these systems on biomass units and that they are unnecessary with the other continuous parametric monitoring systems that EPA has discretion to require. In fact, MWV believes that EPA has the discretion to remove this requirement for coal fired boilers as well for the same reasons and should do so.

Response: The EPA thanks the commenter for their support of the removal of PM CEMS requirements for biomass-fired boilers. The requirement for coal-fired boilers to install a PM CEMS was replaced in the proposal with the requirement to install a PM CPMS.

Commenter Name: David A. Buff, Golder Associates Inc.

Commenter Affiliation: Florida Sugar Industry (FSI)

Document Control Number: EPA-HQ-OAR-2002-0058-3504-A1

Comment Excerpt Number: 25

Comment: It should be clarified in the final Boiler MACT Rule that a PM CPMS is never required for a biomass-fired unit, even when that unit also burns fossil fuels. The rule currently requires a PM CPMS if a unit (including a unit designed to burn biomass) has an average annual heat input rate of 250 MMBTU/hr for fossil fuel. See 63.7525(b).

Response: We agree with the commenter that PM CPMS was not intended to be required for units that are in any of the biomass subcategories. 63.7525(b) has been revised to clarify that the requirement only applies to units in the coal or heavy liquid subcategories.

Commenter Name: Lorraine Gershman

Comment Excerpt Number: 97

Comment: If the PM CPMS requirements aren't removed, EPA should provide clarification that multi-fuel units and units in the biomass subcategories do not have to install PM CPMS, even if they fire more than 250 MMBtu/hr of fossil fuel.⁴⁵ EPA discusses at 76 Fed. Reg. 80609 the reasons why these monitors cannot be feasibly applied to biomass units:

[Footnote 45: Despite EPA pronouncements suggesting biomass units would not be subject to the PM CPMS provisions, rule language at 63.7525(b) fails to exclude biomass units that also fire fossil fuels at more than 250 MMBtu/hr on an average annual basis.]

Response: For a response to the request that biomass units should not be required to install PM CPMS even if co-fired with more than 250 MMBtu/hr of fossil fuel, please see comment EPA-HQ-OAR-2002-0058-3504-A1, excerpt 25. For a response to the request that multi-fuel units should be exempt from PM CPMS requirements, please see comment EPA-HQ-OAR-2002-0058-3505-A1, excerpt 3.

Commenter Name: Ashok K. Jain

Commenter Affiliation: National Council for Air and Stream Improvement, Inc. (NCASI)

Document Control Number: EPA-HQ-OAR-2002-0058-3505-A1

Comment Excerpt Number: 2

Comment: We are concerned about the requirements in section 63.7525 (b) where EPA has proposed that all boilers with an average annual heat input rate greater than 250 MMBtu per hour from solid fossil fuel and/or residual oil and demonstrating compliance with the PM limit, must install, certify, maintain, and operate a PM CPMS. This requirement inadvertently includes biomass units that burn at least 10 percent biomass or bio-based solids on an annual heat input basis, in combination with solid fossil fuels, liquid fuels, or gaseous fuels. Based on rationale and language presented in section D (2) of the preamble, it is our understanding that EPA intended to not require PM continuous emission monitors on biomass units.

1. EPA should clarify the rule by stating that the requirement to install and use PM CPMS does not apply to boilers in the biomass category.
2. EPA should not require the use of a PM CPMS on any multi-fuel boiler.

Response: For a response to the request for clarification that all biomass-fired boilers are exempt from PM CPMS requirements, please see comment EPA-HQ-OAR-2002-0058-3504-A1, excerpt 25. For a response to concern over the viability of PM CPMS for multi-fuel boilers, please see comment EPA-HQ-OAR-2002-0058-3505-A1, excerpt 3.

Commenter Name: Stephen E. Woock

Commenter Affiliation: Weyerhaeuser Company

Document Control Number: EPA-HQ-OAR-2002-0058-3523-A1

Comment Excerpt Number: 18

Comment: In the re-proposed rule EPA substituted a provision to require any unit burning more than 250 mmBtu per hour annual average of solid fossil fuels or residual oil to establish a PM continuous parameter monitoring system (CPMS) operating parameter. This proposed substitute requirement suffers from much the same problems as already discussed, and we refer EPA to the extensive comments on this by our trade groups. In addition, despite public comments from EPA officials that they were removing the PM CEMS requirement for biomass units, the rule language fails to exclude all biomass units from the PM CPMS requirement. The rule language at §63.7525(b) requiring the PM CPMS as an operating parameter for PM would include multi-fuel

units that qualify under the definitions as a unit designed to burn biomass/bio-based solid (>10% biomass by rule definition) –in this case biomass units that also happen to combust on annual average more than 250 mmBtu/hour of solid fossil fuel and/or residual oil. If EPA decides to retain the PM CPMS for fossil fuel units, we request EPA remove this requirement for units qualifying as biomass units by rule definition since the operating parameter would not provide information relevant to compliance with the emission limit.

Response: The EPA acknowledges the commenter's concern of PM CPMS requirements for units larger than 250 MMBtu/hr. For a response to the request for clarification that all biomass units should be exempt from the PM CPMS requirements even if co-fired with greater than 250 MMBtu/hr of fossil fuel, please see comment EPA-HQ-OAR-2002-0058-3504-A1, excerpt 25.

Commenter Name: Annabeth Reitter

Commenter Affiliation: NewPage Corporation

Document Control Number: EPA-HQ-OAR-2002-0058-3662-A2

Comment Excerpt Number: 13

Comment: Based upon the language in the preamble, it is our understanding that it is EPA's intent not to require PM continuous emission monitors on biomass boilers due to a number of technical issues discussed in the preamble (see pages 80609-80610). EPA has also decided not require the installation of PM CPMSs on boilers smaller than 250 MMBtu per hour heat input rate and on boilers complying with the alternative total select metal limit.

In section §63.7525 (b) EPA has proposed that all boilers with an annual heat input rate greater than 250 MMBtu per hour from solid fossil fuel and/or residual oil and demonstrate compliance with the PM limit must install, certify, maintain, and operate a PM CPMS. NewPage is concerned this requirement also includes boilers greater than 250 MMBtu per hour that burn more than 10% biomass or bio-based solids on an annual heat input basis, in combination with solid fossil fuels, liquid fuels, or gaseous fuels (e.g. units in a biomass subcategory). We, therefore, recommend that:

1. EPA clarifies the rule by stating that the requirement to install and use PM CPMSs does not apply to any boilers in a biomass subcategory; and
2. EPA also not require the use of a PM CPMS on any boiler that burns more than one fuel.

The above recommendations are based on the finding of a recent study carried out by Georgia-Pacific (GP) and NCASI. The results of these studies are being submitted to EPA directly by NCASI.

Response: For a response to the request for clarification that all biomass-fired boilers are exempt from PM CPMS requirements, please see comment EPA-HQ-OAR-2002-0058-3504-A1, excerpt 25. For a response to concern over the viability of PM CPMS for multi-fuel boilers, please see comment EPA-HQ-OAR-2002-0058-3505-A1, excerpt 3.

Commenter Name: Robert D. Bessette

Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 88

Comment: PM CEMS have been demonstrated in practice on coal-fired utility boilers and at least one coal-fired industrial boiler. They have not been demonstrated on biomass-burning boilers. A review of all the types of PM CEMS and potential suitability for use on biomass-fired boilers is problematic for a number of reasons.

PM CEMS do not measure mass. Because PM monitors do not measure mass directly, they must be calibrated against some manual, PM reference method measurement procedure like EPA Methods 5, 5i or 17. The fundamental problem arises when the characteristics of the emitted PM exhibit significant variability and this variability in the particulate properties translates into a shift or alteration in the instrument's calibration curve.

Biomass, as well as CISWI units, which combust a mixture of fuels and which operate at variable loadings pose significant challenges in establishing meaningful correlations. In order to establish a calibration curve, one needs to source test the emissions from the stack and correlatethose to specific instrument readings.

Response: For a response to claims that biomass and multi-fuel units will experience significant calibration issues with PM CEMS, please see comment EPA-HQ-OAR-2002-0058-3505-A1, excerpt 3.

Comment: As fuel and fuel mixes vary, particle size distributions generated vary significantly. Biomass combustion emission distributions are characterized by a bimodal particulate distribution.¹⁶ [See submittal for Figure 1.]

This is due to the vaporization of volatile ash species in the wood-like potassium and sodium biomass ash that yields a bimodal characteristic with peaks of nominally 0.5 and 20 to 40 microns. Coal ash, on the other hand, tends to exhibit a more mono modal distribution without the submicron peak. Data available for PM CEMS effective is primarily limited to coal, and data on how PM CEMS will respond to monitoring biomass emissions is expected to be problematic.

[Footnote 16: "BIO-AEROSOLS – Aerosols in Fixed Bed Biomass Combustion," Presented by Professor Ingewald Oberberger, Ph.D., Graz University of Technology, Budapest, October 2003.]

Response: For discussion on the viability of PM CEMS for multi-fuel units, please see comment EPA-HQ-OAR-2002-0058-3505-A1, excerpt 3. The EPA acknowledges the potential for particle size distribution to vary and has allowed for technologies that use other particulate matter characteristics for measurement.

Comment Excerpt Number: 90

Comment: In addition to the variability of the fuels and fuel mixtures the operating load (firing rate) of the boiler will produce varying particulate loading which will challenge the robustness of any PM CEM correlation and calibration. This has been demonstrated during a study conducted by the Electric Power Research Institute (EPRI) of PM CEMS. The results of the study indicate that when inlet loading to ESP's are changed due to different fuel mixtures, the exhaust emissions have a different particle size and distributions. Therefore, a single or even a few correlation curves cannot be used to provide representative compliance correlations over an extensive range of fuels, fuel mixtures and loads. The results of the EPRI Study indicate that when a protocol is developed to simulate varying particle sizes and loads it results in inaccurate mass emissions estimates.¹⁷

For units such as biomass units, which may use a variety of biomass materials and vary production, or for CISWI units, which combust a varying mixture of materials, testing every possible fuel mixture to develop calibration curves for each is infeasible, given the extensive range of possible fuel mixtures.

In practice, changing the fuel mix for the purpose of correlation testing may alter the loadings; however, it would be difficult to do in a systematic way, and in order to gather the reference data needed to develop an acceptable correlation. Thus, for variable fuel and production rate units with variable emission characteristics in the stack where the PM CEMs is being used as a monitor, we conclude that establishing meaningful curves, figuring out how to match those to the fuel and production mixes and finally correlating these with emissions in any meaningful way is impractical. Basically, for each fuel mix that may be used, one would need to be able to establish a correlation curve. Then, the instrument would need to use the right calibration curve for the proper fuel mixture in order for any meaningful correlation with particulate to be established. This solution is not technically feasible.

Beyond this, there are a number of correlation issues. For instance, the PM response to the light scattering instruments are very dependent on particle size, shape and even color. Other technologies have other limitations.

Response: For a response to the claim that biomass and multi-fuel units will experience significant calibration issues with PM CEMS, as well as discussion on the viability of PM CEMS for multi-fuel units, please see comment EPA-HQ-OAR-2002-0058-3505-A1, excerpt 3.

Comment Excerpt Number: 14

Comment: The results of the GPINCASI study raise significant doubts regarding the feasibility of installing and calibrating PM CPMSs on coal-fired boilers which also burn other fuels including petroleum coke, sludge, OCC rejects, TDF, biomass, etc. We therefore recommend that EPA modify the requirement to install PM CPMSs and not make it applicable to any unit that burns more than one kind of fuel.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3505-A1, excerpt 3.

Commenter Name: Robert D. Bessette

Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 86

Comment: CIBO asks EPA to confirm that the boiler size threshold for determination of whether or not a PM CPMS must be installed is the average annual heat input, i.e., annual heat input divided by the number of actual operating hours in the year. Similar to the Utility MACT, CIBO suggests that this value be determined using three consecutive years beginning after the compliance date to determine average annual heat input.

Response: We disagree with the suggestion for the determination to be based on the annual heat input after the compliance date. The required monitoring are to be installed and in operation on the compliance date for demonstrating continuous compliance. 63.7525(b) clearly states that the requirement is based on the "annual heat input" which is defined in the rule as:

Annual heat input means the heat input for the 12 months preceding the compliance demonstration.

Commenter Name: Richard D. Garber

Commenter Affiliation: Boise Inc.

Document Control Number: EPA-HQ-OAR-2002-0058-3686-A2

Comment Excerpt Number: 20

Comment: EPA needs to respond to technical concerns raised by numerous commenters and clarify that PM CEMS are not required for biomass units, including those with a heat input greater than 250 mmBTU/hr.

The technology for continuous particulate monitoring has not been sufficiently demonstrated that it can be installed on boilers in the pulp and paper industry to meet the required calibration and correlation requirements outlined in EPA Performance Specifications (PS-11), especially at the extremely low particulate levels necessary to demonstrate compliance with the standard. For mills that utilize wet electrostatic precipitators as stand-alone control devices or in conjunction with wet scrubbers for particulate and acid gas removal, it will be technically infeasible to use PM CEMS for either direct compliance measurement or as parametric monitoring systems as suggested by EPA in the December 23, 2001 rules. These technical feasibility issues are problematic regardless of the size of the boiler, and the requirements for biomass boilers with a heat input greater than 250 mmBTU/hr should be removed from rule language. Boise references the detailed AF&PA and NCASI technical comments on this issue and requests that EPA make clear in the rule that the PM CEM requirement is removed.

Response: The EPA has removed the requirement for biomass boilers to show compliance with PM CEMs.

11D. CO CEMS: Specifications/Operations

Commenter Name: Gary Melow, Director

Commenter Affiliation: Michigan Biomass (MB)

Document Control Number: EPA-HQ-OAR-2002-0058-3478-A1

Comment Excerpt Number: 4

Comment: We strongly support a longer averaging time for CO for boilers already equipped and required to operate CEMs, with adjusted emission levels to reflect the variability we see when operating CEMs compared to short term stack tests.

Response: The EPA thanks the commenter for their support.

Commenter Name: Ashok K. Jain

Commenter Affiliation: National Council for Air and Stream Improvement, Inc. (NCASI)

Document Control Number: EPA-HQ-OAR-2002-0058-3505-A1

Comment Excerpt Number: 5

Comment: In Section 63.7525 (a) of the proposed rule EPA has specified that if a facility is subject to CO emission limits in Tables 1 or 2, to monitor the CO levels it must install, operate and maintain a CO monitor at the outlet of the boiler or process heater. Such CO monitors are also required to satisfy the requirements of PS 4, 4A or 4B.

EPA is, however, aware that it is not possible to certify any gas monitor according to applicable Performance Specifications if the monitor is located at the outlet to the boiler. This inability to certify is caused by stratification of gases at the boiler/process heater outlet.

We recommend the EPA should change this requirement and permit installation of CO CEMSs in the stack where such monitors can be certified according to PS 4, 4A or 4B. The installation of the monitor in the stack would not have any impact on determining the compliance status of the source since the CO data will have to be corrected to 3% O₂, thus negating the impact of any dilution of the stack gas due to leaks in the system.

Response: The EPA agrees with the commenter and has changed the rule to indicate that a source complying with the rule by using CO CEMS must satisfy the requirements of the appropriate Performance Specification for such monitoring and must sample flue gas following any installed emission control devices or flue gas recirculation ductwork and prior to the stack exit to the atmosphere.

Commenter Name: David A. Buff, Golder Associates Inc.

Comment: Section 63.7525(a)(1) of the Proposed Boiler MACT Rule states "If a CO CEMS is used, the carbon monoxide level shall be monitored at the outlet of the boiler or process heater." Such CO monitors are also required to satisfy the requirements of PS 4, 4A or 4B. It is not

possible to certify any gas monitor according to applicable Performance Specifications if the monitor is located at the outlet to the boiler. This inability to certify is caused by stratification of gases at the boiler/process heater outlet.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3505-A1, excerpt 5.

Commenter Name: Paul Noe

Commenter Affiliation: American Forest & Paper Association (AF&PA) et al.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 85

Comment: Proposed §63.7525(a)(1) requires that a CO CEMS monitor the CO level at the "outlet" of the boiler or process heater. Such CO monitors are also required to satisfy the requirements of PS 4, 4A or 4B. It is not possible to certify any gas monitor according to applicable Performance Specifications if the monitor is located at the outlet to the boiler. This inability to certify is caused by stratification of gases at the boiler/process heater outlet. In addition, for units equipped with add-on controls or flue gas recirculation systems the "outlet" could be construed to be either before or after these controls. Since these systems may impact the CO level, the measurement must be after any controls or recirculation (i.e., just before the gas is released to the atmosphere. EPA should revise the last sentence of §63.7525(a)(1) by adding the underlined language, to read as follows: If a CO CEMS is used, the carbon monoxide level shall be monitored at the outlet of the boiler or process heater, after any add-on controls or flue gas recirculation system and just before release to the atmosphere.

The installation of the monitor in the stack would not have any impact on determining the compliance status of the source since the CO data will have to be corrected to 3% O₂, thus negating the impact of any dilution of the stack gas due to leaks in the system.

Response: For a response to the siting of the CO CEMS, see comment EPA-HQ-OAR-2002-0058-3505-A1, excerpt 5.

Commenter Name: Richard D. Garber

Commenter Affiliation: Boise Inc.

Document Control Number: EPA-HQ-OAR-2002-0058-3686-A2

Comment Excerpt Number: 19

Comment: EPA should correct and clarify the location required for placement of CO CEMS monitoring devices

Boise believes that EPA may have unintentionally specified that CO CEMS monitor the CO level at the "outlet" of the boiler or process heater, as specified in 40 CFR 63.7525(a)(1), rather than downstream of the control device in the stack. As has been stated previously in our comment letter, Boise has two boilers at its facilities that already have CO CEMS installed for reasons other than compliance with the Boiler MACT rules.

In order to achieve quality assurance requirements, these units have been installed not at the boiler outlet, but in the boiler stack following the emissions control device. Boise believes that

EPA does not intend for sources that have CO CEMS already installed to be required to move their existing systems as this would unnecessarily cause the facilities to incur significant relocation costs. Furthermore, because of stratification of gases, it would be difficult if not impossible for CO CEMS to meet required Performance

Specifications if they were installed at the boiler outlet rather than in the stack. For these reasons, we request that the stack location be corrected to indicate CO CEMS, if existing or already installed, shall be downstream of all pollution control device. Minor pollutant concerns due to tramp air or leakage can be addressed by the correction to 3% oxygen.

Response: For a response to the siting of the CO CEMS, see comment EPA-HQ-OAR-2002-0058-3505-A1, excerpt 5.

Commenter Name: David A. Buff, Golder Associates Inc.

Commenter Affiliation: Florida Sugar Industry (FSI)

Document Control Number: EPA-HQ-OAR-2002-0058-3504-A1

Comment Excerpt Number: 41

Comment: The proposed rule requirement may also present conflicts with existing CO CEMS installed as a requirement of their PSD permit. Such systems normally measure CO at the boiler stack, where other parameters (NO_x, O₂, etc.) are also measured. Such systems would have to be relocated to the boiler outlet, where CO levels may be different than at the stack due to leaks in ductwork, air pollution control devices, etc. Boilers which are operated to meet a certain CO level at the stack may have to modify their operations if the CO measurement point is changed. It should be noted that all of the CO data submitted by the FSI, including the stack test data and CEMS data, were obtained at the boiler stack.

Response: For a response to the siting of the CO CEMS, see comment EPA-HQ-OAR-2002-0058-3505-A1, excerpt 5.

Commenter Name: Matthew Todd

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 95

Comment: Requirements associated with the optional CO CEMS need to be clarified.

Proposed §63.7525(a)(1) requires that a CO CEMS must monitor the CO level at the outlet of the boiler or process heater. It is unclear where the “outlet” is and this needs to be clarified. For BPH equipped with add-on controls, such as NO_x catalyst systems, and BPH equipped with flue gas recirculation energy efficiency systems the “outlet” could be construed to be either before or after these controls. Since these systems can impact the CO level, we believe the measurement must be after any controls or recirculation (i.e., just before the gas is released to the atmosphere. We request EPA make this clear in the final rule by revising the last sentence of §63.7525(a)(1) as follows.

If a CO CEMS is used, the carbon monoxide level shall be monitored at the outlet of the boiler or process heater after any add-on controls or flue gas recirculation and just before release to the atmosphere.

Response: For a response to the siting of the CO CEMS, see comment EPA-HQ-OAR-2002-0058-3505-A1, excerpt 5.

Commenter Name: Bart Sponsellar

Commenter Affiliation: Wisconsin Department of Natural Resources

Document Control Number: EPA-HQ-OAR-2002-0058-3527-A2

Comment Excerpt Number: 24

Comment: Many of the Department's comments are formulated from a common basis. The Department believes that there is significant opportunity, in context of the issues open for comment, to achieve the same or better environmental results and reduce compliance cost by allowing CMS parametric monitoring for PM, Hg and CO and O₂ monitoring for good combustion. One basic benefit in pursuing an alternative compliance demonstration is better parametric monitoring and stable combustion conditions which will allow for stack testing on a biennial schedule. This is very important for sources in reducing compliance cost and aligning stack testing with current Wisconsin stack testing requirements.

Although not providing absolute certified values, a CMS system which directly monitors the regulated pollutant ensures better overall environmental results as compared to an annual stack test. EPA has basically followed this premise in proposing the use PM CEMs, CO CEMs and Hg CEMs as an alternative in demonstrating compliance. EPA has also shown with the proposal of a PM CMS and oxygen trim systems for parametric monitoring that they believe quality monitoring can be standardized without requiring full CEMs certification. In this approach CMS data is correlated to the periodic stack test for each source and ensures ongoing compliance. The CO CMS is also correlated to good combustion over different loads with the source required to continuously trim the system to good combustion when operating.

Response: The EPA disagrees with the commenter that a CO CMS system is an applicable compliance alternative for this rule. Compliance with a CO CEMS will provide the necessary data QA/QC to meet a ten day rolling average limit, and compliance with a single stack test measurement per year is much better achieved through an O₂ monitoring system and not a CO CMS trying to comply with the three hour stack test data, as such a monitor is not likely to meet compliance assurance when loads swing or fuel moisture varies greatly.

Commenter Name: Matthew Todd

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 96

Comment: Proposed §63.7525(a)(7) requires that a CO CEMS must collect "at least two 15-minute data values during an hour when CEMS calibration, quality assurance, or maintenance activities are being performed." Such a requirement is impossible if the needed quality assurance

or maintenance activity takes more than 30 minutes, which can occur. Doing required maintenance and quality control is required by this rule and complying with that mandate should not put operators in violation. Rather, time periods with inadequate data should not be included in compliance averages, as provided in the part 63 General Provisions, and all such periods should be recorded and reported, also as specified in the part 63 General Provisions that are applicable to this regulation. Thus we recommend §63.7525(a)(7) be revised to specify that hours where data is unavailable for at least two fifteen minute periods due to CEMS calibration, quality assurance, or maintenance activities are not to be included in daily compliance averages and shall be treated as specified in §63.7535(d) and §§63.8 and 63.10 of the part 63 General Provisions.

Response: The EPA points out to the commenter that a minimum of one cycle of sampling, analyzing, and data recording per fifteen minute period is the requirement of §63.7525(a)(7). Where a CO CEMS is capable of conducting such a cycle in one minute, the first minute and final minute of any hour would meet the requirement of the rule. This would allow up to 58 minutes for the source operator to conduct CEMS calibration, quality assurance, or maintenance activities in any given hour.

Commenter Name: Matthew Todd

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 97

Comment: Proposed §63.7540(a)(8)(ii) specifies that if you are using a CO CEMS you must maintain a CO emissions level below or at your Table 1 or 2 limit at all times [emphasis added]. However, that limit does not apply during startup and shutdown. §63.7540(a)(8)(ii) should be revised to exclude startup and shutdown periods from the requirement to comply with the Table 1 or 2 CEMS CO limit.

Response: The EPA points out to the commenter that startup and shutdown data is exempted by the heading of Table 2.

Commenter Name: Matthew Todd

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 112

Comment: Achievable span values should be specified for CO CEMS.

Proposed §63.7525(a)(6) requires that the span value of a CO CEMS must be two times the applicable emission limit. The availability of CO CEMS for the lower CO standards is unclear. For instance, a quick review indicates 100 ppm is the lowest span advertised by one major manufacturer. Additionally, it is impossible to be this precise. For instance, the proposed CO limit for units designed to burn heavy liquids is 18 ppm. Twice that is 36 ppm. Thus, a CO CEMS that has a span of 35 ppm or 37 ppm is a deviation, even though that difference makes no

difference in the quality of the measurement. Span requirements should be established as a range and be consistent with manufactured units (e.g., include 100 ppm in this case). Thus, we recommend the span requirement be 2-6 times the CO limit, which will include 100 ppm for the lowest CO CEMS limit in the proposal.)

Response: EPA Method 10 for measurement of CO references EPA Method 7E which defines the measurement span as the high level gas value, not the instrument scale/ range. Therefore, where §63.7525(a)(6) requires that the span value of a CO CEMS must be two times the applicable emission limit, this means that the measurement span value must be two times the applicable emission limit, not the particular instrument measurement range.

Commenter Name: Mark Anthony

Commenter Affiliation: Alyeska Pipeline Service Company

Document Control Number: EPA-HQ-OAR-2002-0058-3684-A2

Comment Excerpt Number: 8

Comment: A clarification which would be beneficial in the rule is to acknowledge the acceptability of using a single CO CEMS system to monitor multiple affected boilers simultaneously as long as the measurement criteria of at least one reading every 15 minutes per affected unit is met. At the VMT, the three power boilers route to a common stack and since the rule does not provide a single CO limit for combined stack configurations, like it does for PM/HCI and Mg, it is implied that individual boiler CO exhaust measurements are required. In order to simplify the monitoring, reduce redundancy, and optimize limited space, Alyeska believes there would be benefit in this rule if EPA acknowledged this option.

Response: The EPA allows monitoring of combined stacks to be accomplished through sample system switching, provided that the sampling system provides for a unique and representative emissions measurement from each of the individual sources as required by §63.7525.

Commenter Name: Heather Parent

Commenter Affiliation: Maine Department of Environmental Protection

Document Control Number: EPA-HQ-OAR-2002-0058-3691-A2

Comment Excerpt Number: 17

Comment: The proposed rule specifies in 40 CFR 63.7525(a)(1) that if a CO CEMS is used, the carbon monoxide level shall be monitored at the outlet of the boiler or process heater. CO CEMS operating in Maine do not collect flue gas samples at the outlet of a boiler, but either in the ductwork connecting the last piece of control equipment to the exhaust stack or in the exhaust stack, itself. The location where the flue gas sample is taken should not matter so long as the flue gas sample monitored by the diluent monitoring system (oxygen or carbon monoxide) is taken from the same place. Maine DEP recommends that EPA revise any language in the proposed rule regarding the location where the monitoring takes place to allow for any location that meets the performance specification for the particular monitoring system.

Response: For a response to the siting of the CO CEMS, see comment EPA-HQ-OAR-2002-0058-3505-A1, excerpt 5.

Commenter Name: Samuel H. Bruntz
Commenter Affiliation: Alcoa Power Generating, Inc.
Document Control Number: EPA-HQ-OAR-2002-0058-3755-A1
Comment Excerpt Number: 12

Comment: With respect to CO, the proposed limit is expressed as ppm, dry basis, corrected to 3% O₂. For a wet scrubber controlled boiler, it would be necessary to operate an oxygen CEMS and a continuous moisture measurement system or computer system that calculates moisture content with a psychrometric chart assuming 100% saturation. Alcoa-Warrick has a flow monitor that measures airflow on a wet basis. In order to avoid the additional costs associated with installation of an O₂ CEMS, and some type of moisture monitoring system, Alcoa-Warrick suggests that an item 10 be added to Table 4, as follows:

10. CO CEMS: For boilers and process heaters subject to a carbon monoxide emission limit that demonstrate compliance with a CO CEMS as specified in § 63.7525(a), maintain the carbon monoxide level such that It does not exceed below the concentration recorded during the applicable 40 CFR 60, Appendix B performance specification tests that corresponds to the CO emission limit expressed as corrected to 3% oxygen, dry basis.

Response: The EPA disagrees with the commenter that a moisture correlation determined during annual performance specification test is robust enough to prove compliance with a ten day rolling average limit.

11E. Hg CEMS

Commenter Name: Ashok K. Jain
Commenter Affiliation: National Council for Air and Stream Improvement, Inc. (NCASI)
Document Control Number: EPA-HQ-OAR-2002-0058-3505-A1
Comment Excerpt Number: 4

Comment: In Section 63.7525 (l) of the proposal, EPA has specified that “For each unit for which you decide to demonstrate compliance with the mercury or hydrogen chloride emissions limits in Tables 1 or 2 of this subpart by use of a CEMS for mercury or hydrogen chloride, you must install, certify, maintain, and operate a CEMS measuring emissions discharged to the atmosphere.” EPA has asked for comments on this proposal on the use of mercury CEMSs. NCASI supports EPA’s decision to only require mercury CEMSs on those boilers which demonstrate compliance with the emission standard by using mercury CEMSs. All other boilers are exempt from the requirement to install mercury CEMSs. Our support for not requiring the installation of mercury CEMSs on the excluded category of boilers is based on the findings of a study carried out by NCASI on a biomass boiler which was co-firing coal at the time of the study and was equipped with a wet scrubber for PM control [See submittal for Attachment 2].

A Thermo-Fisher mercury CEM was installed on the boiler and tests were conducted to evaluate the performance of the CEM. During the study, stack gas mercury content was measured using EPA Method 29 to allow a comparison between Method 29 and CEM measured mercury emission rates and to determine whether an acceptable correlation could be developed between

the two measurements. The emission data are plotted in Figure 1. [See submittal for Figure 1]
The results of the regression analysis are summarized in Table 1. [See submittal for Table 1]

The results in Table 1 show that the instrument response of the mercury CEM could not be correlated with the emissions from the boiler when measured with Method 29, and the instrument failed the EPA criteria for CEMSs. Based on these findings, it would not be appropriate to require mercury CEMSs on biomass boilers except for those facilities that demonstrate compliance through a CEMS.

The details of the study are included as Attachment 2 with these comments.

Response: The EPA thanks the commenting organization for their support. We have reviewed the study submitted by the commenting organization in Attachment 2 to their letter and agree that the data presented does not show good correlation between Method 29 and the Hg CEMS; however, we would not immediately conclude that the Hg CEMS cannot perform properly on this source and pose the following potential reasons for the poor correlation documented.

First, the Hg CEMS was not installed at a representative sampling point location. Are there any other data to support the location chosen?

Second, it appears that Method 29 as performed for these tests was not sensitive enough to develop a reasonable correlation with the Hg CEMS. The nine Method 29 emissions values used in the attempted correlation included 18 to 22 percent contribution from non-detect analytical results from some fractions of the sampling trains. Use of a more sensitive method such as Method 30B or ASTM D6784-02 should yield more definitive results.

Finally, we were unclear as to why the commenting organization chose to analyze the data using the correlation approach in Performance Specification 11 for PM CEMS as opposed to the relative accuracy approach of Performance Specification 12A (PS 12A) for Hg CEMS.

Comment: Comment Summary: The proposed CEMS alternatives for mercury and hydrogen chloride are appropriate and should be included in the final rule except that they should not be restricted to use of add-on controls.

EPA included this option at §63.7525(l) with further detailed requirements at §63.7540(a)(14) and (15). We note that while EPA does not mention it in the preamble, it is also proposing a similar option for use of HCl CEMS.

We support inclusion of both of these options. EPA has precedent for allowing use of these CEMS in the Utility MACT. Some facilities may select these options in order to obtain more operating flexibility and to better assure continuous compliance with the standards. We support the use of a 30-day rolling average to determine compliance.

Response: See the responses to comment EPA-HQ-OAR-2002-0058-3510-A1, excerpt 51, and to comment EPA-HQ-OAR-2002-0058-3510-A1 excerpt 48 under the chapter SO₂ CEMS (HCl Alternative).

Comment Excerpt Number: 22

Comment: The only request we have for change to the proposed provisions is the restriction found at §63.7525(1)(8) that allows substitution of CEMS only if you are using an add-on control to comply with the mercury or hydrogen chloride emission limits. We see no need for such a restriction. A source without add-on control should be able to control its fuel supply or feed rate such that it complies with the standards and demonstrates continuous compliance using a CEMS.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3510-A1, excerpt 51.

Comment Excerpt Number: 15

Comment: EPA is proposing to allow sources to use a Mercury (Hg) CEMs in place of the currently required periodic testing, fuel sampling analysis, and parametric monitoring. The Department supports adding this flexibility for demonstrating compliance. The Department asks EPA to consider an option where a source can continuously monitor Hg with a CMS or non-certified continuous monitoring option in conjunction with biennial stack testing and an appropriate level of fuel sampling. The Department believes a biennial stack test option should also apply to sources with activated carbon injection systems or other positive Hg control systems. The Department believes that a source should be subject to biennial stack testing instead of annual stack testing when the pollutant is continuously monitored by a CMS or parametric monitoring of control equipment which positively reduces emissions of the pollutant in question (metals, mercury, CO) for a pollutant which has been demonstrated by the source to correlate with the pollutant in question.

Response: The EPA appreciates the support of the commenter for the option of using an Hg CEMS for compliance monitoring. The commenter requests that the final rule include an additional option of using an Hg CEMS as a CPMS coupled with biennial stack testing and an appropriate level of fuel sampling to determine compliance. Though this is an interesting option that parallels the approach promulgated in the MATS rule where a PM CEMS may be used as a CPMS, EPA does not believe that we currently have sufficient background information nor adequate opportunity for public notice and comment to promulgate such an option. The affected facilities, however, always have the option to request alternative methods/approaches to demonstrating compliance under the provisions of 63.7(f).

Comment Excerpt Number: 76

Comment: EPA has proposed to allow HCl and Hg CEMS as an alternate to complying with fuel analysis or stack testing and continuous parameter monitoring. 76 Fed. Reg. 80,610. CIBO members support the flexibility provided by this option, as facilities that have these monitors installed should be able to take advantage of their use in order to comply with this rule and should not be required to perform additional stack testing or parameter monitoring. As

mentioned above, and for the reasons set forth in prior comments, emissions averaging with no 10% penalty should be allowed if CEMS are used.

Response: The EPA thanks the commenter for their support of flexible monitoring alternatives and we have included these in the final rule. Comments related to the discount factor for emissions averaging when using CEMS are out of scope since we have not reconsidered the emission averaging provision in this notice.

11F. SO₂ CEMS (HCl Alternative)

Commenter Name: Steve Gossett

Commenter Affiliation: Eastman Chemical Company

Document Control Number: EPA-HQ-OAR-2002-0058-3669-A2

Comment Excerpt Number: 23

Comment: Comment Summary: Sulfur dioxide (SO₂) CEMS should be allowed for demonstrating continuous compliance with HCl emission limits.

We agree with EPA's conclusions that acid gas HAP control efficiencies would be better than SO₂ control efficiency (for a given acid gas control device) and that it should be possible to demonstrate a correlation between the two control efficiencies and then to rely on an SO₂ CEMS to demonstrate continuous compliance. EPA drew this same conclusion in the recently finalized Utility MACT and set alternative SO₂ emission limits.

In this case, we agree there is not enough information to set an alternative SO₂ limit that correlates with the HCl emission standard, such as was done in Utility MACT. One key difference is that the Utility MACT HCl emission limit (0.002 lb/mmBtu) is about ten times lower than the proposed Boiler MACT HCl limit for solid-fuel boilers.

Response: The commenter, as well as several other commenters, support the conclusion that acid gas HAP control efficiencies would be better than SO₂ control efficiency and, thus, the option of using measuring SO₂ as a surrogate for demonstrating compliance with the HCl emission limits. One commenter, EPA-HQ-OAR-2002-0058-3543-A1, excerpt 24, found in its emissions testing experience, that HCl is indeed more effectively controlled than SO₂ in wet FGD systems. Another commenter, EPA-HQ-OAR-2002-0058-3491-A1, excerpt 1, reported that HCl and SO₂ removal go hand in hand with dry sorbent injection and that based on test data it is well established that high levels of HCl removal are achieved with modest removals of SO₂.

We agree that there is not enough information to set an alternative SO₂ limit that correlates with the HCl emission standard, such as was done in MATS (i.e., Utility MACT). We agree, however, there is sufficient information and data to allow SO₂ CEMS as an alternation operating

limit for demonstrating continuous compliance with the HCl emission limits under certain conditions. This method of demonstrating continuous compliance would be allowed only on any unit that utilizes an acid-gas control technology including wet scrubber, dry scrubbers, and duct sorbent injection.

Commenter Name: Paul Noe

Commenter Affiliation: American Forest & Paper Association (AF&PA) et al.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 96

Comment: We would suggest SO₂ continuous monitoring be allowed as a continuous parametric monitoring system (CPMS) and that the maximum 30-day rolling average SO₂ operating parameter limit be set during a 3-run performance test where HCl emissions are demonstrated to comply with the final HCl emission limit. This method of continuous compliance should be allowed on any unit that utilizes an acid-gas control technology including wet scrubber, dry scrubbers, and duct sorbent injection.

Response: We thank the commenter for their suggestion which limits the alternative compliance to only unit that utilizes an acid gas control technology. We agree that the operating should be a 30-day rolling average which is consistent with the averaging time for other operating limits and consistent with averaging time for units that are subject to the SO₂ limit in NSPS subpart Db. See response to comment EPA-HQ-OAR-2002-0058-3669-A2, excerpt 23 for further discussion on the approach being incorporated into the final rule.

Commenter Name: Robert D. Bessette

Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 72

Comment: In the 2012 Reconsidered Boiler MACT Rule, EPA is soliciting comment on "the use of SO₂ CEMS for demonstrating continuous compliance with the HCl emission limits." 76 Fed. Reg. 80610. EPA has indicated that it is a "reasonable approach" to allow the use of SO₂ CEMS to demonstrate compliance with the HCl standard if there is a "correlation between SO₂ control and control of other acid gases emitted from each specific unit that chooses to use SO₂ CEMS." 76 Fed. Reg. 80610. As stated in our comments on the Proposed Boiler MACT Rule, SO₂ CEMS is a good indicator of HCl removal and EPA should allow its use in demonstrating compliance with the HCl standard.

A proposed approach to the use of SO₂ CEMS for demonstration of continuous compliance with the HCl limit is to determine the SO₂ emission rate (in lb/MMBTU) at the time of the HCl stack test for Boiler MACT compliance. Compliance with SO₂ emission rate determined during the HCl stack test is proposed to be calculated on a 30-day rolling average.

Response: See response to comment EPA-HQ-OAR-2002-0058-3669-A2, excerpt 23 and comment EPA-HQ-OAR-2002-0058-3521-A1, excerpt 96.

Commenter Name: Samuel H. Bruntz
Commenter Affiliation: Alcoa Power Generating, Inc.
Document Control Number: EPA-HQ-OAR-2002-0058-3755-A1
Comment Excerpt Number: 6

Comment: Proposed regulation 63.7520 (b) requires that performance tests must be conducted as specified in Table 5 for PM, HCl, and mercury. With respect to HCl, the requirement is to perform Method 26A emissions tests to demonstrate compliance with the proposed emission limit of 0.022lb./mmBtu, as specified in Table 2 of the proposed regulation.

Alcoa Warrick has 3 coal-fired industrial boilers that are subject to 40 CFR 60, Subpart Db with respect to SO₂ emissions, and must continuously monitor SO₂ removal performance across the wet FGD scrubbers on each boiler. Test data available to Alcoa Warrick to date indicates that when the SO₂ CEMS is reporting SO₂ removals above 95%, HCl emissions have been measured by EPA Method 26A to be non-detectable.

Alcoa Warrick suggests that EPA consider the concept of using SO₂ CEMS as a surrogate for HCl emissions. In order to implement this concept, Alcoa Warrick suggests that SO₂ removal measured during the initial EPA Method 26A compliance test for HCl become the parametric limit, if the initial Method 26A compliance test demonstrates compliance with the proposed limit. Thereafter, no further Method 26A tests would be necessary, because the SO₂ CEMS would be demonstrating continuous compliance.

Response: See response to comment EPA-HQ-OAR-2002-0058-3669-A2, excerpt 23.

Document Control Number: EPA-HQ-OAR-2002-0058-3543-A1
Comment Excerpt Number: 24

Comment: Using Sulfur Dioxide (SO₂) CEMS for Demonstrating Continuous Compliance with HCl Emission Limits

EPA is requesting comment on adding an additional provision in the rule to allow for the use of SO₂ CEMS for demonstration of continuous compliance with the HCl emission limits for sources that are equipped with acid gas controls. Duke Energy strongly supports this concept and notes that EPA included similar provisions in the final Mercury and Toxics Standards rule. While the EPA states that it does not have enough information to propose specific requirements, it believes that a reasonable approach would be to allow for the use of SO₂ CEMS provided that the source demonstrates a correlation between SO₂ control and control of other acid gases emitted from each specific unit that chooses to use SO₂ CEMS. EPA expects that such a relationship would exist because the available add-on controls for acid gases would provide better control efficiencies for the acid gas HAP than for SO₂. As a result, demonstrating a level of SO₂ control using CEMS would provide assurance that the acid gas HAPs are being controlled. In its emissions testing experience, Duke Energy has found that HCl is indeed more effectively controlled than SO₂ in wet FGD systems. As a result Duke Energy recommends that EPA adopt in the final rule, an option for sources to establish a relationship between SO₂ and

HCl based on emissions testing. That testing would establish a maximum SO₂ emission rate, or minimum percent SO₂ removal rate that would demonstrate compliance with the HCl standard.

The source would then monitor and determine compliance using an SO₂ CEMS.

Response: See the responses to comments EPA-HQ-OAR-2002-0058-3669-A2, excerpt 23, EPA-HQ-OAR-2002-0058-3534-A1, excerpt 72, and EPA-HQ-OAR-2002-0058-3755-A1, excerpt 6.

Commenter Name: David Foerter

Commenter Affiliation: Institute of Clean Air Companies (ICAC)

Document Control Number: EPA-HQ-OAR-2002-0058-3491-A1

Comment Excerpt Number: 1

Comment: ICAC believes that the Industrial Commercial and Institutional (ICI) sector should be afforded the same, or even more, flexibility in meeting the final emission limitations as the utility sector has been afforded in the final Mercury and Air Toxics Standards (MATS) final rule (77 FR 9304-9513, February 16, 2012). One of those flexibilities is for EGUs that use flue gas desulfurization and SO₂ CEMs. Those units are allowed to use SO₂ as a surrogate for compliance with the HCl emission limitation. EPA is soliciting comment on the use of SO₂ CEMS for demonstrating continuous compliance with the hydrogen chloride (HCl) emission limit (80610/1).

Based on both test data and field trials it has been well established that high levels of HCl removal are achieved with modest removals of SO₂. From test data, the use of SO₂ as a surrogate for HCl removal is a reasonable approach. It has been well demonstrated that 30% to 40% SO₂ removal will result in very high removal levels of HCl that easily meet the Industrial Boiler (IB) MACT (Maximum Achievable Control Technology) standard of 0.022 lb/MMBtu. The SO₂ surrogate standard is 0.2 lb/MMBtu for the Utility MATS for a much lower HCl limit of 0.002 lb/MMBtu. Since the ICI Boiler MACT standard for HCl is much higher, we feel the EPA should consider a higher level for the SO₂ surrogate under the ICI Boiler MACT. We encourage EPA to analyze the data from this sector to determine a reasonable SO₂ surrogate standard.

HCl and SO₂ removal go hand in hand with dry sorbent injection and if HCl compliance must be demonstrated, the corresponding SO₂ removal could be considered a suitable substitute for continuous monitoring. The use of SO₂ CEMS then appears to be a very practical alternative to the more difficult HCl monitoring and should be an alternative. While the 0.2 lb/MMBtu SO₂ surrogate level in the Utility MATS could be adopted, there are reasonable arguments and data to support a higher surrogate level in the ICI Boiler MACT Rule.

Response: We thank the commenter for their support of affording the Industrial, Commercial, and Institutional (ICI) sector the same flexibility in meeting the emission limitations as the utility sector has been afforded in the MATS rule. We thank the commenter for providing support, based on both test data and field trials, that high levels of HCl removal are achieved with modest removals of SO₂ and that the use of SO₂ as a surrogate for HCl removal is a reasonable approach. See response to comment EPA-HQ-OAR-2002-0058-3669-A2, excerpt 23 for how this alternative will be incorporated into the final rule.

Commenter Affiliation: National Association of Clean Air Agencies (NACAA)

Document Control Number: EPA-HQ-OAR-2002-0058-3525-A1

Comment Excerpt Number: 58

Comment: NACAA is supportive of EPA efforts to afford maximum flexibility to affected sources in demonstrating compliance, in order to allow lowest cost emission reductions and the best use of limited state and local resources. We agree that properly functioning SO₂ controls will also reduce HCl emissions and so chlorine levels can be correlated with HCl emissions in such units and in such instances. Sources with existing SO₂ monitors should not have to install separate HCl monitors. However, low sulfur concentration in fuels does not guarantee low chlorine levels in those fuels, especially in biomass fuels. NACAA does not support the use of continuous SO₂ monitors as a surrogate for HCl monitoring in units that do not have active SO₂ controls.

Response: We thank the commenter for their support in affording flexibility in demonstrating compliance. We agree that low sulfur concentration in fuels does not guarantee low chlorine levels in those fuels and, thus, we agree with the commenter that the use of continuous SO₂ monitors as a surrogate for HCl monitoring should not be allowed for units that do not have active SO₂ controls. See the response to comment EPA-HQ-OAR-2002-0058-3669-A2, excerpt 23 for further discussion.

Comment: Recent pilot plant tests conducted by a leading reagent supplier at an independent site incontrovertibly prove that dry injection of sodium bicarbonate or trona can achieve >99%

removal rates for HCl; and is able to meet the HCl limit in the Utility MATS and most certainly for the ICI Boiler MACT Rule. The tests effectively demonstrate the selectivity of sodium sorbents to remove HCl in a medium to high sulfur environment.

The pilot boiler tests were conducted at an independent site, the Energy & Environmental Research Center (EERC) facility at the University of North Dakota. Using coal from the Central Appalachian Basin (CAPP), sodium bicarbonate and trona were tested using both ESP and Baghouse to demonstrate that Dry Sorbent Injection with trona or sodium bicarbonate is able to meet the HCl limit (0.022 lb/MMBtu). Both sorbents were easily able to meet the required emissions levels. Depending on the particular application, one may be better than the other, but at least now it is clear that Dry Sodium Sorbent Injection is fully capable of reaching compliance.

Response: We thank the commenter for providing information and data from pilot plant tests that showed dry injection of sodium bicarbonate or trona can achieve >99% HCl removal and meets HCl limits.

Comment: In this case, we agree there is not enough information to set an alternative SO₂ limit that correlates with the HCl emission standard, such as was done in Utility MATS. One key difference is that the Utility MATS HCl emission limit (0.002 lb/mmBtu) is about ten times lower than the proposed Boiler MACT HCl limit for solid-fuel boilers (0.022 lb/mmBtu).

We would suggest in both the Boiler MACT and the CISWI rule that SO₂ continuous monitoring be allowed as a continuous parametric monitoring system (CPMS) and that the maximum 30 day rolling average SO₂ operating parameter limit to be set during a 3-run performance test where HCl emissions are demonstrated to comply with the final HCl emission limit. This method of continuous compliance should be allowed on any unit that utilizes an acid-gas control technology including wet scrubber, dry scrubbers, and duct sorbent injection.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3521-A1, excerpt 96.

Comment: In the 2012 Reconsidered Boiler MACT Rule, EPA is soliciting comment on "the use of SO₂ CEMS for demonstrating continuous compliance with the HCl emission limits." (76 FR 80610). EPA has indicated that it is a "reasonable approach" to allow the use of SO₂ CEMS to demonstrate compliance with the HCl standard if there is a "correlation between SO₂ control and control of other acid gases emitted from each specific unit that chooses to use SO₂ CEMS." (76 FR 80610). Purdue believes SO₂ CEMS is a good indicator of HCl removal and EPA should allow its use in demonstrating continuous compliance with the HCl standard.

EPA is soliciting comment on allowing the use of SO₂ CEMS for demonstration of continuous compliance with the HCl emission limits for sources that are equipped with acid gas controls (see 76 Fed.Reg. 80610).

Purdue suggests SO₂ continuous monitoring be allowed as a form of continuous parametric monitoring system (CPMS) and that the maximum 30 day rolling average SO₂ operating parameter limit to be set during a 3-run performance test where HCl emissions are demonstrated to comply with the final HCl emission limit. This method of continuous compliance should be allowed on any unit that utilizes an acid-gas control technology including wet scrubber, dry scrubbers, limestone sorbent in a CFB, and in duct sorbent injection.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3521-A1, excerpt 96.

Comment Excerpt Number: 73

Comment: In the Final Boiler MACT Rule, EPA required continuous monitoring of sorbent injection for continuous compliance purposes. 76 Fed. Reg. 15,615. In addition to the comment below, CIBO asks that EPA confirm that the use of limestone for SO₂ control in a CFB is a form of sorbent injection and could be included in this compliance strategy. As stated in our comments on the Proposed Boiler MACT Rule, which were filed on August 20, 2010, monitoring sorbent injection rates is problematic and unreasonable. Although the re-proposed rule improved on the proposed Boiler MACT by allowing scaling of injection rate to account for load changes, in some applications this linearization of a system that is not linear in nature causes not only a potentially large amount of sorbent to be wasted but in the case of the CFB utilizing limestone in the furnace for SO₂ control, will cause operational issue for the boiler itself. CIBO suggests that alternative methodologies be considered, such as tracking of the calcium to sulfur ratio of the fuel and the sorbent. This approach allows the source to more closely tune the sorbent injection to the fuel quality and is based upon the presumption that So₂ control correlates to HCl control.

Response: We agree that use of limestone in an CFB is a form of sorbent injection for SO₂ control and have revised the definition of "Minimum sorbent injection rate" to also mean the calcium to sulfur ratio for fluidized bed units.

Comment Excerpt Number: 16

Comment: EPA is proposing to allow continuous CEMs monitoring of SO₂ as a surrogate for demonstrating compliance with HCL emission limitations if the source establishes a positive correlation between the control of SO₂ and HCL (acid gases). The Department supports this compliance demonstration option for HCL. The Department also believes that with a SO₂ CMS system (non-certified) that the source be allowed to perform compliance stack testing on a biennial schedule. The Department believes that a source should be subject to biennial stack testing instead of annual stack testing when the pollutant is continuously monitored by a CMS or parametric monitoring of control equipment which positively reduces emissions of the pollutant in question (metals, mercury, CO) for a pollutant which has been demonstrated by the source to correlate with the pollutant in question.

Response: We thank the commenter for their support. Provisions for reduced performance testing frequency have been added to the final rule that are based on the level of the measured emissions.

Commenter Name: Samuel H. Bruntz

Document Control Number: EPA-HQ-OAR-2002-0058-3755-A1

Comment Excerpt Number: 5

Comment: Alcoa - Warrick supports the position that EPA has expressed in proposed regulation 63.7525 (1)(8) for HCl and mercury, i.e. if add-on control equipment is being used for these pollutants, CEMS can be substituted for the fuel analysis, annual performance test requirements, and Table 4 operating requirements. Alcoa- Warrick suggests that the relief provided by 63.7525 (1)(8) be expanded to include SO₂ CEMS acting as surrogates for HCl, and PM-CEMS. Accordingly, Alcoa-Warrick suggests that 63.7525 (1)(8) be amended-as follows:

If you are using an add-on control to comply with the *PM*, mercury or hydrogen chloride emission limit, you are allowed to substitute the use of the mercury ~~or~~ hydrogen chloride CEMS, *SO₂ CEMS as surrogate for HCl, or PM-CEMS* for the applicable fuel analysis, annual performance test, and operating limits specified in Table 4 to this subpart to demonstrate compliance with the *PM*, mercury, or hydrogen chloride emissions limit.

Response: We agree with the commenter's suggestion and 63.7525(1)(8) has been revised to allow the use of a SO₂ CEMS to demonstrate compliance with the HCl emission limit.

Commenter Name: Lorraine Gershman
Commenter Affiliation: American Chemistry Council (ACC)
Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1
Comment Excerpt Number: 48

Comment: EPA solicited comment in the 2010 Proposed Boiler Rule on its inclusion of an option to use Hg CEMS in lieu of periodic testing, fuel sampling analysis, and parameter monitoring. EPA included this option at § 63.7525(l) with further detailed requirements at § 63.7540(a)(14) and (15). ACC notes that while EPA does not mention it in the preamble to the 2010 Proposed Boiler Rule, it is also proposing a similar option for use of HCl CEMS in response to petitioners' requests.

ACC supports the flexibility provided by this proposed option, as facilities that have these monitors installed should be able to take advantage of their use in order to comply with this rule and should not be required to perform additional stack testing or parameter monitoring. Some facilities may select these options in order to obtain more operating flexibility and to better assure continuous compliance with the standards. EPA has precedent for allowing use of these CEMS as it included this provision in the MATS.

Response: The EPA thanks the commenter for their support.

11G. Averaging Times for Monitored Pollutants

Commenter Name: Paul Noe
Commenter Affiliation: American Forest & Paper Association (AF&PA) et al.
Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1
Comment Excerpt Number: 106

Comment: We support EPA's determination that a 30-day rolling average for parameter monitoring and compliance with operating limits is appropriate for this rule. A longer averaging time for operating parameters is appropriate, because the standards apply over-all operating conditions, and operating conditions of industrial boilers can be highly variable, especially when fuel mix and load change. The operating parameter ranges will be established using test data obtained at one steady state operating condition, so a 30-day averaging period allows for some fluctuations that will occur over the range of operating conditions. EPA is correct in pointing out that variability outside the operator's control such as fuel content, seasonal factors, load cycling, and infrequent hours of needed operation give cause to use a longer averaging period (76 Fed. Reg. 80610).

Response: We thanks the commenter for their support of the 30-day rolling average period for the operating limits. However, the commenter provided no information or data to support its assertion that a longer averaging time is appropriate.

Commenter Name: Russell A. Wozniak

Commenter Affiliation: The Dow Chemical Company

Document Control Number: EPA-HQ-OAR-2002-0058-3449-A1

Comment Excerpt Number: 18

Comment: The proposed rule changes the control device parameter monitoring data averaging period for particulate matter wet scrubbers and hydrogen chloride wet scrubbers from 12-hour block averages to 30-day rolling averages. For fabric filters used to control particulate matter, the proposed rule added an option of maintaining opacity less than 10% (daily block average) and amended provisions for use of bag leak detection system to limit alarms to less than 5% of the operating time during each 6-month operating period.

Dow supports the change in monitoring data averaging time to 30-day rolling averages for PM wet scrubbers and HCl wet scrubbers. As discussed by EPA's comments regarding the proposed change, some variation in combustion unit control occurs during normal day-to-day activities (e.g. changes in fuel characteristics and load cycling). Since scrubber system design takes in to account varying stream flow characteristics, a brief excursion from an operating limit based on a point in time performance test would not result in a significant emissions change. The proposed 30-day rolling average provides a reliable method for demonstrating that the control systems are being properly operated and maintained.

Response: The EPA thanks the commenter for their support.

Commenter Name: Michael D. Wendorf

Commenter Affiliation: FMC Corporation

Document Control Number: EPA-HQ-OAR-2002-0058-3453-A1

Comment Excerpt Number: 5

Comment: A 30-day rolling averaging time for parameter monitoring and compliance with operating limits is a much better metric for demonstration of compliance than the 12-hour block averages in the final rule. A 30-day rolling average is consistent with averaging periods for boiler compliance in NSPS rules and new data points can be readily adapted into existing data acquisition systems.

Response: The EPA thanks the commenter for their support.

Commenter Name: Claudia M. O'Brien, Latham & Watkins LLP

Commenter Affiliation: JELD-WEN, inc.

Document Control Number: EPA-HQ-OAR-2002-0058-3485-A1

Comment Excerpt Number: 6

Comment: In the Boiler MACT reconsideration, EPA has proposed to adopt a 30-day rolling average rather than the 12-hour block averages for parametric monitoring and continuous compliance with operation limits adopted in the final rule "to account for" variability in fuel content, seasonal factors, load cycling, etc. JELD-WEN supports this change, which properly reflects the significant variability in operating conditions that industrial boilers encounter as a result of their role in manufacturing facilities. Industrial boilers are of much smaller scale than utility boilers and must respond rapidly to changing load demands, which increases the variability.

Response: The EPA thanks the commenter for their support.

Commenter Name: Kevin G. Desharnais, Attorney, Mayer Brown LLP

Commenter Affiliation: United States Sugar Corporation

Document Control Number: EPA-HQ-OAR-2002-0058-3496-A1

Comment Excerpt Number: 11

Comment: As referenced above, the Reconsideration Proposal includes a 30-day rolling average for parameter monitoring and demonstrating compliance with a unit's operating limits, rather than the 12-hour rolling average included in the Final Rule. US Sugar supports this change as a more appropriate averaging period, particularly in the case of bagasse-fueled boilers, given the variable nature of bagasse as a fuel source.

Response: The EPA thanks the commenter for their support.

Commenter Name: Jessica Bridges

Commenter Affiliation: United States Clean Heat & Power Association (USCHPA)

Document Control Number: EPA-HQ-OAR-2002-0058-3501-A1

Comment Excerpt Number: 6

Comment: The EPA has determined that the 30-day rolling average for parameter monitoring and demonstration of continuous compliance with operating limits is appropriate for this rule. From review of studies the EPA expects that variability of long term emissions averaging will be about half that represented by the short term testing proposed in the Final Rule (12-hour block). We agree that using the 30-day rolling average will reduce overall variability.

Response: The EPA thanks the commenter for their support.

Commenter Name: Robert D. Bessette

Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 103

Comment: The industrial boilers and process heaters that will be subject to this rule often burn multiple types of fuels and are subject to frequent load swings. Therefore, the emissions from these units vary over the course of a day, depending on the fuel burned and the required production. EPA acknowledged during the Phase 2 ICR test program that emissions from industrial boilers and process heaters are variable by requesting multi-year historical stack test data and conducting 30- day fuel and emissions monitoring studies.

The court reviewing the Brick MACT authorized EPA to consider intra-unit variability and EPA's work on the Hazardous Waste Combustion MACT confirmed the importance of considering variability. Therefore, we believe it is inappropriate for EPA to set limits under the

Boiler MACT that cannot be met consistently by a top performing unit overall operating conditions. One way to consider a unit's variability in emissions is to set a longer averaging time for compliance with an emission limit.

There are factors beyond the boiler operator's control that can cause emissions to vary over a period of days, not hours. For example, the weather will impact moisture content of solid fuels, which will affect how the fuels combust over a period of days. For all types of boilers, the pollutant content of the fuel will vary over a period of days, as evidenced by the range of results obtained during the 30-day fuel sampling required by EPA for many ICR Phase 2 participants. Therefore, we support a 30-day rolling average period to account for operational and emissions variability.

Response: The EPA thanks the commenter for their support.

Commenter Name: John M. Cullen

Commenter Affiliation: Masco Corporation

Document Control Number: EPA-HQ-OAR-2002-0058-3661-A2

Comment Excerpt Number: 7

Comment: Masco supports the proposed 30-day rolling average times for parameter monitoring. Such averaging appropriately accounts for the fact that monitoring occurs over all operating conditions and that such operating conditions for industrial boilers are highly variable.

Response: The EPA thanks the commenter for their support.

Commenter Name: Vickie Woods

Commenter Affiliation: Division of Air Quality, North Carolina Department of Environment and Natural Resources (NCDENR)

Document Control Number: EPA-HQ-OAR-2002-0058-3663-A2

Comment Excerpt Number: 13

Comment: Averaging Times. EPA proposed 30-day rolling average for parameter monitoring and continuous compliance demonstration with operating limits. This would be a change from the final rule, which included 12-1u- block averages corresponding to expected length of longest duration 3-run emission test.

NC DAQ concurs with the 30-day rolling average for parametric monitoring using the most stringent values associated with the operation of the control equipment during performance testing. While NC DAQ recognizes that some parameters measured during performance testing might represent less variability than typical day-to-day operation, with sufficient EPA provided guidance in the future and data we believe that an operations and performance "envelope" can be established.

Response: The EPA thanks the commenter for their support.

Commenter Name: Steve Gossett

Commenter Affiliation: Eastman Chemical Company

Document Control Number: EPA-HQ-OAR-2002-0058-3669-A2

Comment Excerpt Number: 26

Comment: Comment Summary: EPA's proposed changes to a 30-day rolling average for parameter monitoring are appropriate.

Discussion: EPA's discussion of this issue is found on page 80610 of the preamble to the reconsideration proposal. We fully agree and support EPA's reasoning for this change. This proposal will provide needed operational flexibility. The previous 12-hour block averaging periods would have likely caused operators to consider shutdown of units that had some bobble or short term problem with a parameter in an attempt to avoid a potential permit deviation. These shutdowns and restarts would have resulted in more impact on the environment and the plant operation. A 30-day rolling average will allow operators to intervene and correct a problem without shutting down. We agree with EPA that major issues such as ESP transformer failure will show up in a 30-day rolling average and prevent continued operation with malfunctioning control equipment.

Response: The EPA thanks the commenter for their support.

Commenter Name: Matthew Todd

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 98

Comment: Changing operating parameter averaging times from 12 hour to 30 day averages is appropriate and will help adjust for the operating variability that real life operations experience versus the steady state operations during a performance test.

Performance tests are done at very controlled conditions. Typically units are set at a particular high firing rate, feed rates and compositions are held constant, and the unit's air to fuel ratio optimized and held fixed. Where controls are in place, this steady boiler or process heater operation allows the control operating parameters to be optimized and held steady. Furthermore, weather conditions, which can have a significant impact on combustion and control operations, change relatively little over a performance test time period. In the real world, fuel rates and compositions vary, weather conditions vary, and even very well controlled units and control devices go through combustion efficiency and control parameter swings. Longer averaging times for monitored parameters correct for much of this variability and will thus reduce the occurrence of deviations due to nothing other than attempting to match real life operations to the highly controlled, short term operations associated with performance testing. Eliminating deviations that reflect real control device variability, but which are unlikely to reflect significant HAP emission effects, will reduce burdens on both sources and regulators and allow both to focus on events where there are real emission impacts. Thus, we believe this change is entirely justified and appropriate and should be finalized.

Response: The EPA thanks the commenter for their support.

Commenter Name: Douglas A. McWilliams
Commenter Affiliation: American Municipal Power
Document Control Number: EPA-HQ-OAR-2002-0058-3685-A2
Comment Excerpt Number: 36

Comment: Regardless how EPA characterizes the enforceability of operating limits in the final rule, however, AMP supports a 30-day rolling averaging period for all operating parameters (including load and oxygen parameters). Operating conditions of industrial boilers can be highly variable, particularly for municipal utility boilers that may alter load frequently to account for fluctuating demand requirements. Operating parameters will be established using test data from a single steady-state operating period, and the parameter ranges established during this test are unlikely to be representative of the parametric values occurring over a range of operating conditions. Changes in fuel content and seasonal factors can also impact source variability. An extended averaging period helps accommodate some of this variability.

Response: The EPA thanks the commenter for their support.

Commenter Name: Lorraine Gershman
Commenter Affiliation: American Chemistry Council (ACC)
Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1
Comment Excerpt Number: 57

Comment: There are factors beyond the boiler operator's control that can cause emissions to vary over a period of days, not hours. For example, the weather will impact moisture content of solid fuels, which will affect how the fuels combust over a period of days. For all types of boilers, the pollutant content of the fuel will vary over a period of days, as evidenced by the range of results obtained during the 30-day fuel sampling required by EPA for many ICR Phase 2 participants. Therefore, ACC supports a 30-day rolling average period to account for operational and emissions variability.

Commenter Name: Paul Noe
Commenter Affiliation: American Forest & Paper Association (AF&PA) et al.
Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1
Comment Excerpt Number: 108

Comment: Table 4 should specify a 30-day average for the Oxygen Analyzer System. The same reasons for providing a 30-day averaging period for control device operating parameters apply to the oxygen concentration measurement, especially for boilers where steam demand varies, resulting in load swings and variations in combustion conditions. The way the requirement is currently written implies that the oxygen concentration limitation is instantaneous. As startup is currently limited to conditions less than 25 percent load, this requirement may be impossible to meet without an averaging period, as not all boilers are stable at 25 percent load. We note that in Tables 3 and 7 of the Boiler GACT rule, the O₂ monitoring requirement does have a 30-day averaging period specified.

Response: We agree with the commenter that Table 4 should specify a 30-day average. This change has been made to Table 4 to be consistent with item 9(c) in Table 8 which state how continuous compliance is to be demonstrated.

Commenter Name: Russell A. Wozniak

Commenter Affiliation: The Dow Chemical Company

Document Control Number: EPA-HQ-OAR-2002-0058-3449-A1

Comment Excerpt Number: 16

Comment: The requirement that an oxygen trim system control the oxygen to a level established according to Table 4 should be adjusted to provide for a longer averaging time such as a 30 day average similar to other operating limits in Table 4 and similar to EPA's GACT rule. At a minimum, element #8 of EPA's proposed Table 4 should be revised as follows:

For boilers and process heaters subject to a carbon monoxide emission limit that demonstrates compliance with an O2 analyzer system as specified in 63.7525(a), maintain the 30-day rolling average oxygen level such that it is not below the lowest hourly average oxygen concentration measured during the most recent CO performance test.

Such a change would also be consistent with element 9.c. of Table 8 of this rule which requires that one maintain the 30-day rolling average oxygen content at or above the lowest hourly average oxygen level measured during the most recent carbon monoxide performance test.

Response: For response to the request for compliance with oxygen limits to be determined on a 30-day rolling average, please see comment EPA-HQ-OAR-2002-0058-3521-A1, excerpt 108.

Commenter Name: Lee Zeugin and Lauren Freeman

Commenter Affiliation: Utility Air Regulatory Group (UARG)

Document Control Number: EPA-HQ-OAR-2002-0058-3500-A1

Comment Excerpt Number: 33

Comment: EPA proposes to address concerns about variability in control device parameters by lengthening the rolling averaging period for the parameter operating limits from 12 hours to 30 days. 76 Fed. Reg. at 80,610/2-3 and Proposed and Tables 4 and 8. Although a longer averaging period might smooth out some of the normal variability, and therefore would be an improvement over the current rule, EPA's proposal does not address the fundamental flaws in using the chosen parameters to set enforceable operating limits. Averaging periods alone cannot address the fact that the required parameters simply are not well correlated with emissions. Because EPA has never responded to UARG's prior comments on this point, UARG requests that EPA consider and respond to these comments in the context of determining how to address operating and control device variability in the final rule.

Response: We agree that the most direct means of ensuring compliance with emission limits is the use of continuous emission monitoring systems (CEMS). However, we consider other options when CEMS are not available or when the impacts of including such requirements are considered unreasonable. When monitoring options other than CEMS are considered, it is often necessary for us to balance more reasonable costs against the quality or accuracy of the actual

emissions monitoring data. Although monitoring of operating parameters cannot provide a direct measurement of emissions, it is often a suitable substitute for CEMS. The information provided can be used to ensure that air pollution control equipment is operating properly. Because the parameter requirements are calibrated during the initial and annual stack tests, they provide a reasonable surrogate for direct monitoring of emissions. This information reasonably assures the public that the reductions envisioned by the proposed rule are being achieved.

Commenter Name: J. Michael Geers

Commenter Affiliation: Duke Energy

Document Control Number: EPA-HQ-OAR-2002-0058-3543-A1

Comment Excerpt Number: 19

Comment: In the Limited Instances where Operating Limits are Necessary, it is Appropriate for EPA to Increase Averaging Times From 12 Hours to 30 Days. The EPA has determined that a 30-day rolling average for parameter monitoring and demonstration of continuous compliance with operating limits is appropriate for this rule. This is a change from the March 21, 2011 final rule, which generally included 12- hour block averages that corresponded to the expected length of the longest duration 3- run emission test that was required to demonstrate initial compliance with the emission limits. To the extent that operating limits are even appropriate for this rule, Duke Energy supports the change to longer averaging times. The operating limits established through performance testing required by this rule are based on short term, steady state conditions. In its information collection, EPA did not collect sufficient data to characterize the effects of changing load and other operating conditions. These changes can cause short term disruptions to various operating parameters and the longer averaging times will ideally smooth out these differences. Never the less as Duke Energy has indicated in other portions of these comments, EPA's proposed operating parameters generally are not accurate indicators of HAP control.

Response: The EPA thanks the commenter for their support of longer averaging times. For a response to the claim that the proposed operating parameters are not accurate indicators of HAP control, please see comment EPA-HQ-OAR-2002-0058-3500-A1, excerpt 33.

Commenter Name: David A. Buff, Golder Associates Inc.

Commenter Affiliation: Florida Sugar Industry (FSI)

Document Control Number: EPA-HQ-OAR-2002-0058-3504-A1

Comment Excerpt Number: 14

Comment: The FSI respectfully requests that EPA set the O₂ limit for hybrid suspension grate boilers based on a 12-month rolling average. EPA has recognized the unique nature of hybrid suspension grate (bagasse) boilers, and EPA has recognized how the unique features of these boilers affect O₂ levels. In prior submittals to EPA², the FSI has demonstrated that hybrid suspension grate boilers are inextricably tied to the sugar production process. The sugar mill boilers experience significant swings in excess air and oxygen levels because of changes in sugarcane quality (i.e., fuel quality) during the crop season, upsets in the sugar mill, changes in the boiler load, and other factors. These factors not only upset the operation of the boilers, but they also are beyond the control of the boiler operators and the sugar mill operators. Upsets also

can occur in the bagasse feed systems due to plugging of the boiler fuel feeders, fuel piling up on the boiler grates (e.g., due to wet fuel or cold spots in the boiler), and other factors. All of these factors can cause routine, significant swings in the boiler's O2 levels and thus make it difficult to meet an O2 limit based on a 30-day rolling average.

[Footnote]

(2) Florida Sugar Industry's Additional Information in Support of Reconsideration and Amendment of NESHAP For Industrial Boilers, Docket ID No. EPA-HQ-OR-2002-0058. Submitted by Golder Associates Inc, July 15, 2011.

Response: We do not disagree that sugar mill boilers experience significant swings in excess air and oxygen levels because of changes in fuel quality, upsets in the sugar mill, changes in boiler load, and other factors. However, these are the same factors that affect boilers in the other subcategories. We realize that these factors can cause routine, significant swings in the boiler's O2 levels which is why the oxygen operating limit is based on a 30-day average. The commenter has not provided an analysis to support this request.

Comment Excerpt Number: 15

Comment: The FSI has analyzed the continuous O2 data from the only FSI boiler that is equipped with a certified O2 monitor (U.S. Sugar Company's Boiler No. 8). This FSI boiler was designed to comply with the 2004 Boiler MACT standards for new sources. The FSI has used the data from Boiler No. 8 to evaluate the trends in boiler O2 levels, as measured at the stack. A plot of O2 data over a 3-year period is shown in Figures B-1 and B-2 of Appendix B – "O2 Data for New Bagasse Boiler".

The data show that the 30-day rolling average for O2 varied from about 7.5 percent to about 11.5 percent and thus there was a significant (50%) swing from the highest 30-day rolling average to the lowest 30-day rolling average. The highest O2 levels are experienced at the beginning of each crop season, when "take out" sugarcane is being processed in the sugar mill. Take out cane is of lower quality, requiring more excess air to combust. As the crop season progresses over the next 4 to 6 months, the sugarcane quality improves and less excess air is required, resulting in decreasing O2 levels. In contrast, the 12-month rolling average is rather stable over the course of the crop season, varying from only 8.2 percent to 8.7 percent over the course of three years.

Response: For response to the request for oxygen limits for hybrid suspension/grate units to be based on a 12-month rolling average, please see comment EPA-HQ-OAR-2002-0058-3504-A1, excerpt 14.

Comment Excerpt Number: 26

Comment: The FSI agrees with EPA that a longer averaging time is necessary for demonstrating compliance with the EPA's proposed operating parameters. A longer averaging time for operating parameters is appropriate because the EPA standards apply to all operating conditions, and a longer timeframe will help account for variability in a boiler's operations. This issue is especially important to the FSI because the operating conditions for bagasse boilers can be highly variable, especially when there are fluctuations in the boiler's steam load, fuel (e.g., moisture content), fuel mix (i.e., differing varieties of sugarcane), and other factors that are beyond the control of the operator. FSI has presented a substantial amount of evidence to EPA demonstrating that the operation of bagasse-fired boilers is extremely variable because the boilers are interconnected with and intrinsically tied to the sugar mill. By comparison, the operating parameters will be established by using test data that are obtained during one steady-state operating condition. A 30-day averaging period allows for some of the fluctuations that will occur over the normal range of operating conditions.

For these reasons, the FSI supports the use of a 30-day rolling average for demonstrating compliance with the operating parameters, except for O₂, which requires a longer averaging time because O₂ tends to be much more variable than other operating parameters. The averaging time for O₂ is discussed in paragraph 5(b), above.

Response: The EPA thanks the commenter for their support of 30-day rolling averages for parameters other than oxygen. For response to request for oxygen limits for hybrid suspension/grate units to be based on a 12-month rolling average, please see comment EPA-HQ-OAR-2002-0058-3504-A1, excerpt 14.

Comment: *AVERAGING TIMES*

The ICI boilers and process heaters subject to the Final Boiler Rule often burn multiple types of fuels and are subject to frequent load swings. Therefore, the emissions from these units vary over the course of a day, depending on the fuel burned and the required production. EPA implicitly acknowledged during the Phase 2 ICR test program that emissions from ICI boilers and process heaters are variable by requesting multi-year historical stack test data and conducting 30-day fuel and emissions monitoring studies.

The court reviewing the Brick MACT (40 CFR 63, Subpart JJJJ - NESHAP for Brick and Structural Clay Products Manufacturing) confirmed EPA's authority to consider intra-unit variability,²⁰ and EPA's Hazardous Waste Combustor MACT (40 CFR 63, Subpart EEE, NESHAP for Hazardous Waste Combustors) confirmed the importance of considering variability.²¹ Therefore, ACC believes it is inappropriate for EPA to set limits under this boiler rule that cannot be met consistently by a top performing unit under all operating conditions. One way to consider a unit's variability in emissions is to set a longer averaging time for compliance with an emission limit.

[Footnote 20 EPA relied on a 2004 decision, *Mossville Environmental Action Now v. EPA*, 370 F.3d 1232 (D.C. Cir. 2004), holding EPA may consider emission variability in estimating performance achieved by best-performing sources and may set the floor at level that best-performing source can expect to meet “every day and under all operating conditions.”]

[Footnote 21: See for example 73 Fed. Reg. 64071: “To account for the bias in the analytic method, we corrected all TCl emissions data that were below 20 ppmv to 20 ppmv. We accounted for within-test condition emissions variability for the corrected data by imputing a standard deviation that is based on a regression analysis of run-to-run standard deviation versus emission concentration for all data above 20 ppmv. This approach of using a regression analysis to impute a standard deviation is similar to the approach we used to account for total variability (i.e., test-to-test and within-test variability) of particulate matter emissions for sources that use fabric filters.”]

Response: The emission limits established do consider not only operational variability but also fuel variability. Compliance with these emission limits are based on performance tests with continuous compliance based on maintaining operating limits. In most cases, the averaging time for the operating limits is a 30-day rolling average.

Comment Excerpt Number: 58

Comment: ACC also requests that EPA add a 30-day averaging period to the operating load requirement. Table 4 (item 8) and Table 8 (item 11) require operators to maintain the operating load of each unit such that it does not exceed 110 percent of the average operating load recorded during the most recent performance test. For the same reasons provided above for the other operating parameters, EPA should allow a 30-day averaging period for operating load so short term high load periods that are more than 10 percent above the tested load do not result in deviations. Facilities make every attempt to schedule stack tests during periods of high utilization, but sometimes need to operate at more than 100 percent of the load achieved during the stack test for short periods of time in order to meet operational demands. The way the requirement is currently written implies that the 110 percent load limitation is instantaneous. ACC recommends that both Table 4 (item 8) and Table 8 (item 11) be modified to include a stipulation that the operating limit is on a 30-day rolling average basis. For comparison, 40 CFR 63 Subpart JJJJJ Table 7 (item 9) does include the 30-day rolling average basis for the operating load limit.

Response: We agree that an averaging period should be added to the operating load requirement because the requirement, as currently written, implies that the 110 percent load limitation is instantaneous. For the same reasons provided for the other operating parameters, Table 8, item 11(b) has been revised to allow a 30-day averaging period for operating loads so short term high load periods, to meet operational demands, that are more than 10 percent above the tested load do not result in deviations. This change is also consistent with Table 7 of the Boiler Area Source Rule (subpart JJJJJ) rule in which the load monitoring requirement does have a 30-day averaging period specified.

Commenter Affiliation: American Municipal Power

Document Control Number: EPA-HQ-OAR-2002-0058-3685-A2

Comment Excerpt Number: 37

Comment: As the rule is currently written, the averaging period for load and oxygen operating limits is unclear. Sources with highly variable loads, such as utility boilers, may occasionally experience loads in excess of ten percent of the stack tested rate for short periods of time, followed by periods of low load. These load swings will also affect oxygen adjustment, and maintaining a proper oxygen mix during period of load fluctuation is critical to maintaining safe operation of the boiler. The standard as written does not provide sources with clear means of demonstrating compliance in these circumstances, and as a result fails to account for the same variability that affects other operating parameters and that EPA acknowledged made a 30-day averaging period appropriate. EPA should establish a 30-day rolling average for all operating parameters in the final rule.

Response: For a response to the request for a 30-day averaging period to be added to the operating load limits, please see comment EPA-HQ-OAR-2002-0058-3510-A1, excerpt 58. For a response to the request for a 30-day averaging period to be added to the oxygen trim monitoring limits, please see comment EPA-HQ-OAR-2002-0058-3521-A1, excerpt 108.

Commenter Affiliation: American Forest & Paper Association (AF&PA) et al.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 109

Comment: EPA should specify how a 30-day rolling average for the operating parameter limits is calculated, indicating that it includes the previous 720 hours of valid operating data. EPA should make clear that valid data excludes hours during startup and shutdown as well as unit down time. This clarification will be helpful in implementation, as some permitting authorities have interpreted how compliance is demonstrated with rolling averages in odd and sometimes unintended ways. For example, when a unit is down for an outage, state regulators have sometimes sought to continue the 30-day calculation through the outage. We believe that such interpretation would be outside EPA's intention in setting the operating parameter limits on a long term basis in order to accommodate variability. Specification of the minimum number of readings helps to ensure that the 30-day average concept will not be undermined.

Response: We agree with the commenter that how the 30-day average is determined needs to be clarified. The definitions of 10-day rolling average and 30-day rolling average have both been

revised to indicate that it is based on hours, and not days, and what hour periods are to be excluded.

Commenter Name: Mary Sullivan Douglas

Document Control Number: EPA-HQ-OAR-2002-0058-3525-A1

Comment Excerpt Number: 23

Comment: EPA has proposed that owners and operators use parametric monitoring (i.e., pH, pressure drop, scrubant flow rate, etc.) based on stack testing to demonstrate continuous compliance with applicable emission limits. The averaging period used for the parametric monitoring in the original Boiler MACT finalized in March 2011 was a 12-hour average. In the currently proposed amendments, EPA is requiring proposing that owners and operators instead use a 30-day rolling average. This creates an averaging period for parametric monitoring that is grossly inconsistent with the emission standard set through initial performance test (stack testing). The averaging period for a stack test for an emission standard, such as particulate, is typically determined from the average of three stack test runs, which would be only one- to twohour long runs. Where the emission standard is based on the average of three, one-hour stack tests, parametric monitoring with a 30-day rolling average (or even a 12-hour average) will not ensure compliance as the affected unit could be operated outside of the range (and presumably above its three-hour emission limit) for half the month. We do not object to the use of long-term averages *per se*, as such averages can be a solution to the variability issue. However, there is then no technical justification for the very large variability factors adopted by EPA (based on one-hour test runs) in a system that permits 30-day averages to be used for compliance.

Response: We disagree that there is no technical justification for the variability factors adopted. The only variability factors used are fuel variability factors which are based on the actual average variability of the HAP constituent in the fuel combusted by the best performing units. The variability included in the MACT floor analysis is the statistical variability based on the actual variability of the emission test results from the best performing units. While the commenter asserts that parametric monitoring with a 30-day rolling average will not ensure compliance as the affected unit could be operated outside of the range (and presumably above its three-hour emission limit) for half the month, it provides no information or analysis to support this assertions.

Commenter Name: Bart Sponsellar

Commenter Affiliation: Wisconsin Department of Natural Resources

Document Control Number: EPA-HQ-OAR-2002-0058-3527-A2

Comment Excerpt Number: 17

Comment: The EPA is requesting comment on allowing 30-day averaging of parametric operating parameters monitored for compliance. The Department supports averaging over the 30-day rolling period. Based on past experience with sources, this approach is appropriate to address variability in operations while ensuring continuous control effort. However, the Department is aware that existing equipment for facilities is not set up to perform and record this averaging function. One example is the excess air (oxygen) monitoring currently in place for many sources.

These systems are currently set up to produce a value and trim the system on a continuous basis. Other examples are ESP voltage or fabric filter pressure readings. The Department requests for EPA to clarify that such values, which are not averaged, can be used to demonstrate compliance. Basically, this approach is more restrictive than using values averaged over 30 days. Clarifying how to follow this more stringent approach will allow sources to use current monitoring and data systems without additional modifications.

Response: The EPA thanks the commenter for their support of the 30-day rolling average period. We agree with the commenter that it is an unnecessary requirement to require a source using an oxygen trim system to monitor and report oxygen levels on a 30-day rolling average because 63.7525(a)(2) in the final rule requires a source that operates an oxygen trim system to set the oxygen level no lower than the lowest hourly average oxygen level measured during the CO performance test. Tables 4 and 8 have been revised to reflect this change.

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 113

Comment: Achievable flow meter sensitivities should be specified.

Proposed §63.7525(e)(2) specifies that a required flow meter have "a measurement sensitivity of no more than the expected flow rate." However, if the expected flow rate is less than the design flow rate or it does not meet this criteria over the entire range of potential flows an additional, separate flow meter may be needed to meet this sensitivity requirement at all flow rates. This additional instrumentation does not appear to have been considered in evaluating the proposal burden or cost. Nor is it clear what constitutes "expected." Is that what is expected tomorrow, next week, next year, at any time? We see no reason why standard instrumentation is unacceptable and why the existing instruments cannot be used. We, therefore, recommend that this provision be revised to require that the flow meter have a measurement sensitivity of no greater than 2% at the design flow rate.

Response: We agree with the commenter and 63.7525(e)(2) has been revised to change "expected" to "design."

Commenter Name: M.L. Steele

Comment Excerpt Number: 20

Comment: The averaging period for the maximum allowable operating steam load in Table 8 is not specified. CraftMaster requests that the averaging period be specified as the 24-hour average to be consistent with other programs.

Response: The averaging period for the load operating limit in Table 8 has been revised to a 30-day rolling average to be consistent with the other operating limits.

11H. Reduced Testing Allowance

Commenter Name: David A. Buff, Golder Associates Inc.
Commenter Affiliation: Florida Sugar Industry (FSI)
Document Control Number: EPA-HQ-OAR-2002-0058-3504-A1
Comment Excerpt Number: 57

Comment: The FSI fully supports EPA's decision to allow decreased stack testing if the tests consistently demonstrate compliance with the applicable emission limit. EPA adopted the same approach in the New Source Performance Standards for Municipal Waste Combustors (40 CFR 60, Subpart Eb) and it has worked successfully for many years. This approach will save money on testing while providing reasonable assurance of ongoing compliance with the emission limits in the Boiler MACT rule.

Response: The EPA thanks the commenter for their support.

Commenter Name: John S Williams
Commenter Affiliation: Maine Pulp & Paper Association (MPPA)
Document Control Number: EPA-HQ-OAR-2002-0058-3466-A1
Comment Excerpt Number: 11

Comment: The proposed rule will allow units that demonstrate compliance for a particular pollutant at a level at or below 75 percent of the emission limit for 2 consecutive years to forego stack testing for up to 37 months. Since most pollutant testing will be completed during worst case scenarios, this allowance will likely provide no relief of the performance test requirement's costly burden. Also, because of the worst cast fuel mix and operating limit requirements, many multiples of stack testing scenarios will be required

Response: We disagree that because most pollutant testing will be completed during worst case scenarios, the allowance will provide no relief of the performance test requirement's costly burden. The emissions limits are based on the average of the emissions from the best performing units which were conducted under their worst case scenarios. A review of the emissions from these best performing units show that a unit can achieve 75 percent of the limits to which the criterion applies with available controls.

Commenter Name: Lee Zeugin and Lauren Freeman
Commenter Affiliation: Utility Air Regulatory Group (UARG)
Document Control Number: EPA-HQ-OAR-2002-0058-3500-A1
Comment Excerpt Number: 39

Comment: Under the 2011 final rule, periodic performance testing for IB units not relying on CEMS or fuel input sampling must be completed within 13 months of the previous test, except for (1) units subject to certain emission limits specified in Tables 1 and 2, and (2) units with test data showing emissions "at or below 75 percent of the emission limit" for at least 2 consecutive years. Such units may test every third year as long as no changes in source or control device operation have occurred that could increase emissions. 40 C.F.R. § 63.7515(a) - (c). The reduced testing proposal applies to all sources and tests except sources using emission averaging. In

comments on the 2010 proposed rule, UARG supported inclusion of a reduced testing provision, but questioned the reasonableness of the 75 percent criterion given the extremely low levels of EPA's proposed limits. UARG noted the Agency's failure to provide a rationale for the criterion, or data suggesting that any source could achieve 75 percent of the proposed emission limits, some of which are established at or near the detection limit. EPA-HQ-OAR-2002-0058-2880.1 at 24-25. Because EPA finalized the rule without addressing or responding to UARG's comments, UARG included the issue in its reconsideration petition. EPA-HQ-OAR-2002-0058-3324 at 3.

On reconsideration, EPA proposes to retain the current rule but solicits comment on it. EPA asserts that it addressed any concerns with achievability by exempting those limits in Tables 1 and 2 that were replaced in the standard setting process by three times the "representative detection limit" ("RDL") because that was deemed the lowest level that can be measured accurately. 76 Fed. Reg. at 80,617/1.

Although UARG appreciates EPA's recognition of the significance of measurement capabilities and detection levels in establishing a reduced testing criterion, EPA's approach in the final rule fails to address the capabilities of available controls. As a result, although UARG supports the existing exclusions, to make the 75 percent criterion meaningful, EPA still would have to show that a unit could achieve 75 percent of the limits to which the criterion applies with available controls. EPA has provided no data or analysis. The requirement that source and control device operation remain consistent with prior successful testing should be sufficient to ensure representativeness of the prior tests without requiring sources to demonstrate a significant margin of compliance to qualify for reduced testing. If such a margin of compliance is not possible to consistently achieve, the reduced testing provision has no meaning.

Response: We disagree that EPA's approach in the final rule fails to address the capabilities of available controls. The emissions limits are based on the average of the best performing units and including operational variability. A review of the emissions from these best performing units show that a unit can achieve 75 percent of the limits to which the criterion applies with available controls.

Document Control Number: EPA-HQ-OAR-2002-0058-3663-A2

Comment Excerpt Number: 26

Comment: NC DAQ further supports the use of a reduced testing frequency for those sources that are able to demonstrate consistent emission rates well-below the emission limits. However, DAQ believes that this test frequency should be viewed in context of operations between emissions tests.

Response: The EPA thanks the commenter for their support of reduced testing frequency. While the commenter believes that this test frequency should be viewed in context of operations between emissions tests, it provides no information to support this assertion.

Commenter Name: Mary Sullivan Douglas
Commenter Affiliation: National Association of Clean Air Agencies (NACAA)
Document Control Number: EPA-HQ-OAR-2002-0058-3525-A1
Comment Excerpt Number: 51

Comment: EPA has proposed reduced testing frequency for sources whose emission tests are at or below 75 percent of the emission limit. This suggestion is inconsistent with EPA's determination that emissions from well-controlled sources routinely vary by more than an order of magnitude.

Response: We disagree that the proposed reduced testing frequency is inconsistent with our determination that there is variability in emissions from well-controlled sources. The reduced stack testing frequency does not, in any way, reduce the requirement for the source to continuously monitor the appropriate operating limit to demonstrate continuous compliance with the emission limit. The source is required to maintain that operating parameter below or above the operating limit established during the performance test. Maintaining the appropriate operating limit ensures that emissions do not vary by more than an order of magnitude.

Commenter Name: Matthew Todd
Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)
Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2
Comment Excerpt Number: 100

Comment: We support the proposed reduced stack testing frequency if testing demonstrates operation well below the limit (or at the limit if the limit was based on the representative detection limit), but request some additional relief for BPH in the non-continental liquids subcategory. We also recommend this sensible approach to reducing burdens be extended to fuels analysis.

Response: The EPA thanks the commenter for their support of reduced stack testing allowance. We agree with the commenter that a similar allowance should be extended to fuel analysis and, in the final rule, 63.7515(f) has been revised to include similar language as for stack testing frequency.

Commenter Name: Samuel H. Bruntz
Commenter Affiliation: Alcoa Power Generating, Inc.
Document Control Number: EPA-HQ-OAR-2002-0058-3755-A1
Comment Excerpt Number: 4

Comment: Proposed regulation 63.7515 (a) through (d) is unnecessary, if the unit continuously monitors compliance with the PM limit through use of a CEMS. Alcoa-Warrick thus suggests the following revision to 63.7515 (a):

"63.7515(a) Unless you are demonstrating continuous compliance through operation of a PM-CEMS, HCl-CEMS, SO₂ CEMS as a surrogate for HCl, mercury CEMS or mercury Appendix K

absorption tubes, you must conduct all applicable performance tests according to § 63.7 520 on an annual basis, except as specified in paragraphs (b) through (d)(e) of this section."

Response: We disagree with the commenter that units using CEMS should be exempt from performance testing. The emission limits are based on the results of performance testing. Thus, compliance is demonstrated by performance testing. The CPMS required in the rule are operating limits that must be maintained to demonstrate continuous compliance.

11I. Coal Sampling Technique

Commenter Name: Lee Zeugin and Lauren Freeman

Commenter Affiliation: Utility Air Regulatory Group (UARG)

Document Control Number: EPA-HQ-OAR-2002-0058-3500-A1

Comment Excerpt Number: 41

Comment: EPA adds an option for use of an automated sampling system. Proposed § 63.7521(c). EPA replaces the requirements for use of a square shovel, for sampling at a depth of "exactly" 18 inches, and for breaking of pieces larger than 3 inches, with more moderate requirements. Proposed § 63.7521(c)(2) and (d). UARG appreciates and supports these changes, which will reduce burden without sacrificing representativeness.

Response: The EPA thanks the commenter for their support.

Commenter Name: Mary Sullivan Douglas

Commenter Affiliation: National Association of Clean Air Agencies (NACAA)

Document Control Number: EPA-HQ-OAR-2002-0058-3525-A1

Comment Excerpt Number: 52

Comment: NACAA agrees that sources may employ automated fuel-sampling equipment, but notes that the 90th percentile compliance obligation is inconsistent with EPA's determination that MACT floors must be set at a 99th percentile level.

Response: The EPA thanks the commenter for their support of automated fuel-sampling equipment. We disagree that the 90th percentile obligation is inconsistent with the 99th percentile used for development of the MACT floors. In one case (MACT floors), an emission limitation is being established that must be achieved at all times factoring the inherent variability of testing, control performance, operational variations, and fuel variability, so basing the MACT floors on the 99% UPL was appropriate. In the other (compliance by fuel analysis), we conducted an analysis to determine an appropriate statistical approach that would minimize the frequency of conducting fuel analysis to demonstrate continuous compliance. Given the significant variability in the HAP content of coal, there were concerns about requiring only an initial sampling and testing of the fuel as a means of ensuring ongoing compliance. Conceptually, accounting for variability would eliminate the need for frequent sampling; but only if we adopted a statistical analysis that accounts for the variability that can possibly occur in the applicable fuel type. Various percentile confidence levels were analyzed. Based on this statistical analysis, the appropriate percentile confidence level for ensuring continuous compliance was determined to be 90. Coal sets with all monthly values below the benchmark

had their 90th percentile confidence limit also below the benchmark. For coals sets with any monthly values at or above the benchmark, the 90th percentile confidence level was above the benchmark.

Commenter Name: Pat Dennis

Commenter Affiliation: Archer Daniels Midland Company

Document Control Number: EPA-HQ-OAR-2002-0058-3670-A2

Comment Excerpt Number: 16

Comment: EPA should not attempt to prescribe coal sampling methodologies in this rule but rather should simply reference ASTM standards and allow for reasonable equivalency with regard to smaller sources.

Response: The EPA has provided multiple ASTM coal sampling methods in the rule; specifically ASTM D5192 – 09, D7430, D6883, and D2234.

11J. Fuel Analysis Methods

Commenter Name: Douglas Price

Commenter Affiliation: Tesoro Companies, Inc

Document Control Number: EPA-HQ-OAR-2002-0058-3630-A2

Comment Excerpt Number: 2

Comment: For liquid fuel fired sources, the re-proposed 40 C.F.R. Subpart DDDDD rule allows for emission limit compliance to be demonstrated by analyzing the fuel burned in affected boilers and process heaters for mercury (Hg) and chlorine content. Table 6 lists the specific methods to be used for analyzing the fuel and includes one method, EPA SW-846-7470A, for determining the Hg content. Also, the rule language directly above Table 6 states the following:

“As stated in § 63.7521, you must comply with the following requirements for fuel analysis testing for existing, new or reconstructed affected sources. However, equivalent methods (as defined in § 63.7575) may be used in lieu of the prescribed methods at the discretion of the source owner or operator: .. ”

While this rule language could be read that once a source owner or operator determines the alternative method meets the definition of "equivalent," it can be used without further approval, 63.7521 (b)(2) requires a specific process to be followed in order for another test method to be considered "equivalent" to the method listed in Table 6. The process includes requesting the use of the alternative method in the required fuel monitoring plan and then EPA must approve the method, as described in 63.7521 (b)(2)(v). The Table 6 listed method must be used until the alternative method is approved by the EPA, which could be an extended period of time.

The Kapolei Refinery has historically analyzed the fuel oil for Hg content using the laboratory test method SW-846-1631E. Tesoro considers this test method to be the best approach and it has been used for over 10 years, not only for fuel oil analysis but also for crude oil analysis. In addition, in a previous version of 40 C.F.R. Subpart DDDDD, the EPA approved the use of test method SW-846-1631/1631E as being "equivalent."² Lastly, this method was approved by the

EPA for analyzing distillation feed samples as part of the EPA's 2011 Petroleum Refinery information collection request (ICR).³

While the current re-proposed 40 C.F.R. Subpart DDDDD rule provides a process to determine this method SW-846-1631E because it is a method that has already been determined as equivalent by the EPA. If this method is not added to the final 40 C.F.R. Subpart DDDDD, Tesoro would be forced to switch to another method for an unknown period of time until the alternate method is approved by EPA, which we consider to be unnecessary.

Recommendation: For the reasons described above, Tesoro requests that test method SW-846-1631E be added to Table 6 of the final rule.

[Footnote 2: See FR 71 70653]

[Footnote 3: See "Petroleum Refinery Emissions Information Collection: Part IV: Summary of Test Procedures, Methods, and Reporting Requirements for Distillation Feed Composition Analysis" (OMB Control No. 2060-0657)]

Response: The EPA agrees with the commenter and finds SW-846-1631E to be equivalent to SW-846-7470A, as listed in Table 2 of this document:
https://refineryicr.rti.org/Portals/0/Instructions_for_Component_3_Distillation_Feed_Sampling.pdf; and has modified table 6 of the rule as requested.

Comment Excerpt Number: 111

Comment: Compliance procedures do not appear to be included in the proposal for demonstrating compliance with the Total Selected Metals limit for Gas 2 and they should be added. Procedures for showing compliance with TSM limits where solid fuels are combusted are included (e.g., §§63.7530(c)(5) and 63.7530(b)(1)) in the proposal, but Gas 2 procedures appear to be lacking and should be added. These procedures should clearly state that analyses are only needed for metals that are expected to be present in the gas. Typically, only process related metals will be present in Gas 2 and the owner/operator will know what those metals are. There is no reason to require testing for other metals in that case and we request that the gas 2 procedures be clear on this point.

Response: We disagree with the commenter. The TSM compliance procedures in 63.7530(b) and (c) are in regards to fuel analysis not stack testing. We are not aware of proven test methods to quantify the content of metals in gaseous fuel. The procedures listed in Table 5 of the rule for TSM are applicable to Gas 2 units.

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 124

Comment: The requirement to measure the water content of the stack gas in Table 5 Item 4.c. is unnecessary and should be deleted. Item 4 of Table 5 deals with determining the CO content of a boiler or process heater stack. EPA Method 10 is specified as the method for determining the CO content in Item 4.d. Method 10 measures the CO on a dry basis and thus there is no need to determine the moisture content in the stack in order to correct the measured CO concentration to a dry basis.

Method 10 for CO refers back to Method 7E – which specifies the following water removal step as follows.

6.2.4 Conditioning Equipment. For dry basis measurements, a condenser, dryer, or other suitable device is required to remove moisture continuously from the sample gas. Any equipment needed to heat the probe or sample line to avoid condensation prior to the sample conditioning component is also required.

Response: The EPA recognizes that measurements may involve conditioning of stack gas to remove moisture prior to CO measurement; however we are leaving this requirement in the rule to accommodate dilution sampling systems that do not make use of this option. Measurement and reporting in the rule will remain on a dry basis.

Commenter Affiliation: Waste Management (WM)

Document Control Number: EPA-HQ-OAR-2002-0058-3681-A2

Comment Excerpt Number: 22

Comment: According to Table 6 of the Proposed Boiler MACT Reconsideration Rule, you must conduct fuel analysis for mercury using one of the four prescribed test methods, or equivalent method. However, §63.7521(g)(2)(vi) appears to prevent gaseous fuel suppliers from requesting approval to use alternative test methods. The boiler owner/operator on the other hand may request approval to use an alternative test method. No explanation or rationale is provided for this inflexible requirement. Furthermore, it is likely to affect most of the analysis conducted under this section of the rule. We believe it is highly likely that purchasers of gaseous fuels will require their fuel suppliers to develop the analyses and documentation necessary to qualify them as an “other Gas 1 fuel.” We strongly recommend EPA remove this language so that all analyses conducted for use of other Gas 1 fuels may utilize methods listed in §63.7521(f)-(i) or equivalent methods.

Response: We disagree. The requirement in 63.7521(g)(2)(vi) for gaseous fuel suppliers is identical to the requirement in 63.7521(b)(2)(vi) for non-gaseous fuel suppliers. These section require that the fuel suppliers must use the methods required by Table 6 of the rule. Table 6 list certain specific methods but allows the use of any equivalent methods. The term "equivalent" is defined in 63.7575.

Commenter Name: Kerry Kelly
Commenter Affiliation: Waste Management (WM)
Document Control Number: EPA-HQ-OAR-2002-0058-3681-A2
Comment Excerpt Number: 23

Comment: WM requests that EPA incorporate additional test methods in the rule that can be used under §63.7521. §63.7521 states that a gaseous fuel other than natural gas or refinery gas can be qualified as a “Gas 1” fuel by conducting fuel testing according to methods laid out in Table 6. Specifically, Table 6 requires that the mercury concentration in the fuel must be measured using one of the following test methods: “ASTM D5954, ASTM D6350, ISO 6978–1:2003(E) or ISO 6978–2:2003(E) (or an equivalent test method)”. The Agency states that the methods in Table 6 “shall be used” unless an alternative analytical method is specifically approved. The required test methods listed in EPA’s referenced table are typically used for natural gas analyses, and have not been proven to be appropriate for analyzing LFG for mercury. Further, because gaseous fuel suppliers are not allowed to use alternative methods, WM would be forced to use an unproven method to demonstrate our LFG compliance with the certification requirements. All four of the listed test methods were developed to determine mercury levels in natural gas, not LFG, but the composition and physical properties of LFG and natural gas differ.

For example, natural gas is primarily methane with lower concentrations of related alkanes and carbon oxides, and trace quantities of other hydrocarbons. LFG typically contains 45% to 60% methane and 40% to 60% carbon dioxide. LFG also includes small amounts of nitrogen, oxygen, ammonia, sulfides, hydrogen, and carbon monoxide. The complexity of component fuels typically encountered in sampled LFG often renders the methods typically used for natural gas characterizations inappropriate. Either interferences or target analyte levels may disqualify natural gas methods when attempting to acquire representative Hg data in LFG. The performance of these methods in an LFG matrix has yet to be demonstrated. As a result, it is inappropriate for the Agency to categorically require that, in the absence of a pre-approval process, only the four methods listed in Table 6 may be used for mercury testing in LFG.

Response: We disagree that only the four methods listed in Table 6 may be used for mercury testing in LFG. Table 6 allows for methods that are "equivalent" and sources may request to use an alternative analytical method than those in Table 6 as stated in 63.7521(c)(2)(v).

Comment: EPA has included numerous compliance demonstration alternatives in the Proposed Rule. AMP appreciates EPA's efforts to provide flexibility to the regulated community and supports EPA's inclusion of the following optional compliance alternatives:

- Use of fuel testing to demonstrate compliance with HCl, Hg, and TSM limits

Response: The EPA thanks the commenter for their support.

Commenter Name: Russell A. Wozniak
Commenter Affiliation: The Dow Chemical Company
Document Control Number: EPA-HQ-OAR-2002-0058-3449-A1
Comment Excerpt Number: 12

Comment: EPA Reference Method 30B (Determination of Total Vapor Phase Mercury Emissions from Coal-Fired Combustion Sources Using Carbon Sorbent Traps) in 40 CFR 60 Appendix A should be added to the list of approved methods in Table 6 Section 3 or should be considered as an equivalent to the listed methods.

Section 3. of Table 6 lists acceptable analytical methods for measuring the mercury concentration in the off-gas fuel to show that the concentration is less than 40 micrograms per cubic meter. EPA should consider adding EPA Method 30B to the list of approved methods or noting the method as "equivalent" to the listed methods. EPA Reference Method 30B was developed to determine the mercury content in waste gas streams associated with coal combustion. However, our understanding is that external stack testing companies have successfully used this method to measure the mercury concentration in off-gas streams that are used as fuel in boilers and process heaters. External lab partners assure us that from past experience that Method 30B is superior and Dow Chemical Comments Page 6 Docket EPA-HQ-OAR-2002-0058

more accurate than any of the older methods that are currently listed in the rule. The method is also easier and safer to implement and conduct in the field since the other methods listed by EPA require an in-situ analysis of the fuel stream.

Method 30B is designed to measure the mass concentration of total vapor phase Hg, including elemental mercury and oxidized forms of Hg in micrograms per cubic meter. The analytical range and sensitivity is typically in the range of 0.1 micrograms per dry standard cubic meter to 50 micrograms per dry standard cubic meter which should be adequate to demonstrate that the mercury content is less than 40 micrograms per cubic meter.

Response: We have not seen any data to support the contention that Method 30B as written would be appropriate for sampling and analysis of off-gas fuel. In particular, we would be concerned that (1) the sampling approach of Method 30B is not immediately applicable to the pressures in gas lines and (2) we have not yet seen data demonstrating that there is a sorbent appropriate for this type of sample matrix. Given these concerns, we believe it best, in lieu of including Method 30B in Table 6 of the rule at this time, that the alternative test method provisions of 63.7(f) be used during rule implementation to determine if Method 30B could be considered equivalent. The requester would need to provide us with supporting procedures and data as described in 63.7(f) and the [Federal Register Notice](#) at 72 FR 1/7/2007, page 4257.

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2
Comment Excerpt Number: 179

Comment: Method SW-846-1631E should be added to Table 6 as an approved mercury determination method. This method was approved by the EPA for analyzing distillation feed samples as part of the EPA's 2011 Petroleum Refinery information collection request (ICR) and has been used for years by some member companies for determining mercury in fuel oils.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3630-A2, excerpt 2.

Commenter Name: Kerry Kelly

Commenter Affiliation: Waste Management (WM)

Document Control Number: EPA-HQ-OAR-2002-0058-3681-A2

Comment Excerpt Number: 24

Comment: Numerous studies have been conducted to measure mercury in LFG, including several conducted for EPA. The table below [See pg 13 of submittal for table] lists the test methods used in these studies, the methods specified in Table 6, and, for each method, whether it was included in the Agency's proposed Boiler MACT Reconsideration Rule. This table shows that none of the methods used in the published mercury LFG studies, including those sponsored by EPA, were included in Table 6 of the proposed rule. Conversely, none of the methods in Table 6 were relied on in any of the mercury LFG studies.

This examination of fuel testing methods clearly indicates that the Agency should expand Table 6 to include additional options for measuring mercury in gas fuels. At a minimum, methods that have been tested and proven reliable in mercury LFG studies, particularly EPA Method 30B and EPA Method 1631, both of which are already approved EPA testing methods and have been evaluated for accuracy and precision in LFG studies, should be included as acceptable methods in the mercury fuel specification section in Table 6. Additionally, it is recommended that the Agency consider and evaluate the accuracy, precision, selectivity and sensitivity of the current methods included in Table 6, taking into account their applicability to gas fuels other than natural gas or refinery gas.

Response: For a response to the request to include Method 30B testing, see EPA-HQ-OAR-2002-0058-3449-A1, excerpt 12 which states that in lieu of including Method 30B in Table 6 of the rule at this time, that the alternative test method provisions of 63.7(f) be used during rule implementation to determine if Method 30B could be considered equivalent. The rule contains a definition of "equivalent" method. Equivalent methods are voluntary consensus standards (VCS) or EPA methods which are applicable to the fuel type or target analyte being measured. Although we disagree with adding the methods listed in the comment letter to Table 6 in the final rule, we would consider the following methods in the comment letter as equivalent: EPA Method 1631, Modified SW-846 Method 7473, ASTM D5954, ASTM D6350, ISO 6978-1:2003, ISO-6978-2:2003, and CARB Method 436. Equivalent methods may be used in lieu of the prescribed methods in Table 6 to subpart DDDDD at the discretion of the source owner or operator. Therefore, publishing a list of or adding to the list of approved methods is not necessary. Similarly, State or EPA approval of equivalent methods is not necessary.

Commenter Affiliation: Waste Management (WM)

Document Control Number: EPA-HQ-OAR-2002-0058-3681-A2

Comment Excerpt Number: 26

Comment: We had difficulty identifying laboratories that have capability (equipment and experience) to perform the test methods listed in Table 6 for determining mercury in LFG, specifically ASTM D5954. After contacting several large accredited laboratories, including research laboratories and laboratories that service the oil and gas industry, we located only one laboratory that has the required equipment to run ASTM D5954 for mercury analysis in LFG. However, this laboratory has only performed analysis to determine mercury in LFG in a research capacity rather than for clients concerned with ongoing compliance obligations. Unfortunately, after contracting with the laboratory and sending them our samples, the equipment required to perform the sample analysis for ASTM D5954 broke down and will not be repaired for at least two weeks as it requires a replacement part that must be shipped from Japan. This circumstance prevents the laboratory from conducting analysis on collected LFG samples it received February 13. A further complication is that the laboratory's quality control sample hold time is 30 days, which may render our samples unusable. This same laboratory also does not have capability (equipment) to perform ASTM D6350 on the collected samples and cannot identify another laboratory to complete timely analysis using ASTM D6350. This lack of laboratory capability and capacity across the nation amplifies the limitations with Test Methods prescribed in Table 6 of the proposed Boiler MACT Reconsideration Rule for LFG and other gaseous fuels. WM would like to share lessons learned from this field study with EPA, specifically whether the test methods listed in Table 6 for determining mercury (in natural gas) are applicable to other gaseous fuels (e.g., LFG). Therefore, we respectfully request that the Agency accept information gathered as part of this field study as supplemental comments on the proposed Boiler MACT Reconsideration Rule if/once we receive the final ASTM D5954 results from the laboratory. We believe our comments demonstrate the appropriateness of incorporating other test methods in the proposed Boiler MACT Reconsideration Rule.

Response: For a response to using other methods not listed in Table 6, see comment EPA-HQ-OAR-2002-0058-3681-A2, excerpt 24.

Commenter Name: Jim Cetrullo

Commenter Affiliation: TestAmerica

Document Control Number: EPA-HQ-OAR-2002-0058-3744-A1

Comment Excerpt Number: 1

Comment: TestAmerica was recently requested by a client to provide analytical services for determination of mercury in landfill gas using the methods specified in Table 6 of the Proposed Reconsideration of the Final Rule for National Emission Standards for Hazardous Air Pollutants for Major Sources: Industrial, Commercial, and Institutional Boilers and Process Heaters

[EPA-HQ-OAR-2002-0058]. TestAmerica is considered a full service provider of analytical services and none of the methods listed in Table 6 were available to clients at any of our laboratory facilities.

TestAmerica requests that EPA incorporate additional test methods in the rule that can be used under §63.7521. §63.7521 states that a gaseous fuel other than natural gas or refinery gas can be

qualified as a "Gas 1" fuel by conducting fuel testing according to methods laid out in Table 6. Specifically, Table 6 requires that the mercury concentration in the fuel must be measured using one of the following test methods: "ASTM D5954, ASTM D6350, ISO 6978-1:2003(E) or ISO 6978-2:2003(E) (or an equivalent test method)". The Agency states that the methods in Table 6 "shall be used" unless an alternative analytical method is specifically approved.

TestAmerica searched for commercially available laboratories that could perform one or more of the specified methods. The search found only a single laboratory that was able to perform any of the methods; and, the one Table 6 specified method that the laboratory performed was ASTM D5954. Technical discussions with that laboratory revealed that the Table 6 specified method(s) were developed for analysis of natural gas and had not been thoroughly tested and proven to be adequate for landfill gas analysis.

Numerous studies have been conducted to measure mercury in LFG, including several conducted for EPA. None of the studies reviewed by us have used the Table 6 specified methods as the approach for determination of mercury in LFG. However, several have used EPA Method 30B and EPA Method 1631 as the methods of choice for determination of mercury in landfill gas. Since data from EPA 30B and EPA 1631 for mercury analysis in landfill gas are readily available in the public domain, it is recommended that these methods be specifically added to Table 6. It is also recommended that language be added that gives more flexibility in the choice of methods so that there will be some certainty that the regulated community will have an adequate number of qualified laboratories available to them to provide these testing procedures.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3681-A2, excerpt 24.

Commenter Name: Lorraine Gershman

Commenter Affiliation: American Chemistry Council (ACC)

Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1

Comment Excerpt Number: 137

Comment: ACC recommends EPA add Method 30B as an approved method for demonstrating that a gas fuel meets the specification for "Other Gas 1 Fuel" in Table 6 of the rule, or note that the method is "equivalent" to the listed methods. EPA Reference Method 30B was developed to determine the mercury content in exhaust gas streams associated with coal combustion. However, our members have indicated that external stack testing companies have successfully used this method to measure the mercury concentration in off-gas streams that are used as fuel in boilers and process heaters. External lab partners assure our members that Method 30B is superior and more accurate than any of the older methods that are currently listed in the rule. The method is also easier and safer to implement and conduct in the field since the other methods listed by EPA require an in-situ analysis of the fuel stream. Method 30B is designed to measure the mass concentration of total vapor phase mercury, including elemental mercury and oxidized forms of mercury in micrograms per cubic meter. The analytical range and sensitivity is typically in the range of 0.1 to 50 micrograms per cubic meter, which should be adequate to demonstrate that the mercury content is less than 40 micrograms per cubic meter.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3449-A1, excerpt 12.

Commenter Name: Shannon S. Broome
Commenter Affiliation: Auto Industry Forum (AIF)
Document Control Number: EPA-HQ-OAR-2002-0058-3512-A1
Comment Excerpt Number: 30

Comment: Numerous studies have been conducted to measure mercury in LFG, including several that were conducted for EPA. The table that accompanies these comments at Attachment E (attached to these comments) lists the test methods used in these studies and the methods specified in Table 6, and, for each method, whether it was included in the Boiler MACT Reconsideration Proposal. This table shows that none of the methods used in the publicly available, published LFG studies for Hg, including those sponsored by EPA, were included in Table 6 of the reconsideration proposal. Conversely, none of the LFG studies for Hg relied on the methods in Table 6.

This examination of fuel testing methods clearly indicates that EPA should expand Table 6 to include additional options for measuring Hg in gaseous fuels. At a minimum, EPA should include the methods tested and proven reliable in LFG studies for Hg, particularly EPA Method 30B and EPA Method 1631. The Agency may also want to consider including stack sampling and analysis methods for Hg approved by EPA and the State of California—CARB Method 436, EPA Method 101 and EPA Method 29. Additionally, AIF recommends that the Agency consider and evaluate the accuracy, precision, selectivity and sensitivity of the methods currently included in Table 6, taking into account their applicability to gas fuels other than NG or RG. AIF's comments demonstrate the appropriateness of incorporating into the final reconsideration rule additional methods for gathering data as to the concentration of Hg in a gaseous fuel. AIF urges EPA to amend the reconsideration proposal accordingly.

Response: For a response to the request to include method 30B testing, see EPA-HQ-OAR-2002-0058-3449-A1, excerpt 12.

Commenter Name: Kerry Kelly
Commenter Affiliation: Waste Management (WM)
Document Control Number: EPA-HQ-OAR-2002-0058-3681-A2
Comment Excerpt Number: 25

Comment: Method 30B is a stack gas method approved for the characterization of Hg in various off-gas sources, including incinerators, boilers, and other thermal devices. EPA has conducted collection of LFG using Method 30B with success and has used that test data in its 2008 Background Information Document for developing revised AP-42 emission factors for municipal waste landfills. (EPA/600/R-08-116. September). Some advantages of using Method 30B include:

Point source sampling can be conducted using relatively easy to operate and portable instruments;

- The sampling technology is mature and familiar to most well-trained sampling technicians;
- Analysis of samples is relatively inexpensive, and uses a standard EPA methodology;

- Quality assurance/quality control and comparability of data are easily monitored; and
- Data may be validated using standard auditing practices.

WM recently conducted a field study using Method 30B and ASTM D5954 for several projects supplying LFG as fuel to industrial boilers to demonstrate the viability of both applications. We evaluated the sampling and analysis of LFG using Method 30B by employing both an Ohio Lumex mercury analyzer, and by digestion of the sampling tube fractions followed by analysis using Method 7470B (CVAA). The results of the Method 30B analysis range from 0.2 to 1.9 ug/m³, which are consistent with results presented in the published literature previously identified in our comments and validate that mercury concentrations in LFG are well below the fuel specification for other gas 1 fuels.

Response: For a response to the request to include Method 30B testing, see EPA-HQ-OAR-2002-0058-3449-A1, excerpt 12.

Commenter Name: Barry Christensen

Commenter Affiliation: Occidental Chemical Corporation (OCC)

Document Control Number: EPA-HQ-OAR-2002-0058-3477-A1

Comment Excerpt Number: 6

Comment: OCC recommends a broader selection of methods for conducting the sampling and analysis of gaseous fuels.

We provided the required gas sampling methods specified in the final rule to three commercial testing companies. After consulting with their laboratories, they all declined to provide quotations for Gas 2 fuel (hydrogen) sampling using the required methods specified in Table 6. One of the primary reasons cited is the safety concern of sampling an explosive gas mixture. A much safer option would be to allow operators to conduct a one-time stack test for mercury by Method 29 or 30 on a process heater or boiler stack. Also, in a few cases, where a fuel gas can be vented to the atmosphere (e.g. hydrogen), alternative sampling options are available. Existing sampling Methods 101 and 102 for mercury testing should also be an allowed option, in addition to those methods specified in Table 5.

Response: The EPA recognizes the safety concerns of Hydrogen containing fuels and encourages the commenter to seek a lab accustomed to handling such materials. Stack testing for mercury is also a requirement of Table 5. Fuel sampling for mercury using EPA test methods may be problematic on Gas 2 fuels as the low molecular weight of hydrogen may require detailed recalibration of equipment. Additionally, hydrogen containing fuel gas may become explosive if exposed to standard stack testing equipment. We have allowed sampling of Gas 2 fuels with Silonite coated evacuated “bombs” in the recent Refinery ICR testing and such containers may be used pending approval of the administrator, as hydrogen is known to leak from conventional Tedlar bag samples.

Commenter Name: Lee Zeugin and Lauren Freeman

Commenter Affiliation: Utility Air Regulatory Group (UARG)

Document Control Number: EPA-HQ-OAR-2002-0058-3500-A1

Comment Excerpt Number: 40

Comment: EPA proposes some changes to § 63.7521 that are responsive to UARG's comments. For the fuel analysis plan submitted prior to the initial demonstration, EPA makes clear that the information must be provided only for "anticipated" fuel types. Proposed § 63.7521(b)(2).

Response: The EPA agrees with the commenter and has modified the rule language as appropriate.

Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1

Comment Excerpt Number: 29

Comment: *EPA Should Provide a Liquid HCl Emission Limit Compliance Alternative Similar to that in the MATS Rule*

In the final MATS rule, EPA provided the following alternative to measure oil fuel moisture for ongoing compliance with HCl and hydrogen fluoride (HF) emission limits for liquid fired units at §63.10005:

(i) Liquid-oil fuel moisture measurement. If your EGU combusts liquid fuels, if your fuel moisture content is no greater than 1.0 percent by weight, and if you would like to demonstrate initial and ongoing compliance with HCl and HF emissions limits, you must meet the requirements of paragraph (i)(1)-(5) of this section.

(1) Measure fuel moisture content of each shipment of fuel if your fuel arrives on a batch basis; or

(2) Measure fuel moisture content daily if your fuel arrives on a continuous basis; or

(3) Obtain and maintain a fuel moisture certification from your fuel supplier.

(4) Use one of the following methods to determine fuel moisture content:

(A) ASTM D95-05 (Reapproved 2010), "Standard Test Method for Water in Petroleum Products and Bituminous Materials by Distillation," or

(B) ASTM D4006-11, "Standard Test Method for Water in Crude Oil by Distillation," or

(C) ASTM D4177-95 (Reapproved 2010), "Standard Practice for Automatic Sampling of Petroleum and Petroleum Products," or

(D) ASTM D4057-06 (Reapproved 2011) "Standard Practice for Manual Sampling of Petroleum and Petroleum Products."

(5) Should the moisture in your liquid fuel be more than 1.0 percent by weight, you must

(A) Conduct HCl and HF emissions testing quarterly (and monitor site-specific operating parameters as provided in §63.10000(c)(2)(iii) or

(B) Use an HCl CEMS and/or HF CEMS.

EPA discussed inclusion of the above alternative in the preamble to the MATS rule as follows:

The EPA is providing the alternative compliance assurance approaches in the final rule for liquid oil-fired EGUs of demonstrating compliance through either specific HCl or HF measurements or by demonstrating that the moisture content in the fuel oil remains at a level no more than 1.0 percent. The EPA is not aware of any FGD systems installed on oil fired EGUs. Thus, it is only the quality of the oil, and the level of HAP constituents contained therein, that can be relied upon for ensuring compliance.

Commenters refer to certain studies that provide a plausible reason for the chloride/fluoride contamination of fuel oils. We found this reason persuasive and accordingly are providing alternative compliance approaches in the final rule to demonstrate compliance with the acid gas HAP standards. Specifically, sources can demonstrate compliance through either specific HCl or HF measurements or by demonstrating that the moisture content in the fuel oil remains at a level no more than 1.0 percent. (77 Fed. Reg. 9402, February 16, 2012)

In addition, EPA provided further similar support and discussion of the compliance alternative in the Response to Comments documents for the final MATS rule in the document.11

All of the above reasoning and the approach provided by EPA for the MATS final rule are equally applicable to fuel oils utilized by boilers and process heaters subject to 40 CFR 63, Subpart DDDDD. Fuel oil utilized by industrial, commercial, and institutional (ICI) boilers and process heaters is the same commercial grade fuel oil as that used by electric generating units (EGUs), and there is no difference between those oil fuels relative to the potential for chloride content due to water. In addition, none of the Subpart DDDDD liquid subcategory HCl MACT floor units utilize acid gas controls. ACC strongly urges EPA to provide the same compliance flexibility to ICI fuel oil fired sources relative to compliance with the Subpart DDDDD HCl emission limit. With such a compliance alternative for HCl, the same ASTM test methods referenced in the MATS rule should also be incorporated by reference in Subpart DDDDD.

[Footnote 11: EPA's Responses to Public Comments on EPA's National Emission Standards for Hazardous Air Pollutants from Coal- and Oil-Fired Electric Utility Steam Generating Units December 2011 Volume 1 of 2, p. 609-610, 726; and Volume 2 of 2, p. 60-61, 254.]

Response: We disagree with the commenter's suggestion to provide the same compliance flexibility to ICI oil-fired sources as provided by the EPA for the MATS final rule. The alternate compliance in MATS for oil-fired units allows the measuring of the moisture content in oil to demonstrate compliance with the HCl emission limit instead of measuring HCl emissions. In MATS, if moisture content of the oil is below 1%, the unit is deemed in compliance with the HCl emission limit. The reason for our disagreement is that, as part of the information collection conducted during the rulemaking, we have moisture and chlorine contents, and corresponding HCl emission data, for several oil-fired ICI facilities. Of these, 7 oil-fired ICI facilities had reported moisture content below 1% but 3 of these have HCl emissions above the existing MACT limit for HCl in the final rule, and 5 have HCl emissions above the new MACT limit for

HCl in the final rule. Therefore, the approach provided in MATS is not appropriate for subpart DDDDD.

Comment Excerpt Number: 94

Comment: EPA should provide the same compliance flexibility to ICI fuel oil fired sources for compliance with the Subpart DDDDD HCl emission limit as EPA has provided in the utility MATS final rule. While Subpart DDDDD liquid HCl emission limit is also applicable to other liquid fuels, there is no rational reason to not provide the above alternative limited to fuel oils fired in ICI boilers and process heaters. With such an alternative, the same ASTM test methods should also be incorporated by reference in Subpart DDDDD.

All of the reasoning described below, and the approach provided by EPA for the utility MATS final rule, are equally applicable to fuel oils utilized by boilers and process heaters subject to 40 CFR63, Subpart DDDDD. Fuel oil utilized by ICI boilers and process heaters is the same commercial grade fuel oil as that used by electric utility units, so that there is no differentiation between those oil fuels relative to the potential for chloride content due to water.

In the final Utility MATS rule, 40 CFR Part 63, Subpart UUUUU -- National Emission Standards for Hazardous Air Pollutants: Coal- and Oil-fired Electric Utility Steam Generating Units, EPA provided the following alternative to measure oil fuel moisture for ongoing compliance with HCl and HF emission limits for liquid fired units:

63.10005...

(i) Liquid-oil fuel moisture measurement. If your EGU combusts liquid fuels, if your fuel moisture content is no greater than 1.0 percent by weight, and if you would like to demonstrate initial and ongoing compliance with HCl and HF emissions limits, you must meet the requirements of paragraph (i)(1)-(5) of this section. (1) Measure fuel moisture content of each shipment of fuel if your fuel arrives on a batch basis; or

(2) Measure fuel moisture content daily if your fuel arrives on a continuous basis; or

(3) Obtain and maintain a fuel moisture certification from your fuel supplier.

(4) Use one of the following methods to determine fuel moisture content:

(A) ASTM D95-05 (Reapproved 2010), "Standard Test Method for Water in Petroleum Products and Bituminous Materials by Distillation," or

(B) ASTM D4006-11, "Standard Test Method for Water in Crude Oil by Distillation," or

(C) ASTM D4177-95 (Reapproved 2010), "Standard Practice for Automatic Sampling of Petroleum and Petroleum Products," or (D) ASTM D4057-06 (Reapproved 2011) "Standard Practice for Manual Sampling of Petroleum and Petroleum Products."

(5) Should the moisture in your liquid fuel be more than 1.0 percent by weight, you must

(A) Conduct HCl and HF emissions testing quarterly (and monitor site-specific operating parameters as provided in §63.10000(c)(2)(iii) or

(B) Use an HCl CEMS and/or HF CEMS.

EPA also incorporated by reference in the final Subpart UUUUU the following ASTM test methods applicable to the above compliance alternative:

§63.14 Incorporation by Reference.

* * * * *

(b) * * *

EPA discussed inclusion of the above alternative in the Preamble as follows:

2. Moisture Content of Oil

Comment: A number of commenters stated that studies suggest that chloride in fuel oil can result from contamination during transportation and processing of crude oils and then be emitted as HCl during combustion. For example, the commenters asserted that the chloride contamination of crude oils can occur as a result of the ballasting of tanker ships with seawater. However, the Oil Pollution Act of 1990 requires all new oil tankers to be double hulled and establishes a phase out schedule (by the middle of the decade) for existing single hulled tankers with un-segregated ballasts. Because of the role of seawater contamination in introducing contaminants into the oil, the commenters suggest that the EPA set a percent water content limit for fuel oil at a level of 1.0 percent, rather than setting HCl and HF emissions limits. This would encourage handling and transport practices to limit salt water contamination. One commenter recommended a standard of 1.0 percent water because several of the lowest HCl and HF emitting units currently require percent water (or water and sediment) specifications between 0.5 percent and 1.0 percent.

Response: The EPA is providing the alternative compliance assurance approaches in the final rule for liquid oil-fired EGUs of demonstrating compliance through either specific HCl or HF measurements or by demonstrating that the moisture content in the fuel oil remains at a level no more than 1.0 percent. The EPA is not aware of any FGD systems installed on oil fired EGUs. Thus, it is only the quality of the oil, and the level of HAP constituents contained therein, that can be relied upon for ensuring compliance.

In the proposal preamble, we stated:

We believe that chlorine may not be a compound generally expected to be present in oil. The ICR data that we have received suggests that in at least some oil, it is in fact present. EPA requests comment on whether chlorine would be expected to be a contaminant in oil and if not,

why it is appearing in the ICR data. To the extent it would not be expected, we are taking comment on the appropriateness of an HCl limit. See 76 FR 25045.

Commenters refer to certain studies that provide a plausible reason for the chloride/fluoride contamination of fuel oils. We found this reason persuasive and accordingly are providing alternative compliance approaches in the final rule to demonstrate compliance with the acid gas HAP standards. Specifically, sources can demonstrate compliance through either specific HCl or HF measurements or by demonstrating that the moisture content in the fuel oil remains at a level no more than percent.

In addition, the EPA provided further similar support and discussion of the compliance alternative in the Response to Comments documents for the final MATS rule:

EPA's Responses to Public Comments on EPA's National Emission Standards for Hazardous Air Pollutants from Coal- and Oil-Fired Electric Utility Steam Generating Units December 2011 Volume 1 of 2, p. 609-610, 726; EPA's Responses to Public Comments on EPA's National Emission Standards for Hazardous Air Pollutants from Coal- and Oil-Fired Electric Utility Steam Generating Units December 2011 Volume 2 of 2, p. 60-61, 254.

The data from the liquid units setting HCl floors (below) shows the compliance alternative is equally appropriate for these units. As with the MATS units, liquid units setting HCl floors for IB MACT have no acid gas controls, and therefore emission limits are achieved due to the fuels combusted. [See submittal for Table.]

Response: See the response to comment EPA-HQ-OAR-2002-0058-3510-A1, excerpt 29.

Comment: FUEL ANALYSIS OF GASEOUS FUELS AT CO-FIRED UNITS

ACC agrees with EPA's determination that no fuel analysis for chloride is required for gases and that operators are not required to conduct the mercury fuel specification analyses for gaseous fuels that are natural gas, refinery gas, or otherwise subject to another subpart of part 63.38 EPA also should exempt those sources using process gases that otherwise are regulated under Parts 60 and 61 from conducting a fuel specification analysis. Specifically, § 63.7521(f)(2) should be amended with the addition of the bold language noted to read:

"You are not required to conduct the fuel specification analyses in paragraphs (g) through (i) of this section for gaseous fuels for units that are subject to another subpart of this part, part 60, or part 61."

EPA has already extended the exemption for boilers serving as control devices to those controlling gaseous streams subject to Parts 60 and 61. [Footnote 38: 76 Fed. Reg. at 80633, to be codified at § 63.7521(f)(1)-(2).]

Response: We agree that the fuel specification analysis should not be required for gaseous fuels that are subject to another standard. In the final rule, the definition of "Gaseous fuel" has been revised to clarify that off-gases regulated by another standard are exempt from the definition, and, thus, a source would not be required to conduct fuel analysis on that exempted offgas.

Comment: EPA Should Add Alternative Methods for the Fuel Gas Specification

EPA has proposed, in Table 6 of the proposed rule, the analyses required to qualify a gaseous fuel other than natural gas or refinery gas as a Gas 1 fuel. We are concerned that stack testing companies and their laboratories may not be able to provide the required sampling and testing specified in Table 6, and indeed understand that one of our member companies found this to be true for Gas 2 fuel (hydrogen). As an alternative to the proposed methods, EPA should allow the affected source to conduct a one-time stack test for fuel gases that can be vented, such as hydrogen gas, if it can be done safely. Otherwise, the VI recommends that an option be incorporated that allows a onetime stack test for mercury on the affected boilers or process heaters as a substitute for less safe fuel gas sampling. This stack test could be conducted using the methods specified in Table 5 or, alternatively, sampling Methods 101 and 102 for mercury testing. These alternatives would meet EPA's intent to allow clean gases to qualify as Gas 1 fuels while acknowledging the current limitations of laboratory capabilities and sampling services.

Response: The final does prohibit the use of other methods than those listed in Table 6. Table 6 list methods to be used but also allows for the use of "equivalent" test methods. What is meant by an equivalent test methods is defined in 63.7575.

Comment Excerpt Number: 29

Comment: *EPA Should Amend the "Other Gas 1 Fuel" Specification Analysis to Make It More Feasible and Allow for Use of Additional Test Methods.*

The reconsideration proposal appears to prevent gaseous fuel suppliers from using alternative test methods, which are available for use by the boiler owner/operator if they conduct the requisite analysis for using an "other Gas 1 fuel." *See Boiler MACT Reconsideration Proposal*, 76 Fed. Reg. at 80,633 (proposed § 63.7521(g)(2)(vi)). EPA provides no explanation or rationale for this inflexible requirement. While, in the context of the Boiler MACT, AIF members are gaseous fuel purchasers – not suppliers – it appears likely to affect the majority of fuel specification analysis. This is because it is likely that purchasers of gaseous fuels will require their fuel suppliers to develop the fuel specification analyses and documentation necessary to qualify fuels as in "other Gas 1 fuel" category. Accordingly, AIF urges EPA amend the language at § 63.7521(g)(2)(iv) so that all analyses conducted for the demonstration mechanism may utilize all methods listed in § 63.7521(f)-(i). AIF requests that EPA incorporate additional test methods for use under § 63.7521. That subsection limits the fuel testing to qualify a gaseous fuel other than NG or RG as an "other Gas 1 fuel" to methods laid out in Table 6. *See id.* Table 6 requires measurement of the Hg concentration through one of the following test methods: "ASTM D5954, ASTM D6350, ISO 6978–1:2003(E) or ISO 6978–2:2003(E) (or an equivalent test method)." *See id.* at 80,666. EPA requires use of these methods unless it specifically approves an alternative analytical method. *See id.* at 80,633 (proposed § 63.7521(g)(v)). EPA offers no explanation as to why it failed to include EPA Method 30B, the method it prescribed for facilities, including those owned and/or operated by AIF members, to use in gathering the Hg data supplied to EPA in response to its Section 114 requests.

The required test methods listed in Table 6 were developed for NG analyses and their use is typically restricted as such. They have not been proven appropriate for analyzing, *e.g.*, Hg in LFG and the composition and physical properties of LFG differ from those of NG.¹⁸ Further, as gaseous fuel suppliers are not allowed to use alternative methods in the reconsideration proposal, the regulations would force them to use – and gaseous fuel purchasers like AIF's members to rely on – an unproven method to demonstrate the compliance of gaseous fuels like LFG with the Hg fuel specification. The complexity of component fuels typically encountered in sampled LFG often renders the methods typically used for NG characterizations inappropriate.¹⁹ As reported by Waste Management, a supplier of LFG, the performance of these methods in an LFG matrix has yet to be demonstrated. As a result, there is no rational basis for EPA to categorically restrict fuel analysis for gaseous fuels like LFG, in the absence of a pre-approval process, to the four methods listed in Table 6. [Footnote 18: For example, NG is primarily methane with lower concentrations of related alkanes and carbon oxides, and trace quantities of other hydrocarbons. LFG typically contains 45% to 60% methane and 40% to 60% carbon dioxide. LFG also includes small amounts of nitrogen, oxygen, ammonia, sulfides, hydrogen, and carbon monoxide.]

[Footnote 19: Either interferences or target analyte levels may disqualify natural gas methods when attempting to acquire representative Hg data in LFG.]

Response: See the response to comment EPA-HQ-OAR-2002-0058-3449-A1, excerpt 12 regarding Method 30B. See the response to comment EPA-HQ-OAR-2002-0058-3526-A1, excerpt 11 regarding the use of alternative methods to those in Table 6.

Commenter Name: Edward W. Repa

Commenter Affiliation: National Solid Wastes Management Association (NSWMA)

Document Control Number: EPA-HQ-OAR-2002-0058-3539-A1

Comment Excerpt Number: 6

Comment: Under Section 63.7521(g)(2)(vi), gas fuel suppliers appear to be prevented from using alternative test methods that are available to the boiler owner/operator. A rationale is not provided for such a requirement considering that a supplier is the one that will likely be tasked with performing the test.

The Landfill Institute recommends that EPA remove this requirement to allow suppliers to use alternative methods. We further recommend that EPA incorporate EPA test method 30B because it is more appropriate for LFG. This is the same test method used by EPA to determine Hg concentrations by EPA's Office of Research and Development.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3449-A1, excerpt 12 in regards the use of Method 30B. See the response to comment EPA-HQ-OAR-2002-0058-3526-A1, excerpt 11 in regards to using other methods than those listed in Table 6.

Comment Excerpt Number: 2

Comment: The proposed rule outlines that fuel samples for Hg and HCl analysis must be obtained following the requirements of 63.7521(c)(1)(ii). This specifically requires fuel samples be collected at one hour intervals during the testing period for sampling during a performance test. This requirement is not practical. Performance testing does not work in a seamless, clockwork fashion. Performance testing involves discrete one-hour or longer runs. Each run is followed by an interval to collect and preserve samples and prepare for the next run. People conducting performance tests also need to take rest breaks. As written, this requirement is far too inflexible and stringent; it cannot be implemented in the real world. Furthermore, collecting fuel samples from belts and other moving equipment requires planning and execution, while adhering to safe practices such as lock out-tag out / zero potential energy procedures. These essential safety measures conflict with the clockwork requirements specified in the rule. The wording in the rule simply needs to be changed to allow samples to be safely collected contemporaneous with the stack test.

Response: The EPA agrees with the commenter and has modified 63.7521(C)(1)(ii) to read "Each composite sample will consist of a minimum of three samples collected at approximately equal one-hour intervals during the testing period for sampling during performance stack testing where safety permits. If equipment operations, lock out procedures, or other safe work practices preclude simultaneous fuel sampling with the testing make arrangements to provide for

composite fuel samples that are representative of the fuel burned during each performance test. For monthly sampling, each composite sample shall be collected at approximately equal 10-day intervals during the month."

Commenter Name: Sarah Hedrick

Commenter Affiliation: Verso Paper Corp.

Document Control Number: EPA-HQ-OAR-2002-0058-3537-A2

Comment Excerpt Number: 3

Comment: The proposed rule is too rigid in specifying monthly sampling requirements, in that each composite sample must be collected at approximately equal 10-day intervals during the month. This is not a practical requirement which can be implemented to such literal intent. The 10th day could be outage day. The 10th day could be a weekend day where it is not safe and practical to collect a sample, due to reduced staffing. The wording in the rule should simply specify that evenly spaced samples be collected.

Response: The EPA does not agree with the commenter that the wording of "approximately equal 10-day intervals during the month" is too rigid.

Comment Excerpt Number: 105

Comment: Consistent with the general exclusion for control devices, fuel analyses should not be required for gaseous fuels regulated by parts 60, 61, 63, or 65. Additionally, the proposed wording of proposed §63.7510(a)(2)(ii) is confusing and should be revised. Proposed §63.7510(a)(2)(ii), last sentence provides:

... If gaseous fuels other than natural gas, refinery gas, or other gas 1 fuels are cofired with other fuels and those gaseous fuels are subject to another subpart of this part, you are not required to conduct a fuel analysis of those fuels according to §63.7521 and Table 6 to this subpart.

As discussed in Comment II.1.F energy recovery of regulated gases should be encouraged and BPH used as control devices should be excluded from BPH NESHAP requirements. Proposed §63.7510(a)(2)(ii) only excludes from the co-fired fuel analysis requirements gaseous fuels subject to other part 63 subparts. We believe this exclusion should be extended to gaseous fuels regulated under parts 60, 61, and, to avoid confusion as more and more subparts reference part 65, to part 65 as well. **We recommend the last sentence of §63.7510(a)(2)(ii) be revised as follows:**

... Fuel analyses is not required for gaseous fuels regulated by subparts of part 60, 61, 63 or 65 of this chapter that are co-fired with Gas 1 or other Gas 1 fuels.

Response: We disagree that a revision is necessary. Paragraph 63.7510(a)(2)(ii) reads "If gaseous fuels other than natural gas, refinery gas, or other gas 1 fuels are co-fired with other

fuels and those gaseous fuels are subject to another subpart of this part, part 60, part 61, or part 65, you are not required to conduct a fuel analysis of those fuels according to §63.7521 and Table 6 to this subpart."

Comment: Fuel analysis should be allowed for showing compliance with the HCl limit for Gas 2 subcategory BPH.

Proposed §63.7505(c) specifies that "For gaseous fuels, you may not use fuel analyses to comply with the total selected metals alternative standard or the hydrogen chloride standard." No explanation for this restriction is provided in the preamble.

Determining the chloride content of gases is straightforward and any chloride reaching the burners would be expected to convert to HCl. In the many cases where the standard is being met without the use of controls, fuel analysis is a straightforward and much less burdensome approach to demonstrating compliance than is stack analysis. Thus, we strongly encourage EPA to allow fuel analysis for HCl compliance demonstrations. If a source's gas 2 fuel meets the HCl emission limit based on the fuel chloride content, there is no concern about whether any chloride

is removed in the control system (if any). On the other hand, if the fuel contains enough chloride that the HCl emission limit is not being met, the source would have to do stack testing to demonstrate that the controls are adequately removing chloride.

Response: In the March 2011 final rule, we originally examined the possibility of basing the demonstration of process gases being similar to Gas 1 on levels of mercury and chlorine content in the gases. However, we found no proven test methods were identified to quantify chlorine content of natural gas. Therefore, the EPA disagree with revising 63.7505(c) to allow fuel analysis of gaseous fuel.

Commenter Name: Matthew Todd

Comment: The final rule should be clear that initial performance tests are not required if fuel analysis is used as the initial compliance demonstration for HCl and Hg limits.

While it appears the rule text allows for companies that are using fuel analyses to demonstrate compliance with the HCl and Hg limits to not perform performance testing for the initial compliance demonstration, the preamble language of the proposed rule (see page 80602) seems to indicate that performing testing IS required. The final rule language needs to clearly indicate that performance testing is NOT required for companies that elect to demonstrate compliance with the HCl and Hg limits using fuel analyses.

Response: It is the rule language that applies and this is clearly stated in 63.7505(c).

Commenter Name: Matthew Todd

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 109

Comment: Approval should not be required for the site-specific fuel monitoring plan unless alternative analytical methods are being requested.

Proposed §63.7521(b) and (g) require submission and approval of a site-specific fuel analysis plan for review and approval. This plan must be submitted no later than 60 days before the date you plan to conduct the initial compliance demonstrations. There are likely to be API/AFPM Comments on Proposed BPH NESHAPs, CISWI and NHSM Rules Page 78

thousands of such submissions (Table 5 of the preamble estimates 2200 existing BPH subject to numerical emission limits), since fuel analysis is anticipated to be widely used. It is highly unlikely all these plans can be reviewed before the initial compliance date and, unless the source is deviating from the methodologies specified in the rule, there is no reason for such a review.

Thus, we recommend that approval only be required where the source is requesting to use an alternative analytical methodology.

Furthermore, relative to Table 6 methodologies, the proposal allows use of "equivalent" methodologies and defines "equivalent" for this purpose in proposed §63.7575. EPA should clarify in §63.7521(b) and (g) that no further approvals are required for methodologies that meet the definition of equivalent.

Response: Paragraph 63.7521(b) of the final rule has been revised to require submittal of the site-specific fuel analysis plan for review and approval if an alternative analytical method is requested to be used than those listed in Table 6 of the final rule.

Comment Excerpt Number: 3

Comment: The recently-promulgated MATS rule for utility boilers provides several methods of demonstrating compliance for each regulated pollutant or surrogate. One option is to conduct quarterly stack testing. For the most part, no other ongoing parametric monitoring is needed when the stack test option is selected. EPA explains in the preamble that "we removed the other operating limits for control devices based on a review of the comments, after considering other programs in place to ensure proper. 41 operations of controls at EGUs." 77 Fed. Reg. 9384. The basic idea is that enough monitoring is already required under other CAA and state emission standards (and operators always have the goal of energy efficient operation) that EPA already has assurance that the unit will be well operated between the quarterly stack tests.

A similar approach would be justified under the Industrial Boiler MACT and could help resolve the problems described above with the CO stack test limit for units with a high level of

operational variability. In short, if compliance with the CO limit were based solely on quarterly stack tests – with no parametric monitoring in between tests – then affected sources would be better able to ensure compliance because they would judge compliance based on frequent stack testing using the same method and under the same conditions as used during the stack tests used to set the standard – *i.e.*, such an approach would ensure a true "apples to apples" compliance method. No parametric monitoring is needed between stack tests because affected sources have a powerful incentive to maintain efficient combustion conditions. Doing so minimizes the amount of fuel consumed, which typically is the largest cost (by far) of operating an industrial boiler. Since maintaining efficient combustion conditions would minimize CO emissions, EPA will have assurance that CO is well controlled on a continuous basis.

For units that already have CO CEMS for reasons unrelated to the Industrial Boiler MACT, this approach would have to be implemented in conjunction with a determination that CEMS data cannot be used to show compliance with the stack test limit, as described more fully above.

Comment Excerpt Number: 99

Comment: The CEMS QA/QC requirements established by EPA are confusing and extremely burdensome to sources. For example, many industrial boilers and process heaters are subject to a variety of federal and state regulations. The federal and state regulations often require slightly different data reduction requirements and QA/QC for CEMS systems. Another issue is the practical matter of needing to train personnel how to address a data signal, which can be different depending what rule is applicable. CIBO restates by reference here its position set forth in the Petition for Reconsideration, which includes a detailed discussion of the burdens associated with the CEMS QA/QC requirements and a description of a more reasonable and defensible methodology.

Comment: Operating Limits Should Not Be Required In Circumstances Where Continuous Emissions Monitors Are Utilized

In cases where PM monitors, mercury CEMS, HCl or SO₂ CEMS used to demonstrate compliance with PM, mercury or acid gas limits, EPA should not require the establishment of and compliance with operating limits. Because the source is directly measuring the specific emission, or its surrogate, the monitoring of operating parameters serves no useful purpose.

Comment Excerpt Number: 12

Comment: Several NewPage facilities have situations where multiple boilers vent through a common stack. These situations involve solid fuel (coal and biomass) boilers and/or natural gas boilers that share a common stack. In the proposed reconsideration rule, EPA is proposing a number of monitoring requirements for solid fuel units involving opacity monitoring, PM CPMS, and the possible use of other continuous pollutant monitoring systems for determining compliance with the standards. These monitoring devices will most likely be located on the common stack. Units that share a common stack may have situations where one or more of the units maybe in a startup or shutdown mode while the other unit(s) continue to run. In this situation, for example, compliance with an opacity standard as a surrogate for PM/HAPs may be difficult and depending on the circumstances may not be achievable. In the reconsideration

proposal, EPA has not addressed situations when one or more boilers that vent through a common stack are in a startup or shutdown mode while other boiler(s) that also vent through that common stack continue to run. Provisions for common stacks need to be included so as not force a source into a potential noncompliance situation as a result of routine operating modes.

Comment Excerpt Number: 17

Comment: In the Utility MACT, EPA allows existing sources with acid gas controls to comply with an SO₂ limit in lieu of an HCl limit (77 FR 9490, Table 2 (1)(b)). With the upcoming SO₂ NAAQS implementation timing (2017) being very close to Boiler MACT compliance (2015), many industrial sources are not only evaluating compliance with the Boiler MACT but also looking toward compliance with SO₂ SIPs. Allowing a source an alternate of an SO₂ limit could encourage sources to make best use of capital dollars and invest in equipment that is most likely to address both HCl and SO₂. Purdue proposes that an alternate to HCl for industrial boilers be NSPS SO₂ at 0.2 lb/MMBTU or 90% SO₂ reduction at max 1.2 lb/MMBTU.

Comment Excerpt Number: 114

Comment: The ambiguous flow and pressure instrument requirements are not needed and should be deleted. At a minimum, they must be clarified and made consistent with good engineering practice and standard instrument practice.

Proposed §63.7525(e) and (f) specify requirements for flow and pressure CMS. It is unclear whether standard instrumentation installations can meet these requirements. The Agency has not made a case that these concerns occur or occur frequently enough to require installation of new, non-standard systems. EPA should specify the requirements clearly, explain why these are concerns and how frequently these concerns impact flow and pressure measurements, how it expects sources to comply, and identify and consider the costs and burdens associated with adding additional equipment or modifying existing standard installations. If adequate justification for the costs cannot be presented these requirements must be deleted.

Specific requirements that must be addressed include the following. In general we believe all of these requirements, if finalized, should be limited to what is required by good engineering practice.

Commenter Affiliation: Waste Management (WM)

Document Control Number: EPA-HQ-OAR-2002-0058-3681-A2

Comment Excerpt Number: 32

Comment: WM recommends that affected facilities be allowed the flexibility to conduct more than just three stack test runs to demonstrate compliance with applicable limits. Given the wide variety of fuels that boilers may combust, providing flexibility for more than three stack test runs allows for some variability among individual stack test runs while also ensuring the stack test average is below the limit for verification of long term performance and low emission levels. We

suggest the following language be incorporated in the final rule: “You must conduct a minimum of three separate test runs for each performance test required in this section as specified in 63.7(e)(3)... The average of 3 or more test runs shall be used to determine compliance with the emission limits.” This option to use more than three test runs would be specified in the site specific test plan under 63.79 (c). It could be limited to total metals and HCl where variability is more likely to occur in various fuel combinations.

110A. Testing Frequency [DENIED PETITIONER ISSUE]

Commenter Name: Russell A. Wozniak

Commenter Affiliation: The Dow Chemical Company

Document Control Number: EPA-HQ-OAR-2002-0058-3449-A1

Comment Excerpt Number: 19

Comment: Dow supports a reduced frequency of subsequent performance tests, but further comments that testing for light liquid, heavy liquid, and Gas 2 fueled sources should only be required once every five years.

Sections 63.7515(b) of EPA’s proposed rule requires annual retesting until such time that two consecutive annual tests are conducted with all emissions less than 75% of the emission limit. Then, the rule allows for re-testing essentially every three years.

EPA provides no justification in the preamble for requiring annual retesting for sources fueled by liquid or Gas 2 fuels. Annual retesting is an unnecessary and burdensome requirement. Emission testing is costly and it must be coordinated with necessary plant operations and the availability of testing contractors. None of these factors are trivial and such frequent testing for low HAP emission rates is not needed. One of the most strenuous MACT standards, the Hazardous Waste Combustion MACT Section 63.1207(d)(1), requires initial retesting after five years. A number of the MACT Standards do not include retesting requirements unless the source is modified in a manner that would adversely affect compliance with the emission standard. Therefore, we urge EPA to further revise the rules to require testing on a five year frequency.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: Randall D. Quintrell

Commenter Affiliation: Georgia Paper & Forest Products Association

Document Control Number: EPA-HQ-OAR-2002-0058-3451-A1

Comment Excerpt Number: 6

Comment: The requirement for annual compliance testing also is unwarranted, especially for the myriad of parameters required. As we stated in our prior comments, submitted during the comment period for the March 2011 rule, the stack testing requirements proposed are tremendously expensive, resource intensive, difficult to accomplish, and unnecessary. We reiterate all our prior comments on this topic by reference.

The purpose of an initial performance test (IPT) is to demonstrate that the technology chosen has the ability to meet compliance, and parametric monitoring is established at that time to continue to show that the control technology remains in good operating condition over time. Repeat testing is unnecessary as long as the operating conditions are stable and the parametric monitoring shows that the control device remains within its demonstrated performance range. EPA should reconsider this requirement and the compliance testing should be changed to an initial performance test only. This approach has worked well for prior MACTs, and there is no reason to change it for this rule. If repeat testing is deemed necessary, it should be limited to no more often than once/ five years. Annual testing is a waste of resources - including EPA's, the State agencies', and the affected facilities'.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: Claudia M. O'Brien, Latham & Watkins LLP

Commenter Affiliation: JELD-WEN, inc.

Document Control Number: EPA-HQ-OAR-2002-0058-3485-A1

Comment Excerpt Number: 14

Comment: While EPA has proposed a minor revision to the testing frequency for cases where MACT floors were lower than three times the RDL value, EPA retained the general requirement that a source conduct all applicable performance tests on an annual basis. This testing frequency is overly burdensome.

EPA enerally requires that a source conduct all applicable performance tests on an annual basis. The one exception to this requirement, permitting testing "every 3 years, instead of annually, if measured emissions during 2 consecutive annual performance tests are less than 75 percent of the applicable emission limit,'42 is not sufficient to alleviate the overly burdensome nature of the annual testing requirement. JELD-WEN recommends that EPA reconsider the annual source testing requirement for sources which use a control device to demonstrate compliance with the emission limits, sources for which the initial compliance test demonstrates compliance with the emission limits, and sources which bum clean fuels.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Commenter Name: Claudia M. O'Brien, Latham & Watkins LLP

Commenter Affiliation: JELD-WEN, inc.

Document Control Number: EPA-HQ-OAR-2002-0058-3485-A1

Comment Excerpt Number: 15

Comment: The cost burden imposed by the annual source testing requirement in the Boiler MACT rule is overly burdensome and unnecessary. Currently, most Title V sources are only required to perform source tests once every five years (once per permit term). Thus, the estimated cost (between \$20,000 and \$30,000 per test) averages out to between \$4,000 and \$6,000 per year over the permit term. In contrast, when a unit is required to perform source tests annually under the Boiler MACT rule, this will effectively increase the annual source testing costs from \$6,000 a year to \$30,000 a year. The annual source testing cost would be in addition to any annual operating costs associated with using a control device to demonstrate compliance with the emission limits. This additional cost burden imposed on industry is significant and it is unclear whether EPA took annual testing costs into consideration when looking at the financial burden to the industry. Furthermore, while the Boiler MACT allows for demonstrating compliance with the HCl and Mg limits by performing fuel analysis, it requires that the analysis must be performed every month. Monthly fuel analysis is costly and unnecessary if the fuel source does not change from the original fuel sampling and analysis.

Commenter Affiliation: Northeast States for Coordinated Air Use Management (NESCAUM)

Document Control Number: EPA-HQ-OAR-2002-0058-3506-A1

Comment Excerpt Number: 22

Comment: In its reconsideration of the final major source rule, the EPA is proposing to require that all sources subject to the rule undergo PM emissions tests at regular intervals (i.e., at least every five years, in most cases). The NESCAUM states believe that a properly maintained and tuned unit that burns light liquid fuels and that has been initially tested for PM emissions can rely on periodic tune-ups and maintenance to remain clean through its lifetime. Therefore, these scheduled testing requirements will be unnecessary for smaller units (<50 MMBtu/h) burning cleaner fuel types, and we request that the EPA remove PM testing requirements after the initial test for these units.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Commenter Name: Michael L. Krancer

Commenter Affiliation: Pennsylvania Department of Environmental Protection (DEP)

Document Control Number: EPA-HQ-OAR-2002-0058-3507-A1

Comment Excerpt Number: 20

Comment: In the final rule the EPA changed the stack testing requirements to allow units that demonstrate compliance for a particular pollutant at a level at or below 75 percent of the emission limit for two consecutive years to forgo stack testing for up to 37 months. The EPA intends to maintain this provision for most of the emission limits and is soliciting comments on this provision.

The DEP believes that reduced stack testing frequency is appropriate for units demonstrating compliance for a particular pollutant at a level at or below 75 percent of the emission limit for two consecutive years.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Commenter Name: Lorraine Gershman

Commenter Affiliation: American Chemistry Council (ACC)

Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1

Comment Excerpt Number: 134

Comment: REDUCED TESTING FREQUENCY AND DETECTION LEVELS

The Final Boiler Rule requires annual emissions testing (once every 13 months). See § 63.7515 (a). Facilities can conduct performance tests less often for a given pollutant if the performance tests for the pollutant for at least 2 consecutive years show that emissions are at or below 75 percent of the emission limit (or, in limited instances as specified in Tables 1 and 2, at or below the emission limit), unless they are using emissions averaging. See § 63.7515(b). While ACC does agree with EPA’s acknowledgement of the need for reduced stack testing frequency for units with emissions below the standards, the requirement for initial annual stack testing and for ongoing annual stack testing where emissions averaging is being used is unreasonable and out of character with other MACT and NSPS standards and other state performance testing requirements.

EPA has proposed the most aggressive performance testing requirements of which we are aware on the largest MACT source category it has addressed to date. By contrast, the Hazardous Waste Combustor MACT (Subpart EEE) requires a comprehensive performance test only once every 5 years. Many MACT standards and NSPS only require one initial performance test unless there is a physical change to the control device that would increase emissions. The purpose of the initial performance test is to ensure that the technology installed is capable of meeting the emission limits. EPA has proposed extensive monitoring and recordkeeping that is meant to ensure continuous compliance with the emission standards. If these extensive monitoring and recordkeeping provisions are finalized, the frequency of stack testing should be reduced to once every 5 years.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Commenter Name: Paul Noe

Commenter Affiliation: American Forest & Paper Association (AF&PA) et al.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 112

Comment: The proposed rule requires annual emissions testing (once every 13 months). See 63.7515 (a). Facilities can conduct performance tests less often for a given pollutant if the performance tests for the pollutant for at least 2 consecutive years show that emissions are at or below 75 percent of the emission limit (or, in limited instances as specified in Tables 1 and 2, at or below the emission limit), unless emissions averaging is being used. See 63.7515 (b). While we do agree with EPA's acknowledgement of the need for reduced stack testing frequency for units with emissions below the standards, the requirement for initial annual stack testing and for ongoing annual stack testing where emissions averaging is being used is unreasonable and out of character with other MACT and NSPS standards and other state performance testing requirements. EPA has put forth the most aggressive performance testing requirements of which we are aware on the largest MACT source category it has addressed to date. The Hazardous Waste Combustor MACT (Subpart EEE) for example requires a comprehensive performance test only once every 5 years. Many MACT standards and NSPS only require one initial performance test (e.g., pulp and paper MACT standards under Subparts S and MM) unless there is a physical change to the control device that would increase emissions. Other MACT standards do not require more frequent testing where emissions averaging is being used.

The purpose of the initial performance test is to ensure that the technology installed is capable of meeting the emission limits. EPA has proposed extensive monitoring and recordkeeping that is meant to ensure continuous compliance with the emission standards. Therefore, the frequency of stack testing should be reduced to once every years, and facilities using the emissions averaging approach should also qualify for a reduced stack testing frequency.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: Stephen E. Woock

Commenter Affiliation: Weyerhaeuser Company

Document Control Number: EPA-HQ-OAR-2002-0058-3523-A1

Comment Excerpt Number: 16

Comment: We are concerned with the performance testing requirements provisions requiring annual compliance testing, which add to the operating costs without a sound basis for their frequency or complexity. We appreciate that EPA's proposal does offer the potential for reduction from the annual testing frequency when certain compliance margins are demonstrated over periods of time. However, in reality this will bring little relief since it is unlikely to be achieved simultaneously for each of the eligible HAPs and therefore testing will have to continue for those HAPs not meeting the relief criterion. The frequency of stack testing should be reduced. The purpose of the initial performance test is to ensure that the technology installed is capable of meeting the emission limits. In addition to that initial performance test, EPA requires extensive monitoring and recordkeeping that is meant to ensure continuous compliance with the

emission standards. This monitoring should give EPA and the public the assurance needed to allow the stack testing requirements to be eliminated or reduced to once every 5 years after the initial performance test.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Commenter Name: Bart Sponsellar

Commenter Affiliation: Wisconsin Department of Natural Resources (DNR)

Document Control Number: EPA-HQ-OAR-2002-0058-3527-A1

Comment Excerpt Number: 4

Comment: The proposed schedule of annual stack testing for sources subject to emission limitations, especially for smaller sources, is very intensive and costly. We encourage EPA to consider opportunities for consolidating compliance and testing requirements through the use of a carbon monoxide and oxygen continuous monitoring system with combustion trim (CO/O₂ CMS trim) — a non CEMs analyzer based monitoring system. This approach should be allowed as an alternative to the primary defined compliance demonstration requirements.

This approach continuously minimizes emissions and we believe can be allowed under the rule to meet start-up work practices, dioxin/furan work practices, and CO and PM parametric monitoring needs. EPA has acknowledged that an oxygen trim system alone is a better way to operate a boiler. The CO/O₂ CMS trim approach takes the next step in operating a boiler for combustion efficiency. We propose that this approach will allow for performance tests every two years and tune-ups every four years for sources. This is very important as Wisconsin sources are currently subject to biennial stack testing (as applicable). Going to this schedule and simplifying other requirements will significantly reduce the cost of this rule while resulting in the same or potentially better environmental improvement.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Commenter Name: Bart Sponsellar

Commenter Affiliation: Wisconsin Department of Natural Resources

Document Control Number: EPA-HQ-OAR-2002-0058-3527-A2

Comment Excerpt Number: 26

Comment: The Department also believes that stack testing can be allowed on a biennial schedule for pollutants when sources are operating a positive control system for the pollutant in question. Specific cases we have identified where we believe biennial stack testing applies under positive control systems are as follows. The Department proposes that a CO CMS and good combustion trim system is positive control in reducing all organic toxics including dioxin and furans. EPA is proposing that particulate is a combustion based pollutant. Under this approach we believe that a source operating with good combustion (CO CMS) and ESP or fabric filter systems is a positive control system for both PM and non-mercury metals. In this case the source should be able to monitor the necessary parameters and stack test every two years for PM or metals. The Department also believes this approach constitutes an option equal to a PM CMS

compliance demonstration. The Department believes that a similar approach and biennial stack testing schedule can be taken for mercury controlled by activated carbon injection and for hydrogen chlorides controlled by either dry or wet scrubbing. To simplify this option, EPA can allow a source to demonstrate a correlation between the pollutant of interest and the positive control measure. If necessary this correlation can be approved by the delegated authority.

The Department also suggests EPA consider that a CO CMS system with good combustion trim requirements basically constitutes continuous tuning of the source. Along with biennial stack testing the CO CMS trim system is checked every two years. Under this monitoring approach, the Department believes that tune-ups are only necessary every four years. This schedule coincides with the time frame EPA suggests for inspecting burners and other boiler system equipment.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Commenter Name: Robert D. Bessette

Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 95

Comment: EPA should modify the finalized emission testing requirements so that they are consistent with the 5 year Title V permit review cycle. Annual compliance testing is extremely expensive and the benefits of conducting emission tests more frequently than every 5 years do not justify the costs. In addition, as noted in CIBO’s Petition for Reconsideration, there is likely to be a shortage of testing and laboratory resources under the current emission testing schedule.

CIBO appreciates the change in the frequency of performance testing from annually in the final rule to once every three years in the reconsideration rule. However, requiring a performance test once every five years, as is required in many Title V Permit renewals, will still accomplish the same assurance of compliance at a reduced cost to the regulated source.

A significant amount of testing will be required by sources to determine the compliance status with respect to the rule and to evaluate and select available control strategies. Capital projects to install necessary control equipment cannot proceed until the testing and evaluation is complete. Due to the high number of sources affected by the rule that have the same concerns, it is likely that availability of stack testing personnel and laboratory facilities to conduct tests will be limited, adding to the time required to complete this essential first step. As outlined below, annual compliance testing requiring multiple test runs for purposes of compliance will further reduce the availability of testing and laboratory resources.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Commenter Name: Robert D. Bessette

Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 97

Comment: EPA has underestimated the cost of emissions testing necessary to comply with Boiler MACT. Typical industrial boilers combust a variety types of fuels. This practice is necessary for industry to maintain competitive fuel pricing. In the preamble to the rule, EPA cites, industry average costs per compliance test ranging from \$60,000 to \$90,000 per test. In many cases, however, sources may be required to perform 2 to 3 or even more tests to provide data on the range of fuels being combusted. These annual compliance testing costs of \$60,000 to \$270,000 are unreasonable and do not take into consideration the monetary impact associated with the identification and investigation of new fuel sources. In addition, testing annually requires an exorbitant amount of company resources to plan, schedule, and perform the required testing which have not been included in the above mentioned cost estimates.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Commenter Name: Sarah Hedrick

Commenter Affiliation: Verso Paper Corp.

Document Control Number: EPA-HQ-OAR-2002-0058-3537-A2

Comment Excerpt Number: 1

Comment: The proposed rule will allow units that demonstrate compliance for a particular pollutant at a level at or below 75 percent of the emission limit for two consecutive years to forego stack testing for up to 37 months. Since most pollutant testing will be completed during worst case scenarios, this allowance will likely provide no relief of the performance test requirement’s costly burden. Also, because of the worst cast fuel mix and operating limit requirements, many multiples of stack testing scenarios will be required. The yearly stack testing campaign to meet the proposed rule requirements will range from \$40,000 to \$50,000 per boiler. This is an unreasonable cost. Verso believes stack testing be required once every 5 years.

Comment Excerpt Number: 18

Comment: In §63.1515(a), performance tests in the repropoed Boiler MACT are required annually. Purdue University enters into multiple year contracts for fuel supply with specific requirements for the fuel. Hence, fuel supplies do not vary frequently and annual stack testing is a waste of resources. Purdue asks that Boiler MACT testing, at the very least, be synchronized with Title V performance testing. In Purdue's case, this synchronization (biennial instead of annually) would save approximately \$18,000/year in testing costs.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Comment: Additional performance test timing flexibility should be provided.

Proposed §63.7515(a) requires that annual performance tests be performed within 13 months of the previous test. This is a reasonable interval if a facility is dealing with one stack test, but can be a problem if the facility has to perform many stack tests (i.e., has many BPH requiring testing). Burdens for both the facility and inspectors can be reduced if stack tests can be adjusted to space out the testing over a year and to allow test time to be adjusted so that operation at stack test conditions can be matched to operating needs. For instance, if the annual test is due when a process heater must operate at low rates because the process is at low rates, there needs to be a mechanism to allow several months adjustment. To that end we request that the testing interval be revised to annual and that annual be specified as once per calendar year with at least 120 days between tests. EPA is generally adopting such requirements in EPA's new Uniform Standards⁴⁹

and has used this approach successfully for many years under the existing HON (part 63 subparts F, G, and H) and the Generic NESHAP (part 63 subpart YY).

[Footnote 49: Proposed §65.280(b) of the Uniform Standard General Provisions specifies: “(b) You may comply with such periodic requirements by completing the required task any time within the standard calendar period, provided there is a reasonable interval between completion of two instances of the same task. Reasonable intervals are described in paragraphs (b)(1) through (5) of this section. ... (5) Tasks that you are required to complete annually must be separated by at least 120 calendar days.”]

Comment: It is a massive undertaking for non-continental refineries to perform stack tests every year, given that stack testers must be brought in and samples often must be shipped to far off mainland laboratories. One solution would be to allow non-continental sources to skip stack testing if they are willing to continue to meet the continuous compliance parameter established previously. An oxygen level established in an initial performance test should remain a good indicator of good combustion (low CO and particulates) indefinitely. Thus, we request that new performance tests for the non-continental liquids subcategory only be required every five years.

110B. Operating Load Limits During Testing [DENIED PETITIONER ISSUE]

Commenter Name: John S Williams

Commenter Affiliation: Maine Pulp & Paper Association (MPPA)

Document Control Number: EPA-HQ-OAR-2002-0058-3466-A1

Comment Excerpt Number: 8

Comment: EPA should not limit boilers to 110% of the operating load achieved during the last performance test.

It appears that, under the Boiler MACT rule, mills must conduct a compliance test for CO and, thereafter, meet an oxygen limit which is the lowest oxygen level recorded during the three one-hour test runs for CO. The rule requires that a boiler must then be operated at not more than 110% of the operating load achieved during the performance test. The highest operating load in a multi fuel boiler often does not correspond with the lowest oxygen condition. This approach is difficult if not impossible to meet in a multifuel boiler, such as those in use at most of Maine's

mills. If wet fuels happen to be burned during the stack test (EPA requires 60 day notice prior to testing and the weather cannot be predicted) higher levels of oxygen are required and the resulting increase will affect the ability to comply with the CO limit. When burning biomass, stack oxygen concentrations will be much higher than when firing fuel oil.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Comment Excerpt Number: 9

Comment: EPA's stack test compliance approach appears based on the incorrect premise that CO emissions from a biomass boiler exhibit low variability. It is unreasonable to establish a CO emission limit based on a single hourly emission value. Additionally, the rule imposes limitations on boiler steam output operation to that achieved during the CO testing. Paper mill boilers are operated at variable loads based on the process steam demands. It will be impractical to operate at maximum loads during every stack test. Limiting boiler capacity to 110% of the value achieved during a performance test undermines the economic survival of a mill.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Comment Excerpt Number: 10

Comment: The rule appears to require multiple stack test runs for each parameter to demonstrate compliance with each emission limit (two or more tests for CO, two tests for HCL, two tests for Hg, one or more tests for PM ... these tests will not run concurrently). The worst case fuel mix for CO is likely not the same fuel mix needed to establish minimum O₂ parameter or the boiler steaming that is needed for normal operation. If performance testing needs to be at the worst case mix for a pollutant, that worst case fuel mix cannot then be tied to a steaming rate limit of 110% achieved during the performance test. (Table 7 in the proposed rule limits the operation capacity to 110% for all pollutants tested).

Commenter Affiliation: JELD-WEN, inc.

Document Control Number: EPA-HQ-OAR-2002-0058-3485-A1

Comment Excerpt Number: 7

Comment: Although JELD-WEN supports these proposed changes, JELD-WEN believes that EPA did not go far enough in recognizing the importance of operational variability. Specifically, EPA did not account for such variability for sources that demonstrate compliance through performance testing. In its final rule, EPA required sources demonstrating compliance through performance testing to limit their operating load to no greater than 110 percent of the operating load established during the performance test. However, this operating limit raises serious technical problems for facilities due to seasonal variability—the same variability EPA recognized in its proposed revision for sources using parametric monitoring and continuous compliance with operating limits.

As JELD-WEN explained in its petition for reconsideration, during compliance testing, a facility has to show minimum and maximum operational conditions occurring during testing. During the winter, when steam demand is greater (due to greater ambient losses and the addition of building heat), a unit might test, for example, at 30 MMBtu/hr of heat input; the unit would not be permitted to exceed 33 MMBtu/hr during the normal course of operations regardless of season. However, if that same facility tested during the summer when there is the lowest load requirement, it may test at 24 MMBtu/hr and then would not be permitted to exceed 26.4 MMBtu/hr during all seasons.²⁴ Thus, under the Boiler MACT rule the facility would not be able to meet the steam demand in the winter if it conducted performance testing during the summer. While EPA may suggest that such facilities conduct performance testing in the winter to address this consequence, winter testing is simply not feasible in many parts of the country. Testing in winter months in icy conditions and high winds raises serious safety concerns.

JELD-WEN urges EPA to remove this limitation, particularly for those boilers or process heaters that are less than 100 MMBtu/hr. JELD-WEN recognizes the importance of using performance tests to set the operational parameters that ensure compliance on a continuous basis, but submits that such a requirement is unnecessary with respect to operating load. That is, compliance with Boiler MACT is established on a lb/mmBtu basis, not a total tonnage basis, such that a mandated maximum operating load is not necessary to ensure compliance with a tonnage limit. Further, as EPA is well aware, control devices typically perform better at higher loads, such that a performance test occurring at lower loads is likely to overstate emissions at higher loads. As such, an upper limitation on operating load is not necessary to ensure continuous compliance with Boiler MACT's emission rate limitations. Moreover, a 10 percent change in heat output for a small boiler (40 MMBtu/hr for example) would result in a change within the error margin of the testing itself.

Just as EPA proposed a revision of averaging times to address seasonal variability, EPA should likewise eliminate the requirement to limit the operating load to no greater than 110 percent of the operating load established during the performance test. At a minimum, for boilers less than 100 mmBtu/hr, EPA should modify the requirement to allow operating loads of at least 130 percent of the operating load established during the performance test.²⁵

[Footnote 24: Many companies record the boiler's operating load by recording the steam produced by the boiler. When operating in the summer months, a typical steam demand can be 533,000 lbs steam. This steam demand is for the nonnal operation of the facility. However, in the winter months, the steam demand can be approximately 706,000 lbs-steam due to ambient losses, the addition of building heat, and the normal operation of the facility. This results in a 25%

change in steam demand between the two extreme seasonal temperatures, which exceeds the rule's limit of 10%.]

[Footnote 25: Furthermore, the regulation requires that the Method 19 F-factor be used to determine the pollutant emission rate. This method in itself can result in a 5% error in the reported value. Depending on the pollutant being tested and the test method used, the internal QA/QC of the test method can result in an error of up to 30%.]

Comment Excerpt Number: 39

Comment: As discussed in more detail elsewhere in these comments, for units that already have CO CEMS for reasons unrelated to the Boiler MACT Rule, compliance with the Boiler MACT Rule's stack-test-based CO emissions limitations would be difficult to maintain. Stack tests are required to be run under representative operating conditions, typically defined as operating at or near full load consistently for the duration of the stack test. In sharp contrast, CEMS take emissions data on a near-continuous basis, which means CEMS emissions measurements reflect significant variability in emissions (for example, due to load swings and low load conditions) that was not measured during the stack tests used to set the CO standard. This problem is not overcome by statistical manipulation of the CO standard, such as accounting for variability using the UPL method, because such statistical methods unrealistically extrapolate only from the variability measured during stack tests and the variability between stack tests. In other words, this is a classic "apples and oranges" situation where emissions data from CO CEMS are incompatible with emissions data from stack tests used to set the CO standard.

One way for EPA to resolve this incompatibility is to determine that emissions data from CO CEMS are not credible evidence for purposes of assessing compliance with the Boiler MACT Rule's stack-test-based CO emissions limitations. As EPA explained in the "credible evidence rule," data and information derived from methods other than the specified reference test method (so-called "non-reference test data") are relevant to showing compliance only to the degree that "the appropriate reference test would have shown a violation." 62 F.R. 8314, 8323 (Feb. 24, 1997). Because the Boiler MACT Rule's CO standards are based on stack test data, and because the stack tests on which the standards are based were required to be conducted during representative operating conditions (*i.e.*, consistently operating at or near full load), then by definition CO CEMS data taken during periods of operation that do not reflect "representative operating conditions" are not data that are relevant to showing compliance with the standards.

In other words, the stack test data on which the standards are based reflect operation during a narrow, limited, and optimum set of conditions. Conversely, CO CEMS data that are taken during periods of operation that do not reflect those limited conditions are not relevant to determining whether an affected source is in compliance with the standard.

Comment: Performance testing should be carried out at representative conditions and the requirement to establish a BPH operational load operating limit in Table 4 Item 8 and Table 7 Item 5 should be deleted.

Proposed §63.7520(a), following §63.7(e) of the part 63 General Provisions, states “You shall conduct all performance tests under such conditions as the Administrator specifies to you based on representative performance of the affected source for the period being tested.” Table 4 Item 8 and Table 7 Item 5 requires that a BPH demonstrating compliance using a performance test must not be operated at greater than 110% of the load at which the boiler or process heater was tested during the previous performance test. This often requires that all such performance tests be run at greater than or equal to 90% of maximum load, thereby overriding §63.7520(a) and §63.7(e), because otherwise the boiler or process heater would be restricted from raising rates for even short periods. In many cases operating at such a high percent of load presents problems since boiler and process heat operating rate must match the operating rate of the process for which they provide heat or steam. Moving around entire processes just to perform performance tests is costly, wasteful and has not been considered in developing this rule’s costs or burdens. Furthermore, operating at such high loads is not generally necessary to assure compliance, since most boilers and process heaters are likely to operate well below the emission limits where performance testing will be used for demonstrating compliance. We suggest an operating limit is not needed, since if a boiler or process heater operates significantly above the test point, it would be required to test at a higher load on the next test occasion by the regulating authority reviewing the planned performance test conditions.

Comment Excerpt Number: 9

Comment: Maine DEP strongly objects to the inclusion of a steam load limit of 110% of the average steam load attained during the last performance test. The rule requires testing using a worst case mix of fuels. However, a worst case fuel mix will not allow biomass and multi-fuel boilers to operate at high steam loads. The rule would effectively prohibit many boilers from operating at even normal steam loads.

Comment: Requiring daily checks of pressure taps for blockage is not standard practice and not justified in services where such blockage is not likely. Proposed §63.7525(f)(4) should be deleted or, at the most, only apply to pressure taps where there is a history of pressure measurement problems due to tap blockage.

Proposed §63.7525(f)(4) requires daily checks of pressure taps for blockage. This extremely burdensome requirement should be deleted, since pressure tap blockage is highly unusual, particularly around BPH and their controls. If EPA knows of a specific situation where such blockage is likely (and not just possible, in a theoretical sense) it should apply this requirement to just that specific situation. In addition to imposing a large wasteful burden⁵⁰, such checks typically require releases to the atmosphere and exposure of personnel and thus unnecessary checks are to be avoided.

[Footnote 50: For instance, such a check might require 30 minutes per day of technician time per instrument. This cost was not considered in the cost and burden estimates for this rulemaking. Similarly, EPA did not account for the emissions impacts of this requirement or the cost of the additional facilities that would be required.]

110C02. Reduce Fuel Analysis Burden [DENIED PETITIONER ISSUE]

Commenter Name: Michael D. Wendorf

Commenter Affiliation: FMC Corporation

Document Control Number: EPA-HQ-OAR-2002-0058-3453-A1

Comment Excerpt Number: 2

Comment: §63.7530(b) describes the method by which maximum fuel pollutant levels are established for use as operating limits to demonstrate continuous compliance with the alternative TSM emission limit. The fuel operating limit remains in effect until such time as the source conducts another stack emission test and a new fuel TSM limit is established.

This methodology establishes TSM limits that are overly proscriptive, and in fact results in stack emission limits that are lower than the rule dictates. It is nearly impossible to procure a shipment

of fuel from a supplier that would contain the highest TSM concentration anticipated in the future for use during a particular emission stack test.

Consequently, a boiler is constrained to burn fuel that is less than or equal to the prevailing fuel TSM operating limit. The only means to develop a reasonable fuel operating limit would be to continually repeat emission stack testing each time a coal shipment indicates higher fuel TSM levels than the existing operating limit. Unfortunately, analytical results for fuel TSM on any specific coal shipment arrive after the coal is burned; most coal reclaim systems are not designed to segregate an individual coal shipment without significant disruption to the normal reclaim process.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: Michael D. Wendorf

Commenter Affiliation: FMC Corporation

Document Control Number: EPA-HQ-OAR-2002-0058-3453-A1

Comment Excerpt Number: 3

Comment: The problem of repetitive stack testing is acknowledged by EPA in §63.7520(c), albeit with some understatement:

We request EPA to consider allowing the operator to adjust the fuel TSM operating limit based on the results of the stack emission test. Example: an existing coal-fired PC boiler completes Method 29 stack emission testing and demonstrates a TSM emission rate of $4.5E-05$ lb/MMBtu, or 76% of the TSM emission limit. This percentage is then applied to the corresponding fuel TSM value, TSM_{90i} , as calculated from §63.7520(c)(5) Eq. 13:

$$TSM_{oL} = 0.0000655 + (4.5E-05 + 5.9E-05) = 0.0000862 \text{ lb/MMBtu}$$

where:

TSM_{oL} = adjusted TSM fuel operating limit, lb/MMBtu
 $0.000655 = TSM_{90i}$ from fuel analysis during Method 29 stack test

$4.5E-05$ = result of Method 29 stack test, lb/MMBtu

$5.9E-05$ = proposed TSM limit, coal-fired PC boiler, lb/MMBtu

The adjustment would reflect the level of TSM that could have been in the fuel at the time of the stack test that would have still resulted in meeting the TSM emission limit at the stack exit. This assumes a direct relationship between fuel and stack TSM emissions, upon which the rule already relies. This same adjustment mechanism could be applied for HCl and Hg, as well.

FMC requests EPA to consider this approach, as it provides a logical means of establishing an appropriate fuel operating limit reflective of the stack emission rate, all without onerous and expensive retesting. It eliminates a stack emission limit being directly imposed upon the boiler that is lower than specified by the rule simply due to fuel not containing the maximum HAP pollutant concentration at the time of the stack test.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Commenter Name: Sarah E. Amick

Commenter Affiliation: Rubber Manufacturers Association (RMA)

Document Control Number: EPA-HQ-OAR-2002-0058-3503-A1

Comment Excerpt Number: 16

Comment: Section 63.7515(f) requires monthly fuel analysis if a facility is complying with numeric emission limits using fuel analysis rather than stack testing:

“If you demonstrate compliance with the mercury, hydrogen chloride, or total selected metals based on fuel analysis, you must conduct a monthly fuel analysis according to § 63.7521 for each type of fuel burned that is subject to an emission limit in Table 1 or 2 to this subpart.”

RMA member facilities may burn a percentage of light or heavy fuel oil subject to numeric emission standards only part of the year, and burn natural gas at other times. These facilities should not have to conduct monthly fuel analysis if they have not received additional fuel shipments since the last fuel analysis was performed.

Commenter Name: Chris M. Hobson

Commenter Affiliation: Southern Company

Document Control Number: EPA-HQ-OAR-2002-0058-3520-A1

Comment Excerpt Number: 11

Comment: The requirement to set a maximum fuel input level even if a source chooses to demonstrate compliance through performance testing gives no regard to the compliance margin the source may have achieved during the test. In the reconsideration notice, EPA states that "it is impracticable to replicate, during performance testing, all of the varying fuel conditions necessary for calibrating the monitor" specifically for biomass units.⁶ Considering the natural variability in the fuel and the fact that biomass fuel is generally stored for two weeks or less at a time, it is similarly impracticable to ensure that the batch of biomass the facility receives and burns during the performance test represents the maximum fuel input level.

Commenter Name: Paul Noe

Commenter Affiliation: American Forest & Paper Association (AF&PA) et al.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 111

Comment: The general compliance plan outlined in the proposed rule is that sources (1) demonstrate compliance with applicable emissions limitations and work practice standards through the conduct of an initial performance test; (2) establish operating limits based upon results of the performance test; (3) conduct monitoring and maintain records demonstrating that the source is operated on a continuous basis consistent with the operating limits established during the performance test; and (4) periodically repeat the performance testing. Operating parameter limits based on fuel input analysis (e.g., HCl and Hg), are established using Equations 7 and 8 in §63.7530. Then, on a continuing basis, facilities are required to keep extensive records of all fuels burned in each boiler or process heater during each compliance reporting period. If a source changes fuels, it must re-calculate its fuel input values using applicable equation 7 or 8. If the re-calculated value exceeds the existing limit, the source is required to conduct a new performance test and establish new operating limits.

While this compliance approach may be easy to manage for some sources, especially ones with very stable fuel supply and usage, it may be very cumbersome and burdensome for other sources with variable fuel suppliers and fuel mixes. This approach involves a great deal of recordkeeping and potentially subjects the source to frequent testing requirements if fuel content varies, regardless of the margin of compliance shown during the initial performance test. Under the proposed rule, even if a unit is operating at 50 percent of the applicable emission limit, the facility would be required to re-test if the fuel chloride input increases 1 percent over the level achieved during the initial performance test.

A more appropriate approach is to allow the source to set operating parameters at levels that generate emissions at the emission limits established in the rule. This is the only approach which meets the requirements of the Act, since it is the only approach that does not impose a beyond the floor limit which has not been justified per the requirements of 112(d). Under this approach, the source would simply conduct the performance test using its normal fuel mix, determine operating conditions that show compliance and then adjust those conditions, using engineering calculations to assure it would meet the emissions standards established in Table 1 or 2. If the initial performance test shows emissions at 50 percent of the standard at a particular mercury or chloride fuel input, the fuel input limits should be set at a level higher than the performance test values, taking into account control device operating parameters as appropriate. This approach would be environmentally beneficial and would greatly reduce burdens. It is the only practical way to establish fuel input operating limits.

Compliance could also be demonstrated through the use of fuel purchase specifications. Sources would determine from the performance test a maximum fuel pollutant concentration at which the emissions limitations are achieved. For instance, the performance test may demonstrate that fuels containing chlorine in concentrations less than x Ib Cl/MMBtu allow the source to comply with emissions limitations. A facility should be allowed to extrapolate an allowable fuel input based on a comparison of performance test conditions to the applicable emission limit. The source would then set a fuel specification of x Ib Cl/MMBtu and would be allowed to burn any fuel of the same general type (e.g., solid, liquid, or gas) as long as it met this specification. Sources could require that the fuel supplier provide periodic certification that the fuel meets the specification, based on analysis, or could establish an internal sampling and analysis program for

that purpose. In any case, where common fuels are utilized in more than one unit, common fuel quality data would be maintained and considered applicable to all such units. Continuous compliance could also be demonstrated through ongoing fuel analysis.

As an example, sources would (1) establish a fuel input limit (e.g., lb Cl/MMBtu) based on the compliance test as described in the proposal (with an allowance for extrapolation); (2) periodically sample and analyze each fuel for constituent concentration and heating value according to a specified sampling and analysis plan; (3) monitor the daily usage of each fuel; (4) calculate the average total daily constituent input (lb/MMBtu) accounting for all fuels fed; and (5) demonstrate that the average daily constituent input rate averaged over each month of operation does not exceed the operating limit. This option would afford the source the opportunity to vary fuel mixes, while still insuring that protective operating limits are met.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: Paul Noe

Commenter Affiliation: American Forest & Paper Association (AF&PA) et al.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 116

Comment: Section 63.7515(f) requires monthly fuel analysis if a facility is complying with numeric emission limits using fuel analysis rather than stack testing:

"If you demonstrate compliance with the mercury, hydrogen chloride, or total selected metals based on fuel analysis, you must conduct a monthly fuel analysis according to § 63.7521 for each type of fuel burned that is subject to an emission limit in Table 1 or 2 to this subpart."

Some facilities may burn certain fuels subject to numeric emission standards only part of the year, and burn natural gas at other times. These facilities should not have to conduct monthly fuel analysis if they have not received additional fuel shipments since the last fuel analysis was performed.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: Sarah Hedrick

Commenter Affiliation: Verso Paper Corp.

Document Control Number: EPA-HQ-OAR-2002-0058-3537-A2

Comment Excerpt Number: 4

Comment: The monthly fuel sampling requirement is excessively burdensome. While the proposed rule does provide some relief after the first year (in that facilities can request a reduced sampling frequency), monthly sampling during the first year is still too burdensome. Annual sampling is sufficient to demonstrate compliance. As written, the rule is excessively labor-intensive and costly for facilities.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Commenter Name: Bill Lane

Commenter Affiliation: American Home Furnishings Alliance (AHFA)

Document Control Number: EPA-HQ-OAR-2002-0058-3676-A2

Comment Excerpt Number: 11

Comment: AHFA is concerned with the proposed requirement for establishing operating parameters based on initial performance tests and fuel analysis testing for mercury, hydrogen chloride (HCl), and total selected metals (TSM). Under the Proposed Reconsideration Rule, a facility that retests an existing fuel resulting in a higher pollutant concentration due to natural variability of mercury, TSM, or HCl in the biomass fuel supply is required to undertake additional performance testing at considerable cost, even though the additional source testing provides no environmental benefit. The relationship between metal, mercury, and chlorine in a fuel and in an air exhaust stream can be clearly documented, negating the need for additional source testing due to a minor increase in a laboratory result. Instead of a requirement for additional source testing, we urge the EPA to allow establishment of fuel concentrations as a parametric indication of stack emissions. The parametric monitoring limits would be established by concurrent fuel and source testing. If compliance fuels testing calculations exceed a defined threshold (e.g., 90% of the applicable emissions limitation), then source testing would be required at that time to demonstrate continued compliance. Rather than requiring performance testing every time a lab result shows any increase in a regulated pollutant, the Boiler MACT rule should allow affected sources to adjust their fuel mix and demonstrate compliance based on engineering calculations and the fuel analysis.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Commenter Name: Bill Lane

Commenter Affiliation: American Home Furnishings Alliance (AHFA)

Document Control Number: EPA-HQ-OAR-2002-0058-3676-A2

Comment Excerpt Number: 12

Comment: AHFA is concerned that the rule requires monthly fuel testing for facilities using the fuel analysis option, even if the source or type of fuel does not change. Monthly testing of fuel would also be required if fuel is delivered less frequently than monthly. AHFA believes the fuel testing should only be required when the source or type of fuel changes, consistent with previous Boiler MACT proposals.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Commenter Name: Matthew Todd

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 102

Comment: We believe the same burden reduction opportunity exists for the fuel analyses requirements and this reduced testing frequency should be extended to fuels analysis without requiring approval. Proposed §63.7515(f) states:

(f) If you demonstrate compliance with the mercury, hydrogen chloride, or total selected metals based on fuel analysis, you must conduct a monthly fuel analysis according to § 63.7521 for each type of fuel burned that is subject to an emission limit in Table 1 or 2 to this subpart. If you burn a new type of fuel, you must conduct a fuel analysis before burning the new type of fuel in your boiler or process heater. You must still meet all applicable continuous compliance requirements in § 63.7540. If 12 consecutive monthly fuel analyses demonstrate compliance, you may request decreased fuel analysis frequency by applying to the EPA Administrator for approval of alternative monitoring under § 63.8(f).

Using §63.8(f) to obtain approval of a decreased analysis frequency is unworkable and reduced monitoring should be directly implemented in this paragraph. Under the proposal, §63.8(f) alternative approval authority is reserved from delegation and thus would be implemented by EPA. EPA has repeatedly demonstrated a clear inability to consider alternative requests in a timely manner, in some cases never responding to such requests. Thus, using §63.8(f) is not a realistic way of reducing burdens in this kind of low risk situation. After 12 months of data have been collected on a fuel there is little risk of change unless the fuel is purposely switched. In that case, under the proposal, any change in fuel would require a new analysis and under §63.7540 a notice of the change. Thus, we recommend, in line with the stack testing burden reduction proposal, that proposed §63.7515(f) allow, without further approval, a reduction to quarterly fuel testing after the 12 months if the mercury, hydrogen chloride or TSM content was less than 75% of the applicable limit for the previous 12 months.

We suggest the following revision to §63.7515(f).

(f) If you demonstrate compliance with the mercury, hydrogen chloride, or total selected metals based on fuel analysis, you must conduct a monthly fuel analysis according to § 63.7521 for each type of fuel burned that is subject to an emission limit in Table 1 or 2 to this subpart. If you burn a new type of fuel, you must conduct a fuel analysis before burning the new type of fuel in your boiler or process heater. You must still meet all applicable continuous compliance requirements in § 63.7540. If 12 consecutive monthly fuel **analyses** demonstrate 75% or less of the compliance level, you may decrease the fuel analysis frequency to quarterly for that specie. If any quarterly sample exceeds 75% of the compliance level or you begin burning a new type of fuel, you must return to monthly monitoring for that specie, until 12 months of fuel **analyses** again are less than 75 % of the compliance level. If 12 consecutive monthly fuel **analyses** demonstrate compliance, you may request decreased fuel analysis frequency by applying to the EPA Administrator for approval of alternative monitoring under §63.8(f).

Comment: AMP finds EPA's imposition of operating limits based on performance tests to be an impermissible beyond-the-floor requirement that was adopted without considering costs and other factors required by the Clean Air Act. Operating parameters should be indicators that trigger corrective actions to ensure proper control device performance; they should not be enforceable limits that tie an operator to the performance level during a test regardless how far below the MACT floor standard the unit tested.

Comment Excerpt Number: 8

Comment: Alcoa questions the Liquid Flow and Pressure Drop CMS Requirements.

Alcoa~ Warrick may elect not to equip its pulverized coal boilers with mercury CEMS or Appendix K absorption tubes. In that case, the scrubber liquid flow, scrubber pressure drop, and electrostatic precipitator monitoring requirements of 63.7525 (d) would be applicable.

In its current Title V permit, Alcoa- Warrick bases liquid input on the supplied pump curves, which indicate flow as a function of pump motor amperage. Alcoa- Warrick has found this method to be adequate for the intended purpose~ i.e. verification that the scrubber is operating in a similar manner to that measured during the most recent performance test.

63.7525 (e) (1) through (3) does not take into account that there could be issues with spray patterns as nozzles wear over time. Liquid flow measurements would not take that effect into account, and would thus not be an accurate indicator of pollutant removal.

Alcoa- Warrick estimates that \$750,000 would be needed to add the liquid flow measurement and associated data acquisition systems needed to meet 63.7 525 (d). Such an expenditure is not justified, given that highly precise liquid flow measurement may not be a highly accurate indicator of scrubber performance.

Alcoa- Warrick agrees with the concept outlined in the July 29, 2011 comments letter provided with respect *to* the proposed MATS regulatory action by Thomas Easterly, Commissioner of the Indiana Department of Environmental Management, i.e. "Indiana asks that States be allowed maximum flexibility to develop alternate compliance plans that afford the regulated community opportunity to assure timely compliance, while also assuring that consumers are not adversely affected. "

In concert with the sentiment expressed by Commissioner Easterly, Alcoa- Warrick recommends that States be provided the flexibility to approve liquid flow monitoring and other portions of the required CPMS monitoring plan. To that end Alcoa- Warrick recommends that 63.7525 (d) be amended as follows:

(d) If you have an operating limit that requires the use of a flow monitoring system, you must develop a flow monitoring plan in consultation with your State regulatory agency. The plan must be approved by the agency in advance of the initial compliance demonstration.

63.7525 (e) would then be deleted.

Comment Excerpt Number: 16

Comment: Demonstration of HCl and Hg compliance by monthly fuel analyses, §63.7530(c) and §63.7521. For CraftMaster's biomass fuels it will not be possible to use fuel analyses to demonstrate compliance with the proposed HCl limit using the method outlined in §63.7530, equations 10 and 11 *even when the results of all fuel analyses are below the method detection limit*. The ASTM method for Cl has a detection limit for CraftMaster's biomass fuels of 200 mg/kg. This is due to the ASTM procedure available (04208-02) and the relatively low dry bulk density of the biomass fuels. The relatively low higher heating value of the biomass is also a contributing factor. Then, even if all fuel analyses results are not detected and values are considered to be the method detection limit, the Lbs HCl per MMBtu calculated using equation 11 are above the proposed limit. We believe this would be the case for other biomass and biomass-based fuels as well. To address this issue we request that the proposed limit be raised and/ or the averaging period for the compliance demonstration be increased from monthly to semi-annually. This would increase the number of samples considered and reduce the 90% confidence value from 1.89 standard deviations (δ 's) to 1.33 δ 's if three samples per month are analyzed.

We believe similar changes would be appropriate for mercury as well.

Comment: Under §63.7515(f) one must petition the Administrator for a lesser frequency of fuel analyses if results show compliance for twelve consecutive months. CraftMaster requests that this be automatic, as in the case of stack testing in §63.7515(b).

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

111B02. Use Consistent Averaging Times for Initial and Continuous Compliance [DENIED PETITIONER ISSUE]

Commenter Name: James Pew

Commenter Affiliation: Earthjustice, Clean Air Council, Partnership for Policy Integrity

Document Control Number: EPA-HQ-OAR-2002-0058-3511-A1

Comment Excerpt Number: 26

Comment: EPA proposes to allow sources to demonstrate compliance with emissions limits by averaging emissions data over a longer time period. Specifically, EPA proposes to permit compliance determinations to be made on the basis of a 30-day rolling average. Although rolling averages are better than block averages, which allow polluters to comply based on the entirely fortuitous circumstance of a new block period beginning between elevated test runs, EPA has failed to adjust the applicable emissions limits to account for a 30-day averaging period. As a result, EPA’s proposed standards will not require units to control emissions to the level of the best performers. This is true in at least two respects. First, EPA calculated the emissions limits based on the highest one-hour emissions tests of the best sources (adjusting upwards for assumed variability). Thus, the numerical limits reflect peak emissions, not average emissions. By definition, an average emission level is lower than an emissions peak. Yet EPA now proposes to allow all sources to emit *on average* at the same level that the best performers emit *at peak times*. Second, EPA selected the best performers on the basis of one-hour test runs, not 30-day averages. Units not selected as the best performers may actually have yielded lower 30-day average emissions limits than those selected. To comply with the requirement to set the MACT floor based on the best performers, EPA must use the same methodology both in selecting the best performers and then in calculating the limits. For both of these reasons, EPA’s failure to adjust its emissions limits in accordance with the switch to 30-day average compliance determinations is contrary to section 112(d)(3) and arbitrary.

Commenter Name: Mary Sullivan Douglas

Commenter Affiliation: National Association of Clean Air Agencies (NACAA)

Document Control Number: EPA-HQ-OAR-2002-0058-3525-A1

Comment Excerpt Number: 21

Comment: EPA observes that standards are to be complied with “at all times,” but this is a truism that is not particularly helpful.¹⁸ What are helpful are the provisions in the rules that set out the conditions under which compliance will be determined. In years past, facilities were to be

tested under “reasonable worst case conditions.” Today, that standard has been reduced to “representative” conditions – a phrase that suggests that a compliance margin based on a 99th percentile projection¹⁹ of possible emissions may be too large and that industry projections of severe test conditions may be overstated. Moreover, the structure of the compliance obligations itself suggests that the 99th percentile may be too stringent. The following factors, among others set out in the proposed rules, bear on a determination of the appropriate compliance margin:

1. For sources that intend to comply with mercury and hydrogen chloride (“HCl”) fuel sampling, the rules require that a source conduct a stack test and demonstrate compliance using 90th percentile worst-case fuel (employing Student’s t-test to determine that percentile);
2. For other purposes (e.g., PM and CO compliance), the source may select a “representative” operating condition (suggesting that neither a 90th percentile nor a 99th percentile worst-case test is required for these pollutants);
3. A source whose emissions during a test are less than 75 percent of the applicable limit is entitled to a reduced frequency of stack testing (suggesting that EPA does not really believe that replicate testing of sources will vary by more than 33 percent);
4. Parametric operating limits may not generally be less effective than demonstrated during the stack test (a useful provision, but also one that suggests that EPA believes that in-use emissions variability is zero);
5. Many of the applicable standards and other requirements contain exclusions from full compliance at all times (e.g., six-minute exclusion under opacity requirements, 5-percent exclusion for bag leak detection systems);
6. Power (voltage or amperage) to electrostatic precipitators (“ESPs”) may not fall to less than 90 percent of that employed during a stack test²⁰ (for which we can think of no justification); and
7. Parametric limits are allowed to be based on the lowest (least effective) hourly parameters of the three runs of the compliance test. On its face this will not lead to compliance since it will be less than the average flow rate during the test. Moreover, such parametric limits do not provide any allowance for the variations employed in setting the standard. EPA should provide that the operating parameters be set at the levels employed during the test run that yielded the lowest emission rate, plus some additional margin to account for in-use variability.

[Footnotes]

(18) EPA also asserts that the failure of a compliance test is not a violation of a standard until and unless some governmental authority agrees. We understand the reference in the context of the annual certification of compliance (where EPA does not intend sources to have to “confess” to a violation of law), but not otherwise.

(19) We understand that a 99th percentile UPL is not precisely the same as a 99th percentile worst-case condition, but the differences are extremely subtle.

(20) If power to the ESP falls below that employed during the test, PM control efficiency would be reduced. The amount of this reduction is presumably unit-specific and so we can think of no justification for this provision.

Document Control Number: EPA-HQ-OAR-2002-0058-3500-A1

Comment Excerpt Number: 31

Comment: In comments on the 2010 proposed rule, UARG objected to the provisions addressing out-of-control periods for O₂ CEMS and COMS as unreasonable and inconsistent with the general provisions,¹⁵ and asked EPA to revise § 63.7535(b) to exempt out-of-control periods from the monitoring requirement. UARG also asked EPA to specifically exclude maintenance periods from the requirement for operation of monitoring systems. EPA-HQ-OAR-2002-0058-2880.1 at 55-58. In response, EPA revised § 63.7535(b) to exclude out-of-control periods from the monitoring requirement, and included such periods in a list of monitoring system events that did *not* constitute a deviation in a new subsection (d). 40 C.F.R. § 63.7535(d). However, EPA did not revise § 63.7525 to remove the provisions specific to O₂ CEMS and COMS. EPA also made no changes with respect to periods of monitoring system maintenance. Because EPA did not fully address or respond to UARG’s comments, UARG included the issue in its reconsideration petition. EPA-HQ-OAR-2002-0058-3324 at 18-19.

[Footnote]

(15) Section 63.8(c) specifically includes “out-of-control” periods as one of the exceptions to continuous operation of a monitoring system.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

111C01. Pressure Monitoring Taps [DENIED PETITIONER ISSUE]

Commenter Name: Samuel H. Bruntz

Commenter Affiliation: Alcoa Power Generating, Inc.

Document Control Number: EPA-HQ-OAR-2002-0058-3755-A1

Comment Excerpt Number: 9

Comment: Proposed regulation 63.7525 (t) is overly prescriptive. Industrial boiler operators may have experience that pressure drop sensors may provide reliable output at a less frequent cleaning frequency than daily. Alternatively, systems equipped with an auto purge system would not require the daily operator interaction of manually cleaning the sensors. This parameter is another candidate for negotiation between the State regulatory agency and EGU owner in the required CPMS monitoring plan. Accordingly, APGI recommends that 63.7525 (f) be amended as follows;

If you have an operating limit that requires the use of a pressure monitoring system, you must develop a pressure monitoring plan in consultation with your State regulatory agency. The plan must be approved by the agency in advance of the initial compliance demonstration. The plan must include the recommended accuracy, and include a recommended maintenance interval for adequate sensor cleaning if an auto purge system has not been installed."

63.7525 (f) would then be deleted.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

111C02. Revise Max/Min Operating Parameter Language [DENIED PETITIONER ISSUE]

Commenter Name: Lee Zeugin and Lauren Freeman

Commenter Affiliation: Utility Air Regulatory Group (UARG)

Document Control Number: EPA-HQ-OAR-2002-0058-3500-A1

Comment Excerpt Number: 34

Comment: EPA’s proposed operating parameters are not sufficiently connected to emissions to be enforceable limits. UARG objects to EPA’s proposal to use the control device parameter levels measured during performance testing as enforceable operating limits. Establishment of such limits reduces operational flexibility, deprives sources of the use of any control device margin, and allows enforcement for events beyond the owner/operator’s control.

EPA's current proposal is based on the faulty assumptions that the values of the parameters identified by EPA have a direct relationship to the level of emissions, and that exceedances of those limits may indicate an exceedance of the emission limit as well. To the extent possible, source owners and operators will contract for control equipment that is designed to provide a "margin of compliance" with the applicable emission limitation.¹⁶ In addition to reducing the possibility of an exceedance of the limit, this margin is intended to provide flexibility for the source to account for an inevitable control equipment or operational problem. Sources that are able to normally operate with a margin of compliance will lose part of that margin of compliance if they conduct performance testing under normal operations, because they will establish *operating limits* that would require them to continue to over-control forevermore.

[Footnote]

(16) For example, it is relatively common for new ESPs to be purchased with extra fields and sections which will allow the source to continue to operate in compliance with applicable emission limits even when there are problems with other parts of the controls. Fabric filters and scrubbers can also be purchased with extra capacity (*i.e.*, additional modules) for the same purpose.

The only way such sources could avoid surrendering whatever margin of compliance they have would be to deliberately reduce performance of their controls to attempt to generate the least stringent operating limits consistent with achievement of the applicable emission standard. EPA's proposal thus has the perverse result of encouraging sources to focus their attention on learning how to manipulate their operations to allow testing as close as possible to their emission limit by reducing performance of their controls. *See* McRanie Consulting, "Comments on the Proposed Utility MACT Rule - Operating Parameters" (July 2011) (Attachment) at 1-4.¹⁷ [See submittal for McRanie Technical Memo, pages 33-36]

[Footnote]

(17) Although Mr. McRanie's analysis was prepared in response to EPA's proposed EGU MACT, the points he makes are equally applicable to EPA's final IB MACT and reconsideration proposal.

Unfortunately, even the "detuning" of a control device during performance testing will not ensure that the operating limits established during the test are reasonable, or necessary, for achievement of the applicable emission limit. As EPA has previously recognized in the context of the NSPS and the CAM rule, "many sources operate well within permitted limits over a range of process and pollution control device operating parameters," and requiring sources to continuously maintain parameters that "happened to exist" during the most recent performance test may not be "possible or wise." 62 Fed. Reg. 54,900, 54,907, 54,926-27. That is because control device parameters, such as those identified by EPA for scrubbers and ESPs, do not necessarily have a direct relationship to emissions, but instead are interrelated with the design of the control device and the interaction of various parameters. As a result, a single parameter may vary widely with little effect on emissions. Without a clear correlation between such operating parameters and the applicable emission limit, imposition of those values as enforceable limits would unreasonably restrict source and control device operation and subject sources to potential

enforcement without any reliable evidence that an emission limit has been violated. Attachment at 1-4. [See submittal for McRanie Technical Memo, pages 33-36]

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Commenter Name: Lee Zeugin and Lauren Freeman

Commenter Affiliation: Utility Air Regulatory Group (UARG)

Document Control Number: EPA-HQ-OAR-2002-0058-3500-A1

Comment Excerpt Number: 35

Comment: Under EPA’s proposal, IB units that use an ESP in combination with a wet scrubber must comply with operating limits on total power input to the ESP collection plates. Proposed § 63.7530(b)(4)(iv). EPA’s proposal is flawed. As Mr. McRanie explains, ESP power input simply is not directly related to PM removal performance, particularly for the modern multisection ESPs that are likely to be installed to comply with a MACT. Attachment at 8-16. [See submittal for McRanie Technical Memo, pages 40-48] The total amount of power is not nearly as important as the location at which the power is being applied in the ESP.

Moreover, none of the ESP parameters are likely to have any relationship to PM at IB units that also have a wet scrubber, since those scrubber systems also are highly effective in controlling high levels of PM coming out of an ESP that is not performing at its intended control efficiency. Attachment at 6-8. [See submittal for McRanie Technical Memo, pages 38-40] As many sources have discovered while attempting to obtain high PM concentrations for PS 11 correlation of PM CEMS, even a fully disabled ESP may have little effect on resulting PM concentrations when a wet scrubber is operating at expected efficiency. Sources should not be penalized for an ESP failure if another control, like a wet scrubber, is capturing the resulting PM.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Commenter Name: Lee Zeugin and Lauren Freeman

Commenter Affiliation: Utility Air Regulatory Group (UARG)

Document Control Number: EPA-HQ-OAR-2002-0058-3500-A1

Comment Excerpt Number: 36

Comment: Under EPA’s proposal, IB units that use a wet scrubber must comply with operating limits for pH, pressure drop and liquid flow-rate. Proposed § 63.7530(b)(4)(i) and (iii). EPA’s proposal to use these parameters is subject to the same flaws as EPA’s other proposed operating limits - namely the lack of a sufficient relationship between the parameters measured during performance testing and actual emissions. For example, the range of normal pH in a scrubber can be significant. Attachment at 4. [See submittal for McRanie Technical Memo, page 36] As long as pH is within the normal range, its impact on scrubber efficiency is minor. If pH falls too low, however, metal components can corrode. If pH is too high, calcium sulfate deposits can develop. As a result, operators monitor pH to ensure it is within the desired range and react to bring pH back within that range if pH gets too high or too low. Operators have no incentive to allow pH to

fall outside the normal range. *Id.* Likewise, requiring operators to artificially maintain pH at the level during a performance test is not a useful requirement.

Liquid-flow rate also is not directly related to emissions, but it is related to load. When EPA in 2008 considered the relationship between liquid flow rate and PM in the context of the NSPS for electric steam generating units at 40 C.F.R. Subpart Da, EPA concluded that, at the level of the NSPS (*i.e.*, 0.015 lb/MMBtu), PM emissions controlled by an ESP were not particularly sensitive to the actual liquid flow rate. Response to Public Comments on Rule Amendments Proposed June 12, 2008 (73 FR 33642) (Nov. 2008), EPA-HQ-OAR-2005-0031-0284, § 2.5.3. The determinate factor in SO₂ removal in a conventional spray tower is the liquid/gas ratio (“L/G”), not simply liquid flow. L/G is expressed as gallons per 1000 actual cubic feet of flue gas flow. The rate is usually controlled by adding or removing recycle pumps or scrubber modules as unit load changes. Establishment of a liquid-flow rate limit based on conditions during performance testing will say little about actual emissions under other load conditions. Attachment at 4-5. [See submittal for McRanie Technical Memo, pages 36-37]

Pressure drop also is load dependent. When unit load drops, the scrubber pressure drop decreases as a matter of simple physics because the flue gas flow rate decreases. However, this decrease has nothing to do with removal efficiency. In fact, the scrubber performance is likely to improve at reduced load. In a typical spray tower scrubber, pressure drop is not used for control purposes, but to determine when cleaning of a scrubber module is required. As a result, pressure drop also will increase and decrease according to the cleaning cycle for each scrubber module. Unfortunately, because it is not possible to clean all of the modules at once, operators cannot establish an absolute “minimum” pressure drop for the scrubber during performance testing. *Id.* at 5. [See submittal for McRanie Technical Memo, page 37]

EPA also must recognize that not all scrubbers operate the same way. For example, Chiyoda scrubbers operate on a completely different set of parameters than a typical spray tower. Attachment at 5-6. [See submittal for McRanie Technical Memo, pages 37-38]

In short pH, liquid flow rate, and pressure drop are not particularly useful indicators of emission and may vary based on factors completely beyond the operator’s control. L/G is a more useful indicator for some types of scrubbers (*e.g.*, spray tower scrubbers), but it also will vary with load. Because many boilers operate at variable load levels, establishing operating limits on these parameters based on a single performance test is not reasonable. EPA must adopt a more flexible approach that allows operators to define parameters and ranges based on control device design and the interaction of relevant parameters.

Commenter Name: Lee Zeugin and Lauren Freeman

Commenter Affiliation: Utility Air Regulatory Group (UARG)

Document Control Number: EPA-HQ-OAR-2002-0058-3500-A1

Comment Excerpt Number: 37

Comment: Under EPA’s proposal, IB units that use a dry scrubber must comply with an operating limit on dry sorbent (or carbon) injection (“DSI”) rate. Proposed § 63.7530(b)(4)(v)

and (vi). The removal efficiency of a DSI system is directly related to the flue gas concentration of the specific pollutant, the injection rate of the sorbent, and the unit load or flue gas flow rate. Attachment at 16-18. [See submittal for McRanie Technical Memo, pages 48-50] As a result, the DSI rate measured during a performance test also is not particularly useful in determining emissions at other loads. Because the relationship between sorbent injection and load can be characterized more easily than the other control device parameters discussed above, the load adjustment factor provided in the definitions of minimum activated carbon injection rate and minimum sorbent injection rate may be of some use in adjusting a minimum DSI rate to account for changes in load. However, such an adjustment cannot be expected to account for all differences. Similar to boilers using a combination of an ESP and wet scrubber, boilers using DSI also likely will have a secondary control device (*e.g.*, a baghouse or wet scrubber) downstream of the DSI system. EPA should allow sources to take into account the impact of downstream controls when establishing appropriate parameter values and ranges.

Commenter Name: Lee Zeugin and Lauren Freeman

Commenter Affiliation: Utility Air Regulatory Group (UARG)

Document Control Number: EPA-HQ-OAR-2002-0058-3500-A1

Comment Excerpt Number: 38

Comment: EPA Should Require Sources To Establish Source-Specific Control Device Parameter Ranges and Enforceable Response Requirements, Not Enforceable Operating Limits. Rather than establish enforceable operating limits, EPA should use the approach taken in the CAM rule (discussed above with respect to PM CEMS) and require sources to establish site-specific operating parameter ranges to define conditions under which compliance with the applicable limit can be reasonably assured. Source owners and operators would then be required to monitor those parameters and respond to changes that indicate problems with the controls that could jeopardize compliance.

Whether using a single control device or combination of devices, sources are in the best position to determine what parameters and levels are consistent with compliance. In many cases, multiple parameter relationships or supplemental operational data will provide a higher level of compliance assurance than the level that happens to be measured during a discrete performance test. This is particularly true for sources with a significant margin of compliance. Attachment at 1- 4. [See submittal for McRanie Technical Memo, pages 33-36] In addition, units with significant margins of compliance should be allowed to establish operating levels by extrapolating parameter data beyond that obtained during a performance test based on other information. Allowing such extrapolations is essential for some sources to provide needed operational flexibility. Attempting to establish “worst case” test conditions on a scrubber or multi-section ESP, where the possible combinations of parameters are numerous, would at the least be difficult and could be impossible without a major research effort. *Id.* Allowing extrapolation of results avoids the necessity of repeated testing.¹⁹ In other cases, an alternative parameter, like SO₂, may be the best indicator of emissions following multiple controls.

[Footnote]

(19) A similar approach has been used in CAM protocols, including a protocol developed by EPRI for ESPs (allowing extrapolation up to 1.25 times the recorded value for measurements taken at less than 80 percent of the applicable emission limit).

Once sources have established appropriate operating parameter ranges based on data collected during performance tests, as well as other operating data and engineering principles, those parameters would be monitored and any deviation from them would trigger a requirement for investigation and corrective action to return the parameter to the appropriate range. Although this range may in some cases be similar to the minimum values that would be established under the current rule, allowing sources to respond with corrective action (rather than simply record and report deviations) achieves EPA's intended result without subjecting sources to potential unreasonable enforcement. Such an approach also would be consistent with the Agency's final EGU MACT rule, which relies on other requirements (including the CAM rule) to ensure proper operation of controls in between performance stack tests. 77 Fed. Reg. at 9384.

Commenter Name: Lee Zeugin and Lauren Freeman

Commenter Affiliation: Utility Air Regulatory Group (UARG)

Document Control Number: EPA-HQ-OAR-2002-0058-3500-A1

Comment Excerpt Number: 49

Comment: The control device operating parameter procedures do not recognize any margin of control for the control devices. As a general rule sources buy control equipment with an "operational" margin of compliance so that there is flexibility to account for control equipment problems or other operational issues. There will be problems because control equipment is just made up of mechanical and electrical hardware and failures will occur. Therefore, most electrostatic precipitators (ESPs) are bought with extra fields and sections where the source can operate in compliance with the applicable emission regulations even when there are problems with parts of the control equipment. Likewise, fabric filters (FF) or baghouses and scrubbers are often bought with extra capacity (additional modules) in the control equipment.

The control device operating parameter procedures in EPA's proposal call for setting the maximum and/or minimum (as appropriate) parameter value based on the conditions that exist during the performance test. If the performance test is just barely in compliance with any emission limit, and the assumption is that the emissions are directly related to the control device operating parameters¹, this approach might be acceptable. However, many performance tests are performed at a level of control that not only includes a significant margin of compliance, but that also may not be directly correlated to control device operating parameters. Unfortunately, control device parameters, especially with scrubbers and ESPs, are interrelated with the design of the device and the interaction between the various parameters. For example, total ESP power may be completely unrelated to ESP performance for a multi-section ESP. Total ESP power is, therefore, not an appropriate indicator for ESP performance except for the most simple, single chamber ESP. The ESP power issues are discussed more fully later in this memorandum.

Control device operating parameters may vary widely with little effect on the emission rate of the pollutant being controlled. In addition, normal operation of emission control devices contains considerable variability. For example, on a scrubber the pressure drop and liquid flow rate are usually a function of boiler load. As a result, recording of control device parameters at levels above or below those recorded during a performance test might be consistent with good operation of the control device and compliance with the standard. EPA's failure to consider this normal operational variability in the proposed rule could make the proposed standard much more stringent than the proposed numerical limit and could interfere with operation of the control device.

If EPA deems it necessary to specify both an emission limit and control device operating parameter, the operating parameters and levels should be identified by the source based on a variety of factors specific to the source and used to determine whether corrective action is required. Operation outside of an operating parameter limit should not be considered noncompliance with the MACT limit because it does not necessarily mean that the numerical emission limit established as the MACT has been exceeded. Instead, EPA should adopt an approach similar to the one in EPA's Compliance Assurance Monitoring (CAM) (40 C.F.R. Part 64) rule.

Comment Excerpt Number: 50

Comment: The only way to set control equipment parameters at the level recorded during performance testing and still maintain the equipment control margin is to perform a CAM type exercise with multiple tests and the control equipment performance degraded. This testing procedure should be specifically allowed and any emission excesses during the testing should be specifically excused in the rule.

I have conducted a number of CAM tests on particulate control devices and, thus, has considerable experience in this area. In many cases, I find that the State Agency or EPA regional office is very nervous about allowing the performance of the control equipment to be degraded, only for the purpose of CAM testing, to approach the level of the standard. In fact, I have been told by some state regulators that such action would not be allowed. The proposed EGU MACT rule states that, "You must conduct performance tests at the maximum normal operating load while burning the type of fuel or mixture of fuels that has the highest content of chlorine, fluorine, non-Hg HAP metals, and Hg, and you must demonstrate initial compliance and establish your operating limits based on these tests. These requirements could result in the need to conduct more than one performance test."

While this rule language implies that the control equipment can be detuned for the performance tests, it should be explicated stated. In addition, the parameter testing/setting procedure contemplated by EPA in this proposed rule cannot be accomplished unless the source is shielded

from excess emissions during the performance tests. Control device performance can be variable based on a number of different operating parameters and is certainly not precisely predictable in advance. Therefore, it is possible that the control device will inadvertently be detuned to the point that emissions over the limit will be measured. Under such circumstances, the excess emissions should be explicitly excused by the rule.

If excess emissions are not permitted during the performance/parameter setting test period, EPA will be removing compliance margin from the control device and penalizing the source. Surely, this is not EPA's intent.

Comment: Sources that demonstrate a significant margin of compliance during performance testing should be allowed to use other data and information to extrapolate control device parameter levels to a point that would trigger corrective action.

The rule should provide source operators flexibility in the parameter or operating data that can be used to demonstrate proper operation of the control device and a reasonable assurance of compliance rather than dictate the parameters to be used. In addition, sources should be allowed to extrapolate parameter data beyond that obtained during the performance test based on information gathered during the performance test period. This is particularly true for sources that have a wide compliance margin, as will likely be the case for new control equipment. Since there is only a loose relationship between a given operational parameter and the emission rate on many control devices, multiple parameter relationships or supplemental operational data usually provide a higher level of compliance assurance.

We can use the simple example of an ESP to explain this concept. ESP compliance/performance tests are normally conducted near full boiler load because the performance of an ESP is at a minimum with full gas flow and dust loading. The performance of an ESP improves dramatically when the boiler is at 50% load. Therefore, an operational limitation on ESP power developed during a full-load compliance test is not valid when the load is at 50%. A similar example could be made for scrubber pressure drop.

Allowing extrapolation of appropriate operating parameters based on sound engineering and technical practices will be essential to prevent penalizing sources that have a wide margin of compliance and to provide sources with needed operational flexibility. When one considers the possible test matrix to simulate the worse case test condition on a scrubber or multi-section ESP, the combinations are huge. The performance test could become a major research project. The approach of using data extrapolation to initiate corrective action has precedence within the agency. Many compliance assurance monitoring projects have utilized parameter extrapolation to define corrective action levels and excursions.

Comment: EPA proposes to require monitoring the pH of the scrubber slurry as an operating limit. pH is not very useful as an operating limit because of necessary operational variability. In a conventional spray tower limestone scrubber the pH of the scrubber slurry is typically held in the range of 5.4 - 6.0 to prevent corrosion and deposition in the scrubber. A pH below this range accelerates corrosion of metal components and pH above this range encourages development of CaSO₄ deposits in the scrubber. Within that pH range, the pH has a very minor impact on the SO₂ removal rate of the scrubber. The pH is held in the desired range by the continuous addition of concentrated limestone slurry and the removal of spent scrubber liquor.

If the limestone slurry feed is disrupted, the pH in the reaction/slurry tank will begin to drop over the next one to two hours. For example, over a 2-hour period, the pH may drop from about 6.0 to about 5.0. Note that the actual drop in pH will depend on a variety of factors. In this scenario, there are two important points,

1. Data indicates that the SO₂ emissions do not change significantly within this range of pH values, and

2. Before the pH drops any further, the operator will take steps to resolve the problem or shut down the module serving that reaction/slurry tank. The operator does not have any incentive to operate the tank/module at low pH values. This is not an issue of “reducing operating costs.” Limestone is not very expensive, and if the pH gets too low, substantial damage (corrosion) to major scrubber components may result.

Comment: When EPA discusses monitoring “liquid flow-rate” in proposed Subpart UUUUU, Table 4, it is not clear what liquid they are describing. Presumably, EPA is referring to the scrubber slurry flow rate. (Note that there are also editorial errors in the table – e.g., “...the pH at or above the lowest 1-hour pressure drop...”).

The scrubber slurry rate is not to be confused with the limestone slurry flow rates (i.e., the makeup slurry used to control the reaction/slurry tank pH). Limestone slurry feed rates are monitored – typically using magnetic flow meters (also referred to as “magmeters”) or some

other comparable type of meter. The limestone slurry flows are very small relative to the scrubber slurry flows (e.g., 100 gpm v.s. 160,000 gpm for an 800 MW unit).

The determinate factor in SO₂ removal in a conventional spray tower is the liquid/gas ratio (L/G) expressed as gallons per 1000 actual cubic feet of flue gas flow. The recirculating liquid flow rate is usually controlled in discrete stages by adding or removing the number of recycle pumps or scrubber modules in service as the unit load changes. Therefore, the L/G might vary with load at a given scrubber efficiency. If EPA wants a parameter for evaluating scrubber performance, the liquid to gas (L/G) ratio, not just the liquid flow rate, should be used (i.e., the number of pumps in service times the liquid flow rate per pump divided by the exhaust gas flow rate).

Comment: EPA also proposes to require the monitoring of scrubber pressure drop. When unit load drops the scrubber pressure drop decreases as a matter of simple physics because the flue gas flow rate decreases. However, the decrease in scrubber pressure drop has nothing to do with the SO₂ removal rate in the scrubber. When the pressure drop falls below some minimum value observed during testing, it does not mean that the scrubber is not performing properly.

For typical spray tower scrubbers, the pressure drop is not used for control purposes. Pressure drop is used to determine when cleaning is required. Most scrubber operators develop a maintenance schedule for cleaning the scrubber modules based on pressure drops. Consequently, the pressure drops increase and decrease according to the cleaning cycle for each module. They are not necessarily accurate for assessing scrubber performance. When a module requires cleaning, the utility will take it offline (usually overnight) for maintenance while the other modules remain online.

Comment: EPA Must Recognize That Not All Scrubbers Operate the Same Way.

The Chiyoda scrubber operates somewhat differently than does a spray tower scrubber described above. An important difference is that there is no L/G defined because the Chiyoda scrubber vessel has no recirculating slurry spray and is essentially a giant bubbler called a Jet Bubbling Reactor (JBR). The JBR combines the concurrent chemical reactions of limestone dissolution,

SO₂ absorption/neutralization, sulfite oxidation, gypsum precipitation and gypsum crystal growth in a single vessel. Therefore, auxiliary vessels and large recirculation pumps are eliminated.

Flue gas enters the scrubber through a large number of “sparger” tubes below the liquid level in the scrubber vessel and bubbles up to the surface of the liquid and through a thick “froth” layer that forms on the surface of the liquid. The Chiyoda scrubber typically operates at a lower pH than does a spray tower. This is possible because the scrubber vessel and virtually all of the vessel internals are made of fiberglass or plastic. Therefore, the corrosion issues that exist with a spray tower are not a serious issue with a Chiyoda scrubber. In addition, the low pH (3.5-5.0) operation has a number of positive operational impacts. Limestone utilization is high and froth level is high, which enhances SO₂, particulate and mercury removal. The low pH also inhibits Al-F blinding, which interferes with limestone dissolution.

The control scheme for a Chiyoda is a combination of pH and liquid depth above the sparger tube exits. The optimum pH depends on the scrubber liquid, coal, flue gas and ash chemistry. The liquid depth is then adjusted to achieve the desired level of SO₂ control. In some cases it is more convenient to fix the liquid depth and adjust the pH as a control function. A third factor that is in play is the gypsum crystal density in the scrubber liquid, which affects the slurry removal rate from the scrubber vessel. Obviously, the slurry removal rate also affects the pH and liquid depth in the vessel.

In summary, there are a variety of operational parameters and control elements associated with the operation of a Chiyoda scrubber. All of the parameters have a range of operation that will result in successful scrubber operation and it is necessary to adjust the parameters to match the fuel being burned and the flue gas characteristics. As with a spray tower scrubber, it is impossible to match any operating parameter to a fixed parameter operating point as is contemplated by the operating limits in the proposed utility MACT rule.

Comment: EPA Should Recognize That Operating Parameters Are Not Useful Indicators For Wet Scrubbers

A modern wet scrubber removes virtually 100% of the entering HCl, HF, oxidized Hg and particulate with just water (no limestone) as the reagent. This happens because HCl, HF and oxidized Hg are all either highly soluble or 100% miscible in water alone. The particulate is removed by impaction with the scrubber spray droplets and many studies have shown very high levels of particulate removal at normal scrubber operating conditions. In fact, a scrubber has to be operated in a severely degraded manner to achieve significant particulate penetration.

In 2004, RMB conducted a “wet stack opacity” development project³ for EPRI at the Trimble County Plant of LG&E. During this project, a device was designed that extracted an isokinetic flue gas sample for the stack, dried the sample and then measured the opacity using a conventional opacity monitor. Towards the end of the project a series of experiments were performed to evaluate the impact of ESP outlet opacity on stack opacity and mass emissions. The tests were done in two phases as described more fully below.

As a part of the test program, the ESP was partially disabled to determine the impact of increased scrubber inlet particulate on the outlet opacity. Table 1 shows the results of those tests.

[See submittal for Table 1 – Preliminary Opacity Tests for data table provided by the commenter]

Test 1 was the starting point before any ESP electrical sections were disabled and the starting ESP opacity was 7% and the stack opacity was 0.5%. For Test 2 a number of ESP sections were completely turned off to increase the ESP outlet opacity and to evaluate the impact on the stack opacity. The opacity was 16% opacity on the ESP outlet and 1.1% at the stack. At this point, scrubber recycle pumps were removed from service to reduce spray in the scrubber modules. For Test 3, ESP capacity was further reduced and scrubber recycle pumps were reduced from 5 pumps to only 2 pumps per scrubber module (a 60% reduction in L/G). The stack opacity only increased from 1.1% to 1.3%. Unfortunately, the experiment had to be stopped because the SO₂ emissions had increased substantially and there was potential for an SO₂ emissions violation.

Since no significant amount of particulate could be made to penetrate the scrubber without an opacity⁵ and SO₂ violation, it was necessary to obtain a variance from the state before further tests could be done.

After the variance was obtained, the Phase 2 experiments were conducted at very high ESP outlet opacity (40-50%) and a minimum number⁶ of scrubber recycle pumps operating. The Phase 2 tests included Method 5B particulate tests at the stack. The fundamental conclusions did not change after the Phase 2 series of tests. It is very difficult for particulate to penetrate a modern, high efficiency SO₂ scrubber. During normal scrubber operation changes in the ESP outlet particulate loading or opacity have little direct effect on the stack particulate emissions. In addition, when the number of scrubber recycle pumps is decreased, the SO₂ emissions increase rapidly. Table 2 shows the results of the Phase 2 tests.

[See Table 2 – Phase 2 Opacity and Mass Tests for data table provided by the commenter]

As with the preliminary tests, Test 1 is the baseline condition with all available ESP sections in service and the SO₂ scrubber operating normally. The test conditions for Tests 2-3 were created by removing various combinations of ESP sections and scrubber recycle pumps.

I believe these tests clearly illustrate that SO₂ removal is the most difficult job performed by the scrubber. The Phase 2 data show that the SO₂ emissions increased by a factor of 10 from the baseline to the most degraded condition while the particulate emissions only increased by a factor of 2. This is understandable since SO₂ removal requires mass transfer of the SO₂ molecules to the scrubber liquid and then a chemical reaction to form CaSO₃. Given the high solubility and/or completely miscible chemical characteristics of HCl, HF and oxidized Hg, it is safe to assume that the scrubber removed virtually 100% of those compounds, even in the most

degraded condition. Therefore, almost any scrubber operation considered normal for the unit would be sufficient to demonstrate proper scrubber operation for removal of all of the compounds, as well as for particulate removal. For a unit using SO₂ as a surrogate for HCl, if the scrubber is exhibiting operation consistent with the proposed SO₂ limit, operating parameters like pH, pressure drop and L/G are just not relevant. For a unit not using SO₂ as a surrogate, scrubber operation consistent with meeting any applicable short term SO₂ limit should also be more than sufficient to ensure removal of the soluble and miscible compounds.

Comment: A Discussion of ESP Performance Relative To Power and Sectionalization - ESP Power Relationships and a Simple Example

The amount of power^{7,8} that can be applied in any section of the ESP varies from inlet to outlet section. One of the unusual, and fortunate, features of an ESP is as the gas moves through the ESP from section to section, the amount of power that can be applied increases in each subsequent section. This is because the amount of particulate matter in the gas stream is being reduced as the gas moves from the inlet of the ESP to the outlet. In general, the particles in the flue gas form a barrier to charged ions that are moving to the collection plates. As the gas flows through the ESP, and more particles are removed, more current can be applied.

Total ESP power input and corresponding particulate removal effects can be analyzed by using an ESP performance computer model. There are several models available and all of the models work in a similar fashion.⁹ The models are based on fundamental scientific principles and incorporate size specific particle charging and migration, turbulent flow particle collection and other theoretical concepts that have been developed by researchers worldwide. These models have been shown to work very well in predicting a specific ESP's performance, over a limited range, when calibrated to that specific ESP¹⁰ to account for real world, non-ideal conditions.¹¹ The performance that might be expected when a specific operational factor is changed and all other operating parameters are held constant.

This can be done for a variable like total ESP input power because all other ESP parameters and variables can be held constant so that only the total power is changed. In the various analysis cases that are discussed below, the EPRI ESPM model has been used. A simple example case has been setup that uses input that would be similar to that of a real ESP. The ESP example is a simple, single chamber, four-field unit as illustrated by Figure 1.

[See submittal for Figure 1 – Simple ESP Example for diagram provided by the commenter]

The ERPI ESPM model was setup using the input below.

Number of fields in direction of gas flow = 4

SCA = 270 ft²/1000 acfm

Plate height = 30 ft

Field Length = 9 ft

Total Length = 36 ft

Plate-to-plate spacing = 9 in

Wire-to-wire spacing = 9 in

Gas velocity = 6 ft/sec

The field voltages and currents were then applied based on past field experience. This resulted in the power levels shown in Table 3.

[See submittal for Table 3 – Field Power Levels for data table provided by the commenter]

The model was then run with four fields in service, followed by runs with three fields, then two fields and then one field in service. This allows us to calculate the sequential particulate removal contribution of each ESP field. This simulates exactly what happens in the field with a real ESP. The results of this series of model runs are shown in Table 4.

[See submittal for Table 4 – Cumulative Particle Removal for data table provided by the commenter]

It can be readily seen that the particulate removal effectiveness in terms of pounds of particulate removed per kilowatt of ESP input power is much higher in the inlet field of the ESP relative to subsequent fields (on a cumulative basis). This result is completely consistent with ESP charging, collection and rapping reentrainment theory. Particle charging and collection occur very rapidly when the flue gas enters the ESP, so it is only logical that considerable collection takes place in only a few feet. This is clearly illustrated in Table 2 where the model calculates that over 74% of the particulate matter is removed from the gas stream in the first nine-foot field. It should also be noted that the effect shown in Table 2 is cumulative when there is more than one field in service. For example, the 233 lb/kW particulate removal value is for the combined total power of the first two (A+B) fields. If the calculation is performed on an individual field basis, to evaluate the pounds of particulate removed in that field alone, the results are much more dramatic. The results of such a calculation are shown in Table 5.

[See submittal for Table 5 – Individual Field Particle Removal for data table provided by the commenter]

What has been done in Table 5 is to take the amount of particulate removed in each individual field¹³ and divide by the power applied in each individual field¹⁴. The particles that exit Field A and enter Field B are a combination of the more difficult to collect particles because they primarily consist of finer particles, and rapping reentrainment.¹⁵ As the gas stream moves through the ESP there are fewer and fewer particles to collect and, at the same time, more power can be applied in the downstream ESP sections. The result is that less and less particulate mass is available to be collected in each subsequent field, no matter how much power is applied.

The clear conclusion that must be drawn for this analysis is that a kilowatt of power is not related to particulate removal except in a gross manner. The total amount of power is not nearly as important as the location at which the power is being applied in the ESP.

This is, of course, a very simple example to illustrate how applied power effects particulate removal in an ESP. In an actual ESP, the situation is much more complex because there are multiple chambers and fields.

[Footnotes]

(7) For this discussion, power is given the simple definition of transformer rectifier (TR) set secondary volts times secondary amps equals watts. For convenience, I will use standard ESP nomenclature of secondary kilovolts times secondary amps to equal kilowatts.

(8) Many ESPs are not equipped with TR secondary power metering and use only primary power indication. Primary power indication is more than satisfactory for day-to-day operation of the ESP.

(9) The primary models in use include the EPRI ESPM Model, the Environmental Protection Agency (EPA) ESPVI Model and the Southern Research Institute Model. The programmer of the EPRI and EPA models was the same person, Dr. Phil Lawless of Research Triangle Institute; therefore, the core code and results are very similar.

(10) Compliance Assurance Monitoring Protocol Development: Site Test Report, EPRI Report TR-111478, 1998

(11) The models are typically calibrated by adjusting values in the model to account for rapping reentrainment and velocity standard deviation. These values vary from ESP to ESP but usually fall in normal ranges depending on the age, design and size of the ESP.

(13) The pounds of particulate removed in each individual field are derived by subtracting the total particulate removed at each interval shown in Table 4.

(14) See Table 3.

(15) Rapping reentrainment consists of particles that have been previously collected but are resuspended in the gas stream when the collecting plates and wires are rapped to dislodge collected material.

Document Control Number: EPA-HQ-OAR-2002-0058-3500-A1

Comment Excerpt Number: 58

Comment: The amount of sectionalization in an ESP is another factor that significantly influences ESP performance. The simple example ESP that was discussed previously was a four section ESP that has a collection area of about 50,000 ft²/section. Such an arrangement for a large ESP would be very unreliable because any broken wire¹⁶ would disable the entire section and then there would be only three sections in service, which would result in a significant increase in emissions. To maximize ESP reliability and overall performance, it is general practice to limit the plate area in an ESP section to 12,000 - 25,000 ft².¹⁷ Therefore, an ESP of the size of the simple example would likely be built in mechanical and electrical sections as a 3X4, 4X4, 3X5 or 4X5 ESP¹⁸. A likely arrangement would be with a 4X4 section arrangement as shown below in Figure 2. [See submittal] Granted, many modern ESPs were built with significantly more sectionalization than the simple 4X4 arrangement used in this example. This example is useful to illustrate the problem with total power as an indicator of ESP performance and the problem simply becomes magnified with more sections.

[See submittal for Figure 2 – 4X4 ESP Example for diagram provided by the commenter]

Since there are 16 sections in a 4X4 ESP arrangement, if there is an electrical or mechanical problem with one section of the ESP, it only affects 6.25% of the collection area. This greatly improves the reliability of the ESP.

It can be readily noted from Figure 2 [of the submittal] that, no matter what path the flue gas takes through the ESP, it flows through 4 sections arranged in series.¹⁹ This greatly improves ESP performance because each section has its own high voltage transformer/rectifier (TR) set and is electrically isolated from the other sections. Not only does this provide improved reliability; it also improves particulate removal performance because the electrical conditions, or power level, can be optimized in each section.

It is a simple mathematical exercise to analyze the performance of the total ESP under a variety of powering arrangements if the sectional efficiency and emission rate of each ESP section is known. To simplify the experiment, I have assumed that the efficiency and, conversely, emission rate, as well as the ESP power are exactly the same as that used in the simple ESP example.²⁰ The diagram in Figure 2 [of the submittal] can be redrawn to contain each section's emission rate²¹ and power.

[See submittal for Figure 3 – 4X4 ESP Emission rate and Power for diagram provided by the commenter]

To analyze the total performance of this ESP with all sections in service, as shown in Figure 3 [of the submittal], we average the final particulate emission rate of all four lanes and total all of the power. So the equation for emission rate becomes:

$$(0.048+0.048+0.048+0.048)/4 = 0.048 \text{ lb/mmBtu}$$

And the equation for power becomes:

$$(20.00+36.30+46.15+53.25)*4 = 622.8 \text{ kW}$$

Using this exact same procedure, we can now evaluate a number of different section failure scenarios. The first example is what happens when one of the outlet fields in the ESP shorts out because of a broken wire. This short has been shown in Figure 4 by a shaded section.

[See submittal for Figure 4 - 4X4 ESP With One Outlet Section Out-Of-Service for diagram provided by the commenter]

The calculation for emission rate is the same as above except the emission rate and power for only the three fields in service are counted for the lane with the shorted section. The equation for emission rate becomes:

$$(0.048+0.048+0.048+0.143)/4 = 0.072 \text{ lb/mmBtu}$$

The equation for power becomes:

$$(20.00+36.30+46.15+53.25)*3 + (20.00+36.3+46.15) = 569.55 \text{ kW}$$

In the next example there are two outlet sections out-of-service, and this is shown in Figure 5 [see submittal]. As before, shading is used to denote the out-of-service sections.

[See submittal for Figure 5 - 4X4 ESP With Two Outlet Sections Out-Of-Service for diagram provided by the commenter]

The calculation for emission rate is again the same as above except the emission rate and power for only the three fields in service for two lanes are counted. The equation for emission rate becomes:

$$(0.048+0.048+0.143+0.143)/4 = 0.096 \text{ lb/mmBtu}$$

The equation for power becomes:

$$(20.00+36.30+46.15+53.25)*2 + (20.00+36.30+46.15)*2 = 516.3 \text{ kW}$$

Of course, another example of two fields being out-of-service can be setup except this time we will look at the case where two fields in the direction of gas flow are out. A graphic example of this case is shown below in Figure 6.

[See submittal for Figure 6 - 4X4 ESP With Two Sections Out-Of-Service in Series for diagram provided by the commenter]

The equation for emission rate in this example becomes:

$$(0.048+0.447+0.048+0.048)/4 = 0.148 \text{ lb/mmBtu}$$

The equation for power becomes:

$$(20.00+36.30+46.15+53.25)*3 + (20.00+36.30) = 523.4 \text{ kW}$$

Clearly, if the example shown in Figure 5 [of the submittal] is compared to the example shown in Figure 6 [of the submittal], it can readily be seen that the total ESP power is not directly related to particulate emission rate. The power is lower in the Figure 5 example while the emission rate is also lower. The reason for this is simply that power applied closer to the ESP inlet is more effective in removing particulate from the gas stream.

This comparison is even more dramatic where a scenario in which four fields are out-of-service is examined. These two examples are shown in Figures 7 and 8 [of the submittal]. In the first case, all four outlet fields are out-of-service and, in the second case, two fields have been removed in series.

[See submittal for Figure 7 - 4X4 ESP With Four Outlet Sections Out-Of-Service for diagram provided by the commenter]

[See submittal for Figure 8 - 4X4 ESP With Two Sections In Series Out-Of-Service for diagram provided by the commenter]

The equation for emission rate in the Figure 7 example is:

$$(0.143+0.143+0.143+0.143)/4 = 0.143 \text{ lb/mmBtu}$$

The equation for power is:

$$(20.00+36.30+46.15)*4 = 409.8 \text{ kW}$$

The equation for emission rate in the Figure 8 example is:

$$(0.048+0.447+0.048+0.447)/4 = 0.248 \text{ lb/mmBtu}$$

The equation for power is:

$$(20.00+36.30+46.15+53.25)*2 + (20.00+36.30)*2 = 424.0 \text{ kW}$$

In this case, the particulate emission rate for the Figure 8 example is 73% greater than the Figure 7 example even though the power is 3% higher. It is also interesting to note that the emission rates in Figures 6 and 7 are almost exactly the same even though the ESP power levels differ by more than 25%. Table 6 summarizes these examples.

[See submittal for Table 6 - Summary of ESP Performance Examples for data table provided by the commenter]

The point of these multiple examples is to show that total ESP power input is not directly related to particulate removal performance – especially in modern multiple section ESPs. In fact, the more highly sectionalized the ESP, the more difficult it is to relate power to ESP performance. Some larger ESPs have six to eight fields in the direction of gas flow and eight to twelve sections across gas flow.

[Footnotes]

16 The leading cause of ESP section failure is broken wires that short out the electrical system.

17 The mechanical and electrical arrangement of ESPs installed on boilers includes a broad spectrum of designs. The design criterion in the text is the author's opinion concerning appropriate design.

18 The first number is the number of sections across and the second number is the number of sections deep.

19 Various gas flow control devices like perforated plates, turning vanes and channel baffles are used in the ductwork ahead of the ESP to spread the gas flow evenly across the face of the ESP.

20 This simplifying assumption is not likely to occur with a real ESP but it does not change the basic conclusions of the calculations.

21 Emission rate is the particulate concentration in lb/mmBtu at the exit of each ESP section. See Table 2.

Commenter Name: Lee Zeugin and Lauren Freeman

Commenter Affiliation: Utility Air Regulatory Group (UARG)

Document Control Number: EPA-HQ-OAR-2002-0058-3500-A1

Comment Excerpt Number: 60

Comment: Dry sorbent injection (DSI) and activated carbon injection (ACI) systems are dry powder injection systems that are designed to control specific stack emissions. DSI systems typically inject trona or sodium bicarbonate for the control of SO₂, SO₃, HCl and HF. The primary use for DSI systems in a modern coal-fired power plant is for control of excessive SO₃ created by selective catalytic NO_x control devices. ACI systems inject activated carbon primarily for the control of Hg, however; the activated carbon also adsorbs SO₃ as well. Both types of systems operate on the principals of chemical reaction and/or adsorption.

In general, the designs of DSI and ACI systems are very similar. An air blower exhausts into a manifold and distribution piping that feeds injection piping located at intervals in the flue gas ductwork. The sorbent material is fed into the manifold and carried by the air stream to be evenly distributed in the duct as the flue gas flows past the injection piping. Various manifold and injection piping designs are used to ensure the even distribution of sorbents into the flue gas.

The removal efficiency of a DSI or ACI system is directly related to the concentration of the specific pollutant in the flue gas, the injection rate of the sorbent and the unit load or flue gas flow rate. Whether discussing DSI or ACI, each specific installation has an efficiency curve shape similar to those shown below in Figure 9²³.

[See submittal for Figure 9 – Performance of Sodium Bicarbonate in SO₂ Mitigation for diagram provided by the commenter]

These curves are developed during initial setup of the DSI/ACI system and are linear over much of the range. While the DSI curve in Figure 9 uses normalized stoichiometric ratio (NSR) as the units for the X-axis, ACI systems typically use pounds of sorbent per million actual cubic feet (lb/MMacf) of flue gas flow. The decision of whether a very technical operating parameter such as NSR or lb/MMacf is used, or a fairly simple operating parameter such as percent load or percent flue gas flow is used, should be left to the source. Unfortunately, the option of varying the sorbent injection rate with load or flue gas flow rate was not included in the proposed EGU MACT rule.²⁴ The “load fraction” concept used in the industrial boiler MACT rule is available for dry sorbent or carbon injection. The concept is very simple; it is just a percent of heat input. The heat input where the compliance test is performed becomes 100% feed rate for the sorbent. At lower loads the source can reduce the feed rate proportional to heat input and remain in compliance with the operating limit. The load fraction option should be added to the EGU MACT rule to prevent overfeeding of the sorbent at lower loads.

It should also be noted that a unit equipped with DSI or ACI will also have secondary emissions control provided by downstream control devices like baghouses and scrubbers. For example, Figure 9 shows approximately 90% SO₂ capture at a NSR of 1.5 when DSI, using sodium bicarbonate, is followed by a baghouse. Since both HCl and HF are more reactive than SO₂, even higher capture performance should be expected for HCl and HF. In addition, wet scrubber equipped units have no need for a DSI or ACI operating limit. Scrubbers remove virtually 100% of the HCl and HF in the flue gas. The Hg emissions will be directly measured so there is no need for an ACI operating limit.

[Footnote]

(23) Courtesy of Solvay Chemicals, Inc. – It should be noted that this curve is generic and that there is no information about the specific coal being used, the ash chemistry or the size of the ESP or baghouse reflected by the curve. Therefore, conclusions about the performance of DSI on any specific unit should not be made based on this curve.

Comment Excerpt Number: 59

Comment: *EPA Should Provide Flexibility in Determining Appropriate Fuel Input Operating Limits*

The general compliance plan outlined in the Reconsideration Proposal requires that sources: (1) demonstrate compliance with applicable emissions limitations and work practice standards through the conduct of an initial performance test; (2) establish operating limits based upon results of the performance test; (3) conduct monitoring and maintain records demonstrating that the source is operated on a continuous basis consistent with the operating limits established during the performance test; and (4) periodically repeat the performance testing. Operating parameter limits based on fuel input analysis (e.g., HCl and Hg), are established using Equations

7 and 8 in § 63.7530. Then, on a continuing basis, facilities are required to keep extensive records of all fuels burned in each boiler or process heater during each compliance reporting period. If a source changes fuels, it must re-calculate its fuel input values using applicable equation 7 or 8. If the re-calculated value exceeds the existing limit, the source is required to conduct a new performance test and establish new operating limits.

While this compliance approach may be easy to manage for some sources, especially ones with very stable fuel supply and usage, it may be very cumbersome and burdensome for other sources with variable fuel suppliers and fuel mixes. This approach involves a great deal of recordkeeping and potentially subjects the source to frequent testing requirements if fuel content varies, regardless of the margin of compliance shown during the initial performance test. Under the proposed rule, even if a unit is operating at 50 percent of the applicable emission limit, the facility would be required to re-test if the fuel chloride input increases 1 percent over the level achieved during the initial performance test.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Comment Excerpt Number: 60

Comment: A more appropriate approach is to allow the source to set operating parameters at levels that generate emissions at the emission limits established in the rule. This is the only approach which meets the requirements of the Act, since it is the only approach that does not impose a beyond the floor limit which has not been justified per the requirements of § 112(d). Under this approach, the source would do the performance test using its normal fuel mix, determine operating conditions that show compliance and then adjust those conditions, using engineering calculations to assure it would meet the emissions standards established in Table 1 or 2. If the initial performance test shows emissions at 50 percent of the standard at a particular mercury or chloride fuel input, the fuel input limits should be set at a level higher than the performance test values, taking into account control device operating parameters as appropriate. This approach would be environmentally beneficial and would greatly reduce burdens. It is the only practical way to establish fuel input operating limits.

Comment Excerpt Number: 61

Comment: Compliance could also be demonstrated through the use of fuel purchase specifications. Sources would determine from the performance test a maximum fuel pollutant concentration at which the emissions limitations are achieved. For instance, the performance test

may demonstrate that fuels containing chlorine in concentrations less than x lb Cl/MMBtu allow the source to comply with emissions limitations. A facility should be allowed to extrapolate an allowable fuel input based on a comparison of performance test conditions to the applicable emission limit. The source would then set a fuel specification of x lb Cl/MMBtu and would be allowed to burn any fuel of the same general type (e.g., solid, liquid, or gas) as long as it met this specification. Sources could require that the fuel supplier provide periodic certification that the fuel meets the specification, based on analysis, or could establish an internal sampling and analysis program for that purpose. In any case, where common fuels are utilized in more than one unit, common fuel quality data would be maintained and considered applicable to all such units. Continuous compliance could also be demonstrated through ongoing fuel analysis.

As an example, sources would (1) establish a fuel input limit (e.g., lb Cl/MMBtu) based on the compliance test as described in the proposal (with an allowance for extrapolation); (2) periodically sample and analyze each fuel for constituent concentration and heating value according to a specified sampling and analysis plan; (3) monitor the daily usage of each fuel; (4) calculate the average total daily constituent input (lb/MMBtu) accounting for all fuels fed; and (5) demonstrate that the average daily constituent input rate averaged over each month of operation does not exceed the operating limit. This option would afford the source the opportunity to vary fuel mixes, while still insuring that protective operating limits are met.

Comment: *Additional Flexibility is Needed for Determining Appropriate Sorbent Injection Rates*

The Reconsideration Proposal requires development of operating parameter limits (OPLs) based on the values achieved during the performance test. In many cases, these levels will be appropriate only for certain modes of operation. For example, the absolute sorbent injection rate observed during the performance test conducted under full load and using the worst case fuel mix will not correlate to the sorbent injection rate necessary during startup or periods of lower load. Frequently, sorbent injection rates are set using a feedback loop from a CEMS or CPMS to avoid wasting sorbent.

EPA has acknowledged that the sorbent injection rate will vary with load in Table 7 of the Reconsideration Proposal, which allows sources to adjust the sorbent injection rate by a load fraction. However, as EPA requires sources to test at the worst case fuel mix for chloride and mercury and this fuel mix may differ from the typical day to day fuel mix, EPA should also allow adjustments to sorbent injection rates based on fuel mix. For example, if a boiler is capable of burning both coal and biomass and tested at 100% coal firing for the mercury performance test, the carbon injection rate for periods of normal operation should not only be adjusted based

on load but also by the percentage of coal being fired. If a boiler is burning natural gas or other clean fuel during a certain operational period, sorbent injection is not necessary.

Comment: *Additional Flexibility is Needed for Other Operating Parameters*

In Table 7, EPA only allows for operating parameter limit variation due to boiler/process heater load fraction to be applied to sorbent and activated carbon injection rates. However, variations with load and other operating conditions also occur for the other operating parameters- wet scrubber pressure drop, pH, and liquid flow rate, ESP voltage and secondary amperage. Flue gas flow rate and characteristics vary over load and with other operating variables such as fuel quality, to the extent that the single hourly average value determined during the high load steady state performance test will not apply to other conditions if overall performance is optimized. EPA should provide an allowance for any operating parameters to vary with unit load fraction as applicable to the operating parameter and specific affected source, and recognize that those operating parameters do not necessary vary in a linear relationship with load, e.g., pressure drop typically varies with the (flow)².

Commenter Affiliation: Southern Company

Document Control Number: EPA-HQ-OAR-2002-0058-3520-A1

Comment Excerpt Number: 10

Comment: Southern believes that operating and fuel limits should only provide that control technology and fuel is being operated and used in a manner consistent with its operations during performance testing. The operating and fuel limits proposed by EPA go well beyond this purpose and place an undue burden on boiler operators. For example, the method of establishing operating limits requires a "worst case" of three hourly averages attained during the performance test for very specific operating parameters for each control technology. This method of setting the operational limit is too prescriptive and gives no consideration to the compliance margin achieved during the test. EPA should provide more flexibility in how operating parameter limits are set for each source and should allow the relevant permitting authorities to approve of site-specific alternatives.

Document Control Number: EPA-HQ-OAR-2002-0058-3524-A1
Comment Excerpt Number: 9

Comment: CPI NC does not support the EPA's proposal that minimum operating parameters be based on load. The proposed load-based minimum operating parameters do not make sense for facilities which are capable of operating at the same load utilizing different fuel mixes. The Facilities could encounter a situation where, load-based operating parameters, including sorbent injection rates, would be quite costly and because of the fuel mix would have no effect on reducing emissions. CPI NC recommends that EPA consider allowing facilities with multi-fuel units to adjust operating parameters, including sorbent injection rates, either based on load or fuel pollutant content of the fuel mix being fired, as appropriate.

Document Control Number: EPA-HQ-OAR-2002-0058-3543-A1

Comment Excerpt Number: 9

Comment: In order to monitor the effectiveness of the control technologies installed on Industrial Boilers, the re-proposed rule requires sources to set operating limits on control technologies such as flue gas desulfurization (FGD), fabric filters, electrostatic precipitators, and dry sorbent injection (DSI) operations. Duke Energy has reviewed the proposal and in general has found that many of these operating limits do not accurately describe the performance of emission control technologies, nor do they ensure proper removal of the HAPs. If a boiler were to in some way deviate from one or more of these operational limits, even though emissions standards are still being met, that unit would be considered to be in non-compliance, and enforcement actions could be taken.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Commenter Name: J. Michael Geers

Commenter Affiliation: Duke Energy

Document Control Number: EPA-HQ-OAR-2002-0058-3543-A1

Comment Excerpt Number: 10

Comment: The performance tests used to set the proposed operating limits are done infrequently, and at full operating load. While these tests might represent the worst-case conditions, they are not representative of all conditions. In addition, the proposed operating limits constrain lowerload operation to the conditions met at the full-load test conditions which is counterproductive or not even possible to meet. As EPA has previously recognized in the context of the NSPS and the CAM rule, “many sources operate well within permitted limits over a range of process and pollution control device operating parameters,” and requiring sources to continuously maintain parameters that “happened to exist” during the most recent performance test “may not be possible or wise.”² This is because control device parameters, such as those identified by EPA for scrubbers and ESPs, do not necessarily have a direct relationship to emissions removed, but instead are interrelated with the design of the control device and the interaction of various parameters. As a result, a single parameter may vary widely with little effect on emissions.

Comment Excerpt Number: 11

Comment: Establishing emission limits based on specific operating parameters by default makes the devices measuring the operation such as pH monitors, flow meters, pressure transmitters, ESP voltage controllers, and others, equivalent to opacity monitors, which themselves are surrogates for stack PM emissions. In addition, EPA has failed to provide the requisite quality control and certification procedures for these new measurement devices. Maintaining instrumentation to the level of emission control monitoring equipment is a tremendous cost burden for boiler operators; especially when the operating conditions change day-by-day with varying load demands and coal quality.

Comment: Restricting pH is not Necessary to Ensure Effective Removal of HCl and Other Acid Gases The proposed IB MACT rule requires units using FGD systems to demonstrate compliance with the HCl and HF removal by measuring pH during the performance tests, and by maintaining 30 day average pH readings above the level of those collected in the test. This pH measurement is not sufficiently related to acid gas removal to apply enforceable limits. The measurement of pH in an FGD system is only a small part of the very complex chemistry in an SO₂ removal system; the pH is mainly used to prevent scaling of the modules. Maintaining a higher pH does not guarantee any additional removal of SO₂, HCl, or other acid gases. Higher pH values will, however, lead to scaling, which may lead to other operational problems. As an example, scaling can cause plugging of mist eliminators, which in turn could potentially increase particulate emissions.

Acid gases such as HCl and HF are strong acids and very readily dissolve in water. By comparison SO₂ is a weak acid which explains why its transport from the gas phase into the liquid phase in a scrubber occurs at a slower rate. EPA recognizes this relationship in the proposed the Utility MACT standard when it stated.

Acid gases are likely to be removed in typical FGD systems due to their solubility or their acidity (or both). The acid-gas HAP—HCl, HF, and HCN (representing the “cyanide compounds”)—are water-soluble compounds, more soluble in water than is SO₂. This indicates that HCl, HF, and HCN should be more easily removed from a flue gas stream in a typical FGD system than will SO₂, even when only plain water is used. Hydrogen chloride is also a strong acid and will react easily in acid-base reactions with the caustic sorbents (e.g., lime, limestone) that are commonly used in FGD systems.³

These same chemical relationships apply to the FGD systems used for industrial boilers. The conclusion is that HCl and other acid gases are very effectively removed by contact with water in a wet FGD system, so effectively removed in fact that high removal rates will be maintained even at pH levels below those used for effective SO₂ removal, provided there is an adequate

recirculation flow. Instead of requiring FGDs to maintain a specified pH, the rule should require that operators develop site specific plans that incorporate parameters that more appropriately describe the operation of an FGD system. Operators may elect to use parameters such as number of absorber recirculation pumps in service, measured SO₂ levels from CEMS measurements, or other facility specific measurements.

Comment: Operating Limits For Maintaining Minimum Wet FGD Liquid Flow Rate At Values Established During the Performance Test Are Highly Problematic In its proposal, EPA establishes a requirement that boilers utilizing wet FGD systems must establish minimum values during the performance test for liquid flow rate. As a first point, there is ambiguity in what EPA wants to restrict. There are two potential liquid flows in an FGD system. The first is the amount of chemical reagent that is added to the FGD module. This is most commonly either a water slurry of lime or limestone.

The concentration of this material varies depending upon the operating conditions. The mass flow rate of reagent is directly proportional to the mass of sulfur dioxide that is removed in the scrubber per unit of time. Because the chemical reagent must be added at the proper stoichiometric ratio, it is totally inappropriate to require a fixed feed ratio based on full load, worst-case conditions. Doing so will damage the FGD system and will render it ineffective for removing sulfur dioxide and other acid gases. As a result Duke Energy concludes that EPA is not attempting to regulate lime or limestone reagent flow, but instead seeks to regulate the total amount of liquid flow that is recirculated in the module and sprayed into the flue gas stream. For purposes of these comments, Duke Energy defines this as FGD recirculation flow. FGD modules use one or more recirculation pumps to remove large volumes of FGD liquor from a reservoir in the bottom of the module and spray it into the flue gas. These are high volume, centrifugal pumps that run at a single speed. Most sources do not 4 See 76 Fed. Reg. 80,664, Table 4. normally install flow meters in this situation, and installing monitors in this application will not achieve the accuracy that EPA specifies. Most new FGD installations utilize fiberglass reinforced piping (FRP) to transport recirculation flow through the FGD module. The FRP increases reliability, but is not conducive to external flow measurement techniques. Further complicating the matter is size of the piping—the larger the diameter, the more difficult to obtain accurate readings. Flow meters with the proposed accuracy of 2% are not practical for these FGD installations. In addition, while internal flow meters may be able to provide reasonably accurate readings immediately after installation, the harsh conditions of the FGD will cause their accuracy to quickly degrade. Also, the length of FGD piping is short compared to its diameter, and has

many elbows and fittings, so there typically are not enough straight lengths of pipe to allow for the installation of highly accurate flow monitors. Even if the recirculation flow rate could be measured to the desired accuracy, those measurements would not tell the whole story. In a properly operating FGD system, the density of the recirculation flow has to change with different operating conditions to maximize removal efficiency. When the density of a material being pumped increases, the volume of flow through a centrifugal pump decreases. FGD operators do not have control over this recirculation flow because the piping systems do not have any sort of flow control valves. In short, a recirculation pump is either on or off. Therefore, attempting to maintain volumetric flow rates at a level established during the performance test would force operators to chase process parameters that would be counterproductive to achieving the best removal efficiency. Finally, EPA should also realize that when a boiler reduces its load, the volume of flue gas passing through the FGD system decreases, while the amount of recirculation flow stays relatively constant. This results in an increase in the liquid to gas ratio, which in turn promotes even more efficient scrubbing. Therefore the more appropriate operating parameter would be to require that boilers be required to maintain a minimum recirculation flow to gas ratio instead of a simple minimum liquid flow rate. That would best be accomplished by requiring a minimum number of pumps to be kept in service at all times as demonstrated during the performance test. As a result, flow monitors would not be needed. It would also be appropriate for EPA to require sources to demonstrate that the flue gas is indeed going through the scrubber module and is not being bypassed. These operating parameters will adequately ensure that the FGD operation will properly remove the acid gases that will be regulated in the final rule. Duke Energy recommends that EPA make these changes in the final rule.

Comment Excerpt Number: 15

Comment: Restricting Wet PM Scrubbers a Minimum Pressure Drop Requirement Has No Benefit, But Will Force Sources into Non-Compliance EPA proposes to set a minimum pressure drop limitation on wet scrubber systems to ensure proper particulate and acid gas capture. In the proposed rule, boilers would be required to measure differential pressure across the scrubber during the annual performance tests, and maintain a 30-day rolling pressure drop value above the average measured in the performance test. As with other limits EPA has proposed, this limit fails to account for reduced load operation. Pressure drop is a direct function of the amount of flue gas flow through the module, and thus is directly related to boiler load. A basic engineering principle is that the pressure drop through a restriction, such as a PM scrubber vessel, is directly related to the square of the velocity. In a case where velocity doubles, the pressure drop would quadruple. The reverse is also true, in that as the load drops, the scrubber pressure drop would also decrease. There are different types of scrubber systems such as open spray towers, and units with trays; however for all these designs, a reduced pressure drop at lower load does not by itself indicate a reduced level of PM capture. In fact, the performance is more likely to improve at reduced load because there is a higher ratio of liquid flow to flue gas flow.

Boilers constantly operate at many different load conditions, which causes changes in flue gas flow. While Duke Energy has no direct experience, there may be sources, such as hazardous waste combustors, where measuring pressure drop in a scrubber could be more useful. These systems could have a stable pressure drop if they were operated at a steady state with a constant gas flow, and without the load swings typical of an industrial boiler. Unfortunately EPA has proposed this operating limit in such a way that simply reducing load will put a source in a condition of non-compliance, even though scrubber performance is more likely to improve at reduced load. In addition to the lack of correlation with removal, pressure drop across a module can be very difficult to measure consistently, because of its low value. EPA makes the point that sources could elect to test at different loads; however, that is not a feasible option, because properly characterizing a unit's performance would require tests at many load points. Instead of using pressure drop to demonstrate compliance, EPA should require operators to develop site-specific plans to ensure the effectiveness of the FGD for particulate removal and acid gas removal. Those plans would then be subject to review by state and local agencies. These plans would contain more appropriate requirements such as maintaining a minimum number of recirculation pumps in service, eliminating any bypasses of the system, and periodically inspecting internal components.

Comment: Operating Limits For Sorbent Injection Should Be Revised. The proposed IB MACT rule requires boilers that use dry sorbent injection (DSI) for acid gas control and/or activated carbon injection (ACI) for mercury control to measure the feed rate of reactant, and maintain operational feed rates above the level established during the performance test. There are multiple problems with this proposed requirement. Both DSI and ACI feed rates are normally correlated with other plant conditions, such as unit load or flue gas flow, making a single fixed feed rate inappropriate. As an example, sorbent rates are normally set as a mass flow per volume of flue gas, such as a pound of sorbent per hundred thousand cubic feet of flue gas. As a result, half the amount of sorbent would be injected when the flue gas flow is reduced by half. In addition to the problem of using one minimum flow rate for all conditions, the ability to measure the sorbent has problems. The material handling equipment for a dry solid such as Trona, ACI or other materials whether milled or not, is not capable of precise weight measurements. Load cells are typically used to gather injection rates, but because the material can clump or surge, short term measurements such as a fifteen minute interval are too small to average out all the fluctuations. Finally, DSI injection rates are closely linked with ESP performance. Injecting a "minimum" amount of sorbent over the entire operating range of a unit could change the ash resistivity and thus impact precipitator performance, potentially making it impossible to be in compliance with the operating limits for both sorbent injection rate and ESP total secondary electric power.

To account for these issues, EPA should allow sources to use for the “load fraction” parameters such as steam flow, flue gas flow, or if applicable, electric load. These rates would then be monitored over a 30 day average.

Comment Excerpt Number: 17

Comment: Operating Limits on ESP Total Secondary Electric Power Is Not a Reliable Measure of Compliance

Electrostatic precipitators are utilized by boilers for PM removal. The proposed rule puts limits on total secondary power to the ESP, requiring EGUs to maintain power levels above those measured during the annual performance test. This power level approach for ESPs does not work and this fact is easily demonstrated by real world operating experience. Precipitator power will vary depending upon a number of factors, including operating conditions, coal quality, load, and other factors. This is a phenomenon that Duke Energy routinely sees in the operation of its own units. Precipitator operation is complicated even further with the addition of sorbents into the flue gas for emissions control. Different fuels may require more or less DSI, and those fuels will also cause changes in precipitator operation. These changes will likely result in a change in the total secondary power to the ESP, but not necessarily a reduction in removal efficiency. The EPA should instead require site-specific plans to be developed for each affected industrial boiler. Because ESP designs vary greatly, the parameters selected may include total percent of fields in service, or a limit on the number of fields in a given train that may be out of service at one time.

Document Control Number: EPA-HQ-OAR-2002-0058-3668-A2

Comment Excerpt Number: 15

Comment: For units using dry sorbent injection (e.g., CFBs), the proposal mandates that the sorbent injection rate at that time of the HCl performance test is to be the minimum rate scaled for load across the load range of the boiler. Actual operational data analysis (at Purdue’s Boiler #5, a 279 MMBTU/hr CFB burning bituminous coal; see DCN_____) indicates that the relationship between limestone injection rate and load is not linear. In fact, application of EPA’s proposed methodology would actually inhibit the operation of the unit at low loads by interfering with the very fundamental design parameter of coal fired CFBs with limestone co-firing design: the calcium to sulfur ratio of the fuel and the sorbent. In addition, overfeeding limestone in a CFB furnace inhibits the solids recirculation and heat transfer that are other fundamental design parameter of CFBs.

Because ensuring on an ongoing basis that sorbent injection is at least the minimum dictated by linearized extrapolation is unworkable, Purdue requests that EPA consider other monitoring methodologies. For example, because the coal to limestone ratio in a CFB is tuned on a real time basis to account for the sulfur content of the fuel and ensure that the correct amount of limestone is fed as well as comply with the 90% reduction requirement of NSPS, the sulfur content of the fuel Ca/S ratio is maintained through boiler tuning and controls at an optimum ratio. The ratio is not only dependent upon the actual calcium content of the limestone, but also the reactivity of the limestone and the boiler bed temperature which influences the necessary "first step" calcining reaction of the limestone. The bed temperature and reactivity of the limestone are relatively constant; however the sulfur content of the fuel can vary.

Comment Excerpt Number: 104

Comment: Sorbent injection rate operating limits for HCl and Hg control should be allowed to be adjusted for operating rates higher than the performance test operating rate as well as being adjusted for lower rate operation.

For BPH with sorbent injection, you must measure the sorbent injection rate for each acid gas sorbent used during the performance tests for HCl and for activated carbon for Hg and calculate the hourly average for each sorbent injection rate during each test run. The lowest hourly average measured during the performance tests becomes your site specific minimum sorbent injection rate operating limit. When your unit operates at lower loads, you must multiply your sorbent injection rate from the performance test by the load fraction (operating heat input divided by the average heat input during your last compliance test for the appropriate pollutant) to determine the required injection rate operating limit value.

While performance tests are performed at high operating rates, they are not necessarily carried out at the highest operating rate achievable. Since HCl and Hg emissions are a function of fuel composition, not combustion, there is no reason the operating limit should not be adjusted for higher operating rates than during the performance test, just as it is required to be adjusted for lower operating rates and we therefore recommend such an adjustment be allowed.

Commenter Affiliation: American Municipal Power

Document Control Number: EPA-HQ-OAR-2002-0058-3685-A2

Comment Excerpt Number: 40

Comment: Subsequent Performance Tests Should Not Automatically Reset Operating limits

If operating limits remain in the final rule, EPA must clarify the procedures used to establish them. As currently written, § 63.7520 is ambiguous as to whether sources will automatically reset their operating limits each time they conduct a performance test. This provision should clarify that sources have the *option* of resetting their operating limits following each subsequent performance test, but they are not required to do so. Operating limits are established during performance tests because, in EPA's view, these limits represent an operating mode in which the source is known to be in compliance with its emission limits. If a source has demonstrated compliance at a particular operating limit, the source is presumptively in compliance with its emission limit so long as it maintains compliance with that operating limit. Sources should therefore have the flexibility to demonstrate continuous compliance by complying with any operating limit that has been demonstrated through a stack test to be indicative of compliance.

Commenter Name: M.L. Steele

Commenter Affiliation: CraftMaster Manufacturing, Inc.

Document Control Number: EPA-HQ-OAR-2002-0058-3814-A1

Comment Excerpt Number: 17

Comment: §63.7530 Site specific operating limits for Hg, HCl, and TSM input levels from fuels. The proposed rules require performance testing while firing the fuels with the maximum pollutant (Hg, HCl, and TSM) input and establishing operating limits to maintain the pollutant input at or below the levels during the performance test. Compliance is determined by fuel analyses.

CraftMaster requests some latitude here because of the variable nature of its woody biomass fuels. Pollutant levels can vary due to the soil conditions in the area where the biomass is harvested. Also the amount of soil (and pollutants) in the biomass varies with weather conditions. These factors are obviously beyond our control.

It is requested that the fraction of pollutant input from fuels that is actually emitted be determined during performance testing. Then that fraction along with the applicable limit could be used to establish the site-specific operating limit.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Startup, Shutdown, and Malfunction (SSM)

12A. Startup/Shutdown: Rationale for Work Practices

Commenter Name: James Pew

Commenter Affiliation: Earthjustice, Clean Air Council, Partnership for Policy Integrity

Document Control Number: EPA-HQ-OAR-2002-0058-3511-A1

Comment Excerpt Number: 47

Comment: EPA requests comment on the rationale for setting work practice standards for periods of startup and shutdown. EPA has not provided any showing that it is infeasible to set an emission standard during this period. Although the agency claims that it would be difficult to conduct emission testing during startup and shutdown periods, that claim does not establish that it is actually infeasible to measure emissions during such periods, merely that EPA has not done so and believes it would be difficult. Moreover, EPA already relies on measures other than stack testing, such as CEMs or parameter monitoring, to evaluate compliance with emission standards during the vast majority of sources operations. EPA provides no reason why these same measures could not be used to determine compliance during startup and shutdown regardless of whether stack testing can occur during such times. Moreover, the agency proposes to measure compliance with 30-day rolling averages. EPA provides no reason that sources cannot comply with emission standards at all times – especially if their emissions are measured on a 30-day rolling average basis – regardless of whether they are stack tested or can be stack tested during periods of startup and shutdown.

Response: Consistent with *Sierra Club v. EPA*, EPA has established standards in this final rule that apply at all times. In establishing the standards in this final rule, EPA has taken into account startup and shutdown periods and has established different standards (i.e., work practice standards) for those periods. EPA also found no evidence that suggested that emissions were higher during startup or shutdown that would indicate a need for an alternate emission standard for these periods and commenters provided no data or basis to show that sources cannot comply with the standards as proposed. Thus we set standards based on available information as contemplated by section 112.

Compliance with the numeric emission limits (i.e., PM or TSM, HCl, mercury, and CO) are demonstrated by conducting performance stack tests, not on a 30-day rolling average basis. It was determined that it was not feasible to prescribe or enforce an emission standard during startup and shutdown due to technological and economic limitations. Thus, as allowed under section 112(h) of the Clean Air Act, a work practice standard was incorporated for periods of startup and shutdown in the March 2011 final rule. The rationale for justifying work practice standards for periods of startup and shutdown is described in the preamble to the March 2011 final rule. See 76 FR 15642. Additionally, of the emission data submitted in response to the ICR, there were no HAP data for startup and shutdown periods because of the limitations in conducting stack tests during these periods. Thus, we do not have data on emissions that occur during startup and shutdown on which to set emission standards. We therefore established work practice standards rather than numeric emissions standards for periods of startup and shutdown in the March 2011 final rule. The EPA has considered this and other comments and is maintaining the work practice standard for periods of startup and shutdown. Information provided on the amount of time required for startup and shutdown of boilers and process heaters indicates that the application of measurement methodology for these sources using the required procedures, which would require more than 12 continuous hours in startup or shutdown mode to satisfy all of the sample volume requirements in the rule, is impracticable. In addition, the test methods are required to be conducted under isokinetic conditions (i.e., steady-state conditions in terms of exhaust gas temperature, moisture, flow rate) which is difficult to achieve during these

periods where conditions are constantly changing. Upon review of this information, the EPA determined that it is not feasible to require stack testing—in particular, to complete the multiple required test runs—during periods of startup and shutdown due to physical limitations and the short duration of startup and shutdown periods. Operating in startup and shutdown mode for sufficient time to conduct the required test runs could result in higher emissions than would otherwise occur. Based on these specific facts for the boilers and process heater source category, EPA developed a separate standard for these periods, and we are finalizing amendments to the work practice standards to meet this requirement. The work practice standard requires sources: (1) to operate all continuous monitoring systems during startup and shutdown, (2) must use one or a combination of the listed clean fuels, (3) once start firing coal/solid fossil fuel, heavy liquid fuel, or Gas 2 (other) gases must engage all of the applicable control technologies except dry scrubber, fabric filter, SNCR, and SCR during periods of startup and shutdown, (4) to start dry scrubber, fabric filter, SNCR, and SCR systems, if present, appropriately to comply with relevant standards applicable during normal operation, (5) to comply with all applicable emissions and operating limits at all times the unit is in operation except for periods that meet the definitions of startup and shutdown, and (6) to keep records concerning activities (e.g., type and amount of fuel used) and periods (e.g., date and duration of each) of startup or shutdown.

EPA has revised the proposed definitions of “startup” and “shutdown” to separate periods of startup and shutdown from periods of normal operation based on supply of steam under proper conditions instead of specific load conditions (i.e., 25 percent load). We are finalizing definitions of “startup” and “shutdown” as follows:

Startup means either the first-ever firing of fuel in a boiler or process heater for the purpose of supplying steam or heat for heating and/or producing electricity, or for any other purpose, or the firing of fuel in a boiler after a shutdown event for any purpose. Startup ends when any of the steam or heat from the boiler or process heater is supplied for heating and/or producing electricity, or for any other purpose.

Shutdown means the cessation of operation of a boiler for any purpose. Shutdown begins either when none of the steam or heat from the boiler or process heater is supplied for heating and/or producing electricity, or for any other purpose, or at the point of no fuel being fired in the boiler, whichever is earlier. Shutdown ends when there is both no steam or heat being supplied and no fuel being fired in the boiler.

Comment Excerpt Number: 7

Comment: EPA also asks for comments on using work practices during startup and shutdown (76 Fed. Reg. at 80615). CRWI and many other commenters suggested the use of work practices in our comments on the 2010 proposed rule (75 Fed. Reg. 32006, June 4, 2010) (CRWI’s comments are at EPA-HQ-OAR-2002-0058-2824). In those comments we pointed out that it is difficult to use stack testing methods to obtain emissions estimates during transient conditions. Even if data could be obtained during rapidly changing conditions (e.g., use of CEMs), it is difficult to understand what that data means or how it can be used to determine top performers.

However, Congress provided for these types of conditions when they set up the work practice provisions of 112(h). Here Congress stated that EPA may set work practice standards if it is not feasible to prescribe or enforce an emissions standard. CRWI continues to believe that it is infeasible to gather data during startup and shutdowns simply because there are no EPA approved methods to make measurement during non-steady-state. As such, CRWI believes that EPA has properly used work practice standards for startup and shutdown periods.

Response: The EPA thanks the commenter for their support.

Commenter Name: Randall D. Quintrell

Commenter Affiliation: Georgia Paper & Forest Products Association

Document Control Number: EPA-HQ-OAR-2002-0058-3451-A1

Comment Excerpt Number: 16

Comment: The implementation of work practice standards for periods of startup and shutdown also is a necessary and appropriate measure, recognizing that these emissions have not been included in the steady-state floor analysis and that they cannot be measured accurately and reliably to establish a separate numerical standard. To consider these periods in any other fashion, e.g., against the steady-state emissions limits, would require including the typically higher emissions during such periods in the continuous limits, and thus would necessarily increase those limits significantly.

Response: The EPA thanks the commenter for their support.

Commenter Name: Lorraine Gershman

Commenter Affiliation: American Chemistry Council (ACC)

Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1

Comment Excerpt Number: 110

Comment: Section 112(h) allows EPA to set work practice standards for situations where it is not feasible to prescribe or enforce an emission standard. Gathering data for pollutant emissions from startup and shutdown periods would be nearly impossible given the brief nature of these periods, as well as the need to define the exact time period for what is considered “startup” and/or “shutdown,” and the fact that most reference methods are not designed for non-steady state conditions and would not perform well during these periods. Moreover, the definition of “not feasible to prescribe or enforce an emission standard” is defined in §112(h) as any situation where “the application of measurement methodology to a particular class of sources is not practicable due to technological and economic limitations. Startup, shutdown, and malfunction events fit perfectly within this definition for the reasons outlined above and justify establishing work practices to address emissions during these periods. Furthermore, a work practice approach for these periods would be in keeping with the statute’s requirement that MACT standards be “achievable” as well as with the underlying requirement that a standard apply at all times.

Response: The EPA thanks the commenter for their support.

Commenter Name: J. Michael Geers

Commenter Affiliation: Duke Energy

Document Control Number: EPA-HQ-OAR-2002-0058-3543-A1

Comment Excerpt Number: 6

Comment: In the IB MACT proposed rule, EPA is proposing revised work practice standards for periods of startup and shutdown that will make some very necessary improvements.

Duke Energy strongly supports this definition for several reasons. First and foremost, it well encompasses the actual transient period that operators face when starting and shutting down a unit. During this period the unit and its emissions control devices are not and cannot function at the same level of performance as normal operating conditions outside the start-up and shutdown period. Emissions are different in these ranges, and there is not sufficient data to set a different standard during these periods. In addition because start-up and shutdown are by their nature very transient periods, it is not feasible to get the data necessary to set such a standard.

Given these conditions and the amount of data available, it is most appropriate to set work practice standards instead of actual emissions limits.

Response: The EPA thanks the commenter for their support.

Comment: WORK PRACTICES DURING STARTUP AND SHUTDOWN

ACC provided extensive support for establishing work practices for periods of startup and shutdown in our comments on the 2010 Proposed Boiler Rule.³⁴ Our key points supporting work practices for startup and shutdown periods were:

The statute requires that the standards established under §112(d)(2) be "achievable." Sources cannot achieve the proposed numeric standards during periods of startup and shutdown in many cases.

The D.C. Circuit also has recognized that standards based on what sources achieve must account for the limitations inherent in the technology used to reduce emissions. Certain air pollution control equipment (e.g., fabric filters and ESPs) cannot fully operate until certain boiler operating conditions are reached (e.g., appropriate stack gas temperature).

EPA did not use any data obtained during periods of startup and shutdown in setting stack test-based standards.

Sources cannot meet CO standards during low load and transient load periods.

Safety concerns must be accommodated during startup and shutdown.

Other recent MACT rules, such as the RICE MACT, incorporate work practices for startup and shutdown.

[Footnote 34: See Docket ID EPA-HQ-OAR-2002-0058-2792.]

Response: The EPA thanks the commenter for their support.

Commenter Name: Susan J. Miller
Commenter Affiliation: Brick Industry Association (BIA)

Document Control Number: EPA-HQ-OAR-2002-0058-3530-A1

Comment Excerpt Number: 3

Comment: EPA properly concluded that a work practice approach must be applied during startup and shutdown periods. There are many reasons why this approach is justified, including the fact that no data from startup and shutdown periods were used to set any stack test-based emission limits. In addition, safety and good operational practices, including preservation of the integrity of control devices, must be of prime concern during startup and shutdown. A work practice approach is the best approach for periods of startup and shutdown emissions in most industries as opposed to the approach used by EPA in other rules. It is not reasonable to assume that the emissions during start-up and shutdown are represented by the emissions during a relatively short (e.g., 3 hour) stack test. Unless reliable data exists to the contrary, EPA should use the work practice approach in all rules.

Response: The EPA thanks the commenter for their support.

Commenter Name: Traylor Champion

Commenter Affiliation: Georgia-Pacific LLC (GP)

Document Control Number: EPA-HQ-OAR-2002-0058-3465-A1

Comment Excerpt Number: 4

Comment: GP supports EPA's position to include a work practice standard under Section 112(h) of the CAA for periods of startup and shutdown. EPA has proposed specific requirements such as ensuring that good combustion practices are maintained by monitoring O2 levels and optimizing the equipment per manufacturer recommendations, training operators on startup and shutdown procedures, and maintaining records during the startup and shutdown periods. EPA is justified in establishing work practice standards due to the limited periods these events occur; establishing numeric emissions limit is impractical due to unstable unit operations and combustion during this operating mode.

Commenter Name: Jessica Bridges

Commenter Affiliation: United States Clean Heat & Power Association (USCHPA)

Document Control Number: EPA-HQ-OAR-2002-0058-3501-A1

Comment Excerpt Number: 17

Comment: EPA provides an adequate rationale for utilizing work practices rather than emissions limits during startup and shutdown periods. It is appropriate to treat startup periods as upward to 25% load and shutdown periods from 25% load downward. The duration of such periods is significantly both load and technology dependent. At least with CHP systems, running at 25% or less load is generally relatively inefficient and therefore the operation will likely be set to move through this ramping relatively rapidly as long as load needs are met.

Response: The EPA thanks the commenter for their support. See the response to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 46 and comment EPA-HQ-OAR-2002-0058-3659-A2, excerpt 5 under the chapter SS - Elements of Work Practices regarding 25% load SS definition threshold.

Commenter Name: Barry Christensen

Commenter Affiliation: Occidental Chemical Corporation (OCC)

Document Control Number: EPA-HQ-OAR-2002-0058-3477-A1

Comment Excerpt Number: 11

Comment: OCC supports the clarification that emission limitations and operating limits do not apply during periods of startup or shutdown. However, further clarification of these provisions is needed with respect boilers that operate in standby mode.

Industrial boilers operate over a wide range of range of load conditions and must be highly reliable to avoid upsets resulting in the loss of production, damage to equipment and the associated expenses and loss of revenue. To address these risks, many operators maintain back-up boilers in standby mode with significantly reduce load demand. Some boilers in standby mode are stable at operating loads of less than 25%, while others may not be. Consequently, an allowance must be made clear in the final rule for boilers and process heaters that operate in standby mode at low firing rates for extended periods of time. The currently proposed definition of startup uses a cold startup example in the definition, but does not expressly exclude boilers operating in standby mode. Boilers operating in standby mode simply do not perform in the same manner as boilers sequencing through startups and shutdowns.

For example, in our PVC plants the sudden loss of steam from one of our boilers without having another in standby mode would have the following consequences: Higher emissions of volatile organic compounds from the slurry resin process because steam strippers are used to reduce emissions of residual vinyl chloride and other compounds from the PVC slurry produced in the reactors, The production of off-grade product which would also result from loss of these steam strippers. This off spec material would have to disposed of as a waste if a buyer is not available, Increased emissions from wastewater generated from the process which relies on a steam strippers to remove volatile organic compounds from process wastewater, and One of our plants supplies steam to an adjacent chemical plant where the loss of steam can cause at least one of their processes to vent to a flare with increased emissions.

Therefore, it is not practical or reasonable to impose the time limits and capacity minimums applicable to boiler startups and shutdowns on boilers in standby mode. However, good combustion practices can still be followed with standby boilers to minimize emissions.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3510-A1, excerpt 117 under the chapter SS - Elements of Work Practices regarding standby mode and startup/shutdown provisions. See the response to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 46 under the chapter SS - Elements of Work Practices regarding 25% load SS definition threshold.

Comment Excerpt Number: 7

Comment: There is no doubt that startups and shutdowns of BPH are a separate operating regime and that numerical emission limits cannot be met during such periods.

A. We agree with EPA's conclusion that BPH cannot meet numerical emission limits during startup and shutdown and simple work practice requirements are the only realistic way to manage emissions during these periods.

During periods of startup and shutdown, BPH35 cannot meet the numerical emission limits that they can meet during periods of normal operation because combustion controls do not work the same (e.g., oxygen levels cannot be controlled to the low levels achievable during normal operation) and combustion conditions are constantly changing as process duty, firing, air rates,

firebox draft, and firebox temperatures change. As EPA concluded, measurement of emissions is impossible because of the lack of steady state conditions and inability to optimize and hold any particular startup or shutdown operation constant. Thus a work practice approach is the only reasonable approach to dealing with startups and shutdowns.

[Footnote 35: EPA's discussion of startup and shutdown in the proposal preamble only mentions boilers, but process heaters are also subject to these requirements and, in general, are harder to manage during these periods than are boilers. Our comments address both boilers and process heaters.]

Response: The EPA thanks the commenter for their support. See the response to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 46 under the chapter SS - Elements of Work Practices, regarding 25% load SS definition threshold, and comment EPA-HQ-OAR-2002-0058-3659-A2, excerpt 5 also under the chapter SS - Elements of Work Practices, regarding use of manufacturer's specifications.

Comment Excerpt Number: 13

Comment: EPA Should Retain the Work Practice Standard Adopted in the March 21, 2011 Final Rule During Periods of Startup and Shutdown

AMP supports the inclusion of work practice standards for periods of startup and shutdown, but sees no need (and EPA has articulated no reason) to adopt work practice standards different from those adopted in the March 2011 Boiler MACT rule. In that rule, EPA properly determined that it was not feasible to establish numeric emission limits for periods of startup and shutdown due to the limited duration of startup and shutdown and the increased emissions that could result from requiring extended operation in this mode to facilitate testing to quantify emissions. Furthermore, the stack test data relied upon to establish emission limits does not reflect periods of startup and shutdown. In lieu of numeric emission limits, EPA developed a work practice standard pursuant to CAA § 112(h) that required sources to minimize emissions during periods of startup and shutdown using the manufacturer's recommended procedures or the procedures of a unit of similar design. In the Proposed Rule, EPA proposed additional work practice standards, claiming that "[g]eneral duty requirements do not constitute appropriate work practice standards under section 112(h)."22 EPA provided no reason for this change in position. Nothing in CAA § 112(h) suggests that a work practice standard of minimizing emissions using accepted emission reduction procedures is inadequate.

Response: The EPA thanks the commenter for their support. As noted in the preamble to the reconsideration proposal, petitioners requested certain clarification related to the startup and shutdown work practice standards. In addition, the EPA itself felt that certain changes needed to be made in the work practices so as to make them more consistent with other NESHAP actions and with the statutory requirements. Therefore, we proposed and took comment on the revised work practice standards. See elsewhere in this document our responses to suggested additional changes.

12B. Startup/Shutdown: Elements of Work Practices

Commenter Name: Jennifer Youngblood

Commenter Affiliation: National Tribal Air Association

Document Control Number: EPA-HQ-OAR-2002-0058-3667-A2

Comment Excerpt Number: 10

Comment: In specifying requirements related to startups and shutdowns the term "startup event" or "shutdown event" is used in some places in the rule (i.e., §63.7530(h), §63.7550(c)(14), §63.7555(i)). Those terms can be interpreted to mean something different than the definitions which use the word "period". Thus, we recommend all references in the rule to startup events and shutdown events be changed to just startup or shutdown or to startup periods and shutdown periods, as appropriate.

Response: The EPA appreciates the commenter's input. Since the definitions in the final rule refer to 'startup' and 'shutdown' we have removed references to the term events throughout the rule.

Commenter Name: Matthew Todd

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 158

Comment: If the requirement is maintained the certification must be revised. As discussed in Comment II.7.C.2, EPA indicated that the requirement to follow BPH manufacturer's specifications is to be deleted, so that language would need to be deleted from any NCS certification. Even more importantly, nothing in the proposed certification limits the certification to startups and shutdowns that occurred prior to the NCS submittal. Since BPH will be starting up and shutting down forever, any NCS certification must be limited to just the time period from the effective date of the BPH NESHAP to the date of the NCS submittal. Finally, since the startup and shutdown requirements apply to both boilers and process heaters, the certification presumably needs to address both, not just boilers.

Response: The EPA appreciates the commenter's input. The rule language was edited, and the statement requiring mention of startup/shutdown periods in the NCS was removed because startup/shutdown periods can occur at anytime.

Commenter Name: Robert D. Bessette

Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 46

Comment: In the Reconsidered Boiler MACT Rule, EPA is also proposing definitions for "startup" and "shutdown." 76 Fed. Reg. 80,541. (2012 Reconsidered Rule). EPA is proposing to define "startup" as "the period between the state of no combustion in the boiler to the period where the boiler first achieves 25 percent load (i.e., a cold start)." 76 Fed. Reg. 80,654. EPA is

proposing to define “shutdown” as "the period that begins when a boiler last operates at 25 percent load and ending with a state of no fuel combustion in the boiler." 76 Fed. Reg. 80,654. EPA notes in the Reconsidered Major Source Rule, that the proposed definitions of "startup" and "shutdown" are intended to ensure that units cannot cycle in and out of startup or shutdown." 76 Fed. Reg. 80,615. (Reconsidered Boiler MACT Rule) Furthermore, EPA indicates that the definitions should provide "clarity regarding which periods of operation are subject to the work practice standards rather than numeric emission limits and the associated requirements." 76 Fed. Reg. 80,615. (Reconsidered Boiler MACT Rule) EPA is soliciting comment on the proposed definitions.

The proposed revision attempts to place all boilers into the same basket in specifying a 25% load threshold. This is not technically correct or practical on many fronts. How boilers "behave" is a function of fuel type, furnace and boiler design (combustion method), and operating methodologies. For example, some boilers have a minimum stable operating load that is higher than 25 percent, (e.g., stable operation for a stoker boiler may not be reached until 60 percent load). Additional examples include the fact that:

- Most solid fuel boilers do not reach stable operations until 50% load or higher while some oil and gas burners can function as low as 20% load for long duration.
- In facilities with solid fuel boilers that have significant steam load fluctuations (say between night and day), a boiler in hot standby is required to be ready to take on the added load within a short period of time. This standby boiler is "banked", which means the bed of fuel is hot and burning slowly, but no steam is being produced. No combustion air is being supplied. All that it then takes to bring the boiler on line is to initiate the input of combustion air to increase the combustion rate. Depending upon conditions, boilers can be in "banked" mode for hours to several days.
- Solid fuel units, particularly older anthracite units, will have a fire on the grate for several days to allow for slow heat-up of the refractory and other critical metal components. The slow heat up rate is necessary to prevent material damage to the unit. No steam is being produced during the warm-up period.
- Some facilities may have oil fired boilers that are sized correctly for winter heating loads, but are too big summer steam loads. Often, the unit may cycle on and off on the high pressure cutout because the facility steam load is below minimum firing rate for the unit.
- As previously mentioned, some oil boilers have burners that can function reliably down to 20% firing rate and do so for extended periods. In the case of low summer loads as noted above, these units may operate for extended periods between 20% and 25% load.
- Oil fired units in wet layup may use burner heat to generate natural circulation to mix up and circulate boiler water chemicals. No steam is generated during these events. The burner is operated at minimum firing rate which, as noted above, could be below 25%. The time of operation depends upon the size of the boiler and the burner rating at minimum fire.

Considering this, EPA should revise the startup definition to allow facilities to determine the minimum stable operating load on a unit-specific basis and include the minimum stable operating load that defines startup and shutdown and the proper procedures to follow during startup and shutdown in a site-specific plan. Establishment of the minimum stable operating load

on a site-specific basis is analogous to setting other boiler and control device operating parameter limits on a site-specific basis.

Response: A number of commenters indicated that the proposed load specifications (i.e., 25 percent load) within the definitions of “startup” and “shutdown” were inconsistent with either safe or normal (proper) operation of the various types of boilers and process heaters encountered within the source category. As the basis for defining periods of startup and shutdown, a number of commenters suggested alternative load specifications based on the specific considerations of their boilers; other commenters suggested the achievement of various steady-state conditions.

The EPA has reviewed these comments and agrees with the commenters that load conditions separating periods of startup and shutdown from periods of normal operation can be unit-specific and therefore presupposing certain load conditions in the definitions of periods of startup and shutdown is not appropriate. The EPA therefore believes adjustments are appropriate in the proposed definition of “startup” and “shutdown.” Affected boilers and process heaters function to supply steam for heating, supply indirect heating to processes, or, in the case of cogeneration units, generating electricity. Therefore these boilers and process heaters should be considered to be operating normally at all times during which steam of the proper pressure, temperature, and flow rate is being provided to a common header system or energy user(s) for use as either process steam, heat, or for the cogeneration of electricity. Accordingly, it is rational to separate periods of startup and shutdown from periods of normal operation based on supply of steam under proper conditions instead of specific load conditions (i.e., 25 percent load). We are revising the definitions of periods of startup and shutdown to account for these facts. We believe the revised definitions address the comments and are consistent with the definitions of startup and shutdown contained in the 40 CFR Part 63, subpart A General Provisions. We are finalizing definitions of “startup” and “shutdown” as follows:

Startup means either the first-ever firing of fuel in a boiler or process heater for the purpose of supplying steam or heat for heating and/or producing electricity, or for any other purpose, or the firing of fuel in a boiler after a shutdown event for any purpose. Startup ends when any of the steam or heat from the boiler or process heater is supplied for heating and/or producing electricity, or for any other purpose.

Shutdown means the cessation of operation of a boiler for any purpose. Shutdown begins either when none of the steam or heat from the boiler or process heater is supplied for heating and/or producing electricity, or for any other purpose, or at the point of no fuel being fired in the boiler, whichever is earlier. Shutdown ends when there is both no steam or heat being supplied and no fuel being fired in the boiler.

In the final rule, the EPA is requiring sources to operate all continuous monitoring systems during startup and shutdown. For startup, we are requiring the source to use one or a combination of the listed clean fuels and once the source start firing coal/solid fossil fuel, biomass/bio-based solids, heavy liquid fuel, or gas 2 (other) gases, they are required to engage all of the applicable control devices except limestone injection in FBC boilers, dry scrubber, fabric filter, SNCR, and SCR. The source is required to start the limestone injection in FBC boilers, dry scrubber, fabric filter, SNCR, and SCR systems as expeditiously as possible. During shutdown we are requiring the source while firing coal/solid fossil fuel, biomass/bio-based solids, heavy liquid fuel, or gas 2 (other) gases during shutdown to operate all applicable control devices, except limestone

injection in FBC boilers, dry scrubber, fabric filter, SNCR, and SCR. The source is required to keep records during periods of startup or shutdown concerning the date, duration, and fuel usage during startup and shutdown.

The EPA carefully considered fuels and potential operational constraints of air pollution control devices when designing its work practices for periods of startup and shutdown. The EPA is aware that SNCR and SCR systems with ammonia injection need to be operated within a prescribed and relatively narrow temperature window to provide NO_x reductions. Further, the EPA is aware that dry scrubbers also need to be operated close to flue gas saturation temperature, and that fabric filters need to be operated at temperatures above the acid dew point. Because these devices have specific temperature requirements for proper operation, the EPA notes in its work practices that it is the responsibility of the operators of affected boilers and process heaters to start their SNCR, SCR, fabric filter, and dry scrubber systems appropriately to comply with relevant standards applicable during normal operation.

Document Control Number: EPA-HQ-OAR-2002-0058-3453-A1
Comment Excerpt Number: 10

Comment: FMC agrees with EPA's proposed definitions of startup and shutdown periods that identify a 25% load threshold in both cases.

Response: The EPA thanks the commenter for their support. We note, however, that we are modifying the definitions of startup and shutdown; see the response to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 46 regarding the 25% threshold.

Commenter Name: Lee Zeugin and Lauren Freeman
Commenter Affiliation: Utility Air Regulatory Group (UARG)
Document Control Number: EPA-HQ-OAR-2002-0058-3500-A1
Comment Excerpt Number: 24

Comment: UARG supports EPA's proposal to remove the requirement that facilities following manufacturers' recommended procedures to minimize emissions during startup. EPA's choice of 25 percent load as the endpoint for startup of an IB is reasonable.

Response: The EPA thanks the commenter for their support. We note, however, that we are modifying the definitions of startup and shutdown, see the response to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 46 regarding the 25% threshold.

Commenter Name: Michael L. Krancer
Commenter Affiliation: Pennsylvania Department of Environmental Protection (DEP)
Document Control Number: EPA-HQ-OAR-2002-0058-3507-A1
Comment Excerpt Number: 19

Comment: The EPA has proposed to define startup and shutdown periods and more specific requirements than those in the final rule. The proposed definitions specify that only the periods

of time between a complete shutdown of a unit (no fuel being combusted) and the time that a unit first reaches 25 percent load qualify as startup, and only the periods of time between the time a unit last reaches 25 percent load and the time when a unit is completely shut down (no fuel being combusted) qualify as shutdown. The EPA believes that these definitions will ensure that units cannot cycle in and out of startup or shutdown.

The DEP believes that the revised "startup" and shutdown" definitions will provide clarity regarding which periods of operation are subject to the work practice standards rather than numeric emission limits and their associated requirements. Therefore, DEP agrees with EPA's approach of requiring work practice standards that apply during startup and shutdown periods.

Response: The EPA thanks the commenter for their support. We note, however, that we are modifying the definitions of startup and shutdown, see response to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 46 regarding the 25% threshold.

Commenter Name: Mary Sullivan Douglas

Commenter Affiliation: National Association of Clean Air Agencies (NACAA)

Document Control Number: EPA-HQ-OAR-2002-0058-3525-A1

Comment Excerpt Number: 46

Comment: NACAA agrees that a definition limiting the period of "startup" is appropriate. We recommend that such a definition be based on a percentage of the normal operating load of the unit as some sources may operate for extended periods of time at far less than the full rated capacity of the unit.

Response: The EPA thanks the commenter for their support. We note, however, that based on reasons cited by other commenters, we are modifying the definitions of startup and shutdown. See the response to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 46 regarding the 25 percent load threshold.

Commenter Name: Bill Lane

Commenter Affiliation: American Home Furnishings Alliance (AHFA)

Document Control Number: EPA-HQ-OAR-2002-0058-3676-A2

Comment Excerpt Number: 7

Comment: AHFA supports EPA's proposal to refine the work practice standards for periods of startup and shutdown by including new definitions to clarify when the work practice standards would apply. AHFA agrees with EPA's proposed definition of "startup" as the period ramping up to 25 percent of load from a cold start and "shutdown" as the period ramping down from 25 percent of load to no fuel combustion.

Response: The EPA thanks the commenter for their support. We note, however, that we are modifying the definitions of startup and shutdown.

Commenter Name: Randal G. Oswald

Commenter Affiliation: Integrys Energy Group

Document Control Number: EPA-HQ-OAR-2002-0058-3659-A2

Comment Excerpt Number: 5

Comment: Integrys recommends that EPA define "startup" and "shutdown" according to manufacturer specifications. The proposed definitions of startup and shutdown are not readily applicable to all boilers, which have a wide variety of operating modes. EPA proposes to define "startup" as the period between a complete shutdown of a unit (no fuel being combusted) and the time that a unit first reaches 25 percent load, and proposes to define "shutdown" as the period of time between the time that a unit last reaches 25 percent load and the time when a unit is completely shut down (no fuel being combusted). Under the proposed definitions, units that regularly operate at loads below 25 percent of capacity would be in extended periods of startup and shutdown. Also, it would be extremely difficult for units that operate infrequently and do not monitor load, such as small auxiliary units, to determine when they first achieved or last operated at 25 percent load. EPA therefore should allow such units to determine when startup and shutdown begins based on manufacturer specifications. These specifications define startup and shutdown using factors more appropriate than load, such as the completion of specific procedures and run time. Defining startup and shutdown according to manufacturer specifications will address the operational differences among affected boilers and will not adversely impact public health or the environment.

Response: The EPA does not believe it appropriate to rely strictly on "manufacturer specifications" for periods of startup and shutdown. In some cases, the boiler or process heater may be so old that such specifications are either not available any more or are out-of-date. In other cases, modifications or additions to the boiler or process heater (e.g., control devices) have been made so as to make the original manufacturer specifications no longer relevant.

See also the response to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 46, regarding the 25% load SS definition threshold.

Commenter Name: Russell A. Wozniak

Commenter Affiliation: The Dow Chemical Company

Document Control Number: EPA-HQ-OAR-2002-0058-3449-A1

Comment Excerpt Number: 38

Comment: Shutdown time of a combustion unit (e.g. the time between providing heat output and cutoff of fuel feeds) is typically short. For combustion units that are subject to a Table 1 or Table 2 emission limit and only burn Gas 1 fuel or Other Gas 1 fuel, the rule should provide that these units are also exempt from shutdown provisions. Dow believes that it would be appropriate to set the shutdown load criteria at a range from 5% to 25% load as defined by the owner/operator. If a Gas 2 fuel is burned until shutdown is complete, add-on emission control equipment that is otherwise required to meet a Table 1 or 2 emission limit should continue to be operated to minimize emissions.

Dow suggests the following changes to these definitions:

Shutdown means the period that begins when a unit last operates under stable low load conditions defined by the owner/operator (typically between 5 percent and 25 percent load) and ending with a state of no fuel combustion in the unit.

Response: The EPA does not believe it appropriate to exempt any units from the startup and shutdown provisions of the final rule because units subject to the emission limits in Table 1 or 2 of the final rule must be in compliance at all times which includes the work practices that apply to those units.

See the responses to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 46, regarding 25% load SS definition threshold, and comment EPA-HQ-OAR-2002-0058-3659-A2, excerpt 5, regarding use of manufacturer's specifications.

Commenter Name: Robert D. Bessette

Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 45

Comment: In the Reconsidered Boiler MACT Rule, EPA is proposing to expand work practice standards for periods of startup and shutdown. Specifically, among other requirements, EPA is proposing that sources employ good combustion practices. 76 Fed. Reg. 80,602. CIBO supports the good combustion practices as proposed, but EPA should make clear that safety must be of central importance, and should include this critical caveat in its requires practices. consistent with safe operation.

These practices require these actions: You must employ good combustion practices and demonstrate that good combustion practices are maintained by monitoring O₂ concentrations and optimizing those concentrations as specified by the boiler manufacturer; you must ensure that boiler operators are trained in startup and shutdown procedures, including maintenance and cleaning, safety, control device startup, and procedures to minimize emissions; and you must maintain records during periods of startup and shutdown and include in your compliance reports the O₂ conditions/data for each event, length of startup/shutdown and reason for the startup/shutdown (i.e., normal/routine, problem/malfunction, outage).

76 Fed. Reg. 80,602.

Response: The EPA believes that commenter's concerns related to safety are already covered in §63.7500(a)(3) ("At all times, you must operate and maintain any affected source, including associated air pollution control equipment and monitoring equipment, in a manner consistent with safety and good air pollution control practices for minimizing emissions.").

See the responses to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 46, regarding 25% load SS definition threshold, and comment EPA-HQ-OAR-2002-0058-3659-A2, excerpt 5, regarding use of manufacturer's specifications.

Commenter Name: LESLIE SUE RITTS

Commenter Affiliation: National Environmental Development Association's Clean Air Project (NEDA/CAP)

Document Control Number: EPA-HQ-OAR-2002-0058-3529-A1

Comment Excerpt Number: 6

Comment: NEDA/CAP agrees that all references to manufacturers' manuals should be removed from the MACT regulation. NEDA/CAP supports removal of references to either the boiler's manufacturer operation manual and/or pollution control manufacturer's operational manual. While very generally based on good engineering practices, the documents are recommendations and largely contractual elements related to vendor's guarantees and are not good guides for actual manufacturing processes. For instance, a vendor would not be aware of boiler operations that follow load in batching operations because they would likely be confidential and proprietary.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3659-A2, excerpt 5, regarding use of manufacturer's specifications.

Commenter Name: Bruce W. Ramme

Commenter Affiliation: Wisconsin Electric Power Company (WE Energies)

Document Control Number: EPA-HQ-OAR-2002-0058-3452-A1

Comment Excerpt Number: 11

Comment: We Energies requests that EPA define the periods of startup and shutdown for affected units on the basis of source categories since startup and shutdown periods vary by boiler design and the fuel being combusted in those boilers (gaseous, liquid, and solid fuels). Currently, We Energies is constructing a 50-MW circulating fluidized bed boiler (CFB) next to an existing paper mill. This boiler has a maximum design heat input capacity of 800 million Btu per hour. The primary boiler fuels will be wood, bark, wood waste, forest residues, and wastewater treatment plant residue from the Domtar Paper Mill. The boiler will also utilize natural gas for startup fuel and combustion stabilization, with a maximum natural gas firing rate of less than 250 million Btu per hour. The CFB boiler will serve as the main source of steam for the mill, and therefore must have a high availability rate in order to reliably meet the mill's steam needs. The CFB boiler was not designed to come up to load quickly, taking approximately 16 – 18 hours to get up to full load during a typical start-up. By design, the boiler will initially fire on natural gas and then fire on biomass once the boiler is up to temperature, per the boiler manufacturer's startup procedures. The boiler manufacturer estimates that natural gas will be burned for an extended period of time before biomass fueling even begins. Based on EPA's proposed definition of startup, boilers of this type will have a difficult time meeting the proposed emission limits if the boiler experiences any startup complications. This is because at 25% load this boiler will still be firing primarily on natural gas, with inherently lower emission levels. Again, according to the boiler manufacturer, emissions will be at their highest when biomass fueling begins, later during startup, at around 30-45% load. Emissions become controllable when the selective non-catalytic reduction (SNCR) NO_x control equipment becomes effective which is at approximately 65% load. Since natural gas is initially being fired and emissions are low up to the introduction of biomass, EPA's definition of startup for this type of boiler should take into account the initial firing of biomass and its associated emissions.

In summary, even though a circulating fluidized bed boiler is very efficient at minimizing emissions once it reaches full load, this type of boiler and biomass fuel stock does require a longer startup period. Therefore EPA's proposed definition of the startup period as the time period between when no fuel is being combusted and the time that a unit first reaches 25 percent load is not compatible with the startup characteristics of a biomass-fueled CFB boiler.

Response: See the responses to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 46, regarding 25% load SS definition threshold, and comment EPA-HQ-OAR-2002-0058-3659-A2, excerpt 5, regarding use of manufacturer's specifications.

Commenter Name: Bruce W. Ramme

Commenter Affiliation: Wisconsin Electric Power Company (WE Energies)

Document Control Number: EPA-HQ-OAR-2002-0058-3452-A1

Comment Excerpt Number: 12

Comment: We Energies requests that EPA define startup and shutdown that is specific to the source category and takes into account boilers with longer startups and shutdowns. Specifically, for a CFB firing mainly on biomass, We Energies recommends that startup includes the period after biomass fuel is fired in the boiler and up to the point where the SNCR can be started. This definition will provide operational flexibility when starting up the biomass boiler while still achieving the IB-MACT emission limits.

Response: See the responses to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 46, regarding 25% load SS definition threshold, and comment EPA-HQ-OAR-2002-0058-3659-A2, excerpt 5, regarding use of manufacturer's specifications.

Commenter Name: Traylor Champion

Commenter Affiliation: Georgia-Pacific LLC (GP)

Document Control Number: EPA-HQ-OAR-2002-0058-3465-A1

Comment Excerpt Number: 12

Comment: EPA should eliminate the 25%-of-load threshold from the definition of start-up. There are a large number of boiler designs and a single 25% threshold is inappropriate for the full range of boilers. Some boilers with our company are not stable and therefore effectively in a start-up mode until they reach 50-60% of normal operating loads. The criteria for when a start-up ends should be driven by the manufacturer's recommendations and the operator's experience rather than an arbitrary percentage.

Response: See the responses to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 46, regarding 25% load SS definition threshold, and comment EPA-HQ-OAR-2002-0058-3659-A2, excerpt 5, regarding use of manufacturer's specifications.

Commenter Name: Robert E. Hunzinger

Commenter Affiliation: Gainesville Regional Utilities (GRU), Florida

Document Control Number: EPA-HQ-OAR-2002-0058-3488-A1

Comment Excerpt Number: 4

Comment: EPA's proposed definitions of startup and shutdown are not readily applicable to all boilers, which have a wide variety of operating modes. In some cases major source boilers will be of unique or limited design with specific startup and shutdown criteria. This will be the case with the Gainesville Renewable Energy Center (GREC). GRU is concern than a "one size fits all" definition for startup and shutdown may not be appropriate in some cases. GRU recommends

that EPA define "startup" and "shutdown" according to manufacturer specifications. We believe that EPA's proposal to define "startup" as the period between a complete shutdown of a unit (no fuel being combusted) and the time that a unit first reaches 25 percent load, and the proposal to define "shutdown" as the period of time between the time that a unit last reaches 25 percent load and the time when a unit is completely shut down (no fuel being combusted) may be inappropriate for some major source boilers.²

Comment Excerpt Number: 4

Comment: We support EPA's recognition of different emissions during startup and shutdown and its proposal to establish work practice standards during these periods. However, the concept needs two changes. First, the percentage should be calculated on the basis of design load. Design load is established by the physical configuration of the boiler and any threshold level at which the boiler becomes stable during startup is related to its physical design, not some lower load level at which the source may choose to operate.

Second, the percent load at which the unit emissions become normal differs by technology. Gaseous and liquid fuel burners have lower percent threshold than solid stoker boilers or fluidized bed combustors. BPA requests that EPA modify the definitions of startup and shutdown to allow sources and State regulators to specify the numerical percent values appropriate for the technology in the sources permits.

Response: See the responses to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 46, regarding 25% load SS definition threshold, and comment EPA-HQ-OAR-2002-0058-3659-A2, excerpt 5, regarding use of manufacturer's specifications.

Comment Excerpt Number: 7

Comment: EPA proposes to revise the work practice standards for startup and shutdown to include a definition of startup and shutdown as well as to standardize requirements. Startup would be defined as the period between no combustion and 25 percent load, and shutdown would be defined as the period between 25 percent load and no combustion. EPA requests comment on the need for and an

appropriate duration limit for startup and shutdown periods during which numeric emission limits do not apply. The Clean Energy Group agrees with the need for a definition of startup and shutdown in light of the final rule's use of work practices for these periods. However, rather than 25 percent load, which may be inappropriate for many units, we recommend EPA alter the definition of startup to reflect unit-specific considerations, such as defining the end of startup as when the unit reaches the minimum safe operating load or when compliance with Title V emission limits is reached. Similarly, EPA could define shutdown as the period of time from when a unit reduces load with the intent to shut down and ends with the cessation of combustion of fuel. This would avoid defining as "shutdown" those circumstances where units may need to operate at a level below 25 percent, but above the minimum safe operating load.

In this way, EPA would utilize definitions already incorporated into existing air quality operating permits. Typically, these definitions are jointly established by the responsible air permitting authorities and the individual facility because startup and shutdown periods are somewhat unique to each boiler design. Operation below the unit-specific "normal operating mode" is when startup and shutdown requirements should apply. We recommend that EPA not numerically define startup and shutdown in the final rule, and instead defer to the definitions contained in currently active air quality operating permits issued by local and/or state air permitting agencies.

Response: See the responses to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 46, regarding 25% load SS definition threshold, and comment EPA-HQ-OAR-2002-0058-3659-A2, excerpt 5, regarding use of manufacturer's specifications.

Document Control Number: EPA-HQ-OAR-2002-0058-3504-A1

Comment Excerpt Number: 52

Comment: EPA has included a threshold of 25 percent load in its definition of startup and shutdown. Some units have a minimum stable operating load that is significantly higher than 25 percent. For example, stable operation of a hybrid suspension grate boiler may not be reached until the boiler achieves 60 percent load. Therefore, EPA should revise the startup definition to allow facilities to determine the minimum stable operating load on a unit-specific basis. The minimum stable operating load that defines startup and shutdown, and the proper procedures to follow during startup and shutdown, can be included in a site-specific operating plan.

Response: See the responses to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 46, regarding 25% load SS definition threshold, and comment EPA-HQ-OAR-2002-0058-3659-A2, excerpt 5, regarding use of manufacturer's specifications.

Commenter Name: Mark D. Pettegrew

Commenter Affiliation: PolyOne Corporation

Document Control Number: EPA-HQ-OAR-2002-0058-3513-A1

Comment Excerpt Number: 2

Comment: The PolyOne Henry Illinois facility is also equipped with two natural gas boilers which serve as backup to the coal fired boiler. However, during the winter the gas boilers are

used to complement the coal boiler because demand for steam load for both production and building heat can exceed the output capabilities of the coal fired boiler. The gas boilers would run under 25% loading during these circumstances. Under the current proposal, a minimum 25% load is established which means the gas boiler cannot be run under 25% load. The boiler would need to be shut down. Without the capability of running the gas boiler under 25% load, the plant would have to run above this limit, and vent the excess steam produced to the atmosphere wasting energy and increasing operating costs. We suggest a revision to the 25% minimum load requirement.

Response: See the responses to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 46, regarding 25% load SS definition threshold, and comment EPA-HQ-OAR-2002-0058-3659-A2, excerpt 5, regarding use of manufacturer's specifications.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 14

Comment: EPA has included a threshold of 25 percent load in its definition of startup and shutdown. Some units have a minimum stable operating load that is higher than 25 percent (e.g., stable operation for a stoker boiler may not be reached until 60 percent load). Therefore, EPA should revise the startup definition to allow facilities to determine the minimum stable operating load on a unit-specific basis. Startup should end when combustion conditions are stable for a particular unit, which is not always at 25 percent load. In some cases, this may be when the unit begins sending steam to the process.

Response: See the responses to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 46, regarding 25% load SS definition threshold, and comment EPA-HQ-OAR-2002-0058-3659-A2, excerpt 5, regarding use of manufacturer's specifications.

Commenter Name: Ahmed Idriss, Capital Power Corporation

Commenter Affiliation: CPI USA North Carolina (CPI NC)

Document Control Number: EPA-HQ-OAR-2002-0058-3524-A1

Comment Excerpt Number: 5

Comment: CPI NC does not support the EPA's proposed definition for start-up and shut-down. These definitions incorrectly assume that all boilers have similar design and operating parameters.

CPI NC proposes the definitions for start-up and shut-down be revised. Start-up should be defined as the period between the state of no combustion and the minimum stable operating conditions for each unit. Shut-down should be defined as the period between beginning when a unit last operates at the minimum stable operating condition and ending at the state of no combustion. Minimum stable operating conditions should be unit specific depending on the operating profile and qualities of each individual unit. CPI NC believes this definition is reasonable, as the definition provides appropriate parameters for each individual unit.

Response: See the responses to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 46, regarding 25% load SS definition threshold, and comment EPA-HQ-OAR-2002-0058-3659-A2, excerpt 5, regarding use of manufacturer’s specifications.

Commenter Name: LESLIE SUE RITTS

Commenter Affiliation: National Environmental Development Association's Clean Air Project (NEDA/CAP)

Document Control Number: EPA-HQ-OAR-2002-0058-3529-A1

Comment Excerpt Number: 1

Comment: NEDA/CAP submits that EPA’s proposed definitions of “startup” and “shutdown” are arbitrary and unreasonable. A one-size fits all definition of “startup” or “shutdown” does not exist, which is why work practice standards should apply the entire time until a boiler reaches a steady state.

EPA finalized a work practice standard for periods of startup and shutdown in the March 21, 2011 Final ICI MACT, which will require facilities to minimize emissions consistent with manufacturer’s recommended procedures during “startup” and “shutdown” of a boiler – but not during “malfunctions.” (The ICI MACT emission limits will apply to “malfunctions” although sources will be afforded the opportunity to mount an affirmative defense to any violations of the emission limitations attributable to a “malfunction” of either the emissions or pollution control equipment.) EPA now proposes to define startup and shutdown periods “to provide clarity regarding which periods of operation are subject to the work practice standards rather than numeric emission limits and the associated requirements.” *Id.* 80615. EPA reasons that the definitions are intended to ensure that units cannot cycle in and out of startup or shutdown. *Id.*

NEDA/CAP refutes the existence of any basis for EPA’s concern that affected units will circumvent compliance with the ICI MACT emission limits by “cycling” in and out of operation to avoid application of the ICI MACT. Without such a finding, the proposal is an unreasonable solution in search of a problem. If the Agency’s final rule retains definitions of these terms, EPA must provide a factual basis for its concerns that can be addressed on a regulatory rather than an enforcement basis. Otherwise this provision would particularly harm manufacturers that can no longer operate three shifts a day and batch processors whose steam demand (and hence boiler load) swing widely.

Response: See the responses to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 46, regarding 25% load SS definition threshold, and comment EPA-HQ-OAR-2002-0058-3659-A2, excerpt 5, regarding use of manufacturer’s specifications.

Commenter Name: LESLIE SUE RITTS

Commenter Affiliation: National Environmental Development Association's Clean Air Project (NEDA/CAP)

Document Control Number: EPA-HQ-OAR-2002-0058-3529-A1

Comment Excerpt Number: 3

Comment: Seemingly, in recognition of the arbitrary nature of the 25% -based definition, EPA explains that the agency feels that it must establish a “maximum time period to ensure that units

cannot operate in startup or shutdown mode for extended periods of time,” and therefore is soliciting comment on the appropriate time period or time periods for the various unit designs. *Id.* This solicitation appears to us to be a dangerous trap, because there is (as EPA recognizes in the same discussion) very poor information about emissions during startup and shutdown, which is why the Agency properly established a work practice standard in lieu of establishing a numerical limitation. As CAA Section 112(h) states, when it is not feasible for the Administrator to prescribe or *enforce an emission standard* for control of hazardous air pollutants, the Administrator may, in lieu thereof, promulgate a design, equipment, work practice or operational standard, which is consistent with Section 112(d). Further, NEDA/CAP asserts that it is not possible to *prescribe* a numerical definition of “startup” or “shutdown.”

Response: See the responses to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 46, regarding 25% load SS definition threshold, and comment EPA-HQ-OAR-2002-0058-3659-A2, excerpt 5, regarding use of manufacturer’s specifications.

Comment Excerpt Number: 5

Comment: If EPA [maintains a prescriptive 25% threshold], then the Agency needs to provide a rationale that distinguishes the concerns it raises about cycling boilers from multiple startups and shutdowns of boilers in batching industries and due to the economy. The December 23, 2011 Notice suggests that EPA’s concerns about startup and shutdown may be related to how many times a unit starts up or shuts down a unit. The final rule should carefully consider that at least two situations merit multiple starts and shut-offs of a boiler and distinguish these situations from the circumstances that suggest circumvention of the ICI MACT limits. First, manufacturers generally shut off or idle boilers if they are not running three shifts or five days a week, because fuel is generally one of the most expensive commodities in the manufacturing process. As a result multiple startups and shutdowns are legitimate reflections of operations. Second, starting and shutting off a six or seven or nine story building is inherently dangerous and simply stated, one does not want to put hot gases into a cold control technology without bringing both the unit and the control “up” over time. Safety concerns, particularly for some boilers that are still lit manually in fireboxes, also are notorious for dangers and difficulties during startup that may require multiple startups and are unavoidable, though foreseeable. Even oil-fired ignition guns on modern boilers are well-known to require multiple startups on occasion because they plug or misfire in an unavoidable manner. For these reasons and others, defining startup or shutdown with reference to how many times they occur does not necessarily indicate behavior that should be punished under the Clean Air Act.

Response: See the responses to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 46, regarding 25% load SS definition threshold, and comment EPA-HQ-OAR-2002-0058-3659-A2, excerpt 5, regarding use of manufacturer’s specifications.

Comment Excerpt Number: 7

Comment: The NNS Floating Test Steam Facility (FTSF) boilers are marine boilers utilized in a unique manner and are not designed, constructed or operated like industrial, commercial or institutional boilers.

In the Proposed Rule EPA introduced new definitions of “startup” (the period between the state of no combustion and when a unit first reaches 25 percent load) and “shutdown” (the period between when a unit last reaches 25 percent load and the time when a unit is completely shut down). In the Preamble EPA stated that the definitions of “startup” and “shutdown” are intended to ensure that industrial, commercial and institutional units cannot cycle in and out of startup or shutdown. In contrast the FTSF boilers operate the majority of their time within the range that EPA has determined to constitute startup or shutdown. Analysis of the actual, measured daily loads experienced by the FTSF boilers over the entire steaming period of the most recent aircraft carrier at NNS shows that the FTSF boilers operate at or below 25% load approximately 85% of the time, as depicted in Exhibit 3. The unique nature of propulsion plant testing requires that the FTSF boilers operate below 25 percent load for sustained periods up to several weeks. The FTSF boilers routinely achieve high turndown ratios (operation at very low loads) that industrial, commercial and institutional boilers are not designed to accomplish.

Response: See the responses to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 46, regarding 25% load SS definition threshold, and comment EPA-HQ-OAR-2002-0058-3659-A2, excerpt 5, regarding use of manufacturer’s specifications.

Commenter Name: Tangela Niemann
Commenter Affiliation: Texas Commission on Environmental Quality (TCEQ)
Document Control Number: EPA-HQ-OAR-2002-0058-3594-A3
Comment Excerpt Number: 12

Comment: Based on the EPA’s proposed definition of *shutdown*, a shutdown period begins when a boiler last operates at 25% load. Similarly, the proposed definition of *startup* states that a startup period ends when the boiler first achieves 25% load. The 25% load threshold used in both definitions might be interpreted as a percentage of the operating load or as a percentage of the design capacity load of the boiler. In some cases, the boiler may be oversized for the demand and the boiler may rarely operate at or near full capacity. In some instances the normal operating load of a boiler may rarely or never exceed 25% of the design capacity. The EPA should revise the definitions of *startup* and *shutdown* to specify that the 25% threshold is based on the percentage of normal operating load of the boiler and provide a definition of what is considered normal operating load.

Response: See the responses to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 46, regarding 25% load SS definition threshold, and comment EPA-HQ-OAR-2002-0058-3659-A2, excerpt 5, regarding use of manufacturer’s specifications.

Commenter Name: Allison Watkins, Baker Botts
Commenter Affiliation: Class of '85 Regulatory Response Group
Document Control Number: EPA-HQ-OAR-2002-0058-3608-A1
Comment Excerpt Number: 5

Comment: The Group recommends that EPA define “startup” and “shutdown” according to manufacturer specifications. The proposed definitions of startup and shutdown are not readily applicable to all boilers, which have a wide variety of operating modes. EPA proposes to define “startup” as the period between a complete shutdown of a unit (no fuel being combusted) and the time that a unit first reaches 25 percent load, and proposes to define “shutdown” as the period of time between the time that a unit last reaches 25 percent load and the time when a unit is completely shut down (no fuel being combusted).⁵ Under the proposed definitions, units that regularly operate at loads below 25 percent of capacity would be in extended periods of startup and shutdown. Also, it would be extremely difficult for units that operate infrequently and do not monitor load, such as small auxiliary units, to determine when they first achieved or last operated at 25 percent load. EPA therefore should allow such units to determine when startup and shutdown begins based on manufacturer specifications. These specifications define startup and shutdown using factors more appropriate than load, such as the completion of specific procedures and run time. Defining startup and shutdown according to manufacturer specifications will address the operational differences among affected boilers and will not adversely impact public health or the environment.

Response: See the responses to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 46, regarding 25% load SS definition threshold, and comment EPA-HQ-OAR-2002-0058-3659-A2, excerpt 5, regarding use of manufacturer’s specifications.

Commenter Name: C. Richard Neff
Commenter Affiliation: Cogentrix Energy, LLC
Document Control Number: EPA-HQ-OAR-2002-0058-3627-A2
Comment Excerpt Number: 2

Comment: Cogentrix concurs with the work practice standard that requires sources to minimize periods of startup and shutdown following the manufacturer's recommended procedure. For stoker coal boilers designed to operate as electric utility steam generating units, the manufacturer's recommended procedure includes building a stable ash bed on grate - to assure efficient combustion that can minimize both CO and NO_x formation - prior to bringing the unit to its minimum load point. In these instances, the minimum load point is 50 percent, and the time to achieve that point is eight (8) hours after initial firing, whichever is shorter. Therefore, Cogentrix proposes that the definitions for startup and shutdown be revised as follows, so that they reflect manufacturers' recommended procedures:

"Startup means the period between the state of no combustion in the unit and the period when the unit first achieves the manufacturer's recommended minimum load (i.e., a cold start) or a maximum of eight (8) hours, whichever is shorter"; and "Shutdown means the period that begins when a unit last operates at the manufacturer's recommended minimum load and ends with a state of no fuel combustion in the unit."

Response: See the responses to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 46, regarding 25% load SS definition threshold, and comment EPA-HQ-OAR-2002-0058-3659-A2, excerpt 5, regarding use of manufacturer's specifications.

Commenter Affiliation: Division of Air Quality, North Carolina Department of Environment and Natural Resources (NCDENR)

Document Control Number: EPA-HQ-OAR-2002-0058-3663-A2

Comment Excerpt Number: 22

Comment: EPA not proposing to change malfunction provisions, but proposing revised work practice standards for S/S. EPA proposing to define startup as period between state of no combustion to period where unit first achieves 25% load; and define shutdown as period beginning when unit last operates at 25% load and ending with no fuel combustion. Proposing to employ good combustion practices and demonstrate practices are maintained by monitoring O₂ and optimizing those levels as specified by boiler manufacturer; ensure boiler operators are trained in S/S, including safety, control device startup, minimizing emissions; and maintain records during S/S and include in compliance reports the O₂ conditions /data for each startup event, length and reason of S/S.

NC DAQ supports the use of work practices for both startup and shutdown of boiler operations and is generally in favor of simpler definitions for these operational periods. However, the operations during conditions defined as shutdown (less than 25% of load to no fuel) would be easier to meet in practice than the startup conditions. NC DAQ believes that a source should have the option to use another alternative to the proposed startup load definition while maintaining work practice requirements. Other alternatives for defining startup are temperatures associated with control equipment operation and not-to-exceed time limits in reaching these conditions to avoid overly lengthy startups.

Response: See the responses to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 46, regarding 25% load SS definition threshold, and comment EPA-HQ-OAR-2002-0058-3659-A2, excerpt 5, regarding use of manufacturer's specifications.

Comment: It is worth noting that while numerical emission limits (lb/MMBTU) may be exceeded during low firing rate operations, because of the low firing the mass of emission (total pounds) will be quite low.

Response: See the responses to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 46, regarding 25% load SS definition threshold, and comment EPA-HQ-OAR-2002-0058-3659-A2, excerpt 5, regarding use of manufacturer's specifications.

Commenter Name: Robin Mills Ridgway
Commenter Affiliation: Purdue University
Document Control Number: EPA-HQ-OAR-2002-0058-3668-A2
Comment Excerpt Number: 3

Comment: In §63.7575, EPA defines "startup" and "shutdown" as being the operational load of a unit at less than 25% of the unit's design capacity. This arbitrary 25% cutoff is problematic for many industrial units. For example: Purdue University's Boiler #5 is rated at 200 kpph. Using the repropoed rule's cutoff, 25% would be 50 kpph, making 50 kpph the load threshold between startup/shut down and operational. However, at loads as low as 50 kpph, this unit is in danger of tripping due to combustion instability and is not stable until it reaches 80 kpph. Purdue University's Wade Utility Plant's boilers are affected units in the CAIR ozone season NOx program. In Purdue's Part 75 monitoring plan, 80 kpph is the certified minimum stable operating load for Boiler #5. Purdue suggests the use of the "minimum stable operating load" as defined by 40 CFR Part 75 Appendix A 6.5.2.1 instead of the arbitrary 25% design capacity threshold proposed in the Boiler MACT.

Response: See the responses to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 46, regarding 25% load SS definition threshold, and comment EPA-HQ-OAR-2002-0058-3659-A2, excerpt 5, regarding use of manufacturer's specifications.

Commenter Affiliation: Eastman Chemical Company
Document Control Number: EPA-HQ-OAR-2002-0058-3669-A2
Comment Excerpt Number: 33

Comment: The designation of a set percentage of load to define a startup is inappropriate and arbitrary. There are vast differences among boiler designs that would dictate at what load it is safe to end the startup. We give the following two actual examples of boilers at our facility that

demonstrate that 25 percent of rated capacity is arbitrary to define the end of startups for these boilers:

Example 1: Pulverized coal boilers

Both No. 30 and 31 boilers are pulverized coal boilers which produce 1450 psig steam that is routed through a turbine to generate electricity or bypass valve that exhausts to the plant at 600 psig. When starting up from a cold start, operations follows a very detailed (105 steps) check sheet. The general order of startup includes: making sure all valves and dampers are in correct position, warming up boiler using natural gas igniters, placing particulate control device in service, placing a coal mill in service and opening pressure reducing valve in the steam header, placing spray dryer absorber (SDA) in service, and placing steam turbine generator in service. Alternately, if the steam turbine generator is not available, steam can continue to be routed through the pressure reducing valve. Upon startup of the first mill the boiler load is approximately 40% of MCR. It is at this load that the SDA is brought online, and the unit is typically held at this level until the SDA startup is complete and the turbine generator is synchronized and begins producing electricity. Using the EGU logic to define startup, this 40% of MCR would be considered the load at which the unit is considered to be "online."

Example 2: Stoker boilers

Nos. 18-20 Boilers are moving grate spreader stoker coal boilers which produce 600 psig steam. Before coal is ignited, the electrostatic precipitators are energized. Coal is then placed on the grates and ignited. Feeders are cycled on- and offline in order to evenly add heat to slowly pressurize the boiler without damaging the refractory or tubes, per the manufacturer's startup curve for pressure increase with respect to time. As the boiler begins making steam and its pressure begins to increase, steam is vented to atmosphere to provide cooling flow to the boiler superheaters. When the steam pressure nears 600 psig, the header valve is opened. The boiler is equipped with a non-return valve so steam from the header will not flow back into the boiler, so when boiler pressure meets or exceeds the 600 psig header pressure steam will exit the boiler and enter the header. However, for super heater cooling purposes, the vent to atmosphere is not closed until the boiler outlet steam has exceeded 37.5% of MCR. This is the point at which startup is considered complete and the unit is "online."

Startups can vary for a variety of reasons, and the minimum safe and stable load is determined by the boiler OEM based on the unique characteristics and design pressure of the specific unit. For EPA to presume that a universal load point can be identified is false. Rather, EPA should acknowledge the vast diversity of the population of boilers being regulated and allow sources the flexibility to use the OEM's recommended minimum safe and stable operating load to define the end of startup, or to petition the Administrator if such guidance is not available or if other qualified experts can substantiate a different load point.

Response: See the responses to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 46, regarding 25% load SS definition threshold, and comment EPA-HQ-OAR-2002-0058-3659-A2, excerpt 5, regarding use of manufacturer's specifications.

Commenter Name: Heather Parent

Commenter Affiliation: Maine Department of Environmental Protection

Document Control Number: EPA-HQ-OAR-2002-0058-3691-A2

Comment Excerpt Number: 6

Comment: While Maine DEP supports the incorporation of work practice standards in place of emission standards during startup and shutdown periods, Maine DEP disagrees with a 25% percent of load trigger for normal operating conditions. Startup conditions, particularly with biomass and multi fuel units, can occur well beyond 25% of load up to more than 50% load. Maine DEP suggests that EPA reconsider the 25% of load trigger taking into account how biomass units startup differently than liquid or gas fired units.

Response: See the responses to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 46, regarding 25% load SS definition threshold, and comment EPA-HQ-OAR-2002-0058-3659-A2, excerpt 5, regarding use of manufacturer's specifications.

Commenter Name: Samuel H. Bruntz

Commenter Affiliation: Alcoa Power Generating, Inc.

Document Control Number: EPA-HQ-OAR-2002-0058-3755-A1

Comment Excerpt Number: 14

Comment: Proposed regulation 63.7575 defines start-up as the period between the state of no combustion in the unit to the period where the unit first achieves 25 percent load (*i.e.*; a cold start), and defines shutdown as the period that begins when a unit last operates at 25 percent load and ending with a state of no fuel combustion in the unit.

Alcoa - Warrick appreciates the intent of EPA to require compliance with work practice standards instead of emission limits, as indicated in 63.7500(e) during start-up and shutdown events. However, Alcoa~ Warrick is concerned that EPA may not be aware of the requirement that boilers that produce steam to drive a turbine maintain a "soak condition" for a period of approximately 4 hours to allow proper turbine start-up. During that 4 hour period, the associated boiler may fluctuate between 25-27% load, but would attempt to hold the load in a range that does not constantly stay at 25% load. Due to the turbine soak requirement, Alcoa ~ Warrick requests that the definitions of start-up and shutdown in 63.7575 be amended as follows:

Start-up means the period between the state of no combustion in the unit to the period when the unit first achieves 30 percent load (i.e. a cold start).

Shutdown means the period that begins when a unit last operates at 30% load and ending with a state of no fuel combustion in the unit.

Response: See the responses to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 46, regarding 25% load SS definition threshold, and comment EPA-HQ-OAR-2002-0058-3659-A2, excerpt 5, regarding use of manufacturer's specifications.

Commenter Name: Traylor Champion

Comment Excerpt Number: 5

Comment: GP strongly opposes establishing specific time limits due to the wide variation in boiler designs, operating variables and many other factors that affect the time required to safely start up and shut down a boiler. Boiler manufacturers set forth appropriate startup / shutdown sequences for safety as well as minimizing stresses and preventing damage to the equipment. We understand EPA's desire to establish a maximum time limit for startup and shutdown periods and agree that these periods should be minimized to the greatest extent practicable. Unfortunately, there simply is no practical means of developing a "one-size-fits-all" standard that is appropriate for all boiler designs and configurations. In fact, time limits could have the perverse effect of forcing operators to forgo manufacturer's operating guidance and incur unnecessary wear and tear over time. Overstressing the boiler will, in the long run, adversely impact combustion efficiency and the boiler's reliability. All of these outcomes would result in increased emissions. Furthermore, time limits are really unnecessary as operators already have strong economic incentives to minimize these periods to the extend practical and expeditiously transition operation of the boiler to a normal operating range.

Response: The EPA is not specifying time limits for periods of startup and shutdown.

Comment: Boiler manufacturers provide curves that establish the minimum time required to start up and shut down a boiler. These curves are based on specific boiler design and are intended to protect boiler components from excessive stresses resulting from differential expansion. The startup/shutdown curves for an individual boiler must be followed to ensure that the pressure parts of the boiler are not stressed beyond acceptable tolerances. Accelerating the startup/shutdown procedures can significantly reduce the life of boiler components and in some cases can result in immediate pressure part failure. The start-up curve will not be the same for all boilers. The major factor used to develop a start-up curve is drum thickness. The thicker the drum plate, the longer the boiler will take for it to reach equilibrium, and the longer the required start-up curve. Differential expansion of other components, such as headers and downcomers, must also be taken into consideration.

Comment: Many industrial boilers have non-drainable, pendant-style superheater sections and the start-up procedure for these boilers requires that all the water is boiled out of the superheater tubes as part of the start-up process. These tubes are exposed to hot gases from the furnace and depend on steam flow through the tubes for cooling. Any water in the tubes blocks the flow of steam. The superheater tubes will normally be partially or completely full of water following an outage with the source of water being either steam that condensed during the shutdown of the boiler or water used to hydrostatically test the boiler for leaks prior to startup. The start-up process requires that the gas temperature be limited to 900°F entering the superheater until: (1) all the water is boiled out of every element, and (2) steam flow is a minimum of 10% of rated capacity to ensure flow through all the tubes. Failure to clear the superheater of water and establish sufficient steam flow prior to increasing gas temperature can result in overheating and failure of the superheater tubes. The time required to clear a superheater is a function of boiler design, the size and design of the superheater, and the fuel being fired. Clearing the superheater of water, especially on larger, high pressure, high temperature boilers, often exceeds the minimum time established by the manufacturers' startup curve and becomes the controlling factor regarding the duration of start-up events.

Comment Excerpt Number: 1

Comment: EPA is proposing to change the work practice standards to better reflect the maximum achievable control technology and to change the proposed definitions of startup and shutdown. EPA proposes to define startup as the period between the state of no combustion in the boiler to the period where it first achieves 25% load (i.e., a cold start). Similarly, EPA proposes to define shutdown as the period that begins when a unit last operates at 25% load and ending with a state of no fuel combustion in the unit. For periods of startup and shutdown, EPA proposes the following work practice standard:

Affected facilities must employ good combustion practices and demonstrate good combustion practices are maintained by monitoring oxygen (O₂) concentrations and optimizing those concentrations as specified by the boiler manufacturer.

Facilities must ensure boiler operators are trained in startup and shutdown procedures, including maintenance and cleaning, safety, control device startup, and procedures to minimize emissions.

Facilities must maintain records during periods of startup and shutdown and include in their compliance reports the O₂ conditions/data for each startup event, length of startup shutdown and reason for the startup/shutdown (i.e., normal/ routine, problem/malfunction, outage). And

Facilities must comply with all applicable emissions limits at all times except for startup and shutdown periods, during which times facilities must comply with these work practices.

NC DAQ Comment:

We support EPA's proposal on the above points except for the proposed definition of startup. We favor a change in the Boiler MACT's definition of *startup* that resembles the EGU MACT's definition where the end of startup is more closely aligned with normal steady-state operation and includes allowances for high enough temperatures that concerns for condensation are addressed.

Our understanding of facility equipment operations is there are four distinct, mutually-exclusive conditions or periods: *Startup*, *steady-state*, *malfunction*, and *shutdown*. *Steady-state* occurs nearly 99% of the operating periods, while *startup*, *malfunction*, and *shutdown* happen the remainder of the time. EPA has not proposed a definition for *steady-state*, and NC DAQ's view is EPA has too narrowly defined *startup* to be the period between cold start and *steady state*.

Under the EPA proposed definition of *startup*, process and emission control equipment have not reached stable, constant conditions at the end of the *startup* period, as equipment operating temperatures have not reached a suitable level -- for emission controls to reach *steady-state* and perform as intended -- after achieving only 25% load. For example, the manufacturer's recommended operating procedure for common air pollution control equipment (APCE, such as baghouses, electrostatic precipitators, cyclones, selective catalytic reduction, etc.) is to eliminate, or at least minimize, exposure to condensation. This means operators need to wait until the gas temperature is above a certain minimum temperature (e.g., dew point) before subjecting the equipment to the gas stream or before energizing emission controls. If operators prematurely

subject control equipment to temperatures below the dew point, then condensation will occur and damage the equipment, leading to preventable equipment malfunction.

The term *steady-state* is normally defined as "a condition in which the properties of any part of a system are constant," or "a condition of a physical system or device that does not change over time." *Steady-state* occurs after startup, before shutdown, and outside of malfunction. On one hand, EPA requires facility personnel to follow manufacturer's recommendation for equipment operation. On the other, EPA defines startup in such a way as to encourage facility personnel to deviate from manufacturer's recommendation and short-circuit the startup period, thereby increasing the opportunity of equipment *malfunction*, the adverse condition facilities strive to minimize.

EPA could follow the same common-sense approach it applies for emission monitors in which it allows reasonable time for temperatures to reach appropriate levels after *startup* and before producing valid data. It does not consider emission monitoring data valid until after monitoring equipment has heated and reached *steady-state*, nor does it require monitors to produce valid data immediately after a cold start. Accordingly, EPA could define startup as the reasonable length of time after cold start and before steady-state so as not to induce malfunctions.

Comment Excerpt Number: 18

Comment: Perhaps more significantly than these combustion device issues is the variability imposed by process considerations. Often startup and shutdown timing is set by the process demands they serve. For instance, a boiler or process heater often has its time at <25% firing set by the rate at which the process it serves starts up or shuts down. Clearly, a boiler or process heater cannot just crank up to high operating rate unless there is demand for the steam or process heat it provides. Similarly, low levels of steam or process heat are often need to continue while process equipment is shutdown and de-inventoried. For these reasons, the time between initial light-off of a boiler or process heater and 25% firing and between 25% firing and total shutdown (all heat input is stopped) is highly variable. Any limit on the duration of these activities will certainly result in situations where the time limit is exceeded and units will become subject to numerical emission limits that cannot be met at such low operating rates.

Response: See response to DCN EPA-HQ-OAR-2002-0058-3534-A1, Excerpt No. 46, regarding 25% load SS definition threshold, and DCN EPA-HQ-OAR-2002-0058-3659-A2, Excerpt No. 5, regarding use of manufacturer's specifications. Comment Excerpt Number: 4

Comment: Purdue believes the following types of concepts could be used as startup and shutdown definitions (76 FR 80615). being indicative of a boiler or process heater reaching the end of a startup period (the beginning of a startup would occur with first introduction of fuel with combustion in the furnace):

- Boiler or process heater firing its primary fuel for a period of time adequate to provide stable and non- interrupted fuel flow, stable and controlled air flows, and adequate operating temperatures to allow proper fuel drying and air preheat as applicable.
- Emissions controls in service with operating parameters such as flow rates and temperatures being controlled and stable.
- Boiler or process heater supplying steam or energy output to a common header system or energy user(s) at normal operating conditions including pressure, temperature, and above minimum operational output flow rate, as applicable to the unit.
- Similarly, Purdue believes the following types of concepts could be used as being indicative of a boiler beginning a shutdown period (the end of a shutdown would occur with the cessation of combustion of any fuel in the furnace):
- Cessation of introduction of the last remaining primary fuel to the furnace, whether or not a supplemental support fuel is being used.
- Cessation of emissions control system sorbent or other reagent injection.
- Lowering the fuel firing rate to the point that automatic control is no longer effective or possible.
- Lowering of operating rates to the point that emissions control systems no longer can be controlled or be effective due to low flow rates, low temperatures, or other issues.
- Lowering boiler or process heater output to the point that steam or energy output no longer meets operational required conditions of pressure, temperature, or flow.
- Boiler and process heater owners/operators should establish specific operating conditions and parameters defining startup and shutdown in standard operating procedures for each affected unit so that it is clear when each unit is in either startup or shutdown mode. Procedures should also be used to guide operations purposefully through startup or shutdown periods so that protracted periods in startup or shutdown mode beyond that envisioned in the procedures are avoided. Each startup and shutdown should be documented relative to elapsed time and timing of actions prescribed in the procedure so that problems are effectively identified and corrected in a timely manner.

Comment Excerpt Number: 10

Comment: 25% of rated load is not an indication of the end of startup or the beginning of a shutdown for a large fluidized bed boiler. Minimum stable loads for large fluidized bed boilers are approximately 50% of rated load. The purpose of a startup is to get a boiler stabilized and on line as quickly as possible without jeopardizing the safety of personnel or risking damage to the boiler. Also, startups may commonly require the curing of refractory. This process cannot be shortened without risking damage to new refractory. For these reasons, EPA should allow the defining of startup and shutdown periods to be done on a case by case basis and not attempt to regulate the time period required for startup.

Response: See the responses to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 46, regarding 25% load SS definition threshold, and comment EPA-HQ-OAR-2002-0058-3659-A2, excerpt 5, regarding use of manufacturer's specifications. Commenter Name: Russell A. Wozniak
Commenter Affiliation: The Dow Chemical Company
Document Control Number: EPA-HQ-OAR-2002-0058-3449-A1
Comment Excerpt Number: 37

Comment: Dow requests that EPA consider revising the startup/shutdown proposed rule definitions to address variability in combustion unit operational use. Dow operates some combustion units in a standby (operational readiness) mode for extended periods of time at less than 25% load. Operating some boilers in stand-by mode is necessary at larger complex petrochemical facilities and allows for expeditious ramping up of combustion units to provide process operating continuity. When standby mode is reached, combustion unit operating characteristics are stable (e.g. combustion zone flame/oxygen level) and the emissions are insignificant. For combustion units that are subject to a Table 1 or 2 emission limit and only burn Gas 1 fuel/Other Gas 1 fuel during startup, the rule should provide that these units are also exempt from startup provisions. Dow believes that a startup load criteria of 5% of maximum design heat input for these types of combustion units is practical and achievable, but that the criteria should be defined within a range of 5 to 25% load by the owner/operator. *Startup means the period between the state of no combustion in the unit to the period where the unit first achieves stable load conditions defined by the owner/operator (typically between 5 percent and 25 percent load).*

Document Control Number: EPA-HQ-OAR-2002-0058-3492-A1
Comment Excerpt Number: 9

Comment: Alliant Energy supports exempting periods of Startup and Shutdown (S&S) from compliance with the MACT emissions limitations. However, we believe that EPA's S&S definitions require additional clarification and operational flexibility. In particular, it may not be readily apparent when a unit has first achieved or last operated at 25% load. This is especially the case for smaller auxiliary units that support larger facility operations. In this instance, we believe that EPA should allow affected sources to use manufacturer's specifications to define S&S procedures that would define appropriate factors to monitor (rather than load) or establish a time-based approach.

Commenter Affiliation: The Vinyl Institute

Document Control Number: EPA-HQ-OAR-2002-0058-3526-A1

Comment Excerpt Number: 16

Comment: The Agency's approach does not appear to address boilers that operate in standby mode for long stretches of time. There are critical operational requirements that apply to these standby boilers, and it would be inefficient and ultimately result in increased emissions if they had to be completely shutdown and then restarted during these periods in order to comply with the proposed rule. For example, the sudden loss of steam in a PVC plant can have the following consequences:

- Higher emissions of VOC compounds from the slurry resin process, which relies upon steam strippers to reduce the concentrations of residual vinyl chloride and other compounds from PVC slurry produced in the reactors;
- Increased emissions from the process wastewater which relies on steam strippers to remove VOC before atmospheric exposure of wastewater; and
- Production of off-grade product, which may have to be disposed of as a waste if a buyer is not available.

The VI requests that EPA revise the definitions to allow for continued use of these boilers as well.

Commenter Affiliation: Wisconsin Electric Power Company (WE Energies)

Document Control Number: EPA-HQ-OAR-2002-0058-3452-A1

Comment Excerpt Number: 13

Comment: To account for site-specific variability of boiler design and/or fuel specifications, We Energies requests that EPA include an option for affected units to develop a site-specific startup and shutdown plan for subsequent approval by the state permitting authority. This option would be implemented through the construction/operation permitting process, at the same time that the IB-MACT rule requirements are also being incorporated into an affected unit's permit. The permit would include conditions requiring the affected unit to develop a startup and shutdown plan that defines those periods of operation. The state permitting authority would approve the plan prior to the affected unit being authorized to apply the proposed work practice standard during those periods of boiler operation.

Response: The EPA is setting standards that apply at all times, including periods of startup and shutdown. With such standards in place, sources will need to plan for and achieve compliance during startup and shutdown and during malfunctions, so there is no reason to require sources to develop SSM plans.

Comment Excerpt Number: 17

Comment: EPA's proposed definitions specify that only the periods of time between a complete shutdown of a unit (no fuel being combusted) and the time that a unit first reaches 25 percent load qualify as startup, and only the periods of time between 25 percent load and a complete shutdown (no fuel being combusted) qualify as shutdown. Whether 25 percent load is an appropriate determinant for startup and shutdown will vary from boiler to boiler. In the case of bagasse boilers, the 25 percent load limitation is particularly inappropriate, since stable operating conditions may not be reached until the boiler achieves 60 percent load. The 25 percent load

restriction constitutes an arbitrary limitation, and startup and shutdown should instead be defined in accordance with good operating practices for any particular boiler. The minimum stable operating load that defines startup and shutdown, and the proper procedures to follow during startup and shutdown, can be included in a site-specific operating plan.

Response: See the responses to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 46, regarding 25% load SS definition threshold, and comment EPA-HQ-OAR-2002-0058-3659-A2, excerpt 5, regarding use of manufacturer's specifications. Comment Excerpt Number: 2

Comment: EPA should allow sources to define startup and shutdown based on SSM Plans required under 40 CFR §63.6(e) of the General MACT Provisions. The definition of "startup" and "shutdown" cannot be precisely defined, even for the same unit, because it typically differs depending on the type of unit, fuel, method of delivering and dispersing the fuel in the boiler chamber and ambient air temperature, and other process, operational or maintenance circumstances related to the startup or shutdown. Until there is complete combustion in the firebox or, for example, threshold temperatures are reached on operational and certain air emissions control devices, a unit may have the potential to exceed the emission limits that are applicable during continuous operations. It was appropriate therefore for EPA to establish work practice standards for startups and shutdowns. It is *inappropriate* for the Agency to define these terms relative to the load-carrying capability of any boiler since that is not necessarily relevant to the other conditions listed previously. Moreover, it is completely arbitrary for EPA to pick 25 % of full load as a definition, and in fact the agency offers no basis in the proposal for defining startup or shutdown as ramping up or down to 25% of full load. Importantly, and given that EPA has established CO limits based on data outside of start-up and shut-down periods, EPA should recognize that at lower loads which occur during start-ups and shut-down periods emissions of CO may be substantially higher than at the normal operating loads. For this reason, in the original Boiler MACT rule, the CO limit applied only when the load was greater than 50%. EPA has made no reasoned accounting of these circumstances in proposing an arbitrary 25% cut-off for normal non-start-up or shut-down operation.

Response: See the responses to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 46, regarding 25% load SS definition threshold, and comment EPA-HQ-OAR-2002-0058-3659-A2, excerpt 5, regarding use of manufacturer's specifications. Comment Excerpt Number: 4

Comment: In view of NEDA/CAP's concern that it would be unreasonable for EPA to establish "one" definition of "startup" or "shutdown," we would suggest that a boiler operator define these terms under its SSM plan, required under the MACT General Provisions. *See* 40 CFR §63.6(e). That would allow boiler operators to distinguish "startup" or "shutdown" from operations that are simply following load, and it would be based on safety and good engineering practice and experience with existing equipment based on the type of boiler, fuel, operations, etc. Alternatively, or in conjunction with the boiler tune-ups required by the Final MACT Rule, "startup" or "shutdown" definitions can be established for a unit in the facility's SSM plan. EPA or the public can request review of this document if there is actually a basis to believe that an operator is circumventing compliance with the ICI MACT by "cycling in and out of startup or shutdown."

Commenter Name: J. Michael Geers

Commenter Affiliation: Duke Energy

Document Control Number: EPA-HQ-OAR-2002-0058-3543-A1

Comment Excerpt Number: 7

Comment: In the proposal, EPA attempts to place all boilers into the same category using a 25% load as the threshold for ending a startup or beginning a shutdown. This distinction, however, is not always clear cut because boilers have a wide variety of fuel type, furnace and boiler designs (combustion method), and demand requirements and operating methodologies. Some specific examples include the following:

Solid fuel fired boilers, particularly pulverized, cyclone, biomass and fluid bed units, have higher minimum stable loads than do oil and gas fired units. This is because these units require a higher minimum fuel flow to load to prevent fires and/or explosions in the pulverizers, burner lines, burners, and in the furnace. A higher fuel flow keeps the conditions in the pulverizers and burner lines in a “fuel rich” environment above the higher level of explosion. In fluid bed units, a minimum firing rate is required just to ensure that the fire does not continue to go out at low loads.

- Oil and gas fired units have more capability to fire at low levels for longer periods of time. For some units, this can be accomplished by simply substituting an oil gun with a smaller capacity sprayer tip.
- Some facilities with solid fuel boilers have substantial steam load fluctuations such that they operate in a hot standby mode. In this standby mode, the boiler is “banked”, which means the bed of fuel is hot and burning very slowly, but no significant steam is being produced. No combustion air is being supplied. All that it takes to bring the boiler on line is to begin combustion air to increase the combustion rate. Depending upon conditions, boilers can be in “banked” mode for hours to several days.
- Solid fuel units, particularly older anthracite units, will have a fire on the grate for several days to allow for slow heat-up of the refractory and other critical metal components. The slow heat up rate is necessary to prevent material damage to the unit. No steam is being produced during the warm-up period.
- Some facilities may have oil fired boilers that are sized for winter heating loads, but have excess capacity to meet summer steam loads. Often, a unit may cycle on and off because the facility steam load is below minimum firing rate for the unit.
- Biomass units have their own particular operating requirements due to their furnace design and fuel type.

Duke Energy has limited experience with units other than those that are solid fuel fired. However, based on its experience, Duke Energy does believe that a 25% load factor is an appropriate cut off for pulverized, cyclone, biomass, and fluid bed solid fuel fired industrial boilers for both start-up and shutdown. Duke Energy also believes that EPA should not include a maximum time in the startup and shutdown definitions. Sources covered by the rule are highly variable and the amount of time needed for startup and shutdown are different depending on the specific unit. In the operation of its units, Duke Energy specifies minimum operating loads that are consistently above 25%. Once a pulverized coal unit is started, it will ramp up load steadily from low loads to its minimum operating load (greater than 25%) without delay. As a result, while sources could pick different loads in the 10% to 40% range, Duke Energy believes that 25% is a good compromise value and that it should be based on either heat input or steam flow. In the event that an individual source seeks a higher value based on operating safety criteria, that source should approval from its local permitting authority.

Response: See the responses to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 46, regarding 25% load SS definition threshold, and comment EPA-HQ-OAR-2002-0058-3659-A2, excerpt 5, regarding use of manufacturer’s specifications. Commenter Name: Annabeth Reitter
Commenter Affiliation: NewPage Corporation
Document Control Number: EPA-HQ-OAR-2002-0058-3662-A2
Comment Excerpt Number: 10

Comment: EPA has defined startup and shutdown as follows:

- Startup means the period between the state of no combustion in the unit to the period where the unit first achieves 25 percent load (Le., a cold start).
- Shutdown means the period that begins when a unit last operates at 25 percent load and ending with a state of no fuel combustion in the unit.

The conditions EPA has designated for startup and shutdown will be problematical for our units. For example, the design of our circulating Fluidized Bed (CFB) boilers provides many advantages for efficient combustion; however, these boilers do not have a conventional startup curve. The CFB boilers at one of our facilities are started on oil and bed material is introduced into the furnace gradually to build a properly classified bed. Solid fuel is introduced when temperatures are met however the proper classification of the bed is still ongoing. Due to the uniqueness of these units we have had to negotiate alternate startup/shutdown requirements with our State permit authority and these procedures have been incorporated into our permit. We are allowed a 24/36 hour window without opacity limitation to achieve full startup or shutdown. This allows for the introduction/removal of bed material and a proper startup/shutdown curve. These conditions are a result of properly managing and operating the CFBs but also take into account facility specific conditions. These units share a common stack so that startup/shutdown activity in one unit may be ongoing while the other continues to run. In this situation compliance with an opacity standard as a surrogate for PM₁₀HAPs may be a difficult situation and may not be achievable. As part of the startup/shutdown work practice provisions, EPA needs to adequately address this situation for sources that share a common stack. Lastly, not unique to CFBs, after internal maintenance there is commonly a refractory cure that occurs for 24 or 36 hours. This is typically at lower loads, but may approach or exceed of 25% heat input at the end of the cure prior to full startup.

The 25% load thresholds are arbitrary and attempt to place all boilers in the same basket. Due to varying boiler designs, fuel type, combustion method and operating methodologies, this threshold for identifying startup and shutdown conditions is not workable. EPA should abandon the 25% load threshold for startup and shutdown and address startup and shutdown through only the use of work practices and let the sources determine how to acceptably define startup and shutdown for their units. This could be handled through the use of a startup and shutdown plan.

Response: See the responses to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 46, regarding 25% load SS definition threshold, and comment EPA-HQ-OAR-2002-0058-3659-A2, excerpt 5, regarding use of manufacturer's specifications. Commenter Affiliation: Southern Company

Document Control Number: EPA-HQ-OAR-2002-0058-3520-A1

Comment Excerpt Number: 9

Comment: While Southern Company supports the inclusion of work practice standards during startup and shutdown, we believe that the definitions and work practices should be modified to better account for each unit's safety and good engineering practices for startup and shutdown. Our historical operating experience with coal and oil-fired power plants has shown that each unit starts up slightly different depending on the unit design and applicable emission control devices. For many plants, all emission control devices are not fully in service by the time 25 percent load is reached. These plants would be at risk of exceeding the 30-day rolling average simply because good engineering and safety practice did not allow the emission control device to be online during EPA's defined startup period. For a biomass-fired boiler, many control devices, including ESPs, baghouses, or sorbent injections, should be bypassed or used in a limited manner until startup fuel, such as oil, is removed from service. To reduce the risk of fire and equipment fouling from oil carry-over, for example, electrostatic precipitators (ESPs) and baghouses are gradually brought into service, starting with just a small section at a time. For the Plant Mitchell biomass conversion, the startup fuel would not be removed from service until the unit reaches about 50 percent load. In fact, the active introduction of biomass to the boiler may not begin until the unit reaches 20 to 25 percent load. During the transition from startup fuel to 100 percent biomass-firing, which can take several hours, the unit may also experience higher combustion emissions, such as CO, until the unit stabilizes on 100 percent biomass. Startup procedures, time periods, and loads can be highly unit-specific. Thus, EPA should allow each source to work with its relevant permitting authority to develop a site specific startup definition and work practice standard that is tailored for the unique characteristics, control devices, and safety practices of each plant.

Commenter Name: Douglas A. McWilliams

Commenter Affiliation: American Municipal Power

Document Control Number: EPA-HQ-OAR-2002-0058-3685-A2

Comment Excerpt Number: 16

Comment: The proposed boiler operator training requirements are unnecessary and serve only to create additional recordkeeping and reporting requirements and increase the cost of the rule. The Proposed Rule already requires boiler operators to (*f at all times, operate and maintain any affected source, including associated air pollution control equipment and monitoring equipment, in a manner consistent with safety and good air pollution control practices for minimizing emissions.*" To satisfy this condition, and to operate the boiler in a safe manner, boiler operators receive appropriate training. Adding a training work practice standard adds nothing to the rule except additional recordkeeping and reporting requirements that do not serve any beneficial environmental purpose.

These additional recordkeeping and reporting requirements impose particular hardship on small municipal utilities that do not have personnel dedicated solely to environmental compliance. Each additional recordkeeping and reporting obligation created by the Boiler MACT rule must be carried out by boiler operators in addition to their general operating duties. Superfluous recordkeeping and reporting obligations that serve no environmental purpose should be eliminated wherever possible to avoid unnecessary compliance costs that could be better allocated to meaningful emission reduction investments. This is particularly the case here, where EPA has offered no reason for abandoning its previous work practice approach.

Response: We recognize the concerns of the commenter and agree that the training records mentioned by the commenter do not have an impact on human health or the environment. As such, we have removed the operator training requirements from this rule, consistent with the procedures in the recently promulgated MATS rule, 40 CFR part 63, subpart UUUUU.

Commenter Affiliation: American Municipal Power
Document Control Number: EPA-HQ-OAR-2002-0058-3685-A2
Comment Excerpt Number: 14

Comment: Additional Work Practice Standards During Startup and Shutdown Are Unnecessary

The additional work practices EPA has proposed create unnecessary recordkeeping and reporting burdens that increase costs without any additional environmental benefits. The duty to minimize emissions consistent with recommended procedures would necessarily include adherence to good combustion practices. Boiler operators have a business incentive to operate their boilers as efficiently as possible. Furthermore, optimal O₂ concentrations will vary by boiler and design. Many existing units, and all of AMP members' generating units, were constructed prior to 1970, and do not have manufacturer's instructions indicating optimal O₂ concentrations. "Similar units" that are appropriate benchmark for optimal combustion than a numeric O₂ concentration that may or may not represent the most efficient combustion for that unit.

Response: See the responses to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 46, regarding 25% load SS definition threshold, and comment EPA-HQ-OAR-2002-0058-3659-A2, excerpt 5, regarding use of manufacturer's specifications. Commenter Name: Michael D. Wendorf
Commenter Affiliation: FMC Corporation
Document Control Number: EPA-HQ-OAR-2002-0058-3453-A1
Comment Excerpt Number: 11

Comment: Based upon many years of experience operating both PC and stoker coal boilers, FMC requests the EPA to consider a maximum allowed startup time of 24 hours. Boilers restarted after major overhauls may require several hours to shake down systems that have been repaired, installed or replaced. During this period it is essential to keep boiler loads low in order to minimize impacts to the boilers and to the rest of the facility. Interactions between repaired, installed or replaced systems cannot be tested prior to first startup after an extended boiler overhaul. Pollution control equipment such as an electrostatic precipitator (ESP) is sensitive to a minimum flue gas temperature before being capable of being energized and operating at an acceptable level of collection efficiency. A deliberate startup can require several hours for the flue gas temperature to reach that critical minimum temperature.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3465-A1, excerpt 5, regarding maximum time limit for startup/shutdown.

Commenter Name: Michael D. Wendorf
Commenter Affiliation: FMC Corporation

Document Control Number: EPA-HQ-OAR-2002-0058-3453-A1

Comment Excerpt Number: 12

Comment: With respect to a reasonable shutdown period, stoker boilers offer an option not afforded to PC boilers, that being the ability to 'bank' the fire during extended periods of low steam demand rather than to conduct a complete shutdown. This flexibility allows quicker response to resumptions in increased steam demands, places less stress on the boiler than a shutdown/startup sequence, and can result in lower overall emissions than a cold restart. Therefore, FMC requests EPA to consider a maximum shutdown period of 24 hours for stoker boilers.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3465-A1, excerpt 5, regarding maximum time limit for startup/shutdown.

Comment Excerpt Number: 10

Comment: Some degree of refractory repair/replacement is a common element in many, if not most, boiler outages. The repair/replacement materials generally require an extended cure-out period upon start-up to avoid cracks, spalling, etc. caused by moisture exiting the material. The cure-out time will be variable based on the type and extent of refractory material replaced in a given outage and may not be known until internal.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3465-A1, excerpt 5, regarding maximum time limit for startup/shutdown.

Commenter Name: Traylor Champion

Commenter Affiliation: Georgia-Pacific LLC (GP)

Document Control Number: EPA-HQ-OAR-2002-0058-3465-A1

Comment Excerpt Number: 11

Comment: GP has a significant number of boilers that will be impacted by this regulation. These boilers have various designs, fuel types, steam temperature/pressure, ages, refractory designs and physical sizes, all factors that will impact the length of time required for startup and shutdown. We have units that can startup within a matter of hours, while others take upwards of two-days to properly heat and bring online. These examples demonstrate the wide variation in time required to properly and safely start an industrial boiler.

The final rule should not force GP's boiler operators to decide between complying with an emissions limit and protecting fellow employees and the integrity of the equipment. Therefore, we urge EPA not to include arbitrary time limits on startup and shutdown for boilers in general or one that would be consistently applicable to an individual boiler in all circumstances.

Comment: Section 63.7550 (c)(14) creates an unnecessary regulatory burden by requiring facilities to semiannually report the percentage concentration of oxygen in the firebox on an hourly basis throughout each startup or shutdown event, the calendar date and length of each event, and the reason for each event. Again, this reporting requirement is impractical, serves no purpose, and constitutes an unnecessary burden. Each boiler is unique: it has its own startup and shutdown curve, ensuring boiler equipment is not damaged during the startup and shutdown process. Startup and shutdown oxygen concentrations vary from one boiler to the next and are not comparable. Each startup event will differ depending on how warm the boiler is when startup is initiated. Submittal of this data serves no meaningful purpose. This reporting requirement is unreasonable and should be removed from the rule.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3465-A1, excerpt 5, regarding maximum time limit for startup/shutdown.

Comment: Because of the wide range of designs and operating scenarios for liquid and gas-2 fired BPH, it is impossible to define a time period for startups and shutdowns and therefore none should be specified in the final rule.

On page 80615 of the proposal preamble, EPA requests comment on whether a limit should be placed on the duration of startups and shutdowns. Such a limit cannot reasonably be established, particularly for process heaters, and thus should not be imposed. BPH safety and integrity issues are a reasonable basis for not establishing minimum startup and shutdown times. Protecting refractory from failure typically sets startup time minimums, but this timing can vary significantly depending on whether refractory replacement or repair was performed, the type of refractory, and the equipment design. On shutdown, refractory damage is not as much of a concern but the time it takes for process materials to be removed and, perhaps tubes decoked, vary substantially.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3465-A1, excerpt 5, regarding maximum time limit for startup/shutdown.

Comment: U.S. EPA is requesting comments to establish maximum time periods for units to operate in startup or shutdown mode. MSU believes that prescribing specific time constraints is not appropriate as procedures are quite specific based upon boiler subcategory, facility operations and fuel types. Startup and shutdown times can vary at each facility due to boiler type and air pollution control equipment. Additionally, MSU believes that it is important to maintain operator flexibility to safely shutdown each unit while allowing for time to troubleshoot and respond to a particular operating event. Nevertheless, MSU is providing U.S. EPA with typical startup and shutdown timeframes for each boiler subcategory at the facility.

MSU operates three (3) pulverized coal (PC) boilers and one (I) circulating fluidized bed (CFB) boiler. All MSU's boilers fire natural gas during periods of startup. From a "cold start", meaning that the boiler has been brought completely offline for a significant period of time, the PC boilers can take 6-8 hours to reach stable operations. MSU's CFB boiler, on the other hand, can take 8-10 hours to become operational on a "cold start".

CFB boilers require longer periods of combustion of fuels prior to startup. The bed itself must be heated to sufficient temperatures with natural gas prior to incorporating solid fuel. Incorporation of solid fuel prior to those temperatures would result in emissions excursions or damage to the boiler.

Similar to periods of startup, CFB boilers require a longer period of time to shutdown the unit. MSU estimates that our PC boilers can be brought off-line (i.e. no combustion and/or steam being generated) within 1-2 hours. However, shutdown procedures for the CFB involve firing natural gas past steam generation to ensure that complete burn out of combustibles occurs in the bed. This process can take up to 8 hours.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3465-A1, excerpt 5, regarding maximum time limit for startup/shutdown.

Comment: It is Inappropriate to Establish Time Limitations on Startup and Shutdown Periods

EPA requested comment on whether a maximum time should be included in the startup and shutdown definitions. Such a requirement is unnecessary, as safety and proper operation of the boiler and associated equipment dictate the amount of time that is needed for startup and shutdown. This time period will vary from unit to unit and from site to site. Safe operation of a coal-fired boiler, for example, may require operators to bring a unit online from a cold start over a period of several days. A non-cold startup, however, may take a period of hours.

EPA's concern that units will operate in perpetual startup or shutdown mode to avoid emission limits is unfounded. Industrial boilers cannot operate in perpetual startup or shutdown mode because this is, by definition, not a stable operating condition. Attempting to operate the unit for extensive periods of time at these levels would cause flame instability as well as increased fuel costs due to inefficient operation. This creates an additional burden on control equipment, which does not operate efficiently until the boiler reaches a stable load. Furthermore, units used for electricity generation can only serve this purpose if they are supplying a steady and sufficient steam flow to the turbine generators. Turbines can become unstable and pose a safety risk if they do not receive sufficient steam. During periods of startup and shutdown, the steam flow is not sufficient to operate the turbine for any significant period of time. Frequent startups and shutdowns also cause excessive wear on the equipment and controls and are not part of standard practice.

EPA has adequate assurances that startup and shutdown will be minimized without setting an arbitrary time limit. The Proposed Rule places a general duty on operators to use good combustion practices for minimizing emissions, which would necessarily include minimizing periods of startup and shutdown. Operators also have a business incentive to operate their boilers in the most efficient manner possible, which includes minimizing periods of startup and shutdown. Overly prescriptive and non-facility-specific requirements would be counterproductive, restricting the operators' flexibility in a way that hampers their ability to troubleshoot or respond to an event, or that compromises safety. EPA does not need to establish a time restriction on startup and shutdown events in light of these facts.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3465-A1, excerpt 5, regarding maximum time limit for startup/shutdown.

Comment Excerpt Number: 16

Comment: In the Reconsideration Proposal, EPA retains the work practices approach for startup and shutdown set forth in the Final Rule, and adds new definitions of "startup" and "shutdown" during which the work practices will apply. EPA is soliciting comment on whether a maximum time limit should be established for startup/shutdown, and is requesting information about the appropriate time period for the various unit designs. US Sugar generally supports the application of work practice standards during periods of startup/shutdown. However, the time periods for startup and shutdown can vary across different boilers, and the definitions of startup and shutdown set forth in the Reconsideration Proposal are overly restrictive.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3465-A1, excerpt 5, regarding maximum time limit for startup/shutdown.

Comment: EPA requests comment on whether a maximum time should be included in the startup and shutdown definitions. ACC believes that this is not necessary, as safety and proper operation of the boiler and associated equipment dictate the amount of time that is needed for startup and shutdown and vary from unit to unit and site to site. Overly prescriptive and non-facility-specific requirements can actually be counterproductive, restricting the operators' flexibility in a way that hampers their ability to troubleshoot or respond to an event, or that compromises safety.

EPA has included a threshold of 25 percent load in its definition of startup and shutdown. Some units have a minimum stable operating load that is higher than 25 percent (e.g., stable operation for a stoker boiler may not be reached until 60 percent load). Therefore, EPA should revise the startup definition to allow facilities to determine the minimum stable operating load on a unit-specific basis and include the minimum stable operating load that defines startup and shutdown and the proper procedures to follow during startup and shutdown in a site-specific plan.

Response: See the responses to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 46, regarding 25% load SS definition threshold, and comment EPA-HQ-OAR-2002-0058-3659-A2, excerpt 5, regarding use of manufacturer's specifications. Comment: Boiler and process heater owners/operators should establish specific operating conditions and parameters defining startup and shutdown in standard operating procedures for each affected unit so that it is clear when each unit is in either startup or shutdown mode. Procedures should also be used to guide operations purposely through startup or shutdown periods so that protracted periods in startup or shutdown mode beyond that envisioned in the procedures are avoided. Each startup and shutdown should be documented relative to elapsed time and timing of actions prescribed in the procedure so that problems are effectively identified and corrected in a timely manner.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3465-A1, excerpt 5, regarding maximum time limit for startup/shutdown. See the response to comment EPA-HQ-OAR-2002-0058-3452-A1, excerpt 13, regarding site-specific SS plans.

Commenter Name: Paul Noe

Comment Excerpt Number: 15

Comment: EPA should also consider that sources need time to properly startup the air pollution control equipment, and this may not always occur before 25 percent load is reached. For example, electrostatic precipitators (ESPs) must typically warm-up to be effective. This practice is necessary to ensure that boilers are started up in a safe manner. Premature starting of this equipment will lead to short term stability problems that could result in unsafe actions and longer term degradation of ESP performance due to fouling, increased chances of wire damage or increased corrosion within the chambers. Vendors providing this equipment make it part of the standard operating procedures. During periods of startup, combustion begins as fuel is introduced and an ESP warms up on a designated curve that could last for several hours. As the control device is heated up additional fuel is added until the ESP meets its design temperature and normal fuel firing is resumed. During such periods it is likely that emissions will exceed the standards proposed and will never be able to recover to meet the average limitations. The definition of startup should require facilities to develop and include a site-specific definition of startup and shutdown and the proper procedures to follow during startup and shutdown in a site-specific plan.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3465-A1, excerpt 5, regarding maximum time limit for startup/shutdown. See the response to comment EPA-HQ-OAR-2002-0058-3452-A1, excerpt 13, regarding site-specific SS plans.

Comment: Startup and Shutdown Definitions Must Be Established on a Site-Specific Basis

EPA has included a threshold of 25 percent load in its definitions of startup and shutdown. Setting a threshold for all units is inappropriate, particularly a threshold based on percent load. Some units have a minimum stable operating load that is higher than 25 percent (e.g., stable operation for a stoker boiler may not be reached until 60 percent load) . In addition, some control devices cannot be turned on until exhaust gas temperatures reach a certain level, and must be shut off before the temperature dips below this threshold. The ESPs at the City of Painesville, for example, cannot be turned on until the exhaust temperature reaches at least 250 degrees Fahrenheit. At lower exhaust gas temperatures, stack gas can condense on the precipitator plates and cause corrosion. The temperature is dependent on multiple factors, and is not necessarily correlated to a specific load level. AMP agrees that periods of startup and shutdown should be defined for each unit to clearly identify when numeric emission limits apply; however, facilities must be able to define periods of startup and shutdown on a site-specific basis to properly identify the appropriate parameter(s) indicative of stable operating conditions.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3465-A1, excerpt 5, regarding maximum time limit for startup/shutdown. See the response to comment EPA-HQ-OAR-2002-0058-3452-A1, excerpt 13, regarding site-specific SS plans.

Comment: SSM - Normal/routine startup and shutdowns need to be limited in number (not used to avoid emissions limits)

Response: The EPA believes that owners/operators have an economic incentive to minimize the number of periods of startup and shutdown. Further, the EPA does not believe it has the authority to stipulate how many such periods are permissible. We believe the revised definitions in the final rule adequately ensure that emissions will be minimized during such periods.

Document Control Number: EPA-HQ-OAR-2002-0058-3511-A1

Comment Excerpt Number: 46

Comment: As for periods of startup and shutdown, EPA could, at a minimum, require sources to use natural gas (or the cleanest available alternative) as a fuel during periods of startup and shutdown. Further, as the agency recognized, it needs to set limits on the time that sources spend in startup and shutdown mode to prevent the startup and shutdown provisions from being abused as a means to avoid compliance with emission standards. For at least these 18 reasons, EPA's

work practice standards do not reflect the maximum degree of reduction that is achievable and are not, therefore, consistent with § 112(d).

Response: Based on the comments received, the proposed work practice standard for periods of startup and shutdown has been revised. The work practice has been revised to require that all continuous monitoring systems be operated, must use one or a combination of the listed clean fuels, and once start firing coal/solid fossil fuel, heavy liquid fuel, or Gas 2 (other) gases must engage all of the applicable control technologies except dry scrubber, fabric filter, SNCR, and SCR during periods of startup and shutdown. The EPA is not requiring the use of natural gas only during periods of startup and shutdown because natural gas pipelines are not available in all regions of the U.S., and natural gas is simply not available as a fuel or a startup fuel for many industrial, commercial, and industrial boilers. The work practice does require the source to record the type and amount of fuels combusted during each startup, as well as the duration of each startup.

The EPA has also revised the definition of “startup” and shutdown” in the final rule. The EPA is not specifying time limits for periods of startup and shutdown because the time needed for startup depends on many factors, boiler design type, fuel type, type of startup (cold, hot), and control technologies employed. Startup operating procedures vary because of the objectives to protect pressure parts from corrosion, overheating and thermal stresses; to prevent furnace explosions; and production of steam at the desired temperature, pressure and purity. These revisions are tailored for industrial boilers and are consistent with the definitions of “startup” and “shutdown” contained in the 40 CFR part 63, subpart A General Provisions. We believe these revised definitions address the comments and are rational based on the fact that industrial boilers function to provide steam or, in the case of cogeneration units, electricity; therefore, industrial boilers should be considered to be operating normally at all times steam of the proper pressure, temperature, and flow rate is being provided to a common header system or energy user(s) for use as either process steam or for the cogeneration of electricity.

Comment Excerpt Number: 19

Comment: Requiring Specific Startup Fuel is Not Feasible for Many Units and Would Be Inconsistent with EPA's Prior Determinations

EPA also requested comment on whether sources should be required to use specific fuels during periods of startup and shutdown. Not all facilities are permitted for or have access to sufficient natural gas to be able to use it as their startup fuel, and not all units are capable of burning natural gas or distillate oil. Specifying the use of natural gas or distillate fuel oil would also result in increased capital and operating costs for many facilities; these fuels are in many cases more expensive than a unit's primary operating fuel and require different infrastructure to accommodate. EPA has not analyzed the cost of requiring potentially extensive infrastructure changes, such as running natural gas lines to areas where natural gas is not currently accessible. These costs may be significant, and the infrastructure projects themselves may generate more

emissions than they save. It would be inappropriate at this time to include a specific fuel requirement when these factors have not yet been quantified and analyzed.

AMP strongly supports EPA's conclusion in the preamble to the June 2010 proposed rule that fuel switching is not an appropriate control option. Mandated fuel switching would be contrary to the goal of safeguarding fuel diversity, which is a fundamental objective of U.S. energy policy. Requiring facilities to use natural gas or distillate fuel oil even for startup purposes would cut against EPA's efforts to reduce overall fossil fuel consumption. A diverse fuel mix protects energy users from fuel unavailability, price fluctuations, and changes in regulatory practices. We believe that the MACT program is not an appropriate vehicle to force fuel choices.

Response: As part of the revisions to the work practice for periods of startup and shutdown, the EPA is requiring the use of specific clean fuels during periods of startup and shutdown. We agree that not all facilities have access to natural gas or sufficient amount of natural gas. In the final rule, the work practice contains a list of several clean fuels. Fuel listed are: natural gas, synthetic natural gas, propane, distillate oil, syngas, ultra-low sulfur diesel, fuel oil-soaked rags, kerosene, hydrogen, paper, cardboard, refinery gas, and liquefied petroleum gas. In addition, the work practice has been revised to require the applicable control technologies to be engaged, except for dry scrubbers, fabric filters, SNCR, and SCR, during periods of startup and shutdown when firing coal/solid fossil fuel, biomass/bio-based solids, heavy liquid fuel, or gas 2 (other) gases.

Document Control Number: EPA-HQ-OAR-2002-0058-3504-A1

Comment Excerpt Number: 53

Comment: EPA also requests comment on whether sources should be required to use specific fuels during periods of startup and shutdown. Not all facilities are permitted for, or have access to, sufficient supplies of natural gas to be able to use it as their startup fuel. Not all units are capable of burning natural gas or distillate oil. Specifying the use of natural gas or distillate fuel oil would result in increased capital and operating costs for many facilities. The MACT program is not an appropriate vehicle to force the wholesale changes among energy sources that fuel switching to natural gas or distillate fuel oil would entail.

Natural gas and distillate fuel oil are more expensive than the primary operating fuel (bagasse) used in the sugar industry, and the use of these fossil fuels at all sugar mills may require the installation of additional infrastructure. Given these drawbacks with fuel switching, the FSI support EPA's conclusion in the preamble to the June 2010 proposed rule that fuel switching is not an appropriate control option. This conclusion is particularly apt with respect to the FSI's boilers, given the FSI's heavy reliance on clean, renewable, biomass for fuel.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3685-A2, excerpt 19, regarding requiring specific fuels during startup/shutdown.

Comment: EPA also requests comment on whether sources should be required to use specific fuels during periods of startup and shutdown. Not all facilities are permitted for or have access to sufficient natural gas to be able to use it as their startup fuel, and not all units are capable of burning natural gas or distillate oil. Specifying the use of natural gas or distillate fuel oil would also result in increased capital and operating costs for many facilities; these fuels are in many cases more expensive than a unit's primary operating fuel and require different infrastructure to accommodate (which may not be available). We strongly support EPA's conclusion in the preamble to the June 2010 proposed rule that fuel switching is not an appropriate control option²⁶. This conclusion is particularly apt with respect to forest products facilities, due to their need to employ a mix of fuels to control costs and their heavy reliance on biomass residuals and byproducts for fuel.

Many forest products facilities are located in rural areas that lack the necessary gas infrastructure. More generally, gas supplies are limited and industrial uses are of lower priority than residential uses during times of supply shortfalls and cold weather. Industrial boilers also compete with utility boilers for gas supplies and increasing electricity demand in the coming years, coupled with increasing reliance on natural gas to meet that demand, will place further strain on limited gas supplies and distribution networks. Mandated fuel switching for startup would be contrary to the goal of safeguarding fuel diversity, which is a fundamental objective of U.S. energy policy. A diverse fuel mix protects energy users from fuel unavailability, price fluctuations, and changes in regulatory practices. We believe that the MACT program is not an appropriate vehicle to force the wholesale changes among energy sources that fuel switching to natural gas for all unit startups would entail.

Commenter Name: Jennifer Youngblood
Commenter Affiliation: National Tribal Air Association
Document Control Number: EPA-HQ-OAR-2002-0058-3667-A2
Comment Excerpt Number: 8

Comment: Many startups and shutdowns occur under a set of constraints that are outside the control of the BPH operator. For instance, the BPH rate of change needs to meet criteria that protect the boiler or process heater from thermal damage, the BPH rate of change has to match the steam or process heat demand or, in some situations, the rate at which other equipment can fill that demand, and the rate of change has to match the fuel system's ability to rebalance. In some cases, a startup or shutdown may be impacted by weather changes (e.g., a sudden rain storm can significantly impact combustion efficiency during low firing operations, while having little impact on higher firing operations). The presence of associated equipment (e.g., emission controls, energy efficiency controls, combustion air fans, etc.) or the need to accommodate unusual activities (e.g., dry out repaired refractory, adjust new burners, etc.) can also impose constraints on the duration of these activities. While switching fuel may sound attractive, every fuel switch causes CO spikes and temporarily upsets combustion and thus a requirement to use a specific fuel during startup and shutdown would be counterproductive. Furthermore, the time needed for such switches would increase the duration of the startup or shutdown and, in some case, the facilities to store and/or handle a special fuel would cause increased storage vessel and fugitive emissions. For these reasons, a complex work practice that requires the use of particular fuels, limits the duration of a startups or shutdowns, or otherwise imposes constraints on startup and shutdown activities is unworkable.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3685-A2, excerpt 19, regarding requiring specific fuels during startup/shutdown.

Document Control Number: EPA-HQ-OAR-2002-0058-3667-A2
Comment Excerpt Number: 20

Comment: Specifying use of a particular fuel during startup and shutdown is impractical, would lengthen startup and shutdown periods, and should not be considered.

On page 80615 of the proposal preamble, EPA asks for comments on whether the startup and shutdown work practice should include a requirement to operate using specific fuels to reduce emissions during such periods. Such a requirement is impractical, since most boilers and process heaters only have access to one fuel. For those where more than one fuel is available, changing fuels to accommodate such a startup/shutdown requirement would cause enough upset in the operation to likely raise emissions by much more than any potential emissions savings from the relatively short, low mass emission rate startup and shutdown period. Furthermore, switching often fuels requires additional storage and controls and thus increases emissions (storage and fugitive emissions, at least).

Response: See the response to comment EPA-HQ-OAR-2002-0058-3685-A2, excerpt 19, regarding requiring specific fuels during startup/shutdown.

Commenter Name: Jennifer Youngblood
Commenter Affiliation: National Tribal Air Association
Document Control Number: EPA-HQ-OAR-2002-0058-3667-A2
Comment Excerpt Number: 21

Comment: EPA makes clear in this rulemaking that emissions are essentially the same for fuels in a particular subcategory (since there is one emission standard per subcategory). Thus, to impact emissions a source would have to switch to fuels from another subcategory. For instance, presumably, some units have the capability to switch from a liquid subcategory to a gas subcategory fuel. In switching fuels from a liquid to a gas or from a solid to a liquid or gas, where such capability exists, emissions increase because the air controls are not set for that operation (and often excess air must be used during the switch to handle transients). During startup and shutdown there is not time to reoptimize combustion conditions for a different fuel because everything is changing. So, in addition to emissions associated with loss of control and low rates for the normal fuel, there will be increased emissions from firing a different fuel and not starting from optimized operation of that fuel. In addition, changing between subcategories requires notice to permitting Agencies and will require separate reporting under this proposal in the periodic report. Overall, there is unlikely to be any benefit from requiring a unit to change fuels during startup and shutdown, but there will most likely be an increase in emissions and in unnecessary and wasteful regulatory burdens imposed.

Commenter Affiliation: Eastman Chemical Company
Document Control Number: EPA-HQ-OAR-2002-0058-3669-A2
Comment Excerpt Number: 32

Comment: EPA also solicits comments on the idea to require use of specific fuels to minimize emissions during such periods. Eastman objects to any mandated use of such fuels as natural gas during startup. Some boilers such as stoker boilers have no natural gas burners to even consider such use. Emissions are minimized by ensuring control devices are energized (excepting the case

of a spray dryer absorber, when sorbent spray cannot be started until the flue gas reaches a certain minimum temperature). Other units may initiate startup on natural gas but begin the introduction of coal in order to complete the startup because the gas burners are not sized to provide sufficient thermal energy to allow full startup of all downstream equipment.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3685-A2, excerpt 19, regarding requiring specific fuels during startup/shutdown.

Comment: Work Practice Standards for Startup and Shutdown. We welcome the decision to address the startup and shutdown periods and ensure that boiler operators are trained in startup and shutdown procedures, particularly in procedures to minimize emissions. However, the proposal relies only on work practice standards during the startup and shutdown phases while not establishing numeric emission limits or other performance metrics for units for those phases. As suggested in the proposed reconsideration, we would support requiring the use of specific fuels during the startup and shutdown phases that would reduce harmful air emissions in the absence of emissions standards (EPA, 2011d).

Response: Thank you for your support for requiring the use of clean fuels during startup. See the response to comment EPA-HQ-OAR-2002-0058-3685-A2, excerpt 19, regarding requiring specific fuels during startup/shutdown.

Comment Excerpt Number: 7

Comment: In response to EPA solicitation, we oppose any time limitation on shutdowns and startups. The duration of shutdowns and startups should be determined solely by the time required to complete in a safe and effective manner the scope of the work to be performed. Imposing time limitations will be disruptive to the already complex shutdown and startup procedures, and could even create unsafe conditions. Additionally, EPA requested comments on whether to include the use of specific fuels during shutdown and startup periods. We also oppose this provision as a standard requirement, since it would be impractical to implement in many occasions.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3465-A1, excerpt 5, regarding maximum time limit for startup/shutdown. See the response to comment EPA-HQ-OAR-2002-0058-3685-A2, excerpt 19, regarding requiring specific fuels during startup/shutdown.

Commenter Affiliation: Alyeska Pipeline Service Company
Document Control Number: EPA-HQ-OAR-2002-0058-3684-A2
Comment Excerpt Number: 5

Comment: Alyeska supports EPA's recognition that the startup and shutdown of boilers are different from normal operation. Alyeska agrees with the API/NPRA comments that a work standard is the proper standard. For example, the VMT boilers must be run at their intermediate and upper ranges during part of startup to ensure proper tuning over the full operating range before being returned to normal service. For this reason startup will include periods when the boilers are operated at that or above 25%. Only a reasonable work practice approach ensures that boilers are started up safely and efficiently to ensure effective routine operations after startup.

Finally, there is no alternative fuel for these boilers. They can only operate on gaseous fuel as described above and on liquid distillate fuel, also described above. Prescribing a startup alternative fuel is not remotely feasible.

Response: See the responses to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 46, regarding 25% load SS definition threshold, and comment EPA-HQ-OAR-2002-0058-3659-A2, excerpt 5, regarding use of manufacturer's specifications. See the response to comment EPA-HQ-OAR-2002-0058-3685-A2, excerpt 19, regarding requiring specific fuels during startup/shutdown.

Comment: Definitions for Startup and Shutdown Periods Should be Revised to Allow for the Full Range of Startup and Shutdown Events

The VI does not support EPA's proposed definitions for "startup" and "shutdown." As proposed, periods of startup and shutdown include only cold start and complete shutdown (i.e., no fuel in the unit). The VI submits that the proposed definitions are based on boiler operating terms and by their plain language appear to exclude process heaters. Further, these definitions do not account for actual boiler and process heater operating conditions, which may involve periods of cycling up and down without a complete shutdown.

EPA proposes to define startup as "the period between the state of no combustion in the unit to the period where the unit first achieves 25 percent load (i.e., a cold start)." Similarly, EPA proposes to define shutdown as "the period that begins when a unit last operates at 25 percent load and ending with a state of no fuel combustion in the unit." EPA's decision to key these definitions to specific load parameters appears to exclude process heaters, which do not achieve a "percent load" in defining a startup or shutdown sequence. A process heater's startup sequence is based on increased fuel firing rate, not load percent, because process heaters are designed to transfer heat indirectly to a process material in order to create a chemical reaction (e.g., cracking ethylene dichloride into vinyl chloride monomer).

Response: See the responses to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 46, regarding 25% load SS definition threshold, and comment EPA-HQ-OAR-2002-0058-3659-A2, excerpt 5, regarding use of manufacturer’s specifications.

Commenter Name: Richard Krock

Commenter Affiliation: The Vinyl Institute

Document Control Number: EPA-HQ-OAR-2002-0058-3526-A1

Comment Excerpt Number: 15

Comment: The definitions do not accurately capture the range of operations that constitute startup and shutdown for process heaters. EPA states in the preamble that the “definitions are intended to ensure that units cannot cycle in and out of startup or shutdown,” presumably to prevent an affected source from actively managing the load to limit compliance requirements. There are logical reasons for preventing units from cycling in and out of startup or shutdown, such as the decreased efficiency and increased emissions common to such periods; the need for minimizing reintroduction of combustibles into the burners and thereby reducing number of ignitions for safety reasons; protection of refractory material from cracking and spalling during complete cooldowns; and protection of tubes and tube supports from the bending, cracking and breaking consequences associated with rapid thermal expansion or contraction from improper cooling down or heating up. Because of the sometimes intermittent need for a process heater, however, a process heater may be re-started after an activity, which does not bring it down to a “cold start,” but rather to a “warm start.” A “warm start” also may occur after a maintenance activity or a partial shutdown for replacement of equipment. Similarly, there may be shutdown events that do not meet EPA’s proposed definition. For example, a process heater may be on warm shutdown for purposes of maintenance, replacement of a tube, emission monitoring maintenance, or temporary shutdown due to a process-related issue. The CAA requires that the standards established under section 112(d) be “achievable” and is not intended to prohibit necessary maintenance activities. These activities are typically short in duration, infrequent, and meet EPA’s stated reasons in the final Boiler MACT for applying work practice standards to startup and shutdown:

EPA determined that it is not feasible to require stack testing—in particular, to complete the multiple required test runs—during periods of startup and shutdown due to physical limitations and the short duration of startup and shutdown periods. Operating in startup and shutdown mode for sufficient time to conduct the required test runs could result in higher emissions than would otherwise occur. Based on these specific facts for the boilers and process heater source category, EPA has developed a separate standard for these periods, and we are finalizing work practice standards to meet this requirement.

Consequently and because the proposed definitions of startup and shutdown do not address all startup and shutdown events, nor are they written for both process heaters and boilers, the VI recommends that EPA revise the definitions of startup and shutdown and remove the requirements for cold starts and complete shutdown, at least for units that do not normally operate at high load conditions. Good combustion practices can be followed at all times to minimize emissions.

Response: See the responses to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 46, regarding 25% load SS definition threshold, and comment EPA-HQ-OAR-2002-0058-3659-A2, excerpt 5, regarding use of manufacturer's specifications.

Commenter Name: Jennifer Youngblood

Commenter Affiliation: National Tribal Air Association

Comment Excerpt Number: 15

Comment: The proposed work practice in Table 3 Item 5 requires "... you must ensure that boiler operators are trained in startup and shutdown procedures, including maintenance and cleaning, safety, control device startup, and procedures to minimize emissions; ..." We see two issues with this wording. First, it only mentions boiler operators, but the requirements apply to process heaters as well. We suggest the word "boiler" be deleted. Second, maintenance and cleaning are not generally operator responsibilities and certainly are not done during startup and shutdown periods as defined in the rule, and thus there is no need for operators to be trained on these techniques. Where such maintenance is needed mechanics are generally called in. These mechanics may be employees, regular maintenance contractors, or outside boiler or process heater specialists, depending on the need. Furthermore, maintaining a boiler or process heater is a very general term covering everything from sheet metal work to refractory to instrumentation to extremely specialized burner and tube technology, little of which has anything to do with combustion efficiency and none of which has anything to do with startup and shutdown. Thus, we see no need for such a broad and unclear requirement in a startup and shutdown work practice and no way of demonstrating compliance. The requirement to train operators on maintenance and cleaning should be deleted since these activities have nothing to do with assuring good combustion during startup and shutdown and are not the operator's responsibility in any case.

Response: See the responses to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 46, regarding 25% load SS definition threshold, and comment EPA-HQ-OAR-2002-0058-3659-A2, excerpt 5, regarding use of manufacturer's specifications.

12C. Startup/Shutdown: Applicability to Operating Parameters and Opacity

Commenter Name: David A. Buff, Golder Associates Inc.

Commenter Affiliation: Florida Sugar Industry (FSI)

Document Control Number: EPA-HQ-OAR-2002-0058-3504-A1

Comment Excerpt Number: 50

Comment: FSI supports EPA's decision to establish work practice standards for periods of startup and shutdown, rather than enforcing emission limits. The FSI is not aware of any emissions data for bagasse fired boilers that were obtained during startup and shutdown conditions, other than the CO data for U.S. Sugar Boiler No. 8, which has a CO CEMS. The FSI also supports EPA's determination that operating parameter limits and opacity limits should not apply during periods of startup and shutdown, because work practices standards will apply during these times.

Response: The EPA thanks the commenter for their support.

Commenter Name: J. Michael Geers

Commenter Affiliation: Duke Energy

Document Control Number: EPA-HQ-OAR-2002-0058-3543-A1

Comment Excerpt Number: 8

Comment: EPA then describes monitoring O2 levels as part of the work practice standards for startup and shutdown. 76 Fed. Reg. 80,602

In the final standards, Duke Energy strongly cautions EPA about requirements it might impose upon operations regarding O2 levels during start-up periods for safety reasons. During start-up, operators are required to maintain sufficient levels of excess air in their boilers to guard against the danger of explosion and other potential forms of damage. The procedures for operating a specific boiler are first specified by the boiler manufacturer, and then if needed, adapted to reflect site specific circumstances. Failure to use procedures such as these has resulted in fires, explosions, equipment damage, injury and at times loss of life. In no way should EPA attempt to impose limits or controls that would run counter to the safe operating procedures established by manufacturers and operators. Because of the wide variety of boiler sizes, types and classes, EPA should instead require operators to follow established procedures for that particular unit that follow good combustion practices.

Response: The EPA has made clarifications to Table 2 to indicate that operating parameter limits and opacity limits do not apply during periods of startup and shutdown, as work practices and not numeric emission standards apply during these times.

Commenter Name: Jennifer Youngblood

Commenter Affiliation: National Tribal Air Association

Document Control Number: EPA-HQ-OAR-2002-0058-3667-A2

Comment Excerpt Number: 11

Comment: The proposed work practice for BPH during start-up and shutdown are appropriate in concept for units subject to emission limits, but the specifics need revision to make the requirements clearer, less costly, and more workable.

The work practice requirements that apply during startup and shutdown for boilers and process heaters subject to Table 1 or 2 numerical emission limits during normal and malfunction operation are located in Item 5 of Table 3. However, Item 5 of Table 3 is not labeled as being limited to startup and shutdown periods and that labeling should be corrected to only apply the startup and shutdown work practice during periods of startup and shutdown. This work practice

is not needed when the Table 1 and 2 numerical emission limits are being met, since those standards, particularly the CO standard assure good combustion. Furthermore, by referencing "startup and shutdown periods" it would be clear that the O2 monitoring requirement does not apply during periods of no fuel combustion, which is currently unclear.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3543-A1, excerpt 8.

Commenter Name: Jennifer Youngblood

Commenter Affiliation: National Tribal Air Association

Document Control Number: EPA-HQ-OAR-2002-0058-3667-A2

Comment Excerpt Number: 16

Comment: Item 5 in Table 3 could be read to require continuous monitoring of oxygen during periods of startup and shutdown and even automatic control. As we discuss in Comment II.9.A.2, not all BPH have oxygen analyzers and the rule should be clear that continuous monitoring is not required in such cases. Furthermore, where units have automatic control, it is often necessary for safety reasons to go to manual control during portions of the startup and shutdown operation. As burners are lit or extinguished, oxygen demands can swing wildly and large amounts of excess air are needed to avoid firebox vacuum situations or burner extinguishment and explosive reignition. During these times draft is usually set at a fixed position and large amounts of excess air supplied until operations stabilize. The rule should be clear that automatic draft, oxygen or CO control is not required during startup and shutdown periods.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3543-A1, excerpt 8.

Commenter Name: M.L. Steele

Commenter Affiliation: CraftMaster Manufacturing, Inc.

Document Control Number: EPA-HQ-OAR-2002-0058-3814-A1

Comment Excerpt Number: 14

Comment: The CO CEM's limits in Table 2 are not applicable during periods of start-up and shutdown per §63.7575(a), however oxygen must be monitored during these periods. Because CO is being monitored in place of oxygen, the implication is that CO must be monitored at all times including start-up and shutdown. Then CO CEMS data is reported during start-up and shutdown but that data is not considered in the demonstration of compliance with the limits in Table 2. Please confirm that this is USEPA's intent.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3543-A1, excerpt 8.

Commenter Name: Mark Anthony

Commenter Affiliation: Alyeska Pipeline Service Company

Document Control Number: EPA-HQ-OAR-2002-0058-3684-A2

Comment Excerpt Number: 7

Comment: We are concerned that there are interpretations of 63.7535 through 63.7541 that could require that Compliance Requirements be met during periods of startup or shutdown. Specifically: section § 63.7500(e) states that the standards, except the work practice standards in

Table 3, do not apply during periods of startup and shutdown, however under the Continuous Compliance Requirements sections, § 63.7535 through § 63.7541 there is no mention that data taken during episodes of startup or shutdown should not be considered or used in evaluating ongoing emission or monitoring requirements. Several of the provisions, such as § 63.7535(c) acknowledge that monitoring data taken during monitoring system malfunctions, out-of-control periods, or during repairs on the monitoring systems should not be used, but it is silent for periods when the boiler is in startup or shutdown. Another example includes Section § 63.7540(a)(8) for CO CEMS which states under § 63.7540(8)(ii) to "maintain a CO emission limit below or at your applicable alternative CO CEMS based standard in Tables 1 and Table 2 of this subpart at all times" (emphasis added). Perhaps the means to address this concern would be to add to 63.7535(d) and 63.7540(a)(ii): "except during periods of startup and shutdown as described by § 63.7500(e)".

Response: The EPA disagrees with the commenter. Unlike periods of malfunctions or system QA/QC, the EPA intends for data to be collected during startup and shutdown. In the revised work practice for startup and shutdown Table 3 specifies that CMS are to be operated during periods of startup and shutdown. The definition of 30-day rolling average includes a phrase to indicate what data is valid for use in the computation of continuous monitoring and/or emissions requirement and this definition excludes startup and shutdown.

Commenter Name: James Pew

Commenter Affiliation: Earthjustice, Clean Air Council, Partnership for Policy Integrity

Document Control Number: EPA-HQ-OAR-2002-0058-3511-A1

Comment Excerpt Number: 42

Comment: In its final rule, the Agency also provided a separate work-practice standard for start-ups and shut-downs, arguing that the "short duration of startup and shutdown periods," along with unspecified "physical limitations," make the procedures imposed during general operations impracticable. 76 Fed. Reg. at 15,642. The Act does not allow the Agency to avoid numeric standards merely because one set of procedures – here, those established by the Rule to govern normal operations – are impracticable. Work practice standards are permitted only where it is entirely "infeasible to prescribe or enforce an emission standard." 42 U.S.C. § 7412(h)(1). Moreover, the Agency did not exclude start-ups and shut-downs from the data used to determine the MACT floor. By doing so, it inflated its limits substantially (especially in light of its variability adjustment). That inflation is wholly unjustified, if the limits do not apply during start-up and shut-down; startup and shutdown emissions do not reflect the sources' actual emissions during other operations.

Response: Consistent with *Sierra Club v. EPA*, EPA has established standards in this final rule that apply at all times. In establishing the standards in this final rule, EPA has taken into account startup and shutdown periods and has established different standards for those periods. EPA has revised this final rule to require sources to meet a work practice standard, which requires following the manufacturer's recommended procedures for minimizing periods of startup and shutdown, for all subcategories of new and existing boilers and process heaters (that would otherwise be subject to numeric emission limits) during periods of startup and shutdown. EPA believes that the expected startup and shutdown emissions over the averaging periods established for the NESHAP are not likely to cause a violation of the standards. EPA also found no evidence that suggested that emissions were higher during startup or shutdown that would indicate a need for an alternate standard for these periods and the commenter provided no data or basis to show that sources cannot comply with the standards as proposed. Thus we set standards based on available information as contemplated by section 112.

Comment Excerpt Number: 8

Comment: Oxygen is not measured in the firebox. Oxygen is measured at the outlet of the boiler. The rule needs to be revised to more broadly describe where oxygen may be measured.

Response: The EPA agrees with the commenter and has revised the definition of oxygen analyzer system in final rule to explain the location of the measurement more broadly. Further, the requirement to measure oxygen on an hourly basis throughout startup and shutdown has been removed from the final rule.

Commenter Name: Jennifer Youngblood

Commenter Affiliation: National Tribal Air Association

Document Control Number: EPA-HQ-OAR-2002-0058-3667-A2

Comment Excerpt Number: 9

Comment: The terms of "state of no combustion" and "state of no fuel combustion" should be consolidated and explained. We recommend consolidating on "state of no fuel combustion." By either defining this term or adding a sentence to the startup and shutdown definitions, it should be clarified that pilot lights may remain lit during the state of no fuel combustion. When a BPH is shutdown for the purpose of entry, pilot lights will be extinguished, but when the BPH is shutdown but not being entered safety concerns will often require that the pilots remain lit. Even if there is no safety concern, it is often common practice to light pilots well ahead of actually firing up any burners, so as to be prepared, and it is common practice to keep the pilots lit after all the burners are shutdown, until the BPH fuel gas is blinded away. Pilots are very small flames, usually fueled with natural gas and thus result in immeasurably small emissions and having them operating on their own certainly does not justify the burdens associated with the startup and shutdown work practice (O₂ monitoring).

Response: The EPA has revised the definitions of startup and shutdown in the final rule and the terms "state of no combustion" and "state of no fuel combustion" are no longer used in the final rule language.

Commenter Name: Jennifer Youngblood

Commenter Affiliation: National Tribal Air Association

Document Control Number: EPA-HQ-OAR-2002-0058-3667-A2

Comment Excerpt Number: 14

Comment: In those cases where a CO CEMS is being used to demonstrate compliance with the Table 1 or 2 CO limits, operators should be allowed to use CO instead of oxygen for demonstrating good combustion practice during startup and shutdown periods. Thus, we also recommend that the first sentence of the Table 3 Item 5 requirement be changed to allow monitoring of either oxygen or CO.

Response: We have revised item 5 of Table 3 to be consistent with the recent MATS rule at 40 CFR part 63 subpart UUUUU. This adjustment requires the source to operate all CMS during

startup and shutdown, which would include operation of CO CEMS for units demonstrating compliance with the CO emission limits with a CEMS.

Commenter Name: Matthew Todd

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 85

Comment: Proposed §63.7501(a)(3):

The frequency, amount and duration of the excess emissions (including any bypass) were minimized to the maximum extent practicable during periods of such emissions; and

Proposed §63.7501(a)(4):

If the excess emissions resulted from a bypass of control equipment or a process, then the bypass was unavoidable to prevent loss of life, personal injury, or severe property damage; and

Proposed §63.7501(a)(4) correctly identifies safe operation as a necessity and is an improvement over earlier language that suggested the Agency was not concerned about personnel safety unless the injuries avoided were "severe". We appreciate the recognition that all injuries are a concern and should be avoided.

However, similarly, EPA should not be suggesting that they are only concerned with "severe" property damage. Nor is it clear how the Agency expects an operator, during an emergency, to decide whether the property damage that might occur due to a failure to act would be "severe." The word "severe" should be deleted from this proposed language. Any situation that presents a risk to property or equipment could be more or less "severe" in the end, but the level of potential damage cannot be precisely foreseen. In addition, there can be substantial room for disagreement about what constitutes "severe" property damage. The use of "severe" renders this requirement too subjective to be practically enforceable.

Moreover, potential "severity" is not the proper focus. Bypassing control equipment or the process in some cases might be an appropriate exercise of good air pollution control practices. For example, a bypass can be the appropriate response to an upset (e.g., in order to prevent fouling of the pollution control equipment media). Such a bypass could save the control device from damage and thus result in reduced control equipment downtime or increased pollutant removal.

Response: The EPA believes that a bypass of control equipment or a process, which results in a violation, should be an exception and not undertaken lightly, and has maintained the word "severe" in this criteria.

12D. Affirmative Defense for Malfunctions

Commenter Name: Lorraine Gershman

Commenter Affiliation: American Chemistry Council (ACC)

Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1

Comment Excerpt Number: 106

Comment: Turning to the 2-day notification requirement in § 63.7501(b), ACC notes that EPA recently proposed almost identical affirmative defense requirements in the CMAS proposed reconsideration but omitted the 2-day notification. It is ACC's understanding that the Agency has been persuaded by comments submitted by ACC and others that the 2-day notification requirement is onerous and burdensome. ACC also understands that EPA may be revisiting some of the other requirements in the affirmative defense provisions in order to further reduce the burden on facilities, and therefore request that in its reconsideration EPA abandon the 2-day notification requirement in the final provisions for major source boilers and process heaters.

Unlike the 2-day notification which is triggered by the "initial occurrence of the malfunction," the 45-day period for submitting a written report demonstrating that the party qualifies for the affirmative defense commences on the date of "the initial occurrence of the exceedance of the standards." Complying with this timeframe presents several challenges, specifically because most of the content of the report may not be able to be created until the malfunction has ended, which in some cases could be a number of days.

While there is an opportunity for requesting and obtaining an extension of the reporting deadline of up to 30 additional days, the owner/operator must comply with the original 45-day requirement unless and until he hears back from EPA that the extension request is approved. However, there is no requirement for EPA to act timely in granting or denying an extension request. At a minimum, the rule should provide a timeframe within which EPA must act on a request and if it fails to do so, the request would be considered granted.

Response: The EPA has evaluated some of the affirmative defense criteria, and is revising both the immediate notification and 45-day malfunction report. Instead, the final rule allows owners or operators seeking to assert an affirmative defense to demonstrate, with all necessary supporting documentation (as was required under the proposed 45-day report), that it has met the affirmative defense criteria by submittal of the affirmative defense report in the first periodic compliance, deviation report or excess emission report otherwise required after the initial occurrence of the violation of the relevant standard (which may be the end of any applicable averaging period). If such compliance, deviation report or excess emission report is due less than 45 days after the initial occurrence of the violation, the affirmative defense report may be included in the second compliance, deviation report or excess emission report due after the initial occurrence of the violation of the relevant standard. This change provides sources with sufficient time to demonstrate that they have met the required affirmative defense criteria.

Comment: The two-day notice requirement in proposed §63.7501(b) associated with claiming the affirmative defense is unreasonable and will introduce wasteful and unnecessary burdens and

should not be finalized. It serves no purpose and certainly violates the Paperwork Reduction Act and Executive Order 13563 intents.

In order to use the affirmative defense, a source is required by proposed §63.7501(b) to file a notice of that intent within two business days of the start of the event. For many events the information required to decide if there was an exceedance and if the source will claim the affirmative defense will not be available within two business days from the start of the event. In order not to forfeit their rights in light of this unreasonable deadline, sources must file an affirmative defense notice for every event whether or not there was an actual exceedance.

Many compliance requirements have long averaging times (30 day averages are commonly specified in this rule). Where the averaging times exceed two days, a source often will not even know there was an exceedance in the two days after the start of the event. Even with a one day averaging time, sources would have to decide in less than one day if they plan to use the affirmative defense and make the notice that day. If this notice requirement is maintained the time period for the notice (and for meeting the other affirmative defense requirements) should start with the date that the site determined in accordance with rule requirements that there was an exceedance, rather than from the start of the event.

Under the Refinery Consent Decrees, such notices have typically not been required and lack of these notices does not appear to have had any impact on the use of the affirmative defense or caused any increase in emissions or lessened the response to the event. In fact, if anything, diverting resources from dealing with an event and making reports to authorities associated with immediate response to the event is more likely to have detrimental environmental impacts rather than positive impacts. These notices certainly serve no purpose for immediate response, since notices for those purposes are already required to be provided on a much shorter timeframe to the National Response Center and State and Local Authorities.

Additionally, it is unclear how to handle this notice requirement for multiple exceedances associated with a single event. For instance, a single event could cause a 30 day rolling average to be exceeded for each of 30 days. Are 30 2-day notices required? If this requirement is maintained, the Agency should clarify that only one notice (and one follow-up demonstration letter) is required even if an individual event causes multiple excess emission exceedances.

For these reasons, we recommend EPA delete the 2-day initial notification requirement as unnecessary, leaving in place only the written demonstration requirement. We believe there is no reason the notification of the decision to use the affirmative defense should be on a different schedule as the supporting information submittal. In fact, EPA never explains what action they will take as a result of this notice or why they need it, since they will not have any information on which they will evaluate the event and its response until the later submission.

Response: The EPA has removed the requirement to notify the EPA within two days of violation of a standard in order to be able to avail themselves to a claim for affirmative defense and instead requires that the affirmative defense report be included in the first periodic compliance, deviation report or excess emission report otherwise required after the initial occurrence of the violation of the relevant standard (which may be the end of any applicable averaging period). If such compliance, deviation report or excess emission report is due less than 45 days after the initial occurrence of the violation, the affirmative defense report may be

included in the second compliance, deviation report or excess emission report due after the initial occurrence of the violation of the relevant standard .

Comment: Assuming *arguendo* that EPA had authority to promulgate any type of affirmative defense to penalties for malfunctions, EPA should also promulgate the following provision: EPA should promulgate specific public reporting and notification requirements for malfunctions, or any emission exceedance that occurs of which an operator is aware. Specifically, EPA should require that when a facility provides EPA with a notification of a malfunction or emission standard exceedance under the regulations, this notice will be made publicly available on EPA's website within 14 days. In addition, EPA should promulgate the requirement that when such notification is made, the facility must also provide for community notification of the malfunction or emission standard exceedance within 2 business days, through an appropriate public forum that is designed to reach residents who live near the facility, including but not limited to a notice on the facility's own website (if it has one), a written notice to the local municipality and local school district, a press release to the local newspaper, radio, and TV news station that contains information community members may need to protect themselves and their families from the additional air pollution.

Response: The EPA has evaluated some of the affirmative defense criteria, and is revising both the immediate notification and 45-day malfunction report. The EPA has removed the requirement to notify the EPA within two days of violation of a standard in order to be able to avail themselves to a claim for affirmative defense. Instead, the final rule allows owners or operators seeking to assert an affirmative defense to demonstrate, with all necessary supporting documentation (as was required under the proposed 45-day report), that it has met the affirmative defense criteria by submittal of the affirmative defense report in the first periodic compliance, deviation report or excess emission report otherwise required after the initial occurrence of the violation of the relevant standard (which may be the end of any applicable averaging period). If such compliance, deviation report or excess emission report is due less than 45 days after the initial occurrence of the violation, the affirmative defense report may be included in the second compliance, deviation report or excess emission report due after the initial occurrence of the violation of the relevant standard. This change provides sources with sufficient time to demonstrate that they have met the required affirmative defense criteria.

Comment: The immediate notification (within 2 working days) requirement as a pre-requisite for asserting the affirmative defense should be eliminated for at least the following reasons and replaced with a semi-annual reporting requirement:

It is burdensome and duplicative of emergency response reporting requirements under SARA/CERCLA/EPCRA and many state regulations for larger excess emission events.

This new requirement will contradict many existing reporting rules by requiring the reporting of emission quantities well below CERCLA/SARA/State Agency Reportable Quantities. Thus, agencies will be flooded with reports of very small excess emissions.

The rule structure encourages reporting to the agency even if the owner/operator is not sure if an exceedance of an emission limit has occurred for fear of not being able to claim the affirmative defense. Thus, agency reporting systems will become "clogged" with insignificant reports further complicating the ability of all resources to respond to a larger event.

The rule is not clear to whom the reports should be submitted (e.g., the EPA Regional Office, State or Local Agency, LEPC).

Response: See the responses to comment EPA-HQ-OAR-2002-0058-3510-A1, excerpt 106 and EPA-HQ-OAR-2002-0058-3677-A2, excerpt 90 regarding two-day malfunction notice and 45-day affirmative defense requirements.

Comment: The majority of malfunctions that result in excess emissions are likely to be minor in nature and result in only minimal excess emissions. In these cases, the stringent reporting requirements in the proposed rule, which include a notification by telephone or facsimile no later than 2 days after the event and submittal of a follow-up report within 45 days of the event, appear burdensome, particularly in light of the compliance reporting requirements of the rule.

Response: See the responses to comments EPA-HQ-OAR-2002-0058-3510-A1, excerpt 106 and EPA-HQ-OAR-2002-0058-3677-A2, excerpt 90 regarding two-day malfunction notice and 45-day affirmative defense requirements.

Comment: In order to take advantage of the affirmative defense for a malfunction, an IB operator that does “experience[] an exceedance . . . during a malfunction,” must provide notice to EPA within two days of the “initial occurrence” of the malfunction, and must keep logs of actions taken “in response to the excess emissions.” Requiring IB operators to keep logs of malfunctions is not unreasonable. However, requiring notice to EPA of events before the IB operator even knows whether *an exceedance* will occur, requiring logs in response to exceedances (rather than malfunctions), or requiring that the exceedance occur at the same time as the malfunction, are not reasonable. EPA must rework the rule to recognize that some malfunctions that ultimately result in exceedance of an emission limit may occur long before the exceedance is recorded. EPA should simply require the maintenance of the appropriate records surrounding any event identified by the IB operator as a malfunction and leave the reporting until after all of the data relevant to the compliance determination for the affected period are collected.

Response: See the responses to comments EPA-HQ-OAR-2002-0058-3510-A1, excerpt 106 and EPA-HQ-OAR-2002-0058-3677-A2, excerpt 90 regarding two-day malfunction notice and 45-day affirmative defense requirements. Comment: Because the affirmative defense provisions in the Final ICI MACT were based on EPA’s 1999 enforcement policy, cited above, they lack the sharpness of regulatory language,

rendering the provisions arbitrary and capricious. Also, since an affirmative defense exists under the Agency's 1999 SSM Policy, it is unnecessary to codify. Essentially the ICI MACT provisions are a recordkeeping trap for the unwary or the extremely busy – in other words, those responding to crisis events where safety and recovery activities overwhelm the capacity to meet less critical book keeping requirements. A source should be allowed to prove its entitlement to the affirmative defense using any credible evidence which would otherwise be admissible in court. Sources should not have to maintain an operating log which is not required by the underlying NESHAP just to preserve eligibility for the affirmative defense. Perhaps most importantly, sources experiencing a malfunction should not be forced to direct contemporaneous resources to documenting its actions rather than to actually acting to address safety issues and minimize the excess emissions caused by the malfunction and to correct the malfunction itself.

Response: See the responses to comments EPA-HQ-OAR-2002-0058-3510-A1, excerpt 106 and EPA-HQ-OAR-2002-0058-3677-A2, excerpt 90 regarding two-day malfunction notice and 45-day affirmative defense requirements.

Comment: Proposed §63.7501(a)(6):

All emissions monitoring and control systems were kept in operation if at all possible, consistent with safety and good air pollution control practices; and

Proposed §63.7501(a)(7):

All of the actions in response to the excess emissions were documented by properly signed, contemporaneous operating logs; and

Proposed §63.7501(a)(7) should be revised to reflect the use of current recordkeeping technology. The use of signed logs has declined with the use of various forms of electronic recordkeeping. Rather operators are directed to focus on optimizing operations, and responding to malfunctions, if necessary, not filling out paperwork. Records are maintained of the event characteristics (often electronically), the amount of excess emissions and the supporting calculations (generally done after the event ends and kept in an engineering file), and the steps taken to deal with the event and the excess emissions (sometimes electronically, sometimes on paper). In fact, most records are electronic and thus it may not even be possible to have them "signed".

Thus, we recommend the following replace the proposed language.

Records are maintained documenting the event, including actions taken to minimize emissions.

Response: As an alternative, the EPA accepts electronically signed operating logs where the format and method of submission meets the regulatory criteria and are compatible with the EPA

and the delegated authorities' electronic submission systems. Any source submitting records electronically should exercise due diligence to assure receipt by the EPA and the delegated authority.

Comment: DoD supports the terms for affirmative defense provisions during malfunctions as written with one exception regarding the notification. To establish the affirmative defense, the owner or operator must timely meet the notification requirements in §63.7501(b). This notification requirement states that *“The owner or operator of the facility...shall notify the Administrator by telephone or facsimile (fax) transmission as soon as possible, but no later than 2 business days after the initial occurrence of the malfunction....”* DoD believes limiting the notification methods by using telephone or facsimile (fax) transmission would prohibit the use of better and more effective emerging electronic technologies. For example, Wright-Patterson AFB currently reports malfunctions to the Ohio EPA using the e-Business Air Services web-based platform and anticipates doing the same for the Boiler MACT because Ohio EPA is considered the “Administrator” for this rule. The Air Services platform is more effective than telephone or fax in that all data transmittals immediately become part of the permanent record stored by the Agency and the regulator assigned to the facility is instantly notified of the submittal. Thus, there would be no more lost faxes or erased phone messages if EPA were to allow the notification by other approved methods such as e-Business Air Services. In addition, many notifications are currently made via e-mail systems. The rule should not limit notification methods to telephone and fax when other methods are acceptable to the permitting authority.

Recommendation DoD recommends changing §63.7501(b) as follows to allow other notification methods to be used if approved by the permitting authority: *“The owner or operator of the facility experiencing an exceedance of its emission limitation(s) during a malfunction shall notify the Administrator by telephone, ~~or~~ facsimile (fax) transmission, or other commonly used electronic methods as soon as possible, but no later than 2 business days after the initial occurrence of the malfunction, if it wishes to avail itself of an affirmative defense to civil penalties for that malfunction. The owner or operator seeking to assert an affirmative defense shall also submit a written report to the Administrator within 45 days of the initial occurrence of the exceedance of the standard in §63.7500 to demonstrate, with all necessary supporting documentation, that it has met the requirements set forth in paragraph (a) of this section. The owner or operator may seek an extension of this deadline for up to 30 additional days by submitting a written request to the Administrator before the expiration of the 45-day period. Until a request for an extension has been approved by the Administrator, the owner or operator is subject to the requirement to submit such report within 45 days of the initial occurrence of the exceedance.*

Response: See the responses to comments EPA-HQ-OAR-2002-0058-3510-A1, excerpt 106 and EPA-HQ-OAR-2002-0058-3677-A2, excerpt 90 regarding two-day malfunction notice and 45-day affirmative defense requirements. See the response to comment EPA-HQ-OAR-2002-

0058-3677-A2, excerpt 81 regarding affirmative defense provisions. See the response to comment EPA-HQ-OAR-2002-0058-3677-A2, excerpt 87 regarding use of technology for recordkeeping and reporting.

Comment: In a recently proposed rule (77 Fed. Reg. 4522, 4538, January 30, 2012), EPA proposed dropping the immediate notification process and simply requiring a written report within 45 days of the malfunction. CRWI suggests that the Agency adopt the same change in this regulation. If the Agency keeps the immediate notification requirement, faxing is an obsolete technology. EPA should allow notification by e-mail or other electronic means. As facilities and EPA move toward electronic recordkeeping, it makes no sense to require keeping a "properly signed, contemporaneous operating logs" as a requirement for an affirmative defense. There are a number of electronic methods for maintaining records currently available (and more will likely be available in the future). As such, we suggest modifying this provision. It should also be noted that it is impossible to eliminate the causes for certain malfunctions (e.g., lightning strikes).

Response: See the responses to comments EPA-HQ-OAR-2002-0058-3510-A1, excerpt 106 and EPA-HQ-OAR-2002-0058-3677-A2, excerpt 90 regarding two-day malfunction notice and 45-day affirmative defense requirements. Comment: EPA's Reconsideration Proposal retains the requirement that malfunction events be addressed through an affirmative defense. The Reconsideration Proposal does not address the myriad issues arising from its treatment of malfunction events through an affirmative defense and ignores the practical realities of that process. An affirmative defense is not an appropriate substitute for development of an achievable standard applicable during malfunction events reflecting what is actually achieved in practice by the best performing sources when a malfunction occurs.

The affirmative defense regulations inappropriately shift the burden to a source to disprove alleged violations, requiring a detailed analysis of each malfunction event, compiled into a nine-part report due within 45 days of the event. See 40 CFR 63.7501. The drafting of these reports will occupy a significant amount of employee time at significant cost to the regulated community, and the review of the reports will place a significant burden on already understaffed and overtaxed agencies. This is not a workable solution.

Response: See the responses to comments EPA-HQ-OAR-2002-0058-3510-A1, excerpt 106 and EPA-HQ-OAR-2002-0058-3677-A2, excerpt 90 regarding two-day malfunction notice and 45-day affirmative defense requirements.

Comment: We also believe the notification requirements should be streamlined. The initial two-day notification should include telephone, facsimile or e-mail. Facsimile communications are rarely used having been essentially replaced by email correspondence. Email notifications are simple and direct, and can be tracked easily and archived for recordkeeping purposes. WM recommends that the initial two-day notification should include a brief summary of the nature of the malfunction, corrective action taken and root cause analysis. Often the initial notification will

include enough information for the regulators to confirm a malfunction meets the criteria. For example, a lightning strike on a utility interconnect transformer that causes a temporary facility power outage would be easily discernible as a malfunction. If the agency needed more information, it could request a full report in 45 days, or ask the facility to include a full report in the next semiannual compliance report. Such streamlined requirements for malfunction events would be consistent with several states' requirements and would ensure ample regulatory oversight.

Comment Excerpt Number: 10

Comment: To many engineers, the term "root cause analysis" implies a specific formal process. For many malfunctions, the cause is immediately obvious and a formal process for determining the cause is not needed. When a malfunction occurs, the expectation is that the facility will correct the problem as quickly as possible and return to their operating window. A formal root cause analysis is typically limited to very significant events or repeat events. For example, if a thermocouple fails, the most likely cause is a bad thermocouple. The first response is to simply replace the thermocouple. However, if a second thermocouple fails within a short period of time, then something else may be causing that event to happen and a more detailed analysis may be needed. It may take several failures before the real cause is identified. Here a formal root cause analysis may be needed, but it certainly is not needed to replace the first failed thermocouple. The proposed language assumes that all malfunctions are equally significant and need an identical degree of investigation. For example, a missing data point due to a malfunction of the data acquisition system is not as significant as a power failure or a catastrophic event such as fire or explosion. CRWI believes that a formal root cause analysis should only be used when other reasonable methods fail to show what caused the malfunction or when the serious nature of an event might make such an analysis necessary. Moreover, other tools may be more appropriate (e.g., failure mode and effect, fault tree, etc.) or more powerful tools may be introduced in the future. The facility is the only one that can and should decide what tool to use to determine the cause of the malfunction.

Part of this problem may be in communications. To some companies and potentially to some local regulators, the term "root cause analysis" implies a specific formal process. There are several techniques that may be called "root cause analysis," depending on the author and industry. If EPA intends for the facility to investigate and fix the source of the malfunction so that it is less likely to recur, CRWI supports that concept but suggests that the Agency use an alternative term that does not carry a specific meaning. However, if the Agency envisions a formal process for determining the root cause for every malfunction, no matter how simple, CRWI believes this is unnecessary and would result in excess efforts with no environmental gains.

Response: The EPA did not intend to prescribe a specific methodology, given that “root cause analysis” is not a defined term in the rule. The EPA believes it has provided clear criteria within the affirmative defense provisions to support the development of an affirmative defense report. The EPA believes that these provisions will result in a minor administrative burden, but will result in sources analyzing their violation emissions to reduce or avoid those emissions in the future, which is an environmental benefit. A root cause analysis is not mandatory and is only required if a source seeks to assert an affirmative defense. However, such an analysis is beneficial in resolving or preventing violations and excess emissions whether the source seeks to assert the affirmative defense or not. A root cause analysis is one example of what constitutes good air pollution control practices to minimize emissions. A root cause analysis is not required for every malfunction, it is *only required* for those malfunctions for which the source chooses to assert an affirmative defense.

Comment: 40 CFR §63.7501 (a)(9) A written root cause analysis has been prepared, the purpose of which is to determine, correct, and eliminate the primary causes of the malfunction and the excess emissions resulting from the malfunction event at issue. The analysis must also specify, using best monitoring methods and engineering judgment, the amount of excess emissions that were the result of the malfunction.

~~40 CFR §63.7501 (a)(9) A written root cause analysis has been prepared, the purpose of which is to determine, correct, and eliminate the primary causes of the malfunction and the excess emissions resulting from the malfunction event at issue. The analysis must also specify, using best monitoring methods and engineering judgment, the amount of excess emissions that were the result of the malfunction.~~

Dow Comment: EPA should not require preparation and submission of a formal root cause analysis as this would have a chilling effect on internal communications regarding the root cause investigation and would detract from the goal of ensuring a candid inquiry into the event. The cause of even smaller malfunction events is routinely investigated within the industry, and no regulation is necessary to require this to happen.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3454-A1, excerpt 10 regarding root cause analysis requirement.

Comment: Requirement (a)(9) is problematic in that it requires a party to prepare a “written root cause analysis to determine, correct and eliminate the primary causes of the malfunction and the excess emissions resulting from the malfunction event at issue.” This directive assumes that the cause of any and all malfunctions can be determined, corrected and eliminated. If a malfunction by definition is unavoidable, unforeseeable, and not reasonably preventable, it may be that the first time it happens its primary cause cannot be determined. If the cause cannot be determined, it cannot be corrected. So unless a party can figure out why something malfunctioned, it cannot claim to have had a “malfunction.” Not only is this nonsensical, it is a significant departure in EPA policy with no justification provided. For example, in the General Provisions applicable to New Source Performance Standards (NSPS), EPA recognizes that the cause of a malfunction cannot always be known. *See*, 40 CFR 60.7(b)(2) which requires that written reports of excess emissions include the “nature and cause of any malfunction, *if known...*” (Emphasis added.) Lastly, requiring a party to eliminate the primary causes of the malfunction, without regard to “taking into consideration the cost of achieving such” elimination and the “non-air quality health and environmental impacts and energy requirements” associated with its elimination is unreasonable and entirely inconsistent with the criteria for standards established under § 112(d) of the CAA.³³ [Footnote 33: For example, it might be theoretically possible to eliminate the excess emissions associated with the malfunction by installing totally redundant pollution control equipment, or pollution control equipment with far more capacity than needed for normal operations. But this would not reflect the performance of the best performers on which the MACT “floor” is to be based, nor would it appear to take cost and other factors into consideration as the statute requires for beyond-the-floor MACT standards. Moreover, the proposed requirement to eliminate “the primary causes of the malfunction” and not just to eliminate “the excess emissions resulting from the malfunction event” lies entirely outside of EPA’s authority under the CAA, which is limited to establishing and enforcing emission limitations, not dictating plant operations.]

Comment: §63.7501(a)(1)(ii) and (iii) are vague, subjective and potentially impossible criteria to meet. Once an event occurs, you may learn enough to realize that you “could” have prevented it. In fact, that is the very basis for the later requirement to do a root cause analysis (RCA) – so a facility can identify the root cause and plan to prevent such events. Even being hit by a meteor would fail this test, since one theoretically could have planned for it, even if the chance of such an occurrence is infinitesimal. In short, these demonstration requirements are so vague and subjective as to make the affirmative defense potentially unavailable and applicable only at the whim of the interpreting regulator.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3454-A1, excerpt 10 regarding root cause analysis requirement.

Comment: Proposed §63.7501(a)(9):

A written root cause analysis has been prepared, the purpose of which is to determine, correct, and eliminate the primary causes of the malfunction and the excess emissions resulting from the malfunction event at issue. The analysis shall also specify, using best monitoring methods and engineering judgment, the amount of excess emissions that were the result of the malfunction.

EPA should clarify that the requirement to perform a RCA "to determine, correct, and eliminate the primary causes of the malfunction" does not require that identified corrective actions be completed within the demonstration period. Long-term corrective action can require facility modifications that can take months to years to design and execute or procedural changes that can take weeks to months to safely implement.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3454-A1, excerpt 10 regarding root cause analysis requirement.

Comment Excerpt Number: 19

Comment: Specifying work practice standards for malfunctions is more consistent with the CAA, and the D.C. Circuit's interpretation of it in *Sierra Club*, than EPA's proposed affirmative defense. Although the court found that the existing "general duty to minimize emissions" was not sufficient to qualify as a § 112(d) standard, and that EPA had "not purported to act under section 112(h)," it also made clear that the CAA *does not require* that the same standard apply to all periods. *Id.* at 1021 (recognizing that "continuous" under CAA § 302(k) does not mean "unchanging"), 1028. In short, nothing prohibits EPA from establishing § 112(h) standards for periods that include a malfunction, even if § 112(d) standards apply at other times. In fact, establishing § 112(h) standards for malfunctions would be more consistent with the *Sierra Club* ruling than applying clearly unachievable standards and allowing a defense to penalties, since an unachievable § 112 standard is not "section 112-compliant." It also would be more consistent with Congressional intent. By allowing work practice and other requirements under § 112(h), Congress clearly intended that sources be *provided the opportunity to be fully in compliance with some standard at all times*. Nothing in § 112 suggests that Congress intended to require a source owner or operator to certify "violation" of a § 112 standard as a result of an event the source could not reasonably control. EPA should adhere to that intent and specify reasonable work practice or operational requirements for periods of malfunctions.

Response: The affirmative defense criteria are not requirements that a source must meet. In an action to enforce a violation of a standard caused by a malfunction, a source can choose to assert

an affirmative defense. The affirmative defense is not relevant to malfunctions that do not result in violations of emission standards.

The EPA has determined that CAA section 112 does not require that emissions that occur during periods of malfunction be factored into development of CAA section 112 standards. As the EPA further explained, accounting for malfunctions would be difficult, if not impossible, given the myriad different types of malfunctions that can occur across all sources in the category and given the difficulties associated with predicting or accounting for the frequency, degree, and duration of various malfunctions that might occur. Setting work practice standards under section 112 presents the same issues as setting numerical emission limits given the varied nature of malfunctions. Thus EPA does not agree with commenter's suggestion that EPA apply work practices for malfunction events.

Comment Excerpt Number: 23

Comment: *Affirmative Defense Provisions During Malfunctions*

ACA believes that EPA's approach to malfunction episodes including the proposed affirmative defense for violating an emissions standard during a malfunction episode is inconsistent with the Clean Air Act (CAA), and EPA should address this issue by promulgating a separate standard for malfunction periods. In the proposed reconsideration EPA plans to apply the emissions standards, which were calculated during periods of normal operation, at all times, including during a malfunction event. EPA is seeking comment on an affirmative defense provision requiring the owner or operator of a boiler to meet a list of criteria during a malfunction episode, and failing to meet these criteria exposes the source to potential civil penalties for violating the emissions standards. This approach, including the proposed affirmative defense, is inappropriate for the following reasons.

EPA fails to provide an adequate legal justification or explain why the emission standard that applies during normal operations should also apply during an unexpected malfunction period, even though the Agency did not consider malfunction periods when calculating and establishing the MACT requirements for this source category. Under the CAA § 112(d)(3), EPA must calculate and promulgate emissions standards that are achievable by the best performing existing sources. When calculating this emissions level, however, EPA did not consider the potential for malfunctions or how these events would affect achievable emissions levels. Therefore, during a malfunction episode, the Agency cannot expect affected sources to meet the emissions limits that were calculated during normal periods of operation. The Agency's approach in this regard is contrary to the CAA § 112(d).

Response: EPA recognizes that even equipment that is properly designed and maintained can sometimes fail and that such failure can sometimes cause an exceedance of the relevant emission standard. (See, e.g., State Implementation Plans: Policy Regarding Excessive Emissions During Malfunctions, Startup, and Shutdown (Sept. 20, 1999); Policy on Excess Emissions During Startup, Shutdown, Maintenance, and Malfunctions (Feb. 15, 1983)). EPA, therefore, added an

affirmative defense to civil penalties for exceedances of numerical emission limits that are caused by malfunctions. The affirmative defense criteria are not requirements that a source must meet. In an action to enforce a violation of a standard caused by a malfunction, a source can choose to assert an affirmative defense. The affirmative defense is not relevant to malfunctions that do not result in violations of emission standards.

EPA disagrees with comments that criticize the affirmative defense criteria as being overly vague or unduly restrictive and complex. The EPA believes that courts are well equipped and often do evaluate and apply the type of criteria set forth in the affirmative defense. Many of the conditions were modeled after the conditions of the affirmative defense in the EPA's SIP SSM policy, which several states have adopted into their SIPs. (See, e.g., State Implementation Plans: Policy Regarding Excessive Emissions During Malfunctions, Startup, and Shutdown (Sept. 20, 1999); Policy on Excess Emissions During Startup, Shutdown, Maintenance, and Malfunctions (Feb. 15, 1983)). We do not have any indication that parties to enforcement proceedings have had any significant difficulties applying the terms of these SIP affirmative defenses. In addition, the EPA's view is that use of consistent terms in establishing affirmative defense regulations and policies across various CAA programs will promote consistent implementation of those rules and policies.

EPA explained its view that a formal approach of an affirmative defense was preferable to an informal enforcement discretion approach for the following reasons: "First, the existence of a formal process better informs the public of the policy and factual issues which will underline enforcement of the standards. Second, affected industries which are making good-faith efforts to meet the standards will on the whole welcome a regularized means of informing the Agency in detail of the circumstances surrounding unavoidable emission excesses. Third, the Agency expects to benefit substantially from the information it will gain about the operation of the processes in question, for both future enforcement and standard setting." 37 Fed. Reg. 17,214, 17,214-15 (Aug. 25, 1972). The affirmative defense is not an informal enforcement discretion approach of the type that EPA rejected in 1972 and provides the benefits associated with the formalized approach that EPA identified in its 1972 proposal. See, *Mont. Sulphur & Chem. Co. v. United States EPA*, 2012 U.S. App. LEXIS 1056 (5th cir. Jan 19, 2012)(in rejecting industry argument that reliance on the affirmative defense was not adequate, court stated "[h]owever, here the EPA does not rely on enforcement discretion alone, but specifically promulgates an affirmative defense in the FIP, which clearly defines the requirements to avoid penalties.").

Comment: Although EPA has eliminated its unlawful compliance exemption for periods of startup, shutdown, and malfunction, the agency's final rule includes an "affirmative defense to penalties that purports to bar courts from imposing any penalties on sources that violate their emission standards during a malfunction and satisfy certain agency created conditions related to preventing malfunctions and controlling malfunction emissions. 76 Fed. Reg. at 80615. See 76 Fed. Reg. at 15642.

Response: The EPA has determined that CAA section 112 does not require that emissions that occur during periods of malfunction be factored into development of CAA section 112 standards. As the EPA further explained, accounting for malfunctions would be difficult, if not impossible, given the myriad different types of malfunctions that can occur across all sources in the category and given the difficulties associated with predicting or accounting for the frequency, degree, and duration of various malfunctions that might occur. Setting work practice standards under section 112 presents the same issues as setting numerical emission limits given the varied nature of malfunctions. Thus EPA does not agree with commenter's suggestion that EPA apply work practices for malfunction events. EPA recognizes that even equipment that is properly designed and maintained can sometimes fail and that such failure can sometimes cause an exceedance of the relevant emission standard. (See, e.g., State Implementation Plans: Policy Regarding Excessive Emissions During Malfunctions, Startup, and Shutdown (Sept. 20, 1999); Policy on Excess Emissions During Startup, Shutdown, Maintenance, and Malfunctions (Feb. 15, 1983)). EPA, therefore, added an affirmative defense to civil penalties for exceedances of numerical emission limits that are caused by malfunctions. The affirmative defense criteria are not requirements that a source must meet. In an action to enforce a violation of a standard caused by a malfunction, a source can choose to assert an affirmative defense. The affirmative defense is not relevant to malfunctions that do not result in violations of emission standards.

EPA disagrees with comments that criticize the affirmative defense criteria as being overly vague or unduly restrictive and complex. The EPA believes that courts are well equipped and often do evaluate and apply the type of criteria set forth in the affirmative defense. Many of the conditions were modeled after the conditions of the affirmative defense in the EPA's SIP SSM policy, which several states have adopted into their SIPs. (See, e.g., State Implementation Plans: Policy Regarding Excessive Emissions During Malfunctions, Startup, and Shutdown (Sept. 20, 1999); Policy on Excess Emissions During Startup, Shutdown, Maintenance, and Malfunctions (Feb. 15, 1983)). We do not have any indication that parties to enforcement proceedings have had any significant difficulties applying the terms of these SIP affirmative defenses. In addition, the EPA's view is that use of consistent terms in establishing affirmative defense regulations and policies across various CAA programs will promote consistent implementation of those rules and policies.

EPA explained its view that a formal approach of an affirmative defense was preferable to an informal enforcement discretion approach for the following reasons: "First, the existence of a formal process better informs the public of the policy and factual issues which will underline enforcement of the standards. Second, affected industries which are making good-faith efforts to meet the standards will on the whole welcome a regularized means of informing the Agency in detail of the circumstances surrounding unavoidable emission excesses. Third, the Agency expects to benefit substantially from the information it will gain about the operation of the processes in question, for both future enforcement and standard setting." 37 Fed. Reg. 17,214, 17,214-15 (Aug. 25, 1972). The affirmative defense is not an informal enforcement discretion approach of the type that EPA rejected in 1972 and provides the benefits associated with the formalized approach that EPA identified in its 1972 proposal. Commenter Name: Jennifer Youngblood
Commenter Affiliation: National Tribal Air Association
Document Control Number: EPA-HQ-OAR-2002-0058-3667-A2
Comment Excerpt Number: 22

Comment: EPA Is required to take malfunctions into account when adopting BPH emission limits, either by including them in the data used to develop the emission limitation that applies to normal operations or by treating any emission limitation that does not consider malfunctions as a beyond-the-floor limit and providing all the required regulatory analysis needed to support such a conclusion for comment.

EPA says it “has determined that malfunctions should not be viewed as a distinct operating mode.”⁴⁰ Since, as defined in §63.2, a malfunction must result in “excess” emissions, and to be “excess” emissions must exceed the emissions that occur during normal operations, it is clear that an emission occurrence cannot be both a malfunction and normal operations. EPA made this clear in the preamble to the original finalized part 63 General Provisions⁴¹ where they stated “Excess emissions occur during [SSM] when air pollution is emitted in quantities greater than anticipated by the applicable standard. . . . Excess emissions are typically direct indications of noncompliance with the emission standard and, therefore, are directly enforceable.” Thus, EPA has been clear that excess emissions, a malfunction criterion, can only occur when emissions exceed the emission limit for normal operations.

The natural outgrowth of the new position that malfunctions are normal operations is to consider malfunctions in developing the emission limit for normal operations. Yet, EPA concludes the opposite but offers no explanation of its contradictory positions that malfunctions are normal operations, but should not be considered in developing the emission limitations applicable during normal operations. In fact, EPA specifically draws the illogical conclusion that since malfunctions are normal operations “any emissions that occur at such times do not need to be factored into development of CAA section 112(d) standards, which, once promulgated, apply at all times.”⁴² Once again no explanation is provided for this nonsensical statement.

[Footnote 40: 76 Fed. Reg. 15613 (March 21, 2011)]

[Footnote 41: 59 Fed. Reg. Preamble Section IV.F.1, (March 16, 1994)]

[Footnote 42: 76 Fed. Reg. 15613 (March 21, 2011)]

Response: The commenter appears to have misinterpreted EPA’s explanation for its approach to malfunctions and to have confused several concepts. As explained in the preamble, EPA has determined that CAA section 112 does not require that emissions that occur during periods of malfunction be factored into development of CAA section 112 standards. EPA’s position is not that “malfunctions *are* normal operations” as commenter claims. During periods of malfunction, the otherwise applicable standard applies. Specifically, if a malfunction occurs during a period of startup or shutdown and the standard for startup or shutdown is different than the standard during normal operations, then the standard that applies during that malfunction is the startup or shutdown standard.

Further, 40 CFR 63.2 defines malfunctions a type of failure of equipment or process which causes, or have the potential to cause, “the emissions limitations” in an applicable standard to be exceeded, and does not refer to the emission limit “for normal operations” as commenter suggests. EPA included this limitation in the definition of malfunction to ensure that minor or routine events need not be addressed by SSM plans or reported to the Agency. 68 Fed. Reg. 32592 (May 30, 2003). Nothing in the definition of malfunction contradicts EPA’s rationale for its approach to malfunctions.

Document Control Number: EPA-HQ-OAR-2002-0058-3449-A1

Comment Excerpt Number: 21

Comment: For malfunctions that result in only small levels of excess HAP emissions, instead of requiring the regulated entity to establish and prove an affirmative defense, EPA should establish a work practice requirement that requires the owner/operator to stop the emissions, stop the malfunction, and to return to normal operations as soon as practical. For example, if a CO concentration limit is exceeded as a result of a fuel system malfunction, but is quickly corrected (e.g. within 1 to 2 hours), then the owner/operator should not have to go through the exercise of asserting an affirmative defense.

Response: See the responses to comments EPA-HQ-OAR-2002-0058-3500-A1, excerpt 19 and EPA-HQ-OAR-2002-0058-3502-A1, excerpt 23 regarding establishing work practice standards for malfunctions.

Document Control Number: EPA-HQ-OAR-2002-0058-3452-A1

Comment Excerpt Number: 8

Comment: We propose that owners and operators be able to utilize an exemption for malfunctions if:

(1) they maintain records documenting that the event in question met the definition of a malfunction contained in 40 CFR 63.2, the owner and/or operator took steps to minimize emissions during the malfunction to the extent practicable, and the owner and/or operator took reasonable actions designed to minimize the possibility that this type of event will occur in the future; and

(2) they report the malfunction event in their annual or biennial compliance report. Maintenance of such records would generally be required under proposed 40 CFR 63.7555(d)(7) and (8) of the proposed rule and compliance reporting would be required under 40 CFR 63.7550. To the extent that the recordkeeping and reporting requirements described above are met for a malfunction event, that event should be presumed to be a malfunction and exempt from the emission limitations of the rule without the need for the owner or operator to present information in affirmative defense of an enforcement proceeding.

Response: See the responses to comments EPA-HQ-OAR-2002-0058-3500-A1, excerpt 19 and EPA-HQ-OAR-2002-0058-3502-A1, excerpt 23 regarding establishing work practice standards for malfunctions.

Document Control Number: EPA-HQ-OAR-2002-0058-3454-A1

Comment Excerpt Number: 13

Comment: CRWI believes that not allowing an affirmative defense in an action for injunctive relief is arbitrary and capricious. As the D.C. Circuit Court stated in *Essex Chem. Corp. v. Ruckelshaus*, 486 F.2d 427, 433 (D.C. Cir. 1973) a case reviewing a § 111 rule, the court held that startup, shutdown, or malfunction ("SSM") provisions are "necessary to preserve the reasonableness of the standards as a whole." The D.C. Circuit Court of Appeals has also noted that "[a] technology-based standard discards its fundamental premise when it ignores the limits inherent in the technology." *NRDC v. EPA*, 859 F.2d 156, 208 (D.C. Cir. 1988). Therefore, EPA should not apply a policy drafted to "ensure that SIPs provide for attainment and maintenance of the national ambient air quality standards ("NAAQS") and protection of prevention of significant deterioration (PSD) increments" and other risk-based programs, SIP SSM Memo at 2, to the CAA § 129 technology-based program.

Response: See the responses to comments EPA-HQ-OAR-2002-0058-3500-A1, excerpt 19 and EPA-HQ-OAR-2002-0058-3502-A1, excerpt 23 regarding establishing work practice standards for malfunctions.

Commenter Affiliation: United States Sugar Corporation

Document Control Number: EPA-HQ-OAR-2002-0058-3496-A1

Comment Excerpt Number: 2

Comment: The CAA allows the enactment of work practice standards whenever "it is not feasible in the judgment of the Administrator to prescribe or enforce an emission standard for control of a hazardous air pollutant or pollutants." 42 U.S.C. § 7412(h)(1). This is the case for malfunctions. As EPA acknowledged, "even equipment that is properly designed and maintained can sometimes fail" and "cause an exceedance of the relevant emission standard." 76 Fed. Reg. at 15613. In the case of bagasse boilers, many of the malfunctions stem from variations in the physical properties of the cane itself, which can be affected by factors beyond the control of the operator, such as cane variety, cane quality (*e.g.*, early take out VB, second or third ratoon cane), and environmental factors (*e.g.*, weather, seasonal variation, moisture level, freeze damage). The variable nature of the fuel can in turn cause mechanical difficulties, and sugar mill boilers routinely experience significant fluctuations in operations that are beyond the reasonable control of the boiler and sugar mill operators. Therefore, "it would be difficult to set a standard that takes into account the myriad different types of malfunctions that can occur across all sources in the category." *Id.* This is precisely the context in which a work practice standard is most effective.

U.S. Sugar requests EPA reconsider its use of an affirmative defense for malfunction events and instead develop a feasible work practice standard.

Response: See the responses to comments EPA-HQ-OAR-2002-0058-3500-A1, excerpt 19 and EPA-HQ-OAR-2002-0058-3502-A1, excerpt 23 regarding establishing work practice standards for malfunctions.

Commenter Name: Lee Zeugin and Lauren Freeman

Commenter Affiliation: Utility Air Regulatory Group (UARG)

Document Control Number: EPA-HQ-OAR-2002-0058-3500-A1

Comment Excerpt Number: 17

Comment: The CAA does not require EPA to apply numerical emission standards to all operating periods. CAA § 112(h)(4) only requires numerical emission standards if it "is feasible" to promulgate and enforce them. If it is "not feasible" in the "judgment of the Administrator" to prescribe or enforce an emission standard, CAA § 112(h)(4) allows EPA to promulgate "design, equipment, work practice, or operational standards, or a combination thereof," instead. Infeasibility includes situations where emissions cannot be measured due to "technological and economic limitations." CAA § 112(h)(2)(B).

EPA acknowledges that even properly designed and maintained equipment can fail. 76 Fed. Reg. at 15,642. However, rather than make a determination whether or not it is "feasible" to prescribe emission standards for these periods, as § 112(h)(1) and (4) seem to contemplate, EPA chooses to ignore such periods in the standard setting process. Specifically, EPA concludes that malfunctions should "not be viewed as a distinct operating mode" and therefore, "emissions that occur at such times do not need to be factored into development of CAA section 112(d) standards." *Id.* Because EPA does not factor malfunctions (even malfunctions of "best performing" sources) into its proposed standards, it is unlikely the standards will be achievable if a significant malfunction occurs.

Response: See the responses to comments EPA-HQ-OAR-2002-0058-3500-A1, excerpt 19 and EPA-HQ-OAR-2002-0058-3502-A1, excerpt 23 regarding establishing work practice standards for malfunctions.

Commenter Name: Lee Zeugin and Lauren Freeman

Commenter Affiliation: Utility Air Regulatory Group (UARG)

Document Control Number: EPA-HQ-OAR-2002-0058-3500-A1

Comment Excerpt Number: 18

Comment: UARG agrees with EPA that equipment can and will fail unexpectedly, and that some allowance must be made for periods of malfunction. Application of numerical limits to such malfunctions without a defense to penalties clearly would violate the Due Process Clause and the Eighth Amendment prohibition on Cruel and Unusual Punishment.¹³ Although UARG appreciates EPA’s willingness to exercise enforcement discretion and to provide a defense to civil penalties, EPA’s refusal to take malfunctions into account when setting standards is not reasonable. Section 112 does not limit EPA’s standard setting obligation to “distinct operating modes.” As the D.C. Circuit ruled in *Sierra Club v. EPA*, CAA § 112 requires that some “section 112-compliant standard” apply at all times (not just during distinct operating modes). 551 F.3d 1019, 1027 (D.C. Cir. 2008). If EPA has determined that it is not technologically or economically “feasible” to gather emissions data necessary to establish numerical emissions standards that “take malfunctions into account,” EPA should promulgate operational and work practice standards as § 112(h) specifies. To the extent EPA is attempting to distinguish between the “impracticality” of taking malfunctions into account, and the “infeasibility” of prescribing and enforcing standards for such events, EPA’s position is difficult to square with the Act.

[Footnote]

Comment: The affirmative defense is not an adequate replacement for standards during malfunction episodes and EPA should establish a separate standard for periods of malfunction. The affirmative defense provisions do not remedy the underlying problems with the Agency’s approach to malfunction periods. Furthermore, it would likely be impractical for the Agency to recalculate the entire standard and account for malfunctions. Instead, EPA should break down the standard and establish different requirements for periods of malfunction. This approach realizes the limitations of control technology and its effect on emissions levels, and also satisfies

the court's decision in *Sierra Club v. EPA*, 551 F.3d 1019 (D.C. Cir. 2008), by ensuring that standards (even though there may be multiple different standards) are in place at all times during periods of startup, shutdown, and malfunction.

Response: See the responses to comments EPA-HQ-OAR-2002-0058-3500-A1, excerpt 19 and EPA-HQ-OAR-2002-0058-3502-A1, excerpt 23 regarding establishing work practice standards for malfunctions.

Comment: AFFIRMATIVE DEFENSE PROVISIONS DURING MALFUNCTIONS

In the Final Boiler Rule, EPA for the first time stated that boilers and process heaters would be required to comply at all times with emission limitations derived from and established for normal operations, even during periods of malfunction. This is contrary to a long history of recognition by EPA and the courts that technology-based emission standards and requirements established in NESHAP and new source performance standard (NSPS) rules need to account for unavoidable excess emissions associated with malfunctions. EPA now chooses to disregard its historical position and instead proposes an "affirmative defense" that may be available to avoid civil penalties (but not other relief available under the CAA) for emission exceedances associated with malfunctions. The affirmative defense provisions appear in § 63.7501 of the final rule and require an owner/operator of a major source boiler or process heater to prove by a preponderance of evidence that it has met each and every requirement in order to avail itself of the affirmative defense to a claim for civil penalties. ACC believes that EPA should abandon the approach it is taking to addressing malfunctions, that is, offering an affirmative defense, and instead should use its statutory authority in § 112(h) to establish a work practice or operational standard that would reduce emissions during a malfunction event.

Response: See the responses to comments EPA-HQ-OAR-2002-0058-3500-A1, excerpt 19 and EPA-HQ-OAR-2002-0058-3502-A1, excerpt 23 regarding establishing work practice standards for malfunctions.

Comment: The *Sierra Club* ruling vacated the exemption for excess emissions during periods of startup, shutdown and malfunction (SSM) contained in the General Provisions, 40 C.F.R. part 63 subpart A, for emission standards for hazardous air pollutants regulated under CAA § 112. At issue was EPA's determination that excess emissions during periods of SSM experienced by major sources are not violations as long as the owner/operator has prepared a startup, shutdown and malfunction plan and complies with a "general duty" to minimize emissions. The court concluded that the "general duty" was not a "section 112-compliant standard." However, the court did not state nor even imply that the same emission limits that EPA establishes for normal operations must apply during SSM events.

In fact, the court clearly indicated that section 302(k)'s "inclusion of [the] broad phrase" "any requirement relating to the operation or maintenance of a source to assure continuous emission reduction" in the definition of "emission standard" suggests that EPA can establish MACT standards consistent with CAA section 112 "without necessarily continuously applying a single standard." 551 F.3d 1019, 1021. The court accepted that "continuous" for purposes of § 302(k) "does not mean unchanging...." *Id.* at 1021. The court also highlighted the fact that Congress recognized that it might not be feasible in all cases to prescribe or enforce a numeric emission standard. Congress therefore provided in § 112(h) for the establishment of a "work practice" or "operational standard." *Id.* at 1028.

Response: See the responses to comments EPA-HQ-OAR-2002-0058-3500-A1, excerpt 19 and EPA-HQ-OAR-2002-0058-3502-A1, excerpt 23 regarding establishing work practice standards for malfunctions.

Comment: EPA is now soliciting comments on its determination in the final rule that boilers and process heaters must meet the numeric emission standards established for steady-state operations at all times, including periods of malfunction, and that the only enforcement relief that may be available in the event of a malfunction is an "affirmative defense" to civil penalties. EPA is completely silent on why it is not exercising the discretion and authority provided by Congress in § 112(h) to address boiler and process heater malfunctions; in fact, it does not even mention that statutory authority in discussing malfunctions. If EPA wants to act "consistent with" the court's decision in *Sierra Club*, it should promulgate standards for periods of malfunction pursuant to its § 112(h) authority. If EPA chooses to reject the flexibility that Congress clearly intended the Agency to use when it is not feasible to prescribe or enforce a numeric emission standard, it needs to explain its legal authority for these affirmative defense requirements and why each of the requirements is reasonable and justified, taking into consideration alternative solutions.

Response: See the responses to comments EPA-HQ-OAR-2002-0058-3500-A1, excerpt 19 and EPA-HQ-OAR-2002-0058-3502-A1, excerpt 23 regarding establishing work practice standards for malfunctions.

Comment: *EPA Failed To Present Any Rationale or Justification for its Decision To Apply the Same Numeric Emission Standards Established for Normal Operations for an Abnormal Event, i.e., A Malfunction.*

As highlighted above, the court in *Sierra Club* did not state that EPA must apply the same standards it establishes for normal operations during periods of SSM. The court's holding is clear that "some" § 112 standard must "govern" SSM events but it did not specify which § 112 standard. In this rulemaking, EPA concluded that the numeric emission limitations established for normal operations also must be attained during a malfunction event. However, EPA has provided no explanation as to why it believes that boilers and process heaters reasonably could be expected to meet the emissions standards applicable to steady-state operations during a malfunction event.

EPA claims that it somehow "presents significant difficulties" to attribute malfunctions to a "best performing" source. *Id.* To the contrary, it "presents significant difficulties" when EPA ignores the undisputed existence of malfunctions even at best-performing sources, and claims falsely that the best-performing sources "achieve" emission levels that they undisputedly do not achieve part of the time. Since EPA describes malfunctions as being sometimes unavoidable or "not reasonably preventable," despite proper design and maintenance of equipment, there is no basis

for EPA's conclusion that malfunction events are not representative of best-performing sources. See 76 Fed. Reg. 15613. True, one goal (although not "the goal") "of best performing sources is to operate in such a way as to avoid malfunctions of their units." *Id.* But that is all the more reason why EPA must acknowledge the fact that those sources nevertheless experience malfunction events, rather than pretend otherwise.

[Footnote 30: See 40 C.F.R. § 60.8(c). For example, the D.C. Circuit recognized, in *Portland Cement Ass'n v. Ruckelshaus*, 486 F.2d 375, 398 (D.C. Cir. 1973), a decision reviewing standards under CAA section 111, that "'start-up' and 'upset' conditions due to plant or emission device malfunction, is an inescapable aspect of industrial life and that allowance must be made for such factors in the standards that are promulgated." *Id.* at 399. Similarly, in *Essex Chem. Corp. v. Ruckelshaus*, 486 F.2d 427, 432 (D.C. Cir. 1973), *cert. denied*, 416 U.S. 969 (1974), another section 111 case, the court held that SSM provisions are "necessary to preserve the reasonableness of the standards as a whole." *Id.* at 433. In *National Lime Ass'n v. EPA*, 627 F.2d 416 (D.C. Cir. 1980), another case reviewing emission standards promulgated under CAA section 111, the court held that the CAA requirement that NSPS be "achievable" means that the standards must be capable of being met "on a regular basis," including "under most adverse circumstances which can reasonably be expected to recur," including during periods of SSM. 627 F.2d at 431 n.46. See also *Marathon Oil Co. v. EPA*, 564 F.2d 1253, 1273-74 (9th Cir. 1977); *NRDC v. EPA*, 859 F.2d 156, 207-208 (D.C. Cir. 1988) (similar conclusion when considering analogous Clean Water Act requirements).]

Comment: EPA should look to the "best performing" sources to establish the appropriate § 112(h) work practice standards for a malfunction event. After all, a work practice standard like a numeric emission standard must be based on the emission reductions achieved by the best performing sources.

In failing to articulate the basis for its decision, the Agency also ignores the comments submitted by ACC and others strongly advocating for EPA to establish a work practice standard for malfunction events. This is not reasoned decision-making and ACC hopes that the Agency's "reconsideration" of its affirmative defense approach will prompt EPA to give reasonable consideration to the fact that a boiler that has a malfunction is not likely to be able to achieve the same level of emission reductions that it achieved and can achieve while operating at steady-state.

Response: See the responses to comments EPA-HQ-OAR-2002-0058-3500-A1, excerpt 19 and EPA-HQ-OAR-2002-0058-3502-A1, excerpt 23 regarding establishing work practice standards for malfunctions.

Comment Excerpt Number: 92

Comment: EPA's offering of an affirmative defense does not bear a reasonable relationship to the purpose of § 112 or its requirement to establish standards that consider and address the reality of a potential malfunction of technology. If EPA chooses to reject the flexibility that Congress clearly intended the Agency to use when it is not feasible to prescribe or enforce a numeric emission standard, it needs to explain why its affirmative defense approach is a better alternative than using the statutory authority provided in § 112(h) to establish a work or management practice for a malfunction period.

Response: See the responses to comments EPA-HQ-OAR-2002-0058-3500-A1, excerpt 19 and EPA-HQ-OAR-2002-0058-3502-A1, excerpt 23 regarding establishing work practice standards for malfunctions. Comment Excerpt Number: 94

Comment: EPA cannot rationally defend its view that applying the concept of —best performing is somehow inconsistent with a source experiencing a malfunction. See 76 Fed. Reg.15613. This ignores that there are work practices – such as monitoring operating parameters to identify a malfunction and stopping or cutting back the process accordingly – that represent the best practices for minimizing emissions during a malfunction. While the measures that represent these best practices will depend on facility-specific issues, such as process design, pollution control train, and other factors, they nonetheless represent the "the maximum degree of reduction in emissions of the hazardous air pollutants...achievable...through application of measures, processes, methods, systems or techniques" and reflect "the emission control that is achieved in practice by the best controlled similar source[s]" CAA § 112(d)(2) and (3).

Response: See the responses to comments EPA-HQ-OAR-2002-0058-3500-A1, excerpt 19 and EPA-HQ-OAR-2002-0058-3502-A1, excerpt 23 regarding establishing work practice standards for malfunctions.

Comment: For all of the reasons above, and in keeping with the court's holding in *Sierra Club*, ACC strongly encourages the Agency to abandon its affirmative defense approach as an appropriate and legal way to address excess emissions during a malfunction, and instead to use

its authority in § 112(h) to establish an emission standard using a management practice, work practice or operational standard to reduce emissions during a malfunction of a boiler or process heater.

Response: See the responses to comments EPA-HQ-OAR-2002-0058-3500-A1, excerpt 19 and EPA-HQ-OAR-2002-0058-3502-A1, excerpt 23 regarding establishing work practice standards for malfunctions.

Comment Excerpt Number: 17

Comment: As the NAM has previously commented, the EPA should establish work practices to address emissions during periods of malfunction. Given that the EPA's floor data does not consider malfunctions and that the statute requires that the MACT standard be "achievable," The EPA should set work practice requirements to address periods of malfunctions as well. CAA Section 112(h) allows the EPA to set work practice standards for situations where "it is not feasible in the judgment of the Administrator to prescribe or enforce an emission standard" Malfunctions fit with the situations described in the definition of "not feasible to prescribe or enforce an emission standard" as any situation where "the application of measurement methodology to a particular class of sources is not practicable due to technological and economic limitations." Emission testing for malfunctions would be near impossible to conduct given the sporadic and unpredictable nature of the events. Section 112(h) work practice standards, therefore, are well-suited to address malfunction periods and the complexities and challenges surrounding collecting data and establishing numerical standards for those events.

The NAM disagrees with the EPA's proposal to provide an affirmative defense for periods of malfunction. As has been discussed in various comments in this rulemaking, as well as others where the EPA has proposed a similar affirmative defense, the proposed affirmative defense is not a permissible substitute for setting emissions standards for periods of malfunction, and it is unreasonable and impracticable.

Response: See the responses to comments EPA-HQ-OAR-2002-0058-3500-A1, excerpt 19 and EPA-HQ-OAR-2002-0058-3502-A1, excerpt 23 regarding establishing work practice standards for malfunctions.

Comment: NEDA/Submits that the ICI MACT Outlaws Safety By Failing to Provide a Work Practice Standard for Boiler Malfunctions. Because EPA failed to take comment on the Affirmative Defense Provisions in the Final ICI MACT rule, codified at §63.7501, the December NPRM requests comment on the provisions. NEDA/CAP submits that the EPA has violated the Clean Air Act by failing to provide an “achievable” emission standard during malfunction events. While EPA recognizes that startup and shutdown are separate emission events that require establishment of work practice standards, the Agency determined that malfunctions should not be viewed as a distinct operating mode. 76 Fed. Reg. 15642. Therefore, the Agency determined that any emissions that occur at such times do not need to be factored into development of CAA section 112(d) standards, which, once promulgated, apply at all times and in the event that a source fails to comply with the applicable CAA section 112(d) standards as a result of a malfunction event EPA’s failure to provide an applicable standard during malfunction events outlaws good safety practices and violates CAA Section 112(d), which requires EPA to establish achievable MACT standards.

By requiring that a boiler meet the continuous emission limits during malfunctions, the ICI MACT Rule outlaws safety because it is not always possible to achieve emission limits during malfunction events. By doing so, EPA violated CAA Section 112(d)(4) by not providing for the development of work practice standards for malfunctions under CAA Section 112(h). The regulation must therefore be amended to provide for an applicable standard based on good work practices during unforeseeable and/or unavoidable malfunction events. EPA has provided no analysis showing that the best-performing, or MACT floor, boilers in each subcategory are capable of achieving the relevant emission limits during malfunction events.

Response: See the responses to comments EPA-HQ-OAR-2002-0058-3500-A1, excerpt 19 and EPA-HQ-OAR-2002-0058-3502-A1, excerpt 23 regarding establishing work practice standards for malfunctions.

Comment: EPA and Courts recognize that malfunction events are inescapable aspects of technology. EPA has consistently recognized that it may be technically infeasible for industrial sources to comply at all times with technology-based pollution control standards, particularly

during periods of startup and shutdown and during periods of malfunction. See e.g. 40 CFR §60.8 (general exclusion from compliance with the New Source Performance Standards that became law in 1973). The Courts also have explicitly recognized that start-up and upset conditions due to plant or emission device malfunctions are “an inescapable aspect of industrial life and that allowance must be made for such factors in the standards that are promulgated.” *Portland Cement Ass’n v. Ruckelshaus*, 486 F.3d 375. At 398 (D.C. Cir 1973) (reviewing CAA Sec. 111); see also *National Lime Association v. EPA* 627 F.3d 416, 431 n. 46 (D.C. Cir. 1980) (reviewing CAA Sec. 111); *NRDC v. EPA* 859 F.2d 156, 208 (D.C. Cir 1988); (CAA); *Marathon Oil Co. v. EPA*, 564 F.2d 1253, 1273-1274) (9th Cir. 1977) (EPA violated Clean Water Act by failing to provide an upset provision to address effluent conditions beyond the control of the permit holder).

Response: See the responses to comments EPA-HQ-OAR-2002-0058-3500-A1, excerpt 19 and EPA-HQ-OAR-2002-0058-3502-A1, excerpt 23 regarding establishing work practice standards for malfunctions.

Commenter Name: LESLIE SUE RITTS

Commenter Affiliation: National Environmental Development Association's Clean Air Project (NEDA/CAP)

Document Control Number: EPA-HQ-OAR-2002-0058-3529-A1

Comment Excerpt Number: 9

Comment: *Sierra Club v. EPA* does not bar the Agency from establishing applicable work practice standards during malfunctions. EPA argues that not only does it have insufficient information on which to establish a standard during malfunction events, but it suggests that such a standard would be prohibited under *Sierra Club v. EPA*, 551 F. 3d 1019 (D.C. Cir. 2008), *cert. denied*, 130 S. Ct. 1735 (2010). *Sierra Club* only found, however, that EPA could not automatically excuse emission violations during malfunction events by referencing the general MACT provisions. The case notably did not address standards that established where emission limitations were not feasible to prescribe work practice standards. See A. Kushner, Letter to Counsel *Re: Vacatur of Startup, Shutdown, and Malfunction (SSM) Exemption (40 CFR §§ 63.6(f)(1) and 63.6(h))* (July 22, 2009). That letter states that “EPA recognizes, however, that some sources * * * may be unable to comply with such standards during SSM events despite their best efforts, including adherence to 40 CFR §63.3(e)(1)(i) (*general requirement to minimize emissions at all times including periods of SSM, consistent with safety and good air pollution control practices*). Therefore EPA stated that the Agency:

“Commits to evaluating concerns raised with respect to specific Section 112(d) source category standards where the Agency determines that sources within a source category may have a limited ability to comply with those standards during periods of SSM. EPA intends to give the highest priority to reviewing and revising those Section 112(d) source category standards that may be difficult for sources to meet during an SSM period given the technological limitations of the processes involved.”

Id. 4. NEDA/CAP therefore submits that the Agency was unreasonable in failing to establish a work practice standard that was applicable when ICI boilers malfunction. The Affirmative Defense Provisions in the Final ICI MACT rule are not a substitute for failing to provide for

work practice standards similar to those provided for startup and shutdown. Most importantly they fail to protect an operator from criminal penalties and injunctive relief when reacting to malfunctions that result in emissions in excess of MACT emissions limits in the effort to protect employee and community safety and property.

Response: See the responses to comments EPA-HQ-OAR-2002-0058-3500-A1, excerpt 19 and EPA-HQ-OAR-2002-0058-3502-A1, excerpt 23 regarding establishing work practice standards for malfunctions.

Document Control Number: EPA-HQ-OAR-2002-0058-3529-A1

Comment Excerpt Number: 10

Comment: The “affirmative defense” provision in the Final ICI MACT Rule contains arbitrary language because it is an enforcement policy; on this basis it would be arbitrary and capricious to codify it in the ICI MACT. In lieu of establishing a work practice standard during malfunction events, as EPA has done for “startups” and “shutdowns” the ICI MACT provides for an affirmative defense to civil penalties for emission violations that occur during malfunctions. The December 23, 2011 NPRM requests comment on affirmative defense provision. NEDA/CAP notes that the affirmative defense is *sub voce* recognition that malfunctions do occur and thus requires EPA to establish a standard based on work practices because the agency is not able to prescribe an enforceable emission limitation during malfunction events. CAA Section 112(h).

Response: See the responses to comments EPA-HQ-OAR-2002-0058-3500-A1, excerpt 19 and EPA-HQ-OAR-2002-0058-3502-A1, excerpt 23 regarding establishing work practice standards for malfunctions.

Commenter Name: Susan J. Miller

Document Control Number: EPA-HQ-OAR-2002-0058-3530-A1

Comment Excerpt Number: 4

Comment: EPA’s proposal to provide an “affirmative defense” for periods of malfunctions is without merit. BIA is part of the “SSM Coalition” who recently submitted comments on EPA’s proposed “Risk and Technology Review” rule for Mineral Wool and Wool Fiberglass manufacturing. These comments explain in detail that: (1) EPA must take malfunctions into account when setting §112 emissions standards; (2) the proposed affirmative defense is not a permissible substitute for setting emissions standards for periods of malfunction; and (3) the proposed affirmative defense is unreasonable and impracticable.² We incorporate these comments of the SSM Coalition by reference. For these reasons, EPA should set aside the proposed affirmative defense for periods of malfunction and, instead, set a work practice standard for such periods.

Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 50

Comment: Unlike startup and shutdown periods, EPA has determined that malfunctions should not have work practice standards and has instead provided for an affirmative defense. 76 Fed. Reg. 80,629.

Given that malfunctions are essentially the same as periods of startup and shutdown, work practice standards should also apply. As CIBO points out in its Petition, EPA recognizes in both the Boiler MACT and Area Source rule, "that it is not feasible to require stack testing – in particular, to complete the multiple required test runs – during periods of startup and shutdown due to physical limitations and the short duration of startup and shutdown periods. Operating in startup and shutdown mode for sufficient time to conduct the required test runs could result in higher emissions than would otherwise occur." 76 Fed. Reg. 15577, 15642. It is irrational to view malfunctions any different than startup/shutdown periods. As such, EPA should establish work practice standards for malfunctions. The rule is unreasonable as it is and subjects sources to the risk of noncompliance especially given the fact that malfunctions are unavoidable and unpredictable.

In doing so, EPA has inappropriately placed the burden on the source to prove that excess emissions were caused by a malfunction. As CIBO asserted in earlier comments, malfunctions are in all material respects the same as startup and shutdown and therefore clearly meet the CAA definition for when work practice standards are appropriate. CAA §112(h). EPA should establish a work practice standard that requires pre-determined malfunction plans with practices and procedures for potential malfunctions; require reporting of any malfunctions; address any malfunctions not contemplated and add to the plan and address as appropriate.

Response: See the responses to comments EPA-HQ-OAR-2002-0058-3500-A1, excerpt 19 and EPA-HQ-OAR-2002-0058-3502-A1, excerpt 23 regarding establishing work practice standards for malfunctions.

Comment Excerpt Number: 11

Comment: Unlike startup and shutdown periods, EPA has determined that malfunctions should not have work practice standards and has instead provided for an affirmative defense. (see 76 Fed. Reg. 80629).

In the preamble to the March 2011 final Boiler MACT rule, EPA recognizes the need to exclude malfunction events when setting emission standards. As such, EPA should re-establish work practice standards for malfunctions in place of the affirmative defense approach included in the reconsideration proposal.

With the use of affirmative defense, EPA has placed unreasonable burdens on the source to prove that excess emissions were caused by a malfunction. The affirmative defense approach is unreasonable as it potentially subjects sources to the risk of noncompliance, especially given the fact that malfunctions are unavoidable and unpredictable. Overall, these provisions impose vague obligations on malfunctioning sources which will lead to inconsistent interpretations in different jurisdictions, and lack precision that is fundamental to an adequate defense in an enforcement proceeding. This could lead to the EPA or a court imposing extreme MACT regulations on sources during malfunctions.

EPA identifies many reasons in the preamble supporting its establishment of work practice standards during periods of startup and shutdown. These same bases support the establishment of work place standards being applicable to malfunctions. Malfunctions meet the CAA definition (CAA §112(h)) for when work practice standards are appropriate. Instead of using the affirmative defense approach, EPA should establish a work practice standard that requires pre-determined malfunction plans with practices and procedures for addressing potential malfunctions that will minimize emissions in a manner consistent with good safety practices and good air pollution control practices; require reporting of any malfunctions; and include provisions for modifying the plan to incorporate any malfunctions not contemplated.

Response: See the responses to comments EPA-HQ-OAR-2002-0058-3500-A1, excerpt 19 and EPA-HQ-OAR-2002-0058-3502-A1, excerpt 23 regarding establishing work practice standards for malfunctions.

Commenter Name: Janice E. Nolen

Commenter Affiliation: American Lung Association

Document Control Number: EPA-HQ-OAR-2002-0058-3679-A2

Comment Excerpt Number: 13

Comment: Affirmative defense for malfunctions. EPA should review the exposure estimates to recognize that significant air emissions are likely to result from malfunctioning equipment as well. Although some malfunctions may be unpredictable and sudden, EPA must account for the harmful emissions that occur during malfunctions when determining whether or not a facility is in compliance with emissions standards. EPA needs to acknowledge that malfunctions are likely events which must be factored into the exposure estimates. EPA's language implies that these are rare events, but such is not the case, as recent reports have shown (EPA, 2011d). The historical industry evidence should provide more than adequate information on likely malfunctions and exposures.

Unfortunately, the proposed "affirmative defense" option creates a loophole that will not likely reduce the risk of malfunctions, providing facilities with a way to avoid penalties that could provide incentives to reduce malfunctions. The EPA needs to close this loophole as standards need to limit emissions during all phases of operation, including when equipment fails to work properly. Assessing compliance with emissions standards based on the "good faith efforts" of boiler and incinerator operators to minimize emissions during malfunctions are not a sufficient safeguard against harmful air pollution.

Response: See the responses to comments EPA-HQ-OAR-2002-0058-3500-A1, excerpt 19 and EPA-HQ-OAR-2002-0058-3502-A1, excerpt 23 regarding establishing work practice standards for malfunctions.

Comment Excerpt Number: 28

Comment: EPA admits it does not have emissions data for startup and shutdown periods sufficient to establish numeric emission limits, and due to this dearth of data has sensibly adopted a work practice standard for these periods. Malfunction periods are no different and should be treated similarly. Since EPA also lacks emissions data for malfunction periods, and would find it difficult to obtain sufficient emission data for all the varying types of malfunction-related events, EPA should adopt work practice standards for malfunction periods.

Response: See the responses to comments EPA-HQ-OAR-2002-0058-3500-A1, excerpt 19 and EPA-HQ-OAR-2002-0058-3502-A1, excerpt 23 regarding establishing work practice standards for malfunctions.

Commenter Name: Russell A. Wozniak

Commenter Affiliation: The Dow Chemical Company

Document Control Number: EPA-HQ-OAR-2002-0058-3449-A1

Comment Excerpt Number: 27

Comment: In 40 CFR 63.7535(a), EPA requires the owner/operator to complete monitoring system repairs in response to monitoring system malfunctions or out-of-control periods and to return the monitoring system to operation as expeditiously as practicable. Dow supports this work practice requirement for monitoring system malfunctions. However, the proposed rule text in 40 CFR 63.7501 regarding "malfunctions" should clearly exclude monitoring system malfunctions if no excess emissions occur as a result of the monitoring system malfunction. EPA's proposed 63.7501 provides that the owner/operator may assert an affirmative defense to a claim for civil penalties for exceeding such standards that are caused by a malfunction as the term is defined in 40 CFR 63.2:

Malfunction – means any sudden, infrequent, and not reasonably preventable failure of air pollution control and monitoring equipment, process equipment, or a process to operate in a normal or usual manner which causes, or has the potential to cause, the emission limitations in an applicable standard to be exceeded. Failures that are caused in part by poor maintenance or careless operation are not malfunctions.

If the owner/operator can show that a monitoring system malfunction does not result in an exceedance of an emission limitation, then the final rule should clarify that the owner/operator does not need to assert an affirmative defense for such monitoring system malfunction.

Response: The affirmative defense criteria are not requirements that a source must meet. In an action to enforce a violation of a standard caused by a malfunction, a source can choose to assert an affirmative defense. The affirmative defense is not relevant to malfunctions that do not result in violations of emission standards.

Commenter Name: Lorraine Gershman

Commenter Affiliation: American Chemistry Council (ACC)

Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1

Comment Excerpt Number: 93

Comment: EPA asserts that "it is reasonable to interpret section 112(d) as not requiring EPA to account for malfunctions in setting emissions standards." 76 Fed. Reg.15613. EPA offers little support for that assertion, however, other than stating its own, often counterintuitive, conclusions. For example, EPA says it "has determined that malfunctions should not be viewed as a distinct operating mode and, therefore, any emissions that occur at such times do not need to be factored into development of CAA section 112(d) standards, which, once promulgated, apply at all times." *Id.* EPA provides no explanation for why it "believes" that malfunctions are not a distinct operating mode. Moreover, EPA offers no explanation of its contradictory position that, even though it believes malfunctions are not a distinct operating mode, emissions during malfunctions should not be used to characterize the source's operating mode. On its face, asserting that malfunctions are part of normal operations, but then excluding emissions during malfunctions when determining emission limitations for normal operations, makes no sense.³¹

EPA's statement that "nothing in section 112(d) or in case law requires that EPA anticipate and account for the innumerable types of potential malfunction events in setting emission standards," *id.*, has it backwards. There is nothing in CAA § 112 that allows EPA to ignore malfunctions and set MACT standards—which are supposed to represent the performance actually achieved by the

MACT “floor” sources—based on a level of emissions that even these best-performing sources only achieve part of the time. [Footnote 31: The *Weyerhaeuser Co. v. Costle* decision EPA cites in the March 21, 2011 preamble, 590 F. 2d 1011 (D.C. Cir. 1978), does not support EPA’s position. See 76 Fed. Reg. at 15613. In that case, the court was discussing a “technology forcing” standard, rather than one, like MACT, that is to be based on what is already being “achieved” or has been demonstrated to be achievable. Also, the SSM events that EPA acknowledges are expected to occur at sources subject to the MACT standards or boilers and process heaters are a far cry from the “uncontrollable acts of third parties, ‘ such as strikes, sabotage, operator intoxication, or insanity” that the Court was considering in the passage quoted by EPA, see *id.* Industry is not requesting that the emission standards provide relief from numerical emission limitations during those unusual types of events. Perhaps most importantly, the *Weyerhaeuser* decision came long before *NRDC v. EPA*, 859 F.2d 156 (D.C. Cir. 1988) which, as noted above, affirmed the need for an upset provision to address circumstances where compliance with effluent limitations is impossible through no fault of the permittee.]

Comment: EPA fails to explain how the Mossville criterion [*Mossville Environmental Action Now v. EPA*, 370 F.3d 1232, 1242 (D.C. Cir. 2004)] is met for a reasonable standard of factoring in variability under all operating conditions, when no malfunction emission data is included in the database used to make the variability adjustment. Nor does EPA explain how the *Weyerhaeuser* decision (that they do not have to consider every type of malfunction) allows EPA to ignore all types of malfunctions in establishing emission limits. EPA fails to explain how it concluded under section 112(d) that it is reasonable to ignore all malfunctions in setting emission limits. Even best performing sources have malfunctions and section 112(d)(3) requires EPA to understand the “emission control that is achieved in practice” by such sources. Finally, EPA has not shown how it concluded it did not have to treat emission limits that do not consider malfunctions as “beyond the floor” limits, since the floor must include malfunctions, since such a standard is not achievable by the best performing sources when they malfunction.

Comment Excerpt Number: 25

Comment: If it is possible to gather sufficient representative data reflecting emissions during malfunctions, then EPA is obligated to consider these data in its calculations of numerical emission limits for steady-state operating conditions (since EPA asserts malfunctions are not a

separate operating mode). If it is not possible to gather sufficient representative data reflecting emissions during malfunctions then EPA is obligated to treat malfunctions as a separate operating mode. We note that at least for the proposed CO emission limits for most source categories, EPA has adequate continuous monitoring data to develop alternative standards and thus may have data that includes malfunctions and thus may, as we discuss in Comment II.4.A, actually may be able to establish an emission limitation for CO that does consider malfunctions (i.e., establish the proposed alternative standard as the primary standard for CO for those subcategories.)

Comment: The proposed Affirmative Defense is not a substitute for addressing malfunction events in the emission limitations themselves.

EPA acknowledges that the sources that will be subject to the proposal sometimes will be unable to comply with the standards because of malfunctions, even if their equipment is properly designed and maintained, through no fault of the source.⁴³ Rather than promulgate a standard of performance that eliminates that situation, so that the regulated emission sources will be subject to differentiated requirements including during malfunction events, EPA offers instead an “affirmative defense.” As discussed in our next comment, the proposed affirmative defense shifts the burden to the source to prove that a myriad number of criteria are met and actions were taken by the source (which criteria bear no direct relation to the statutory factors for standards of performance in the CAA or delineated in the definition of malfunction in §63.2), in order to avoid “civil penalties.” Inclusion of the affirmative defense does not cure EPA’s failure to set emission standards that are achievable during malfunctions. The proposed standards, incorporating the affirmative defense, still do not represent emission limitations that have been achieved in practice by the best performers.

Comment Excerpt Number: 88

Comment: *EPA Failed to Consider Malfunctions in Establishing MACT Numeric Emission Standards.*

Under CAA § 112(d)(2), MACT emission standards must be "achievable." Moreover, when EPA establishes emission standards for existing sources based on the "best performing 12% of units in the category" (the "MACT floor"), those emission standards must on average be "achieved" by the best performers. *See*, § 112(d)(3). If EPA is going to require sources to meet a numeric standard at "all times" then the Agency must demonstrate that the standard accommodates the variability in emissions experienced, i.e., "achieved", by best performing sources "at all times", which would have to take into account, among other things, a potential malfunction. Based on our review of documents in the docket for this rulemaking it appears that EPA did not consider any data identifying the level of HAP emissions that may result when a best performing source experiences a malfunction. EPA therefore has failed to show that HAP emission numeric limits that apply at all times reflect the reductions that are "achieved" by best performing sources during a malfunction.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3667-A2, excerpt 22 regarding developing emission limits and malfunctions. See the responses to comments EPA-HQ-OAR-2002-0058-3500-A1, excerpt 19 and EPA-HQ-OAR-2002-0058-3502-A1, excerpt 23 regarding establishing work practice standards for malfunctions.

Comment Excerpt Number: 91

Comment: *EPA's Inclusion of an Affirmative Defense Is Not a Substitute for Establishing a § 112-Compliant Standard for Malfunction Events.*

ACC believes that EPA should either revise the numeric emission limitations in the rule so that they consider and reflect the variability of emissions resulting from malfunction events, or use its statutory authority to establish a §112 work practice or management standard applicable during a malfunction event. There is no language in § 112 that authorizes EPA to offer an owner/operator an "affirmative defense" to civil penalties to cure the fact that it has finalized numeric emission standards that do not represent the emission levels actually "achieved by the best performing sources "at all times".

Response: See the response to comment EPA-HQ-OAR-2002-0058-3667-A2, excerpt 22 regarding developing emission limits and malfunctions. See the responses to comments EPA-HQ-OAR-2002-0058-3500-A1, excerpt 19 and EPA-HQ-OAR-2002-0058-3502-A1, excerpt 23 regarding establishing work practice standards for malfunctions.

Commenter Name: Jennifer Youngblood

Commenter Affiliation: National Tribal Air Association

Document Control Number: EPA-HQ-OAR-2002-0058-3667-A2

Comment Excerpt Number: 24

Comment: Rather than supporting EPA's decision to ignore the fact that malfunction events can lead to higher emissions even at well-operated facilities with the best control equipment, the difficulty in measuring emissions during malfunctions should lead EPA to its conclude that

malfunctions are not normal operations and that their authority under CAA section 112(h) to prescribe alternative design, equipment, work practice, or operational standards where it is not feasible to set or enforce a numerical emission limit should be employed. EPA cannot rationally defend its position that malfunctions are normal operations but then ignore those operations in defining the emission limits that are "achieved in practice" by the best performing sources.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3667-A2, excerpt 22 regarding developing emission limits and malfunctions. See the responses to comments EPA-HQ-OAR-2002-0058-3500-A1, excerpt 19 and EPA-HQ-OAR-2002-0058-3502-A1, excerpt 23 regarding establishing work practice standards for malfunctions.

Commenter Name: Melvin E. Keener

Commenter Affiliation: Coalition for Responsible Waste Incineration (CRWI)

Document Control Number: EPA-HQ-OAR-2002-0058-3454-A1

Comment Excerpt Number: 12

Comment: CRWI notes that EPA does not allow facilities to assert an affirmative defense for the exceedance of an emission limit during malfunctions if EPA is seeking to enforce that emission limit through injunctive relief. Apparently the Agency takes that position based on a memorandum, State Implementation Plans: Policy Regarding Excessive Emissions During Malfunctions, Startup, and Shutdown at 2 (Sept. 20, 1999). (SIP SSM Memo). CRWI asserts that this policy is wrong. The type of legal action or relief should have no bearing on the availability of this defense. A malfunction "is a sudden, infrequent, not reasonably preventable failure of air pollution control equipment, process equipment, or a process to operate in a normal or usual manner." 40 CFR § 60.2. It is not affected by the type of enforcement action EPA may eventually bring. Indeed, because a malfunction is not reasonably preventable, enforcement actions, regardless of type, have no deterrent effect on them. Therefore, the type of legal action EPA uses to enforce a violation of its emission limits is simply irrelevant to whether the violation should be excused because of circumstances beyond the facilities control.

Response: In exercising its authority under section 112 to establish emission standards (at a level that meets the stringency requirements of section 112), the EPA necessarily defines conduct that constitutes a violation. The EPA's view is that the affirmative defense can be viewed as defining two categories of violation. If there is a violation of the emission standard and the source demonstrates that all the elements of the affirmative defense are met, only injunctive relief is available. All other violations of the emission standard are subject to injunctive relief and penalties. The CAA does not require that all violations be treated equally. Further, a citizen suit claim under section 304 allows citizens to commence a civil action against any person alleged to be in violation of "an emission standard or limitation under this chapter." The CAA, however, allows the EPA to establish such "enforceable emission limitations." Thus, the citizen suit provision clearly contemplates enforcement of the standards that are defined by the EPA. As a result, where the EPA defines its emissions limitations and enforcement measures to allow a source the opportunity to prove its entitlement to a lesser degree of violation (not subject to penalties) in narrow, specified circumstances, as the EPA did here, penalties are not "appropriate" under section 304.

The EPA's view is that an affirmative defense to civil penalties for exceedances of applicable emission standards during periods of malfunction appropriately balances competing concerns. On the one hand, citizen enforcers are concerned about additional complications in their enforcement actions. On the other hand, industrial sources are concerned about being penalized for violations caused by malfunctions that could not have prevented and were otherwise appropriately handled (as reflected in the affirmative defense criteria). The EPA has utilized its Section 301(a)(1) authority to issue regulations necessary to carry out the Act in a manner that appropriately balances these competing concerns.

Commenter Affiliation: Utility Air Regulatory Group (UARG)

Document Control Number: EPA-HQ-OAR-2002-0058-3500-A1

Comment Excerpt Number: 16

Comment: EPA solicits comment on malfunctions and the affirmative defense provision included in the 2011 final rule. In that rule, EPA addresses periods of malfunction by providing an "affirmative defense" to a claim of civil penalties. 40 C.F.R. § 63.7501. To establish the defense an owner/operator must (1) provide notice by telephone or facsimile no later than two business days after the "initial occurrence" of the malfunction, and (2) submit a written report within 45 days proving certain facts by a "preponderance of evidence." *Id.* EPA's "affirmative defense" approach is not the exclusive, or even the best, option available for treatment of malfunctions under CAA § 112. Because the final rule treats exceedances caused by malfunctions as "violations," it does not prevent owners and operators from being penalized for events that cannot be reasonably prevented, even if civil penalties do not apply. It also raises a number of practical issues.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3454-A1, excerpt 12 regarding malfunctions being preventable.

Comment Excerpt Number: 29

Comment: Malfunction work practice standards could include limitations on the duration to ensure quick and effective corrective action is taken, and if the malfunction cannot be quickly resolved the unit would be shut down for repair. Facilities should still be required to submit a notification of a malfunction excess emission event with the underlying root cause analysis. If EPA or the administering agency decides the excess emission event was not a malfunction, it would then be reported as a deviation of the limit and enforcement action, including imposition of penalties, would still apply consistent with the deviation definition in 63.7575. EPA could also choose to take enforcement action should a facility report "excessive" malfunction events.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3454-A1, excerpt 12 regarding malfunctions being preventable.

Document Control Number: EPA-HQ-OAR-2002-0058-3511-A1
Comment Excerpt Number: 58

Comment: Assuming *arguendo* that EPA had authority to promulgate any type of affirmative defense to penalties for malfunctions, EPA should also promulgate the following provision: A specific amount of compensatory damages should apply to each reported malfunction. These funds should be dedicated to enforcement, inspections, and monitoring in the local community around the specific facility, to create greater assurance that malfunctions will not happen again.

Response: The EPA is not adopting commenters' suggestion with respect to compensatory damages or limits on the frequency of use of the affirmative defense. It is not clear that EPA has authority to require the automatic imposition of compensatory damages and even if such authority exists, the EPA does not think automatic imposition of damages is appropriate, as it would unduly complicate the enforcement process. Ensuring that malfunctions do not recur can be handled through imposition of appropriate injunctive relief.

Commenter Name: James Pew
Commenter Affiliation: Earthjustice, Clean Air Council, Partnership for Policy Integrity

Document Control Number: EPA-HQ-OAR-2002-0058-3511-A1

Comment Excerpt Number: 59

Comment: Assuming *arguendo* that EPA had authority to promulgate any type of affirmative defense to penalties for malfunctions, EPA should also promulgate the following provision: EPA should modify the regulations so that the affirmative defense cannot be used by a specific facility or company more than once within a set period of time, such as 10 years. The affirmative defense should become automatically unavailable to a facility that has previously had a malfunction within the last 10 years, to ensure that this defense does not swallow the value of the standards.

Response: It is EPA's view is that it would not be appropriate to limit a source's ability to take advantage of the affirmative defense to one time over a specified period of time such as ten years given that the affirmative defense is only available when the source could not have prevented the excess emissions. With respect to commenters' suggested reporting requirements, the reporting requirements in the rules promulgated today already require malfunction reporting and the affirmative defense provisions require that parties choosing to assert the affirmative defense meet additional malfunction reporting requirements. Any such reports submitted to the EPA are publicly-available pursuant to CAA section 114.

Commenter Name: LESLIE SUE RITTS

Commenter Affiliation: National Environmental Development Association's Clean Air Project (NEDA/CAP)

Document Control Number: EPA-HQ-OAR-2002-0058-3529-A1

Comment Excerpt Number: 12

Comment: Sub par. (2) of the affirmative defense requires that an owner/operator establish by a preponderance of the evidence that repairs were made as expeditiously as possible when the applicable emission limitations were being exceeded and that "*Off-shift and overtime labor were used, to the extent practicable to make these repairs...*". The requirement for off-shift and overtime labor should be deleted from the regulation. Bringing in off-shift or overtime labor is not always wise or necessary to demonstrate that repairs have been made as expeditiously as practicable. Expertise, not numbers of unskilled employees or tired employees, is paramount to resolving most safety issues created by malfunctioning equipment. If retained in the final rule, it should be used as an example of how an operator *may* demonstrate that a problem was resolved as expeditiously as practicable.

Response: We have also re-evaluated the language concerning the use of off-shift and overtime labor to the extent practicable and believe that the language is not necessary. Thus, we have deleted that phrase from section 63.7501(a)(2).

Commenter Name: Matthew Todd

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 81

Comment: Proposed §63.7501(a) follows.

§63.7501(a) To establish the affirmative defense in any action to enforce such a limit, you must timely meet the notification requirements in paragraph (b) of this section, and must prove by a preponderance of evidence that:

We comment separately below (Comment II.8.D) on the wasteful and unreasonable notification requirements proposed in §63.7501(b).

Proposed §63.7501(a)(1):

The excess emissions:

(i) Were caused by a sudden, infrequent, and unavoidable failure of air pollution control and monitoring equipment, process equipment, or a process to operate in a normal or usual manner, and

(ii) Could not have been prevented through careful planning, proper design or better operation and maintenance practices; and

(iii) Did not stem from any activity or event that could have been foreseen and avoided, or planned for; and

(iv) Were not part of a recurring pattern indicative of inadequate design, operation, or maintenance; and

§63.7501(a)(1)(i) reflects the key criteria from the definition of malfunction in §63.248 . However, the (ii) through (iv) paragraphs are unreasonable, arbitrary, and capricious restatements and expansions of the last sentence of the §63.2 malfunction definition and should be deleted and replaced with the language from the definition. EPA has not explained in the rulemaking record their legal or logical basis for expanding and changing the malfunction criteria and, in particular, have not proposed changing the definition, either through proposing a revised definition in this rulemaking or proposing to amend §63.2. As explained below, these new malfunction criteria would not allow any event to be a malfunction, since the criteria, if interpreted literally, cannot be met. The phrases used in these paragraphs are subject to a wide range of interpretations, and on their face do not recognize any need for reasonableness or cost-effectiveness. The language used presumes guilt and imposes an unclear and apparently impossible level of proof for a source to defend itself. The proposed wording doesn't even track the language of the definition of "malfunction" by including an analysis of whether an event was due to poor maintenance or careless operation. Instead, the proposal focuses on whether "proper design" or "better operation and maintenance practices" could have prevented a malfunction. There are no objective criteria that can be used to determine what "could" have been and there is probably no situation where, in hindsight and without considering cost or likelihood, that an event could not have been prevented.

[Footnote 48: *Malfunction* means any sudden, infrequent, and not reasonably preventable failure of air pollution control and monitoring equipment, process equipment, or a process to operate in a normal or usual manner which causes, or has the potential to cause, the emission limitations in

an applicable standard to be exceeded. Failures that are caused in part by poor maintenance or careless operation are not malfunctions.]

Response: EPA disagrees with comments that criticize the affirmative defense criteria as being overly vague or unduly restrictive and complex. The EPA believes that courts are well equipped and often do evaluate and apply the type of criteria set forth in the affirmative defense. The EPA recognizes that some of the criteria for establishing an affirmative defense may be redundant of the general duty, but does not agree that such redundancy is a problem. The EPA notes that the affirmative defense criteria and the general duty to minimize emissions do not operate in the same manner. The general duty is applicable to a source at all times. The affirmative defense criteria are only relevant if a source chooses to take advantage of the affirmative defense. The EPA's view is that use of consistent terms in establishing affirmative defense regulations and policies across various CAA programs will promote consistent implementation of those rules and policies.

The EPA revised certain criteria of the affirmative defense provisions that may ease the burden for owners and operators. The EPA is eliminating both the immediate notification and 45-day malfunction report requirement. Instead, the final rule allows owners or operators seeking to assert an affirmative defense to demonstrate, with all necessary supporting documentation (as was required under the proposed 45-day report), that it has met the affirmative defense criteria by including the report in the first periodic compliance, deviation report or excess emission report otherwise required after the initial occurrence of the violation of the relevant standard (which may be the end of any applicable averaging period). If such compliance, deviation report or excess emission report is due less than 45 days after the initial occurrence of the violation, the affirmative defense report may be included in the second compliance, deviation report or excess emission report due after the initial occurrence of the violation of the relevant standard. This change provides sources with sufficient time to demonstrate that they have met the required affirmative defense criteria. With regard to severe property damage, the EPA believes that a bypass of control equipment or a process, which results in a violation, should be an exception and not undertaken lightly, and has maintained the word "severe" in this criteria.

Document Control Number: EPA-HQ-OAR-2002-0058-3449-A1

Comment Excerpt Number: 23

Comment: 40 CFR §63.7501 (a) (2) Repairs were made as expeditiously as practical possible when the applicable emission limitations were being exceeded. Off shift and overtime labor were used, to the extent practical to make these repairs; and

Dow Comment: Responding to malfunctions is many times a case-by-case situation depending on the specifics of the malfunction and equipment to be repaired, and the language regarding off-shift and overtime labor is unnecessary and confusing. The use of overtime or off-shift labor is only one consideration in how to address a malfunction event. If EPA wants to point out that the use of overtime or off-shift labor must be used, then this language is best included in the preamble rather than the rule itself.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3529-A1, excerpt 12 regarding use of off-shift and overtime labor during a malfunction.

Commenter Name: Lorraine Gershman

Commenter Affiliation: American Chemistry Council (ACC)

Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1

Comment Excerpt Number: 100

Comment: Turning to the individual requirements in § 63.7501(a)(1) through (9) that a facility must meet to be allowed to raise an affirmative defense, a number of these requirements are not relevant to whether a "malfunction", as defined in 40 CFR 63.2 occurred.

Malfunction means any sudden, infrequent, and not reasonably preventable failure of air pollution control and monitoring equipment, process equipment, or a process to operate in a normal or usual manner which causes, or has the potential to cause, the emission limitations in an applicable standard to be exceeded. Failures that are caused in part by poor maintenance or careless operation are not malfunctions.

Most of the conditions for establishing an affirmative defense in § 63.7501 may be relevant to determining whether the facility undertook appropriate and necessary measures to mitigate any excess emissions resulting from the specific malfunction, but do not in any way inform a determination of whether a piece of equipment has met the definition of a malfunction. For example, § 63.7501(a)(2) requires that "off-shift and overtime labor, to the extent practicable" were used to make the repairs needed. ACC fails to understand how this requirement relevant to determining whether a piece of equipment has "malfunctioned". See also (a)(3), (a)(5), (a)(6), (a)(7), (a)(8) and (a)(9).

Response: See the response to comment EPA-HQ-OAR-2002-0058-3529-A1, excerpt 12 regarding use of off-shift and overtime labor during a malfunction.

Commenter Name: Robert D. Bessette

Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 51

Comment: Alternatively, if EPA rejects such work practice standards and, instead, includes an affirmative defense for malfunctions, the terms of the defense need to be changed. First, a source should not have to prove it meets every criterion to successfully claim the affirmative defense. Rather, the different criteria should be factored in evaluating whether the excess emissions should be excused.

The proposed criteria in the Reconsideration Rule for establishing an affirmative defense, which did not change from the Final Rule, are poorly defined and do not reflect on whether a malfunction actually occurred. For example, the requirement that sources rely on overtime workers to address the malfunction, 76 Fed. Reg. 80,629, objectively proves nothing. The personnel onsite at the time of the malfunction event may not be the personnel with the expertise to resolve the malfunction, yet if they do not remain onsite as overtime personnel, under EPA's

structure, that source fails to meet one of the indicia of a malfunction. Moreover, the affirmative defense criteria in some cases impose draconian obligations on malfunctioning sources without any regard for their cost-effectiveness. For example, the source must show "[r]epairs were made as expeditiously as possible . . . excess emissions (including any bypass) were minimized to the maximum extent practicable . . . [a]ll possible steps were taken to minimize the impact of the excess emissions on ambient air quality, the environment and human health." 76 Fed. Reg. 80,629 (emphasis added). This could lead to the EPA or a court imposing extreme MACT regulations on sources during malfunctions. Overall, the provisions impose vague obligations on malfunctioning sources which will lead to inconsistent interpretations in different jurisdictions, and lack precision that is fundamental to an adequate defense in an enforcement proceeding.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3529-A1, excerpt 12 regarding use of off-shift and overtime labor during a malfunction. See the response to comment EPA-HQ-OAR-2002-0058-3677-A2, excerpt 81 regarding affirmative defense provisions.

Commenter Name: Russell A. Wozniak

Document Control Number: EPA-HQ-OAR-2002-0058-3449-A1
Comment Excerpt Number: 20

Comment: EPA should modify Section 63.7501 of the rule that cover malfunctions and should significantly revise the affirmative defense provisions.

Dow recognizes that the proposed regulatory text is not unique to this MACT standard; EPA is inserting similar requirements in other MACT rules. However, the "affirmative defense" as currently written imposes such onerous requirements that the defense will be of extremely limited use as a practical matter. EPA should programmatically (including in this rule) revise the affirmative defense so that it is meaningful for larger events that may occur.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3677-A2, excerpt 81 regarding affirmative defense provisions.

Commenter Name: Bruce W. Ramme
Commenter Affiliation: Wisconsin Electric Power Company (WE Energies)
Document Control Number: EPA-HQ-OAR-2002-0058-3452-A1
Comment Excerpt Number: 7

Comment: We Energies understands that the intent of the affirmative defense provision is to provide owners and operators with protections in the event of an unforeseeable malfunction. We Energies supports the creation of an exemption from the emissions and operating limitations contained in the IB-MACT rule for malfunctions. The affirmative defense provisions proposed by EPA, however, would place unnecessary reporting burdens on sources, and could lead to unwarranted litigation and general confusion regarding the sufficiency of the factual information required to be maintained in order to qualify for the exemption.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3677-A2, excerpt 81 regarding affirmative defense provisions.

Comment Excerpt Number: 10

Comment: The various items that an owner or operator seeking to use the affirmative defense must “prove by preponderance of the evidence” are in many instances subjective, and EPA has not yet provided sufficient guidance regarding how it will interpret these requirements. We request that EPA provide guidance containing concrete examples that illustrate the actions that must be undertaken to address a malfunction in order to qualify for the affirmative defense. This would provide more clarity and eliminate unnecessary speculation.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3677-A2, excerpt 81 regarding affirmative defense provisions.

Commenter Name: Melvin E. Keener
Commenter Affiliation: Coalition for Responsible Waste Incineration (CRWI)
Document Control Number: EPA-HQ-OAR-2002-0058-3454-A1
Comment Excerpt Number: 14

Comment: CRWI suggests that EPA consider making the following modifications to the regulatory language in § 63.7501 to address the concerns mentioned above and to make an affirmative defense a more useful tool (using ~~strikeout~~ to show text deleted and underline to show text added).

§ 63.7501 How can I assert an affirmative defense if I exceed an emission limitations during a malfunction?

In response to an action to enforce the emission limitations and operating limits set forth in § 63.7500 you may assert an affirmative defense to a claim for civil penalties for exceeding such standards that are caused by malfunction, as defined at § 63.2. Appropriate penalties may be assessed, however, if you fail to meet your burden of proving all of the requirements in the affirmative defense. The affirmative defense shall not be available for claims for injunctive relief.

(a) To establish the affirmative defense in any action to enforce such a limit, you must timely meet the notification requirements in paragraph (b) of this section, and must prove by a preponderance of evidence that:

(1) The excess emissions:

(i) Were caused by a sudden, infrequent, and unavoidable failure of air pollution control and monitoring equipment, process equipment, or a process to operate in a normal or usual manner, and

(ii) Could not have been reasonably prevented through careful planning, proper design or better operation and maintenance practices; and

(iii) Did not stem from any activity or event that could have been reasonably foreseen and avoided, or planned for; and

(iv) Were not part of a recurring pattern indicative of inadequate design, operation, or maintenance; and

(2) Repairs were made as expeditiously as possible when the applicable emission limitations were being exceeded. Off-shift and overtime labor were used, to the extent practicable to make these repairs; and

(3) The frequency, amount and duration of the excess emissions (including any bypass) were minimized to the maximum extent practicable during periods of such emissions; and

(4) If the excess emissions resulted from a bypass of control equipment or a process, then the bypass was unavoidable to prevent loss of life, personal injury, or severe property damage; and

(5) ~~All possible~~ Reasonable steps were taken to minimize the impact of the excess emissions on ambient air quality, the environment and human health; and

(6) ~~All e~~ Emissions monitoring and control systems were kept in operation if at all possible, consistent with safety and good air pollution control practices; and

(7) ~~All of the a~~ Actions in response to the excess emissions were documented by ~~properly signed, contemporaneous operating logs~~; and

(8) ~~At all times, t~~ The facility was operated in a manner consistent with good practices for minimizing emissions; and

(9) A written ~~root cause analysis~~ report has been prepared, the purpose of which is to determine, ~~correct~~, and ~~eliminate~~ mitigate the primary causes of the malfunction and the excess emissions resulting from the malfunction event at issue. Facility personnel will determine the appropriate type of analysis

required (may include but not limited to root cause analysis, failure mode and effect, fault tree, etc.) to identify the cause of the malfunction. The analysis report shall also specify, using best monitoring methods and engineering judgment, the amount of excess emissions that were the result of the malfunction.

(b) *Notification.* The owner or operator of the facility experiencing an exceedance of its emission limitation(s) during a malfunction shall ~~notify the Administrator by telephone or facsimile (fax) transmission as soon as possible, but no later than 2 business days after the initial occurrence of the malfunction, if it wishes to avail itself of an affirmative defense to civil penalties for that malfunction. The owner or operator seeking to assert an affirmative defense shall also submit a~~ written report to the Administrator within 45 days of the initial occurrence of the exceedance of the standard in § 63.7500 to demonstrate, with all necessary supporting documentation, that it has met the requirements set forth in paragraph (a) of this section. The owner or operator may seek an extension of this deadline for up to 30 additional days by submitting a written request to the Administrator before the expiration of the 45-day period. Until a request for an extension has

been approved by the Administrator, the owner or operator is subject to the requirement to submit such report within 45 days of the initial occurrence of the exceedance.

Comment: Finally, as a practical matter, the burden of proving all the requirements in the affirmative defense and notifying the Agency during a malfunction is excessively high; if EPA intends to maintain an affirmative defense provision, however, the Agency should clarify the language in this provision and make it reasonably possible to meet these criteria. The affirmative defense provisions from the reconsideration require the owner or operator of a boiler to prove by a preponderance of the evidence that the source meets a list of criteria. As the list is currently written, affected entities will struggle to meet many of the criteria in the affirmative defense, effectively limiting or eliminating any practical use of this defense. For example, the fifth criterion requires a facility to demonstrate that “[a]ll possible steps were taken to minimize the impact of the excess emissions on ambient air quality, the environment and human health.” 76 Fed. Reg. 80629. This is a standardless condition and it would be extremely difficult, if not impossible, to demonstrate that all possible steps were taken to minimize the impact of a malfunction episode. A facility could always take one additional step to minimize the impact of a malfunction, and therefore, no facility could ever meet this criterion. If EPA does intend to finalize the affirmative defense, the Agency should clarify these provisions to ensure that the requirements are realistically attainable.

Commenter Affiliation: Florida Sugar Industry (FSI)

Document Control Number: EPA-HQ-OAR-2002-0058-3504-A1

Comment Excerpt Number: 47

Comment: EPA’s requirements for establishing an affirmative defense are extremely onerous and unreasonable. Sugar mill boilers routinely experience significant fluctuations in operations that are beyond the reasonable control of the boiler and sugar mill operators. Fluctuations in the sugar mill that affect boiler operations include: processing of a biomass fuel that is harvested within the 24-hour period prior to processing; variations in sugarcane quality and type that occur throughout the crop season; weather conditions that affect cane quality (moisture and soil content) at varying times during the crop; starting and stopping of the sugar mill tandems;

sugarcane feed problems; mill equipment breakdown, etc. Factors associated with the boilers themselves can include: high and variable moisture content fuel; required high excess air rates; fuel feeder pluggage; wet bagasse piling up on the grates; load swings because all boilers are tied to a single steam header; etc.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3677-A2, excerpt 81 regarding affirmative defense provisions.

Comment Excerpt Number: 48

Comment: One of the newest hybrid suspension grate boilers in the FSI (U.S. Sugar Boiler No. 8) has a CO CEMS and CO emission limit. The facility submits quarterly excess emission reports. Review of these reports reveals that up to 98 upset conditions were identified as malfunctions during any one quarterly period. A number of quarterly reports reported no malfunctions; however, upset conditions did occur, but ultimately none were excluded for purposes of demonstrating compliance with the CO limit for the boiler.

These fluctuations and other upset conditions would not qualify for an affirmative defense under the criteria set forth in the March 2011 Boiler MACT Rule. Even if they did qualify, the reporting and recordkeeping requirements established by EPA for proving an affirmative defense are too extensive and time-consuming. As a result, the FSI believes the EPA's affirmative defense is illusory and fails to provide a "safe harbor" from unwarranted enforcement cases.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3677-A2, excerpt 81 regarding affirmative defense provisions. Comment Excerpt Number: 95

Comment: *EPA'S AFFIRMATIVE DEFENSE REQUIREMENTS ARE UNREASONABLE AND NOT CONSISTENT WITH § 112.*

The affirmative defense regulatory language in § 63.7501 opens with the words "*In response to an action to enforce* the emission limitations and operating limits set forth in..." and repeats this thought in paragraph (a) of the section: "To establish the affirmative defense

in any action to enforce such a limit..." (emphasis added). This opening language leaves a regulated party to believe that if any action is taken against that party to enforce an emission limit exceeded during a malfunction, the party may avail itself of an affirmative defense if it meets various criteria. However, this is not the way this would play out.

In § 63.7501(b) EPA establishes strict notification requirements that must be followed for the owner/operator to be able even to raise an affirmative defense if and when an enforcement action is brought. First, the owner/operator must notify EPA by phone or FAX as soon as possible, but no later than two business days after the "initial occurrence of the malfunction." Then, within 45 days of the "initial occurrence of the initial occurrence of the exceedance of the standard," the owner/operator must submit a written report accompanied by all necessary supporting documentation to show that it has met each and every requirement set forth in paragraph (a) of § 63.7501. Because of these short time frames, the reality is that EPA is requiring the facility to present its entire detailed defense in writing to EPA before EPA has even decided whether to take any enforcement action. To require a party to lay out its entire defense to a potential future enforcement action before that action may be taken is wholly inappropriate and unacceptable.

Response: See the responses to comments EPA-HQ-OAR-2002-0058-3510-A1, excerpt 106 and EPA-HQ-OAR-2002-0058-3677-A2, excerpt 90 regarding two-day malfunction notice and 45-day affirmative defense requirements. Comment Excerpt Number: 101

Comment: A number of the requirements are extremely subjective and fail to allow for consideration of reasonableness or cost-effectiveness. For example, § 63.7501(a)(1)(ii) requires the owner/operator to show that the malfunction could not have been prevented through "careful planning," "proper design" or "better operation and maintenance practices." This subjective requirement leaves open the possibility that an enforcement official could always find actions that "could" have been taken without any consideration of costs, resources or feasibility. Moreover, it fails to consider that an owner/operator may have chosen to redesign a process or equipment configuration, or make other adjustments to achieve the emission reductions necessary to comply with the standard. In so doing, the owner/operator would have evaluated various options to determine which one was the most cost-effective approach to achieve the emission standard, keeping in mind that cost-effectiveness would include long-term safe and proper operation of the equipment or process. If a malfunction were to occur, it could be difficult if not impossible for the owner/operator to prove that the malfunction "could not have been prevented" if cost and resources were never an issue.

Comment: Requirement (a)(4) would disallow the affirmative defense if a malfunction involved bypassing control equipment or a process, and the bypass was not taken "to prevent loss of life, severe personal injury, or severe property damage." This language is both unyielding and subjective. It is unyielding in that it fails to allow any consideration of the fact that bypassing the control equipment or the process may have been an appropriate exercise of good air pollution control practices. For example, a bypass can constitute the best air pollution control practice in response to an upset in order to prevent excess emissions, e.g., to avoid fouling of pollution control equipment media that in turn would result in reduced pollution control equipment efficiency or increased pollution control equipment downtime. Additionally, in some cases the air emissions from a venting event are lower than if the facility had an uncontrolled shutdown to avoid venting. An uncontrolled shutdown could also impact other media, e.g., a wastewater dump from scrubbers, solid waste, etc. And, a shutdown would necessitate additional startup emissions. Arguably, venting for a short period due to malfunction could result in less emissions than a non-orderly shutdown and subsequent restart. Yet, as worded, this requirement would discourage an owner/operator from taking the less-impactful option because it would mean that he could not avail himself of an affirmative defense for the malfunction.

This requirement is subjective in its use of the word —severe. Reasonable minds could disagree on what constitutes "severe" property damage, or "severe" personal injury. Lastly, this requirement is not supported by any explanation as to why "bypassing" control equipment or a process is absolutely unacceptable except when an owner/operator is faced with these dire consequences.

Comment Excerpt Number: 4

Comment: EPA proposes to treat malfunction events as if emission standards established based on normal process conditions and control equipment operations should apply. The "Affirmative Defense" policy EPA proposes to codify as potential protection when malfunctions lead to

emissions that exceed standards does not adequately address the issue. On its own it is overly complex in its documentation and reporting requirements that would be difficult, if not impossible, to meet during extreme or catastrophic malfunction events. The legally defensible and feasible approach is to set work practice standards as the NESHAP during malfunction events, as detailed in our trade group comments.

Response: See the responses to comments EPA-HQ-OAR-2002-0058-3500-A1, excerpt 19 and EPA-HQ-OAR-2002-0058-3502-A1, excerpt 23 regarding establishing work practice standards for malfunctions. Document Control Number: EPA-HQ-OAR-2002-0058-3529-A1

Comment Excerpt Number: 13

Comment: Subpar. (4) of the affirmative defense that an owner operator establish by a preponderance of the evidence that if the excess emissions resulted from a bypass of control equipment or a process, then the bypass was unavoidable to prevent loss of life, personal injury, or severe property damage. NEDA/CAP suggests that this is an unnecessary regulatory requirement and should be deleted from the final rule or that the word "potential" be inserted before the phrase "loss of life, personal injury or severe property damage." Bypassing emissions may be the only way to prevent "*potential*" risk to life or property in order to be eligible to an affirmative defense from injuries. In addition, when pollution equipment malfunctions, it may be unavoidable but not create a safety situation such as when there is a bypass of hot gases so that the pollution control equipment or even the process equipment can be taken apart to be repaired.

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 84

Comment: Proposed §63.7501(a)(2):

Repairs were made as expeditiously as possible when the applicable emission limitations were being exceeded. Off-shift and overtime labor were used, to the extent practicable to make these repairs; and

Proposed §63.7501(a)(2) imposes an unreasonable requirement and focuses on the wrong endpoint and should be deleted.

The phrase “as expeditiously as possible” is ambiguous and potentially impossible to meet. “Possible” is yet another subjective and ill-defined concept. In addition, acting as “expeditiously as possible” may cause safety or other problems as opposed to minimizing emissions to the maximum extent practicable, as the (a)(3) paragraph requires.

Furthermore, requiring the “repairs” to be done rapidly is not the correct focus because excess emissions may have ceased before repairs are complete or repairs may not be required. The correct focus should be on reducing the excess emissions as rapidly as practical, which is addressed in the proposed (a)(3) paragraph. Eliminating excess emissions may or may not involve repairs. For instance, the proper response to a particular event may require adjusting a control set point, bypassing a stuck control valve or other operator actions, shutting down the equipment or process, or routing the emissions to an alternate control. Requiring repairs, when no repair is needed is unreasonable and illogical.

The second sentence in proposed (a)(2), regarding the use of off-shift and overtime labor, is based on misperceptions that repairs are always needed and that using additional labor somehow indicates expediency. As mentioned previously, often the excess emissions have ceased prior to repair work occurring or do not require a repair to be made. Even where repairs are the critical path to minimizing emissions, work often may be managed adequately by shift personnel. In any given case, the enforcement authority may choose to question whether appropriate steps were taken to minimize emissions, so a firm requirement to bring in off-shift or overtime personnel when they are not needed serves no enforcement purpose. As proposed, this language requires use of off-shift and overtime labor if a source wants to use the affirmative defense, even if the excess emissions were stopped before such personnel could be called or no repair is needed or all needed personnel were already available onsite.

§63.7501(a)(2) should not be finalized and proposed §63.7501(a)(3) should remain as the basis for demonstrating an appropriate response to a malfunction, if these provisions remain in the final rule.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3677-A2, excerpt 81 regarding affirmative defense provisions. See the response to comment EPA-HQ-OAR-2002-0058-3529-A1, excerpt 12 regarding use of off-shift and overtime labor during a malfunction.

Comment: API/AFPM Comments on Proposed BPH NESHAPs, CISWI and NHSM Rules
Page 65

Proposed §63.7501(a)(5):

All possible steps were taken to minimize the impact of the excess emissions on ambient air quality, the environment and human health; and

Proposed §63.7501(a)(5) sets an impossible requirement that invalidates the possibility of using the affirmative defense and so should be deleted.

This provision is ambiguous at best and impossible to demonstrate at worst. A facility cannot necessarily know in real time what "impacts" or potential impacts emissions might have on air quality, the environment, and human health, nor can a facility do anything other than minimize emissions to minimize the potential environmental impact. In addition, it is impossible to demonstrate that "all possible steps" were taken to do anything. Paragraph (a)(3) already requires a source to minimize the excess emissions. We do not know what other steps the Agency expects or how we could demonstrate that the impacts of those already minimized emissions could be further minimized. This paragraph should be deleted.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3677-A2, excerpt 81 regarding affirmative defense provisions.

Commenter Name: Matthew Todd

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Comment Excerpt Number: 88

Comment: Proposed §63.7501(a)(8):

At all times, the facility was operated in a manner consistent with good practices for minimizing emissions; and

Proposed §63.7501(a)(8) is a general requirement and serves no purpose in the affirmative defense provisions since §63.7501(a)(3) already requires that malfunction emissions be minimized. Furthermore, this paragraph deals with the entire facility not just the malfunctioning equipment or operation. Its inclusion in the affirmative defense provisions suggests that you cannot defend yourself for a particular malfunction event if there are excess emissions (e.g., from a startup or shutdown activity) anywhere else in the facility having nothing to do with the malfunctioning operation.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3677-A2, excerpt 81 regarding affirmative defense provisions.

Commenter Name: Kerry Kelly

Commenter Affiliation: Waste Management (WM)

Document Control Number: EPA-HQ-OAR-2002-0058-3681-A2

Comment Excerpt Number: 30

Comment: The sheer number of eligibility criteria that must be proven by a “preponderance of evidence and the vague terms such as “unpreventable,” “could not have been foreseen,” and “all possible steps were taken” all but guarantees that no malfunction event will ever meet the criteria. WM suggests modifying the eligibility criteria as follows to make it more reasonable and eliminate such vague language: “To establish that an exceedance of an emission limit or operating standard was the result of a malfunction and therefore not a deviation you must timely meet the notification requirements in paragraph (b) of this section and demonstrate that:

(1) the malfunction:

(i) was not caused by a sudden infrequent and unavoidable failure of air pollution control equipment or failure of a process to operate in a normal or usual manner;

(ii) was not caused by operator error or careless operation;

(iii) was not the result of inadequate design, maintenance or operating procedures; and

(2) Corrective actions were taken immediately to minimize the duration and amount of excess emissions; and

(3) All emission monitoring and control systems were kept in operation if possible in a manner consistent with safety requirements and good air pollution control practices; and

(4) Preventive measures were implemented to address the root cause of the malfunction; and

(5) The root cause analysis and actions in response to the excess emission event were documented in signed contemporaneous log. (b)...”

Response: See the response to comment EPA-HQ-OAR-2002-0058-3677-A2, excerpt 81 regarding affirmative defense provisions.

Commenter Name: Lee Zeugin and Lauren Freeman

Commenter Affiliation: Utility Air Regulatory Group (UARG)

Document Control Number: EPA-HQ-OAR-2002-0058-3500-A1

Comment Excerpt Number: 20

Comment: UARG also has some more practical concerns about the way EPA’s affirmative defense is structured. The defense applies to any malfunction as defined in 40 C.F.R. § 63.2, which is:

any sudden, infrequent, and not reasonably preventable failure of air pollution control and monitoring equipment, process equipment, or a process to operate in a normal or usual manner which causes, or has the potential to cause, the emission limitations in an applicable standard to be exceeded. Failures that are caused in part by poor maintenance or careless operation are not malfunctions.

Subsection § 63.7501(a)(1)(i) refers to an “unavoidable” failure. Although the difference between “reasonably preventable” and “unavoidable” may seem small, the IB MACT rule seems to require a stronger showing than the definition anticipates in that it leaves room to argue whether a failure could have been prevented even if the acts necessary to do so were “unreasonable.” Other provisions in (a)(1) - (ii) (“[c]ould not have been prevented”), (iii) (“could [not] have been foreseen and avoided, or planned for”), and (a)(5) (“all possible steps”) - also seem to remove the requirement of “reasonableness.” In contrast, other provisions include references to practicability. At a minimum, EPA must revise its criteria consistent with the § 63.2 definition to include the concept of “reasonableness.”

Response: See the response to comment EPA-HQ-OAR-2002-0058-3677-A2, excerpt 81 regarding affirmative defense provisions.

Commenter Name: Lee Zeugin and Lauren Freeman

Commenter Affiliation: Utility Air Regulatory Group (UARG)

Document Control Number: EPA-HQ-OAR-2002-0058-3500-A1

Comment Excerpt Number: 21

Comment: Section § 63.7501(a) makes a number of references to “excess emissions.” However, there is no general definition of “excess emissions” in § 63.2. According to § 63.10(c)(7) and (8), “excess emissions” are supposed to be defined in the applicable subpart. Subpart DDDDD contains no such definition. EPA should issue a proposal to define “excess emissions” in the context of any final rule that uses the term.

Response: The EPA has revised § 63.7501(a) to remove the reference to the term 'excess emissions' and thus a definition of this term is no longer necessary. Please see the final rule language for the revised wording of this section.

Commenter Name: Matthew Todd

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 79

Comment: The proposal states that: “The affirmative defense shall not be available for claims for injunctive relief.” The preambles to this proposed rule or the March 21, 2011 final rule do not give any explanation for why the affirmative defense would not apply to injunctive relief. If in fact the excess emissions associated with the equipment or process failure are not reasonably preventable, then there is no apparent reason why injunctive relief should be available either. As a matter of law, injunctive relief may not be available in cases where a civil penalty cannot be imposed.⁴⁶

Maintaining liability for injunctive relief renders the affirmative defense particularly ineffective with respect to citizen suits. If the source is even potentially subject to injunctive relief, and therefore could be required to pay the citizen-plaintiff's attorneys fees even if the source successfully demonstrated that it otherwise qualified for the affirmative defense, then the affirmative defense would not accomplish EPA's stated objective of providing relief in situations where the emission limitations cannot be met despite proper design and operation of process and control equipment.

At a minimum, EPA should state that the affirmative defense applies to civil penalties, civil administrative penalties, noncompliance penalties, and injunctive relief, in an action brought by EPA, a state, or a citizen-suit plaintiff. EPA also should reword the "affirmative defense," so that it states that a source "will not be deemed in violation of" the NESHAP for excess emissions or other deviations from the standards, associated with a malfunction event, unless the event, and the source's response to the event, do not meet the criteria spelled out in the regulations.⁴⁷ Configured in that way, this provision should be called something other than an "affirmative defense," such as an "alternative standard for SSM events."

[Footnote 46: See *Sierra Club v. Otter Tail Power Co.*, 615 F.3d 1008 (8th Cir. 2010) (under concurrent remedy doctrine, injunctive relief for a CAA violation is barred when civil penalty is barred by statute of limitations).]

[Footnote 47: *Compare, e.g.*, 40 C.F.R. § 80.613 (stating that persons demonstrating specified defenses "will not be deemed in violation" and are not "deemed liable for a violation" of diesel fuel sulfur program regulations).]

Response: In exercising its authority under section 112 to establish emission standards (at a level that meets the stringency requirements of section 112), the EPA necessarily defines conduct that constitutes a violation. The EPA's view is that the affirmative defense can be viewed as defining two categories of violation. If there is a violation of the emission standard and the source demonstrates that all the elements of the affirmative defense are met, only injunctive relief is available. All other violations of the emission standard are subject to injunctive relief and penalties. The CAA does not require that all violations be treated equally. Further, a citizen suit claim under section 304 allows citizens to commence a civil action against any person alleged to be in violation of "an emission standard or limitation under this chapter." The CAA, however, allows the EPA to establish such "enforceable emission limitations." Thus, the citizen suit provision clearly contemplates enforcement of the standards that are defined by the EPA. As a result, where the EPA defines its emissions limitations and enforcement measures to allow a source the opportunity to prove its entitlement to a lesser degree of violation (not subject to penalties) in narrow, specified circumstances, as the EPA did here, penalties are not "appropriate" under section 304. The affirmative defense criteria are not requirements that a source must meet. In an action to enforce a violation of a standard caused by a malfunction, a source can choose to assert an affirmative defense. The affirmative defense is not relevant to malfunctions that do not result in violations of emission standards.

Comment: Section 63.7501 states: "The affirmative defense shall not be available for claims for injunctive relief." The preamble is silent as to why the affirmative defense would not apply to injunctive relief. If the facility meets the requirements of the affirmative defense provision, why may it not be raised as a defense to a claim for injunctive relief? EPA's assertion to the contrary is unsupported by any explanation.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3677-A2, excerpt 79 regarding injunctive relief and affirmative defense.

Comment: Another subjective and particularly problematic requirement is (a)(8) which requires that: "At all times, the *facility* was operated in a manner consistent with good practices for minimizing emissions." ACC strongly objects to EPA reaching beyond the *equipment* that malfunctioned to require a party to prove by a preponderance of the evidence that "at all times, the *facility* was operated in a manner consistent with good practices for minimizing emissions." (Emphasis added.) First, EPA does not define "facility" or "affected facility" in the final major source boiler rule, nor is it included in the definitions at 40 CFR 63.2; common usage of the term facility suggests that it means the entire plant.³² Second, and more importantly, EPA is requiring a party to comply with a requirement that is ambiguous, highly subjective, and therefore impossible to satisfy. This is not reasoned decision-making. ACC notes that in its proposed reconsideration of various provisions of the Chemical Manufacturing Area Source Rule ("CMAS", EPA has revised this requirement and changed the word "facility" to "affected source." (77 Fed. Reg. 4522, January 30, 2012.) If the affirmative defense provision is included in the final reconsidered boiler major source rule, EPA should follow what it has done in CMAS and change "facility" to a more appropriate and defined term, such as "affected source."

[Footnote 32: The term "affected facility" is used in NSPS and is defined in the NSPS General Provisions at 40 CFR 60.2, but the MACT standards in Part 63 use the term "affected source," and the definition of affected source in 40 CFR 63.2 states: "Affected source may be defined differently for part 63 than affected facility and stationary source in parts 60 and 61, respectively." EPA does define the "affected source" in § 63.7490(a) ("the collection at a major source of all existing industrial, commercial, and institutional boilers and process heaters within a subcategory" or "each new or reconstructed industrial, commercial, or institutional boiler or process heater...located at a major source").

Response: We agree with the commenters concerning the use of "affected facility" versus "affected source." As a result, the EPA has changed "affected facility" to "affected source."

Comment: EPA should modify the affirmative defense provisions so that it is a "rebuttable presumption."

As EPA knows, malfunctions will occur. Even the best run facilities will have circumstances where events happen that are out of their control. While CRWI believes that EPA must take into account the conditions that occur during malfunctions and establish limits that consider these circumstances, CRWI also agrees that some form of enforcement discretion is needed for malfunctions. As such, we support EPA maintaining a regulatory provision for malfunctions. However, we are concerned that by allowing a facility to interpose an affirmative defense for violations caused by malfunctions implies that the facility is guilty until proven innocent and improperly shifts the burden to the facility. Therefore, CRWI suggests that EPA establish a rebuttable presumption (rather than affirmative defense) where it is presumed any violation occurring during the malfunction was not the operator's fault unless the Agency proves certain facts that are enumerated in the rules. This will allow the Agency to challenge the alleged deviation without compromising the legal rights of either party.

Response: The EPA does not agree that the affirmative defense provisions should be modified in the form of a "rebuttable presumption". The EPA also believes that the burden of proof, if a violation of a standard occurs, appropriately lies with the owner/operator of a facility. The EPA also agrees that the conditions during a malfunction event must be taken into account and believes that the affirmative defense provisions will support this review. For malfunctions, the EPA is finalizing the proposed affirmative defense language for violations of the numerical emission limits that are caused by malfunctions. The EPA recognizes that even equipment that is properly designed and maintained can fail and that such failure can cause a violation of the relevant emission standard. The EPA is including an affirmative defense in the final rule as we have in other recent section 111, section 112, and section 129 rules so as to balance the tension, inherent in many types of air regulation, to ensure adequate compliance while simultaneously recognizing that despite the most diligent of efforts, emission limits may be exceeded under circumstances beyond the control of the source. The EPA must establish emission standards that "limit the quantity, rate, or concentration of emissions of air pollutants on a continuous basis." 42 U.S.C. § 7602(k)(defining "emission limitation and emission standard"). See generally *Sierra Club v. EPA*, 551 F.3d 1019, 1021 (D.C. Cir. 2008) (emissions limitations under must both continuously apply and meet minimum stringency requirements, even during periods of startup, shutdown and malfunction). Thus, the EPA is required to ensure that emissions limitations are continuous. The affirmative defense for malfunction events meets this requirement by ensuring that even where there is a malfunction, the emission limitation is still enforceable through injunctive relief. See generally, *Luminant Generation Co. v EPA*, 2012 U.S. App. LEXIS 15722 (5th Cir. 2012) (upholding EPA's approval of affirmative defense provisions in a CAA State Implementation Plan).

While "continuous" limitations, on the one hand, are required, there is also caselaw indicating that in some situations it is appropriate for the EPA to account for the practical realities of technology. For example, in *Essex Chemical v. Ruckelshaus*, 486 F.2d 427, 433 (D.C. Cir. 1973), the D.C. Circuit acknowledged that in setting standards under CAA section 111 "variant provisions" such as provisions allowing for upsets during startup, shutdown and equipment

malfunction “appear necessary to preserve the reasonableness of the standards as a whole and that the record does not support the ‘never to be exceeded’ standard currently in force.” See also, *Portland Cement Association v. Ruckelshaus*, 486 F.2d 375 (D.C.Cir. 1973). Though intervening caselaw such as *Sierra Club v. EPA and the CAA 1977 amendments* calls into question the relevance of these cases today, they support the EPA’s view that a system that incorporates some level of flexibility is reasonable. The affirmative defense simply provides for a defense to civil penalties for excess emissions that are proven to be beyond the control of the source. By incorporating an affirmative defense, the EPA has formalized its approach to upset events. In a Clean Water Act setting, the Ninth Circuit required this type of formalized approach when regulating “upsets beyond the control of the permit holder.” *Marathon Oil Co. v. EPA*, 564 F.2d 1253, 1272-73 (9th Cir. 1977). But see, *Weyerhaeuser Co. v. Costle*, 590 F.2d 1011, 1057-58 (D.C. Cir. 1978) (holding that an informal approach is adequate). The affirmative defense provisions give the EPA the flexibility to both ensure that its emission limitations are “continuous” as required by 42 U.S.C. § 7602(k), and account for unplanned upsets and thus support the reasonableness of the standard as a whole.

Further, the EPA’s view is that the affirmative defense is consistent with CAA sections 113(e) and 304. Section 304 gives district courts jurisdiction “to apply appropriate civil penalties.” Section 113(e)(1) identifies the factors that the Administrator or a court shall take into consideration in determining the amount of a penalty to be assessed only after it has been determined that a penalty is appropriate. The affirmative defense regulatory provision is not relevant to the amount of any penalty to be assessed under section 113(e) because if a court determines that the affirmative defense elements have been established, then a penalty is not appropriate and penalty assessment pursuant to the section 113(e)(1) factors does not occur.

In exercising its authority under section 111 to establish emission standards (at a level that meets the stringency requirements of section 111), the EPA necessarily defines conduct that constitutes a violation. The EPA’s view is that the affirmative defense can be viewed as defining two categories of violation. If there is a violation of the emission standard and the source demonstrates that all the elements of the affirmative defense are met, only injunctive relief is available. All other violations of the emission standard are subject to injunctive relief and penalties. The CAA does not require that all violations be treated equally.

The EPA’s judgment is that the affirmative defense criteria capture the appropriate considerations in determining whether penalties are appropriate when a violation occurs as the result of a malfunction. As noted above, the affirmative defense criteria overlap to some extent with the penalty assessment criteria set forth in section 113(e), but are not identical. For example, size of business is one of the factors listed in section 113(e), but is not reflected in EPA’s affirmative defense. This reflects the EPA’s view that when a violation is caused by a malfunction, the size of the business is not relevant to whether penalties should be excused. If the violation was unavoidable and could not have been prevented, the EPA’s view is that it would be unfair to impose a penalty no matter the size of the business.

Comment: It is unclear where EPA finds the legal authority in the CAA to shift the burden to the regulated community of proving (or disproving) essential elements of an alleged violation. The statute is silent as to the issue and "the ordinary default rule [is] that plaintiffs bear the risk of failing to prove their claims." *Shaeffer v. Weast*, 546 U.S. 49 (2005), quoting *McCormick on Evidence* §337, at 412 ("The burdens of pleading and proof with regard to most facts have and should be assigned to the plaintiff who generally seeks to change the present state of affairs and who therefore naturally should be expected to bear the risk of failure or proof or persuasion"); C. Mueller & L. Kirkpatrick, *Evidence* § 3.1, p. 104 (3d ed. 2003) ("Perhaps the broadest and most accepted idea is that the person who seeks court action should justify the request, which means that the plaintiffs bear the burdens on the elements in their claims"). While the Supreme Court has recognized exceptions such as affirmative defenses, courts retain the authority to establish such rules unless Congress acts to delegate that authority. In this instance, EPA has not provided any statutory authority, or any real justification, for requiring a source to prove its innocence; moreover, to fully demonstrate its innocence within 45 days of the event, without even being charged. Rather, if EPA adopts an approach along the lines of the proposed affirmative defense, it should be stated instead in terms that, once a source has claimed that its excess emissions were related to a malfunction, it will not be considered to be in violation of the standards unless the enforcement authority demonstrates that the source is not entitled to claim the malfunction.

Response: See the responses to comments EPA-HQ-OAR-2002-0058-3510-A1, excerpt 106 and EPA-HQ-OAR-2002-0058-3677-A2, excerpt 90 regarding two-day malfunction notice and 45-day affirmative defense requirements.

The EPA disagrees that the affirmative defense provision will hamper citizen enforcement. First, injunctive relief is still available and the threat of penalties would not deter violations in cases where all of the conditions of the affirmative defense have been satisfied because the affirmative defense criteria ensure that all reasonable steps were taken to prevent a malfunction that causes excess emissions.

Further, litigating whether a source has met the affirmative defense will not burden citizen groups any more or less than would litigating the appropriate penalty amount in the penalty assessment stage of a citizen suit enforcement action, because the 113(e) penalty assessment criteria and the affirmative defense criteria are similar and in fact overlap. For example, the requirement that the Administrator or the court consider "good faith efforts to comply" is bound to generate the type of fact-intensive disputes that the commenter complains of. In addition, several of the affirmative defense criteria are exactly the type of criteria the Administrator or Court might consider in determining whether a source made "good faith efforts to comply." For example, to take advantage of the affirmative defense, the source must prove by a preponderance of the evidence that, among other things, the excess emissions "were caused by an unavoidable failure of air pollution control and monitoring equipment, process equipment, or a process to operate in a normal or usual manner" and "could not have been prevented through careful planning, proper design or better operation and maintenance practices" and "did not stem from any activity or event that could have been foreseen and avoided, or planned for."

Thus, the EPA does not expect the affirmative defense provision to significantly alter the burden of bringing a citizen enforcement action. For those cases that do proceed to trial, even in the absence of this affirmative defense, sources generally raise equitable arguments to argue for a low penalty and citizens often rebut such arguments. Therefore, as a practical matter, the EPA does not expect the affirmative defense provision to materially affect the practice of CAA enforcement.

Comment Excerpt Number: 9

Comment: CRWI suggests that EPA clarify its affirmative defense provisions.

While we prefer EPA use a rebuttable presumption, should the Agency keep the affirmative defense concept, CRWI suggests the following modifications to the language to make it more usable. CRWI understands that most of the provisions EPA has proposed for the affirmative defense comes from earlier guidance memos. While these provisions were in guidance, the Agency did not need to be careful of the wording since they were only guidance and did not have the weight of regulation. However, if the Agency wants to codify this guidance into regulatory language, several changes are needed. For example, EPA should drop the reference to "any" activity in this paragraph. There are also several references to "All" that would make it difficult to satisfy the requirements of an affirmative defense. In addition, the language in the provision is contradictory. In paragraph (a), the phrase "preponderance of evidence" is used while later in that paragraph (iii), the language refers to "any activity" meaning that more than a preponderance of evidence is needed. This same trend occurs in paragraphs (5) – EPA-HQ-OAR-2002-0058 8

"All possible," (6) "All," (7) "All of the actions," and (8) "At all times." While "all" would include "preponderance," "preponderance" does not mean all of the time. CRWI suggests that the phrase "preponderance of evidence" is adequate and the references to "all" and "any" in the later paragraphs should be modified.

Commenter Affiliation: Pennsylvania Department of Environmental Protection (DEP)

Document Control Number: EPA-HQ-OAR-2002-0058-3507-A1

Comment Excerpt Number: 18

Comment: The EPA has finalized affirmative defense provisions for malfunctions and as part of the reconsideration proposal is soliciting comments on the affirmative defense provisions that were included in the final rule. The March 21, 2011, final rule defines affirmative defense as follows: "Affirmative defense means, in the context of an enforcement proceeding, a response or defense put forward by a defendant, regarding which the defendant has the burden of proof, and

the merits of which are independently and objectively evaluated in a judicial or administrative proceeding." Ultimately, to assert the affirmative defense, the owner or operator of the source must prove by a preponderance of the evidence that excess emissions were caused by a sudden, infrequent, and unavoidable failure of air pollution control and monitoring equipment, process equipment or a process to operate in a normal or usual manner.

The DEP believes that the burden of proof rests with the owners or operators of the sources to show that the emission limit exceedances are beyond their control and that they took every step necessary to prevent such occurrences from taking place. However, the criteria specified in section 63.7501 (a)(1)(ii) and section 63.7501 (a)(1)(iii) are too subjective and may preclude owners and operators from using the affirmative defense provisions.

Response: See DCN-EPA-HQ-OAR-2002-0058-3677-A2, Excerpt No. 81 regarding affirmative defense provisions. See DCN EPA-HQ-OAR-2002-0058-3454-A1, Excerpt No. 8 and EPA-HQ-OAR-2002-0058-3677, Excerpt No. 76 regarding rebuttable presumption and affirmative defense.

Comment: EPA states that the affirmative defense may be raised to a "claim for civil penalties" but does not define "civil penalties". It is unclear, for example, whether this claim is meant to include a "civil administrative penalty" imposed by EPA under § 113(d) of the CAA? A "noncompliance" penalty sought under § 120 of the CAA? A "civil penalty" imposed by a court?

Response: See the responses to comments EPA-HQ-OAR-2002-0058-3454-A1, excerpt 8 and EPA-HQ-OAR-2002-0058-3677, excerpt 76 regarding rebuttable presumption and affirmative defense.

The affirmative defense applies to civil penalties, including civil administrative penalties and penalties under section 120, but does not apply to injunctive relief. **Commenter Name:** LESLIE SUE RITTS

Commenter Affiliation: National Environmental Development Association's Clean Air Project (NEDA/CAP)

Document Control Number: EPA-HQ-OAR-2002-0058-3529-A1

Comment Excerpt Number: 11

Comment: Subpar. (1) of the affirmative defense requires that the operator must demonstrate that excess emissions: (i) Were caused by a sudden, infrequent, and unavoidable failure of air pollution control and monitoring equipment, process equipment, or a process to operate in a normal or usual manner, and (ii) *Could not have been prevented through careful planning, proper design or better operation and maintenance practices.* NEDA/CAP appreciates that EPA understands that it is not always possible to design equipment to avoid malfunctions and while this reveals an error in EPA's logic for considering malfunctions to be violations of the regulation, it is vital for the regulation to recognize unavoidable events. Nonetheless, NEDA/CAP objects to the regulatory requirement that shifts to the operator the burden of proving that equipment could not have been better designed; it turns the doctrine of "innocent until proven guilty" on its head. We therefore recommend that EPA delete the phrase "proper design" from Subpar. 1 of the affirmative defense.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3677-A2, excerpt 81 regarding affirmative defense provisions. See the response to comment EPA-HQ-OAR-2002-0058-3454-A1, excerpt 8 and EPA-HQ-OAR-2002-0058-3677, excerpt 76 regarding rebuttable presumption and affirmative defense.

Comment: The affirmative defense content provisions of proposed §63.7501(a) are unworkable and should be revised if not deleted.

On page 80615 of this proposal, EPA requests comment on the affirmative defense provisions. As we have indicated in previous comments on various rules, these provisions are so broad that they provide no practical value to affected parties. We explain our concern in more detail below.

The affirmative defense is based on the presumption that all malfunctions are violations without providing for any due process. If the affirmative defense is finalized, EPA should separate it from that presumption and make clear that a source's use of the affirmative defense is not an admission by the source that the malfunction was a violation.

Response: See the responses to comments EPA-HQ-OAR-2002-0058-3454-A1, excerpt 8 and EPA-HQ-OAR-2002-0058-3677, excerpt 76 regarding rebuttable presumption and affirmative defense.

Document Control Number: EPA-HQ-OAR-2002-0058-3681-A2

Comment Excerpt Number: 27

Comment: Although EPA acknowledges that malfunctions occur in well operated and maintained facilities equipped with the best technologies, EPA's affirmative defense concept

essentially presumes that malfunctions never occur. Under the rule as written, any emissions occurring above the limits set using emission data obtained exclusively during normal operation (emphasis added) are considered deviations, regardless of the underlying root cause of the emissions. The reality is that malfunctions infrequently occur even on the best designed, maintained and operated units. Therefore, a facility should not be presumed guilty of having a deviation in the first place if it has experienced a legitimate malfunction.

Response: See the responses to comments EPA-HQ-OAR-2002-0058-3454-A1, excerpt 8 and EPA-HQ-OAR-2002-0058-3677, excerpt 76 regarding rebuttable presumption and affirmative defense.

Document Control Number: EPA-HQ-OAR-2002-0058-3684-A2

Comment Excerpt Number: 6

Comment: Alyeska strongly agrees with the APIINPRA comments regarding the heavy handed treatment of malfunctions in the proposed rule. The proposed text implies a presumption of guilt and imposes an unreasonable burden on the facility for each incident that may occur. The simple fact is that malfunctions will occur and no amount of planning or expense can completely eliminate them. Alyeska agrees that if a malfunction occurs and an emission limit is exceeded that the agency (either EPA or the Title V delegated agency) should be provided notification of the event including a description of the event and the corrective actions taken at the time. However, Alyeska believes that the level of information necessary to "assert the affirmative defense" should only be necessary 1) if a facility has a history of having repetitive "similar type" exceedences, and 2) the information is specifically requested by the agency. The EPA and delegated state agencies should take an enforcement discretion approach instead of treating every incident as an enforcement case.

Response: See the responses to comments EPA-HQ-OAR-2002-0058-3454-A1, excerpt 8 and EPA-HQ-OAR-2002-0058-3677, excerpt 76 regarding rebuttable presumption and affirmative defense.

105A. Civil Penalties

Commenter Name: James Pew

Commenter Affiliation: Earthjustice, Clean Air Council, Partnership for Policy Integrity

Document Control Number: EPA-HQ-OAR-2002-0058-3511-A1

Comment Excerpt Number: 52

Comment: The statute makes clear how the courts are to assess civil penalties, whether a case is brought by EPA or a citizen. 42 U.S.C. § 7413(e). Congress plainly intended citizens to be able to enforce emission standards under the CAA using the full range of civil enforcement mechanisms available to the government, and, in the HAP context, subject only to the limitation that government not be "diligently prosecuting" its own civil enforcement action, CAA § 304(b)(1)(B), 42 U.S.C. § 7604(b)(1)(B). EPA's rule proposal, by shifting this careful balance and contravening these mandates, violates the CAA.

Response: The EPA does not agree that the affirmative defense provisions should be modified in the form of a "rebuttable presumption". The EPA also believes that the burden of proof, if a violation of a standard occurs, appropriately lies with the owner/operator of a facility.

The EPA also agrees that the conditions during a malfunction event must be taken into account and believes that the affirmative defense provisions will support this review. For malfunctions, the EPA is finalizing the proposed affirmative defense language for violations of the numerical emission limits that are caused by malfunctions. The EPA recognizes that even equipment that is properly designed and maintained can fail and that such failure can cause a violation of the relevant emission standard. The EPA is including an affirmative defense in the final rule as we have in other recent section 111, section 112, and section 129 rules so as to balance the tension, inherent in many types of air regulation, to ensure adequate compliance while simultaneously recognizing that despite the most diligent of efforts, emission limits may be exceeded under circumstances beyond the control of the source. The EPA must establish emission standards that

“limit the quantity, rate, or concentration of emissions of air pollutants on a continuous basis.” 42 U.S.C. § 7602(k)(defining “emission limitation and emission standard”). See generally *Sierra Club v. EPA*, 551 F.3d 1019, 1021 (D.C. Cir. 2008) (emissions limitations under must both continuously apply and meet minimum stringency requirements, even during periods of startup, shutdown and malfunction). Thus, the EPA is required to ensure that emissions limitations are continuous. The affirmative defense for malfunction events meets this requirement by ensuring that even where there is a malfunction, the emission limitation is still enforceable through injunctive relief.

While “continuous” limitations, on the one hand, are required, there is also caselaw indicating that in some situations it is appropriate for the EPA to account for the practical realities of technology. For example, in *Essex Chemical v. Ruckelshaus*, 486 F.2d 427, 433 (D.C. Cir. 1973), the D.C. Circuit acknowledged that in setting standards under CAA section 111 “variant provisions” such as provisions allowing for upsets during startup, shutdown and equipment malfunction “appear necessary to preserve the reasonableness of the standards as a whole and that the record does not support the ‘never to be exceeded’ standard currently in force.” See also, *Portland Cement Association v. Ruckelshaus*, 486 F.2d 375 (D.C.Cir. 1973). Though intervening caselaw such as *Sierra Club v. EPA* and the CAA 1977 amendments calls into question the relevance of these cases today, they support the EPA’s view that a system that incorporates some level of flexibility is reasonable. The affirmative defense simply provides for a defense to civil penalties for excess emissions that are proven to be beyond the control of the source. By incorporating an affirmative defense, the EPA has formalized its approach to upset events. In a Clean Water Act setting, the Ninth Circuit required this type of formalized approach when regulating “upsets beyond the control of the permit holder.” *Marathon Oil Co. v. EPA*, 564 F.2d 1253, 1272-73 (9th Cir. 1977). But see, *Weyerhaeuser Co. v. Costle*, 590 F.2d 1011, 1057-58 (D.C. Cir. 1978) (holding that an informal approach is adequate). The affirmative defense provisions give the EPA the flexibility to both ensure that its emission limitations are “continuous” as required by 42 U.S.C. § 7602(k), and account for unplanned upsets and thus support the reasonableness of the standard as a whole.

Further, the EPA’s view is that the affirmative defense is consistent with CAA sections 113(e) and 304. Section 304 gives district courts jurisdiction “to apply appropriate civil penalties.” Section 113(e)(1) identifies the factors that the Administrator or a court shall take into consideration in determining the amount of a penalty to be assessed only after it has been determined that a penalty is appropriate. The affirmative defense regulatory provision is not relevant to the amount of any penalty to be assessed under section 113(e) because if a court determines that the affirmative defense elements have been established, then a penalty is not appropriate and penalty assessment pursuant to the section 113(e)(1) factors does not occur.

In exercising its authority under section 111 to establish emission standards (at a level that meets the stringency requirements of section 111), the EPA necessarily defines conduct that constitutes a violation. The EPA’s view is that the affirmative defense is part of the emission standard and defines two categories of violation. If there is a violation of the emission standard and the source demonstrates that all the elements of the affirmative defense are met, only injunctive relief is available. All other violations of the emission standard are subject to injunctive relief and penalties. The CAA does not require that all violations be treated equally.

The EPA's judgment is that the affirmative defense criteria capture the appropriate considerations in determining whether penalties are appropriate when a violation occurs as the result of a malfunction. As noted above, the affirmative defense criteria overlap to some extent with the penalty assessment criteria set forth in section 113(e), but are not identical. For example, size of business is one of the factors listed in section 113(e), but is not reflected in EPA's affirmative defense. This reflects the EPA's view that when a violation is caused by a malfunction, the size of the business is not relevant to whether penalties should be excused. If the violation was unavoidable and could not have been prevented, the EPA's view is that it would be unfair to impose a penalty no matter the size of the business. The EPA disagrees that the affirmative defense provision will hamper citizen enforcement. First, injunctive relief is still available and the threat of penalties would not deter violations in cases where all of the conditions of the affirmative defense have been satisfied because the affirmative defense criteria ensure that all reasonable steps were taken to prevent a malfunction that causes excess emissions. Further, litigating whether a source has met the affirmative defense will not burden citizen groups any more or less than would litigating the appropriate penalty amount in the penalty assessment stage of a citizen suit enforcement action, because the 113(e) penalty assessment criteria and the affirmative defense criteria are similar and in fact overlap. For example, the requirement that the Administrator or the court consider "good faith efforts to comply" is bound to generate the type of fact-intensive disputes that the commenter complains of. In addition, several of the affirmative defense criteria are exactly the type of criteria the Administrator or Court might consider in determining whether a source made "good faith efforts to comply." For example, to take advantage of the affirmative defense, the source must prove by a preponderance of the evidence that, among other things, the excess emissions "were caused by an unavoidable failure of air pollution control and monitoring equipment, process equipment, or a process to operate in a normal or usual manner" and "could not have been prevented through careful planning, proper design or better operation and maintenance practices" and "did not stem from any activity or event that could have been foreseen and avoided, or planned for." Thus, the EPA does not expect the affirmative defense provision to significantly alter the burden of bringing a citizen enforcement action. For those cases that do proceed to trial, even in the absence of this affirmative defense, sources generally raise equitable arguments to argue for a low penalty and citizens often rebut such arguments. Therefore, as a practical matter, the EPA does not expect the affirmative defense provision to materially affect the practice of CAA enforcement.

In exercising its authority under section 112 to establish emission standards (at a level that meets the stringency requirements of section 112), the EPA necessarily defines conduct that constitutes a violation. The EPA's view is that the affirmative defense is part of the emission standard and defines two categories of violation. If there is a violation of the emission standard and the source demonstrates that all the elements of the affirmative defense are met, only injunctive relief is available. All other violations of the emission standard are subject to injunctive relief and penalties. The CAA does not require that all violations be treated equally. Further, a citizen suit claim under section 304 allows citizens to commence a civil action against any person alleged to be in violation of "an emission standard or limitation under this chapter." The CAA, however, allows the EPA to establish such "enforceable emission limitations." Thus, the citizen suit provision clearly contemplates enforcement of the standards that are defined by the EPA. As a result, where the EPA defines its emissions limitations and enforcement measures to allow a source the opportunity to prove its entitlement to a lesser degree of violation (not subject to

penalties) in narrow, specified circumstances, as the EPA did here, penalties are not “appropriate” under section 304.

The EPA’s view is that an affirmative defense to civil penalties for exceedances of applicable emission standards during periods of malfunction appropriately balances competing concerns. On the one hand, citizen enforcers are concerned about additional complications in their enforcement actions. On the other hand, industrial sources are concerned about being penalized for violations caused by malfunctions that could not have prevented and were otherwise appropriately handled (as reflected in the affirmative defense criteria). The EPA has utilized its Section 301(a)(1) authority to issue regulations necessary to carry out the Act in a manner that appropriately balances these competing concerns.

Comment Excerpt Number: 53

Comment: The affirmative defense that EPA proposes to allow in case of malfunctions goes directly against congressional intent in two ways. First, Congress expressed a clear intent as to how judges should determine the size of civil penalties whenever they are sought and thus Congress 20 flatly barred EPA from limiting when civil penalties can be assessed. See *Chevron, U.S.A., Inc. v. Natural Res. Def. Council, Inc.*, 467 U.S. 837, 842-43 (1984). In this proposal, EPA acts outside of its delegated authority to limit civil penalties available in citizen suits or its own enforcement actions. Second, the proposal will impermissibly chill citizen participation, and the ability to win an effective, deterrent remedy, in CAA enforcement actions.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3511-A1, excerpt 52 regarding civil penalties.

Comment: The CAA grants EPA minimal discretion that only applies to administrative penalties, allowing EPA to "compromise, modify, or remit, with or without conditions, any administrative penalty which may be imposed under [subsection 113(d)]." 42 U.S.C. § 7413(d)(2)(B). However, there is no similar grant of authority to EPA to compromise, modify or limit civil penalties that a court may impose under section 113(e) or section 304. Section 304(a), 42 U.S.C. § 7604(a), grants courts the sole authority "to apply appropriate civil penalties" in citizen suits. The explicit reference to EPA's ability to modify penalties in one subsection and its absence in the other subsection of the same provision can only be understood as an intentional decision by Congress that EPA cannot contravene by rule.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3511-A1, excerpt 52 regarding civil penalties.

Comment: Citizen participation in CAA enforcement also will be hampered, in violation of citizens' rights to protect themselves from pollution and in direct conflict with congressional intent. The affirmative defense would likely be used on a routine basis by polluters seeking to avoid penalties, just as the malfunction exemption was. As a result, citizens who seek civil penalties against polluters in order to protect themselves and achieve the Act's goals may be forced to engage in fact-intensive disputes over the cause of emission violations and adequacy of responsive measures - an outcome Congress intended to prevent with the simple straightforward enforcement and penalty provisions in the Clean Air Act. As a result, enforcement of the Act could suffer, for civil penalties provide a powerful deterrent to violators as Congress intended.

Thus, the affirmative defense also runs counter to two clearly expressed intentions of Congress: (1) the burden it places on citizens makes it less likely that they will enforce the Act, *see, e.g., Pennsylvania v. Del. Valley Citizens' Council for Clean Air*, 478 U.S. 546, 560 (1986); and (2) several of the factors at issue in the affirmative defense undercut Congress's intent that citizen suit enforcement should avoid re-delving into "technological or other considerations," *NRDC v. Train*, 510 F.2d 692, 700 (D.C. Cir. 1974). Both result from the technical burden EPA imposes on citizens with the affirmative defense, and both render the defense impermissible.

Commenter Affiliation: Earthjustice, Clean Air Council, Partnership for Policy Integrity

Document Control Number: EPA-HQ-OAR-2002-0058-3511-A1

Comment Excerpt Number: 57

Comment: There is simply no need for an affirmative defense to penalties 21 to be written into the regulations and cause the harm that will result. EPA has discretion to decide what cases to prosecute, to consider settlements, and to request civil penalties in a case-by-case manner, as long as it acts consistent with the Clean Air Act to protect clean air as its top priority, see 42 U.S.C. § 7401. Promulgating this affirmative defense is equivalent to giving polluters "get out of jail free" cards for serious emission exceedances and MACT violations. Polluters are likely to claim that any violation of the standard is due to a malfunction in order to evade the requirements. Allowing polluters to evade financial penalties - which are the real teeth of the standards - through this type of measure is likely to lead to polluters simply ignoring or factoring potential standard violations into their cost of doing business, rather than actually trying to prevent malfunctions and violations of the standards as a way to avoid financial losses from the application of penalties.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3511-A1, excerpt 52 regarding civil penalties.

Commenter Name: James Pew

Commenter Affiliation: Earthjustice, Clean Air Council, Partnership for Policy Integrity

Document Control Number: EPA-HQ-OAR-2002-0058-3511-A1

Comment Excerpt Number: 54

Comment: The affirmative defense is fatally flawed because EPA cannot decide when civil penalties will not be allowed. The CAA itself spells out the only limits that Congress intended to impose on citizens' ability to seek and recover penalties in enforcement suits under CAA § 304, 42 U.S.C. § 7604. See 42 U.S.C. § 7413(e). By attempting to impose additional agency-created limits, EPA exceeds its authority.

Congressional intent on civil penalties is clear—they are a remedy available to citizen plaintiffs, and the Act gives judges a list of factors to consider in assessing them. As such, EPA cannot interpret the statute to contravene that intent. By attempting to rewrite this provision, via regulation, EPA has done just that.

Response: See DCN EPA-HQ-OAR-2002-0058-3511-A1, Excerpt 52 regarding civil penalties.

The EPA has determined that CAA section 112 does not require that emissions that occur during periods of malfunction be factored into development of CAA section 112 standards. As the EPA further explained, accounting for malfunctions would be difficult, if not impossible, given the myriad different types of malfunctions that can occur across all sources in the category and given the difficulties associated with predicting or accounting for the frequency, degree, and duration of various malfunctions that might occur. Setting work practice standards under section 112 presents the same issues as setting numerical emission limits given the varied nature of malfunctions. Thus EPA does not agree with commenter's suggestion that EPA apply work practices for malfunction events. EPA recognizes that even equipment that is properly designed and maintained can sometimes fail and that such failure can sometimes cause an exceedance of the relevant emission standard. (See, e.g., State Implementation Plans: Policy Regarding Excessive Emissions During Malfunctions, Startup, and Shutdown (Sept. 20, 1999); Policy on Excess Emissions During Startup, Shutdown, Maintenance, and Malfunctions (Feb. 15, 1983)). EPA, therefore, added an affirmative defense to civil penalties for exceedances of numerical emission limits that are caused by malfunctions. The affirmative defense criteria are not requirements that a source must meet. In an action to enforce a violation of a standard caused by a malfunction, a source can choose to assert an affirmative defense. The affirmative defense is not relevant to malfunctions that do not result in violations of emission standards.

EPA disagrees with comments that criticize the affirmative defense criteria as being overly vague or unduly restrictive and complex. The EPA believes that courts are well equipped and often do evaluate and apply the type of criteria set forth in the affirmative defense. Many of the conditions were modeled after the conditions of the affirmative defense in the EPA's SIP SSM policy, which several states have adopted into their SIPs. (See, e.g., State Implementation Plans: Policy Regarding Excessive Emissions During Malfunctions, Startup, and Shutdown (Sept. 20, 1999); Policy on Excess Emissions During Startup, Shutdown, Maintenance, and Malfunctions (Feb. 15, 1983)). We do not have any indication that parties to enforcement proceedings have had any significant difficulties applying the terms of these SIP affirmative defenses. In addition, the EPA's view is that use of consistent terms in establishing affirmative defense regulations and

policies across various CAA programs will promote consistent implementation of those rules and policies.

EPA explained its view that a formal approach of an affirmative defense was preferable to an informal enforcement discretion approach for the following reasons: “First, the existence of a formal process better informs the public of the policy and factual issues which will underline enforcement of the standards. Second, affected industries which are making good-faith efforts to meet the standards will on the whole welcome a regularized means of informing the Agency in detail of the circumstances surrounding unavoidable emission excesses. Third, the Agency expects to benefit substantially from the information it will gain about the operation of the processes in question, for both future enforcement and standard setting.” 37 Fed. Reg. 17,214, 17,214-15 (Aug. 25, 1972). The affirmative defense is not an informal enforcement discretion approach of the type that EPA rejected in 1972 and provides the benefits associated with the formalized approach that EPA identified in its 1972 proposal. *See, Mont. Sulphur & Chem. Co. v. United States EPA*, 2012 U.S. App. LEXIS 1056 (5th cir. Jan 19, 2012)(in rejecting industry argument that reliance on the affirmative defense was not adequate, court stated “[h]owever, here the EPA does not rely on enforcement discretion alone, but specifically promulgates an affirmative defense in the FIP, which clearly defines the requirements to avoid penalties.”).

Recordkeeping and Reporting Requirements

Document Control Number: EPA-HQ-OAR-2002-0058-3506-A1

Comment Excerpt Number: 6

Comment: Under the current and proposed rules, emission sources make their own determination about whether they are exempt from the boiler rules, but are not required to maintain records to support their determination. This creates an untenable situation for state enforcement staff who must determine whether a given unit is subject to the rules. Without adequate recordkeeping requirements, agencies will find it impossible to enforce these rules. Having emission sources maintain these records will assure that enforcement agencies can accurately assess the applicability determinations. Records should include the reasoning for

determining whether each unit is exempt from the requirements of the area source rule, e.g., whether it can be classified as a residential or temporary boiler. Similarly, sources should be required to maintain records of fuel use by units. This will assist enforcement officials in determining the compliance and exemption status of sources.

To address these issues, NESCAUM recommends that EPA insert language requiring sources asserting exemptions from the area and major source boiler rules to maintain records to support their exemption determination. In addition, NESCAUM recommends that sources be required to maintain records of fuel use for each unit.

Commenter Affiliation: American Forest & Paper Association (AF&PA) et al.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 141

Comment: The Boiler MACT requires several plans to be submitted by facilities using various compliance options. An emissions averaging plan must be submitted at least 180 days prior to the date that the facility intends to demonstrate compliance using emissions averaging. A site-specific fuel analysis plan must be submitted at least 60 days prior to the initial performance test. There are likely to be hundreds of such submissions, since fuel analysis is anticipated to be widely used as a component of demonstrating compliance with numerical emission limits. It is highly unlikely all these plans can be reviewed before the initial compliance date and, unless the source is deviating from the methodologies specified in the rule, there is no reason for such a review. Thus, we recommend that approval only be required where the source is requesting to use an alternative analytical methodology. EPA should also make it clear in the final rule that if the permitting authority does not respond to the facility with approval or disapproval of the plan prior to the compliance demonstration, then the plan is considered approved.

Comment Excerpt Number: 9

Comment: Pulp and paper manufacturing facilities in the US must be efficient and globally costcompetitive.

The proposed rule's data collection (Section 63.7555 recordkeeping) and reporting requirements in Section 63.7550 include redundant reporting burdens. Redundant requirements include having to re-submit performance test and fuel analysis results which have already been submitted to the delegated authority. This is labor intensive and overly burdensome. Facilities cannot compete globally when encumbered with such costly, excessive, and unreasonable regulatory obligations.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Commenter Name: Sarah Hedrick

Commenter Affiliation: Verso Paper Corp.

Comment: Initial notification requirements in 63.7545(b) for existing boilers and process heaters are not appropriate for natural gas-fired boilers and the rules should be clarified to exclude boilers that do not have emission limits.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Commenter Name: Matthew Todd

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 153

Comment: The proposal requires submission of an Initial Notification no later than 120 calendar days after a facility becomes subject to rule , even if an initial notification was previously submitted. We see no reason for having to file another initial notice since the only information it provides is that certain facilities are subject to the subpart. If initial notifications were submitted in 2004 or in response to the 2011 rule, why is it necessary to submit additional notifications? EPA and permitting authorities were notified of BPH NESHAP applicability and, in many cases, have already reflected that applicability in permits. A new initial notice submittal serves no purpose and should only be required if a facility was not previously subject to the rule and has not previously submitted an initial notice.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Commenter Name: Janice E. Nolen

Commenter Affiliation: American Lung Association

Document Control Number: EPA-HQ-OAR-2002-0058-3679-A2

Comment Excerpt Number: 14

Comment: Public records for monitoring and compliance with emissions limits. The Lung Association recommends that the records and reports of monitoring and compliance measures for emissions limits be made easily and readily accessible to the public. The public has an established right to know about the emissions of toxic substances. For 25 years, EPA has required companies to make public information on toxic chemicals released into the community through the Toxic Release Inventory (TRI). We support a system similar to TRI, where facilities are required to report toxic emissions to the database and make data relating to those emissions available online.

EPA should require boiler operators to publicly disclose and report all monitoring data and compliance documentation—including with required work practices standards—and submit those data reports to EPA for public access online. These would include data and results from performance tests of facilities and emissions that occur during malfunctions of boiler equipment. Communities have a right to know what toxic air pollutants are emitted by boilers and incinerators, the quantities of each type of pollutant being emitted, when those emissions are occurring, particularly when the emissions exceed limits set by EPA.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Commenter Name: M.L. Steele

Commenter Affiliation: CraftMaster Manufacturing, Inc.

Document Control Number: EPA-HQ-OAR-2002-0058-3814-A1

Comment Excerpt Number: 24

Comment: §63.7545(h). Thirty days notice is required for a fuel switch that would result in the applicability of a different subcategory. If a change in biomass firing method by a unit capable of firing in more than one biomass subcategory would trigger this notice requirement, this is further justification for better guidance on the applicability of the biomass subcategories. 30-day notice

would not be practical for such a unit because changes in biomass firing method can occur on an hourly basis.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Commenter Name: Gretchen Brewer

Commenter Affiliation: PT AirWatchers

Document Control Number: EPA-HQ-OAR-2002-0058-3825-A1

Comment Excerpt Number: 6

Comment: Fuel reporting requirements -- regular analysis reports with breakouts by fuel types and ratios are increasingly important as boilers are using shifting varieties and mixes of fuels, such as waste fuel oils, construction and demolition debris, tires (!), medical and agricultural wastes, and pretty much anything that can be burned. The given mix at any time profoundly affects the resulting pollution, and the effects that it has on those of use who have to breathe it.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Compliance

14A. Emissions Averaging: Output-Based Standards

Commenter Name: Lisa Jacobson

Commenter Affiliation: Business Council for Sustainable Energy (BCSE)

Document Control Number: EPA-HQ-OAR-2002-0058-3497-A1

Comment Excerpt Number: 1

Comment: *Clarifying that facilities may simultaneously adopt the alternative output-based compliance standard and average emissions.* BCSE members expressed concern in reaction to the March 21, 2011 rule's apparent prohibition against combining both an output-based emissions standard and emissions averaging. The Council commends EPA for correcting this oversight in the re-proposed rule by allowing averaging for units that elect to comply with the output-based standards and for providing clear direction on how a facility may opt simultaneously for output-based emissions limitations and emissions averaging. As EPA notes in the re-proposed rule, "there is no technical reason why averaging of output-based limits is inappropriate."

Response: The EPA thanks the commenter for their support. The commenter is referring to the addition of equations 1b and 3b in §63.7522 (Can I use emissions averaging to comply with this subpart?) of the December 2011 Reconsideration Proposal which were proposed to be added to clarify that averaging of the output-based limits was allowed.

Commenter Name: Peter Pagano

Commenter Affiliation: American Iron and Steel Institute (AISI)

Document Control Number: EPA-HQ-OAR-2002-0058-3490-A1

Comment Excerpt Number: 32

Comment: The emissions averaging provision should be expanded to provide operational flexibility and lowest compliance costs.

Affected parties may choose to comply with output-based emission limits in lieu of input-based standards for boilers that generate steam. Although the Reconsidered Rule does not provide for averaging, EPA recognizes that there is no technical reason why averaging of output-based limits should not be included. We agree and strongly encourage EPA to include emissions averaging in its output-based standards, as originally argued by the Council of industrial Boiler Owners.⁴¹

[Footnote]

(41) Comment attachment submitted by Robert D. Bessette, President, CIBO, EPA-HQOAR-2002-0058-2702; Revised Methodology for Estimating Cost and Emissions Impacts for Industrial, Commercial, Institutional Boilers and Process Heaters NESHAP- Major Source, EPA-HQ-OAR-2002-0058-3259.

Response: The EPA thanks the commenter for their support. See the response to comment EPA-HQ-OAR-2002-0056-3497-A1, excerpt 1 regarding output-based standards.

Commenter Name: Michael Bradley

Commenter Affiliation: The Clean Energy Group

Document Control Number: EPA-HQ-OAR-2002-0058-3495-A1

Comment Excerpt Number: 6

Comment: Additionally, EPA notes that, due to time constraints, the Agency did not finalize a process by which units complying with the output-based standards could utilize the emissions averaging provisions. In this rulemaking, EPA proposes to specifically allow units to use emissions averaging regardless of compliance with input- or output-based standards. EPA also proposes to include methodology to allow units that only generate electricity to comply with output-based standards. The Clean Energy Group supports this change to allow units complying with output-based standards to utilize all compliance flexibilities.

Response: The EPA thanks the commenter for their support. See the response to comment EPA-HQ-OAR-2002-0056-3497-A1, excerpt 1 regarding output-based standards.

Commenter Name: Michael L. Krancer

Commenter Affiliation: Pennsylvania Department of Environmental Protection (DEP)

Document Control Number: EPA-HQ-OAR-2002-0058-3507-A1

Comment Excerpt Number: 5

Comment: The EPA is also proposing to allow averaging for units that elect to comply with the output-based standards. The DEP supports EPA's proposal to allow averaging for the owners or operators of units that elect to comply with the output-based standards. We also agree that these standards are equivalent to the input-based standards and promote energy efficiency.

Response: The EPA thanks the commenter for their support. See the response to comment EPA-HQ-OAR-2002-0056-3497-A1, excerpt 1 regarding output-based standards.

Commenter Name: Vickie Woods

Commenter Affiliation: Division of Air Quality, North Carolina Department of Environment and Natural Resources (NCDENR)

Document Control Number: EPA-HQ-OAR-2002-0058-3663-A2

Comment Excerpt Number: 5

Comment: Boiler efficiency calculation changes; EPA is proposing to add equations to allow for emissions averaging of output-based emission limits; averaging of output based limits was not previously included, although there is no technical reason why averaging of output based limits is inappropriate, given output-based limits are equivalent to input-based limits and promote energy efficiency.

NC DAQ supports the addition of output based emission limits to promote energy efficiency. We believe this is consistent with other sections of the subpart promoting and requiring energy efficiency measures.

Response: The EPA thanks the commenter for their support. See the response to comment EPA-HQ-OAR-2002-0056-3497-A1, excerpt 1 regarding output-based standards.

Commenter Name: David Gardiner

Commenter Affiliation: The Alliance for Industrial Efficiency

Document Control Number: EPA-HQ-OAR-2002-0058-3683-A2

Comment Excerpt Number: 4

Comment: We Commend EPA for Allowing Facilities to Simultaneously Adopt the Alternative Output-Based Compliance Standard and Average Emissions.

As elaborated above, the Alliance for Industrial Efficiency appreciates that the December Rule includes an output-based limitation option, which provides incentives for undertaking energy efficiency measures, including CHP and WHR, and that energy efficiency measures undertaken by the regulated entity can be credited toward compliance with the Rule. We also commend EPA for allowing emissions averaging within the Rule. As we noted in our Petition for Reconsideration, we were concerned about the apparent inability to combine both an output-based emissions standard and average emissions in the March 21, 2011 Rule. This limitation would force facilities to choose between two approaches that would support energy efficiency improvements.

We commend EPA for correcting this oversight in the re-proposed rule by allowing averaging for units that elect to comply with the output-based standards and for providing clear direction on how a facility may opt simultaneously for output-based emissions limitations and emissions averaging. As EPA notes in the re-proposed rule, "there is no technical reason why averaging of output-based limits is inappropriate."

Response: The EPA thanks the commenter for their support. See the response to comment EPA-HQ-OAR-2002-0056-3497-A1, excerpt 1 regarding output-based standards.

Comment: EPA has included numerous compliance demonstration alternatives in the Proposed Rule. AMP appreciates EPA's efforts to provide flexibility to the regulated community and supports EPA's inclusion of the following optional compliance alternatives:

Output-based emission limits tied to an emission credit scheme.

Response: The EPA thanks the commenter for their support. See the response to comment EPA-HQ-OAR-2002-0056-3497-A1, excerpt 1 regarding output-based standards.

14B. Emissions Averaging: Fuel Switching to Natural Gas

Commenter Name: Robert D. Bessette

Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 53

Comment: The emissions averaging provisions should allow owners or operators of a solid fuel or liquid fuel boiler to repower (convert) that boiler to natural gas (gas 1) within the averaging process.

EPA, in response to input from stakeholders, solicits comment on a suggested approach to allow an existing unit that is converted to natural gas to be included in an emissions average with other similar existing units.

76 Fed. Reg. 80617. CIBO strongly supports allowing companies to convert coal-fired units to cleaner-burning gas fuels without revoking that unit's eligibility for emissions averaging with remaining coal-fired units. For some companies, switching boilers from coal to cleaner-burning natural gas will offer the best environmental and business outcome because it will (1) result in greater emission reductions than what will be achieved through a standard end-of-stack control option and (2) it will allow facilities to implement a more cost-effective solution, conserving their capital for productive use in growth projects that may assist with the nation's economic recovery.

Moreover, this approach is fully consistent with both the express language of §112, which gives EPA considerable discretion in establishing source subcategories, and §112's underlying intent, which is to promote a "maximum degree of reduction in emissions of the hazardous air pollutants while "taking into consideration the cost of achieving such emission reduction, and any non-air quality health and environmental impacts and energy requirements." 42 U.S.C.

§7412(d). Given EPA's support for emissions averaging between coal-fired units where operators elect to invest in capital-intensive pollution control technologies, EPA should support emissions averaging where operators select fuel switching as the most effective compliance strategy. While natural gas conversion is not available to every facility in every region, where it is technically and economically feasible, it offers the ability to reduce emissions far below the levels available with end-of-stack controls alone. 12

[Footnote 12: Here, it is important to distinguish between a mandatory fuel switching policy, as would occur if EPA presumed fuel switching to be a universal option for the purpose of setting MACT floor and beyond-the-floor standards, and voluntary fuel switching as a compliance strategy option. EPA has correctly recognized that it would be inappropriate to consider fuel switching as a universally-available factor for the purposes of setting MACT floor and beyond-the-floor standards. Specifically, EPA's 2010 proposed rule included a lengthy discussion of the pros and cons of fuel switching as a basis for setting floor and beyond the floor standard, ultimately dismissing the approach based on: 1) uncertainties regarding whether such a strategy would result in a net reduction of HAP emissions on a category-wide basis; 2) whether fuel switching would be technically achievable on a category wide basis; and 3) whether alternative fuels like natural gas would be reasonably available to all units within a category. See 75 Fed. Reg. 32,019 ("After considering these factors, we determined that fuel switching was not an appropriate control technology for purposes of determining the MACT floor level of control for any subcategory. This decision was based on the overall effect of fuel switching on HAP emissions, technical and design considerations discussed previously in this preamble, and concerns about fuel availability"). EPA's conclusion remains sound with respect to setting subcategory-wide standards. As numerous commenters have noted in the administrative record, the significant diversity of engineering, technological, and fuel-availability infrastructure available to units within any given subcategory make fuel substitution an impractical, if not arbitrary and capricious, basis for setting industry-wide floor or beyond-the-floor standards]

Response: EPA interprets section 112(d) to provide discretion to establish provisions that allow for emissions averaging, with certain restrictions to ensure that averaging does not violate the requirements of section 112. See 59 Fed. Reg., 19402, 19425 (Apr. 22, 1994). EPA first notes that section 112 does not require that the Agency allow emissions averaging in all MACT rules, but rather provides the discretion to do so where appropriate. In the boiler MACT, EPA has established an emissions averaging provision that is consistent with similar provisions in other MACT rules. It has been EPA's longstanding position that emissions averaging is not appropriate between sources that are not subject to the same emissions standard, such as coal-fired and natural gas-fired boilers, which are subject to different standards. While we understand that switching boilers from coal to cleaner-burning natural gas can offer environmental benefits, allowing emissions from natural gas boilers to be averaged with emissions from coal boilers when determining compliance would be inconsistent with this long-standing interpretation of EPA's discretion under section 112. See 62 Fed. Reg. 52384, 52388 (Oct. 7, 1997) and 77 Fed. Reg. 9304, 9384 (Feb. 16, 2012) (noting that emissions averaging in the MATS rule can only be used between EGUs in the same subcategory at a particular facility). In addition, such an approach would allow averaging among multiple sources, which would again be inconsistent with EPA's long-standing interpretation of its discretion to establish averaging provisions under section 112. *Id.* (referring to averaging within the same facility). The affected source as defined in the Boiler MACT is the collection of boilers and process heaters at a single facility within the

same subcategory. Each subcategory has its own emissions standards. As explained in the preamble to EPA's earlier establishment of emissions averaging programs, if averaging were permitted between units subject to different standards (such as coal-fired and natural gas-fired boilers), it is likely that one of the sources' emissions would violate the standard that applies to it. See 59 Fed. Reg. at 19427. The commenters provide no explanation as to how the long-standing restrictions that EPA has applied to averaging provisions will be met if EPA allows averaging between coal-fired boilers and boilers converted to combust natural gas. For these reasons, EPA is not revising the proposed rule to allow such averaging.

Comment Excerpt Number: 21

Comment: The EPA is soliciting comment on the potential benefit of switching to cleaner fuels such as natural gas, which are environmentally beneficial, for purposes of averaging emissions with units of the original unit design.

The DEP believes that units that are retrofitted to switch to natural gas should be allowed to average emissions with units of the original unit design; this approach is environmentally beneficial. In addition, the DEP agrees with the petitioners that allowing averaging across subcategories when fuel-switching has been used to achieve compliance and would encourage fuel-switching to cleaner fuels.

Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1

Comment Excerpt Number: 139

Comment: *THE EMISSIONS AVERAGING PROVISIONS SHOULD ALLOW OWNERS OR OPERATORS OF A SOLID FUEL OR LIQUID FUEL BOILER TO REPOWER (CONVERT) THAT BOILER TO NATURAL GAS (GAS 1) WITHIN THE AVERAGING PROCESS.*

On page 80617 of the Reconsidered Proposal, EPA, in response to input from stakeholders, solicits comment on a suggested approach to allow an existing unit that is converted to natural

gas to be included in an emissions average with other similar existing units. EPA's request for comment is shown below: *Stakeholders asked the EPA to consider, for units that are retrofitted to switch to natural gas as a compliance option, allowing those units to average emissions with units of the original unit design. These parties suggested that continuing to allow such averaging would be consistent with EPA's general approach of specifying emission standards for affected facilities, but otherwise allowing the facilities to comply however they see fit. They also pointed out that this may allow for more effective controls overall. For example, they suggested that without allowing for averaging of units that switch to cleaner fuels as a compliance option, natural gas conversion is a less attractive option than if such averaging was allowed, because a facility would not have the ability to offset emissions using that unit. In this case, these stakeholders believe that installing controls that result in fewer emissions reductions than switching to natural gas may be a perverse outcome. They suggested that continuing to allow averaging across subcategories in cases where fuel switching has been used to achieve compliance would instead encourage fuel switching to cleaner fuels, which is environmentally beneficial. The EPA is requesting comment on the potential benefit of this suggested approach, and how such an approach could be justified and incorporated into the rule.*

ACC strongly supports allowing companies to convert coal-fired units to cleaner-burning gas fuels without revoking that unit's eligibility for emissions averaging with remaining coal-fired units. For some companies, switching boilers from coal to cleaner-burning natural gas will offer the best environmental and business outcome because it will (1) result in greater emission reductions than what will be achieved through a standard end-of-stack control option and (2) it will allow facilities to implement a more cost-effective solution, conserving their capital for productive use in growth projects that may assist with the nation's economic recovery.

Comment Excerpt Number: 1

Comment: Purdue thanks EPA for continuing to incorporate emissions averaging into the rule. In addition, Purdue supports the proposal discussed in the preamble to allow units switched to natural gas for Boiler MACT compliance to be used in emissions averaging with other boilers of the same category as the fuel switched boiler was prior to Boiler MACT compliance. To determine the emission value of the fuels switched unit to be used in the averaging equation, Purdue suggests the use of the method detection limits for the averaged pollutants.

Comment Excerpt Number: 52

Comment: Sec. 63.7522 Can I use emissions averaging to comply with this subpart?

(a) As an alternative to meeting the requirements of §63.7500 for particulate matter, hydrogen chloride, or mercury on a boiler or process heater-specific basis, if you have more than one existing boiler or process heater in any subcategory subject to a numerical emission standard in Table 2 to this subpart located at your facility, you may demonstrate compliance by emissions averaging if you satisfy the requirements in paragraphs (b) through (m).

(b) You may not include new boilers or process heaters in an emissions average.

(c) For purposes of this section, an existing boiler or process heater that is part of any subcategory listed in Table 2 to this subpart as of December 23, 2011 may be included in an emissions average group with other existing units within these subcategories even if the boiler or process heater is converted to be part of the *unit designed to burn gas 1 subcategory* after December 23, 2011. Such a converted boiler or process heater shall not be required to conduct subsequent annual performance tests as required by §63.7515(b). Such a unit shall be subject to the other applicable requirements in this subpart for units designed to burn gas 1.

(d) For a group of two or more existing boilers or process heaters that each vent to a separate stack, you may average particulate matter, hydrogen chloride, or mercury emissions among existing units to demonstrate compliance with the limits in Table 2 to this subpart as specified in paragraph (b)(1) through (3) of this section, if you satisfy the requirements in paragraphs (e) through (g) of this section.

(e) For each existing boiler or process heater in the averaging group, the emission rate achieved during the initial compliance test for the HAP being averaged must not exceed the emission level that was being achieved on [DATE 60 DAYS AFTER PUBLICATION OF THE FINAL RULE IN THE Federal Register] or the control technology employed during the initial compliance test must not be less effective for the

HAP being averaged than the control technology employed on [DATE 60 DAYS AFTER PUBLICATION OF THE FINAL RULE IN THE Federal Register].

(f) For all boilers or process heaters included in an emissions average, the owner or operator shall:

(1) Calculate and record monthly debits for all boilers and process heaters that are controlled to a level less stringent than the applicable emission standard from Table 2 to this subpart. Equations in paragraph (g) of this section shall be used to calculate debits.

(2) Calculate and record monthly credits for all boilers and process heaters that are over-controlled to compensate for the debits. Equations in paragraph (h) of this section shall be used to calculate credits.

(3) After 12 complete calendar months of operation, and at the end of each subsequent calendar month, following the compliance date specified in §63.7495, demonstrate that the 12-month moving total credits calculated according to paragraph (h) of this section are greater than or equal to debits calculated for the same 12-month moving period according to paragraph (g) of this section.

(i) The owner or operator may choose to include more than the required number of credit-generating boilers and process heaters in an average in order to increase the likelihood of being in compliance.

(ii) The initial demonstration in the implementation plan for emissions averaging required in § 63.7522(i) that credit-generating boilers and process heaters will be capable of generating sufficient credits to offset the debits from the debit-generating boilers and process heaters must be made under representative operating conditions. After the compliance date, actual operating data will be used for all debit and credit calculations.

(4) Record and report 12-month moving credits and debits in the compliance reports required in §63.7550(c) of this subpart.

(g) Debits are calculated as follows:

(1) If you are complying with emission limits on a heat input basis, debits are generated by the difference between the actual emissions from a boiler or process heater that is uncontrolled or is controlled to a level less stringent than the applicable emission standard from Table 2 to this subpart, and the emissions allowed for the boiler or process heater by the applicable emission standard from Table 2 to this subpart. Debits shall be calculated as follows:

The overall equation for calculating source-wide debits is:

n

$$\text{Debits} = \sum_{i=1}^n (E_r - E_l) H_b \text{ Eq 1a}$$

i=1

Where:

E_r = Emission rate (as determined during the most recent compliance demonstration or from continuous emissions monitoring systems) of particulate matter, hydrogen chloride, or mercury from unit, i , in units of pounds per million Btu of heat input. Determine the emission rate for particulate matter, hydrogen chloride, or mercury by performance testing according to Table 5 to this subpart, or by fuel analysis for hydrogen chloride or mercury using the applicable equation

in §63.7530(c). Alternative equations and sampling and analytical plans for determining emission rate by fuel analysis may be proposed to and approved by the applicable delegated authority as part of the implementation plan for emissions averaging required in to §63.7522(i). If you are taking credit for energy conservation measures from a unit according to §63.7533, use the adjusted emission level for that unit, E_{adj} , determined according to §63.7533 for that unit.

E_l = Emission limit from Table 2 to this subpart for unit, i , in units of pounds per million Btu of heat input.

H_b = The heat input for that calendar month to unit, i , in units of million Btu. If you are not capable of monitoring heat input, use the following equation to determine H_b :

$$H_b = S_a \times C_{fi}$$

Where:

S_a = Actual steam generation for that calendar month, by boiler or process heater, i , in units of pounds.

C_{fi} = Conversion factor, as calculated during the most recent compliance test, in units of million Btu of heat input per pounds of steam generated for boiler or process heater, i .

n = number of units participating in the emissions averaging option.

(2) If you are complying with emission limits on steam generation (output) basis, debits are generated by the difference between the actual emissions from a boiler or process heater that is uncontrolled or is controlled to a level less stringent than the applicable emission standard from Table 2 to this subpart, and the emissions allowed for the boiler or process heater by the applicable emission standard from Table 2 to this subpart. Debits shall be calculated as follows:

The overall equation for calculating source-wide debits is:

n

$$\text{Debits} = \sum_{i=1}^n (E_r - E_l) \text{ So Eq 1b}$$

$i=1$

Where:

E_r = Emission rate (as determined during the most recent compliance demonstration or from continuous emissions monitoring systems) of particulate matter, hydrogen chloride, or mercury from unit, i , in units of pounds per million Btu of steam output. Determine the emission rate for particulate matter, hydrogen chloride, or mercury by performance testing according to Table 5 to this subpart, or by fuel analysis for hydrogen chloride or mercury using the applicable equation in §63.7530(c). Alternative equations and sampling and analytical plans for determining emission rate by fuel analysis may be proposed to and approved by the applicable delegated authority as part of the implementation plan for emissions averaging required in to §63.7522(i). If you are taking credit for energy conservation measures from a unit according §63.7533, use the adjusted emission level for that unit, E_{adj} , determined according to §63.7533 for that unit.

El= Emission limit from Table 2 to this subpart for unit, i, in units of pounds per million Btu of heat input.

So = Maximum steam output capacity of unit, I, in units of million Btu per hour, as defined in §63.7575.

n = number of units participating in the emissions averaging option.

(h) Credits are calculated as follows:

(1) If you are complying with emission limits on a heat input basis, credits are generated by the difference between the emissions that are allowed for boiler or process heater by the applicable emission standard from Table 2 to this subpart and the actual emissions from a boiler or process heater that is uncontrolled or is controlled to a level less stringent than the applicable emission standard from Table 2 to this subpart. Credits shall be calculated as follows:

The overall equation for calculating source-wide credits is:

n

Debits = $D \sum_{i=1} (El - Er) H_b$ Eq 2a

i=1

Where:

D= Discount factor=0.9 for all credit generating boilers or process heaters.

El= Emission limit from Table 2 to this subpart for unit, i, in units of pounds per million Btu of heat input.

Er = Emission rate (as determined during the most recent compliance demonstration or from continuous emissions monitoring systems) of particulate matter, hydrogen chloride, or mercury from unit, i, in units of pounds per million Btu of heat input. Determine the emission rate for particulate matter, hydrogen chloride, or mercury by performance testing according to Table 5 to this subpart, or by fuel analysis for hydrogen chloride or mercury using the applicable equation in §63.7530(c). Alternative equations and sampling and analytical plans for determining emission rate by fuel analysis may be proposed to and approved by the applicable delegated authority as part of the implementation plan for emissions averaging required in to §63.7522(i). If you are taking credit for energy conservation measures from a unit according §63.7533, use the adjusted emission level for that unit, Eadj, determined according to §63.7533 for that unit.

Hb = The heat input for that calendar month to unit, i, in units of million Btu. If you are not capable of monitoring heat input, use the following equation to determine Hb:

$H_b = S_a \times C_f$

Where:

Sa = Actual steam generation for that calendar month, by boiler or process heater, I, in units of pounds.

C_{fi} = Conversion factor, as calculated during the most recent compliance test, in units of million Btu of heat input per pounds of steam generated for boiler or process heater, i.

n = number of units participating in the emissions averaging option.

(2) If you are complying with emission limits on a steam generation (output) basis, credits are generated by the difference between the emissions that are allowed for boiler or process heater by the applicable emission standard from Table 2 to this subpart and the actual emissions from a boiler or process heater that is uncontrolled or is controlled to a level less stringent than the applicable emission standard from Table 2 to this subpart. Credits shall be calculated as follows:

The overall equation for calculating source-wide credits is:

n

$$\text{Debits} = D \sum_{i=1} (E_i - E_r) S_{o_i} \quad \text{Eq 2b}$$

i=1

Where:

D= Discount factor=0.9 for all credit generating boilers or process heaters.

E_i= Emission limit from Table 2 to this subpart for unit, i, in units of pounds per million Btu of heat input.

E_r = Emission rate (as determined during the most recent compliance demonstration or from continuous emissions monitoring systems) of particulate matter, hydrogen chloride, or mercury from unit, i, in units of pounds per million Btu of heat input. Determine the emission rate for particulate matter, hydrogen chloride, or mercury by performance testing according to Table 5 to this subpart, or by fuel analysis for hydrogen chloride or mercury using the applicable equation in §63.7530(c). Alternative equations and sampling and analytical plans for determining emission rate by fuel analysis may be proposed to and approved by the applicable delegated authority as part of the implementation plan for emissions averaging required in to §63.7522(i). If you are taking credit for energy conservation measures from a unit according to Sec. 63.7533, use the adjusted emission level for that unit, E_{adj}, determined according to Sec. 63.7533 for that unit.

S_o = Maximum steam output capacity of unit, I, in units of million Btu per hour, as defined in §63.7575.

n = number of units participating in the emissions averaging option.

(i) You must develop, and submit to the applicable delegated authority for review and approval, an implementation plan for emission averaging according to the following procedures and requirements in paragraphs (i)(1) through (4) of this section.

(1) You must submit the implementation plan no later than 180 days before the date that the facility intends to demonstrate compliance using the emission averaging option.

(2) You must include the information contained in paragraphs (i)(2)(i) through (viii) of this section in your implementation plan for all emission sources included in an emissions average:

(i) The identification of all existing boilers and process heaters in the averaging group, including for each either the applicable HAP emission level or the control technology installed as of [DATE 60 DAYS AFTER PUBLICATION OF THE FINAL RULE IN THE Federal Register] and the date on which you are requesting emission averaging to commence;

(ii) The process parameter (heat input or steam generated) that will be monitored for each averaging group;

(iii) The specific control technology or pollution prevention measure to be used for each emission boiler or process heater in the averaging group and the date of its installation or application. If the pollution prevention measure reduces or eliminates emissions from multiple boilers or process heaters, the owner or operator must identify each boiler or process heater;

(iv) The test plan for the measurement of particulate matter, hydrogen chloride, or mercury emissions in accordance with the requirements in Sec. 63.7520;

(v) The operating parameters to be monitored for each control system or device consistent with §63.7500 and Table 4, and a description of how the operating limits will be determined;

(vi) If you request to monitor an alternative operating parameter pursuant to §63.7525, you must also include:

(A) A description of the parameter(s) to be monitored and an explanation of the criteria used to select the parameter(s); and

(B) A description of the methods and procedures that will be used to demonstrate that the parameter indicates proper operation of the control device; the frequency and content of monitoring, reporting, and recordkeeping requirements; and a demonstration, to the satisfaction of the applicable delegated authority, that the proposed monitoring frequency is sufficient to represent control device operating conditions; and

(vii) A demonstration that compliance with each of the applicable emission limit(s) will be achieved under representative operating load conditions. Following each compliance demonstration and until the next compliance demonstration, you must comply with the operating limit for operating load conditions specified in Table 4 to this subpart.

(viii) Any requested alternative equation and sampling and analytical plans for determining emission rate by fuel analysis for use in calculating credits and debits pursuant to §63.7522(g) and (h).

(3) The delegated authority shall review and approve or disapprove the plan according to the following criteria:

(i) Whether the content of the plan includes all of the information specified in paragraph (i)(2) of this section; and

(ii) Whether the plan presents sufficient information to determine that compliance will be achieved and maintained.

(4) The applicable delegated authority shall not approve an emission averaging implementation plan containing any averaging between emissions of differing pollutants.

(j) For a group of two or more existing affected units, each of which vents through a single common stack, you may average particulate matter, hydrogen chloride, or mercury emissions to demonstrate compliance with the limits for that pollutant in Table 2 to this subpart if you satisfy the requirements in paragraph (k) or (l) of this section.

(k) For a group of two or more existing units in the same subcategory, each of which vents through a common emissions control system to a common stack, that does not receive emissions from units in other subcategories or categories, you may treat such averaging group as a single existing unit for purposes of this subpart and comply with the requirements of this subpart as if the group were a single unit.

(l) For all other groups of units subject to the common stack requirements of paragraph (j) of this section, including situations where the exhaust of affected units are each individually controlled and then sent to a common stack, the owner or operator may elect to:

(1) Conduct performance tests according to procedures specified in Sec. 63.7520 in the common stack if affected units from other subcategories vent to the common stack. The emission limit (El in Equations 1a, 1b, 2a, and 2b) for the group is determined by the use of Equation 3 of this section.

$$N \text{ n El} = \Sigma (\text{Eli} \times \text{Hi}) \div \Sigma \text{Hi} \text{ Eq. 3}$$

i=1 i=1

Where:

El = HAP emission limit, pounds per million British thermal units (lb/MMBtu).

Eli = Appropriate emission limit from Table 2 to this subpart for unit i, in units of lb/MMBtu.

Hi = Heat input from unit i, MMBtu.

(2) Conduct performance tests according to procedures specified §63.7520 in the common stack. If affected units and non-affected units vent to the common stack, the non-affected units must be shut down or vented to a different stack during the performance test unless the facility determines to demonstrate compliance with the non-affected units venting to the stack; and

(3) Meet the applicable operating limit specified §63.7540 and Table 8 to this subpart for each emissions control system (except that, if each unit venting to the common stack has an applicable opacity operating limit, then a single continuous opacity monitoring system may be located in the common stack instead of in each duct to the common stack).

(m) The common stack of a group of two or more existing boilers or process heaters in the same subcategory subject to paragraph (j) of this section may be treated as a separate stack for purposes of

paragraph (f) of this section and included in an emissions averaging group subject to paragraph (f) of this section.

§63.7541 How do I demonstrate continuous compliance under the emissions averaging provision?

(a) Following the compliance date, the owner or operator must demonstrate compliance with this subpart on a continuous basis by meeting the requirements of paragraphs (a)(1) through (5) of this section.

(1) For each calendar month, comply with requirements specified in §63.7522(f) to demonstrate that 12-month moving total credits calculated according to paragraph (h) of this section are greater than or equal to debits calculated for the same 12-month moving period.

(2) You must maintain the applicable opacity limit according to paragraphs (a)(2)(i) and (ii) of this section.

(i) For each existing unit participating in the emissions averaging option that is equipped with a dry control system and not vented to a common stack, maintain opacity at or below the applicable limit.

(ii) For each group of units participating in the emissions averaging option where each unit in the group is equipped with a dry control system and vented to a common stack that does not receive emissions from non-affected units, maintain opacity at or below the applicable limit at the common stack.

(3) For each existing unit participating in the emissions averaging option that is equipped with a wet scrubber, maintain the 30-day rolling average parameter values at or below the operating limits established during the most recent performance test.

(4) For each existing unit participating in the emissions averaging option that has an approved alternative operating plan, maintain the 30-day rolling average parameter values at or below the operating limits established in the most recent performance test.

(5) For each existing unit participating in the emissions averaging option venting to a common stack configuration containing affected units from other subcategories, maintain the appropriate operating limit for each unit as specified in Table 4 to this subpart that applies.

(b) Any instance where the owner or operator fails to comply with the continuous monitoring requirements in paragraphs (a)(1) through (5) of this section is a deviation.

Document Control Number: EPA-HQ-OAR-2002-0058-3674-A2

Comment Excerpt Number: 8

Comment: U.S. EPA is requesting comments to allow emissions from retrofitted units that switched to cleaner fuels (i.e. natural gas) to be averaged with emissions from units that remain of the original unit design (i.e. solid fuel, oil-fired) that operate at the same facility. MSU believes that this type of emissions averaging is a beneficial option for existing sources for pollutants such as mercury, hydrogen chloride and particulate matter. Without allowing for the averaging of units that switch to cleaner fuels with other existing units at the campus, the use of fuel switching as a compliance option becomes expensive and burdensome as it would not be possible to offset emissions using the converted unit. However, allowing units where fuel switching has occurred to be averaged across subcategories would encourage fuel switching on older, higher emitting units. Therefore, as stated above, MSU is in support of allowing emissions averaging across subcategories in situations where fuel switching is involved.

Comment: EPA's policy should not discourage or penalize companies that adopt fuel switching as a voluntary compliance strategy. Yet, EPA's proposed rule does just that. Currently, the rule would restrict emissions averaging to boilers in the same subcategory (*see* §63.7522(b)). Under our understanding of the proposed rule, a solid or liquid fuel boiler converted to natural gas could not be part of an emissions average with other solid or liquid fuel boilers at a site because that boiler would no longer belong to the same subcategory of boilers with which it would be averaged. This situation is further complicated by EPA's proposal to subcategorize solid and liquid fuel boilers even more narrowly, a step that will reduce the opportunities for averaging and decreases compliance options with little environmental benefit.

Such bureaucratic limits and distinctions put form over substance and are nonsensical from both a legal and policy perspective. EPA's mandate under §112 is to promote a maximum degree of reduction in emissions of the hazardous air pollutants "taking into consideration compliance

costs, and any non-air quality health and environmental impacts and energy requirements." EPA should not mandate which technologies companies select to lower their net emissions from EPA existing sources, particularly where EPA's policy results in *less* pollution control. EPA should eliminate the restriction on averaging across subcategories and focus on reducing emissions.

Response: We disagree that the rule discourages or penalizes companies that adopt fuel switching to natural gas as a compliance strategy. The final rule establishes a work practice standard for natural gas boilers instead of numeric emission limits, as explained in the record for the March 2011 final rule. The commenter further claims that EPA has "further complicated" the situation by proposing additional subcategories, but does not allege that or explain how it believes the additional subcategories are unwarranted. As explained in [cite to earlier response], EPA's long-standing position when establishing emissions averaging in MACT rules has been that averaging between units in different subcategories subject to different emissions standards is not appropriate.

Comment Excerpt Number: 55

Comment: Alternatively, EPA can eliminate the unintended impact of its cross-subcategory policy by using its considerable statutory authority to develop subcategories that allow fuel switching and other innovative emissions reduction strategies. As the Agency itself has acknowledged, EPA has broad discretion to establish such categories and subcategories as it deems appropriate, *Id.* §7412(c)(5), and to distinguish among classes, types, and sizes of sources within a category or subcategory in establishing standards. *Id.* §7412(d)(1). There is nothing in the statute, or in ensuing case law interpreting EPA's discretion, that would prevent the Agency from setting categories and subcategories based on their operational characteristics at a specific point in time. *See, e.g.,* Utility MACT at 411; *Northeast Maryland Waste Disposal Authority v. EPA*, 358 F.3d 936, (D.C. Cir. 2004) ("[The Clean Air Act] gives the EPA broad discretion to differentiate among units in a category. . . , provided the EPA indicated why such a subcategorization was appropriate."); *Davis County Solid Waste Mgmt. v. EPA*, 101 F.3d 1395, 1411 (D.C. Cir. 1996) ("Class is an ambiguous term. It is not defined in the Clean Air Act, and the dictionary definition -- "a group, set, or kind marked by common attributes" -- could hardly be more flexible.").

Using this flexibility, EPA should revise the subcategories used for the MACT rule to establish that, for purposes of emissions averaging, an existing unit belongs to the subcategory within which it fits as of the rule proposal date (December 23, 2011). Suggested regulatory language is shown below:¹³

§63.7522(a): As an alternative to meeting the requirements of 63.7500 for particulate matter, hydrogen chloride, or mercury on a boiler or process heater-specific basis, if you have more than one existing boiler or process heater in any subcategory, you may demonstrate compliance by emissions averaging, if your averaged emissions are not more than 90 percent of the applicable emission limit, according to the procedures of this section. For purposes of this section, an existing boiler or process heater that is part of any subcategory listed in Table 2 to this subpart as of December 23, 2011 may be included in an emissions average group with other existing units within these subcategories even if the boiler or process heater is converted to be part of the unit designed to burn gas 1 subcategory after December 23, 2011. Such a converted boiler or process heater shall not be required to conduct subsequent annual performance tests as required by §63.7515(b) but such a unit shall be subject to the other applicable requirements in this subpart for units designed to burn gas 1. You may not include new boilers or process heaters in an emissions average.

[Footnote 13: As reflected in the recommended language, an existing natural gas unit should not be able to convert to a solid fuel boiler (burning at least 10 percent solid fuel) and using this as a strategy for compliance.]

Response: As the commenter notes, EPA has broad discretion to decide whether to subcategorize sources within a source category based on differences in class, type, or size pursuant to CAA section 112(d)(1). The EPA maintains that, normally, any basis for subcategorization must be related to an effect on HAP emissions that is due to the difference in class, type, or size of the units. *See* 76 Fed. Reg at 25036-37. If sources can achieve the same level of emissions reductions notwithstanding such differences, the purposes of section 112 are better served by requiring a similar level of control for all units in the category or subcategory. *See* *Lignite Energy Council v. EPA*, 198 F.3d 930, 933 (D.C. Cir. 1999). In this case, the emissions from a converted (to natural gas) coal-fired boiler will not be different than those from

a boiler designed for and originally operated using natural gas combustion, and the commenter has not provided any information to demonstrate otherwise. Therefore, the EPA disagrees with the commenter's suggestion that the Agency should exercise its discretion to establish a separate subcategory for units converted to natural gas, as compared to those that first operated using natural gas.

Comment Excerpt Number: 56

Comment: The Agency has expressed its concern that it may lack authority to allow averaging across subcategories or that such allowance would be inconsistent with its policy in providing emissions averaging options in other rules. However, as discussed in the preamble to the HON (Hazardous Organic NESHAP for the Synthetic Organic Chemicals Manufacturing Industry (SOCMI) (Federal Register, April 22, 1994, starting on page 19425)), the rule EPA cites as precedent for emissions averaging, EPA has itself acknowledged its wide discretion to define "source" broadly. Indeed, in the case of the HON, EPA defined the source category to include all emission points relating to SOCMI production at a facility – a range of emission points and technologies far more diverse than the differences between coal-fired and converted coal-to-gas boilers. The HON allows all emission points that have numerical emission standards to participate in an emissions average. Process vents, storage vessels, transfer rack, and wastewater streams are all allowed in the emissions average and they all have differing emission standards. Only equipment leaks, which have no defined allowable emission level, are excluded.

To be clear, CIBO proposes that units sub-categorized as solid or liquid fuel boilers or process heaters on December 23, 2011, and thereafter converted to fire gas 1 fuels, will remain sub-categorized as solid or liquid fuel boilers or process heaters, only for purposes of emissions averaging. While the conversion of a solid or liquid fuel boiler or process heater to gas 1 will not change the unit's sub-categorization for purposes of emissions averaging, the boiler or process heater would be required to comply with work practice standards and other recordkeeping and reporting requirements applicable to gas 1 boilers or process heaters.

Response: We specifically disagree that broader averaging is consistent with the statute as explained in the preamble to the HON NESHAP. Moreover, the commenter ignores the fact that the HON specifically declined to allow averaging between sources subject to different emissions standards, as are coal-fired and natural gas-fired boilers. See 62 Fed. Reg. at 52388. Moreover, as EPA explained in the HON: "The fundamental problem with the broader averaging approach, beyond sources in the same subcategory, is that it allows averaging among multiple sources. The HON has defined the affected source, for the purposes of that standard, as the collection of SOGMI emission points within a major source. Many major sources containing such points will also contain other points not covered by the HON standard but to be covered by later, different MACT standards. Each of these standards will have a separate floor, and the statute requires that each standard be no less stringent than its floor. *If averaging were allowed between sources covered by two separate standards, it is likely that one of the sources involved in the average would be emitting HAP's at a level that violates the standard applicable to it.* Thus, averaging

between multiple sources in different subcategories is not legally defensible.” 59 Fed. Reg. at 19427 (emphasis added).

The affected source under the Boiler MACT is the collection of all existing boilers and process heaters within the same subcategory, and each subcategory within the Boiler MACT has separate standards based on separate floors, including coal-fired and natural gas-fired boilers. Consistent with EPA’s long-standing position, emissions averaging is not allowed between different affected sources (i.e., subcategories). Moreover, the commenter emphasizes that, while it believes that boilers converted to natural gas should be treated as being in the same subcategory as before such conversion, the converted boiler should be in a separate subcategory for the purpose of setting MACT standards – and further, that the appropriate standard for natural gas-fired boilers (including boilers converted to natural gas) is the work practice standard that EPA has adopted. EPA believes the commenter’s position contains an internal inconsistency that cannot be reconciled. Specifically, the commenter provides no basis for establishing a separate subcategory based on differences in class, type, or size for one purpose (standard-setting) while not doing so for another (emissions averaging), and does not explain why a different subcategorization approach for different purposes for the same units is not arbitrary.

Comment Excerpt Number: 57

Comment: EPA’s decision to propose work practice standards for gas 1 units is based on its determination that the application of measurement technology to this particular class of sources is not practicable due to technological and economic limitations (*see* §112(h)(2)(B) of the Act). This decision was driven, in part, by the extremely low numerical emission limits that EPA would have proposed if it had made MACT floor determinations. The measurement methods are technically limited such that some of the detection limits are above the numerical standards that would have been applicable. There was also an element of cost as many of the sources in this class of units have no means to obtain a representative sample for the measurement methodologies. Concerns about how to characterize the emissions profile from a converted boiler

could be addressed by using a default value equal to three times the detection limit of the reference test method (3xDL) for use in the emissions averaging calculation. This would enable sources to realize the environmental benefits of converting to natural gas (gas 1) without trying to test for pollutants with very low emission rates. However, if an owner/operator determined it to be feasible and desirable, they could alternatively conduct one time emissions testing with the natural gas/other gas 1 fuels to determine actual emission rates and use those if they are above detection levels. Further, as we have stated, such a converted unit would otherwise comply with the requirements for a gas 1 boiler or process heater.

Response: The EPA acknowledges this comment and thanks the commenter for their suggestion on how to address the emission profile from a converted coal-fired boiler.

Comment: EPA's decision to propose work practice standards for gas 1 units is based on its determination that the application of measurement technology to this particular class of sources is not practicable due to technological and economic limitations (see section 112(h)(2)(B) of the Act). This decision was driven, in part, by the extremely low numerical emission limits that EPA would have proposed if it had made MACT floor determinations. The measurement methods are technically limited such that some of the detection limits are above the numerical standards that would have been applicable. There was also an element of cost as many of the sources in this class of units have no means to obtain a representative sample for the measurement methodologies. Concerns about how to characterize the emissions profile from a converted boiler could be addressed by using a default value equal to three times the detection limit of the reference test method (3xDL) for use in the emissions averaging calculation. This would enable sources to realize the environmental benefits of converting to natural gas (gas 1) without trying to test for pollutants with very low emission rates. However, if an owner/operator determined it to be feasible and desirable, they could alternatively conduct one time emissions testing with the natural gas/other gas 1 fuels to determine actual emission rates and use those if they are above detection levels. Further, as we have stated, such a converted unit would otherwise comply with the requirements for a gas 1 boiler or process heater.

As both the case law and prior EPA precedent demonstrate, EPA has all the latitude it needs under the Clean Air Act to allow emissions averaging across all units at a given facility that are subject to Subpart DDDDD, so long as they have an applicable numeric emission limit. Our suggested revisions would establish the numeric emission limit for an existing solid or liquid fired unit converted to gas1 based on the emission limit applicable to the unit prior to conversion.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 57.

Commenter Name: Robert D. Bessette

Comment Excerpt Number: 58

Comment: As both the case law and prior EPA precedent demonstrate, EPA has all the latitude it needs under the Clean Air Act to allow emissions averaging across all units at a given facility that are subject to Subpart DDDDD, so long as they have an applicable numeric emission limit. Our suggested revisions would establish the numeric emission limit for an existing solid or liquid fired unit converted to gas 1 based on the emission limit applicable to the unit prior to conversion. In reality, choosing to convert a solid- or liquid-fired unit to fire natural gas/gas 1 fuels is one among many control technologies that a source could evaluate as it seeks to find the most cost-effective approach to comply with the rule. Some member companies have already invested a considerable amount of resources into studying exactly that question: What is the most cost-effective compliance strategy? One member company performed in-depth engineering evaluations of a wide variety of technologies to identify the most rational approach for the simultaneous control of HAPs, SO₂ (for the NAAQS), NO_x (for ozone season controls), and greenhouse gases from its coal fired units. If that company concluded that co-firing 50% natural gas with 50% coal was the optimal MACT control technology for some of its boilers, EPA would allow that company to average the emissions from those 50/50 units along with the emissions of similar units firing 100% coal. Likewise, if it concluded that co-firing 90% natural gas with 10% coal was the optimal MACT control technology for some of its boilers, EPA would allow it to average the emissions of those 90/10 units with similar units firing 100% coal. It is inconceivable why EPA would not then allow that company to convert a coal unit to fire 100% natural gas and average with similar units firing coal provided that the company demonstrated to its own satisfaction that such co-firing and full conversion approaches are technically feasible and commercially advantaged. Yet EPA's arbitrarily narrow interpretation of emissions averaging stands as the greatest impediment to such a solution.

Converting a solid- or liquid-fired unit to natural gas should be treated by EPA as one among the many control technologies that a source may elect to adopt to comply with the rule. Such a reading would not require that a converted unit be "re-subcategorized"; rather, EPA should only require that the unit use a default three times the detection limit of the applicable reference method (3xDL) for use in emissions averaging calculations to demonstrate its emissions profile (or actual test results if feasible and above detection limits at the owner/operators discretion). This would allow EPA to maintain the integrity of its original Gas 1 subcategory and the legal precedents which resulted in its reasonable conclusion to require work practice standards for units in that subcategory. But it would also allow sources the flexibility to adopt, if the source so chooses, to install a firing system technology to comply with the rule, rather than a back-end equipment technology.

Response: The agency has considered all but disagrees with most of the commenters' assertions and notes that the commenters provide no data to support their assertions regarding the comparative cost-effectiveness of various control technologies. Further, as explained response to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 53, we do not believe emissions averaging between units in different subcategories is appropriate. Finally, the commenter appears to suggest that units converted to natural gas should be subject to the numeric emissions limits for the type of boiler from which the unit was converted (e.g., solid or liquid fuel). However, the commenter does not provide any explanation or analysis as to whether or how such a numeric limit would represent MACT for units converted to natural gas, or even for the commenter's suggested subcategory of units that combust (for example) solid fuel plus units converted from solid fuel to natural gas, as would be required by section 112(d).

Comment: Attachment 1

Example of How Allowing Coal-to-Gas Conversion to Emissions Average In Boiler MACT Achieves Far Superior Environmental Results

Case A: Base Case:

A facility has two pulverized coal-fired boilers with a design rating of 315 mmBtu/hr and two older stoker boilers with a design rating of 200 mmBtu/hr. All four burn the same bituminous coal supply containing 1.5 percent sulfur and emit 0.6 lb/mmBtu NO_x. The boilers all have ESPs for particulate matter control and have no control device for acid gases or mercury. The table [see table in Attachment 1 of submittal] shows how the emission rates for these boilers compare to the Boiler MACT final rule:

Case B: Control to Boiler MACT Standards:

To comply with the Boiler MACT, the facility would have to (1) replace the ESPs with fabric filters (2) install a dry injection system to reduce HCl emissions by 56 percent with sorbent, and (3) install an activated carbon injection system to reduce mercury emissions by 56 percent. In this scenario, the sorbent injection system, designed to meet the HCl standard, gets marginal SO₂ reductions of 10 percent.

Case C: Coal-to-Gas Conversion on Two Boilers and Use of Emissions Averaging:

The facility is considering converting the two pulverized coal boilers to natural gas by installing natural gas burners and burner control system. No other major changes are required to the boiler itself (boiler, economizer, fans, feed water, etc.). This approach will cost far less than 50 percent of the replacement cost of the boilers, so this will not constitute a new or reconstructed unit. The facility is considering this option to avoid a large capital investment in air pollution controls so that it can make further capital investments in its growth strategy. The facility has access to an existing natural gas pipeline that can supply this demand and the facility may select this alternative even though it expects its annual operating costs to increase.

This option is far superior to Case B because natural gas (1) has essentially no sulfur, mercury, or chlorine contaminants, (2) natural gas boilers emit lower levels of particulate matter, (3) natural gas burners will emit much less NO_x (0.25 lb/mmBtu compared to 0.6 lb/mmBtu), and (4) combustion of natural gas emits much less greenhouse gases than does combustion of coal (see attached chart).

Comparison of Options: Figure 3 [see submittal for Figure 3] shows the potential benefits of allowing converted coal units to be included in emissions averaging.

Comment: Under the best of circumstances, a major retrofit of a boiler takes years from project start to finish. EPA has estimated that the installation of an activated carbon injection control system on one combustion unit – a comparatively simple installation – takes about 15 months.³⁵ However, EPA expects a range of control devices will be used to meet the standards, including

fabric filters, activated carbon injection, electrostatic precipitators, wet scrubbers, replacement burners, and combustion controls.³⁶ Further, the sheer number of boilers impacted by the rule will make finding – and then scheduling – the design and construction resources almost impossible. EPA estimates that there are approximately 14,111 units located at 1,704 facilities covered by this rule, and more than 2,000 of these units fire fuels other than gas. 76 Fed. Reg. 80622. Given that EPA has set emissions standards that only a small percentage of non-gas fired existing units can currently meet, almost every single existing unit subject to an emission standard will need to be retrofitted. Boiler owners will need to hire consultants to assist them in designing and performing the retrofit. Thus, across the multitude of industries impacted by this rule, boiler owners will be scrambling to find the very few qualified consultants who can perform the retrofits necessary to make boilers compliant with this stringent rule. There are a limited number of consulting companies with the expertise to assist in such retrofits, and they will likely be unable to assist all of the boiler owners in less than three years, especially when the electric utility industry will be competing for the same resources in order to comply with their own MACT standard. There will be a similar scarcity in equipment vendors, construction contractors, construction equipment (e.g., heavy lifting cranes), skilled labor (e.g., boilermakers), and other critical suppliers. Companies may even be unable to secure the basic building materials and control equipment (e.g., baghouses and scrubbers).

[Footnote 35: EPA, Engineering and Economic Factors Affecting the Installation of Control Technologies for Multipollutant Strategies (2002).]

[Footnote 36: EPA, Regulatory Impact Analysis: National Emission Standards for Hazardous Air Pollutants for Industrial, Commercial, and Institutional Boilers and Process Heaters, 3-1 (April 2010) ("The control analysis considered fabric filters, carbon bed adsorbers, and activated carbon injection to be the primary control devices for mercury control, electrostatic precipitators for units meeting mercury limits but requiring additional control to meet the PM limits, wet scrubbers to meet the HCl limits, tune-ups, replacement burners, and combustion controls for CO and organic HAP control....")]

Response: Three years is the maximum compliance time authorized under the statute. *See* CAA section 112(i)(3)(A). If sources are unable to comply within 3 years, the owner or operator may seek a 1 year extension of the compliance period from its Title V permitting authority if the source needs the additional time to install controls necessary to comply with the final rule. *See* CAA section 112(i)(3)(B).

Document Control Number: EPA-HQ-OAR-2002-0058-3818-A2

Comment Excerpt Number: 1

Comment: I urge you to provide a one year categorical extension of the compliance deadline for Boiler MACT regulations to exceed the existing three year deadline. As you know, Boiler MACT regulations are extremely complex and will touch the lives and livelihoods of thousands of individuals working across our nation's manufacturing industry.

Due to the complicated nature and widespread impact of these rules, many facilities will be forced to implement costly and speedy changes to comply. Specifically, existing Boiler MACT regulations will create enormous demand for both the necessary pollution control equipment and the skilled labor workforce to install such equipment. Not only are these updates costly, but the workforce of skilled laborers to meet this demand is incredibly limited.

Furthermore, in the face of such urgency to comply with Boiler MACT regulations, all affected facilities will be vying for the same resources at the same time. During this timeframe, access to both resources and labor will be limited and strained.

As you can certainly understand, these shortages will result in skyrocketing prices, which will be passed on to customers on the back end by American utilities. We, unfortunately, cannot even pass them along - but facilities within the forest products industry will be forced to absorb them. In addition, this scarcity of resources will lead many to look outside of the United States, creating jobs abroad that could be given to hardworking Americans.

As you can see, this type of shortage would lead to many unnecessary complications. Such a race for compliance would certainly lead to scarcity of resources, loss of American jobs, and an undeniable gridlock in permit offices as an insurmountable number of permits clog up the pipeline.

Response: Section 112(i)(3) provides that EPA must establish a compliance date for existing sources that provides for compliance with emissions standards as expeditiously as practicable, but no later than three years after the effective date of the emissions standard. This provision does not provide EPA authority to categorically extend the compliance date due to factors such as the potential implementation of other MACT standards. Moreover, EPA believes that sources can comply with the numeric emissions limits within three years. Therefore, for the reasons explained in the preamble, EPA is establishing a compliance date for existing sources subject to numeric limits that is three years from the date of publication of today's final action. The EPA disagrees with the commenters that the 3-year compliance deadline is too short considering the number of sources that will be competing for the resources and materials from engineering consultants, permitting authorities, equipment vendors, construction contractors, financial institutions, and other critical suppliers. Section 112(i)(3)(B) allows EPA and state permitting authorities, on a case-by-case basis to grant an extension permitting an existing source up to one additional year to comply with standards if such additional period is necessary for the installation

of controls. This provision should assist those sources for which the 3-year deadline will not provide adequate time to to comply with the requirements of the standard.

The CAA allows CAA Title V permitting authorities the discretion to grant extensions to the compliance time of up to one year if needed for installation of controls. If an existing source is unable, despite best efforts, to comply within 3 years, a permitting authority has the discretion to grant such a source up to a 1-year extension, on a case-by-case basis, if such additional time is necessary for the installation of controls. Permitting authorities should be familiar with the operation of the 1-year extension provision because EPA has established regulations to implement the provision and the provision applies to all NESHAP. *See* 40 CFR 63.6(i)(4)(A). We believe that the permitting authorities have the discretion to use this extension authority to address a range of situations in which installation schedules may take more than 3 years. The EPA believes that building replacement power constitutes the “installation of controls” at a facility to meet the regulatory requirements.

Comment: It will be extraordinarily difficult – if not impossible – for all of the entities with existing boilers to make the changes necessary to comply with this rule in three years. Put simply, the normally Herculean task of performing a boiler retrofit in three years will be made impossible by factors such as the enormous competition for critical resources and the likely gridlock in many state permitting processes that the broad application of this rule and other new rules for utility boilers will create. Many boiler owners will be simply unable to secure equipment and assistance and/or to obtain the state/local permits needed to retrofit their units within three years.

For many reasons, an extended compliance deadline is critical for the regulated community to comply with the uniquely complex and costly Boiler MACT rules, including:

- enormous demands for equipment and skilled labor converging simultaneously from multiple rules requiring billions in investment that will likely force outsourcing equipment fabrication overseas;
- continuing confusion about whether sources are boilers or incinerators and what standards apply when some determinations will depend on responses to the non-hazardous secondary materials (NHSM) petition process;
- within Boiler MACT, uncertainty of which specific subcategory will apply to a combustion unit given definition changes and related uncertainty of the final limits for the subcategory that ultimately is applicable;
- the need for a carefully calibrated control strategy to address multiple regulations and avoid conflicts between control options;
- the need for major capital planning at a time of uniquely challenging economic conditions;
- engineering and permitting logjams due to overwhelmed state staffs;
- complex installation and testing processes to ensure compliance;
- the breadth of sources covered by the Boiler MACT rules; and
- competitive pressures on U.S. manufacturers and the fragile state of our economy.

EPA has extended the compliance timeline in previous MACTs, it would seem appropriate to do so for this standard as it is unique in its impact to virtually all manufacturing.

Comment: We request EPA consider longer timelines in light of the economic conditions impacting wood products facilities since the onset of the recession and associated "housing bust" has severely undermined markets for wood products. In particular, we are most concerned with affordability of investments in one of the most prevalent biomass boiler types –stokers burning "wet" biomass– at lumber and other forest products mills, especially for controls that would be necessary to meet the particulate matter (PM) limits. While we question generally whether boiler design is consistently a rational basis for differentiating among subcategories for PM3, EPA's new proposal to establish subcategories for PM among boiler types burning solid fuels would exacerbate the economic concerns by making the "wet" biomass stoker limit more stringent than the solid fuel limit in the March 2011 final rule and by creating uneven winners and losers. This could be offset to some degree by providing longer time for evaluating and installing controls as the nascent economic recovery builds, which would enhance the likelihood of affording investments in this struggling sector. Otherwise many of these facilities will be at risk of closing since sustainable business practices cannot support investment where no return can be generally anticipated.

Document Control Number: EPA-HQ-OAR-2002-0058-3685-A2
Comment Excerpt Number: 10

Comment: Approximately 1600 boilers will be required to reduce emissions to comply with the expected final Boiler MACT rule. EPA estimates that investments in control equipment will cost more than \$5 billion. As noted in the comments submitted by Paul Noe of the American Forest and Paper Association, submitted on behalf of a group of industry representatives (hereinafter "AF&PA Industry Comments") these costs are significantly underestimated and are more likely to exceed \$14 billion. In a challenging economy, justifying and acquiring the necessary capital for these improvements will require lengthy negotiations with banks and other financial institutions. Facilities requiring control upgrades will be required to devote significant resources to capital planning purposes. This burden is particularly acute for municipal utilities that do not have personnel dedicated exclusively to environmental compliance planning. Municipally-owned utilities must work through their local council or other political organization to initiate capital planning, solicit and approve bids, finalize compliance plans and allocate necessary funding, which adds significant time to an already complicated compliance planning process. For the City of Orrville, the entire process from initial planning to installation of control equipment is expected to take 4.5 years, assuming no significant adverse public reaction or delays.¹⁷

Comment: The 1600 sources expected to require new control equipment or retrofits will also place an enormous demand on state permitting and regulatory authorities, engineering design firms, stack testing companies, and fabricators. Sources subject Boiler MACT will not only be competing with each other for access to qualified engineers and equipment they will also be competing with sources subject to the updated NO_x and SO₂ NAAQS, the Cross-State Air Pollution Rule, the Utility MACT, and various Risk and Technology Review sector rules. Given these realities, it is appropriate for EPA to establish the latest compliance date allowed by law.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3818-A2, excerpt 1.

Commenter Name: Richard D. Garber

Commenter Affiliation: Boise Inc.

Document Control Number: EPA-HQ-OAR-2002-0058-3686-A2

Comment Excerpt Number: 10

Comment: EPA should provide sources with an alternative to the three-year compliance timeline.

Given the vast number of affected industries, public institutions, utilities and emission units that will be required to engineer, purchase and install new control equipment and implement other process modifications (more than 1600 major source boilers), a 3-year compliance timeline, in many cases, is impracticable.

As stated previously, Boiler MACT, CISWI, and NHSM rules are complex requirements demanding a thorough review of final regulations before a compliance implementation plan can be prepared for a given facility. A critical path timeline is provided below based on information Boise engineers have obtained in conversations and proposals from boiler manufacturers, equipment suppliers, and vendors.

(Conceptual Compliance Timeline)

- Begin 36-month compliance timeline with final promulgation of Boiler MACT, CISWI, and NHSM final rule language
- Months 0-3 -final rule evaluation, fuel testing for determination of fuel or waste under final NHSM rule, identify gaps between existing control equipment and final regulatory requirements
- Months 3-6 - begin design engineering, complete air emissions review and begin preparation of Title V air permit modification applications, and initiate request for vendor guarantees

- Months 6-9 -obtain vendor design guarantees, complete regulatory analyses, emissions modeling, state and federal air regulatory applicability review, control technology review; address regulatory permitting issues and submit Title V air permit application to state and federal permit authorities
- Months 6-24 (12-18 month average) it may be necessary in some cases to obtain a PSD permit due to increases in NOx emissions or other pollutants caused by fuel switches and the inverse relationship between CO and NOx pollutants. PSD permits are complex and the following steps are routinely necessary to obtain a final permit from state and/or federal air permit authorities, including: application review, "completeness" determination, BACT/LAER and regulatory review, modeling review, Title V permit, preparation, negotiation and modification, 30-day public notice, 45-day EPA review, response to comments, and permit issuance.
- Months 12-18- once air permit modification has received preliminary agency review and completeness determination, expected at approximately month 12, company may initiate (inherent risk of stranded funds) final detailed design engineering with suppliers and engineering design firms, expected to take 6 months
- Months 18-30 - once the Title V air permit modification (if necessary) is placed on public notice, company may initiate placement of order, expected at approximately month 18, company may be willing to take risk and place equipment orders (significant risk of stranded funds). Pressure parts, boiler generator tubes, and large fabricated equipment such as electrostatic precipitators and boiler grates have a lead time of 9-12 months from placement of orders (Jansen, B&W), assuming fabrication shop availability.
- Month 24 - receipt of final Title V air permit modification. Beginning of actual construction cannot commence until final signed permit is obtained.
- Months 24-30 - on site construction (preparatory) work begins to include: receipt of ordered equipment, site preparation and foundation work, scheduling of manpower and detailed construction engineering plans to coincide with a major mill outage. Outage must occur prior to compliance deadline and must coincide with available customer, vendor and manpower availability. Furthermore, seasonal cold temperatures preclude shutdowns during certain time periods at many locations in the midwest and northeast locations.
- Months 30-36- receipt of all equipment on site, mill outage scheduled, project construction completed prior to 36 month compliance deadline.
- Additional time needs -for new equipment demonstration and completion of preliminary emissions engineering tests an additional 60-90 days is needed after the final construction, startup, and compliance testing prior to the 36-month compliance deadline.

Commenter Name: Dakota Gasification Company Great Plains Synfuels Plant

Commenter Affiliation: David W. Peightal

Document Control Number: EPA-HQ-OAR-2002-0058-3424

Comment Excerpt Number: 9

Comment: In the event of promulgation of any new MACT or other competing EPA standards being promulgated, DGC would prefer more time than the proposed three years in order to safely and adequately assess and address all impacts of the rule or other competing EPA rules, such as the new Ambient Air Quality Standards. This assessment would subsequently involve consideration of the availability of resources (internal and external), engineering involvement, technology options, and new equipment installation. EPA should consider the number of sources affected by this rule and the availability of advanced technological equipment that would be required by those affected sources. In addition, some sources would need adequate time to plan, design, engineer, purchase equipment and materials and then to construct and install equipment. Skilled manpower may be impacted in areas that are in short supply and could be affected by seasonal issues in extreme cold climates which potentially increase contractor and operational personnel safety risk, not to mention additional environmental risk to expedite the changes.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3818-A2, excerpt 1.

Commenter Name: Traylor Champion

Commenter Affiliation: Georgia-Pacific LLC (GP)

Document Control Number: EPA-HQ-OAR-2002-0058-3465-A1

Comment Excerpt Number: 13

Comment: GP supports EPA's proposal to reset the compliance clock for the Boiler MACT rule.

Our company has been actively engineering options to comply with the anticipated standards but final designs and compliance options cannot be selected until a final standard has been established. With hundreds of millions of dollars expected to be necessary to comply with this rule, expenditures of this magnitude cannot possibly be committed until final standards are promulgated. As noted below, complying with the promulgated standards will be difficult, if not impossible to achieve within the normal three-year compliance period.

GP has 84 solid fuel and oil-fired boilers subject to Boiler MACT and it is anticipated that all but 2 of these boilers will require the addition of one or more add-on devices or modifications/upgrades to combustion systems to meet the proposed limits. The normal duration of GP major capital projects from initial concept to completion is three-years, consisting of one-year for technology review and vendor/equipment selection, one-year for engineering and equipment manufacturing, and one-year for construction, startup, commissioning and compliance testing. There are a number of factors that will make it very difficult to get all 82 units in compliance within the proposed three-year time frame.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3818-A2, excerpt 1.

Commenter Name: Traylor Champion

Commenter Affiliation: Georgia-Pacific LLC (GP)

Document Control Number: EPA-HQ-OAR-2002-0058-3465-A1

Comment Excerpt Number: 14

Comment: Internal – The GP corporate engineering group is currently staffed to manage 2-3 major boiler projects at a time. Even if external engineering resources are hired to augment internal resources, we would still need GP engineering/project management to manage and supervise the external resources. Mill staffs at a large pulp and paper mill can typically manage 1-2 ongoing boiler projects at a time, but some of the mills will have as many as 5 boilers that will be impacted by Boiler MACT. Attempting to manage 82 projects concurrently will be difficult or impossible and in addition will increase the cost of compliance due to errors and inefficiency.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3818-A2, excerpt 1.

Commenter Name: Traylor Champion

Commenter Affiliation: Georgia-Pacific LLC (GP)

Document Control Number: EPA-HQ-OAR-2002-0058-3465-A1

Comment Excerpt Number: 15

Comment: External – There are limited engineering, manufacturing and construction resources to design, manufacture and install the required control equipment. All of industry will be placing demands on these resources at the same time. This situation is worse than it normally would be due to the fact that the economy is coming out of a major recession and many of these companies have significantly reduced their workforce.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3818-A2, excerpt 1.

Commenter Name: Traylor Champion

Commenter Affiliation: Georgia-Pacific LLC (GP)

Document Control Number: EPA-HQ-OAR-2002-0058-3465-A1

Comment Excerpt Number: 16

Comment: Utility MACT – The utility version of Boiler MACT is going into effect at essentially the same time as Boiler MACT. Since utilities and industry share the same engineering, manufacturing and construction resource base, we will be competing with the utilities for these resources. The inherent larger size of utility projects will make it difficult for industrial companies to compete.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3818-A2, excerpt 1.

Commenter Name: Traylor Champion

Commenter Affiliation: Georgia-Pacific LLC (GP)

Document Control Number: EPA-HQ-OAR-2002-0058-3465-A1

Comment Excerpt Number: 17

Comment: Outage scheduling – Large pulp and paper mills with multiple boilers typically stagger boiler outages throughout the year due to resource constraints and to minimize the impact on production. In facilities with multiple boilers requiring addition of control devices, it will be necessary to complete some of the installations as much as 12-15 months prior to the compliance

deadline which will significantly compress the normal schedule duration and place additional stress on limited resources.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3818-A2, excerpt 1.

Commenter Name: Dirk J. Krouskop

Commenter Affiliation: MeadWestvaco Corporation (MWV)

Document Control Number: EPA-HQ-OAR-2002-0058-3493-A1

Comment Excerpt Number: 5

Comment: MWV believes that the three year compliance timeline outlined by EPA is insufficient to ensure that adequate well conceived control systems will be employed. EPA proposes to reset the compliance deadline for existing affected sources to three years after the date of publication of the Final Reconsideration Rule in the Federal Register. MWV supports this proposal but doesn't believe it goes far enough. It would be inappropriate for EPA to expect sources to comply with this set of rules within 3 years of the original date of March, 20 11 after more than one year of reconsideration. MWV believes that it will be extremely difficult to install the necessary equipment across our fleet of boilers within the three year timeline. MWV has been developing compliance strategies for each of its impacted boilers over the past three years and as the requirements continue to change major and minor adjustments to the strategy continue to be made. To properly engineer, permit, procure, install and learn to operate the equipment within three years may be achievable for one unit, but it is not reasonable to expect the same for multiple units across multiple facilities.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3818-A2, excerpt 1.

Commenter Name: Dirk J. Krouskop

Commenter Affiliation: MeadWestvaco Corporation (MWV)

Document Control Number: EPA-HQ-OAR-2002-0058-3493-A1

Comment Excerpt Number: 6

Comment: MWV is concerned that the overlap of requirements from these rules with existing provisions that existing units face and are expected to encounter in future regulatory actions will result in an unworkable set of requirements. EPA has the freedom in its regulatory approach to consider only the impact of this set of rules (includes the major and area source rule, non-hazardous secondary materials rule and solid waste incinerator rule). MWV does not have that luxury. MWV must consider the impact of this set of rules, existing requirements and control technologies, as well as impacts on water and waste regulations. MWV must also factor in future requirements that could potentially apply such as more stringent ambient air quality standards or transport rules. These impacts are real considerations for MWV and require broader strategic decisions than merely compliance with this rule. For this reason alone, EPA should allow for additional time to comply than the three years that have been proposed.

Commenter Name: Lorraine Gershman
Commenter Affiliation: American Chemistry Council (ACC)
Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1
Comment Excerpt Number: 129

Comment: In order to retrofit a boiler, the owner will need to line up the capital necessary to pay for the retrofit. In these difficult economic times, just securing the necessary capital may take months, if not years, assuming the capital can be obtained from lending sources. In addition, the owner will need to go through the relevant permitting process(es), which will similarly take months, if not years. Finally, once the finances are secure and the permitting is complete, the owner will actually need to perform the retrofit. The design, procurement, installation, and shakedown of a retrofit project (e.g., installing a scrubber on a large boiler) can easily take more than three years. An example of a rulemaking that involved control retrofits over an extended compliance period is the implementation of the 1-hour ozone SIP requirements in Houston, Galveston, and Brazoria Counties in Texas. Due to the magnitude of the NO_x emissions reductions required and the number of sources affected, emission reduction projects were implemented over a 6-year timeframe (2001-2007), with a total capital investment of over \$3 billion. As the Boiler MACT will involve more significant emission controls retrofits, it is appropriate to allocate a longer compliance timeframe.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3818-A2, excerpt 1.

Commenter Name: Lorraine Gershman
Commenter Affiliation: American Chemistry Council (ACC)
Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1
Comment Excerpt Number: 130

Comment: In addition, the timing of the retrofit work needs to be carefully planned, particularly for boilers that provide the primary and/or base load energy supply for their facilities. A facility owner will only shut down a boiler when everything is properly staged to ensure minimal disruption of the facility's operation. In addition to ensuring that the design work is completed and the control equipment and other supplies are on-site and ready for installation, the facility owner needs to make sure that the full suite of consultants and laborers are available for the

installation. Based on a discussions with a number of potentially affected companies, the turnaround or shutdown cycles for boilers and process heaters at many of the facilities can vary from 1 to 5 years, making this type of precise staging exceedingly difficult to do in a three year period without substantial business interruption.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3818-A2, excerpt 1.

Commenter Name: Lorraine Gershman

Commenter Affiliation: American Chemistry Council (ACC)

Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1

Comment Excerpt Number: 131

Comment: Finally, in many instances, the installation of pollution control equipment and associated charges to boiler must be permitted under state air pollution statutes and/or construction codes (building permits, etc.). The proposed rule will result in an increase in the number of permit applications, potentially swamping the state and local agencies. Even in those areas where the rule may not result in significant increases in permitting work, the normal delays associated with permitting may make meeting the three year compliance deadline impossible.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3818-A2, excerpt 1.

Comment: Impractically truncate capital planning time. These proposed rules do not provide enough time for capital planning and compliance, given the complexity of the rules and competition for a limited pool of qualified domestic vendors and installers for emission controls and boilers. Additional time is needed to allow businesses to synch up compliance with these rules with compliance on upcoming National Ambient Air Quality Standard rules.

Comment Excerpt Number: 11

Comment: The EPA proposes to set the compliance deadline for existing affected sources at three years after the date of publication of the Final Rule in the Federal Register. 76 Fed. Reg. At 80,605. It will be extraordinarily difficult – if not impossible – for all of the entities with existing boilers to make the changes necessary to comply with this rule in the three year timeframe that the EPA proposes. Put simply, the task of performing a boiler retrofit in three years will be made nearly impossible by the competition for critical resources and the likely gridlock in many state permitting processes that the broad application of this rule will create. Many boiler owners will be simply unable to secure equipment and assistance and/or to obtain the state/local permits needed to retrofit their units within three years.

Even under the best of circumstances, a major retrofit of a boiler takes years from project start to finish. The EPA has estimated that the installation of an activated carbon injection control system on one combustion unit – a comparatively simple installation – takes about 15 months.³ However, the EPA expects a range of control devices will be used to meet the standards, including fabric filters, carbon bed adsorbers, activated carbon injection, electrostatic precipitators, wet scrubbers, replacement burners, and combustion controls.⁴

Further, the sheer number of boilers impacted by the rule will make finding – and then scheduling – the design and construction resources almost impossible. The EPA estimates that approximately 5,500 boilers would need to meet emission limits under the rules.⁵ Many, if not all, of these boilers would need to be retrofitted. Boiler owners will need to hire engineers to assist them in designing and performing the retrofit. Thus, across the various industry sectors impacted by this rule, boiler owners will be competing for qualified engineers to design, permit and perform the retrofits necessary to make boilers compliant with this stringent rule. There will be a similar scarcity in equipment vendors, construction contractors, construction equipment (e.g, heavy lifting cranes), skilled labor (e.g., boilermakers), and other critical suppliers. Companies may even be unable to secure the basic building materials and control equipment(e.g., baghouses and scrubbers).

In order to retrofit a boiler, the owner will need to line up the capital necessary to pay for the retrofit. In these difficult economic times, just securing the necessary capital may take significant time. In addition, the owner will need to go through the relevant permitting process(es), which will take a number of months. Finally, once the finances are secure and the permitting is complete, the owner will actually need to perform the retrofit. The design, procurement, installation, and shakedown of a retrofit project (e.g., installing a scrubber on a large boiler) can easily take multiple years.

Comment: The timing of the retrofit work needs to be carefully planned, particularly for boilers that provide the primary and/or base load energy supply for their facilities. A facility owner will only shut down a boiler when everything is properly staged to ensure minimal disruption of the facility's operation. Based on a discussions with a number of potentially affected companies, the turnaround or shutdown cycles for boilers at many of the facilities is so long as to make this type of precise staging exceedingly difficult to do in a three year period without substantial business interruption.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 23

Comment: Since the boiler rules establish limits on multiple pollutants, multiple controls will be required, and trade-offs posed by the various controls must be considered. For example, presence of SO₃ can have a significant negative impact on the Hg removal that is achieved by activated carbon injection, and use of catalysts for NO_x and CO control can oxidize SO₂ in flue gas to SO₃. However, presence of SO₃ in flue gas tends to improve PM collection efficiency of ESPs by lowering ash resistivity. Fuels with higher sulfur or chloride contents will combine with available mercury to form particulates that are more easily captured in particulate control devices, while boilers burning fuels with low sulfur and chloride contents will emit any mercury present in the fuel in its elemental form, which is harder to capture. Injection of sorbent to control HAPs prior to a PM control device may increase PM emissions over baseline. Weighing these many considerations will increase the time required to formulate and evaluate control strategy, and a strategy cannot be finalized prior to the promulgation of the rules. The standard three year compliance timeframe does not recognize or address these pollutant interactions and control implications and their impact on compliance approaches or required compliance timing.

Commenter Name: Steve Gossett
Commenter Affiliation: Eastman Chemical Company
Document Control Number: EPA-HQ-OAR-2002-0058-3669-A2
Comment Excerpt Number: 34

Comment: Comment Summary: We fully support EPA's proposal to re-set the three-year compliance period and urge EPA to seek methods similar to Utility MACT to grant extensions beyond the additional year provided under the Clean Air Act.

Discussion: Eastman supports EPA's intent to "reset" the three year compliance period and to exercise its enforcement discretion with regards to the administrative requirements that followed from the court's vactur of EPA's administrative stay of the final rule (Jackson, L. Letter to Senator Ron Wyden. 18 January 2012). Eastman is uniquely impacted by this rule by virtue of having ten coal-fired units at the company's Tennessee Operations (TNO) potentially subject to the rule. Eastman recognized that complying with the MACT rule in three or four years, and simultaneously with the other rulemakings underway on overlapping timeframes (e.g. SO2 NAAQS, Regional Haze SIP, and CISWI), etc.), would be extremely challenging and could potentially expose the company to significant business risk if no actions were taken until the rule was finalized. Eastman therefore proactively committed a significant amount of time and resources into planning a coordinated response to this rule before the rule was finalized based on our best guess as to the rule's final outcome. This effort to "hit the ground running", which included technical analysis and optimization of pollution control technologies as well as development of detailed project and life cycle cost estimates and construction schedules, was essential to understanding the overall business risk to the company. One of the key learnings that resulted from these investigations was the duration of the overall project at a site of exceptional complexity such as TNO. Given reasonable assumptions about the duration of detailed engineering, equipment lead times, pre-outage fabrication and site preparation, and unit shutdowns for pollution control tie-ins and commissioning, Eastman concluded that it would take between 39 and 42 months from the rule's finalization to get the first unit converted & in full compliance with the new rule. Given that Eastman has ten units potentially subject to the rule, each of which will require nominally four to six weeks of conversion and commissioning; and given that TNO is complex integrated site that requires nominally fourteen steam generating boilers in service to remain operational; and given that the statute allows 36 to 48 months to be in compliance; it is self-evident that Eastman cannot convert all its potentially subject units without dramatically increasing its business risk.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3818-A2, excerpt 1.

Commenter Name: Steve Gossett
Commenter Affiliation: Eastman Chemical Company
Document Control Number: EPA-HQ-OAR-2002-0058-3669-A2
Comment Excerpt Number: 35

Comment: Eastman recognizes that EPA lacks the authority to grant additional time because the statue establishes the compliance period to be three years from the final rule's publication in the federal register, with a provision for a fourth year. However, Eastman noted with great

interest that EPA has chosen to exercise its enforcement discretion subsequent to the court's vacatur of the EPA's administrative stay of this rule, as well as the ongoing debate around the Utility MACT Rule (MATS) and the President's authority under Section 112 to exempt stationary sources from compliance for two years where the President determines that "the technology to implement such standard is not available". Having already demonstrated its commitment to responsible environmental stewardship by investing many millions of dollars in engineering before the rule has even been finalized, EPA should recognize that Eastman is attempting to position itself to comply with all possible haste. Eastman contends that the air pollution control industry's ability to manufacture the equipment required to comply with this rule for all sources nationwide, and sources ability to deploy the construction labor necessary to install it, is going to be seriously challenged due to the concurrent timing of the Industrial Boiler MACT rule with the Utility MACT rule. When these strains on the supply of engineering, equipment, and construction labor are considered alongside the impending additional demands due to CSAPR, Regional Haze and the NAAQS for SO₂, Eastman is not convinced that the required hardware and labor will be available within the statutory deadline. As one of the nation's largest exporters, competing daily against foreign competitors both at home and abroad, Eastman encourages EPA to exercise as much discretion as it is allowed under the statute to enable sources to balance the goals of environmental stewardship against the considerable business risk incurred by rushing the implementation of this rule.

Commenter Name: Traylor Champion

Commenter Affiliation: Georgia-Pacific LLC (GP)

Document Control Number: EPA-HQ-OAR-2002-0058-3465-A1

Comment Excerpt Number: 18

Comment: Control technologies – There are four different pollutants regulated by Boiler MACT – PM, CO, HCl, and Hg. The control of these pollutants can directly impact emissions of other pollutants or impact the performance of existing pollution control devices:

Pollutant interactions – The most notable is the relationship between NO_x and CO. The inverse relationship between NO_x and CO is well established. The generation of both pollutants is a function of combustion conditions in the furnace – excess air, time, temperature and turbulence. CO emissions are minimized by having high excess air and significant time at high temperature and turbulence. These same conditions maximize NO_x emissions. Most industrial boilers control NO_x emissions by controlling combustion conditions in the furnace utilizing a combination of techniques including low excess air, low NO_x burners, staged combustion, and flue gas-recirculation. The requirement to also control CO emissions may require development of a strategy for controlling one of the two by controlling combustion conditions and the other by back-end cleanup. If it turns out that the most cost effective solution is to control CO in the furnace and NO_x by back end clean-up, existing NO_x control systems will have to be replaced with SCR or SNCR which will take additional time to implement.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3818-A2, excerpt 1. Also address pollutant interactions.

Commenter Name: Traylor Champion
Commenter Affiliation: Georgia-Pacific LLC (GP)
Document Control Number: EPA-HQ-OAR-2002-0058-3465-A1
Comment Excerpt Number: 19

Comment: Interaction Between Control Technologies – Control of Hg may require utilization of activated carbon injection (ACI). The additional particulate loading in the gas stream will have to be collected by the PM control device. The net impact on PM emissions won't be known until the ACI system is operational and stack PM emissions are measured. In these situations, the optimal control strategy would be a staged implementation consisting of installation of new control technology to address the Boiler MACT pollutants followed by corrective action to address the impact on other pollutants or pollution control devices. The time constraints make this impractical and compliance costs may increase as a result.

The absorption efficiency of ACI in any given system is unknown. Degree of mixing, duct length (retention time), duct geometry, and amount of ACI introduced all play important roles in capture efficiency. ACI is much more effective on oxidized Hg vs elemental Hg. To reach any given level of Hg reduction, optimizing ACI usage and Hg oxidizers will require some time to get the right combination. Because the amount of ACI needed to accomplish the required HG+ absorption is unknown, it makes the design of the baghouse much more complicated. Simply overdesigning the baghouse and the ACI delivery system would waste precious resources.

Commenter Name: Mark Anthony
Commenter Affiliation: Alyeska Pipeline Service Company
Document Control Number: EPA-HQ-OAR-2002-0058-3684-A2
Comment Excerpt Number: 1

Comment: Our organization has been evaluating the timeframe necessary to comply with Boiler MACT, assuming the final rule is similar to the present vacated final rule and this proposed rule. The 3 year time line will be extraordinarily difficult to meet because the modifications required of the boiler facility to provide for controls is very challenging.³ After those changes the addition of emission controls will be equally difficult and time consuming. We are not optimistic we can meet a three year timeframe to perform this project. We are without other options for power for the VMT so any project is particularly challenging because it directly impacts the ability of the facility to perform its primary function of storing oil and loading it onto marine tankers.

[Footnote]

(3) The Valdez boiler facility is located on the side of a mountain with very little room for construction equipment and to make changes to provide the additional area for the emission controls to be added. The boiler facility is a very tightly configured facility that houses the boilers, power generation and vapor handling all within one constricted area. Valdez is a very remote location with limited facilities. Much of the construction must be accomplished during

the "peak" summer months. Acquiring contractors with the necessary skilled workers has historically been a challenge for large projects.

Commenter Name: Randall D. Quintrell

Commenter Affiliation: Georgia Paper & Forest Products Association

Document Control Number: EPA-HQ-OAR-2002-0058-3451-A1

Comment Excerpt Number: 7

Comment: The three year compliance window totally ignores the logistical challenges of implementation. This is particularly true when one considers the extremely stringent emission limits being proposed, the uncertainty that a particular technology may even achieve compliance with such limits on a particular unit, and the very large number of boilers that are affected by this rule that will stretch engineering, design and construction resources beyond realistic expectations and escalate costs due to scarcity of such resources within such a tight framework. The compliance deadline should rationally be set at no less than 5 years for all solid fuel boilers and all liquid fuel boilers, and EPA should move forward immediately to secure an extension of the deadline to 5 years for these units.

Commenter Affiliation: Florida Sugar Industry (FSI)

Document Control Number: EPA-HQ-OAR-2002-0058-3504-A1

Comment Excerpt Number: 56

Comment: At a minimum, EPA should automatically allow an additional one year to comply, as provided in 40 CFR Part 63, Subpart A. Moreover, EPA should recognize that a one year extension is not sufficient in this case due to the large number of sources that will need to make modifications at their existing facilities. Accordingly, the compliance deadline for the upcoming boiler rules should be extended to five years to ensure affected facilities will be able to achieve the required emissions reductions prior to the compliance dates of the rules.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3818-A2, excerpt 1.

Commenter Name: Matthew Todd

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 10

Comment: We strongly support the proposed reset of the three year compliance time, but believe five years is needed for existing sources subject to numerical emission limits to comply with this proposal.

1. EPA is proposing to reset the compliance date for existing sources to 3 years after the date of publication of these amendments in the Federal Register.

We strongly support extending the existing source compliance date, since design, engineering, procurement and installation of controls will take a long time. Furthermore, facilities cannot be sure what will be required for many BPH since changes from this proposal are likely and thus the facilities cannot begin project activities until this proposal is finalized. In addition to the actual time needed to install controls, compliance time also needs to be extended due to the potential triggering of other rules and regulatory requirements, such as the NSPS standards for new steam generating units (boilers) and NSR/PSD or state construction permitting (e.g. due to NO_x increases) which delays construction until a permit is received. Finally, the coincident impact of the electric utility unit NESHAP, the area source and CISWI rules, the NSPS Ja rule, and a variety of other regulations impacting BPH, on the availability of combustion and combustion emission control resources and equipment will certainly extend the time to implement the controls required under this rule. [See submittal for referral to comments previously submitted on 2010 proposal.]

Commenter Name: Gretchen Brewer
Commenter Affiliation: PT AirWatchers
Document Control Number: EPA-HQ-OAR-2002-0058-3825-A1
Comment Excerpt Number: 3

Comment: Proposed compliance date: Yes. Given that EPA's imminent rule changes have been well publicized, it is more than reasonable that boiler plans embarked upon after the original date of June 4, 2010 must be considered as new boilers. The technology to comply is well known to the industry and readily available, so they have every reason to go with the better technology.

We have been particularly concerned about this issue given the glut of plans for new boilers, as an example for biomass power generation, in which it is widely discussed by proponents whether they will "be able to beat" the new regulations. The wide publicity and protracted lead time of these regulations is more than sufficient for the owners of these facilities to incorporate the new emissions limits into their plans.

Response: The EPA thanks the commenter for their support. CAA section 112(a)(4) states that a new source is a stationary source if "the construction or reconstruction of which is commenced after the Administrator first proposes regulations under this section establishing an emissions standard applicable to such source." EPA first proposed the Boiler MACT standards under this particular rulemaking record on June 4, 2010, following the DC Circuit's vacatur of the previous major source boilers rule in 2007. While today's action revises certain new source standards, it is a reconsideration action and is premised on the same general rulemaking record. It is thus reasonable to view the date EPA "first proposes" standards for the area source category to be the June 4, 2010 date. Further, the commenter essentially advocates an approach whereby any time the Agency changes a new source standard, in any way, on reconsideration, the new source trigger date would change. Such a result is not consistent with Congress' intent in defining the term "new source" in section 112(a)(4), to be the date the Agency "first proposes" standards.

Commenter Name: Lorraine Gershman

Commenter Affiliation: American Chemistry Council (ACC)

Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1

Comment Excerpt Number: 123

Comment: EPA proposes to reset the compliance deadline for existing sources to 3 years from the effective date of the final reconsidered boiler major source rule. For new sources, EPA proposes to reset the compliance date to 60 days after promulgation of the final reconsidered rule.

EPA clearly has authority to reconsider and revise standards pursuant to §307 of the Clean Air Act. After such reconsideration and revision to the standards, “there will be circumstances where EPA changes a rule so extensively that the amended rule should be regarded as a new standard.”

Pesticide Active Ingredient (PAI) NESHAP, 67 Fed. Reg. 38200, 38201 (June 3, 2002). Sources need time to come into compliance with such “new standards.” *Id.*

Section 112(i)(3)(a) gives EPA the flexibility to allow existing sources up to 3 years to meet “any emissions standard”. As noted above, EPA used this authority in the revised PAI rule to establish a new compliance deadline for existing sources that was an additional 16 months from the deadline in the original final rule. *Id.* EPA took similar action in establishing a new compliance deadline after reconsideration and promulgation of revised standards in the Miscellaneous Organic Chemicals Manufacturing (MON) NESHAP, 71 Fed. Reg. 10439, 10440 (Mar. 1, 2006).

EPA’s reasoning in extending/resetting the compliance deadline in both the PAI and the MON is equally applicable to this rulemaking. In those NESHAP rules, EPA reasoned that § 112(i)(3) is ambiguous as to whether an initial compliance date applies to a rule that has been substantially revised. EPA asserted, and in the case of the MON ACC concurred in comments, that when provisions of a rule are changed to such a degree that the amended rule triggers a new effective date, this is a new “emission standard” requiring a new compliance deadline. Additionally, § 112(d)(6) requires EPA to review and if necessary revise § 112 standards no less than every 8 years. If the underlying standard is revised, it is axiomatic that a new compliance deadline would have to be established to allow sources to come into compliance with the revised rule.

Response: The EPA thanks the commenter for their support.

Document Control Number: EPA-HQ-OAR-2002-0058-3500-A1

Comment Excerpt Number: 13

Comment: Compliance with the final rule has been greatly complicated by two events that occurred following the publication of the rule in the Federal Register: (1) the indefinite stay of the rule that EPA issued on May 18, 2011¹⁰ and (2) the subsequent vacatur of that stay by the U.S. District Court for the District of Columbia.¹¹ EPA's stay request caused many IB owners to suspend their efforts to comply with the 2011 IB MACT limits until they were sure of the exact details of the final limits. Their uncertainty was only heightened by EPA's statements about the numerous reconsideration petitions it had received and the possible revisions it may make in response to those petitions. Almost a year has passed since the rule was published in the Federal Register and IB owners still do not know what limits they will ultimately need to meet. Under these circumstances, it would be unfair to base the date of compliance on the March 21, 2011 publication date.

Comment: The need for EPA to reset the compliance deadline in this rulemaking is all the more compelling because of some unique circumstances:

EPA administratively stayed the rule on May 18, 2011, two days before the rule was to become effective. See, 76 Fed. Reg. 28662 (May 18, 2011). EPA stayed the rules because it had already determined that significant requirements of the rule needed to be reconsidered and needed additional public comment. Additionally, the Agency received a number of petitions for reconsideration from interested parties, including ACC, asking the Agency to reconsider additional provisions. That stay remained in place until January 9, 2012, when it was vacated by a federal district court. *Sierra Club v. EPA*, No. 11-1278-PLF, 2012 U.S. Dist. LEXIS 2457, (D.D.C. Jan. 9, 2012).

Comment: A. Tying the Compliance Date to Issuance of the Final Reconsideration Rules is Consistent with the Notice of Reconsideration and the Delay Notice: Resulting Uncertainty Limited Affected Sources' Ability to Make Appropriate Selections of Control Technologies and Carry Out Other Compliance Decisions.

As noted above, contemporaneously with the issuance of the three final rules, EPA immediately announced that it was reconsidering fundamental aspects of the final rules. EPA published the same day as the three final rules a Notice of Reconsideration, stating that it was "convening a proceeding for reconsideration of certain portions of [the] emissions standards." *Notice of Reconsideration*, 76 Fed. Reg. at 15,267. The Notice of Reconsideration appropriately recognized that the final rules that were issued required revision due to numerous technical, legal and policy issues that the Agency had not had sufficient time to address in its final rulemakings. By the same token, however, the notice created uncertainty on multiple levels as to the final limits and standards of the Boiler MACT and CISWI Rules.

First, it created uncertainty as to the final composition of "a number of issues" EPA enumerated in the Notice of Reconsideration. Those included fundamental aspects of the Boiler MACT and CISWI Rules, e.g., revisions to the proposed subcategories and to the fuel specification through which gas-fired boilers using a fuel other than natural gas ("NG") can qualify as Gas 1 units in the Major Source Boiler MACT. *See id.* Second, the Notice of Reconsideration created uncertainty as to which other elements not enumerated by EPA would become part of the reconsideration process and how reconsideration might alter the form of those elements as finalized on March 21, 2011. This is because EPA explicitly set forth that it was still "in the process" of determining the full extent of those subjects and that it was committed to including "all additional issues" appropriate for reconsideration, including those raised in any then-prospective petitions for reconsideration. Even to the extent that the Notice of Reconsideration enumerated certain, specific subjects as under reconsideration, it acknowledged that the list was only a portion of the subjects that EPA would ultimately reconsider. *See id.*

Indeed, the scope of the issues that EPA intended to reconsider was not identified until the December 23, 2011, reconsideration proposal, some 9 months later than the publication of the final rule (and a substantial portion of the way into the compliance planning period for affected sources). The Notice of Reconsideration, therefore, literally put affected sources, including those

owned and/or operated by AIF members, on notice that they should not – and, indeed, could not – initiate selections of control technologies or make other compliance decisions because elements of the Boiler MACT and CISWI Rules were subject to change.

The subsequent Delay Notice reinforced the notion that affected sources should postpone the start of internal compliance procedures because it expressly delayed the May 20, 2011, effective date of the Boiler MACT and CISWI Rules, pending the conclusion of judicial review or EPA’s reconsideration process. *See Delay Notice*, 76 Fed. Reg. at 28,662. In the notice, EPA again reiterated that a reconsideration proposal would be forthcoming and that the full extent of the subjects under reconsideration would not be known until issuance of that proposal. *See id.* at 28,663. In the Delay Notice, therefore, EPA induced reasonable reliance on the part of affected sources, including those owned and/or operated by AIF members, to put off making the necessary compliance decisions until further notice.

When weighing various energy strategies to comply with the Boiler MACT, automotive companies face a number of choices. For instance, facilities with coal-fired boilers must decide between several options for meeting the anticipated rules and optimizing energy usage, including adding control equipment to current boilers; converting less efficient steam-powered heaters to NG-fired units; and eliminating coal boilers altogether by either converting them to, or replacing them with, NG-fired units or resource-preserving, landfill gas-fired boilers. The control options associated with the CISWI rule will be even more numerous due to the higher emission restrictions involved. Uncertainty as to the final form of the regulations – including which controls, work practices, and emission standards will apply – inhibits automotive companies from judiciously making these involved energy policy decisions.

Response: The EPA thanks the commenter for their support.

Comment Excerpt Number: 9

Comment: Once the rules are finalized, implementation of the changes required to achieve compliance can require significant time, beginning with the company’s internal review process. First, the automotive company’s legal and technical personnel must analyze the newly promulgated requirements to determine the best course of action based on the company’s production requirements and its short- and long-term financial situation. After selecting a strategy, the technical staff must compile and present a budget and informational package to facilitate the managerial decision-making process. Next, the automaker’s management must review and approve the compliance strategy. Management approval is followed by compilation of a bid package and vendor list to assist the company in identifying the best equipment and value. The automaker then submits bid packages to identified bidders and, after several rounds of clarifications and negotiations, selects and hires a bidder. It can easily take 6-8 months after the rule is finalized to select a control option and hire an installation contractor, assuming a qualified vendor is available to begin work immediately. Under current regulatory timetables, this would give all affected sources slightly more than a year to design, build, install, and test required control equipment, an insufficient period of time.

Even after a company hires a vendor, it needs additional time to order and install equipment. The length of time depends on the types of equipment or controls chosen, and obtaining certain pieces of equipment sometimes involves significant lead times. In addition, as EPA acknowledges, only a limited number of vendors are qualified to fabricate and install the equipment that the Boiler MACT and CISWI and NHSM Rules will ultimately require.³ A short implementation window would result in flooding these vendors with bid requests and aggressive equipment delivery and installation demands, causing increased wait times and increasing compliance risk for owners and operators. Moreover, as EPA is aware, installation of controls or changes to a process to comply with a rule typically requires air construction permits to be issued under the state implementation plan ("SIP") and revision of Title V operating permits. Construction permit processing times can range from 3 months to over a year and revision of operating permits typically takes no less than 6 months but can take longer.

After the required permits are issued and the requisite equipment is delivered, the speed of installation can depend on the weather in northern climates (where many of AIF members' facilities are located), which inhibits the pouring of concrete foundations depending on the season. A start-up time follows equipment installation and then, generally, the vendor must test the equipment to demonstrate that it meets performance claims. Moreover, as EPA is aware, the rules, once finalized, will require some type of third-party equipment performance testing. Regulated entities will need to select those third-party testing companies by a process similar to vendor-selection process described above and, again, the regulated community would expect shortages of qualified testing vendors in any truncated or expedited rule-implementation window. If, as evaluated through the testing process, the equipment does not meet performance requirements, then it may need additional modification or adjustment.

In the reconsideration proposals, EPA recognizes in general terms the effect of the Notice of Reconsideration and the Delay Notice, describing the "resulting uncertainty" as having "limited the ability of affected sources to begin making appropriate selections of control technologies and other compliance decisions." *E.g., Boiler MACT Reconsideration Proposal*, 76 Fed. Reg. at 80,616. As described above, the compliance process for regulated entities like facilities owned and/or operated by AIF members is protracted and involves many interconnected steps. Given that the regulated community cannot begin the compliance process without knowing the final contours of the rules, any delay in EPA finalizing the Boiler MACT and CISWI Rules necessitates a corresponding delay in the beginning of the compliance period. Otherwise, affected sources, including those owned and/or operated by AIF members, will have insufficient time to comply. Therefore, AIF supports EPA's proposal for the compliance period to begin 60 days after it publishes the final reconsideration rules.

[Footnote 3: In the Boiler MACT Reconsideration Proposal, EPA notes that, even under the statutory maximum of 3 years, the availability of control equipment and vendors to facilitate installation of control technologies is likely to pose a problem, given the thousands of facilities across multiple, diverse industries that will become subject to the final reconsideration rules. *See Boiler MACT Reconsideration Proposal*, 76 Fed. Reg. at 80,616. The potential scarcity in availability of equipment and vendors promises to be exacerbated, as EPA recognizes, by the "large number of units requiring controls in conjunction with the parallel rulemaking for electric generating units that will require controls from many of the same vendors." *Id.*]

Comment: EPA's Compliance Date Approach is also Consistent with the Fact that EPA Has Not Yet Finalized the Reconsideration Proposals: Until Then, EPA Will Not Resolve the Persistent Uncertainty as to the Content of the Final Rules.

As EPA acknowledges, even after issuance of the reconsideration proposals, affected sources' uncertainty as to the final form of the Boiler MACT and CISWI Rules persists because the reconsideration proposals put forward a number of substantive revisions to the definitions, subcategories, emission limits, work practice standards and other components of the rules. *See CISWI and NHSM Rules Reconsideration Proposal*, 76 Fed. Reg. at 80,465; *Boiler MACT Reconsideration Proposal*, 76 Fed. Reg. at 80,616. In the Boiler MACT Reconsideration Proposal, for example, EPA "proposed changes to emission limits for units in *every* subcategory." *Boiler MACT Reconsideration Proposal*, 76 Fed. Reg. at 80,616 (emphasis added). Revision to emission limits and standards across the subcategories will trigger different compliance responses and control selection than would have flowed from the final rules of March 21, 2011. Those proposed changes, coupled, for example, with the shift to work practice standards for dioxin/furan emissions for *all* subcategories, significantly impacts the ability of affected sources, including those owned and/or operated by AIF members, to develop and decide upon final compliance strategies while the reconsideration process remains ongoing. *See id.* As EPA notes, facilities must design emission controls to work properly when operated together, so they cannot initiate appropriate design of those controls (and make corresponding compliance decisions) until the final limits and standards are known and fixed. *See id.*

The fact that the Boiler MACT and CISWI and NHSM Rules all simultaneously remain in development adds a special level of complication to system analysis prior to the finalized rules. For example, in one process, a company must analyze a system to evaluate which materials the NHSM Rule might be interpreted as a "solid waste." This determination will dictate whether the equipment must ultimately meet the Boiler MACT or the CISWI Rule. In the case of the CISWI Rule, a particular process would likely require addition of an afterburner or recuperative oxidizer, selective catalytic reduction ("SCR"), a scrubber, activated carbon injection and a baghouse. If the material is considered a fuel and not subject to CISWI, however, it would have to meet the Boiler MACT requirements, which would likely involve only a scrubber and a baghouse. Moreover, uncertainty regarding the final limits required by the rule complicates decisions on the process order of the equipment layout. Determination of the final pollutant emission limits dictates, for instance, whether to use a SCR and spray dryer combination versus a multi-pollutant, Tri-NO_x system followed by an acid gas scrubber. The regulated community, including AIF members, simply cannot make these decisions until EPA finalizes the reconsideration proposals. Therefore, such persistent uncertainty delays the start of the implementation process.

Once EPA finalizes the Boiler MACT and CISWI Rules, the compliance strategy process for affected sources, including those owned and/or operated by AIF members, must begin anew. As EPA does not expect to finalize the reconsideration proposals until later this Spring, maintaining

the original compliance dates would provide affected sources with an insufficient amount of time to meet the standards of the forthcoming final reconsideration rules. For the Boiler MACT, for example, maintaining the original compliance date of March 21, 2014, would effectively provide affected sources with less than 2 years. Even under the maximum time of 3 years from the effective date allotted under Section 112 of the Clean Air Act ("CAA"), with which EPA sought to provide affected sources in the March 21, 2011, final rule, EPA characterized the compliance timetable as "pressing." *Delay Notice*, 76 Fed. Reg. at 28,663. AIF concurs. As EPA suggests in the reconsideration proposals, if the Agency does not key the compliance period to the final reconsideration rules, sources will have insufficient time to achieve compliance. EPA should finalize its proposal to begin the compliance period 60 days after publication of the final reconsideration rules.⁴

[Footnote 4: Consistent with its proposal as to affected sources, EPA proposes to delay the start of the compliance period for new sources until 60 days after publication of the final reconsideration rules. See *CISWI and NHSM Rules Reconsideration Proposal*, 76 Fed. Reg. at 80,465; *Boiler MACT Reconsideration Proposal*, 76 Fed. Reg. at 80,616. AIF supports this proposal for many of the same reasons articulated with respect to affected sources.]

Comment Excerpt Number: 11

Comment: EPA Possesses the Authority to Set the Compliance Dates Based on the Effective Date of the Reconsideration Rules.

Section 112(i)(3)(A) of the CAA is the key statutory provision governing EPA's authority to establish compliance dates for emission standards. In pertinent part, it sets forth:

After the effective date of any emissions standards, limitation or regulation ...the Administrator shall establish a compliance date or dates for each category or subcategory of existing sources, which shall provide for compliance *as expeditiously as practicable, but in no event later than 3 years after the effective date of such standard* ...CAA § 112(i)(3)(A); 42 U.S.C. § 7412(i)(3)(A) (emphasis added). The plain language of § 112(i)(3)(A) directs EPA to establish a compliance date "no later than 3 years after the effective date" of any emission standard, limitation, or regulation. Here, consistent with that directive, for the Boiler MACT, EPA initially set a compliance date for the Boiler MACT of March 21, 2014, or 3 years after the March 21, 2011, publication of the final rule in the *Federal Register* and slightly less than 3 years after the initial effective date of May 20, 2011. Now, as discussed above, EPA proposes to start the 3-year compliance period beginning 60 days after publication of the final reconsideration rule. As discussed above, the rationale is that EPA proposes substantial revisions of the reconsideration proposals and that the Notice of Reconsideration, along with the Delay Notice, generated uncertainty as to the final form of the rules throughout the regulatory community. As a result of this process, affected sources have not been able to initiate the compliance process—the composition of the final rule remains unclear and those sources continue to operate in reliance on

EPA's representations that the effect of the Boiler MACT is stayed and that the 3-year compliance period will begin only after publication of the final reconsideration rule.

Looking first to the statute, while Section 112 provides that emission standards or other regulations promulgated under Section 112(d) "shall be effective upon promulgation," CAA § 112(d)(10); 42 U.S.C. § 7412(d)(10),⁵ the statute does not address what that means in the current context, in which EPA is revising – and doing so in a substantial way – a previously promulgated standard and promulgating a *new* standard. It does not state, when it directs EPA to establish a compliance date within 3 years of the "effective date," whether the effective date must be the date on which the emission standard is effective as first promulgated or as subsequently revised on reconsideration. EPA's final action will essentially act as a *new issuance* of an emissions standard, which itself will have a new "effective date." Under Section 112(i), therefore, EPA may, indeed must, determine the compliance date for existing sources based on that effective date.

[Footnote 5: Note that the Congressional Review Act had the effect of delaying this date by 60 days to allow time for congressional review. 5 U.S.C. § 801(a)(3)]

Document Control Number: EPA-HQ-OAR-2002-0058-3512-A1

Comment Excerpt Number: 12

Comment: Case law does not prohibit the Agency from taking this approach. The D.C. Circuit has not squarely taken up this issue; instead, it has merely considered EPA's authority to extend compliance deadlines beyond the 3-year statutory maximum. *See NRDC v. EPA*, 489 F.3d 1364, 1373-74 (D.C. Cir. 2007). Specifically, in *NRDC*, the D.C. Circuit vacated a portion of an EPA rulemaking that had *extended* the original compliance date by one year for sources in the low-risk subcategory of the MACT for plywood and composite wood products (40 C.F.R. § 63, Subpart DDDD). *See id.* The court held that EPA had not relied on Section 112(i)(3)(B) for this extension – the provision that addresses *extensions* – but instead had relied on Section 112(i)(3)(A), which addresses the compliance period keyed to the effective date of an emissions standard. *See id.* In *NRDC*, according to the court's holding, EPA went astray when it promulgated emission standards in 2004, setting a compliance deadline for 3 years later (2007) and *then* endeavored to *extend* the compliance deadline for 2008 – or 4 years after the effective date – based on a finalized reconsideration proposal but without undergoing the case-by-case extension process provided in Section 112(i)(3)(B). *See id.*

By contrast, here EPA is resetting the clock on the emissions standard because it is re-promulgating the action. In the case of the Boiler MACT, for example, EPA proposes the following amendments to § 63.7495, concerning "When do I have to comply with this subpart?":

(a) If you have a new or reconstructed boiler or process heater, you must comply with this subpart by [DATE 60 DAYS AFTER THE FINAL RULES IS PUBLISHED IN THE *Federal Register*] or upon startup of your boiler or process heater, whichever is later.

(b) If you have an existing boiler or process heater, you must comply with this subpart no later than [DATE 3 YEARS AFTER PUBLICATION OF THE FINAL RULE IN THE *Federal Register*], except as provided in § 63.6(i).

Boiler MACT Reconsideration Proposal, 76 Fed. Reg. at 80,628 (formatting in original). The reconsideration proposal, then, avoids the problem created by EPA's approach to extending the compliance deadlines in *NRDC* because it does not stretch the compliance deadlines beyond 3 years after the effective date. Instead, this proposal sets a new effective date of 60 days after publication of the final reconsideration rule and then fixes the compliance deadline to 3 years after that date. As a corollary, it fixes the date on which new or reconstructed sources must comply with the emission standards as 60 days after the final reconsideration rule, which adheres to the mandates of § 112(i). EPA's proposal, therefore, is consistent with the holding of *NRDC* and the statutory directive of § 112(i)(c)(A). EPA has the legal authority to finalize the proposed regulations as to the compliance period 6

[Footnote 6: In the alternative, at a minimum, EPA could invoke authority under Section 112(i)(3)(B) and create a streamlined case-by-case process for granting extensions of one year.]

Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 2

Comment: EPA proposes to reset the compliance date for existing sources to 3 years after publication of the final reconsideration rule and for new sources, to the later of 60 days after publication of the final reconsideration rule or startup. 76 Fed. Reg. 80605. Sources need a substantial period to come into compliance and CIBO strongly supports resetting the dates. Internal planning for compliance with major rules requires involvement of personnel at all levels of the company, and in the case of this major rule, will require major capital projects at many facilities covered by this rule. CIBO has commented in earlier comments at length on the need for sufficient time for the complex undertaking of retrofitting a major boiler facility, including compliance planning, engineering design, capital approval, equipment purchase, installation and testing, all in advance of the compliance date.

Here, because EPA issued an immediate Notice of Reconsideration of the rule, sources understood as of the publication of the March 2011 Final Rule that there would be amendments to the rule that could very well alter compliance strategies. At the time, it was unclear whether the rule would change considerably from the final version, and with respect to which sources and emission limits. One significant element of the BMACT rule that would clearly undergo change, based in part on EPA's flawed or incomplete data, was the inventory of units in some subcategories, and their emission limits. In addition, several clear problems in the March 2011 Final NHSM rule made it clear that the definitions of NHSM and fuel were highly likely to be amended. Changes to correct data and likely revisions to the fuel definition would clearly affect the inventories of units in boiler subcategories and therefore floor calculations and emission limits. Under those circumstances, it would not have been rational for sources to develop

compliance strategies and begin the complicated, costly process of compliance with a rule that EPA had announced would be changed.

Document Control Number: EPA-HQ-OAR-2002-0058-3455-A1

Comment Excerpt Number: 3

Comment: American Electric Power (AEP) agrees with EPA's proposal to extend the compliance date for this rule to 3-years after the publication of the final version of this reconsideration of the IB Boiler MACT Rule. Allowing this compliance schedule will provide

additional time to the facility owners to make the needed enhancements and installations needed to meet the requirements in this rule.

Response: The EPA thanks the commenter for their support.

Commenter Name: Claudia M. O'Brien, Latham & Watkins LLP

Commenter Affiliation: JELD-WEN, inc.

Document Control Number: EPA-HQ-OAR-2002-0058-3485-A1

Comment Excerpt Number: 4

Comment: EPA has proposed to extend the compliance deadlines for existing sources to three years after publication of the final Boiler MACT reconsideration rule. JELD-WEN strongly supports this extension of the compliance deadline as the extension is both necessary and consistent with EPA's statutory authority.

JELD-WEN agrees with EPA that the deadline extension is required to enable sources to make compliance-related decisions and to install controls if needed. As EPA explained, the Boiler MACT reconsideration "proposed changes to the emission limits for units in every subcategory." From a practical standpoint, the different standards may change the type of controls needed for compliance or the design of the controls. EPA also rightly noted that the uncertainty caused by the reconsideration limited sources' ability to prepare for compliance. Leaving the existing compliance deadline in place from the March 2011 final rule would provide less than two years for sources to meet the standards, and sources still do not know what the *final* standards will be until the final reconsideration rule is published.

Response: The EPA thanks the commenter for their support.

Commenter Name: N.W. Bernstein & Associates, LLC

Commenter Affiliation: Eco Power Solutions (USA) Corporation

Document Control Number: EPA-HQ-OAR-2002-0058-3499-A1

Comment Excerpt Number: 1

Comment: The most important part of EPA's proposed HAPs rule revision for major source industrial boilers, and also in a sense the most legally challenged portion of the proposed reconsideration and revision of the Boiler Rule, is the "reset" of the schedule for compliance. Without a "reset," compliance must be achieved within three years from the date the original Boiler Rule was originally effective, May 20, 2011 (i.e. May 2014 – slightly more than two years from now), plus one year for source by source extensions (i.e. May 2015 at the latest).² It is critically important that the compliance date be reset not only for the reasons given by EPA in its proposed reconsideration of the original Boiler Rule, but additionally because without a reset, it will be virtually impossible for operators of industrial boilers that are major sources to achieve compliance without rushing to install conventional technology without any realistic opportunity to evaluate innovative multi-pollutant removal technology such as Eco Power's COMPLY 2000® and other new technologies.

[Footnote]

(2) The original Boiler Rule was published in the Federal Register on March 21, 2011, but did not become effective until May 20, 2011. 76 Fed. Reg. No. 54 at 14608.

Response: The EPA thanks the commenter for their support.

Commenter Affiliation: Eco Power Solutions (USA) Corporation

Document Control Number: EPA-HQ-OAR-2002-0058-3499-A1

Comment Excerpt Number: 2

Comment: EPA has proposed to “reset” the compliance date for existing sources to the date three years after the date effective date of the final reconsideration of the Boiler Rule. 76 Fed. Reg. at 80,605, 80,616-17. EPA specifically requested comment on the proposed changes to the compliance dates. *Id.*, at 80,617. Part of the rationale provided by EPA for doing the “reset” is that when EPA announced its reconsideration and its attempted postponement of the effective date, it indicated that requirements were to change significantly and that the resulting uncertainty has limited the ability of affected sources to begin making selection of control technologies and compliance decisions. Moreover, even if significant changes were not being proposed, “an extended compliance date would likely be necessary to provide enough time for facilities to achieve compliance.” *Id.*, at 80,616.³

[Footnote]

(3) EPA also noted that the availability of control equipment and vendors to install control equipment for boilers is in question due to the demands of the EGU rulemaking which will require controls from many of the same vendors. *Id.*

Response: The EPA thanks the commenter for their support.

Commenter Name: David A. Buff, Golder Associates Inc.

Commenter Affiliation: Florida Sugar Industry (FSI)

Document Control Number: EPA-HQ-OAR-2002-0058-3504-A1

Comment Excerpt Number: 54

Comment: The FSI supports EPA’s proposal to re-set the compliance deadline during the reconsideration process. Affected sources have not been able to begin detailed compliance planning because the final Boiler MACT Rule requirements are still uncertain. It will be extraordinarily difficult – if not impossible – for all of the entities with existing boilers to make the changes necessary to comply with the Boiler MACT rule in three years. The normally Herculean task of performing a boiler retrofit in three years will be made virtually impossible by the enormous competition for critical resources and the likely gridlock in many state permitting processes that the broad application of this rule and other new rules for utility boilers will create. Many boiler owners will be unable to secure equipment and assistance, as well as obtain the state/local permits needed to retrofit their units, within three years. The FSI sugar mills are acutely affected by these rules because each mill have as many as 6 (six) boilers, all of which must comply with the new EPA requirements by the compliance date. The members of the FSI have been trying to determine what they must do to comply with the Boiler MACT Rule, but it

has been very difficult to move forward with any capital projects because the EPA requirements for industrial boilers, CISWI units, and utility boilers have created a complex set of interrelated requirements and a "moving target" for compliance.

Response: The EPA thanks the commenter for their support.

Commenter Name: James Johnson

Commenter Affiliation: United States Beet Sugar Association (USBSA)

Document Control Number: EPA-HQ-OAR-2002-0058-3508-A1

Comment Excerpt Number: 9

Comment: In the reconsideration of the major source Boiler Rule, EPA proposed to reset the compliance

date for existing sources such that it would reflect a timeline three years after the date of publication of the eventual final rule. USBSA supports EPA's approach for adjusting this compliance deadline. CAA section 112(i)(3) allows for three years for compliance from the effective date of a final rule, and thus a revision to the compliance deadline in the rule is appropriate. There is currently a large amount of uncertainty in the regulated community surrounding the eventual shape of the Boiler Rules, and EPA's approach seeks to provide affected sources with at least the full three years intended by section 112(i)(3). Even with the adjustment to reflect the intent of section 112(i)(3), however, USBSA members will have difficulty meeting the rule's very tight timeframe for compliance.

Response: The EPA thanks the commenter for their support.

Commenter Name: Lorraine Gershman

Commenter Affiliation: American Chemistry Council (ACC)

Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1

Comment Excerpt Number: 126

Comment: Due to the vacatur of the stay, the regulated community has lost almost a year from the original compliance time frame. If EPA does not reset or extend the compliance date in the final reconsidered boiler major source rule, affected sources will have only about two years to undertake all of the actions and testing required to try to meet the existing compliance deadline. Given the complexity of this rule and all of the necessary actions that thousands of affected sources will have to take, meeting a 2 year compliance deadline is going to be impossible for most sources, even if the final reconsidered rule were to remain unchanged from the March 2011 final rule.

Response: The EPA thanks the commenter for their support.

Commenter Name: Paul Noe

Commenter Affiliation: American Forest & Paper Association (AF&PA) et al.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 18

Comment: EPA proposes to reset the compliance deadline for existing affected sources to three years after the date of publication of the Final Reconsideration Rule in the Federal Register. EPA promulgated a Boiler MACT rule in March 2011 but also announced that it would reconsider certain portions of the rule and then subsequently stayed the effective dates of the rule on May 18, 2011. A recent court decision vacated the stay, resulting in the original compliance timeline of 3 years from March 21, 2011 for existing sources becoming effective again. We support EPA's proposal to re-set the compliance timeline with the reconsideration rule, as affected sources have not had the ability to begin detailed compliance planning because the final requirements are uncertain. EPA recognizes in its January 18, 2012 letter from Administrator Lisa Jackson to Senator Ron Wyden that industry needs sufficient time to comply with these new standards.

Response: The EPA thanks the commenter for their support.

Comment: EPA Should Extend the Compliance Deadline to Three Years After Promulgation of the Final Boiler MACT

On January 9, the U.S. District Court for the District of Columbia vacated EPA's May 18, 2011, stay of the Boiler MACT.¹⁷ This vacatur restored the compliance deadlines for affected sources set in the final Boiler MACT promulgated on March 21, 2011. These included notification requirements under the General Provisions in 40 C.F.R. Part 63, as well as the three-year deadline for complying with emission standards. The former is addressed in the proposed rule, which states that the notification requirements of the General Provisions must be met no later than 120 calendar days after the final rule is published in the Federal Register.¹⁸ This revision is necessary because EPA has added additional subcategories and clarified exemptions, and as a result the information that must be provided in the notification, namely "the types of emission points within the affected source subject to the relevant standard and types of hazardous air pollutants emitted," has changed.

Comment Excerpt Number: 13

Comment: EPA stated in the proposed rule that existing sources must comply with the Boiler MACT no later than three years after the publication of the final reconsidered rule.²⁰ The VI fully supports this updated compliance date. The reconsideration, stay, and subsequent vacatur have created significant regulatory uncertainty for affected sources, necessitating a "reset" of the compliance clock to allow existing sources the full statutory time to make necessary investments in emission controls. EPA is authorized to set the compliance date up to three years after the effective date of an emission standard.²¹ EPA has proposed revised emission standards for most but not all subcategories. Given that emission control technology must be designed as a whole, to address all regulated HAPs, EPA's revision of some emission limits has effectively changed the emission standards for all sources and subcategories. EPA therefore correctly set the compliance date for all emission standards to three years from the date of the final reconsidered Boiler MACT.

Comment Excerpt Number: 8

Comment: AHFA strongly supports EPA’s decision to reset the compliance date for existing source boilers at three years after promulgation of a final reconsideration rule, rather than the current compliance date of March 21, 2014. A minimum of three years will be needed for our members to comply with the requirements of the final Boiler MACT rule. Even with three years notice, there is considerable uncertainty about the ability of boiler industry suppliers to meet demand for tuneups and control equipment engineering, installation, and testing.

Response: The EPA thanks the commenter for their support.

Comment Excerpt Number: 4

Comment: In *Natural Res. Def. Council v. EPA*, 489 F.3d 1363 (D.C.Cir. 2007), the D.C. Circuit rejected an effort by EPA to extend by one year the compliance date for emissions standards established in 2004 in light of what EPA characterized as substantial changes made in the 2006 version of the rule at issue. The Court relied on the plain language of the CAA, Subsection 112(i)(3)(A), that after the effective date of any [Section 112] emission standard, limitation or regulation, the Administrator shall establish a compliance date or dates: “which shall provide for compliance as expeditiously as practical but in no event later than 3 years after the effective date of *such standard*” *Id.*, at 1373 (emphasis in original).

The D.C. Circuit read the phrase “such standard” as meaning the effective date of a Section 112 emission standard. Accordingly, it rejected EPA’s argument that extensions of compliance should be allowed when EPA determines that substantial changes and amendments to the rule have been made. *Id.*, at 1374.

The reasoning of *Natural Res. Def. Council* was followed in *Sierra Club v. EPA*, 551 F.3d 1019 (D.C. Cir. 2008). In dealing with EPA’s attempt to exempt major sources from compliance with Section 112 emissions standards during startups, shutdowns, and malfunctions, the Court rejected EPA’s claim that it retained discretion: where “Congress explicitly enumerate[d] certain exceptions to a general prohibition, additional exceptions are not to be implied, in the absence of the contrary legislative intent.” *Id.*, at 1028 (quoting *Natural Res. Def. Council*, 489 F.3d at 1374).

Finally, the specific and somewhat limited rationale for the “reset” of the compliance deadlines as set forth by EPA in the preamble to the proposed revision to the original Boiler Rule is virtually the same rationale that was recently rejected in *Sierra Club v. Jackson*, Case No. 11-1278, 2012 WL 34509, at *16-20 (D.C. Cir. Jan 9, 2012). Accordingly, it is likely that environmental groups will contend that EPA’s actions in resetting the time clock are both unauthorized under the CAA and arbitrary and capricious under the APA.

Response: EPA thanks the commenter for their support of the reset of three years from publication of the final rule for existing sources. The three years from this final action on

reconsideration is "as expeditiously as practicable," because the sources are getting more stringent limits. Each of the subcategories with emission limits have at least one more stringent limit that will drive different control measures compared to the March 2011 final rule and the facilities will need time to finance and develop their control measures.

Document Control Number: EPA-HQ-OAR-2002-0058-3485-A1

Comment Excerpt Number: 5

Comment: The CAA permits EPA to extend the compliance deadline as it has proposed here. Section 112(i)(3)(A) requires EPA, upon promulgating "any emissions standard, limitation," to set a compliance schedule for any category or subcategory of existing sources, and mandates that the compliance deadline may be "no... later than 3 years after the effective date of such standard."¹⁸ Therefore, EPA's proposal of requiring existing sources to comply with the Boiler MACT within three years after the final rule is published complies with the statute.

The proposed extension here is distinguishable from the extension that the D.C. Circuit invalidated in *Natural Resources Defense Council v. EPA*,¹⁹ for EPA's wood products MACT rule. In that case, EPA finalized the wood products MACT in 2004, but amended the rule in 2006 to change definitions, "procedures for the low-risk demonstration process, and other permitting and timing issues" and to reset the compliance date from October 1, 2007 (within three years of the initial rule) to October 1, 2008? The court found that this compliance extension violated EPA's statutory authority because "the trigger for the three-year compliance period" is the effective date of the emissions standards-not the effective date of modifications to regulatory definitions, procedures, permitting, etc? That is not the case here. In the Boiler MACT reconsideration, EPA has proposed new emissions limitations and replaced dioxin/furan limitations with work practice standards for every source. As such, JELD-WEN strongly supports EPA's proposed extension to the compliance deadline.

Comment: EPA has proposed to extend the compliance date for all sources and all limits. We agree that such an extension is appropriate where more stringent limits are imposed following reconsideration, since sources should not have to comply with standards that ratchet in

stringency after only one year. We note that EPA's stay pending reconsideration has been rejected by the Court and caution that an effort to provide an extended compliance deadline for sources whose emission limits are not made more stringent may invite litigation that affects an extension for sources facing more stringent limits. We further note that the CAA provides the option of an additional year for compliance where a source demonstrates a need for more time.

Response: The EPA thanks the commenter for their support to reset the compliance date three years from publication of this final rule for existing sources having more stringent standards. The commenter recommended caution against compliance deadlines for sources where emission limits are not more stringent. We agree that the three years from the final action on reconsideration is "as expeditiously as practicable," for the sources for which the numeric emissions limits are more stringent than in the March 2011 final rule. All of the subcategories that are subject to emission limits have at least 1 HAP limit (most have 2) that is more stringent as compared to the March 2011 final rule. Also, in this final rule, three of the March 2011 subcategories have split: biomass stoker subcategory split into wet biomass stoker and dry biomass stoker; biomass suspension subcategory split into suspension grate and suspension burner; and liquid subcategory split into heavy liquid and light liquid. All the subcategories subject to emission limits will be getting at least one more stringent limit compared to the March 2011 final rule and given that emission control technology is typically designed as a whole the facilities will need time to finance and develop their control measures. Thus, they need the full three years.

The emissions standards for the Gas 1 subcategory and for units less than 10 million Btu/hr are not more stringent than the March 2011 final rule. However, the reconsideration, stay, and subsequent vacatur have created significant regulatory uncertainty for affected facilities and that given that affected facilities have affected units in other subcategories in addition to Gas 1 and small units and that a facility's compliance strategy is generally designed as a whole, we are resetting the compliance date for existing units for all requirements.

Commenter Name: N.W. Bernstein & Associates, LLC

Comment: EPA should properly set the compliance schedule in a way that is consistent with the CAA and the APA. EPA should exercise its authority under the APA, 5 U.S.C. §§ 551(5) and 553(c), to propose to "repeal" the original Boiler Rule promulgated on March 21, 2011 in its entirety, and then after receipt of comments on the proposal, proceed to repeal the original Boiler Rule in its entirety. Instead of reconsidering that rule, EPA should promulgate a new final Boiler Rule containing the corrected standards and containing compliance deadlines consistent with the three plus one year provisions of Section 112 of the CAA, starting on the effective date of the new rule.⁴

It is certainly true that,

"When an agency acts to rescind a standard it previously adopted, a reviewing court will subject that rescission to the same level of scrutiny applicable to the agency's original promulgation."

Association of Public-Safety Comm. Officials-Int'l, Inc. v. F.C.C., 76 F.3d 395, 398 (D.C. Cir.1996) (citing *Motor Vehicle Mfrs. Ass'n v. State Farm Mut. Auto. Ins. Co.*, 463 U.S. 29, 41, 103 S.Ct. 2856 (1983)).

To justify the rescission of the original Boiler Rule in its entirety and the promulgation of a new Boiler Rule, EPA needs to say more than simply “industry needs the time.” It needs also to point to societal benefits that will be lost if EPA does not act to rescind the original Boiler Rule and promulgate a new rule. A principal societal benefit of that approach will be the restoration of the opportunity that would otherwise be lost for the deployment of innovative multi-pollutant removal technologies that have numerous benefits. In capital-intensive industries involving long lead times, industrial companies operating major sources need time to evaluate new technology. They need also to try to adapt strategies that reflect the need to control multiple pollutants being covered by different EPA rulemakings.

[Footnote]

(4) What EPA should do is not to attempt to “postpone” or “reset” compliance dates that were triggered by the original promulgation of the Boiler Rule on March 21, 2011, as part of any “reconsideration” of certain provisions of final rule. Attempting to do so will likely run afoul of the plain language of the CAA and the above noted D.C. Circuit cases.

Response: The boiler MACT was issued pursuant to section 307(d) of the Clean Air Act to satisfy certain Agency obligations under section 112 of the Act. Section 307(d) expressly provides that sections 553 through 557 of the APA shall not apply to section 307(d) actions except as specifically provided in section 307(d). Further, the commenter points to nothing in section 551(5) of the APA (which simply defines the term “rule making”) or 553(c) (which addresses public participation requirements for APA rules) relevant to “repealing” the boiler MACT, and EPA sees nothing in those sections –even if they did apply to CAA section 307(d) actions – that would be relevant. Further, the commenter provides no explanation for its view that revising the compliance deadline as part of today’s action is inconsistent with the Act or with DC Circuit caselaw. As explained above, EPA is establishing a compliance date for existing sources that requires compliance as expeditiously as practicable and is consistent with the requirements of section 112(i)(3).

Comment: We Commend EPA for Recognizing that Coal-Fired Facilities Seeking to Incorporate Clean and Efficient Combined Heat and Power or Waste Heat Recovery Are Eligible for a One-Year Compliance Extension.

CHP and WHR developers and environmental engineering firms have worried that three years would not be sufficient time for boiler owners to design, permit and install a CHP or WHR system. EPA regulations clearly recognize the potential delays for boiler owners seeking to install add-on pollution controls, allowing those boiler owners to petition for a one-year extension if necessary for the installation of such controls.³ In the re-proposed rule, EPA

clarifies that the installation of a CHP or WHR system could, in fact, support a request for a compliance extension. We thank EPA for this clarification and believe that treating CHP and WHR as controls in this manner may encourage facilities to pursue these technologies, which will ultimately lead to greater fuel savings and emission reductions. We look forward to working with EPA and with regulated entities to alert them to this provision and encourage them to pursue industrial efficiency projects.

[Footnote 3: See 40 CFR 63.6 (Authorizing the Administrator or delegated state authority to “grant an extension allowing the source up to 1 additional year to comply with the standard, if such additional period is necessary for the installation of controls”).]

Response: The EPA thanks the commenter for their support for clarifying that Combined Heat and Power (CHP) and Waste Heat Recovery (WHR) are eligible for a 1-year extension.

Comment: Compliance timetables and non-enforcement of violations of the March 2011 rules should be clarified in light of the vacated stay.

The recently vacated stay of the effective date for the initial final Major Source ICI Boiler Rule and CISWI Rule has introduced much uncertainty for businesses that are now faced with compliance deadlines, some already past, which cannot be met. In the revised final rule, EPA should clarify that compliance timetables will be based on the effective date established by the re-promulgated final rules, rather than the initial March 2011 promulgation date, meaning compliance deadlines will fall in 2015 (assuming a 2012 re-promulgation effective date) instead of 2014. Furthermore, as already indicated in the February 7, 2012 "no action" memo from Gina McCarthy at EPA, the revised final rule should reaffirm that technical violations of the March 2011 regulations will not be subject to enforcement.

Response: In the final rule, we are finalizing the proposed resetting of the compliance date to three years after publication of this reconsideration final rule.

Commenter Name: Robert D. Bessette

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 1

Comment: EPA should stay the effect of the March 2011 Boiler MACT rule and issue additional guidance or no enforcement assurance to address compliance exposure faced by sources during the period before EPA issues a Final Reconsideration Rule.

EPA had delayed the effective dates of the March 2011 Final Boiler MACT and CISWI rules.⁴ However, on January 9, 2012, the U.S. District Court for the District of Columbia vacated EPA's Delay Notices,⁵ and any compliance obligations for sources covered by the Boiler MACT and CISWI rules became effective immediately. EPA recognized that the vacatur triggered some compliance obligations, and on January 18, 2012 EPA announced in a letter to Senator Wyden⁶ its plan to address the implications of the vacatur. Then on February 7, 2012, EPA issued a No Action Assurance memorandum that addresses some – but not all – of the implications of the vacatur.⁷ EPA's memorandum assures sources in a limited scope of circumstances that their failure to have met a deadline to file an initial notification would not be the basis of an enforcement action brought by EPA, given that the deadline fell during the period when the Boiler MACT and CISWI rules were not in effect. In the letter to Senator Wyden, EPA asserts that for any "permitting or compliance challenges" arising from the vacatur, EPA will issue a stay for 90 days or longer, and in the event of lawsuits arising from the vacatur, EPA is "confident" that it has the legal tools to address those matters. Notwithstanding its assurances, EPA's memorandum does not alleviate many pressing continuing compliance concerns faced by sources because the rules remain in effect.

[Footnote 5: Opinion, *Sierra Club v. EPA*, No. 11-1278 (DDC Jan. 9, 2012).]

Response: This comment is in regards to the No Action Assurance letter issued by the EPA and is out-of-scope with the proposed rulemaking.

Comment: Some fossil fuel fired electric generating units may convert to biomass fired electric generating units after the compliance date for existing sources. Thus the deadline for completing the initial compliance demonstration for these existing sources should be no later than 180 days after becoming an affected source, not 180 days after the compliance date specified in 63.7495.

Response: We agree with the commenter that the proposed reconsideration rule does not address the situation when a fossil fuel-fired utility boiler switches from coal to biomass and switches from being subject to MATS to being subject to Boiler MACT. In the final rule, we have added subparagraphs to §63.7490, §63.7495, and §63.7510 to clarify that the deadline for completing the initial compliance demonstration for existing EGU sources to be no later than 180 days after becoming an affected source under the Boiler MACT.

Comment Excerpt Number: 3

Comment: We believe that compliance dates for all requirements, including tune-ups, should be no sooner than March 21, 2014 — the maximum time allowed under the Clean Air Act. EPA needs to consider that sources will be planning and applying resources to fulfill multiple requirements. Under these circumstances sources need flexibility to determine where best to apply resources, whether for emission limitations, tune-ups, or energy assessments. The rule should not mandate the priority or approach in reducing emissions. EPA must also realize that the same equipment providers and vendors will be needed by sources affected by either the major or area source rules as well as the EGU boiler MACT. We also believe EPA has flexibility to provide an additional year for performing energy assessments because implementation is voluntary. If it aids in compliance, a source will pursue energy improvement measures prior to March 21, 2014.

Response: The commenter is referring to the proposed change to the compliance date for conducting the tune-up in the Boiler Area Source Rule, subpart JJJJJ, which is out-of-scope for this rulemaking. We disagree with the commenter that the EPA has the flexibility to provide an extra year for performing the energy assessments. Section 112(i)(3)(B) of the Clean Air Act clearly state that the Administrator "may issue a permit that grants an extension permitting an existing source up to 1 additional year to comply with standards under subsection (d) if such additional period is necessary for the installation of controls."

Commenter Name: John M. Cullen
Commenter Affiliation: Masco Corporation
Document Control Number: EPA-HQ-OAR-2002-0058-3661-A2
Comment Excerpt Number: 5

Comment: EPA has proposed to extend the deadline from one year to two years from the original promulgation date (March 21, 2011) for sources to complete initial compliance demonstrations of the tune-up requirements for regulated boilers, so that the initial compliance demonstration date for a boiler tune-up would be March 21, 2013. EPA also seeks comment on whether to extend the initial compliance date for an additional year, or three years from promulgation (i.e. March 21, 2014). Masco supports extending the initial compliance date for the additional year. Such a change would harmonize the compliance dates for existing sources. The additional time would also serve to ensure that regulated sources are provided with adequate time to retain contractors for boiler tune-ups, and implement recordkeeping, personnel training and compliance programs to comply with the rule

Response: The commenter is referring to the proposed change to the compliance date in the Boiler Area Source Rule, subpart JJJJJ, which is not part of this rulemaking. Thus, the comment is out-of-scope with this rulemaking.

Comment Excerpt Number: 9

Comment: Because of the significant changes being made to the existing BPH NESHAP, the applicability date used to distinguish new and existing sources must be changed to December 23, 2011, the date of the current proposal.

EPA has not proposed to change the date that identifies whether a source is new or existing from that in the current BPH NESHAP. That date, June 4, 2010, is the publication date of the original proposed rule. The current proposal significantly changes the requirements imposed and even the subcategories to which a boiler or process heater may be assigned. Since this is the first time these particular emission limits have been proposed, section 114(a)(4) of the CAA requires that the date that establishes what units are considered new sources and what units are considered existing sources must be changed to the date of the current proposal, December 23, 2011. Because the proposed changes to the major source BPH NESHAP are so extensive (as shown by the fact that EPA published this proposal as a total replacement for the existing final rule, rather than proposing only amendments), we recommend the change in applicability date needs to be made across the board. Even for the Gas 1 subcategory, where relatively little change is proposed, there are still significant changes in requirements and the many sources that meet the other gas 1 criterion will be now be in the gas 1 subcategory, rather than the gas 2 subcategory.

Response: We disagree with the commenter that the applicability date for the new unit definition should be reset from June 4, 2010 to December 23, 2011. The definition of a "New source" in section 63.2 clearly states that "New source means any affected source the construction or reconstruction of which is commenced after the Administrator first proposes a relevant emission standard under this part establishing an emission standard applicable to such source," EPA first proposed emissions standards for new major source boilers on June 4, 2010, and proposed to revise some of those standards in December 2011.

Comment: Additional time is needed for some new sources subject to numerical emission limits to comply with this rule.

Under this proposal, new sources subject to numerical emission limits have 60 days to come into compliance and 180 days to complete the performance testing and demonstrations needed to demonstrate such compliance.

Because the applicability date is being maintained at June 4, 2010, there will be "new sources" for which construction will have begun or may even have been completed. Yet, in some cases, these new sources will be unable to comply within 60 days, because they were designed on the basis of the June 2010 proposal or March 21, 2011 final rule. Paragraph 63.6(b)(3) of the part 63 General Provisions, which is applicable to this rulemaking per Table 10 of the proposal, deals with this situation and allows 3 years for compliance if the final standard is more stringent than the proposed standard, as long as the source complies with the proposal. This will be a critical allowance for some new source boilers and process heaters and we therefore recommend that the compliance time language in §§63.7495, 63.7510, and 63.7525 specifically reference §63.6(b)(3).

Response: The compliance date for new affected sources in the final rule is the effective date of the final rule which is the date of publication or upon startup whichever is later. We agree with the commenter that paragraph 63.6(b)(3) of the General Provisions is applicable and have revised 63.7495(a) to add "except as provided in §63.6(b)(3)." In the final rule, §63.7500(a)(1) has been revised to what emission limits new affected sources constructed between June 4, 2010 and May 20, 2011 may comply with as well as those new affected sources constructed between May 20, 2011 and the effective date of this final rule.

Comment: We are sensitive to the stated concern that the availability of equipment and installers will clash with the needs of electricity generating facilities affected by parallel rulemakings. Most users of CHP technology are much smaller than electricity generating facilities and may be placed further behind in the queue. Additional time is appropriate.

As indicated above in discussion of the Energy Assessments and the re-set Compliance timetable, we are supportive of the extension of the compliance schedule for existing facilities to at least three years from less than two years in the earlier version with provision for an extra year for installation of controls approvable on a case-by-case basis.

With respect to new sources, instead of the 60 day period after publication of the final reconsideration rule or 60 days after start-up whichever is later we recommend a 90 day period for similar reasons as stated above for the first five years then a switch to 60 days could be allowed.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3677-A2, excerpt 13.

Comment: The proposal provides for three years compliance time from the publication of the final rule in the Federal Register. However, the rule is not effective until 60 days after that publication, since Congress has provided that time for its own review. As is done for new and reconstructed sources, compliance for existing sources should be based on the effective date, the date from which facilities can be fairly sure of the requirements that must be met, and the compliance date should therefore be three years and 60 days from the Federal Register publication date.

Response: Section 112(i)(3)(A) requires existing sources to comply with the emissions standards as expeditiously as practicable, but in no event more than 3 years from the effective date of the standards. The effective date of the final rule is the date of publication of the rule in the Federal register. The reconsideration is not a major rule under the Congressional Review Act, so under section 112(d)(10), the final rule is effective on publication.

Comment Excerpt Number: 30

Comment: EPA can and must do more in the final Boiler MACT reconsideration rule. In particular, as it has done in at least one prior MACT standard, EPA should grant a categorical one- year extension. In promulgating MACT standards for marine tank vessel loading operations, the Agency determined that the rule "shall allow existing sources regulated solely under section 112 four years to be in full compliance with the emission control requirements promulgated under section 112." 60 Fed. Reg. 48388, 48392 (Sept. 19, 1995). EPA observed that "section 112(i) of the Act specifically allows EPA to provide sources with a waiver of up to 1 year to achieve full compliance" and that a categorical extension was warranted in that case because "standards containing similar compliance dates for a large number of sources would result in numerous facilities competing for a limited number of experienced contractors in order to meet the standards at the same time." *Id.* Thus, EPA clearly has construed § 112(i)(3)(B) as authorizing categorical compliance extensions.

Comment Excerpt Number: 1

Comment: The International Association of Machinists and Aerospace Workers requests you support our mission to extend the compliance timeframe for Boiler MACT regulations beyond the three years provided in existing rules. These regulations will certainly impact the lives and jobs of thousands of hardworking American citizens.

We urge you to implement a categorical one-year extension to comply with Boiler MACT Rules. The complexity and widespread nature of these rules will introduce a number of obstacles for American manufacturers competing in this global environment.

Given the urgency to meet the three-year deadline, thousands of manufacturing facilities will be vying for the same resources and skilled laborer, creating a scarcity of both. We are not equipped with the sufficient resources to meet these demands, and the shortage will lead to increased costs. Utility companies can pass these costs along to end users. Manufacturers in the forest products industry will be forced to absorb these costs. Unfortunately, we do not have the capital to absorb these costs and will be forced to immediately withdraw resources from this pending financial

disaster that will result in zero growth in manufacturing and immediate job loss within our communities.

We recognize the need to continue to improve the status of our environment, and we are committed to that end. Without responsible actions by our government we will not be able to compete with global competition. Once again, we urge you to implement a categorical one-year extension to comply with Boiler MACT Rules.

I thank you for your consideration of this request, and I look forward to your support.

Comment: In light of the difficulty in meeting a three year compliance deadline as explained above, EPA and authorized states should be prepared to readily grant one-year extensions under CAA § 112(i)(3)(B) to those units that have problems installing the necessary control equipment to comply with the final rule. EPA should also make clear in this rule, as it did in the MATS rule³⁷, that the 1-year extension also applies to repowering projects as they are applicable to ICI boilers and process heaters:

"The EPA took comment on whether the construction of on-site replacement power could be considered the "installation of controls" such that a fourth year would be available while the replacement unit is being completed for a unit that is retiring (e.g., a case when a coal-fueled unit is being shut down and the capacity is being replaced on-site by another cleaner unit such as a combined cycle or simple cycle gas turbine). After reviewing the comments, EPA believes that it is reasonable for permit authorities to allow the fourth year extension to apply to the installation of replacement power at the site of the facility. The EPA believes that building replacement power constitutes the "installation of controls" at a facility to meet the regulatory requirements."

[Footnote 37: 77 Federal Register 9410, February 16, 2012]

Response: See the response to comment EPA-HQ-OAR-2002-0058-3818-A2, excerpt 1. We agree that the 1-year extension applies to repowering projects and will include similar language as in the MATS rule.

Comment Excerpt Number: 13

Comment: In many instances, the installation of pollution control equipment and associated charges to boiler must be permitted under state air pollution statutes and/or construction codes (building permits, etc.). The proposed rule will result in an increase in the number of permit applications, potentially swamping the state and local agencies. Even in those areas where the rule may not result in significant increases in permitting work, the normal delays associated with permitting may make meeting the three year compliance deadline impossible.

In light of the difficulty in meeting a three year compliance deadline, the EPA and authorized states should be prepared to readily grant one-year extensions under CAA § 112(i)(3)(B) to those units that have problems installing the necessary control equipment to comply with the industrial Boiler MACT rule.

Commenter Name: J. Michael Geers

Commenter Affiliation: Duke Energy

Document Control Number: EPA-HQ-OAR-2002-0058-3543-A1

Comment Excerpt Number: 1

Comment: Compliance Time - On May 18, 2011, EPA announced the reconsideration of the rule and issued a stay of the effective date of the March 21, 2011 final IB MACT rule. When EPA did so, Duke Energy understood that EPA was signaling that it was likely to significantly change the requirements of the rule upon reconsideration. The resulting uncertainty inhibited Duke Energy's ability to make appropriate selections of control technologies and make other compliance decisions. In the current rulemaking, EPA is proposing to not only change the requirements, but also to revise the compliance date for existing sources to three years after the date of publication of the final reconsideration rule in the Federal Register (FR). For new sources, the EPA has also proposed a compliance date 60 days after the date of publication of the final reconsideration rule in the FR, or upon startup, whichever is later. EPA's rationale is that these dates are appropriate so as to give affected facilities sufficient time to make compliance-related decisions and install controls. Duke Energy agrees with EPA and strongly supports this proposed approach, but urges EPA in the final rule to grant owners of all affected sources that are installing controls a one year extension of the three year compliance deadline.

In the preamble, EPA stated that Section 112 allowed for up to 3 years after promulgation for compliance along with an additional year for installation of controls that must be approved on a case-by-case basis by the permitting authority. EPA stated that it believed this provided enough time for boilers to achieve compliance. EPA also stated that maintaining the compliance dates

from the March 2011 final rule would essentially provide less than 2 years for sources to meet the final standards, whose stringency could not be determined until the reconsideration is final. For those reasons EPA proposed revising the compliance date for existing sources to three years after the date of publication of the final reconsideration rule. As a legal matter, Duke Energy asserts that EPA really has no alternative but to revise the compliance dates. However even with the compliance date reset to 3 years after the publication of the final reconsidered rule, Duke Energy continues to believe that this is inadequate time for some facilities to undertake the retrofits necessary to meet the new MACT standards.

In its comments on the initial proposed rule, Duke Energy asserted that it anticipated that industry will face severe constraints on permitting, construction time and material that will make it extremely difficult, if not impossible, for many facilities to meet the retrofit deadline of three years. Most of the targeted solid fuel-fired units are located at facilities that will have to undergo substantial re-engineering, e.g., due to space constraints, to accommodate new controls. Design, permitting, procurement, installation, and shakedown of many projects will easily consume three years. In short, more time is needed for some facilities. Moreover it is inevitable that many existing boilers will be forced to convert to an alternative fuel such as natural gas, or even construct entirely new boilers. EPA has not adequately considered these factors in either its initial final IB MACT rule or in its December 23, 2011 proposal.

Commenter Name: J. Michael Geers

Commenter Affiliation: Duke Energy

Document Control Number: EPA-HQ-OAR-2002-0058-3543-A1

Comment Excerpt Number: 2

Comment: Duke Energy urges EPA in the final rule to grant owners of all affected sources that are installing controls a one year extension of the three year compliance deadline. External factors will also jeopardize compliance within three years. A large number of companies will be competing nationwide for limited resources and materials from engineering consultants, equipment vendors, construction contractors, financial institutions, and other critical suppliers. It is likely many companies will find themselves unable to procure the necessary goods and services to complete the retrofitting of their affected units within three years. In particular, Duke Energy is concerned about sources being able to procure bag houses and scrubbers because immediate industry demand will outstrip immediately available supplies. Industry must continue to operate as best as possible while retrofitting to meet the new MACT standards. In general, the existing solid fuel-fired boilers that will be subject to this new rule comprise the most critical part of the base load energy supply for their facilities. These units typically have high capacity utilization rates. Extensive outages for retrofitting must be carefully planned. Only when all of the critical prerequisites for the retrofit have been lined up, e.g., the engineering is complete and the control equipment is staged for immediate installation, can an owner afford to shut down a facility's base load boiler to install the new controls. This will take careful planning and coordination both within the company and outside the company that will involve with engineering consultants, equipment vendors, and construction contractors. Duke Energy does not believe three years is sufficient to allow owners of many of the affected sources the time necessary to make the retrofits without substantial disruption to the operation of their facilities.

Document Control Number: EPA-HQ-OAR-2002-0058-3685-A2

Comment Excerpt Number: 9

Comment: EPA Should Reset the Compliance Date to Provide Existing Sources with the Maximum Compliance Time Allowed by Law

EPA proposed resetting the Boiler MACT compliance date for existing sources to the date three years after publication of the reconsidered final rule. AMP supports resetting the compliance date, and encourages EPA to use the discretion granted under CAA § 112(i)(3) to grant a categorical 1-year extension to all sources installing control equipment to comply with the standards. The uncertainty generated by the complicated history of this regulation has made it impossible for sources to begin compliance planning prior to issuance of the final reconsidered rule. Even now, sources are uncertain of the final emissions limits, what controls may be necessary to achieve these limits, and whether they will be regulated by the Boiler MACT rule or the CISWI rule. The Boiler MACT rule will establish limits for multiple pollutants that require multiple controls and facilities cannot analyze the trade-offs posed by various control options until the final emission limits are published.¹⁶ Sources must also be cognizant of other regulations imposing emission limits for different pollutants when adopting a Boiler MACT control strategy. For example, a facility cannot implement a CO reduction strategy that will result in a NO_x increase if the facility is located in a non-attainment area or is otherwise subject to stringent NO_x emission limits. Some control options may affect pollutants subject to a National Ambient Air Quality Standard and changes in the concentration, temperature, velocity and height of the exhaust gas may adversely impact air dispersion modeling results triggering new concerns and complications. These complexities will require extensive and detailed planning that cannot take place until EPA finalizes the Boiler MACT emission standards.

[Footnote¹⁶: For example, presence of SO₃ can have a significant negative impact on the Hg removal that is achieved by activated carbon injection, and use of catalysts for NO_x and CO control can oxidize SO₂ in flue gas to SO₃. However, presence of SO₃ in flue gas tends to improve PM collection efficiency of ESPs by lowering ash resistivity and also may improve dioxin capture.]

Commenter Affiliation: Boise Inc.

Document Control Number: EPA-HQ-OAR-2002-0058-3686-A2

Comment Excerpt Number: 11

Comment: Critical path timeline risks are significant for these projects and may include, but are not limited to, delays caused by:

- Permit authority staff availability;
- Design engineering resource availability;
- Control equipment and fabricators supply equipment and/or manpower availability; and
- Delays in Title V and PSD permit review and approval at the state or regional EPA.

As can be seen from the schedule above, the full 36 months from promulgation of final regulations will be necessary for many facilities and will likely be insufficient for some facilities. With 36 months from final rule promulgation, scheduling will be tight and subject to risk. Failure to provide meaningful alternatives for facilities that will need additional time puts them at risk of not meeting the compliance deadline. For this reason, EPA needs to provide additional alternatives that can be used by sources to obtain more time to complete their projects. At a minimum, EPA should make clear that it will approve and authorize the use of the 12-month extension provisions in 40 CFR 63.6(i) to grant additional time for installation of control equipment and such other requirements that are necessary to achieve compliance with the standard.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3818-A2, excerpt 1.

Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 12

Comment: Sections 63.6(i)(4) through (16) of the part 63 General Provisions deal with the process for obtaining up to an additional year for compliance. This is a very cumbersome process, particularly since, as discussed above, many BPH and other combustion sources will be making these applications at the same time. To make this cumbersome process more feasible in the case-by-case scenario, EPA should specify in the BPH rule that multiple BPH can be addressed in a single application, that the request can be submitted as soon after the effective date of this rule as the source has adequate information to know it needs the extension, and that overall engineering and construction workload and BPH outage impacts may be a basis for the request in addition to equipment availability and delivery issues. In addition, the rule should be revised to include an automatic approval of an extension request if EPA fails to respond within 90 days of submission of the request.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3818-A2, excerpt 1. Section 112(i)(3)(A) states that EPA shall require existing sources to comply with emissions standards as expeditiously as practicable, but "...in no event later than 3 years after the effective date of such standards. The effective date of this final rule is the date of publication and the compliance date in the final rule is 3 years from the date of publication. Section 112(i)(3)(B) does allow the Administrator or State permitting authority to issue a permit that grants up to 1 year extension if necessary for the installation of controls. There is nothing in section 112(i)(3)(B) to indicate that a source can not address multiple affected units in a single application. The commenter's request for automatic approval of extension requests upon EPA failure to respond within 90 days is out-of-scope with this reconsideration rulemaking.

Commenter Affiliation: American Forest & Paper Association (AF&PA) et al.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 31

Comment: The DC Circuit decision in the PCWP MACT case, *NRDC v. EPA*, 489 F.3d 1364 (D.C. Cir. 2007), does not take away EPA's authority to grant categorical 1-year compliance extensions. That case involved EPA's MACT standard for plywood and composite wood products (PCWP) manufacturing. EPA promulgated the rule in 2004 and amendments to the rule in 2006. The 2006 amendments did not change the emissions standards established in the 2004 rule. The 2006 rule only revised certain compliance assurance provisions. According to the court, "In the 2006 Rule, EPA extended by one year the compliance date for the emission standards established in the 2004 Rule in light of what it characterized as "substantial" changes made in the 2006 Rule." *Id.* at 1373. The court overturned the extension on the grounds that the 2006 amendments did not involve changes to the 2004 emissions standards and, therefore, the compliance deadline could not be extended because Congress "set an outer limit of three years after *emissions standards* took effect." *Id.* at 1374 (emphasis added).

The court expressly noted that EPA "did not rely" on § 112(i)(3)(B) (the 1-year compliance extension provision) in granting the extra year. *Id.* Thus, the meaning of § 112(i)(3)(B) was not

at issue in the case. But, the court did observe that "Congress enumerated specific exceptions to the three-year maximum, which indicates that Congress has spoken on the question and has not provided EPA with authority under subsection 112(i)(3)(B) to extend the compliance date in the 2006 rule." *Id.* Even if this dicta were assumed to have some legal force, that effect clearly would be limited to the given circumstances – *i.e.*, where EPA granted a compliance extension to accommodate new compliance assurance provisions and not because it made a finding that additional time was needed "for the installation of controls."

In the case of the Boiler MACT, EPA is proposing changes to several emissions standards, changes to the number and type of subcategories, and (in related proceedings) changes to the criteria that will be used in the first instance to determine whether a unit is covered by the Boiler MACT or the CISWI rule. All of these proposed changes will affect the level of the standards and the manner in which these standards will be applied to affected sources. This means that EPA's proposal to reset the compliance deadline for existing sources is justified by the facts and wholly consistent with the holding in *NRDC v. EPA*.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3818-A2, excerpt 1.

Commenter Name: J. Michael Geers

Commenter Affiliation: Duke Energy

Document Control Number: EPA-HQ-OAR-2002-0058-3543-A1

Comment Excerpt Number: 3

Comment: Duke Energy recommends EPA address the foregoing problems by clearly extending the compliance deadline to four years after the publication of the final regulations in the Federal Register for units that need the additional time to install controls. EPA must clearly articulate the conditions under which a source is eligible for this extension at the time that the rule is finalized. If it is uncertain whether a source can qualify for an extension or it must go through an uncertain regulatory approval process, there is no way that source can effectively count on that extension into its planning process and risk possible non-compliance. Duke Energy made similar arguments in the Utility MACT rulemaking only to see EPA fail to provide the needed certainty. Subsequently the company has met with at least one state agency that advised the company that it could not provide a final answer for at least a year on whether a facility contemplating an extensive emissions controls retrofit would qualify for a fourth extension year. This has put the company in the unacceptable position that if it begins a control retrofit project that will require more than three years to implement, it will not know until a year into the project whether an extension will be granted. Duke Energy believes the Agency is fully justified in invoking § 112(i)(3)(B) of the Clean Air Act to grant owners of all affected sources that are installing controls a one year extension of the compliance deadline. Four years would provide critically needed time for industry to conduct the necessary control retrofits. Given the magnitude of the retrofit requirements and the likelihood of substantial difficulties fulfilling these requirements, it is essential that EPA provide a clear, specific answer at the time the rule is finalized on what qualifies for a fourth year, rather than just articulate an uncertain process.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 32

Comment: Additional air pollution controls will need to be installed on thousands of industrial boilers and utility boilers over the next few years. Engineering firms and air pollution control suppliers simply do not have the capacity to satisfy all of the demand within the next three years. Thus, as in the marine vessel tank loading standard, EPA can and should issue a categorical one-year extension of the compliance deadline for existing industrial boilers.

If a categorical exemption is not issued, then EPA should provide guidance to permitting authorities on situations where a 1-year extension should be granted upon request. EPA should make clear in this rule, as it did in the MATS rule, that the 1-year extension not only applies to installation of pollution control measures but also applies to repowering projects:

"The EPA took comment on whether the construction of on-site replacement power could be considered the "installation of controls" such that a fourth year would be available while the replacement unit is being completed for a unit that is retiring (e.g., a case when a coal-fueled unit is being shut down and the capacity is being replaced on-site by another cleaner unit such as a combined cycle or simple cycle gas turbine). After reviewing the comments, EPA believes that it is reasonable for permit authorities to allow the fourth year extension to apply to the installation of replacement power at the site of the facility. The EPA believes that building replacement power constitutes the "installation of controls" at a facility to meet the regulatory requirements." (see 77 Fed. Reg. 9410)

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 34

Comment: Industry is committed to complying with all applicable air regulations. However, many industry sectors have evaluated and concluded that a 3-year compliance window will not allow facilities to meet the emission standards for the boiler rules in the required timeframe. The demand for resources will be such that even the most proactive site will not be guaranteed it can develop an emissions reduction strategy, secure funding, engage qualified consulting firms and vendors, install equipment, and complete testing and tuning in a 3-year period in a manner that can ensure compliance. While a one year extension could provide additional time for some sources, one year is not enough in this case due to the high number of sources that will need to make modifications at their existing facilities. Accordingly, the compliance deadline for the upcoming boiler rules should be extended to five years to ensure affected facilities will be able to achieve the required emissions reductions prior to the compliance dates of the rules.

If faced with an impossible compliance deadline, many affected sources in the industries affected by these rules would have no choice but to curtail the operation of affected combustion units,

which could compromise the productivity of affected facilities or even cause them to shut down. The resulting impact on the Nation's basic manufacturing capacity and the corresponding impacts on the economy as a whole – particularly in this time of protracted economic malaise – would be severe.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 33

Comment: Because at least 5 years of compliance time will be needed under the Boiler MACT, EPA and the President should take the additional step of extending the compliance deadline by at least one additional year using a Presidential exemption. Under CAA § 112(i)(4), the President is authorized to exempt affected sources for a period of up to two years (which may be renewed an indefinite number of times) upon a finding that: (1) it is in the national security interest to do so; and (2) the technology to implement the standard is not available. There should be little doubt that protecting the viability of affected industries is in the national security interest. Moreover, for all of the reasons described above, a solid case can be made that the needed air pollution controls will not be available. Therefore, a Presidential exemption is justified and should be issued. We note that the time and effort required to issue such an exemption should not be materially greater than the time and effort needed to produce the Presidential memorandum that was issued at the time the MATS rule was signed. So, EPA and the administration have demonstrated that issuing such an exemption is practicable and can be done in a timely manner.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3818-A2, excerpt 1. Further, the existing source compliance date in MATS is three years from the effective date of that rule. Moreover, any Presidential exemption pursuant to section 112(i)(4) must be issued by the President – not by EPA -- based on his determination that the technology to implement a standard is not available and that it is in the national security interests of the United States to grant an exemption from compliance. Further, while the commenter asserts that “protecting the viability” of industries subject to the boiler MACT is in the interest of national security, it provides no explanation to support this assertion.

Document Control Number: EPA-HQ-OAR-2002-0058-3686-A2

Comment Excerpt Number: 12

Comment: More appropriate in our view, EPA should adopt a significantly longer compliance deadline. Nominally, EPA should adopt by rule an across-the-board one-year extension pursuant to § 112(i)(3)(B). However, even a four-year compliance period will be inadequate for many affected sources. Therefore, EPA should provide additional time by: (1) granting in the final rule a Presidential extension under § 112(i)(4), given that it is in the "national security interests of the United States" to prevent widespread noncompliance in the industrial base; (2) declaring that the statutory three-year compliance period is impossible to meet or otherwise produces "absurd

results," which as demonstrated in EPA's recent PSD Tailoring Rule are doctrines that allow EPA to depart from clear statutory directives in appropriate circumstances; and/or (3) establishing phased or sequenced requirements such that certain element of the rule become effective no later than three years after promulgation (thus satisfying § 112(i)(3)(A)), while others are phased in at later times.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3818-A2, excerpt 1 regarding extending the compliance date past 3 years from publication of final rule for existing sources. See the response to comment EPA-HQ-OAR-2002-0058-3521-A1, excerpt 33 regarding issuing a Presidential extension.

Commenter Name: Alicia Meads

Comment Excerpt Number: 14

Comment: In addition, the EPA should establish an extended two-step compliance period for situations where a boiler owner voluntarily elects to replace or retrofit a boiler to burn a cleaner fuel source.⁶ If a facility decides to switch to a cleaner fuel, the replacement or retrofit work required to make that switch will potentially take years, for all of the reasons discussed above. Rather than require the facility to add emissions controls to its existing boiler in time for the proposed three year compliance deadline – likely eliminating the possibility that the facility would switch to a cleaner fuel source – the EPA should allow five years total for facilities to change their boilers and meet the MACT requirements for the cleaner fuel source. This five year period would occur in two steps; a no-backsliding provision would apply for two years from publication of the rule in the Federal Register, and then the facility would have three years to comply with MACT standard for the subcategory for the cleaner fuel subcategory. The EPA promulgated exactly this type of extended MACT compliance deadline for certain facilities that voluntarily elected to install new technology as part of the Pulp and Paper Cluster Rule. *See* Pulp and Paper Cluster Rule, 60 Fed. Reg. 18503, 18,508 (Apr. 15, 1998).⁷ In addition to providing an incentive for facilities to switch to cleaner fuel sources, this approach would reduce some of the competition for resources discussed above by extending the deadline to complete the work to replace or retrofit certain boilers.

[Footnote 6: EPA recognizes the MACT rule should be crafted to encourage the use of cleaner fuels, such as natural gas. 75 Fed. Reg. 32025.]

[Footnote 7: This two-step approach for the MACT standard is consistent with the D.C. Circuit's decision in *NRDCv. EPA*, 89 F.3d 1364 (D.C. Cir. 2007) (finding invalid EPA's decision to extend the compliance deadline for a promulgated MACT rule by a year because of the substantial changes that the agency made to the rule). Rather than functioning as an extension of the compliance deadline, this MACT standard for certain facilities would become applicable in two steps. For the first three years, a no-backsliding MACT standard would be applicable, then the three year deadline to implement the MACT standard for the applicable "cleaner" source would begin to run.]

Response: See the response to comment EPA-HQ-OAR-2002-0058-3818-A2, excerpt 1 regarding extending the compliance date past 3 years from publication of final rule for existing sources. See the response to comment EPA-HQ-OAR-2002-0058-3521-A1, excerpt 33 regarding issuing a Presidential extension.

Comment Excerpt Number: 18

Comment: Replacement of the NNS Floating Test Steam Facility (FTSF) marine boilers is not cost-effective and cannot be accomplished by the Boiler MACT compliance date. NNS has also evaluated the possibility of scrapping its existing oil-fired FTSF marine boilers and replacing them with an entirely new, natural gas or propane-fired system, since no numeric emission limits would apply to gas-fired units pursuant to the Boiler MACT. Replacement with a distillate oil-fired system is not a viable option, because the emission limitations for the “Units designed to burn liquid fuel” subcategory, identified earlier, would still apply, and new, distillate oil-fired boilers would not be able to meet all of the applicable emission limitations without add-on controls. NNS has already determined that it is not feasible to install the add-on emission control equipment on a floating, portable steam generating facility that would be required by firing oil. The time and cost to construct a new test steam facility can be accurately estimated due to actual, relevant NNS experience. The Navy’s aircraft carrier delivery and overhaul schedules are established many years in advance and, for example, revealed several years ago that concurrent steaming of two aircraft carriers would be required in 2008. NNS is required by the Navy to adhere to the Navy’s carrier overhaul schedule and plan accordingly. As a result in 2002, six years before the schedule steaming date, NNS completed a study to determine the recommended approach for providing the needed additional test steam capacity in 2008. The Navy subsequently authorized and funded a plan to construct a second, temporary, land-based “test steam” facility that would be dedicated to the steaming of one specific aircraft carrier at one aircraft location at NNS beginning in 2008, while the existing NNS-owned FTSF would concurrently provide test steam to another aircraft carrier at a second shipyard location, as originally scheduled. A new, distillate-oil fired, temporary, land-based test steam facility was designed and constructed over a five-year period, was utilized for steaming the assigned aircraft carrier as scheduled beginning in 2008, and was then dismantled in 2010 in accordance with Navy contract directions. The temporary test steam facility consisted of two distillate oil-fired watertube boilers, each rated at 245.3 million BTU per hour, which compares very closely with the size of NNS’ existing FTSF boilers, which are rated at 213.26 million BTU per hour. Due to the unique and highly specialized nature of propulsion system test steam boilers, the construction cost of this temporary test steam facility was over \$25 million, and would have been higher if the facility had been constructed as a permanent system inside a permanent building, as would a conventional industrial boiler system. This high actual cost of a replacement test steam facility is further evidence that aircraft carrier test steam boilers systems are fundamentally different than industrial boiler systems and should not be regulated as industrial boilers under the Boiler MACT. Based on the actual cost of this temporary test steam facility, NNS believes that, while technically feasible to replace the existing FTSF marine boiler system with a new, gas-fired, portable system mounted on a barge to meet the aforementioned portability requirements for

aircraft carrier steaming, the current-day cost is expected to be in the range of at least \$30-\$35 million, which again significantly exceeds EPA's Boiler MACT compliance cost estimates for industrial boilers of this size. Furthermore, because the required natural gas supply is currently not available at NNS, this cost does not include the cost of constructing a new, high pressure natural gas pipeline from a distant location in the City of Newport News, Virginia, to the NNS shipyard and then to several potential points of use along the waterfront. The estimated additional cost for extending the natural gas distribution system from the NNS property line to at least two distinct waterfront locations within the shipyard is estimated at between \$1.5 million and \$2.5 million. The overall time required to design the temporary, land-based test steam facility, construct the facility, make it operational and achieve acceptance from the Navy was 45 months. NNS believes that approximately the same amount of time would be required to construct a similar replacement system for the FTSF. Preceding the construction phase, at least nine months would be required to obtain funding from the Navy, bringing the total time required to about 54 months. This time does not include the time required prior to commencement of construction to prepare applications for and obtain permits under the New Source Review, Greenhouse Gas PSD and Part 70 Permit programs (currently estimated to require 12 months or longer). NNS notes that under Clean Air Act provisions and federal and state environmental rules NNS may not enter into any binding agreements or contractual obligations, which cannot be canceled or modified without substantial loss to NNS, prior to obtaining all required air permits and meeting all preconstruction requirements. Therefore, NNS does not believe that replacement of its FTSF marine boilers with new, gas-fired units can be accomplished by the Boiler MACT compliance date, currently March 21, 2014 (even if eventually delayed as a result of the pending proposed amendments to the Boiler MACT).

Response: We agree with the commenter that FTSF aircraft carrier test steam boiler systems are unique. In the final rule, the exemption for boilers or process heaters that are used specifically for research and development has been revised to include these types of boilers because these test boilers perform the same function as boilers exempted at research and development facilities. These test boilers do not provide heat or steam to a process. The boilers are used only to test the propulsion systems on nuclear powered aircraft carriers.

Document Control Number: EPA-HQ-OAR-2002-0058-3548-A2

Comment Excerpt Number: 20

Comment: The Presidential Exemption provided by section 112(i)(4) of the Clean Air Act, if obtained, would not provide a permanent exemption from the Boiler MACT, but rather would serve only to temporarily delay applicability of the Boiler MACT. The Presidential Exemption provided by section 112(i)(4) of the Clean Air Act does not provide sufficient relief to allow NNS to continue operation of the FTSF and provide carrier steamings on the schedule required by future RCOH events. This provision of the Clean Air Act provides for an exemption from compliance with a MACT regulation for an initial period of not more than two years. Thereafter by statute such an exemption may be extended for one or more additional periods, each period not to exceed two years. Even if an initial Presidential Exemption were sought by NNS at this time and obtained, NNS has no assurance that such an exemption would be extended one or more times by future administrations, and the failure to obtain any one extension in the future on

which NNS had relied would then immediately jeopardize NNS' ability to meet its obligations to the Navy and would significantly impact the readiness of the Navy's fleet. The Presidential Exemption process thus provides only a temporary delay mechanism and does not satisfactorily resolve the infeasibility of meeting the Boiler MACT requirements.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3548-A2, excerpt 18.

14Z. Out of Scope: Compliance

Comment Excerpt Number: 16

Comment: EPA should permit alternative, less burdensome means to demonstrate compliance for sources which use a control device to demonstrate compliance with the emission limits, sources for which the initial compliance test demonstrates compliance with the emission limits, or sources which burn clean fuels. For instance, EPA could allow a source, group of sources, or industry sector to make a demonstration that certain fuels are "clean," or inherently low-HAP, with emission rates less than the relevant emission limits. Using this approach EPA could allow facilities to do a composite sampling of an appropriate time frame based upon the complexity of the fuel mix/fuel feed to predict the upper-limit of potential contaminant levels for acid gases and metals based upon the potential combination of fuels and the representative operating conditions. Continuous compliance with the acid gas and metals emission standards would be demonstrated by fuel feed monitoring rather than requiring annual source testing (or monthly fuel analysis) for these sources that burn clean fuels with inherently low-HAP emissions. Under this approach EPA could require sources to certify the type of fuel they are burning to ensure that the same clean fuels tested in the composite sampling remain in use, guaranteeing that the emission standards are met. The facilities would be required to perform the composite sampling again if the fuel source changes. For any pollutants not covered by the fuel testing, the facilities would be required to conduct initial compliance testing with subsequent testing performed every two years as EPA has required in other MACT regulations.

Comment Excerpt Number: 5

Comment: If a CO emissions limitation is left in the final reconsidered rule, then averaging should be allowed for this pollutant as well. In particular, there may be instances where multiple units regulated by this rule vent to a combined stack and this may be the only acceptable location for measuring compliance. In this case, the only accurate measurable location would be the averaged emission rate.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Comment Excerpt Number: 2

Comment: As discussed in more detail elsewhere in these comments, for units that already have CO CEMS for reasons unrelated to the Industrial Boiler MACT, compliance with the Industrial Boiler MACT stack-test-based CO emissions limitations would be difficult to maintain. Stack tests are required to be run under representative operating conditions, typically defined as operating at or near full load consistently for the duration of the stack test. In sharp contrast, CEMS take emissions data on a near-continuous basis, which means CEMS emissions measurements reflect significant variability in emissions (for example, due to load swings and low load conditions) that was not measured during the stack tests used to set the CO standard. This problem is not overcome by statistical manipulation of the CO standard, such as accounting for variability using the UPL method, because such statistical methods unrealistically extrapolate only from the variability measured during stack tests and the variability between stack tests. In other words, this is a classic "apples and oranges" situation where emissions data from CO CEMS are incompatible with emissions data from stack tests used to set the CO standard.

One way for EPA to resolve this incompatibility is to determine that emissions data from CO CEMS are not credible evidence for purposes of assessing compliance with the Industrial Boiler MACT stack-test-based CO emissions limitations. As the Agency explained in the "credible evidence rule," data and information derived from methods other than the specified reference test method (so-called "non-reference test data") are relevant to showing compliance only to the degree that "the appropriate reference test would have shown a violation." 62 Fed. Reg. 8314, 8323 (Feb. 24, 1997). Because the Industrial Boiler MACT CO standards are based on stack test data, and because the stack tests on which the standards are based were required to be conducted during representative operating conditions (*i.e.*, consistently operating at or near full load), then by definition CO CEMS data taken during periods of operation that do not reflect "representative operating conditions" are not data that are relevant to showing compliance with the standards.

In other words, the stack test data on which the standards are based reflect operation during a narrow, limited, and optimum set of conditions. Thus, CO CEMS data that are taken during periods of operation that do not reflect those conditions are not relevant to determining whether an affected source is in compliance with the standard.

Comment Excerpt Number: 19

Comment: The NAM supports the EPA's proposal to allow a co-fired unit to opt out of the CISWI rule and into the Boiler MACT rule, or vice versa. This will provide a beneficial measure of flexibility to operators. However, the EPA should eliminate the arbitrary restriction in the proposal that would limit a facility from moving from being regulated under CISWI to being regulated under Boiler MACT for a six month period after it had stopped burning solid waste. As a policy matter, forcing operators to remain regulated under the one standard when there are reasons to switch would needlessly penalize them with little to no benefit gained.

Commenter Affiliation: American Forest & Paper Association (AF&PA) et al.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 20

Comment: The industrial boiler, solid waste incinerator, and utility boiler rules will require major equipment installations across a large number of existing facilities. The industrial Boiler MACT will require reductions of air emissions from almost 1600 major source boilers for at least one of the following four pollutants: particulate matter (PM), hydrogen chloride (HCl), mercury (Hg), and carbon monoxide (CO). The solid waste incinerator rule is expected to require emissions reductions from about 90 units classified as solid waste incinerators for one or more of the following nine pollutants: PM, lead, cadmium, HCl, CO, dioxin/furan, mercury, sulfur dioxide (SO₂), and nitrogen oxides (NO_x).³² The electric utility MACT (MATS rule) will require reductions of air emissions from the majority of the affected 1350 coal- and oil-fired utility boilers for at least one of the following pollutants: HCl, PM, and Hg for coal and pet coke, and HCl, hydrogen fluoride (HF) and Total HAP Metals for oil. These emissions reductions will be accomplished with installation of air pollution control equipment, fuel system changes, combustion air changes, or some combination of these measures, assuming facilities elect to continue operating these units and using current fuels. Because the limits for each pollutant in each rule were set individually, they do not represent the real world performance of any one boiler or incinerator, and it is likely that almost all units will have to make retrofits or install new controls for at least one if not multiple pollutants. Therefore, there are about 3000 units that

could require at least one new control device or retrofit to existing emissions control devices or fuel feed systems, or both.

[Footnote 32: Hundreds of additional units may be regulated as incinerators depending on the final definition of Non-Hazardous Secondary Materials.]

Commenter Name: Paul Noe

Commenter Affiliation: American Forest & Paper Association (AF&PA) et al.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 21

Comment: The compliance schedule is approximately the same for all of the boiler and incinerator rules. In addition, there are several other promulgated or pending rules that will add to the competition for quality consultants and vendors including implementation of NOX and SO2 NAAQS, Cross-State Air Pollution rule, other MACTs, and various Risk and Technology Review sector rules. Therefore, companies will be competing for consulting, stack testing, engineering, and fabrication resources at the same time. Increased demand will result in greater costs for these services. Never before has EPA simultaneously promulgated multiple rules that require such a large number of controls over such a short time period. Affected facilities cannot make decisions on what controls to implement prior to promulgation of the final rules.

Not only are the final numerical standards in each rule unknown, but in the case of facilities affected by the NHSM rule, such facilities cannot yet determine whether they are burning "fuel" (and thus subject to Boiler MACT) or "solid waste" (and thus subject to the Commercial and Industrial Solid Waste Incinerator (CISWI) rule). This problem is exacerbated in EPA's re-proposal due to the complexity of required analyses and the need to go through petition processes to receive final EPA determinations about whether a material is a waste or a fuel. These factors will aid in determining what emissions reductions options will work best, and the best control strategy for a particular unit will depend on many factors: configuration of the unit, amount of reduction required of each pollutant, fuel(s) fired, availability of alternate fuels, available space, unit operating characteristics, and other constraints.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Commenter Name: Paul Noe

Commenter Affiliation: American Forest & Paper Association (AF&PA) et al.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 25

Comment: Following project approval, a facility must engage a firm to perform detailed engineering. Air permits also have to be obtained in order to authorize the modifications that will be made. State permitting agencies are already overloaded, and the boiler rules will only cause an increase in their workload and permit issuance times. When the detailed engineering is

complete, a bid package must be prepared in order to solicit proposals from firms that will be engaged to actually fabricate the equipment required. The fabrication and delivery of equipment is typically the step in a capital project that takes the longest, with some specialized equipment (e.g., rotating equipment) requiring very long lead times. With potentially 3000 capital projects that will need equipment, it is anticipated that delivery times will increase dramatically, with larger (and potentially more profitable) utility projects likely taking precedence with equipment suppliers. Equipment and installation costs also will rise due to increased demand, thus further straining resources.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Commenter Name: Paul Noe

Commenter Affiliation: American Forest & Paper Association (AF&PA) et al.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 26

Comment: Once equipment is fabricated and delivered, there is another set of steps for installation and testing. Facilities will have to schedule shutdowns for equipment to be installed, or preferably wait until normally scheduled shutdowns occur. For companies with multiple facilities, shutdowns will need to be staggered over the course of a year or more so production doesn't drop off (creating additional pressures for economic sectors that are supported by the facilities we represent) and customer demands can be met. The timing of the actual retrofit work must be carefully planned far in advance, particularly for boilers that provide the primary energy supply for a facility. In many cases, this timing must coincide with periods of reduced steam demand, thus severely limiting the ability to install equipment and in some cases requiring phasing over two or more years. Once equipment is installed, it must be tested and tuned to ensure emission limits will be met over all operating conditions. For units burning multiple fuels, the testing will be more involved to make sure emission limits are met for multiple fuel firing configurations. Different boiler operating scenarios might require different control equipment operating scenarios (e.g., different sorbent injection rates). In addition, since industrial boiler owners have not previously had to control CO emissions, additional testing and tuning will be required to ensure the efficacy of these control strategies. Scheduling and conducting these complex emission tests over extended time periods will also be very difficult. Many of the emission limits are lower than these types of combustion units and emissions controls have ever been required to achieve, with actual emission rates near test method detection limits. Therefore, the configuration of the control equipment will take time, and facilities will need to evaluate the equipment well before the compliance date in case adjustments need to be made.

Commenter Name: Paul Noe

Commenter Affiliation: American Forest & Paper Association (AF&PA) et al.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 76

Comment: We agree that incorporating emissions averaging into the Boiler MACT is a proper way to encourage flexibility and cost savings for affected facilities. There is ample precedent in the MACT program for allowing emissions averaging. Emissions averaging is a well demonstrated technique for meeting or exceeding environmental objectives at lower cost and with greater flexibility tailored to individual affected facilities. Provisions such as these allow plants to optimize their investments by installing controls on units where the lowest emission rates can be achieved in the most cost-effective manner possible. For example, a source could decide to over-control a newer unit (with either add-on controls or use of a lower-polluting fuel) in order to avoid costly investments in an older unit that may be retired before the useful life of the control device is reached. More flexible emissions averaging provisions would encourage additional use of lower- polluting fuels. Emissions averaging provisions also provide environmental benefit by allowing for control options that minimize energy use. Energy efficient decisions benefit the environment by reducing power demands and the secondary pollutant impacts they generate.

Comment: It is possible that a CO CEMS-equipped boiler may be required to conduct CO stack tests for reasons unrelated to the Boiler MACT (e.g., the unit may have a PSD permit or state construction permit that requires such testing). To prevent confusion, EPA should clearly specify in the final rule that, if an affected source chooses to comply with the CO CEMS-based standard, it is not subject to the stack test-based CO standard – even if it conducts CO stack tests for other purposes. Conversely, EPA should also clarify that even if a unit has CO CEMS installed, it may choose to comply with the stack test-based CO limit, and in this case, CO CEMS data are not to be used for compliance.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Commenter Affiliation: American Forest & Paper Association (AF&PA) et al.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 121

Comment: EPA has proposed a mechanism for units to move between the boiler and CISWI rules, but sources must wait 6 months after cessation of solid waste burning to move back under Boiler MACT and must provide 30 days notice of intent to re-commence combustion of solid waste.⁵⁴ EPA arbitrarily chose 6 months. With the extensive monitoring and testing required under both rules and the fact that any facility's Title V permit will include extensive compliance assurance provisions, facilities will be able to adequately ensure compliance under either rule without being restricted on the frequency of fuel switching. Sources should be allowed to make

the switch between waste and fuel as often as operational concerns require as long as they keep adequate records. EPA has also not adequately addressed startup and shutdown emissions under the CISWI rules. As startup and shutdown have been addressed using a work practices approach that requires operators to follow established procedures and use good combustion practices, coverage of ERUs as boilers during these periods (as long as they are not firing waste) is appropriate.

The 6-month waiting period will also pose a problem for a boiler operator that inadvertently fires a small amount of solid waste. The facility will not be able to comply with the CISWI requirements for the 6-month period specified. The boiler would have to be shut down for a 6 month period, which is a disproportionate penalty. The probability of such a scenario is increased by the unclear criteria in the NHSM rule and the fact that operators may be challenged by third parties on their non-waste fuel determinations.

Commenter Name: Robert D. Bessette

Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 37

Comment: As another alternative compliance method for the stack test CO limits, EPA could establish a performance standard that would apply during the periods between stack tests. Such a standard could consist of a numeric value indicative of good combustion – such as oxygen or CO levels in the furnace or stack. Under this approach, EPA would also specify appropriate monitoring methods, such as oxygen meters or CO CEMS. But, if parametric monitoring indicated an exceedance of the performance standard, such an exceedance would not constitute a violation if appropriate corrective action were taken within a reasonable time after the exceedance was measured.

In concept, such an approach would be analogous to bag leak detection systems on baghouses, which EPA routinely requires in its standards. When a leaking bag is detected, EPA's rules typically do not define such an event as a violation. Instead, the affected source is required to replace the leaking bag and only might be found in violation if this corrective action is not taken within a specified period. So, there is clear precedent for applying this concept to the IB MACT stack test CO standards.

EPA would have ample justification to adopt this approach as a work practice under § 112(h). Among other things, EPA is authorized to adopt work practices under § 112(h) when "the application of measurement methodology to a class of sources is not practicable due to technological and economic limitations." That is clearly the case with the IB MACT stack-test-based CO emissions limitations. While it is true that certain relevant constituents such as oxygen

and CO can be measured, the "application" of such methods is not technologically practicable because the data that are collected cannot reasonably be used to show compliance with a stack test CO limit. As explained above, the data largely would be taken during periods when the affected source was not operating under the same conditions as existed during the stack tests used to set the standards (again, creating an irreconcilable "apples to oranges" problem). Available methods such as oxygen or CO monitoring are not economically practicable because the "apples to oranges" problem cannot be solved merely by spending more money refining the methods.

Thus, EPA has authority and justification to set performance standards for the periods between periodic stack tests.

Commenter Name: Robin Mills Ridgway

Commenter Affiliation: Purdue University

Document Control Number: EPA-HQ-OAR-2002-0058-3668-A2

Comment Excerpt Number: 10

Comment: As an alternate to replacing the CO numerical standard with a work practice standard, Purdue suggests that in addition to the two CO compliance options in the reproposal (CO CEMS or a CO stack test), EPA could endorse a petition process for unit-specific CO limits for units that cannot implement cost-effective modifications to comply.

EPA could allow for a petition to the permitting authority for determination of a unit-specific CO emission limit if it is determined that a boiler or process heater cannot attain the final rule CO emission limit without major unit redesign, oxidation catalyst addition with associated stack gas reheat and increased fuel usage, exceedance of an applicable NOx standard, or derating the unit. As EPA has monetized benefits for only PM2.5 and its precursors (NOx and SO2) it is apparent that requiring drastic reductions in CO emissions to the detriment of NOx emissions and unit efficiency is not the desired outcome.

The process of determining a unit-specific CO limit could include:

- performing a tune-up according to a standard industry protocol (e.g., ASME PTC 4-2008, Fired Steam Generators, which provides rules and instructions for conducting performance tests of fuel fired steam generators)
- inspection and maintenance of the boiler/process heater and its fuel supply system to ensure they are in good operating condition,
- testing for CO emissions over the range of operating conditions to determine a site-specific CO limit and appropriate operating parameter limits, and
- establishment of a protocol for ongoing unit operation to ensure good combustion practices.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Comment Excerpt Number: 50

Comment: More flexibility is needed for sources wanting to use more comprehensive fuel analysis to demonstrate compliance with emissions averaging.

Section 63.7522(f)(1) requires a source to determine the monthly emission rate from each unit participating in an emissions average. For those units using fuel analysis rather than performance testing, a source must use the applicable equation from §63.7530(c), which requires calculation of the 90th percentile confidence level based on a monthly composite sample made up of a minimum of three grab samples taken at 10-day intervals with each grab consisting of two pounds of coal taken from the coal belt in a 6 inch wide sample of the full cross-section.

While this requirement to use the 90th percentile may be appropriate if a source is using such a limited sampling program, it is entirely inappropriate and ultra-conservative for a source using a much more comprehensive sampling program. Eastman, for example, analyzes composite samples (taken at the supplier yard using ASTM automated sampling methods) of each shipment of coal from each of its suppliers. For one of Eastman's powerhouses, this program produced 264 composite samples in 2011. In a case like this, use of the monthly average concentrations should be allowed instead of the 90th percentile.

Eastman requests the final rule include the option for a source to request an alternative equation and sampling program to be approved in a site-specific emissions averaging plan. One way to accomplish providing this flexibility is to add the following provision in the definition of Er (emission rate) in equations 3a and 3b to §63.7522:

...Determine the emission rate for particulate matter, hydrogen chloride, or mercury by performance testing, according to Table 5 to this subpart, or by fuel analysis for hydrogen chloride or mercury using the applicable equation in §63.7530(c). Alternative equations and sampling and analytical plans for determining emission rate by fuel analysis may be proposed to

and approved by the applicable delegated authority as part of the implementation plan for emissions averaging required in to §63.7522(g).

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 62

Comment: Procedures are needed to assure single events do not cause longer term averages to be exceeded day after day.

Many of the proposed numerical emission limits are rolling averages over extended periods, typically 10 days. Because numerical limits are low, a single event will often cause the rolling average to exceed the limit for the entire 10-day averaging period. Thus, a single event can cause 10 deviations rather than 1 deviation. 22

[Footnote 22: If the event extends over more than one day the average could exceed the limit for more than 10 days.]

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 27

Comment: While a 3-year compliance time could be feasible if only a few boilers needed to implement emissions controls, because of the sheer number of sources that will be competing for resources and the time it will take to successfully complete these emissions reduction projects will mean that many affected facilities will need up to 5 years to implement their projects. Boiler MACT will require a stepwise compliance program given the multiple controls for multiple pollutants. For example, after preliminary testing, if a CO reduction strategy is developed that requires state permit revisions, but then further analysis reveals conflicts with PM, HCl, or mercury, this will require a different CO strategy to maximize reductions across the suite of pollutants. Finally, facilities will need up to six months prior to the compliance date to undertake testing, identify problems, make adjustments to equipment and/or operations, and even retest to verify improvements.

Comment Excerpt Number: 29

Comment: There is precedent for extended compliance schedules for MACT regulations. For example, the pulp and paper industry had staggered MACT compliance deadlines for pulping source under Subpart S, with "phase 2" compliance due 8 years after publication of the final rule. As part of this process, facilities were required to establish timelines for compliance as well as provide updates and submit reports for certain milestones in the rule, to demonstrate progress.

More recently, in the MATS rule for the power sector, EPA acknowledged that many existing sources likely will need more than 3 years of compliance time, but took only limited and ineffective steps to provide the needed relief. EPA explained in the preamble to the rule and in a companion Presidential memorandum that the 1-year case-by-case MACT extension provision should be made broadly available to affected sources – but neither the Agency nor the President exercised available CAA authority to provide such extensions. In addition, the enforcement office issued a memorandum explaining that, in certain highly prescribed circumstances, an additional one-year "extension" might be made available through the use of administrative enforcement orders.

109A. Remove Emission Averaging 10% Penalty [DENIED PETITIONER ISSUE]

Commenter Name: Peter Pagano
Commenter Affiliation: American Iron and Steel Institute (AISII)
Document Control Number: EPA-HQ-OAR-2002-0058-3490-A1
Comment Excerpt Number: 34

Comment: The rule should not include a 10% penalty for opting to use averaging.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: Kevin G. Desharnais, Attorney, Mayer Brown LLP
Commenter Affiliation: United States Sugar Corporation
Document Control Number: EPA-HQ-OAR-2002-0058-3496-A1
Comment Excerpt Number: 12

Comment: The Reconsideration Proposal fails to address US Sugar objections to the ten percent discount factor applied to facilities that utilize emissions averaging. USEPA's justification of the ten percent discount factor, set forth in the preamble to the Final Rule, is incongruous with the

provision's origin and purpose. U.S. Sugar requests that EPA reconsider and eliminate the ten percent discount factor.

In EPA's response to the comments, it explained that the "legal basis and rationale for emissions averaging were provided in the preamble to the final Hazardous Organic NESHAP (59 FR 19425, April 22, 1994)." See EPA's Responses to Public Comments on EPA's *National Emission Standards/or Hazardous Air Pollutants/or Major Source Industrial Commercial Institutional Boilers and Process Heaters*, p. 975. However, EPA itself discouraged reliance upon that rule when it stated in the HON preamble: "the HON emissions averaging system, and its provisions for interpollutant trading, should not be viewed as setting a precedent for future MACT standards." 59 Fed. Reg. at 19425.

EPA also provided the following explanation for its emissions averaging provision in the Final Rule:

Averaging across affected units in the same subcategory is permitted only if it can be demonstrated that the total quantity of any particular HAP that may be emitted by that portion of a contiguous major source that is subject to the NESHAP will not be greater under the averaging mechanism than it would be if each individual affected unit complied separately with the applicable standard.

See EPA's Responses to Public Comments on EPA's *National Emission Standards for Hazardous Air Pollutants for Major Source Industrial Commercial Institutional Boilers and Process Heaters*, p. 975. But nowhere has EPA provided support for the necessity of a discount factor to achieve this stated goal, let alone for the particular ten percent discount factor selected. Basic math can demonstrate whether over-compliance with the standards at one boiler, coupled with under-compliance at another boiler, results in equal emissions reductions to those achieved by obtaining minimum compliance at each boiler. No discount factor is necessary to ensure the emissions reduction is equal under either the emissions averaging or the individual boiler compliance approach. And if any discount factor were appropriate, there has been no showing that a ten percent factor is reasonable.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: Kevin G. Desharnais, Attorney, Mayer Brown LLP

Commenter Affiliation: United States Sugar Corporation

Document Control Number: EPA-HQ-OAR-2002-0058-3496-A1

Comment Excerpt Number: 13

Comment: Although relying upon the Hazardous Organic NESHAP (HON) rule to support its ten percent discount factor, EPA overlooks that the HON rule did not universally apply the factor. Rather, the rule contained an exception for emissions reductions obtained through pollution prevention measures. See 59 Fed. Reg. at 19431 ("Credits generated through use of a pollution prevention measure need not be discounted, because the EPA recognizes that encouraging pollution prevention will result in more overall emission reductions, possibly including multimedia reductions and lower overall releases into the environment"). EPA's boiler MACT rule contains no similar provision. The HON rule defined "pollution prevention measure"

broadly. In that rule, EPA explained that "[f]or the purposes of the rule, the EPA is referring to any pollution prevention activities described in the Agency's Pollution Prevention Strategy (56 FR 7849) that are applicable to this industry." *Id.*

The Pollution Prevention Strategy outlines a wide variety of pollution prevention measures, including "[i]ncreasing reliance on clean renewable energy sources or alternative, less polluting fuels." 56 FR 7849. Because bagasse is a by-product of the sugar processing industry, it is among the most renewable of energy sources. According to the terms of EPA's Pollution Prevention Strategy, its use should be encouraged.

Therefore, U.S. Sugar requests EPA reconsider its ten percent discount factor for facilities that choose to achieve compliance with the new rule by averaging their emissions. In reconsidering the ten percent discount factor, we renew our request that EPA solicit comments on whether the factor should be applied universally or whether, as required by the HON rule, the use of pollution prevention measures, including the use of renewable fuels, should be excepted from the provision.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: David A. Buff, Golder Associates Inc.
Commenter Affiliation: Florida Sugar Industry (FSI)
Document Control Number: EPA-HQ-OAR-2002-0058-3504-A1
Comment Excerpt Number: 59

Comment: FSI continues to object to the 10-percent emission "penalty" for using the emissions averaging provision. This penalty is unnecessary and overly restrictive. The emission averaging provision, without the 10-percent penalty, would achieve reductions in HAP emissions that are equivalent to the reductions afforded by the MACT limits as applied separately to each boiler.

Commenter Affiliation: Southern Company
Document Control Number: EPA-HQ-OAR-2002-0058-3520-A1
Comment Excerpt Number: 12

Comment: EPA should not discourage facility averaging by requiring a discount factor. The CAA provides EPA broad authority to regulate sources, instead of individual units. See Cong. Rec. S16927; see also 42 U.S.C. § 7412(d) (CAA § 112(d)). Tightening the standards by any percentage for sources that choose to average emissions makes an impossible compliance situation even worse. There is no legitimate reason for imposing a discount factor for sources seeking to average emissions of multiple units. In the final Utility MACT, EPA concluded that "emissions averaging represents an equivalent, more flexible, and less costly alternative to controlling certain emission points to MACT levels" and that averaging "would not lessen the stringency of the MACT floor limits and would provide flexibility in compliance, cost and energy savings to owners and operators."⁷ EPA therefore determined that the use of a discount factor was unwarranted. Given that both the Utility MACT and the IB MACT are being adopted under § 112, and given the similarity of the source categories, there is no obvious reason for fundamentally different approaches in the two rules. EPA should not require a discount factor for sources that choose to average emissions across multiple sources at a plant site.

Comment Excerpt Number: 79

Comment: Emissions averaging should be allowed and the 10 percent discount factor should be eliminated, particularly where a source is using CEMS or sorbent traps for all emissions units in an emissions averaging scheme for a particular pollutant. EPA provides the following rationale in the MATS preamble⁴² for not requiring a discount factor when sources use CEMS in their emissions averaging approach, and the same rationale applies under this rule:

"The rule allows EGUs that rely on CEMS for compliance demonstrations to be able to participate in emissions averaging and the emissions limits are not subject to a discount. The EPA believes that the data certainty provided by units that use CEMS would be ideal for emissions averaging and the flexibility and cost-effectiveness it offers. Given the homogeneity of fuels within the rules subcategories, along with other emissions averaging criteria, the Agency believes use of a discount factor to be unwarranted for this rule."

Commenter Name: Douglas A. McWilliams

Commenter Affiliation: American Municipal Power

Document Control Number: EPA-HQ-OAR-2002-0058-3685-A2

Comment Excerpt Number: 44

Comment: Emissions Averaging Should Not Be Subject To a Ten Percent Penalty

AMP supports EPA's continued inclusion of emissions averaging as a flexible compliance alternative for facilities with multiple units. Emissions averaging requires overall compliance with the MACT standards, and thus protects human health and the environment while also lowering costs and increasing flexibility for the regulated community. However, AMP does not support the continued inclusion of a ten percent penalty factor for sources choosing to demonstrate compliance through emissions averaging. This penalty erodes the very compliance flexibility that emissions averaging is designed to create. Despite multiple rounds of rulemaking, EPA still has not offered a rational explanation for why the penalty is necessary to uphold the stringency of the MACT floor.

EPA has included emissions averaging provisions in other rules without imposing a ten percent penalty. In the 2004 version of the Boiler MACT rule, EPA included emissions averaging provisions that were substantially similar to those in the Proposed Rule, but did not include a penalty for utilizing this compliance alternative.⁴⁵ Similarly, EPA is allowing units equipped with CEMS to participate in emissions averaging under the Utility MACT rule with no penalty.

EPA has never explained why such a penalty is necessary to ensure compliance with the MACT limits, and its failure to do so in light of the 2004 Boiler MACT rule, make the penalty provision in the Proposed Rule arbitrary and capricious. The Proposed Rule already contains safeguards to prevent the "backsliding" that may otherwise occur when emissions averaging is employed. Averaged sources must: (1) demonstrate that the emission rate achieved during the compliance test does not exceed the emission rate that was being achieved at a set time after publication of the final rule; (2) demonstrate that the control equipment used during the compliance test is no less effective than it was at the same set time, and; (3) develop and submit an emissions averaging implementation plan for approval. Furthermore, sources demonstrating compliance through emissions averaging must test annually regardless of test results, and must demonstrate compliance on a monthly basis. These requirements are already more stringent than the requirements for units that are not using emissions averaging, and they are sufficient to ensure compliance with the MACT limits.

[Footnote 45: *See, e.g.*, 69 Fed. Reg. at 55257.]

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

109B. Allow Emission Averaging Across Subcategories [DENIED PETITIONER ISSUE]

Commenter Name: Peter Pagano

Commenter Affiliation: American Iron and Steel Institute (AISI)

Document Control Number: EPA-HQ-OAR-2002-0058-3490-A1

Comment Excerpt Number: 33

Comment: Some affected units involve multiple boilers operating in different subcategories (*e.g.*, coal and biomass, coal and natural gas). These boilers are generally located in separate powerhouses and have separate stacks. The goal of emissions averaging is to allow facilities to over-control some emissions points while under-controlling others, thus achieving the required

reductions in the most cost-effective manner possible. This could be best achieved by EPA removing the restriction (or clarifying its intent) to permit averaging for all affected units, regardless of whether the boilers emit through separate or "common stacks." It also has corresponding environmental benefits, by creating an incentive to burn more natural gas or renewable fuels such as biomass as a strategy to average out emissions from coal-fired units. As EPA explained in the Boiler MACT, emissions averaging does not result in higher total HAP emissions than those permitted under the Rule, and therefore there is no additional risk to human health or the environment. The rule should allow for averaging across all units regardless of category or fuel type.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: Dirk J. Krouskop

Commenter Affiliation: MeadWestvaco Corporation (MWV)

Document Control Number: EPA-HQ-OAR-2002-0058-3493-A1

Comment Excerpt Number: 13

Comment: MWV is supportive of EPA's inclusion of emission's averaging and common stack provisions. Incorporating emissions averaging into the Boiler MACT is a proper way to encourage flexibility and cost savings for affected facilities. MWV does, however, believe that EPA has the discretion to broaden its view and should allow averaging across different subcategories within a given facility.

Commenter Name: Allison Watkins, Baker Botts

Commenter Affiliation: Class of '85 Regulatory Response Group

Document Control Number: EPA-HQ-OAR-2002-0058-3608-A1

Comment Excerpt Number: 9

Comment: The Class of '85 supports the use of emissions averaging as an important tool for compliance flexibility. Emissions averaging is an equivalent, more flexible, and less costly alternative to controlling emissions. The use of averaging does not reduce the stringency of the maximum achievable control technology (“MACT”) limits; it provides flexibility in compliance and promotes cost and energy savings. However, EPA’s prohibition on the use of emissions averaging for units in different subcategories and for units using CEMS or PM CPMS frustrates the purposes of an emissions averaging option. The Group urges EPA to eliminate these restrictions.

The Major Source Rule unnecessarily restricts the use of emissions averaging among units in different subcategories. Averaging across subcategories could be accomplished by requiring the units to develop an emissions averaging plan, similar to the plan required for NO_x emissions averaging under the Acid Rain Program at 40 C.F.R. § 76.11. The NO_x averaging provisions allow units meeting different NO_x standards to collectively average their emissions and demonstrate compliance either individually or collectively using Btu-weighted annual average emission rates. EPA could develop an approach based on a similar methodology, which would allow more affected facilities to take advantage of the regulatory flexibility provided by the emissions averaging option. For example, multiple regulated units in different subcategories may vent to a combined stack, where only the averaged emission rate could be readily measured. Without the option of emissions averaging, these facilities must shut down units to conduct stack tests for each unit in isolation. This expensive and inefficient procedure is exactly the type of result the emissions averaging option is designed to avoid.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Commenter Name: Timothy Serie

Commenter Affiliation: American Coatings Association (ACA)

Document Control Number: EPA-HQ-OAR-2002-0058-3502-A1

Comment Excerpt Number: 16

Comment: ACA generally supports the following proposed changes in the Boiler MACT rule: Incorporation of an emissions averaging provision into the emissions standard.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Commenter Name: Eric Guelker, Alliant Energy Corporate Services, Inc.

Commenter Affiliation: Interstate Power and Light Company (IPL) and Wisconsin Power and Light Company (WPL), Alliant Energy Corp.

Document Control Number: EPA-HQ-OAR-2002-0058-3492-A1

Comment Excerpt Number: 4

Comment: Alliant Energy supports emissions averaging as an important option for flexibility of compliance demonstration. EPA should expand the use of averaging to any impacted units under this rule at a given facility. Furthermore, there should not be any restrictions on the ability to average HAP emissions. Currently, it would not be allowed for units that apply continuous emissions monitoring systems (CEMS) or particulate monitoring (PM) continuous parametric monitoring systems (CPMS).

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Commenter Name: Allison Watkins, Baker Botts

Commenter Affiliation: Class of '85 Regulatory Response Group

Document Control Number: EPA-HQ-OAR-2002-0058-3608-A1

Comment Excerpt Number: 11

Comment: Similarly, the Proposal clarifies that emissions averaging may not include units using CEMS or PM CPMS. 14 This restriction penalizes sources with multiple regulated units that vent to a combined stack. In these circumstances, the only location to install a CEMS or PM CPMS is the common stack, which would foreclose emissions averaging for all connected units even if emissions averaging would otherwise be available for these units. This result runs counter to the purpose behind the emissions averaging option. Accordingly, the Group requests that EPA delete the restrictions on the emissions averaging provisions and allow units in different subcategories and units using CEMS or PM CPMS to be part of an emissions averaging plan.

[Footnote 14: The Group specifically requests that averaging be allowed for CO emissions, if EPA chooses to adopt limits for this pollutant.]

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Commenter Name: Steve Gossett

Commenter Affiliation: Eastman Chemical Company

Document Control Number: EPA-HQ-OAR-2002-0058-3669-A2

Comment Excerpt Number: 44

Comment: Averaging for PM across solid fuel subcategories should be allowed.

In the March 21, 2011, final rule, EPA allowed any solid fuel units at a given facility to use averaging to comply with the Hg, PM, and HCl standards. Now, in the reconsidered proposed rule, EPA has reverted to the case where solid fuel units in different subcategories with different PM emission standards are not allowed to use emissions averaging (*see* §63.7522(b)(3)).

Such restriction on the use of emissions averaging is arbitrary and will only serve to increase the cost of the final rule. While EPA claims the commenters gave no justification for allowing averaging across subcategories, that is not the case as is reflected in the excerpt below from Eastman's comments:

On page 32034 of the preamble, EPA states one of its limits on the scope of emissions averaging is to not allow averaging between sources that are not part of the same affected source. In this case, EPA has elected to define the affected source in §63.7490(a)(1) as all units within a subcategory. We see no reason for EPA to use this definition. Rather all units at a given facility subject to the subpart should be collectively considered the "affected source". This is how EPA has defined the term in other rules with which we are familiar (e.g. the HON in Subpart F, Polymer and Resins 4 in Subpart JJJ, the MON in Subpart FFFF). The HON in particular we understand is the model EPA is using to guide its policy. By defining the term affected source as all chemical manufacturing process units (CMPUs) at a facility, the HON allows emissions averaging across CMPUs and across emission unit types (vents, storage vessels, transfer racks, wastewater stream). There is no reason in the boiler and process heater MACT for EPA to restrict the emissions averaging alternative as it has proposed. To do so, will prevent some facilities from taking advantage of the opportunity to avoid otherwise cost-prohibitive compliance options by over-controlling some other emission unit in a more cost-effective combination.

Also, by not allowing averaging across the different fuel categories, EPA removes an incentive to burn more natural gas or renewable fuels such as biomass as a strategy to average out emissions from a coal-fired unit.

EPA states in its response that allowing averaging across mixed streams (i.e. subcategories) would be swaying from its precedent. Just the opposite is true: the HON, which is the emissions averaging precedent setting rule, allows emissions averaging across different types of emissions units from different chemical manufacturing process units. It does not allow averaging across different pollutants – which Eastman is not suggesting EPA allow in the Boiler MACT. The preamble to the HON Final Rule (Federal Register, April 22, 1994, starting on page 19425) provides EPA's rationale for the emissions averaging provisions. It states that the Agency has broad discretion to define "source." In the case of the HON, "source" is defined as all emission points relating to SO₂ production at a facility. It allows all emission points that have numerical emission standards to participate in an average. Process vents, storage vessels, transfer rack, and wastewater streams are all allowed in the emissions average and they all have differing emission standards. Only equipment leaks, which have no defined allowable emission level, are excluded. Accordingly, EPA has all the latitude it needs to allow emissions averaging across all units at a given facility that are subject to Subpart DDDDD, so long as they have an applicable numeric emission limit.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: Lorraine Gershman
Commenter Affiliation: American Chemistry Council (ACC)
Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1
Comment Excerpt Number: 140

Comment: AVERAGING FOR PM ACROSS SOLID FUEL SUBCATEGORIES SHOULD BE ALLOWED.

In response to comments received on the 2010 Proposed Boiler Rule that emissions averaging should be allowed across subcategories, EPA stated:

"While EPA did not make major adjustments to the emissions averaging provisions, the change to a solid fuel subcategory will enable all solid fuel-fired units at a facility to use the emissions averaging provision for Hg, PM, and HCl. Beyond this, EPA disagrees that it is appropriate to average across subcategories for affected sources with mixed streams (e.g. SOCFI) and the commenter does not provide sufficient justification for swaying from this precedent." (see Response to Comments Document (Document Control Number EPA-HQ-OAR-2002-0058-3137.1))

In the Final Boiler Rule, EPA allowed any solid fuel units at a given facility to use averaging to comply with the Hg, PM, and HCl standards. Now, in the Reconsidered Proposal, EPA has reverted to the case where solid fuel units in different subcategories with different PM emission standards are not allowed to use emissions averaging (*see* §63.7522(b)(3)).

Such restriction on the use of emissions averaging is arbitrary and will only serve to increase the cost of the final rule. While EPA claims the commenters gave no justification for allowing averaging across subcategories, that is not the case as is reflected in the excerpt below from comments submitted by the Eastman Chemical Company, an ACC member:

On page 32034 of the preamble, EPA states one of its limits on the scope of emissions averaging is to not allow averaging between sources that are not part of the same affected source. In this case, EPA has elected to define the affected source in §63.7490(a)(1) as all units within a subcategory. We see no reason for EPA to use this definition. Rather all units at a given facility subject to the subpart should be collectively considered the "affected source". This is how EPA has defined the term in other rules with which we are familiar (e.g. the HON in Subpart F, Polymer and Resins 4 in Subpart JJJ, the MON in Subpart FFFF). The HON in particular we understand is the model EPA is using to guide its policy. By defining the term affected source as all chemical manufacturing process units (CMPUs) at a facility, the HON allows emissions averaging across CMPUs and across emission unit types (vents, storage vessels, transfer racks, wastewater stream). There is no reason in the boiler and process heater MACT for EPA to restrict the emissions averaging alternative as it has proposed. To do so, will prevent some facilities from taking advantage of the opportunity to avoid otherwise cost-prohibitive compliance options by over-controlling some other emission unit in a more cost-effective combination.

Also, by not allowing averaging across the different fuel categories, EPA removes an incentive to burn more natural gas or renewable fuels such as biomass as a strategy to average out emissions from a coal-fired unit.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Comment: Additional flexibility should be incorporated into the proposed emissions averaging provisions in order to ensure facilities have options to reduce the cost of compliance. Boilers of any design firing any fuel (e.g., in any subcategory) should be included in the emissions averaging provisions and facilities should not be limited to use of emissions averaging only for boilers in the same subcategory. There is no justification for restricting emissions averaging only to boilers in a specific subcategory; facilities should be able to average emissions from stoker boilers with emissions from pulverized coal boilers and liquid boilers. This approach has been used in several other rules. For example, the Pulp and Paper Chemical Recovery Combustion MACT and the HON allow emissions averaging across different types of units. The equivalency by permit provisions under 40 CFR 63.94 allow sources to "trade" emissions from unregulated sources for emissions of regulated sources, so this is an additional reason not to restrict use of emissions averaging to boilers within the same subcategory.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Comment: Heretofore, the Agency has expressed its concern that it may lacks authority to allow averaging across subcategories or that such allowance would be inconsistent with its policy in providing emissions averaging options in other rules., However, as discussed in the preamble to the HON (Hazardous Organic NESHAP for the Synthetic Organic Chemicals Manufacturing Industry (SOCMI) (Federal Register, April 22, 1994, starting on page 19425)), the rule EPA cites as precedent for emissions averaging, EPA has itself acknowledged its wide discretion to define “source” broadly. Indeed, in the case of the HON, EPA defined the source category to include all emission points relating to SOCMI production at a facility – a range of emission points and technologies far more diverse than the differences between coal-fired and converted coal-to- gas boilers. The HON allows all emission points that have numerical emission standards to participate in an emissions average. Process vents, storage vessels, transfer rack, and wastewater streams are all allowed in the emissions average and they all have differing emission standards. Only equipment leaks, which have no defined allowable emission level, are excluded.

Comment: There is precedent in MACT standards for allowing averaging across different types of units of a single source. For example, the HON Rule allows process vents, storage vessels, transfer racks, and wastewater streams all to be included in an emission average across an affected source.⁴² EPA reasoned that averaging needed to be allowed across all emission points (except equipment leaks) to provide as much flexibility as possible while maintaining an enforceable emission limitation.⁴³ Similar mechanisms have been adopted in other MACT standards.⁴⁴ The same considerations apply here.

EPA should allow long-term averaging across all affected units regardless of fuel type.

Comment: If EPA is concerned that it cannot allow emissions averaging across subcategories because the subcategories have different emission standards, this concern is easily addressed. As in the HON, the compliance methodology can easily accommodate subcategories with different emission limits for a given pollutant. This is done by calculating debits and credits and assuring that credits (after discount) are equal to or greater than debits (*see* §63.150(e)). An example is provided below to demonstrate this concept:

A facility has one pulverized coal (PC) boiler with a rated capacity of 500 mmBtu/hr and a PM emission rate of 0.07 lb/mmBtu and one stoker boiler with a rated capacity of 250 mmBtu/hr and a PM emission rate of 0.07 lb/mmBtu. Both of these boilers exceed their respective PM emission standards of 0.044 lb/mmBtu and 0.028 lb/mmBtu. The stoker is older, smaller, and much more difficult to retrofit and use of a fabric filter poses a safety hazard (due to sparks). In order to conserve capital (which it can use for growth projects and assist with the nation's economic recovery), the facility would like to install a state-of-the art fabric filter (with a PM emission rate

of 0.01 lb/mmBtu) on the PC boiler and avoid a capital investment on the stoker. If the rule were to allow averaging, the credits and debits based on rated heat input capacities would be determined as follows (likewise, each month, the credits and debits are calculated based on actual heat inputs for that month for each unit in the average and a twelve month rolling sum of credits vs. debits is recorded):

Credits from PC Boiler = $0.9 * [500 \text{ mmBtu/hr} * (0.044 - 0.01 \text{ lb/mmBtu})] * 720 \text{ hours/month} = 11,016 \text{ lbs}$

Debits from Stoker Boiler = $[250 \text{ mmBtu/hr} * (0.07 - 0.028 \text{ lb/mmBtu})] * 720 \text{ hours/month} = 7,560 \text{ lbs}$

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Eastman is not suggesting units that have no numerical emission standard be included in an emissions average. A numerical emission standard is required in order to calculate credits and

debits as in the HON precedent. Therefore, a unit designed to burn gas 1 could not be included in an emission average unless (as we have commented elsewhere) it was in a subcategory with an applicable numerical emission limit as of the date of proposal. In that case, the unit's credits are determined by the difference in the emission profile proposed above (i.e. three times the detection limit of the applicable reference method) from the converted gas unit and the applicable emission rate limit defined for that unit as it existed on the date of proposal (multiplied times its heat input or steam load).

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: Regina Hopper

Commenter Affiliation: America's Natural Gas Alliance (ANGA)

Document Control Number: EPA-HQ-OAR-2002-0058-3444-A1

Comment Excerpt Number: 5

Comment: ANGA believes that this rule, like other rules promulgated by the Agency, should reflect the use of the best data and science that is available, and that the ongoing reconsideration presents an opportunity for EPA to do so. As part of its reconsideration, we request that the Agency look more closely at its analysis of both the capital costs and operating costs of fuel switching. For example, in its 2010 Cost Memorandum, the Agency claimed that its regulatory requirements for multiple post-combustion controls on coal-fired boilers would achieve roughly the same emissions reductions as switching to gas (2010 Cost Memo, Appendix A-7); however,

it never compared the \$4.5 billion capital cost for those controls³ to its capital cost figure of \$1.171 billion for the capital cost of fuel-switching to natural gas.

We also repeat our request that the Agency look more closely at that \$1.171 billion capital cost for fuel switching in the 2010 Cost Memo. We continue to believe that using cost data from one 1986 feasibility study that is actually based on converting oil, not coal fired boilers, is inappropriate for purposes of estimating costs in 2010-2011. Furthermore, our analysis suggests that the boiler conversions that were the subject of the 1986 feasibility study all involved conversions from oil-to-gas, not coal-to-gas, and that the Agency may have inadvertently included a separate cost estimate -- not actual costs -- for one of those three boilers as the fourth "conversion".

Finally, with respect to operating costs, ANGA requests that as part of its reconsideration process, EPA revisit the price of natural gas that it used in its analysis. **In** its cost analysis for the ICI Boiler MACT Rules the Agency used a gas price of \$11.66 per MMBtu; however, in the cost analysis in the Technical Support Document that the Agency published for its proposed utility EGU MACT -- which was signed two weeks after the ICI Boiler MACT Rules were finalized -- it used \$5.74 per MMBtu. ANGA suggests that the Agency look to more recent price data⁴, including its own contemporaneous data, to support a more robust cost analysis for the ICI Boiler MACT Rules.

Comment Excerpt Number: 9

Comment: Additionally, this combustion environment is counter to good energy efficiency; the additional combustion air that will be heated in the furnace will not produce additional steam but will waste fuel. The add-on NO_x controls will also increase energy consumption per unit of steam produced.

FMC requests EPA to consider retaining the existing CO limits for PC-coal units as specified in the final rule. The existing CO limits provide an opportunity *to* balance existing NO_x compliance obligations with the desired initiatives of the MACT Rule.

Commenter Affiliation: Maine Pulp & Paper Association (MPPA)
Document Control Number: EPA-HQ-OAR-2002-0058-3466-A1
Comment Excerpt Number: 7

Comment: The Boiler MACT CO limits would necessitate combinations of emission controls that would have adverse effects on each other, and even then are unachievable for certain biomass boilers at Maine mills.

For example, the conditions that affect the optimum emissions of CO may run contrary to minimizing emissions of NO_x. Although NO_x is not addressed in the Boiler MACT, for years the northeastern states, including Maine, have focused on the control and reduction of NO_x emissions to improve ozone. Minimizing CO emissions conflicts with the State's efforts to minimize NO_x.

Comment Excerpt Number: 11

Comment: Dominion owns and operates an 83 MW biomass facility (consisting of 3 wood-burning boilers) in Hurt, Virginia and is considering additional biomass power investments to enhance its portfolio of renewable and carbon-neutral generation. Such investments will require reasonable environmental regulations that can be met with currently available and economically feasible emissions control technology. As a matter of environmental policy, EPA should encourage the combustion of biomass as substitute fuel for more polluting fuels. The combustion of biomass will become increasingly important to utilities as renewable portfolio standards (RPS)

or targets are adopted by more states and are possibly applied to all states as a result of federal mandates. The combustion of biomass may also have an important role as an option for achieving existing or anticipated greenhouse gas emission (GHG) reduction goals or targets. Biomass power is a key strategy for many utility companies, including Dominion, in the southeastern U.S., since there are more limited renewable energy resources than in other parts of the country. In addition, biomass power utilizing waste wood is currently the lowest-cost commercially available renewable generation option that is also a base-load (dispatchable) generation resource.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Commenter Name: Lenny Dupuis

Document Control Number: EPA-HQ-OAR-2002-0058-3486-A1

Comment Excerpt Number: 13

Comment: Emissions of mercury (Hg), dioxin and hydrochloric acid (HCl) are present in very small amounts in wood. Biomass units are inconsequential sources of these HAPs. In addition, the biomass limits are unduly influenced by tests that could not detect some of the hazardous air pollutants to be regulated ("non-detects"). Given these issues and the important role biomass units can have in achieving GHG reduction and RPS targets, biomass units should be given special consideration in this rule.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Commenter Affiliation: MeadWestvaco Corporation (MWV)

Document Control Number: EPA-HQ-OAR-2002-0058-3493-A1

Comment Excerpt Number: 1

Comment: The rule represents a set of air regulatory requirements that impact virtually all manufacturing sectors at a time where the national economy is recovering from a severe economic slump. EPA estimates the cost of the rule to be \$ 5.4 billion, while industry estimates the cost to be \$14.3 billion. MWV believes that EPA has significantly underestimated the costs for retrofitting control systems on the suite of boilers that must be modified to meet these standards. For example, EPA assumes that fabric filters are sufficient to meet the mercury standards, while EPA's database indicates that several units equipped with fabric filters cannot meet these requirements. EPA also assumes that low NO_x burners can be installed on certain units to achieve the carbon monoxide standards imposed by the rules. The technology employed by low NO_x burners tends to lower overall thermal efficiency and thereby increase CO emissions.

These are just a couple of examples where the technologies EPA believes will work may not and thereby increase costs and complexity to individual facilities.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Commenter Name: Roger Martella

Commenter Affiliation: National Alliance of Forest Owners (NAFO)

Document Control Number: EPA-HQ-OAR-2002-0058-3519-A1

Comment Excerpt Number: 1

Comment: Wood from sustainably managed forests provides a renewable, low-carbon alternative to fossil fuels. According to U.S. Energy Information Administration ("EIA") data, biomass already supplies more than 50% of the nation's renewable energy.² Forests can provide ample sustainable, domestic supplies of biomass to produce liquid transportation fuels, electricity, thermal energy (heat and power for manufacturing and other industrial uses), and synthetic natural gas.³

When evaluating the GHG emissions associated with fuels, a lifecycle analysis incorporates all steps in a "product system" to evaluate broader environmental impacts of products and processes. Using forest biomass as a renewable fuel source has significant carbon benefits because its lifecycle GHG emissions are more favorable than those of petroleum and other fossil fuels. For example, the Department of Energy ("DOE") estimates that "[c]ellulosic ethanol use could reduce GHGs by as much as 86%."⁴ In addition, EPA has determined, in conjunction with its Renewable Fuel Standard Program, that the lifecycle GHG emissions reductions associated with cellulosic ethanol may be as much as 92.7 percent.⁵

Lifecycle analyses of biomass feedstocks used for electricity generation have produced similar results.⁶ In addition to reducing GHG emissions through the displacement of fossil fuel, biomass energy can provide additional climate benefits. For example, combusting biomass for energy can avoid emissions of other biogenic GHGs (such as methane) that would result from alternative disposal fates of biomass residues and replace them with lower potency CO₂ emissions from energy production.⁷

Thus the prevailing science – in both the public and private sectors – acknowledges the significant carbon benefits of energy produced using renewable biomass from managed forests.

Commenter Name: Roger Martella

Commenter Affiliation: National Alliance of Forest Owners (NAFO)

Document Control Number: EPA-HQ-OAR-2002-0058-3519-A1

Comment Excerpt Number: 2

Comment: The prevailing view in the science community is that, when forests are managed sustainably, CO₂ emissions from forest biomass are part of the natural carbon cycle and are balanced by carbon sequestration as forests grow. In other words the carbon that enters the atmosphere when forest biomass is combusted was previously absorbed from the atmosphere by the forest biomass and will be reabsorbed when new biomass is grown.

As EPA has concluded, there is "[s]cientific consensus . . . that the CO₂ emitted from burning biomass will not increase total atmospheric CO₂ if this consumption is done on a sustainable basis."⁸ Recognizing that CO₂ emissions from biomass combustion are inextricably tied to the forests where biomass is grown, EPA follows international convention and does not include emissions from biomass combustion in its national emissions totals.⁹ Instead, EPA accounts for CO₂ emissions from biomass combustion by measuring changes in forest carbon stocks over time, recognizing that there is no net climate impact as long as forest carbon stocks are stable or increasing.¹⁰ Similarly, DOE's Voluntary Reporting of Greenhouse Gases Program, authorized by Section 1605(b) of the Energy Policy Act of 1992, provides for exclusion emissions from the combustion of biomass fuels.¹¹

More recently, EPA has affirmed the climate benefits of biomass energy combustion when compared to fossil fuels by reconsidering its treatment of biogenic CO₂ emissions under the Prevention of Significant Deterioration ("PSD") and Title V Programs.¹² Recognizing that imposing regulatory burdens on the biomass energy sector would discourage development of this important renewable fuel supply, EPA has deferred regulation of CO₂ emissions from stationary sources – including boilers and incinerator units – for three years while it seeks to identify a method to quantify the climate benefits offered by biomass energy.¹³ EPA has also convened a Biogenic Carbon Emissions Panel under the auspices of the Science Advisory Board to provide advice and recommendations as EPA completes the reconsideration process.¹⁴

EPA has consistently recognized the climate benefits of biomass energy and is committed to a regulatory approach that rewards bioenergy facilities for the climate benefits that they provide in relation to fossil fuel facilities. EPA must ensure that the treatment of biomass boilers and incinerators under these proposed rules is consistent with its overarching regulatory approach.

Comment: As described above, forests and forest products can play an important role in reducing and managing GHG emissions. Expanding the sources of renewable energy is a central feature of both national and international policy to reduce reliance on fossil fuels.

EPA, in considering approaches toward addressing climate change, has long recognized that responsibly managed forests are considered one of five key "groups of strategies that could substantially reduce emissions between now and 2030."¹⁵ Similarly, the United Nation’s Intergovernmental Panel on Climate Change ("IPCC") report on mitigation technologies

highlights forest management as a primary tool to reduce GHG emissions.¹⁶ In fact EIA projects that biomass energy will account for 30% of the growth in electricity produced by renewable fuels between now and 2035.¹⁷

President Obama has repeatedly emphasized that renewable energy derived from feedstocks such as forest biomass hold the key to transitioning the nation to a "sustainable, low carbon energy future."¹⁸ Recognizing the benefits of all types of biomass, he recently stated that "another substitute for oil that hold tremendous promise is renewable biomass – not just ethanol, but biofuels made from things like switchgrass and wood chips and biomass."¹⁹ And in last month's State of the Union Address the President advocated an "all-out, all-of-the-above strategy that develops every available source of American energy," specifically referencing a "clean energy standard" that would encourage the development of clean renewable energy including biomass.²⁰

With Presidential endorsement, if not direction, of national renewable energy policy and the role of biomass in that policy, EPA must conduct its programs in manner consistent with that policy. In light of this policy, EPA must avoid mandatory environmental controls, such as those included in the existing Major Source, CISWI, and NHSM rules, that will require large expenditures of time and resources by industry, but are not necessary to protect human health and the environment. Similarly, to act consistently with the nation's renewable energy policy, EPA must not impose restrictions on biomass boilers and incinerator units that are not legally required and will disadvantage the use of biomass as a fuel source. The proposed rules are a significant step in correcting the errors of the existing rules and conforming them to the administration's policies. Still the proposed rules do not go far enough and, as explained below, there are several ways in which the proposed rules can be altered to ensure consistency with the administration's policies and the legal requirements of the Clean Air Act.

Comment: Even if EPA properly finalizes the regulations in a way that classifies biomass energy feedstocks as non-waste, this clean, renewable, and climate-beneficial energy supply will not be developed without significant changes to the current emissions limits imposed on biomass boilers under the Major Source rule. Despite the fact that biomass energy is a clean, renewable alternative to fossil fuel combustion, the current regulations impose stringent emissions limits on biomass boilers that will require installation of expensive control technology while providing minimal (and sometimes undetectable) environmental and health benefits. Unless changes are made to the existing emissions limits, the high costs of compliance for biomass boilers will inevitably cause energy producers to turn to fossil fuel alternatives with lower compliance costs.

The proposed changes to the Major Source rule offer a number of improvements that will reduce compliance costs without sacrificing environmental and health benefits, particularly with respect to dioxin/furan emissions limits and the standards for new biomass boilers. However, these changes will not be sufficient to properly encourage and incentivize biomass energy development. NAFO urges EPA to consider additional changes with respect to emissions limits for other HAPs – including particulate matter standards for existing boilers. Without additional changes, future growth in the biomass energy sector will be discouraged and the potential climate benefits of biomass energy will not be fully realized.

Comment: Facilities will need to evaluate the applicability of other environmental regulations when selecting compliance options for the boiler and incinerator rules. For example, a facility cannot implement a CO reduction strategy that will result in a NOX increase if the facility is located in a non-attainment area or implement an air emissions control strategy that has adverse impacts on their water or waste discharges. Depending on the amount of NOX emission increases, the facility could have to go through PSD review, which can take a year or more to complete. Some controls may affect SO2 emissions and with the new short-term SO2 limits, states are frequently requiring extensive dispersion modeling which can take months to complete. Complex dispersion modeling would also be required to evaluate any effects of ammonia injection for NOX controls that are required as a result of lowering CO emissions.

Comment: Formulating the control strategy is just the beginning of a long process to procure and install the necessary equipment. Facilities must get approval for the capital required to implement the controls. As we are in the worst economy in the history of the Clean Air Act, capital planning cycles have been lengthened, and many companies must borrow capital through bank loans which have lengthier review periods. For many facilities, the compliance costs will dominate capital spending for several years, especially in the wood products sector, where little capital will remain for other facility upgrades or even maintenance projects. Since Boiler MACT is the most costly and complex MACT standard ever promulgated for U.S. manufacturers, acquisition of sufficient capital will be a more time consuming enterprise and companies cannot reasonably commit capital until the "final," final rules are in place.

Comment: Regardless of changes to the rule, billions of dollars will be required to comply, and, unlike the electric utilities whose compliance costs will be passed on to all electricity consumers, manufacturers face a globally competitive marketplace. Raising prices can result in loss of customers, which can lead to shut downs and job losses. Additional time to comply will spread out the burden and help maintain a competitive position.

Comment: Most boilers are designed to mix fuel and air at an appropriate ratio, and to provide sufficient residence time (and temperature) for the fuel to combust completely. Obviously, these factors are fuel-dependent, as a gaseous fuel will require less time for complete combustion than a liquid fuel, which in turn requires less time to burn than a solid fuel. The need for longer residence time is why the radiant sections in solid fuel- fired boilers are larger than for gas-fired

units. The size of the boiler is typically optimized to allow for complete combustion, while minimizing the cost of construction materials. If the construction cost were not a concern, a new boiler could be designed with additional residence time to complete the combustion process and minimize CO emissions. For these reasons, the geometry of individual furnaces has a significant impact on the level of CO attainable. In general, larger furnace sizes have a greater ability to allow for greater oxidation of organics (but absent any furnace or burner constraints, fuel type, load, and load transitions also remain factors).

Obviously, increasing the size of the furnace is not an option for existing units. For these units, the strategy for reducing CO emissions is typically to raise the level of excess oxygen which, to a point, improves combustion, destroys organic HAP and minimizes CO. In this range, increasing oxygen concentration has two positive effects. First, it acts to overcome poor distribution of the fuel. Second, it increases the furnace bulk gas temperature, which speeds up the combustion reactions, allowing more complete combustion to occur for the same residence time.

However, there are also a number of negative impacts associated with operating a boiler at higher levels of excess oxygen. One is that the residence time of combustion gases in the furnace decreases, resulting in less time for complete burnout of intermediates such as CO. Many boilers do not have sufficient fan capacity to run with elevated excess oxygen at the high end of the load range. Therefore, these units would effectively be derated by such a strategy. A site might have to add another boiler to offset the reduction in steam generating capacity. If the excess oxygen is increased to very high levels, CO and hydrocarbon emissions will increase as flame stability is impaired, mainly because this leads to a cooler flame. Under these conditions boiler efficiency drops as well, so the heat value of the fuel consumed provides less value in useful process heat and neither emissions nor process economic interests are served.

Comment: The minimization of excess oxygen in boiler applications is a key feature for maximizing boiler efficiency, and is therefore an appropriate operating parameter to use as an indicator of good combustion. For a given fuel, the boiler efficiency is defined by the amount of combustion air that is used, and the difference between the ambient temperature and the stack exhaust temperature. The more air that is heated up through the combustion process, the more heat is lost to the atmosphere, causing the boiler to be less efficient. A less efficient boiler will require more fuel to be fired to produce a given amount of steam. The additional fuel firing results in higher operating costs, and higher greenhouse gas emissions.

Comment: Minimizing the level of excess oxygen is also a primary strategy for reducing NOX emissions from a boiler. The NOX formation mechanisms are dependent upon the temperatures in the flame zone, and the stoichiometry of the fuel and oxygen introduced into the furnace. Reducing the level of excess oxygen reduces the bulk gas temperature, which reduces the rate at which the nitrogen in the air dissociates. As such, there is less monatomic nitrogen available to be oxidized to form "thermal NOX". Similarly, if there is less oxygen present, the monatomic nitrogen is less likely to be oxidized (and more likely to react with a second monatomic nitrogen to form diatomic nitrogen). This reduces both the amount of thermal NOX, and the "fuel NOX" (NOX that is formed by the release of fuel-bound nitrogen). Therefore, increasing the level of excess oxygen will result in higher NOX emissions.

Comment: For boilers with HAPs emissions above the proposed limitations, EPA has estimated the emissions control equipment at \$5.4 billion in capital expenditures³. For coal-fired units, EPA estimates a capital cost of \$4.4 million per boiler. However, the actual capital costs could be at least 2 to 3 times higher. Before a final rule is completed, sources affected by the Boiler MACT requirements need to have the opportunity to compile and submit to EPA refined projected capital cost expenditures and operational costs. Accurate cost estimates are a critical element of the Boiler MACT regulations. We request that EPA develop a questionnaire for affected sources to collect, compile and analyze this information. The proposed regulations should be delayed until the capital cost estimates are verified by EPA.

Comment: The preamble lacks a detailed economic impact analysis for the increased costs required to switch boilers from coal or oil to natural gas (this may not be feasible for many boilers)⁴. Historically, natural gas costs have been approximately 3 to 4 times higher than coal costs. As a result, switching to natural gas will severely impact the profitability of most companies. The economic evaluation needs to address increased natural gas usage by all potential users including electric utilities, heating of homes and buildings and transportation sources. Please provide a detailed long-term feasibility analysis for natural gas utilization including availability and projected costs for all users including industry.

Comment: There are numerous concerns with the complex array of the monitoring, recordkeeping and reporting requirements associated with the proposed and reconsidered Boiler MACT regulations. When utilizing solids fuels Amalgamated's estimated capital costs for continuous emissions monitors (CEM's), is estimated at \$100,000 per facility. The estimated annual stack testing costs for auditing the CEM's and annual HAP's performance tests are approximately \$150,000 per facility. In addition, increased manpower will be necessary to comply with these requirements. The preamble to the proposed rule does not justify the public health benefits associated with the increased monitoring. Please provide the justification of these additional monitoring costs.

Comment: These rules will affect a very significant number of sources which have never been subject to similar regulations. We cannot stress enough our concern in regulating so many sources for multiple pollutants for the first time. We are also very concerned that these rules will have significant and as yet unknown implications for biomass fired boilers and processes. This is very important to Wisconsin, where a significant number of our small businesses, as well as the paper industry, depend on biomass fired power. Wisconsin also feels that biomass is one vital key to growing renewable energy supplies, reducing pollutant emissions from fossil fuels, and growing our local economies.

Comment: EPA should not misrepresent the costs of this regulation. EPA has followed the costing assumptions and techniques in the OAQPS Control Cost Manual (EPA 452/B-02-001), which has not been updated in many years. This approach underestimates the total installed cost of air pollution control equipment, as discussed in previous comments submitted on this and various other proposed emission standards. While the EPA is not obligated to consider costs in establishing a MACT emission standard at the MACT floor level, the costs reported in the rule (and used for review by outside agencies, the public, and the Office of Management and Budget) should be accurate and based on the most up-to-date available information. Industry has provided more accurate and current costs to EPA and EPA should verify and use these costs.¹ [Footnote] (1) See Letter to EPA Docket from the American Forest and Paper Association, comments on 2010 Proposed Boiler rule (EPA-HQ-OAR-2002-0058-3213), "Evaluation of Air Pollution Control Costs for the Pulp and Paper Industry," May 1, 2003, prepared by Stone and Webster Management Consultants for National Economic Research Associates (NERA) [Appendix E] and "Cumulative Cost Burden Analysis of Air Regulations Potentially Impacting the Forest Products Industry" [Appendix C] for more current information available to EPA for estimating impacts of this rule.

Comment Excerpt Number: 31

Comment: Most boilers are designed to mix fuel and air at an appropriate ratio, and to provide sufficient residence time for the fuel to combust completely. Obviously, these factors are fuel-dependent, as a gaseous fuel will require less time for complete combustion than a liquid fuel, which in turn requires less time to burn than a solid fuel. The need for longer residence time is why the radiant sections in solid-fuel fired boilers are larger than for gas-fired units. The size of the boiler is typically optimized to allow for complete combustion, while minimizing the cost of construction materials. If the construction cost were not a concern, a new boiler could be designed with additional residence time to complete the combustion process and minimize CO emissions.

Unfortunately, increasing the size of the furnace is not an option for existing units. For these units, the strategy for reducing CO emissions is typically to raise the level of excess oxygen. The increase in oxygen concentration has two positive effects. First, it acts to overcome poor distribution of the fuel. Second, it increases the concentration of oxygen in the gas, which speeds up the combustion reactions, allowing more complete combustion to occur for the same residence time.

However, there are a number of negative impacts associated with operating a boiler at higher levels of excess oxygen. Many boilers do not have sufficient fan capacity to run with elevated excess oxygen at the high end of the load range. Therefore, these units would not be able to operate at capacity under this strategy. A site might have to add another boiler to offset the reduction in steam generating capacity.

The minimization of excess oxygen in boiler applications is a key feature for maximizing boiler efficiency. The boiler efficiency is defined by the amount of combustion air that is present, and the difference between the ambient temperature and the stack exhaust temperature. The more air that is heated up through the combustion process, the more heat is lost to the atmosphere, causing the boiler to be less efficient. A less efficient boiler will require more fuel to be fired to produce a given amount of steam. The additional fuel firing results in higher operating costs, and higher greenhouse gas emissions.

Minimizing the level of excess oxygen is also a primary strategy for reducing NO_x emissions from a boiler. The NO_x formation mechanisms are dependent upon the temperatures in the flame zone, and the stoichiometry. Reducing the level of excess oxygen reduces the average gas temperature, which reduces the rate at which the nitrogen in the air dissociates. As such, there is less monatomic nitrogen available to be oxidized to form 'thermal NO_x'. Similarly, if there is less oxygen present, the monatomic nitrogen is less likely to be oxidized (and more likely to react with a second monatomic nitrogen to form diatomic nitrogen). This reduces both the amount of thermal NO_x, and the 'fuel NO_x' (NO_x that is formed by the release of fuel-bound nitrogen). Therefore, increasing the level of excess oxygen will result in higher NO_x emissions. Low-NO_x burner (LNB) designs for some applications manipulate the stoichiometry within the flame to minimize NO_x formation. These designs establish a fuel-rich zone for the initial phase

of combustion, and then add air at a later stage in the outer regions of the flame. In the initial phase, there is not sufficient oxygen available to form significant amounts of NO_x, and in the secondary phase, the flame is much cooler, which also inhibits NO_x formation. However, using natural gas combustion as an example, these burners often operate with CO emissions up to 10 ppmvd in the upper part of the load range. At mid loads, the CO begins to increase to near 50 ppmvd, and at low loads, it may exceed 100 ppmvd. As the EPA is continually establishing a lower ozone standard, many more facilities will likely be installing low-NO_x burners.

Comment Excerpt Number: 74

Comment: EPA states that the presumed technology for controlling acid gases, Duct Sorbent Injection (DSI), will achieve significant control of SO₂ simultaneously to the control of HCl. EPA further states that reduction in HCl will produce a co-beneficial reduction in SO₂ of 558,400 tons per year from existing sources. This reduction is based on EPA's assumptions of an overall HCl removal efficiency of 71% and corresponding overall SO₂ reduction of 57%. EPA did not address the co-beneficial removal of SO₂ relationship in this rule, but did address the technology basis in the preamble to the Utility MACT (MATS) rule (pp. 592-602). In that discussion, EPA references multiple sources to support its application of DSI as a reasonable approach to control of HCl. Unfortunately, EPA's citations present a biased and incomplete view of the technology's efficacy for SO₂ removal.

First, EPA cites the BART analysis submitted for Dominion Energy's Kincaid Power Plant (<http://www.epa/state/il.us/air/drafts/regional-haze/bart-kincaid.pdf>). The source concludes on that DSI with Trona would achieve approximately 60% SO₂ reduction on a 30-day rolling average basis. On its surface, this would appear to support EPA's assumptions for SO₂ removal efficiency for industrial boilers. However, the SO₂ removal efficiency expected at Dominion's Kincaid Power Plant is based on the assumption that the unit will fire PRB coal with 0.3% sulfur. Because most industrial coal fired units use bituminous coals which have sulfur and chlorine contents several times higher than PRB coals, it is impossible to extrapolate any conclusions from a PRB unit to units firing bituminous coals. This BART analysis serves merely to demonstrate what one power plant with one variety of coal can achieve, but fails as a predictive tool for units firing other types of fuels.

Second, EPA cites literature published by Babcock and Wilcox, an OEM with deep experience in coal-fired power generation and the installation and retrofit of advanced emission controls. In PS-451 (<http://www.babcock.com/library/pdf/ps-451.pdf>), Babcock and Wilcox holds that Dry Sorbent Injection systems can provide "up to 80 percent SO₂ removal efficiency," which again appears to support EPA's general approach to estimating SO₂ co-benefits. However, that same document also states that in a typical DSI application, an "oversized electrostatic precipitator or new baghouse [is] required." Very few industrial units have the luxury of oversized particulate collectors, which calls into question whether a more typical unit with a correctly-sized or under-

sized particulate collector would be able to achieve high rates of SO₂ removal efficiency. In short, this paper confirms that high co-benefits are possible, but it fails to provide a predictive tool to evaluate the probability or extent of those co-benefits.

A further review of Babcock and Wilcox's published literature on DSI reveals helpful additional information correlating the technology's removal efficiency of HCl with SO₂. In BR-1851 (<http://www.babcock.com/library/pdf/BR-1851.pdf>), figure 3 shows simultaneous removal efficiencies of both HCl and SO₂ for a pilot unit configured with a pulse jet fabric filter (PJFF) firing bituminous coal. Using EPA's metric of approximately 70% HCl removal as the benchmark, a curve fitting analysis shows that the OEM's own data predicts a 30% SO₂ removal efficiency, or less than half what EPA's assumes when it calculates co-benefits.

Babcock and Wilcox also gives valuable insight into the significant variability of predicting SO₂ co-benefits in its BR-1866 (<http://www.babcock.com/library/pdf/BR-1866.pdf>). In that paper, figure 11 shows how SO₂ removal efficiency is highly dependent upon the selection of reagent. EPA rightly assumes that most sources will adopt the most cost-effective approach to controlling acid gases, which in many cases would be Trona. However, curve fitting analysis of figure 11 shows that while achieving EPA's benchmark of 57% SO₂ removal efficiency can be achieved with relatively low normalized stoichiometric ratios using Milled Sodium Bicarbonate, achieving that same level of SO₂ removal efficiency requires substantially more reagent if Milled Trona or Trona is used instead. Sources will optimize their DSI systems to control HCl, and both EPA and the OEM's acknowledge that DSI systems will preferentially treat HCl before SO₂. Thus, when a source optimizes a DSI system to satisfy the HCl requirement of this rule, it will be using significantly less reagent than required to achieve aggressive SO₂ removal efficiency. It is evident that EPA's assumptions for SO₂ co-benefits are optimistic, rather than realistic.

EPA references results published by another long-established OEM (United Conveyor Corporation) in its preamble to the Utility MACT (MATS) on page 597 (http://unitedconveyor.com/uploadedFiles/Systems/Systems_Sub/McIlvaine%20Multipollutant%20Removal%20Oct%202011.pdf). That reference shows that the SO₂ removal efficiency can vary between 30% and 70% for a HCl removal efficiency over 90% when firing eastern bituminous coal. With such a broad range of possible SO₂ removal efficiencies, it is clear that predicting a single representative value for the co-benefit is extremely challenging. EPA also describes the pilot testing of fine-milled trona at EERC's pilot facility in the preamble on page 596, stating that "fine-milled trona . . . provides 90 percent HCl removal at a SO₂ removal rate of less than 20 percent...." This comment was intended to demonstrate the selectivity of trona to target HCl rather than SO₂, but it serves to illustrate that not only is EPA's assumption of 57% SO₂ removal unrealistic, but also that EPA was aware of data that showed much smaller co-benefits than it claimed in its analysis of the benefits of the rule.

These conclusions are supported by other sources as well. Notably, Solvay Chemicals reports data substantially less optimistic than EPA's assumptions for SO₂ removal co-benefits. The slide deck by Solvay in the docket includes, on Slide 13, test data showing the simultaneous control of HCl and SO₂ compared to the total stoichiometric ratio. In this test, Solvay shows that while substantial SO₂ removal is technically achievable, approximately 35% SO₂ removal efficiency would be expected if the source controlled HCl removal efficiency to approximately 80%. In Solvay's whitepaper http://www.powermag.com/whitepapers/dry_sorbent_injection_with_trona_or_sodium_bicarbon

ate/dl/, Figure 7 predicts that when 80% HCl removal efficiency is achieved, the simultaneous SO₂ removal efficiency would be between 10% and 25%. All of these results cast doubt on the amount of credit EPA takes in its analysis of co-benefits.

Taken together, the balance of published knowledge strongly indicates that EPA's assumptions when calculating co-benefits due to SO₂ removal is grossly optimistic [see submittal for table].

CIBO agrees that some SO₂ removal co-benefit will occur with DSI systems installed to control HCl. However, experience shows that the amount of co-benefit will depend on the type of fuel being fired (e.g. bituminous, PRB, oil, etc.), the concentration of chlorine and sulfur in a given units particular fuel, the reagent selected (trona, milled trona, sodium bicarbonate, etc.), the temperature and residence time available for the reagent to react with the HCl and SO₂, and the particulate collector type and size. These variables mean the actual co-benefit will be highly site specific. Based on a review of published results (summarized in the table above) [see submittal for table], it is clear that EPA has overstated the co-beneficial removal of SO₂ by at least a factor of two, and perhaps as much as a factor of five or six.

Comment Excerpt Number: 1

Comment: URS Corporation (URS) worked with the Council of Industrial Boiler Owners (CIBO) and its members to develop a rough order of magnitude estimate of the initial capital cost of complying with the Industrial Boiler MACT. The cost estimates were compiled in a Microsoft Excel workbook; were based on published information or similar project costs; have been reviewed by member company representatives; and have been made available to the US EPA and others for review. The Boiler MACT estimated costs are in large part based on information in EPA's December 2011 survey and emissions databases. Capital and operating costs estimates are not intended to represent a worst case analysis. Rather, they represent median costs for the various scenarios based on published reports, industry information on specific project costs, EPA reports or control device fact sheets, or actual BACT or BART analyses submitted to permitting agencies. A primary resource was the document "Evaluation of Air Pollution Control Costs for the Pulp and Paper Industry," prepared by National Economic Research Associates (NERA) in May 2003. All costs were discussed with a core team of CIBO members and reviewed by URS engineers familiar with boiler operations and controls prior to finalizing the study.

The Boiler MACT will require emissions controls for particulate matter, hydrogen chloride, mercury, and carbon monoxide. The control technologies that EPA has identified as necessary to comply with the Boiler MACT are a fabric filter for control of particulate matter, carbon injection for control of mercury, a scrubber for control of hydrogen chloride, and combustion improvements or an oxidation catalyst for control of carbon monoxide. Although in some cases, the emission limits will be very difficult to achieve over all operating conditions, our cost analysis assumes that for each boiler, we can apply emissions controls to achieve the Boiler

MACT limits with a comfortable margin of compliance. In some cases, existing equipment configurations may prove impossible to upgrade, and boilers and process heaters may need to be replaced, which is a cost that is not reflected in our analysis. Note also that many facilities may choose fuel switching as a compliance option; however, as the cost of fuel switching is highly dependent on site specific factors (e.g., whether the boiler can burn the alternate fuel, what upgrades must be made to the fuel supply system) and the price of fuel will change over time due to factors like supply and demand, we did not attempt to quantify costs for fuel switching. The EPA collected information during Phase 1 of the Boiler MACT information collection request (ICR) on thousands of boilers and process heaters at hundreds of facilities. A detailed spreadsheet was developed to estimate costs for Boiler MACT for individual boilers and process heaters, based on EPA's major source boiler inventory database table and the emissions data included in EPA's boiler MACT database. URS extracted information from EPA's major source boiler inventory database including boiler ID, size, fuel category, emissions, and current air pollution control equipment. Based on the information in EPA's database and the baseline emission factors developed by EPA by boiler fuel, design, and control device, URS determined whether each unit would require additional air pollution controls to meet the Boiler MACT limits. Note that we did not perform any quality assurance on the information in EPA's database, but where we had knowledge that a boiler had been mis-categorized (e.g., a biomass boiler was listed as a liquid boiler) we did make those changes in our spreadsheet. A spreadsheet was developed that represents only the units that will have numeric emission limits (excludes natural gas boilers and process heaters, boilers and process heaters less than 10 MMBtu/hr heat input, and limited use units). Based on the information in the EPA emissions database and other docketed EPA cost memos, we estimated costs of controls that would likely be necessary to comply with the Boiler MACT for coal, biomass, liquid, and Gas 2 boilers 10 MMBtu/hr and greater (note that EPA has moved all process gas-fired boilers to the Gas 1 subcategory unless they were burning any amount of coke oven gas). Information from various sources was used to determine a base capital cost for a 250 MMBtu/hr boiler for each PM, CO, and HCl control technology option and then scaled using an 0.6 power function based on the size of each boiler in the inventory. For example, the capital cost of a wet scrubber on a 100 MMBtu/hr boiler is calculated as the base cost times $(100/250)^{0.6}$. A fixed cost of \$1 million was assumed for installation of a carbon adsorption system for Hg control, as these systems do not vary much in cost by boiler size. Base cost assumptions are presented below.

[See submittal for Table]

Controls were evaluated separately, first for particulate matter, then for hydrogen chloride, then for mercury, and last for carbon monoxide. To estimate Boiler MACT controls and costs for each unit, if there was no emissions information available for a particular boiler, we use the baseline emission factors developed by EPA for their analysis. In their boiler inventory table, EPA put the boiler pollution controls into categories. The categories are explained in greater detail in EPA's baseline emission factor memo, but basically are as follows: for the PM control code, 1=FF, 2=EFB/ESP, 3=venturi scrubber, 4=wet scrubber, 5=multiclone, 6=none/mist eliminator/unknown. If a unit did not already have a FF or ESP and there was information that indicated the unit cannot meet the limit, we assumed a new FF. If the unit already had a FF or ESP and there was information that indicated the unit cannot meet the limit we assumed an upgrade to the existing control equipment. For the HCl control code, 1=wet scrubber or spray dryer, 2=dry scrubber, 3=sorbent injection, 4=venturi scrubber, 5=none/dry PM only. To

estimate control costs for HCl, if there was information that indicated the unit cannot meet the limit, we assumed no additional capital cost for codes 1-3 (there would be an increase in sorbent injection but no additional capital), a scrubber upgrade for code 4 (venturi scrubber), and a new scrubber for code 5 (no scrubber). For the Hg control code, 1=carbon injection, 2=FF plus sorbent injection or spray dryer, 3=FF only, 4=wet scrubber, 5=venturi scrubber, 6=none/multiclone/EFB/mist eliminator. For Hg, if there was information that indicated the unit cannot meet the limit, we added carbon injection. For CO, if there was stack test information that indicated the unit cannot meet the CO stack test-based limit, then we assumed that capital would be necessary to either perform combustion/fuel feed improvements or other boiler improvement projects to reduce CO or install a CO catalyst. Although EPA's estimates indicate that the total capital cost of the final rule will be \$5.4 billion, CIBO has estimated that the total capital cost of the rule will be \$14.3 billion for industry. It is evident major capital investments in add-on control technology will be required for continued operation of solid and liquid fueled boilers and process heaters.

Comment: Our capital cost estimates differ from EPA's cost estimates as follows:

- EPA has used the outdated Control Cost Manual and we have based our cost estimates on more recent information, including actual vendor cost estimates, actual project costs, BACT and BART analyses, industry control cost studies, etc.

We used a CO catalyst cost higher than EPA's. Ours is based on a recent quote from BASF and EPA's is based on the 1998 Control Cost Manual section on catalytic oxidizers for VOC control.

EPA has estimated that a tune-up or burner replacement will be adequate for many units to achieve the CO limits. We do not agree with this assumption because some of the CO limits are fairly low and must be met over all operating conditions except startup and shutdown, so we have estimated higher costs to implement combustion controls, burner replacements, fuel feed system improvements, or CO catalyst.

Our CO control capital costs are higher than EPA's, mostly because EPA assumed that tune-ups and replacement burners will be adequate for the vast majority of boilers to comply, and we disagree with that assumption. EPA has estimated that activated carbon injection will be required on only 35 existing units because installation of a fabric filter is expected to achieve the mercury emission limits, except in cases where a unit already has a fabric filter and does not meet the limits. We do not agree that fabric filters will be sufficient to reduce mercury emissions to the some of the ultra-low levels in this rule. There is a flaw in the logic that fabric filters are expected to achieve mercury emission limits when there are many boilers in the database that are equipped with fabric filters and have measured mercury emissions higher than the applicable

limit. EPA's estimated industry-wide capital cost for activated carbon injection presented in the ERG cost and emissions impacts memo is extremely low, at only \$115,000 per unit.

EPA has estimated costs to install packed bed scrubbers for HCl control. Industrial boilers do not use packed bed scrubbers for acid gas control, as the limitations of these devices make them impractical for use on applications with high flow rates, high PM loading, and high inlet pollutant concentration. EPA's own fact sheet on these devices, located at <http://www.epa.gov/ttn/catc/dir1/fpack.pdf>, lists these limitations of these devices and indicates that they are only used in applications up to 75,000 scfm, which limits their use to small units only (EPA responded to this comment by applying multiple packed bed scrubbers to units with higher flow rates). Facilities will instead install wet scrubbers, dry scrubbers, or semi-dry scrubbers to control acid gas emissions from industrial boilers. EPA has estimated HCl control costs for equipment that industry is not likely to install. The following capital costs for control additions/upgrades were estimated by URS/CIBO for coal, biomass, liquid, and gas 2 units having numerical emission limits under Boiler MACT: [See submittal for Table]

EPA has estimated a control cost of only \$5.4 Billion for the rule. Note that the initial cost estimate increases to \$14.5 billion for coal, biomass, liquid, and gas 2 units when the costs of testing, monitoring, tune-ups, and energy assessments are factored in.

Comment: A concern is the impact this rule will have on new projects. Since the company I work for has been contemplating a biofuels project, our experience with the rule can give a new project perspective. The Boiler MACT rule put a major wrench into our planning process when exorbitant pollution control costs required us to switch from an advanced, state of the art drying process to the old, regular type. Is this what we want our rules to do? Don't we want our rules to encourage new technology? The return on the project was lost when we looked at how much pollution control technology would be required. Having to put two wet electrostatic precipitators in series to ensure that the limit was met was enough to take away the return on the project.

Comment: One of my other main concerns with Boiler MACT is that it pushes companies towards firing their boilers with natural gas. This is very short term thinking for several reasons.

While that decision might be easy to make now while natural gas prices are low, as recent as 2008 the US was experiencing high natural gas costs. How many companies will be able to afford the 5x swing in natural gas pricing when that happens the next time around? Companies need to have flexibility so they can have long term survival. One of the main reasons our mill closed for several months in 2006 was because of the high natural gas costs. Another reason that this is short-term thinking is because of the fossil fuel impact of natural gas. How can we say that long-term we want to reduce fossil fuel emissions yet Boiler MACT will push most businesses towards natural gas?

Comment: If the Clean Air Act requires that the top 12% of boilers be used to set the new limits then why are the estimates showing that approximately 94% of boilers impacted by the rule will be requiring major capital investments? Something is not adding up. The mill that I work at can't afford the \$5 million initial and \$1.5 million additional annual costs. With an annual economic impact of \$300 million to the state economy and an \$18 million federal and state tax loss the sting of our little mill closing will be felt throughout the state. Other mills that are looking at similar investments will add to many more manufacturing jobs being lost because of this rule. With the present state of the economy this is not the time to be adding costly rules.

Comment: It boggles my mind why we would want to force ourselves to take on some of the strictest limits internationally. How are we supposed to compete with foreign markets? Although there are a few countries that appear to have similar limits, they are allowed more flexibility with their regulators versus what is seen in the United States. While US companies will be pouring billions into pollution control equipment other countries will be able to make a return on their investments. A cost benefit analysis must be accurately measured before this rule is finalized. It is disconcerting to see groups such as AFPA say that the costs associated with this rule have been underestimated by almost 3 fold.

Document Control Number: EPA-HQ-OAR-2002-0058-3547-A2

Comment Excerpt Number: 5

Comment: As we noted in our August 23, 2010 comments on the originally proposed Boiler MACT, if EPA finalizes a rule that subjects coke oven gas-fired boilers to the stringent numeric emissions limitations proposed for Gas 2 sources, the additional cost of controls would functionally eliminate valuable efforts to reclaim energy. The U.S. Department of Energy has awarded competitive grant funds to energy recovery projects that convert flared coke oven gas to usable steam and electricity. The rule's requirements would discourage the type of energy recovery project that DOE is actively trying to promote. This is because the annualized cost of control required to meet the Gas 2 emission limits exceeds the cost of replacement natural gas for many units. Facing this economic reality, coke oven gas will be flared and natural gas will be combusted to generate steam to the detriment of the environment and our national goals of energy independence. The economic analysis is clear. Gas 2 requirements establish numeric emission limits for multiple pollutants. At this time, coke oven gas-fired units are not controlled for these compounds. Using EPA's projected cost of control (annualized capital cost plus annual operating cost) for each pollutant, including monitoring, recordkeeping and reporting, an ACCCI member company has calculated an annualized cost of control of \$8.6 million for a single 650 MMBTU/hr boiler combusting coke oven gas.²⁶ At a cost of \$5/MMBTU for natural gas, it is economically unreasonable for the boiler operator to use coke oven gas to displace the first 1,720,000 MMBTU per year of natural gas in this boiler and the coke oven gas would be flared. The use of natural gas to replace coke oven gas in this situation would be to the detriment of the environment and our energy policies. The constraint on available capital is an additional impediment to the installation of emission control equipment because increased natural gas consumption does not require a capital investment. Before a company will invest \$8.6 million in annualized control costs for a single boiler, it will need to justify a return on the capital investment far greater than \$8.6 million per year in displaced natural gas. Moreover, as discussed below, there is no expectation that expenditures of this magnitude will be sufficient to meet the proposed Gas 2 subcategory emission limits.

[Footnote]

(26) The capital cost for the unit is \$27,747,000 and the annual non-capital cost is \$5,678,000.

Comment Excerpt Number: 14

Comment: Installation of add-on emission controls on the NNS Floating Test Steam Facility (FTSF) marine boilers is infeasible and not cost-effective. The FTSF marine boilers currently do not meet all of the Boiler MACT emission limitations identified in the table above. Based on

NNS' evaluation of its FTSF marine boilers and demonstrated air pollution control technologies, NNS has identified the following add-on control technologies as apparently most applicable to controlling the FTSF marine boiler emissions to the levels required by the Boiler MACT:

- Fabric Filter (baghouse) w/Dry sorbent injection
- Fabric Filter (baghouse) w/Activated carbon injection
- Wet or Dry Electrostatic Precipitator (ESP)
- Wet Scrubber (Packed Bed)
- Flue Gas Desulfurization (FGD)

These identified technologies are consistent with those considered by EPA in its Regulatory Impact Analysis (EPA-HQ-OAR-2002-0058-3290). However, a conventional land-based air pollution control system employing any of these technologies would not be a viable option for the FTSF marine boilers at NNS, because the FTSF barge must operate at more than one distinct waterfront location, depending on ship locations during overhaul, thus requiring redundant emission control systems. In addition, unique and unproven methods would also be required to be successfully designed and constructed in order to capture the stack exhaust gases from both of the FTSF marine boilers while the barge rises and falls with the tide, or moves slightly with the wind and currents, or when the barge must be moored at slightly different locations alongside the NNS piers depending on the particular aircraft carrier being serviced and the location of a particular ship's interconnecting steam piping. Furthermore, the cost of redundant landbased emission control systems to accommodate a portable emission source such as the FTSF barge would multiply the actual emission control cost in real dollars, as well as on a "dollars per ton of pollutant removed" basis, to a level far above EPA's own estimates of Boiler MACT compliance costs.

To address the concerns associated with movement of the FTSF barge relative to an air emission control system located on fixed land, NNS considered the possibility of designing and constructing a separate barge-mounted emission control system which could be placed alongside the FTSF barge and lashed to it at any of its possible waterfront operating locations. Such an arrangement presents the difficult problem of safely placing and maintaining large-diameter interconnecting ductwork between the two barges using a crane, and also precludes bringing the fuel oil delivery barge alongside the FTSF when delivering fuel. Furthermore, the two barges themselves will move slightly with respect to each other, thus not fully resolving the movement concern. Lastly, the cost of designing and constructing a floating emission control system compact enough to fit on a barge is considerably higher than the cost of an equivalent land-based system, again exceeding EPA's own estimates of Boiler MACT compliance costs. NNS also considered the possibility of installing add-on emission control equipment on the FTSF barge itself. The two FTSF marine boilers comprise nearly the entire breadth and width of the FTSF barge. Exhibit 1 shows a photograph of the FTSF barge while undergoing routine maintenance in dry dock between successive carrier steaming activities. Exhibit 2 shows an overhead view of the FTSF barge while moored adjacent to an aircraft carrier in preparation for steaming the carrier. Exhibit 4 shows several photographs of the working spaces surrounding the boilers on the FTSF barge. It can be seen from these photographs that no significant additional space is available on the barge to construct or install any of the identified emission control technologies considered to be applicable to the FTSF emissions. [See submittal for Exhibits 1, 2, and 4.] NNS considered

the possibility of erecting a superstructure on the FTFSF barge and placing the add-on control equipment above the boilers' exhaust stacks. The weight of the add-on control equipment is estimated to be 140,000 to 200,000 pounds. The barge would require a rigorous naval architectural review if it were to be burdened with this additional weight of emission control equipment, especially considering that the weight of the added equipment could significantly affect the center of gravity and also would likely not be evenly distributed across the barge. In fact, listing of the barge (leaning to one side) when fuel oil is loaded and as it is consumed during operation commonly occurs and must be carefully controlled by monitoring the barge's list and trim and by using the fuel oil itself as ballast by pumping the oil through a network of tanks and piping below deck. The FTFSF barge was specifically designed by NNS naval architecture personnel to accommodate the weight of the two boilers as well as over 500,000 gallons of fuel oil stored in tanks below deck. NNS believes that significant additional weight cannot be accommodated without extensive, costly structural modifications to the barge. Furthermore the suitability of existing emissions control equipment for the unique FTFSF has not been demonstrated. EPA has not considered or included in its economic analysis the additional cost of constructing and operating portable emission control systems for portable emission sources like the FTFSF, nor has it considered the cost of redundant emission control systems that would be required for portable emission sources such as the FTFSF. This is not surprising, since the FTFSF is a unique facility, as described earlier. Based on EPA's Regulatory Impact Analysis, EPA's estimated average capital cost for add-on controls for liquid-fired boilers is approximately \$3.7 million per boiler (derived from Table 3.1 of the analysis). The need for NNS to employ redundant land-based air pollution control systems or, more likely, a bargemounted system to meet the Boiler MACT emission limitations for its FTFSF marine boilers, drives the capital cost of emission controls for FTFSF boilers up two to three times that of regulated industrial boilers of equivalent size. Furthermore, NNS believes that at least four years would be required to conduct the unique and complex engineering required to design a suitable emission control system for the FTFSF marine boilers, construct the system, and evaluate and troubleshoot its performance to ensure its reliability and effectiveness. The Boiler MACT as promulgated only allows three years from the effective date to come into compliance, which is not sufficient. While §112(i)(3)(B) of the Clean Air Act allows EPA or a state the authority to issue a permit that grants an extension allowing an existing source up to one additional year to comply with the Boiler MACT, if such additional period is necessary for the installation of controls, NNS cannot assume that it would be granted such an extension and cannot rely on an extension as its Boiler MACT compliance plan. Further, the unique nature of the FTFSF as well as the difficulty of designing engineering solutions for the installation of pollution control equipment under these conditions mean that NNS cannot be certain that initial designs will be workable. Therefore, NNS does not believe it to be reasonable that this option could be accomplished by the Boiler MACT compliance date (which is currently March 21, 2014), even if slightly delayed pursuant to EPA's delay of the Boiler MACT effective date

Comment Excerpt Number: 7

Comment: The proposed Boiler MACT reconsideration rule has the potential to still be very costly for NewPage.

We have conducted limited engineering review to estimate the compliance costs for the proposed reconsideration rule. The re-subcategorization and more stringent emission standards results in preliminary estimates of compliance costs significantly higher than the March 2011 final rule. These preliminary engineering estimates indicate extraordinary capital expenditures and several million dollars in additional annual operating costs. These costs are significant and will put NewPage at a distinct disadvantage as we compete in a global marketplace with other paper producers located in jurisdictions that do not have to comply with these requirements. In order to remain cost competitive with foreign competition, we cannot pass-on these substantial compliance costs. Due to significant economic pressure and a struggling economy, NewPage has had to close several of our manufacturing facilities and eliminate hundreds of high paying jobs. The compliance cost estimates for the proposed Boiler MACT reconsideration rule indicates that U.S. manufacturing will need to spend billions of dollars to fund compliance requirements. With a still struggling economy, additional manufacturing facilities may close and jobs will be shed. With the large financial burden for compliance, additional mill closures may be the final fate for some of our facilities unless changes to the proposed reconsideration rule are made to significantly lessen the impact.

Document Control Number: EPA-HQ-OAR-2002-0058-3675-A2

Comment Excerpt Number: 1

Comment: As potential regulated entities, American Crystal Sugar Company and Michigan Sugar Company request that the Environmental Protection Agency carefully consider the following comments to the proposed rule making. The proposed rule, as written, has the potential to greatly impact operations at not only our facilities, but at every one of the twenty-two sugar

beet processing facilities located throughout the United States, which will result in significant costs both for initial compliance as well as ongoing compliance. Existing operations will require significant physical modification at many facilities in order to comply with the proposed rule requirements. Initial compliance studies performed for American Crystal Sugar facilities indicate initial compliance costs in the range of \$10 million to \$20 million for each of the existing facilities. This excludes the additional cost of ongoing annual compliance, which as yet has not been quantified.

Physical modifications required to comply with the proposed rule may also have the secondary impact of triggering additional rule requirements, such as New Source Performance Standards and Prevention of Significant Deterioration Regulations. These secondary compliance requirements have the potential for additional major capital investment. Furthermore, future operations of affected sources may be seriously jeopardized due to constraints imposed on fuel flexibility and future availability of fuels.

In addition to compliance requirements of the proposed rule, significant costs will, and have been, incurred in advance of rule applicability dates to determine compliance options and strategy. This is evidenced by the fact that American Crystal Sugar Company has already made investments exceeding several hundred thousand dollars to develop compliance options and strategy prior to the finalization of rulemaking activities. This investment is necessary for companies with multiple potentially affected sources due to the significance of required modifications as well as the short time frame for compliance allowed under the proposed rule.

Comment Excerpt Number: 3

Comment: EPA's analysis shows that, despite high costs, there are essentially no emission or health benefits from the imposition of the proposed requirements for gas-fired units. While the costs imposed on BPH that fire natural gas, refinery gas and other gas 11 is certainly less than the costs that would have been incurred from imposing numerical emission limitations, the costs and burdens imposed by the work practice requirements, particularly the energy assessment work practice, are still very substantial and are not justified. Not only are there little or no benefits from HAP reductions from gas fired BPH, there are also little or no PM benefits. EPA estimates that there will be just 132 tons per year of potential PM emissions reduction from gas-fired BPH reduced nationally, compared to their estimate of 42,695 Tons per year total reduction from major source BPH 2 . EPA didn't provide the estimated amount of organic HAP reduced for gas-fired units in Table 4 of the proposal preamble, but EPA estimated that the total VOC reduction is only 246 tons from gas-fired units and organic HAP certainly will be a small part of the VOC reduction.

The perspective of the petroleum industry on the BPH NESHAP proposal is that it imposes enormous costs and potentially jobs reductions without any substantial emission or health benefits from the industry sectors in which we operate. For gas-fired equipment, EPA's docketed data shows that there are no health benefits or other benefits associated with regulating these sources. Gas is the primary fuel of the petroleum industry. Our industry is unquestionably already economically incentivized to maintain a high level of energy efficiency. To recapitulate, EPA should document in their analysis - to inform their decision making process - that for gas fired equipment there are no benefits associated with new standards and that any standard will only impose additional costs.

Comment Excerpt Number: 4

Comment: A CO catalyst could be installed upstream of the particulate emission control device where the flue gas temperature is above the minimum effective temperature (600 °F) where the catalyst becomes effective. This installation location is not feasible because of the high amount of particulate in the flue gas stream that would rapidly foul the CO catalyst rendering it ineffective. The same CO catalyst could be installed downstream of the final particulate emission control device to minimize fouling however the flue gas stream temperature would be well below the required 600 °F. It is feasible that the flue gas stream could be reheated with a natural gas burner to allow the CO catalyst to be effective but the trade-off is an increase in the emission rate of NOx. An increase in the emission rate of NOx may be prohibited by new source review especially in a non-attainment area. NOx may be able to be controlled by installing selective non-catalytic NOx reduction (SNCR) in the furnace section but additional study is required to determine its feasibility with a flue gas particulate content that is significantly higher than a unit firing bituminous coal for example.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Comment Excerpt Number: 4

Comment: ANGA requests that EPA revise its unsupported conclusion that fuel switching to natural gas would lead to an increase in HAP emissions. For a further discussion of this issue, see pages 5-7 of ANGA's August 23, 2011 comments. EPA correctly concludes that natural gas is the "cleanest fuel available for boilers" in the rulemaking. We encourage the agency to make its control decisions based on the scientifically supported fact that natural gas is a clean burning fuel.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Executive Orders

16A. Executive Order 12866, Regulatory Planning and Review

Commenter Name: Robert E. Hunzinger

Commenter Affiliation: Gainesville Regional Utilities (GRU), Florida

Document Control Number: EPA-HQ-OAR-2002-0058-3488-A1

Comment Excerpt Number: 7

Comment: GRU has concerns that EPA's estimate for the direct monetized health benefits of the final and reconsideration rule are significantly lower than the direct costs. EPA's economic analysis actually depends on co-benefits related to PM_{2.5} reductions to produce benefits for the rule that exceed the costs. Based on the stringency of the Major Source NESHAPS, GRU believes that the direct benefits of the rule should exceed the costs. In addition, since the National Ambient Air Quality Standard (NAAQS) for PM_{2.5} has been established at a level to protect human health and welfare with a margin of safety, there appears to be some question as to the quantification of the co-benefits for this rule.

Response: The EPA disagrees with this commenter that co-benefits should be excluded in the estimation of benefits expected by this regulation. The EPA has determined that the proposed rule will lead to reductions of criteria and HAP responsible for significant adverse health effects and that such reductions will produce substantial public health benefits. Accounting for ancillary impacts is standard practice in benefit-cost assessment since these benefits are a consequence of the rule, regardless of the rule's intended purpose. The EPA estimates all of the anticipated costs and benefits associated with a regulatory action, to the extent feasible, for the purpose of determining the likely impacts, not to justify an action. This rule is expected to achieve substantial PM_{2.5} health benefits resulting from primary PM and SO₂ emission reductions, and these co-benefits have been included in the regulatory impact assessment.

Consideration of ancillary benefits in benefit-cost analysis is directed by OMB Circular A-4 (2003) (p. 26, available at: http://www.whitehouse.gov/omb/circulars_a004_a-4/): “Your analysis should look beyond the direct benefits and direct costs of your rulemaking and consider any important ancillary benefits and countervailing risks. An ancillary benefit is a favorable impact of the rule that is typically unrelated or secondary to the statutory purpose of the rulemaking (e.g., reduced refinery emissions due to more stringent fuel economy standards for light trucks) while a countervailing risk is an adverse economic, health, safety, or environmental consequence that occurs due to a rule and is not already accounted for in the direct cost of the rule (e.g., adverse safety impacts from more stringent fuel-economy standards for light trucks).”

It is also directed by the EPA's *Guidelines for Preparation of Economic Analyses* (2010) (p. 11-2, available at:

<http://yosemite.epa.gov/ee/epa/eed.nsf/pages/Guidelines.html>): “An economic analysis of regulatory or policy options should present all identifiable costs and benefits that are incremental

to the regulation or policy under consideration. These should include directly intended effects and associated costs, as well as ancillary (or co-) benefits and costs.”

In line with this guidance, the EPA estimates all of the anticipated costs and benefits associated with a regulatory action, to the extent feasible. We further note that we were unable to monetize other important benefits, including health benefits of ozone reductions, additional PM_{2.5} health benefits, and direct health benefits of reducing SO₂. If we were able to fully monetize these benefits, the benefits would exceed the costs by an even greater amount than we currently estimate.

The EPA also notes that while the PM co-benefits are appropriately included in the benefit-cost analysis accompanying the rule, the benefit-cost analysis is not the justification for the rule. The rule is justified based on the requirements of the CAA, which requires EPA to issue standards to reduce HAPs for listed source categories.

The EPA disagrees that the existence of a NAAQS for PM_{2.5} somehow undermines the benefits estimated for this rule. The PM_{2.5} health benefits anticipated from this rule are based on the best available peer-reviewed science and methods that have withstood scrutiny from EPA’s independent Science Advisory Board, the National Academy of Sciences, and continuous interagency review. These benefits are not double-counted with benefits estimated in other RIAs. The NAAQS RIAs illustrate the potential costs and benefits of attaining a new air quality standard nationwide based on an array of emission control strategies for different sources. In short, NAAQS RIAs hypothesize, but do not predict, the control strategies that states may choose to enact when implementing a NAAQS. The setting of a NAAQS does not directly result in costs or benefits, and as such, the NAAQS RIAs are merely illustrative and are not intended to be added to the costs and benefits of other regulations that result in specific costs of control and emission reductions. In implementing these rules, emission controls may lead to reductions in ambient PM_{2.5} below the PM NAAQS in some areas. Although benefits occurring below the standard may be less certain than those occurring above the standard, the EPA considers them to be legitimate components of the total benefits estimate.

Document Control Number: EPA-HQ-OAR-2002-0058-3659-A2

Comment Excerpt Number: 14

Comment: Integrys requests that EPA reevaluate the monetized health benefits of the Major Source Rule and the Proposal without accounting for co-benefits from reductions in fine PM. We are concerned that the monetized health benefits *directly* associated with the rule do not exceed the actual costs of the rule. EPA should accurately identify the direct costs of regulation as compared to the benefits expected.

Response: The EPA disagrees with this commenter that co-benefits should be excluded in the estimation of benefits expected by this regulation. The EPA has determined that the proposed rule will lead to reductions of criteria and HAP responsible for significant adverse health effects and that such reductions will produce substantial public health benefits. Accounting for ancillary impacts is standard practice in benefit-cost assessment since these benefits are a consequence of

the rule, regardless of the rule's intended purpose. The EPA estimates all of the anticipated costs and benefits associated with a regulatory action, to the extent feasible, for the purpose of determining the likely impacts, not to justify an action. This rule is expected to achieve substantial PM_{2.5} health benefits resulting from primary PM and SO₂ emission reductions, and these co-benefits have been included in the regulatory impact assessment.

Consideration of ancillary benefits in benefit-cost analysis is directed by OMB Circular A-4 (2003) (p. 26, available at: http://www.whitehouse.gov/omb/circulars_a004_a-4/): “Your analysis should look beyond the direct benefits and direct costs of your rulemaking and consider any important ancillary benefits and countervailing risks. An ancillary benefit is a favorable impact of the rule that is typically unrelated or secondary to the statutory purpose of the rulemaking (e.g., reduced refinery emissions due to more stringent fuel economy standards for light trucks) while a countervailing risk is an adverse economic, health, safety, or environmental consequence that occurs due to a rule and is not already accounted for in the direct cost of the rule (e.g., adverse safety impacts from more stringent fuel-economy standards for light trucks).”

It is also directed by the EPA's *Guidelines for Preparation of Economic Analyses* (2010) (p. 11-2, available at: <http://yosemite.epa.gov/ee/epa/eed.nsf/pages/Guidelines.html>): “An economic analysis of regulatory or policy options should present all identifiable costs and benefits that are incremental to the regulation or policy under consideration. These should include directly intended effects and associated costs, as well as ancillary (or co-) benefits and costs.”

In line with this guidance, the EPA estimates all of the anticipated costs and benefits associated with a regulatory action, to the extent feasible. We further note that we were unable to monetize other important benefits, including health benefits of ozone reductions, additional PM_{2.5} health benefits, and direct health benefits of reducing SO₂. If we were able to fully monetize these benefits, the benefits would exceed the costs by an even greater amount than we currently estimate.

The EPA also notes that while the PM co-benefits are appropriately included in the benefit-cost analysis accompanying the rule, the benefit-cost analysis is not the justification for the rule. The rule is justified based on the requirements of the CAA, which requires EPA to issue standards to reduce HAPs for listed source categories.

Document Control Number: EPA-HQ-OAR-2002-0058-3522-A1

Comment Excerpt Number: 1

Comment: The preamble of the proposed rule and reconsideration continues to inappropriately document the overall air quality benefits associated with the proposed boiler MACT emissions limitations¹. The preamble needs to include an analysis of the percentage decrease in annual HAPs emissions relative to all HAPs emissions sources. Because of the staggering costs to industries and small businesses associated with this rule, it is critical that the net air quality benefits are considered when establishing the Boiler MACT HAPs limits. Please revise the preamble to include this important documentation.

The preamble does not appropriately document cost savings associated with the rule². The preamble to the reconsidered rules suggests that there will be \$27 billion to \$67 billion in future human health benefits. The calculation of these benefits is not clear and cannot be measured or verified. As explained above, it is critical that the reduction in HAPs be accurately determined in order to assist in evaluating the overall projected benefits of the proposed rule. Please summarize the assumptions associated with these projections, the accuracy of these estimates and whether EPA will verify the cost saving estimates. In addition, please explain why this estimate is different from the previous proposed rule estimates.

[Footnotes]

(1) Section V. A. Air Impacts (pg 80620)

(2) Section V. F. Social Costs & Benefits (pg 80622)

Response: The EPA disagrees that benefits of this rulemaking have been inappropriately documented. In fact, the health benefit is fully documented in the Regulatory Impact Analysis that accompanied the final regulation in February 2011 in the docket (also available at http://www.epa.gov/ttn/ecas/regdata/RIAs/boilersriafinal110221_psg.pdf). For this reconsideration, EPA has applied the same methodology to the revised emission reductions reflecting the revised provisions in the reconsideration, which is documented in the December 1st memo to the docket (also available at <http://www.epa.gov/ttn/ecas/regdata/RIAs/boilermactreconria.pdf>). This memo breaks down the benefits changes attributable to the addition of 300 boilers as well as the provision changes

in the reconsideration. For the final reconsideration package, we have added an estimate of the percent reduction in HAP from boilers, as requested by the commenter.

It is important to note that the health benefits are not “cost-savings” as indicated by the commenter. The monetization of the health benefits is largely dominated by willingness to pay to avoid small risks of premature death. The EPA has determined that the proposed rule will lead to reductions of criteria and HAP responsible for significant adverse health effects and that such reductions will produce substantial public health benefits. Accounting for ancillary impacts is standard practice in benefit-cost assessment since these benefits are a consequence of the rule, regardless of the rule’s intended purpose. The EPA estimates all of the anticipated costs and

benefits associated with a regulatory action, to the extent feasible, for the purpose of determining the likely impacts, not to justify an action. This rule is expected to achieve substantial PM2.5 health benefits resulting from primary PM and SO2 emission reductions, and these co-benefits have been included in the regulatory impact assessment. The PM2.5 health benefits anticipated from this rule are based on the best available peer-reviewed science and methods that have withstood scrutiny from EPA's independent Science Advisory Board, the National Academy of Sciences, and continuous interagency review. We further note that we were unable to monetize other important benefits, including health benefits of ozone reductions, additional PM2.5 health benefits, and direct health benefits of reducing SO2. If we were able to fully monetize these benefits, the benefits would exceed the costs by an even greater amount than we currently estimate.

Comment Excerpt Number: 11

Comment: The proposed monitoring requirements disregard and ignore President Obama's January 2011 Executive Order 13563 for "Improving Regulation and Regulatory Review". The purpose of this order is to identify and correct overly burdensome regulations that impact economic growth. The proposed Boiler MACT monitoring requirements are in direct conflict with this order, especially considering the real public health benefits have never been documented.

Response: The EPA disagrees that the public health benefits have never been documented. In fact, the health benefit is fully documented in the Regulatory Impact Analysis that accompanied the final regulation in February 2011 in the docket (also available at http://www.epa.gov/ttn/ecas/regdata/RIAs/boilersriafinal110221_psg.pdf). For this reconsideration, EPA has applied the same methodology to the revised emission reductions reflecting the revised provisions in the reconsideration, which is documented in the in the December 1st memo to the docket (also available at <http://www.epa.gov/ttn/ecas/regdata/RIAs/boilermactreconria.pdf>). Furthermore, the PM2.5 health benefits anticipated from this rule are based on the best available peer-reviewed science and methods that have withstood scrutiny from EPA's independent Science Advisory Board, the National Academy of Sciences, and continuous interagency review. Hundreds of studies have documented human health risks from exposure to air pollution, including EPA's *Integrated Science Assessment for Particulate Matter* (U.S. EPA, 2009) and the *Integrated Risk Information System* (IRIS) for various hazardous air pollutants.

Commenter Name: Janice E. Nolen

Commenter Affiliation: American Lung Association

Document Control Number: EPA-HQ-OAR-2002-0058-3679-A2

Comment Excerpt Number: 4

Comment: Many face greater risk because of their age, health conditions, or rate of exposure to the pollutants. They include: infants, children and teenagers; older adults; pregnant women;

people with asthma and other lung diseases; people with cardiovascular diseases; diabetics; people with low incomes; and people who work or exercise outdoors (EPA 1997, 2009b). The discussion below highlights special concerns for several of these groups.

Response: The EPA agrees that the scientific literature indicates that certain populations as having a greater likelihood of experiencing health effects related to air pollution than others. In the *Integrated Science Assessment for Particulate Matter* (U.S. EPA, 2009), the EPA concluded that “[o]verall, the epidemiologic, controlled human exposure, and toxicological studies evaluated in this review provide evidence for increased susceptibility for various populations, including children and older adults, people with pre-existing cardiopulmonary diseases, and people with lower SES.” Exposure to fine particulates and toxic air pollutants is associated with many adverse health effects and reducing exposure to these pollutants is associated with substantial public health benefits.

Commenter Name: Janice E. Nolen

Commenter Affiliation: American Lung Association

Document Control Number: EPA-HQ-OAR-2002-0058-3679-A2

Comment Excerpt Number: 6

Comment: People with chronic diseases, including cardiovascular diseases, respiratory diseases and diabetes, face higher risk regardless of age. Their diseases make them at much higher risk for harm. Current estimates include these groups:

- Asthma - 24.6 million people, including 7.0 million under age 18 (American Lung Association, 2011)
- Cardiovascular diseases – 82.6 million people (Roger et al., 2011)
- Diabetes – 25.8 million people (CDC, 2011)

As adults age, their body’s physiological process declines naturally, placing even healthy older adults at risk from airborne pollutants. In addition, many older adults also have one or more chronic diseases that increase their susceptibility (EPA, 2009b).

Response: See the response to comment EPA-HQ-OAR-2002-0058-3679-A2, excerpt 4.

Commenter Name: Janice E. Nolen

Commenter Affiliation: American Lung Association

Document Control Number: EPA-HQ-OAR-2002-0058-3679-A2

Comment Excerpt Number: 8

Comment: Socioeconomic position has been more consistently associated with greater harm from air pollution. Recent studies show evidence of that link. Low socioeconomic status consistently increased the risk of premature death from fine particle pollution among 13.2 million Medicare recipients studied in the largest examination of mortality associated with particulate matter levels nationwide (Zeger et al., 2008).

Response: See the response to comment EPA-HQ-OAR-2002-0058-3679-A2, excerpt 4.

Commenter Name: Janice E. Nolen
Commenter Affiliation: American Lung Association
Document Control Number: EPA-HQ-OAR-2002-0058-3679-A2
Comment Excerpt Number: 3

Comment: Cleaning up these toxic emissions will provide substantial health benefits. The EPA's analysis estimates the health benefits each year beginning in 2015, which includes the prevention of up to 8,100 premature deaths, the avoidance of 5,100 nonfatal heart attacks and the prevention of 52,000 asthma attacks (EPA, 2011b).

In fact, these estimates undercount the total benefits. Studies that would enable researchers to quantify many health endpoints affected by these toxics were not available for modeling. For example, critical, real benefits such as reductions in the number of infants born with low birthweight or impaired cognitive development were not included in the projections. However, the benefits to public health that can be estimated alone provide powerful support to require facilities to meet the strongest possible limits on these toxic emissions. The evidence shows that the strongest possible limits on the emissions of these toxics are both appropriate and necessary.

Response: The EPA agrees that this rule is anticipated to provide substantial health benefits and that many benefits remain unquantified. In the Regulatory Impact Analysis, the EPA estimates all of the anticipated costs and benefits associated with a regulatory action, to the extent feasible. Both Executive Orders 12866 and 13563 acknowledge that many benefits are difficult to quantify. The EPA agrees that we were unable to monetize other important benefits, including health benefits of reducing exposure to hazardous air pollutants, ozone, SO₂, and additional PM_{2.5} health benefits such as low birthweight, as well as ecosystem effects and visibility impairment. These rules are expected to achieve important HAP and criteria pollutant benefits, but monetization of some of these benefits is limited by currently available data and methods. For example, monetization of the HAP benefits of reductions in cancer incidences requires several important inputs, including central estimates of cancer risks, estimates of exposure to carcinogenic HAP, and estimates of the value of an avoided case of cancer (fatal and non-fatal). Our limited ability to monetize these benefits does not indicate that they are non-existent or less important. If we were able to fully monetize these benefits, the benefits would exceed the costs by an even greater amount than we currently estimate.

Comment: Hazardous Air Pollutants from Boilers and Incinerators Cause Wide-ranging Health Harm

During the process of burning coal, oil, and biomass, boilers and incinerators emit highly toxic chemicals that threaten human health through the air we breathe, the water we drink, and the food we eat. These hazardous air pollutants that harm human health include: corrosive substances (acid gases, such as hydrogen chloride); carcinogens (formaldehyde, benzene, toluene, and other compounds); organic carbon-based toxics (formaldehyde, dioxins, furans);

metals (such as arsenic, nickel, and beryllium); and neurotoxins (such as mercury and lead) (EPA 2007; ATSDR 2011a). They also include criteria air pollutants: sulfur dioxide, carbon monoxide, and fine particulate matter.

Some hazardous pollutants, such as acid gases, mercury, and sulfur dioxide, have immediate impacts on people, neighborhoods, and towns located near boilers or incinerators. However, other pollutants, such as dioxins and metals, can travel much farther from the pollution source. When they adhere to fine particles, these pollutants can remain in the air for more than a week and be carried away by winds to distant locations. This makes toxic air pollution dangerous to public health and human health near and far from these sources (EPA, 2009b).

The discussion below summarizes the evidence that these toxics pose serious threats to health and must be reduced.

Carbon Monoxide. Carbon Monoxide is a colorless, odorless, nonirritating gas that occurs in outdoor and indoor air through both natural and human-made sources (ATSDR, 2009). Exposure to moderate or high levels of this gas can be fatal by causing severe damage to the heart and/or brain (ATSDR, 2009). Breathing high levels may cause a miscarriage for women who are pregnant, and exposure to lower levels can cause permanent damage to the mental development of the fetus (ATSDR, 2009).

Dioxins and Furans (Example: 2,3,7,8-tetrachlorodibenzo-p-dioxin, known as TCDD). Dioxins and furans are a family of toxic chemicals that primarily arise from the burning of fossil fuels, such as coal, and exist in the atmosphere both as a gas and particles. (Oh et al., 2001). As particles, they may remain airborne for more than ten days, spreading widely from their source, and depositing in water and soil (Atkinson, 1991). Dioxins have been found in the U.S. food supply; in 2002-2003, the U.S. Department of Agriculture found dioxin-like substances in meat and poultry (Hoffman et al., 2006). Researchers have found dioxins in the breast milk of nursing mothers (Lorber and Phillips, 2002).

Short-term exposures can cause liver damage and skin lesions, while long-term exposures can harm the immune system, the developing nervous system, the reproductive system, and disrupt hormone function. One form of dioxin—2,3,7,8-Tetrachlorodibenzo-p-dioxin, or TCDD—is recognized as a known human carcinogen. (NTP 2011). (WHO, 2010, 2011; ATSDR, 1994, 1998a, 2000b). Researchers are currently exploring the potential for dioxins to act as endocrine disruptors, by mimicking natural hormones in the body and altering their normal function (Casals-Casas and Desvergne, 2011). Last year, the World Health Organization concluded that the developing fetus and the newborn child were the most vulnerable to dioxin and furan exposure because of the rapid growth of their organ systems (WHO, 2010).

Mercury (Including Methylmercury). Mercury is a primary metal emitted from coal-fired boilers and incinerators. Mercury emissions occur in three forms: as a vaporous gas of elemental mercury; oxidized, and bound with particles. Elemental mercury stays airborne, resulting in widespread distribution. Oxidized and particle-bound mercury deposit nearer to the sources. Once released to the atmosphere, mercury returns to the earth in rain or snowfall, and pollutes waterways and the wildlife in them (EPA, 2011) Microorganisms convert mercury into methylmercury, a highly toxic form of mercury that bioaccumulates in fish and shellfish (ATSDR, 1999b; Grandjean, 2010). Although a person can be exposed to mercury through breathing contaminated air or through skin contact, methylmercury is most easily absorbed by

eating contaminated food, especially fish or shellfish. The long-term, low-level exposure to methylmercury that results from the regular consumption of contaminated fish is a primary health concern (EPA, 1997). Eating foods containing methylmercury can expose the brains of adults, children and developing fetus to harm. Critical periods are during pregnancy and in the early months after children are born (ATSDR 1999b). Mercury exposure can lead to developmental birth defects and interfere with neurological development (Bose-O'Reilly et al., 2010). Pregnant women who consume fish and shellfish can transmit that methylmercury to their developing fetuses, and infants can ingest methylmercury in breast milk. Children can also become exposed by eating contaminated fish (ATSDR 1999). Each year, more than 300,000 children born in the US have levels of mercury in their blood high enough to impair performance on brain development test and permanently affect intelligence (Trasande et al., 2005; Axelrad et al., 2007). Mercury can damage the kidneys, liver, brain, and nervous system as a potent neurotoxin, even in adults (ATSDR, 1999b, 2011a; WHO, 2011). A recent study has also found that methylmercury exposure may lessen the cardiovascular benefits of regular fish consumption (Domingo, 2007).

Fine Particulate Matter (PM_{2.5}). Reductions in sulfur dioxide and nitrogen oxides through the final boiler and incinerator standards would provide a crucial collateral benefit: reduction in secondary fine particulate matter. Sulfates formed from sulfur dioxide comprise the majority of fine particulate matter in much of the United States, especially in the summer months. Nitrates from nitrogen oxides are also a major source of fine particulate matter in the fall, winter and spring (EPA, 2011). PM_{2.5} is made up of microscopic particles, including aerosols, that can bypass the body's natural defenses and lodge deep within the lungs (EPA, 2004, 2009). Fine particles elevate risk of heart attacks and strokes (Dominici et al., 2002; Hong et al., 2002; Franklin et al., 2007; D'Ippoliti et al., 2003; Miller et al., 2007); stunt lung function and development (Gauderman et al., 2002; Gauderman et al., 2004); inflame and damage lung tissue and airways (Ghio et al., 2000; Churg et al., 2003); increase hospital visits for respiratory and cardiovascular problems (Dominici et al., 2006; Tsai et al., 2003); and aggravate asthma attacks (Lin M et al., 2002; Norris et al., 1999; Tolbert et al., 2000; Slaughter et al., 2003; Lin S et al., 2002). The evidence shows that PM 2.5 causes cardiovascular harm and is likely to cause respiratory harm. More seriously, PM_{2.5} can cause premature death from lung cancer and cardiovascular effects and is likely to cause death from respiratory effects as well (Pope et al., 2002; Pope et al., 2004).

The most vulnerable populations, including children, teens, senior citizens, people with low incomes and people with chronic lung disease, such as asthma, chronic bronchitis, and emphysema, are at risk of being sickened by fine particulate matter. People with diabetes, heart disease, high blood pressure, coronary artery disease, and congestive heart failure, are also at risk (EPA, 2004, 2009). The evidence suggests that long-term exposure to PM_{2.5} causes reproductive and developmental effects as well as cancer, mutagenicity and genotoxicity (EPA, 2009).

Non-Mercury Metals. Non-mercury metals and metal-like substances (e.g. arsenic and selenium) comprise a significant part of fine particulate matter (PM_{2.5}) emitted from boilers and incinerators. These primary particles come in addition to the secondary particles formed as a result of chemical reactions in sulfur dioxide and nitrogen oxide emissions. Those secondary particles, notably sulfates and nitrates, pose similar life-threatening risks. Inhaled particles deposit along the respiratory tract or penetrate deeply into the gas-exchange region of the lung.

The EPA has already concluded that exposure to fine particulate matter (PM_{2.5}) causes cardiovascular effects and premature mortality and is likely to cause respiratory harm. They concluded that the evidence suggests that long-term exposure to PM_{2.5} causes reproductive and developmental effects as well as cancer, mutagenicity and genotoxicity (EPA, 2009).

The risks of cardiovascular harm include acute myocardial infarction, congestive heart failure, cardiac arrhythmias and strokes. Risks of respiratory harm include coughing, wheezing, difficulty breathing, asthma exacerbations, and increased hospitalization for chronic obstructive pulmonary disease (COPD) (EPA 2009). Evidence has also grown to warn that long-term exposure to PM 2.5 can increase the risk of low birth weight and infant mortality, as well as cancer, especially lung cancer (EPA, 2009).

The level of toxicity of fine particles varies and is likely impacted by the presence of metals or other pollutants (Bell et al., 2007). Metals interact with particles to create —reactive oxygen species|| which limit the body’s ability to repair damage to its cells and contribute to tissue inflammation (Carter et al., 1997; Gurgueira et al., 2002; Wilson et al., 2002). Research has shown that sulfate, selenium, iron, nitrate, and organic carbon affect immune cell response and heart variability (Huang et al., 2003; Chuang et al., 2007). Elevated presence of chromium, lead, and other metals in PM has been associated with greater effects on hospital admissions for cardiovascular disease, according to a study of Medicare recipients in 26 communities (Zanobetti et al., 2009). Zanobetti et al. found that admissions for heart attacks were higher where the PM was enriched in arsenic, chromium, manganese, nickel, and organic carbon. The same study found that high levels of arsenic, organic carbon, and sulfate in PM—potential indicators of coal combustion—were associated with increased hospital admissions for diabetics (Zanobetti et al., 2009). A large study of 25 U.S. communities found more deaths when the fraction of aluminum, sulfate, and nickel in PM was highest (Franklin et al., 2008). This study found additional evidence warning that the combination of metals in particles, a common occurrence, may increase their toxicity.

Arsenic. Arsenic exposure can occur through the dermal, oral, and inhalation routes. As a known carcinogen, inhalation of arsenic has been strongly associated with lung cancer (HHS, 2011). Short-term inhalation can harm the gastrointestinal tract, cause nausea and diarrhea, and even adversely affect the nervous system. Long-term inhalation has been associated with irritation of the skin and mucous membranes. Exposure can lead to respiratory tract irritation and conjunctivitis, and damage nasal tissue (ATSDR, 1998b). Similar to effects of inhaling arsenic, arsenic in drinking water has also been linked to skin, bladder, lung, and liver cancer (HHS, 2011). Over a long period, the metal-like substance can result in anemia, lesions, liver, kidney, and nerve damage, and affect the digestive system (ATSDR, 2007c).

Beryllium. Beryllium is a known carcinogenic metal (HHS, 2011). Inhaled beryllium has been found to increase the risk of lung cancer (Steenland and Ward 1991, Ward et al., 1992). Breathing large amounts of beryllium compounds can damage the lungs and cause the lungs to resemble pneumonia with reddening and swelling. Long-term exposure over many years may cause chronic beryllium disease, when a chronic inflammatory reaction, called a granuloma, within people who are allergic to beryllium occurs. People with chronic beryllium disease may experience weakness, fatigue, difficulty breathing, anorexia, weight loss, and blueness of the hands and feet. The disease can lead to heart enlargement, heart disease, and even death (ATSDR, 2002).

Cadmium. Cadmium is another known carcinogenic metal (HHS, 2011). Exposure to airborne cadmium causes lung cancer, as the International Agency for Research on Cancer reaffirmed in 2009 (Straif, et al., 2009). Prolonged inhalation of cadmium can also lead to gradual accumulation of the metal in the kidneys, resulting in kidney disease (ATSDR, 2008a).

Chromium. Chromium occurs in three main forms, one of which, chromium (IV) is a known carcinogen that can increase the risk of lung cancer (ATSDR, 2008b; HHS, 2011). The metal primarily affects the respiratory system, though chromium (VI) can impact the gastrointestinal, immunological, hematological, reproductive and developmental systems, particularly if ingested. Inhaling chromium (VI) can cause coughing and wheezing, shortness of breath, bronchitis, pneumonia, decreased lung function, and other respiratory conditions. In some workers, inhaled chromium (VI) caused them to develop asthma and have asthma attacks (ATSDR, 2008b).

Lead. The health effects of lead exposure mainly focus on the nervous system and damaging its functions. Lead may cause weaknesses in the joints, anemia, and increases in blood pressure (ATSDR, 2007d). Although lead is harmful to both adults and children, children are most susceptible to the effects of lead exposure. Lead exposure can cause developmental disorders whose effects can persist beyond childhood (ATSDR, 2007e). Exposure can affect a child's physical and mental growth, resulting in slower mental development and lower levels of intelligence. Lead is also a probable carcinogen (HHS, 2011).

Manganese. Similar to lead, manganese mostly affects the nervous system. For example, adverse effects to hand-eye coordination, hand steadiness, and visual reaction time were observed in humans exposed to manganese (ATSDR, 2008c). High exposure levels may result in feelings of lethargy and weakness, psychological impacts, and tremors.

Nickel. Compounds containing nickel have been determined to be carcinogenic (HHS, 2011). A known health effect of nickel exposure is the increased risk of lung and nasal cancers from nickel dust (ATSDR, 2005b).

Selenium. Selenium exposure can harm the respiratory system by irritating mucous membranes and causing pneumonia, bronchitis, and pulmonary edema (ATSDR, 2003a). One selenium compound, selenium sulfide, is also considered to be a probable human carcinogen (HHS, 2011).

Volatile Organic Compounds (Examples: acetaldehyde, benzene, formaldehyde, toluene, xylene). Volatile organic hazardous air pollutants are specific toxic gases that react easily with other gases and particles. These take in a host of chemicals that include carcinogens and other toxins. While many of these toxic air pollutants can cause cancer, they can also irritate the eyes, skin, and respiratory tract, impair lung function, and affect vital organs. Benzene and formaldehyde are recognized as known human carcinogens, while ethylbenzene and acetaldehyde are considered probable carcinogens (HHS, 2011). Long-term exposures to benzene can cause leukemia, a blood cancer, and other blood disorders such as anemia and depressed lymphocyte count in blood. Exposure to formaldehyde can also cause chronic bronchitis and nasal epithelial lesions. A recent review of the research found evidence that formaldehyde may increase the risk of asthma, particularly in the young (McGwin et al., 2010). Non-cancer effects associated with exposure to these organics range from irritation of the skin, eyes, nose, throat, and respiratory tract, and dizziness, nausea, and vomiting. These compounds can also cause difficulty in breathing, impaired lung function and respiratory symptoms, damage

to the liver and kidneys, and stomach discomfort. They may also cause developmental disorders, adverse effects to the nervous system, impairment of memory and neurological function, and slow response to visual stimuli. These pollutants can also affect hearing, speech, vision, and motor coordination (ATSDR, 1999a, 1999c, 2000a, 2007a, 2007b, 2010a).

Sulfur Dioxide (SO₂). Sulfur dioxide (SO₂) a gaseous air pollutant composed of sulfur and oxygen. The sulfur dioxide standard will help reduce this harmful pollutant, long recognized for its harm to health. Sulfur dioxide causes a range of harmful effects on the lungs, including wheezing, coughing, shortness of breath and chest tightness, and other problems, especially during exercise or physical activity. Continued exposure at high levels aggravates asthma, increases respiratory symptoms, and reduces the ability of the lungs to function. Short exposures to peak levels of SO₂ in the air can make it difficult for people with asthma to breathe when they are active outdoors. Rapid breathing during exercise helps SO₂ reach the lower respiratory tract, as does breathing through the mouth. SO₂ pollution increases the risk of hospital admissions or emergency room visits, especially among children, older adults, and people with asthma (EPA, 2009a). In addition, sulfur dioxide poses another threat to human health by reacting in the air to form sulfates (SO₄) which exist as aerosolized fine particulate matter (PM 2.5), another harmful air pollutant discussed below (EPA, 2009).

Nitrogen Oxides (NO_x). Nitrogen oxides (NO_x) are a class of gaseous air pollutants composed of nitrogen and oxygen. NO_x is emitted during the combustion of natural gas in engines, turbines, heaters, and boilers during production and processing operations for oil and gas wells. NO_x is also emitted during pit flaring of VOC emissions from well completions. The pollutant itself can inflame the airways and reduce lung function, worsened cough and wheezing, increase asthma attacks and hospital visits; and increase risk of respiratory infection (EPA, 2008). EPA's own review of the science found that exposure to NO_x can increase the risk of hospitalization by up to 20 percent (EPA, 2008). Nitrogen oxides are also precursors to nitrates (NO₃) which also are recognized as aerosolized fine particulate matter (PM 2.5) and discussed below. (EPA 2008)

Hydrogen chloride (HCl). Hydrogen chloride is a strong acid gas that reacts with moisture to form hydrochloric acid. Hydrogen chloride intensely irritates the mucous membranes of the respiratory system. At high concentrations, hydrogen chloride can cause swelling and spasms in the throat and suffocation. In addition, inhaled hydrogen chloride can lead to a chemical- or irritant-induced form of asthma called Reactive Airway Dysfunction Syndrome (RADS). (ATSDR, 2010b). Both hydrogen chloride and hydrogen fluoride can irritate the eyes, nasal passages, and lungs (EPA 2000a, 2000b).

Response: The EPA agrees that exposure to fine particles and hazardous air pollutants is associated with many adverse health effects and reducing exposure to these pollutants is associated with substantial public health benefits.

Comment Excerpt Number: 75

Comment: EPA's total claimed monetized benefit of \$27 billion to \$67 billion, of which \$25 billion to \$65 billion is due to the co-beneficial removal of SO₂ rather than the control of HAPs, should be reduced commensurately. Reducing the co-benefit attributable to SO₂ by a factor of between two and six would produce a more realistic monetized benefit of between \$4 billion and \$33 billion.

Response: We disagree that the estimated co-benefits of controlling SO₂ emissions should be reduced by a factor between 2 and 6. The SO₂ emissions reductions are based on actual SO₂ emissions reported by industry and contained in the Boiler MACT emission database. For units that did not report SO₂ emission test, average baseline emission factors were developed using data from other boilers and process heaters with similar controls, fuels, and combustor designs. The SO₂ emission reductions analysis for existing combustion units was done for each boiler and process heater in the major source inventory. Each combustion unit was assigned a unit-specific or average baseline SO₂ emission factor, depending on the availability of emission data reported for the unit. In the impact analysis, a combustion unit is required to install a scrubber for HCl control if it is not currently meeting the HCl floor limit, and if it doesn't already have a scrubber installed. For units required to install a scrubber, it was assumed that the scrubber will achieve a 95 percent reduction from baseline for SO₂. To calculate emission reductions for SO₂, baseline emissions were multiplied by a factor of 0.95. This resulted in the total SO₂ reductions used in the benefits analysis.

16B. Executive Order 13132, Federalism

Commenter Name: Tangela Niemann

Commenter Affiliation: Texas Commission on Environmental Quality (TCEQ)

Document Control Number: EPA-HQ-OAR-2002-0058-3594-A3

Comment Excerpt Number: 9

Comment: By mandating case-by-case review and approval of the emissions averaging plans in §63.7522 and the emission credit plans in §63.7533, the EPA is imposing requirements and additional work on the agencies tasked with enforcing these rules and the EPA must account for the fiscal impact. The fact that the EPA proposed these provisions by specifically stating the delegated authority must review and approve the plans indicates that the EPA fully intends for the states to perform this work. The additional work created by these case-by-case review requirements in the rule is above and beyond the resources necessary for the state to accept enforcement authority of the rule, and the EPA should have accounted for the impact to the state agencies in the fiscal analysis and regulatory impact analysis for 40 CFR 63 Subpart DDDDD. The TCEQ has found no such impact analysis regarding these requirements in the current proposal or with the March 21, 2011, adoption of the final rule.

In the preamble of the recently finalized utility NESHAP rule, 40 CFR 63 Subpart UUUUU, the EPA indicated that "While the EPA has not prepared an analysis of the impacts of the rule on state programs, the Agency does not believe the rule will be unduly burdensome to the state regulatory agencies." If the EPA did not analyze the impact of the utility NESHAP rule on state agencies, then the EPA has no basis for claiming it is not a burden on state agency resources. Since the EPA has not provided any analysis of the impact of these requirements on state agencies for 40 CFR 63 Subpart DDDDD, the TCEQ concludes that the EPA has made the same

assumption that the review and approval of the implementation plans is not a burden to the states. The EPA has an obligation to evaluate the impact of its regulations on the agencies that will be expected to implement the EPA's rules. State agencies do not have unlimited resources available to implement whatever requirements the EPA decides to include in its rules. The EPA cannot just assume its rules are not costly or burdensome to state environmental agencies as it did with the utility NESHAP rule. If the EPA has not considered the number of staff hours required to review and approve the implementation plans on a case-by-case basis, the possible total number of facilities requesting approval of emissions averaging and emission credit implementation plans, and the approximate cost to state agencies to perform these reviews, then the EPA does not know the burden it is imposing of the states.

Response: We agree that the EPA has an obligation to evaluate the impact of its regulations on the agencies that will be expected to implement the EPA's rules. We realize that State agencies do not have unlimited resources available to implement whatever requirements the EPA decides to include in its rules. We disagree that the EPA just assume its rules are not costly or burdensome to state environmental agencies. However, we did not considered the number of staff hours required to review and approve the implementation plans on a case-by-case basis, the possible total number of facilities requesting approval of emissions averaging and emission credit implementation plans, and the approximate cost to state agencies to perform these reviews. Based on similar comments from other State agencies, the final rule have been revised to remove the requirement mandating case-by-case review and approval of the emissions averaging plans in §63.7522 and the emission credit plans in §63.7533. In both sections, the requirement has been revised from "must ... submit to ... for review and approval.." to "submit upon request..." In both cases the source must still prepare the plan.

Commenter Name: Tangela Niemann

Commenter Affiliation: Texas Commission on Environmental Quality (TCEQ)

Document Control Number: EPA-HQ-OAR-2002-0058-3594-A3

Comment Excerpt Number: 10

Comment: While the TCEQ supports flexibility in regulatory implementation by providing options for compliance such as the emissions averaging approach, the rule provisions to implement these options should be designed as much as possible to allow for implementation without case-by-case review and approval. The EPA has revised the utility NESHAP rule emission averaging plan requirements to only require review and approval of the emissions averaging implementation plans upon request by the administrator and, as discussed elsewhere in these TCEQ comments, the TCEQ is requesting the EPA make the same change to the §63.7522 and §63.7533. If the emissions averaging option or the emission credit option cannot be implemented without a case-by-case review of each implementation plan, the EPA should reevaluate §63.7522 and §63.7533 to determine if revisions are necessary to ensure appropriate self-implementation or if the options should be removed from the final rule. If the mandatory case-by-case review of the implementation plans remains a requirement in the final rule, the EPA has an obligation to evaluate and disclose the impact that has on the state agencies.

Commenter Name: Myra Reece

Commenter Affiliation: South Carolina Department of Health and Environmental Control

Document Control Number: EPA-HQ-OAR-2002-0058-3629-A2

Comment Excerpt Number: 1

Comment: Emission Credits Earned From Implementation Of Energy Conservation Measures To Demonstrate Compliance With This Rule Cannot Be Effectively Implemented Or Enforced By Approving Implementation Plans

The emission credit compliance approach in Section 63.7533 requires facilities electing to use this compliance option to submit an “Implementation Plan” to the delegated authority for review and approval. The Implementation Plan shall identify all existing affected boilers to be included in applying the emission credits and include a description of the energy conservation measures implemented, the energy savings generated from each measure, and an explanation of the criteria used for determining savings.

There is no clear justification to require that the delegated agencies approve the Implementation Plans nor is there a clear explanation of its benefit in the preamble of the rule. A more efficient process would be requiring facilities electing this compliance option to submit the Implementation Plan requirements specified in Section 63.7533(d) within the Notification of Compliance Status (NOCS) required by Section 63.7545. While DHEC appreciates that it has been granted authority to administer the requirements under 40 CFR 632, it is clear that the EPA is not considering the additional burden the Implementation Plan approval process will pose to the already limited resources of delegated agencies and is downplaying the complexities of implementing and enforcing the emission credit compliance option.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3594-A3, excerpt 9.

Commenter Name: Myra Reece

Commenter Affiliation: South Carolina Department of Health and Environmental Control

Document Control Number: EPA-HQ-OAR-2002-0058-3629-A2

Comment Excerpt Number: 4

Comment: The EPA proposes to require facilities choosing to demonstrate compliance by the emission averaging option to submit an “Implementation Plan” for review and approval by the delegated authority. However, the EPA did not provide a clear process for implementing and enforcing this complex compliance option. We strongly request that the EPA eliminate the requirement for delegated authorities to approve implementation plans and instead develop an emission averaging certification mechanism within the Notice of Compliance Status (NOCS). The NOCS process is established, and states have experience implementing it.

As stated in our comment letters on the proposed Boiler and Utility MACT dated August 17, 2010 and July 20, 2011 respectively, DHEC received several implementation plans from facilities trying to comply with the vacated Boiler MACT in 2007. We encountered many problems with the approval process and received little help and guidance from the EPA. The EPA proposed the same approval process in this Boiler MACT reconsideration, disregarding the

known problems states faced in 2007 trying to implement the emission averaging compliance option in the vacated Boiler MACT.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3594-A3, excerpt 9.

Commenter Name: Myra Reece

Commenter Affiliation: South Carolina Department of Health and Environmental Control

Document Control Number: EPA-HQ-OAR-2002-0058-3629-A2

Comment Excerpt Number: 5

Comment: We believe that the requirement to establish an emission cap and submit an implementation plan to the permitting agencies for approval is problematic as written. Because the emission cap is not used in the initial compliance demonstration or in demonstrating continuous compliance with the emission averaging option, it is of little use.

If the intent of this option is for facilities to not exceed the cap at any time, then the EPA should include a demonstration methodology that shows that a facility is not exceeding the cap in the compliance equations in section 63.7522. If the cap is included in the compliance equations, facilities could certify compliance with the cap in the NOCS and within each required semiannual report. Additionally, if the initial and continuous compliance measures include the emission cap, the implementation plan will not be necessary and states will not have to spend valuable time and resources to approve these duplicative plans.

As stated previously, DHEC received several implementation plans from facilities trying to comply with the vacated Boiler MACT in 2007. We encountered many problems with the approval process and received little help and guidance from the EPA.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3594-A3, excerpt 9.

Commenter Name: Myra Reece

Commenter Affiliation: South Carolina Department of Health and Environmental Control

Document Control Number: EPA-HQ-OAR-2002-0058-3629-A2

Comment Excerpt Number: 6

Comment: Requirement For Delegated Agencies To Approve Implementation Plans Is Burdensome And Unnecessary. The EPA Should Provide Specific Guidance And Examples On What Constitutes An Acceptable Emission Cap.

The requirement to establish an emission cap and submit an implementation plan to the permitting agencies for approval is problematic as written. DHEC noted this issue in our comments for the 2010 proposed Boiler MACT. While the EPA attempted to correct the enforceability problem related to the emission cap in the final Boiler MACT by requiring facilities to report the emission cap in the NOCS (see 40 CFR 63.7545(e)(5)(i)), and certify compliance with the cap in the compliance reports (see 40 CFR 63.7550(c)(13)), there is no guidance or clear process on what constitutes an acceptable and enforceable emission cap that delegated agencies can follow to approve the cap.

If the EPA decides that the submittal and approval of implementation plans are necessary for the emission averaging compliance option, DHEC believes that the EPA should retain the authority to approve the implementation plans.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3594-A3, excerpt 9.

16D. Executive Order 13045, Protection of Children from Environmental Health Risks and Safety Risks

Commenter Name: Janice E. Nolen

Commenter Affiliation: American Lung Association

Document Control Number: EPA-HQ-OAR-2002-0058-3679-A2

Comment Excerpt Number: 5

Comment: Children face quite different risks from air pollutants than adults. The lungs and their alveoli are not fully grown until children become adults (Dietert et al., 2000). Biological defenses that help adults fight off infections are still developing in young bodies (WHO, 2005). Furthermore, children don't behave like adults, and their behavior also affects their vulnerability. They are outside for longer periods and are usually more active when outdoors. Consequently, they inhale more polluted outdoor air than adults typically do (AAP, 2004). Toxic substances may put children more at risk than adults. For example, the California Environmental Protection Agency explored improved methodologies to determine susceptibility to carcinogens in utero and childhood after finding in 2001 that the existing approaches did not adequately reflect the risks to children. Their subsequent research found that the children generally display greater sensitivity to environmental carcinogens than did adults (CalEPA, 2009).

Response: Exposure to methylmercury is associated with substantial public health effects. For more information on the health effects associated with mercury, please consult <http://www.epa.gov/mercury>.

16F. Regulatory Flexibility Act as Amended by the Small Business Regulatory Enforcement Fairness Act (RFA) of 1996 (SBREFA), 5 U.S.C. 601 et Seq.

Commenter Name: Douglas A. McWilliams

Commenter Affiliation: American Municipal Power

Document Control Number: EPA-HQ-OAR-2002-0058-3685-A2

Comment Excerpt Number: 3

Comment: It Would Be Arbitrary for EPA to Ignore the Advice of the Small Business Advocacy Panel Given the Increased Stringency of the HCI Limits

The Regulatory Flexibility Act ("RFA") requires EPA to analyze the impacts of its rules on small entities (including small government entities) for rules that will have a significant impact on a substantial number of small entities. 7 To assist with this analysis, EPA convened the SBA Review Panel to recommend ways the Agency could alleviate the rule's impacts on small businesses and governments. The Small Business Advocacy Review Panel identified HBELs as *"the most important step* EPA could take to mitigate the serious financial harm the Boiler MACT

would otherwise inflict on small entities using solid fuels nationwide ... "8 All of AMP's generating members now anticipate needing controls to comply with the proposed HCI limits. Even the best-performing AMP member must now concede that fuel management may not be a sufficient strategy to meet an emission limit of 0.022 lb/mmBtu. Given the increased stringency of the HCI limit in the Proposed Rule, it is likely that many more entities would be forced to install controls than under the March 2011 rule.

EPA estimated a median compliance cost for small public entities of \$1.1 million, with cost-to-revenue ratios greater than 10 percent.⁹ EPA has estimated no change in costs for these entities, despite proposing more stringent emission limits on coal-fired units for nearly every pollutant. Furthermore, AMP provided EPA with additional cost information in the 2010 AMP Comments that demonstrated many entities will experience significantly higher annual costs. The City of Orrville and the City of Painesville have independently evaluated the cost of controlling HCI emissions at their coal-fired electric utilities and determined that the capital cost for a single unit would reach \$5-16 million, with annual operating costs between \$900,000 and \$1.2 million. The City of Painesville operates three boilers, and the City of Orrville operates four. These facilities would incur \$3-4 million in operating costs each year *for HCI control alone*.¹⁰ Many small entities will be unable to absorb these unnecessary costs and be forced to severely curtail or shutdown operations entirely. This would significantly hinder municipal utilities' ability to provide reliable electrical services to their communities, grid support during high demand periods to avoid brownouts, and quality work opportunities for local residents. Adopting MACT standards that force small entities to severely curtail or eliminate operations is contrary to the intent of Congress, which has stated that "MACT is not intended to . . . drive sources to the brink of shutdown." House REP. No. 101-490, Part 1 (1990) at 328. But that is precisely what will happen to small entities under the Proposed Rule unless changes are made.

[Footnote 7: 5 U.S.C. § 603.]

[Footnote 8: SBA REVIEW PANEL, FRNAL REPORT at 23 (emphasis added).]

[Footnote 9: Memorandum from Tom Walton to Brian Shrager, re: Regulatory Impact Results for the Reconsideration Proposal for National Emission Standards for Hazardous Air Pollutants for Industrial, Commercial, and Institutional Boilers and Process Heaters at Major Sources (Dec. 1, 2011). 10 This represents \$33,000 per customer in capital costs and an additional \$3,000 per customer for annual operating costs.]

Response: The EPA appreciates the concerns of the regulated small entities. During this rulemaking process we have incorporated several suggestions from the small business panel, and we made several changes in the March, 2011 final rule (76 FR 15608) to reduce the burden on all sources, including small entities. The EPA has maintained its consideration of small sources in the final rule. See the Final Regulatory Flexibility Analysis (FRFA) section of the Regulatory Impact Analysis (RIA) which has been prepared for this rule for further discussion of the impact on small entities.

Commenter Name: Douglas A. McWilliams
Commenter Affiliation: American Municipal Power

Document Control Number: EPA-HQ-OAR-2002-0058-3685-A2

Comment Excerpt Number: 6

Comment: EPA has articulated no legitimate reason for ignoring the advice of the SBA Review Panel, which was convened for the express purposes of helping EPA to analyze the impact of the Boiler MACT rule on small entities. The Panel 's recommendations are even more relevant now that EPA has proposed to reduce the HCI limit by an additional 30 percent. EPA did not adequately consider and analyze regulatory options to reduce the impact of the rule on small government entities as required by the RFA and UMRA, and has acted arbitrarily and capriciously in rejecting the SBA Review Panel's recommendations using meritless arguments.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3685-A2, excerpt 3 for discussion of impact on small entities.

Commenter Name: Douglas A. McWilliams

Commenter Affiliation: American Municipal Power

Document Control Number: EPA-HQ-OAR-2002-0058-3685-A2

Comment Excerpt Number: 8

Comment: Including a Health-Based Emission Limit Alternative for Small Entities Is Supported by the Record

AMP and numerous other commenters provided EPA with significant legal and factual support for including HBELs in the final rule, and demonstrated that EPA's concerns were unfounded. EPA has offered no legitimate justification for ignoring this data and refusing to adopt an HBEL. EPA's actions are even more problematic in light of the Proposed Rule, in which EPA has imposed even more stringent HCI limits than in the March 2011 rule. Municipalities have been hit particularly hard by the economic downturn, as federal and state money and local tax revenues have declined sharply since 2008. They face severe budget constraints that are driving difficult resource allocation choices. Congress gave EPA a tool to mitigate cost when relaxed limits are adequately protective, and EPA should use this tool to mitigate some of the burden on small entities and small governments. Given all of the data now before the Agency, it would be arbitrary and capricious for EPA to publish a final rule that sets HCI limits that are far more stringent than necessary to protect human health and the environment.

EPA could avoid this arbitrary and capricious finding and avoid violating the RFA by crafting an HBEL alternative for those units operated by qualifying small entities under the RFA. EPA has ample authority for adopting an HBEL for HCI, and doing so here would harmonize EPA's actions with the findings it made - and never refuted - in the 2004 Boiler MACT rule. If EPA is unwilling to include a blanket HBEL for HCI in the final rule, the rule should, at minimum, include a provision allowing small entities to petition for an HBEL on a site-specific basis. Because the petition process would be limited to small entities, the number of potential petitions would be limited to a manageable number. Site-specific evaluations would allow for an evaluation of potential cumulative impacts from nearby sources and provide sources an opportunity to demonstrate that they can adequately protect human health and the environment without wasting millions of dollars on unnecessary controls. Preserving the possibility of a site-specific HBEL through a petition process will provide necessary relief to small entities without

compromising human health or the environment and without necessitating a complete rewrite of the HCI standards in the final rule.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3685-A2, excerpt 3 for discussion of impact on small entities.

Commenter Name: Dan Bosch

Commenter Affiliation: National Federation of Independent Business (NFIB)

Document Control Number: EPA-HQ-OAR-2002-0058-3460-A2

Comment Excerpt Number: 1

Comment: NFIB's comments will focus solely on the cost and compliance burden these rules will impose on small businesses. We are greatly concerned that even though many emissions limits have been lowered and other improvements in flexibility have been made, these rules are simply too costly and complex for affected small businesses to comply without serious economic harm.

Regulation affects small businesses in a substantially different way than it does large businesses. When a large business needs to comply with a new regulation, it designates its regulatory compliance officer – or officers – with the task. These individuals know their way around regulatory technicalities that most lay persons do not easily understand.

For the small-business owner, there is no regulatory compliance officer. This burden falls squarely on the owner, who, more times than not, is responsible for everything from ordering inventory and hiring employees, to taking out the trash at the end of the day. And while they may be expert in their craft, comprehending regulations, formalizing plans for their implementation and filling out paperwork is an extremely burdensome exercise.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3685-A2, excerpt 3 for discussion of impact on small entities.

Commenter Name: Dan Bosch

Commenter Affiliation: National Federation of Independent Business (NFIB)

Document Control Number: EPA-HQ-OAR-2002-0058-3460-A2

Comment Excerpt Number: 2

Comment: Even beyond the significant time regulations take away from a small-business owner trying to make a living, the per-employee cost of regulation is significantly greater for small businesses. The U.S. Small Business Administration's Office of Advocacy released a study in 2010 that showed the smallest businesses – those with fewer than 20 employees – spend 36 percent more per employee per year complying with federal regulations¹. Alarming, that disproportionality increases to 364 percent when it comes to environmental regulation. These findings do not suggest that all regulation is bad or unnecessary, but rather clearly demonstrate that agencies need to take extra care to make sure their regulations are well-reasoned and flexible. Without such flexibility, the ability of small businesses to grow and create jobs is severely inhibited.

This regulatory scheme is among the most complex in recent memory and as such, the compliance burdens presented by these rules are vast. Small-business owners will need to spend significant time to attempt to understand these rules, make expenditures to expensive consultants to bring the facility up to compliance, and greatly increase the amount of time he or she spends on paperwork compliance. The result will have serious and harmful consequences for the small businesses forced to comply with these rules. [Footnote]

Comment Excerpt Number: 3

Comment: NFIB suggests that to improve these rules further, the EPA should adopt the suggestions the small-entity representatives provided the agency during the Small Business Advocacy Review

(SBAR) panel held in 2009. Though some of these suggestions have been proposed, such as additional subcategories for boilers, other recommendations have not been proposed that we believe would lessen the compliance burden for small businesses. These recommendations include:

- Allowing facilities meeting the SBA definition of a small business to have reduced and less frequent monitoring, testing and reporting requirements;
- Allowing facilities to use work practice standards rather than emission limits for additional pollutants;
- Adopting health-based compliance options in areas where there is no significant risk to nearby residents;
- Requiring annual boiler tune-ups as a way to improve boiler efficiency instead of emissions standards; and

Exempting area sources from Title V permitting requirements.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3685-A2, excerpt 3 for discussion of impact on small entities.

Commenter Name: Bart Sponsellar

Commenter Affiliation: Wisconsin Department of Natural Resources (DNR)

Document Control Number: EPA-HQ-OAR-2002-0058-3527-A1

Comment Excerpt Number: 2

Comment: Another major concern we have regards the intensity of compliance requirements for sources subject to emission limitations. We believe that with further work on the rule, costs

can be significantly reduced while achieving the same or better environmental improvement. Once again, we are especially concerned for small sources which contribute significantly less in emissions but are subject to the same intensity of compliance requirements — specifically annual performance testing.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3685-A2, excerpt 3 for discussion of impact on small entities.

16G. Paperwork Reduction Act

Commenter Name: John V. Corra, Director

Commenter Affiliation: State of Wyoming Department of Environmental Quality

Document Control Number: EPA-HQ-OAR-2002-0058-3435-A1

Comment Excerpt Number: 2

Comment: EPA has provided cost estimates for the annual monitoring, recordkeeping, and reporting burdens that companies and the Federal government will incur, as well as total yearly labor costs. No estimate of the associated burden on state and local governments was provided. Wyoming recommends that EPA estimate and report the additional burden that the reconsidered rules place on state and local governments. The evaluation should consider the development of staff expertise necessary to evaluate energy assessments, as well as the addition of staff resources needed to effectively review industry's annual monitoring, reporting and recordkeeping requirements.

Wyoming believes that EPA should also evaluate the permitting burden placed on states, as companies may need to make process modifications to be more energy efficient. Permitting entities with minor source authority, such as Wyoming, may be faced with additional permit applications to address equipment changes associated with improving energy efficiency, especially if the equipment modifications are beyond insignificant or like-kind replacement. Energy efficiency could also bring into question the applicability of Prevention of Significant Deterioration review for increased capacity, process optimization, or increased reliability that may not result in a permit but will require the facility, and possibly the permitting authority, to evaluate.

Response: The EPA appreciates the concerns related to the burden on state agencies. The Agency revised permitting provisions in the March, 2011 final rule notice (76 FR 15608) to reduce the burden on states. These revised permitting provisions have been retained in the final rule.

16I. Executive Order 12898, Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations

Commenter Name: Janice E. Nolen

Commenter Affiliation: American Lung Association

Document Control Number: EPA-HQ-OAR-2002-0058-3679-A2

Comment Excerpt Number: 2

Comment: The EPA estimates that 1.5 million boilers and 95 solid waste incinerators are in use throughout the United States (EPA, 2011b; EPA, 2011c). Boilers and process heaters comprise some of the most common industrial equipment, but they also provide heat and power to commercial buildings and institutions, such as churches, colleges and hospitals. Because boilers are so widely used, their toxic emissions can threaten local communities, especially lower income or minority communities that are often located closer to the larger industrial sources.

Response: "Nearness" to a source is not necessarily an indicator of greater "harm." However, we believe that the controls placed on these combustion units by this rule will substantially reduce emissions and will result in positive benefits to all those communities previously impacted by this source category. EPA expects that those who live nearest to sources that are impacted by this rule will benefit the most from the rule.

Commenter Name: Janice E. Nolen

Commenter Affiliation: American Lung Association

Document Control Number: EPA-HQ-OAR-2002-0058-3679-A2

Comment Excerpt Number: 7

Comment: Toxic Air Pollution Disproportionately Threatens Many Communities

Communities of color and poorer people also appear to face higher risk, underscoring the need to properly assess this margin of safety. Research indicates that minorities live in greater concentrations both in areas that do not meet federal air quality standards and in areas with above average numbers of air-polluting facilities (NAS, 1999). Both African Americans and Hispanics have been found to be more likely than Caucasians to live in areas with high levels of air toxics (Morello-Frosch and Lopez, 2006).

A study in Maryland found that the risk of cancer related to air toxics was greatest in areas with the largest African American population proportions and lowest among those with the smallest African American population proportions. In addition, the estimated cancer risk decreased for every 10 percent increase in the percentage of Caucasians living in an area. Having a low income also increased the risk among African Americans more so than among Caucasians (Apelberg BJ et al., 2005).

In Houston, Houston is home to one of the world's largest petrochemical complexes, researchers found that the risk of cancer in an area increased along with the proportion of the population that was Hispanic and as measures of social disadvantage increased (Linder et al., 2008).

Response: Because the final rule does not allow emission increases, the EPA has determined that the rule will not have disproportionately high and adverse human health or environmental effects on minority, low-income, or Tribal populations. This statement supports EPA's determination that it has complied with the terms of the Executive Order, which by its terms focuses on adverse impacts. The preamble to the March, 2011 final rule notice (76 FR 15608) discusses environmental justice issues more broadly by focusing on the demographic analysis that shows that that major source boilers are located in areas where minorities' share of the population living within a three-mile buffer is higher than the national average. For these same areas, the percent of the population below the poverty line is also higher than the national average. Because of the emissions reductions mandated by the final rule, EPA believes that the

beneficial effects from the rule will be larger for the average minority and low income American than for all Americans.

16Z. Other Executive Orders

Commenter Name: Susan J. Miller

Commenter Affiliation: Brick Industry Association (BIA)

Document Control Number: EPA-HQ-OAR-2002-0058-3530-A1

Comment Excerpt Number: 1

Comment: This proposal represents an ongoing practice by EPA of establishing a rulemaking without sufficiently reviewing and analyzing available information due to insufficient time and resources being allocated to this important project. The court orders that drive this unreasonable pace are, in part, self-imposed by the EPA. With these incredibly short time periods to review tremendous volumes of information, EPA has not allowed itself the ability to establish the rule based on “careful analysis” as required by Executive Order 13563. This order calls for:

...careful analysis of the likely consequences of regulation, including consideration of underlying science, or alternatives, of costs and benefits, and of simplified, harmonized, and flexible methods for achieving regulatory goals. Under the Executive Order, agencies may not proceed unless the benefits justify the costs (unless the law requires them to do so). In addition, agencies are required to maximize net benefits, to select the least burdensome alternatives, and to consider approaches that promote freedom of choice for the public.

A rush to regulate, without considering all alternatives, would be unacceptable during any economic conditions. However, as our nation continues to struggle to recover, this rush to over-regulate is inexcusable.

Response: We disagree with the commenter that this proposal represents an ongoing practice by EPA of establishing a rulemaking without sufficiently reviewing and analyzing available information due to insufficient time and resources being allocated to this important project. The proposal was due to the reconsideration of the March 2011 final rule initiated because of significant changes made to the final rule, based on *careful analysis of the likely consequences of regulation*, including consideration of underlying science, or alternatives, of costs and benefits, and of simplified, harmonized, and flexible methods for achieving regulatory goals, for which the public did not previously have an opportunity to comment. As was clearly present in the preamble to the March 2011 final rule, the benefits of the regulation clearly justify the costs. In the March 2011 final rule and in the reconsideration proposal, alternatives were developed and analyzed that provide more flexibility in complying with the standards at lower costs without reducing the benefits of the standards. Section 112 of the Clean Air Act mandates the minimum stringency (i.e., MACT floors) in establishing these standards.

Commenter Name: Susan J. Miller

Commenter Affiliation: Brick Industry Association (BIA)

Document Control Number: EPA-HQ-OAR-2002-0058-3530-A1

Comment Excerpt Number: 6

Comment: EPA is not unavoidably committed to one and only one particular approach to determining these standards. Executive Order 13563 dictates that alternatives be considered. EPA has ample discretion to make pragmatic choices that would appropriately balance EPA's responsibility to protect health and the environment with the Agency's (and the US Government's) need to protect and promote the productive capacity of the Nation.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3530-A1, excerpt 1.

Commenter Name: Dean C. DeLorey

Commenter Affiliation: The Amalgamated Sugar Company LLC (TASCO)

Document Control Number: EPA-HQ-OAR-2002-0058-3522-A1

Comment Excerpt Number: 12

Comment: Based on these comments and in accordance with Executive Order 13563, it is requested that the monitoring requirements be substantially reduced to only one source test per 5-year Title V Operating permit period.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3530-A1, excerpt 1, for discussion on Executive Order 13563.

The EPA disagrees with reducing the source testing requirements to be in accordance with Title V permit scheduling. Given the inherent operational and fuel variability of sources subject to the rule, it cannot be guaranteed that the results of one test will remain consistent over a period of five years.

Gas Specification

17A. Appropriateness of Gas Specification

Commenter Name: Dave Copeland, Manager, Air Quality, Corporate Safety and Environmental Services

Commenter Affiliation: Praxair Inc.

Document Control Number: EPA-HQ-OAR-2002-0058-3437-A2

Comment Excerpt Number: 1

Comment: Praxair supports that the rule now contains a mechanism for gases that are not natural gas nor refinery gas to be classified as an "other gas 1 fuel" as spelled out in 40 CFR 63.7521 (f). This is especially important because many of the gases that meet the definition of "other gas 1 fuel" are actually as clean as, if not cleaner than, natural gas/refinery gas. Regulating these types of gases under more stringent requirements than natural gas/refinery gas would unfairly place those gases at a competitive disadvantage and become a hindrance to the productive utilization of these gases as alternative fuels. For example, tail gas produced in hydrogen production process is similar to natural gas but would need to comply with the stringent limits of the "gas 2 fuel" category if not for this option. In a brief summary, tail gas is what is left over in the steam methane reforming (SMR) process used to make hydrogen from natural gas. Natural gas is fed into the SMR along with steam and broken down into methane,

CO, CO₂, nitrogen and hydrogen. The majority of the hydrogen is removed as a product and the remaining material is tail gas, which is fed back to the SMR as a fuel to heat the reaction. This tail gas, which is derived from natural gas, is a clean burning fuel, comparable to natural gas, and it is very appropriate for it to be regulated similar to natural gas rather than as "gas 2 fuel".

Response: The EPA thanks the commenter for their support.

Commenter Name: Elizabeth McMeekin

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 24

Comment: Comments on subcategories and definitions associated with subcategorization.

A. The proposed "other gas 1" fuels specification is technically sound and appropriate.

As we pointed out in detail in our comments on the June 4, 2010 proposal, with very limited exceptions, the technical data developed by EPA indicate no HAP emission basis for treating gas 1 and 2 differently and the combined gas category should have only design or work practice standards, since establishing and enforcing an emission limitation for gas-fired BPH is not feasible.

In the preamble to the current proposal, EPA reports its reanalysis essentially reached the same conclusions as the original analysis. Thus, the proposal to treat all gases with mercury levels below 40 micrograms/cubic meter the same as natural gas and refinery gas is technically sound and defensible. All gases combust similarly and thus the fuel mercury level is the only variable that would be an indicator of potential health concerns. Hydrogen sulfide level, which was also included as a criterion in the March 21, 2011 final rule, is not related to the production of HAPs in the combustion process and thus is not a technically appropriate surrogate for HAP emissions. EPA is therefore correct in removing H₂S as an "other gas 1" criterion.

Since gases combust with very low levels of HAP emissions, the overwhelming majority of those emissions are below the level that can be accurately quantified by the available test methods and thus application of a design or work practice standard is appropriate and compliant with section 112(h) of the CAA.

Response: The EPA thanks the commenter for their support.

Commenter Name: Richard Krock
Commenter Affiliation: The Vinyl Institute
Document Control Number: EPA-HQ-OAR-2002-0058-3526-A1
Comment Excerpt Number: 8

Comment: The VI continues to support EPA's proposal to allow other fuels to qualify as Gas 1 fuels subject to work practice standards instead of emission limits.

Response: The EPA thanks the commenter for their support.

Commenter Name: Peter Pagano
Commenter Affiliation: American Iron and Steel Institute (AISI)
Document Control Number: EPA-HQ-OAR-2002-0058-3490-A1
Comment Excerpt Number: 15

Comment: Sections pertaining to the gas 1 fuel specification analysis should be amended to give process gases/coke oven gases a fair opportunity to be considered gas 1 fuels.

Gaseous fuels that qualify as "other gas 1 fuels" are given preferential treatment under the Boiler MACT. Indeed, operators of gas 1 units (*i.e.*, boilers or process heaters that burn fuels considered "clean", namely natural gas, refinery gas, or other gas 1 fuels) have only to comply with work practice standards and regular tune-ups instead of emissions standards. Qualifying as a gas 1 unit is, therefore, an important undertaking for affected sources. While we strongly believe the iron and steel industry should be exempt from the Boiler MACT altogether, we provide the following comments in support of changes to the gas 1 fuel specification analysis to ensure that steel industry process gas have a fair opportunity to be considered for gas 1 treatment.

Response: Sources that are burning coke oven gas or other process gases (other than blast furnace gas or process gases regulated under another subpart of part 63, or part 60, part 61, or part 65) may qualify as a unit designed to burn gas 1 if the gaseous fuels demonstrate compliance with the mercury fuel specification.

Commenter Name: Peter Pagano
Commenter Affiliation: American Iron and Steel Institute (AISI)
Document Control Number: EPA-HQ-OAR-2002-0058-3490-A1
Comment Excerpt Number: 21

Comment: The data suggest that the distinction between gas 1 and gas 2 is not material to the control of HAP emissions. Therefore, EPA should collapse the distinction and allow all gas-fired units to meet the work practices designed to ensure proper combustion. Alternatively, the data support a mercury threshold significantly higher than 40 ug/m³ and, based upon available objective literature, possibly as high as 440 ug/m³.

Response: For a response to the request for all process gases to be given the opportunity to be treated as an other gas 1 fuel, please see comment EPA-HQ-OAR-2002-0058-3490-A1, excerpt 15. EPA disagrees that the distinction between gas 1 and gas 2 should be removed. An analysis was conducted on the gaseous fuel analysis data reported to EPA, the results of which show that

mercury levels in natural gas are approximately equivalent to 40 micrograms per cubic meter. Similar analyses on additional gaseous fuel types show mercury levels much higher than 40 micrograms per cubic meter. Therefore, EPA has retained the gas 1 and gas 2 distinctions in the final rule, as well as the 40 microgram per cubic meter specification required for classification as an other gas 1 fuel. Further, the commenter has provided no information to support the findings required by section 112(h) as a prerequisite to establishing work practice standards in lieu of numeric emissions limits.

Commenter Name: Peter Pagano

Commenter Affiliation: American Iron and Steel Institute (AISI)

Document Control Number: EPA-HQ-OAR-2002-0058-3490-A1

Comment Excerpt Number: 22

Comment: An appropriate and approved testing methodology currently does not exist for process gases. Those methodologies enumerated in Table 6 of the Reconsidered Rule have not been verified as accurate for any fuel other than natural gas. Although the rule allows "equivalent" methodologies be used, EPA must clarify which test methodology is approved for the iron and steel industry to use in testing process gases.

Response: EPA has provided an alternative method for testing other gases at the outlet of the boiler or process heater using traditional stack-test based methods that will work on gases from the iron and steel industry. The affected source can also petition the EPA for alternative methods.

Commenter Name: James Pew

Commenter Affiliation: Earthjustice, Clean Air Council, Partnership for Policy Integrity

Document Control Number: EPA-HQ-OAR-2002-0058-3511-A1

Comment Excerpt Number: 41

Comment: In its final rule, EPA now allows some units burning "other process gases" (Gas 2 Units) to substitute work-practice standards for the numeric standards applicable to other such units. 76 Fed. Reg. at 15,639. The units escaping numeric standards need only demonstrate that the gases burned "have levels of H₂S and Hg that are no higher than those found in Gas 1 units." EPA's decision to set work practice standards instead of numeric emission standards for Gas 2 Units is unlawful and arbitrary for all the reasons that its decision to set work practice standards for natural gas units was unlawful and arbitrary. Accordingly, all the comments on the proposed subcategories made in the Comments (Comments at 42-48) are incorporated by reference as if fully stated herein and reiterated with respect to Gas 2 Units.

EPA has not shown and the record does not suggest that the presence of other HAP in the fuel burned necessarily correlates with the presence of H₂S and Hg. Nor has the agency demonstrated that it is not feasible to prescribe or enforce emission standards for Gas 2 units. Indeed, EPA has set numeric standards for Gas 2 units, it just chooses to exempt some of them from compliance by means of allowing them to meet a work practice standard instead. EPA's policy goal of allowing some Gas 2 units to meet work practice standards instead of emission standards does not suffice. Absent a showing that it would be infeasible to prescribe or enforce emission standards for Gas 2 units – a showing that appears nowhere in the record – setting work practice standards for these units is unlawful. And, assuming arguendo that EPA has placed

some rationale for its work practice standards for Gas 2 units somewhere in the record, the agency's decision is nonetheless unlawful and arbitrary and capricious for the reasons given in the 2010 Comments, which are incorporated by reference as if fully stated herein, and above.

Response: As discussed in the March 2011 final rule, the EPA determined that it is not feasible to prescribe numerical emissions standards for Gas 1 units because the application of measurement methodology is not practicable due to technological and economic limitations. Therefore, the EPA is finalizing the work practice standards for Gas 1 units. The measured emissions from these units are routinely below the detection limits of EPA test methods, and, as such, EPA considers it impracticable to reliably measure emissions from these units. Even CO was below the level EPA considers to be a reliable measurement. The case for other pollutants was even more compelling as the majority of measurements are so low as to cast doubt on the true levels of emissions that were measured during the tests. Overall, the available test methods are greatly challenged, to the point of providing results that are questionable for all of the pollutants, when testing natural gas units. Because of these technological limitations that render it impracticable to measure emissions from Gas 1 units, EPA was also unable to establish the actual performance of the best performers as well as sources outside of the top performing 12 percent. The inability to accurately measure emissions from Gas 1 units and the related economic impracticability associated with measuring levels that are so low that even carefully conducted tests do not accurately measure emissions warrant setting a work practice standard under CAA section 112(h).

It was also discussed in the March 2001 final rule preamble that several comments requested that the Gas 1 subcategory be expanded to include gases similar to natural gas and refinery gas. One of the commenter stated that pilot scale and field data studies have concluded that emissions of organic HAP from gaseous fuels are not significantly affected by fuel type. Another commenter submitted combustion properties of refinery gas and petrochemical gas in order to show that they are very similar in composition and should be categorized with natural gas in the Gas 1 category. Based on the information submitted, the EPA determined that to the extent that process gases are comparable to natural gas and refinery gas, combustion of those gases in boilers and process heaters should be subject to the same standards as combustion of natural gas and refinery gas. Boilers that combust other gaseous fuels that have comparable emissions levels to Gas 1 units are similar in class and type to Gas 1 units because they share common design, operation, and emissions characteristics. Therefore, we provided a mechanism by which units that combust gaseous fuels other than natural gas and refinery gas can demonstrate that they are similar to Gas 1 units and therefore be subject to the standards for Gas 1 units. Since the combustion-related pollutants are similar from the various types of gaseous fuel, the fuel related HAP of concern is mercury. Therefore, the EPA believe it is appropriate to base such a demonstration on levels of mercury content in the gases.

We believe that this provision provides the benefit for recovering the waste heat from these offgases. Commenters argue that installation of controls will be prohibitively expensive and thus sources will flare the offgas, instead of burning in a boiler to recovery its energy, and replace it with natural gas.

Commenter Name: Paul Noe

Commenter Affiliation: American Forest & Paper Association (AF&PA) et al.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 133

Comment: EPA should clarify that mixed gas fuels should be evaluated as combusted to determine whether the gaseous fuel meets the Gas 1 mercury criterion. Many industrial sources mix a process gas with natural gas to ensure a high enough heat rate to sustain a stable flame in the combustion unit. The individual gas streams may come from a number of different vessels that are captured and evacuated to a common gas main. It would be impractical to measure each of these individual source streams. That mixed gas is then combusted with natural gas or other process gas fuels to achieve the right Btu value for efficient combustion. EPA should clarify that the mercury concentration used to determine Gas 1 status is based on the mixture of gaseous fuel(s) as they are combusted. Companies should also have the flexibility to either sample the mixed gas before the combustion chamber or, if more convenient, sample the constituent gas streams and calculate the mercury concentration based on an equation that considers the volume of each gas contributed to the combustion chamber. The mercury content of the fuel as it is combusted is the only number relevant to the control of HAP emissions.

Response: The fuel spec was finalized in March as intended, which was based on a test of individual fuel types. Since natural gas and process gases are two different fuel types, the specification finalized by EPA in this rule remains the same as March and ensures that only those gaseous fuels that are as clean as natural gas or refinery gas, via the fuel specification requirements, qualify for work practices. This approach is consistent with the subcategorization in the final rule which does not allow units co-fire natural gas with coal or other fuel types and qualify for a work practice in lieu of numeric emission limits, even if their blended gas stream is consistent with emission levels of natural gas, refinery gas, or other gas 1 fuels. To qualify for a work practice under Section 112(h) of the CAA EPA must conclude that one of the criteria in section 112(h)(2) are met, e.g., that the application of measurement methodology is not practicable due to technological and economic limitations. It is possible to extract other gaseous fuel types for analysis of mercury emissions prior to mixing with natural gas in order to demonstrate that the fuel is comparable to other gas 1 fuel types. Therefore, the EPA has not changed the measurement location of fuel specification in the final rule.

Commenter Name: Peter Pagano

Commenter Affiliation: American Iron and Steel Institute (AISI)

Document Control Number: EPA-HQ-OAR-2002-0058-3490-A1

Comment Excerpt Number: 23

Comment: The definition of "fuel type" must be amended to clarify that process gases mixed with other fuels constitute a single fuel type that should be evaluated "as combusted" to determine its mercury content. Under the current Reconsidered Rule, if both coke oven gas and blast furnace gas fuel a boiler, it is not clear if the operator must separately test the coke oven-gas stream and the blast furnace gas stream or if the combined gas stream entering the boiler must be tested. The rule should clarify that the operator must determine the mercury content of the mixed gas stream to evaluate whether it is a gas 1 fuel. This would also be consistent with the current practice of some iron and steel facilities that employ fuel mixing stations where gaseous fuel (including coke oven gas, blast furnace gas, and natural gas) is mixed to obtain the desired heat value prior to being beneficially reused and combusted in boilers and process heaters. If the

use of process gases determines whether a unit is regulated under the Boiler MACT, how process gases are treated as a fuel type needs to be clarified.

Response: See the response to comment EPA-HQ-OAR2002-0058-3521-A1, excerpt 133. As a result of this determination the EPA has not changed the definition of fuel type for process gases.

Commenter Name: Peter Pagano

Commenter Affiliation: American Iron and Steel Institute (AISI)

Document Control Number: EPA-HQ-OAR-2002-0058-3490-A1

Comment Excerpt Number: 24

Comment: It is the fuel mixture used to fuel the boiler that should be tested and then only at the point of combustion where feasible. As noted above, in iron and steel manufacturing, coke oven gas has multiple purposes. Approximately forty percent of the coke oven gas is sent back to the coke oven as fuel to underfire the ovens. The remainder is distributed elsewhere in the plant wherever fuel or heat is needed. Depending on the type of boiler and its required heat input, different mixtures of fuels are used. Coke oven gas often is supplemented in boilers by natural gas, fuel oil, or blast furnace gas, among others, to optimize heat input and efficient combustion. It is the fuel mixture, not its individual constituents, that determines a boiler's mercury emissions³⁵ Therefore, compliance with a gas 1 specification should be determined by analysis of the fuel mixture as combusted.

[Footnote]

(35) EPA recognizes this fact in its preamble and in its reciprocal output-based regulations corresponding to the input-based (*i.e.*, fuel-based) regulations. *See* 76 Fed. Reg. at 80,607, 80,642.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3490-A1, excerpt 23.

Commenter Name: Peter Pagano

Commenter Affiliation: American Iron and Steel Institute (AISI)

Document Control Number: EPA-HQ-OAR-2002-0058-3490-A1

Comment Excerpt Number: 25

Comment: A process gas fuel mixture should constitute a "fuel type" under section 63.7575. Currently, the Boiler MACT muddies the concept. The preamble states that to demonstrate compliance with mercury emission limits by fuel analysis, the mercury content of the "inlet fuel" must be evaluated. Section 63.7521 (a) states, "For purposes of complying with this section, a fuel gas system that consists of multiple gaseous fuels collected and mixed with each other is considered a single fuel type. We think this is the correct approach for all fuel mixtures and is consistent with the current practice of optimizing the use of fuels based upon their heat content. Nevertheless, both of these provisions lead to the conclusion that the mixed fuel is to be tested, not its individual components. The problem is further complicated, however, when considering the definition of "fuel type," stating that a fuel type is each category of fuels that share a common name or classification, such as bituminous coal, sub-bituminous coal, lignite, anthracite, biomass, and residual oil. This definition should be clarified to ensure that process gases sent to

boilers qualify as a fuel type and to ensure that mixed gaseous fuels are to be tested in the mercury fuel specification analysis as combusted. This can either be accomplished by testing the mixed fuel or by testing two or more contributing gas streams and calculating the as-combusted mercury content. The preamble should contain clarifying language to this point.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3490-A1, excerpt 23.

17B. Subcategories: Specification Used to Determine Gas 1 Category Typical of NG and RFG

Commenter Name: Matthew Todd

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 20

Comment: Streams directly derived from natural gas during its initial processing should be presumed to be "other gas 1".

Natural gas, as described in paragraph 1 of the proposed definition⁵, must be separated from oil, production water, and solids and adjusted to pipeline specifications in production batteries and in natural gas plants. Additionally, intermediate gas streams (i.e., gas streams that are separated from the hydrocarbon/water mixture removed from the ground that do not yet meet the pipeline quality natural gas specifications) are combusted in BPH at the production site or the gas plant. Since natural gas is gas 1 by definition, the gas streams derived directly from natural gas should also be considered gas 1. Thus we recommend that gas streams derived from natural gas at the production site or gas plant be identified as "other gas 1" and that mercury testing be waived.

Specifically, we recommend addition of a paragraph (4) to §63.7521(f) as follows.

(4) You are not required to conduct the fuel specification analyses in paragraphs (g) through (i) of this section for gas streams directly derived from natural gas at natural gas production sites or natural gas plants. [Footnote 5: (1) A naturally occurring mixture of hydrocarbon and non-hydrocarbon gases found in geologic formations beneath the earth's surface, of which the principal constituent is methane; or]

Response: We agree with the commenter that any derivatives of natural gas are considered natural gas and are therefore Gas 1. In the final rule §63.7521(f) has been revised to add paragraph 4 as follows.

(4) You are not required to conduct the fuel specification analyses in paragraphs (g) through (i) of this section for gas streams directly derived from natural gas at natural gas production sites or natural gas plants.

17C. Subcategories: Specification Used to Determine Gas 1 Category (Removal of H2S)

Commenter Name: Felix Mestey, on behalf of Donald R. Schregardus

Commenter Affiliation: Clean Air Act Services Steering Committee, Department of Defense (DoD)

Document Control Number: EPA-HQ-OAR-2002-0058-3427

Comment Excerpt Number: 20

Comment: EPA correctly reexamined the fuel specification and concluded that H2S is not directly related to potential HAP emissions from boilers and process heaters. This proposed change will increase the use of landfill gas, which is often burned off by flaring, as a boiler/process heater fuel. Recent studies at one military installation indicated that landfill gas would not meet the definition of Gas 1 fuel and thus could not be used in existing boilers unless new emission controls for gas 2 fuel units were installed. Including the H2S limit in the definition of other gas 1 fuel in the final rule that was issued on March 21, 2011 made the use of landfill gas at this facility cost-prohibitive.

Recommendation

DoD supports EPA's proposal to eliminate H2S in the definition of other gas 1 fuel and remove related H2S fuel analysis requirements.

Response: The EPA thanks the commenter for their support.

Commenter Name: William C. Herz

Commenter Affiliation: The Fertilizer Institute (TFI)

Document Control Number: EPA-HQ-OAR-2002-0058-3448-A1

Comment Excerpt Number: 6

Comment: In the final *Industrial Boiler Major Source NESHAP* and Proposed Rule, EPA allows entities to demonstrate that process gases are comparable to natural gas and refinery gas and, therefore, that units combusting these gases are subject to the standards for Gas 1 units (referred to as "other gas 1 fuel"). TFI supports this flexibility, generally, and the proposed deletion of a hydrogen sulfide standard in the Proposed Rule, in particular.

As EPA may be aware, a typical ammonia plant uses desulfurized natural gas as both a process gas and a fuel gas. Some of the process gas containing unreacted methane is purged from the ammonia loop section and routed back to the primary reformer where it is burned with incoming desulfurized natural gas as fuel. This purge gas does not contain sulfur because the feed to the reformer is desulfurized natural gas, therefore, there is no need to perform testing to determine the hydrogen sulfide concentration.

Response: The EPA thanks the commenter for their support.

Commenter Name: Angela D. Marconi

Commenter Affiliation: Delaware Solid Waste Authority (DSWA)

Document Control Number: EPA-HQ-OAR-2002-0058-3545-A2

Comment Excerpt Number: 3

Comment: DSWA is pleased that the reconsideration has eliminated the unreasonable hydrogen sulfide (H₂S) limit of 4 ppm that was present in the March 21, 2002 publication. Use of H₂S in this respect is inappropriate because H₂S is neither a hazardous air pollutant (HAP) nor a HAP surrogate. Additionally, imposing this limit on "gas 2" fuels is not warranted because some "gas 1" fuels are not able to meet this requirement (such as some varieties of RG). Although removal of the H₂S limit is helpful, DSWA still recommends classifying LFG as a "gas I".

Response: The EPA thanks the commenter for their support.

Comment Excerpt Number: 10

Comment: Alternatively, if EPA does not qualify landfill gas as Gas 1, CIBO supports the mechanism for a unit to demonstrate its fuel specifications enable it to qualify for Gas 1 treatment. CIBO supports the removal of the H₂S fuel specification from this demonstration mechanism because H₂S is not related to potential hazardous air pollutants that will be emitted from combusting gaseous fuels. 76 FR at 80,609.

Response: The EPA thanks the commenter for their support.

Commenter Name: Robert D. Bessette

Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 27

Comment: CIBO supports the EPA's proposal to drop H₂S fuel specifications, for the purpose of regulating a source under Gas 1 standards as opposed to Gas 2 standards, from the proposed Reconsideration Rule. 76 Fed. Reg. 80,609. In its Petition for Reconsideration, CIBO stated that "[s]ince H₂S . . . has limited relevance to HAP emissions other than partial conversion to SO₂, its selection as a Gas 2 to Gas 1 qualifier seems to be arbitrary." In its Reconsideration Rule, EPA agreed that "the key contaminant for demonstration of comparability from a HAP perspective is Hg and that the H₂S fuel specification that was finalized does not provide a direct

indication of potential HAP from combustion of gaseous fuel. Accordingly, the EPA is proposing a fuel specification based only on the Hg level in the gaseous fuel . . ." 76 Fed. Reg. 80,609 (2012 Reconsideration Rule). CIBO supports this proposal.

Response: The EPA thanks the commenter for their support.

Document Control Number: EPA-HQ-OAR-2002-0058-3501-A1

Comment Excerpt Number: 4

Comment: With respect to the inclusion of a gaseous fuel specification based only on Hg level in the gaseous fuel EPA is correct in realizing that emissions data for natural gas-fired units show the overwhelming majority of emissions to be below the level that can be quantified by available test methods and in applying that understanding to units combusting other gases with contaminant levels similar to natural gas.

Response: The EPA thanks the commenter for their support.

Commenter Name: Kerry Kelly

Commenter Affiliation: Waste Management (WM)

Document Control Number: EPA-HQ-OAR-2002-0058-3681-A2

Comment Excerpt Number: 12

Comment: Although EPA has created a fuel specification for "other Gas 1 fuels" by which LFG and other gases may qualify for Gas 1 regulatory treatment, as proposed in the Boiler MACT Reconsideration Rule, the fuel specification does not provide a viable avenue by which LFG

combustion in industrial boilers would be relieved of the regulatory burdens associated with unnecessarily stringent emission limits, sampling and testing. While problems exist with the fuel specification as proposed, WM commends the Agency and supports its proposed removal of the inappropriate hydrogen sulfide (H₂S) limit from the Gas 1 fuel specification. In the preamble to the proposed Boiler MACT Reconsideration Rule, EPA explains that:

“EPA has reexamined the fuel specification and agrees that the key contaminant for demonstration of comparability from a HAP perspective is Hg and that the H₂S fuel specification that was finalized does not provide a direct indication of potential HAP from combustion of gaseous fuel. Accordingly, the EPA is proposing a fuel specification based only on the Hg level in the gaseous fuel, and that level is the same level that the EPA included in the March 2011 final rule.”

Waste Management agrees with the Agency’s conclusion that use of an H₂S limit is not an appropriate indicator of potential HAP emissions. As discussed above, WM contracted with CH2M Hill to conduct a comparison of the emissions properties of boilers firing LFG as fuel to those of boilers firing Gas 1 fuels, and to examine the publicly available information to compare LFG to Gas 1 fuels, specifically natural gas and refinery gas. [See submittal for report in Attachment 3] In this report, CH2M Hill noted that EPA based its fuel specification in the March 21, 2011 rule on sweetened, pipeline-quality natural gas. However, refinery gas, the other named Gas 1 fuel, typically contains much higher levels of H₂S than the Gas 1 fuel specification in that rule. CH2M Hill evaluation found that the H₂S concentrations in refinery gas can range from 0 to 450,000 ppm. Based on this data evaluation, WM asserted that LFG should not be held to a higher H₂S standard than refinery gas for qualification as a Gas 1 fuel. We also commented that as H₂S is not a HAP, nor a HAP precursor, nor a surrogate for HAP emissions, it is therefore an inappropriate limit to use in a demonstration of comparability for HAP emissions. While we commend EPA for correcting its Gas 1 fuel specification related to the H₂S limit, we continue to believe that the Boiler Reconsideration Rule, as proposed, creates a significant disincentive to using LFG as an alternative, renewable fuel. Our primary concern with the fuel specification is that despite the proposed correction to remove the H₂S limit from use as a demonstration of comparability, the Gas 1 fuel specification requirements are still unworkable and burdensome. The requirements preclude its use as a viable mechanism for boiler owner/operators or fuel suppliers to demonstrate fuel comparability with the two designated Gas 1 fuels.

Response: The EPA thanks the commenter for their support of the removal of the H₂S limit from the gas 1 fuel specification. The EPA disagrees that the remaining aspects of the gas 1 fuel specification are unworkable and burdensome or that the rule creates a disincentive for the combustion of landfill gas. If landfill gas can meet the Hg fuel specification, it can qualify as other Gas 1 in the same manner as other gaseous fuels.

17D. Subcategories: Specification Used to Determine Gas 1 Category (Rationale for Hg and Hg Level Selected)

Commenter Name: Peter Pagano

Commenter Affiliation: American Iron and Steel Institute (AISI)

Document Control Number: EPA-HQ-OAR-2002-0058-3490-A1

Comment Excerpt Number: 18

Comment: The Gas 1 fuel mercury specification analysis should be amended.

To demonstrate that a fuel qualifies as another gas 1 fuel, an operator must test "a single fuel sample for each fuel type" and verify it contains less than 40 ug/m³. We question this analysis in three key areas: (1) the mercury concentration limit of 40 ug/m³ for other gas 1 fuels, (2) the concept of a "fuel type," and (3) sampling requirements.

First, we question the basis by which EPA established the 40 ug/m³ concentration limit for clean fuels and suggest that a higher threshold be used. The Boiler MACT touts natural gas as the preeminent clean fuel and uses its pollutant concentrations as benchmarks for determining whether other fuels similarly qualify. While AISI does not question that natural gas is a clean fuel and, in fact, supports the work practice standards for natural gas-fired units, EPA appears to have inappropriately derived the 40 ug/m³ concentration from a letter dated January 2011 appearing in the docket.³⁰ The letter details a 40 ug/m³ mercury content in natural gas from a quantity supplied by "Calgon Carbon Corporation", who is a supplier of mercury control technology. The Calgon material cited in the letter in fact was company literature. This information does not qualify as an objective or scientific data source to characterize the level of mercury in U.S. natural gas supplies, nor do we think that Calgon intended it to be used for those purposes. Moreover, while mercury can and is commonly removed from natural gas supplies, that is not always the case. In reality, not all natural gas even meets the 40 ug/m³ limit.

[Footnote]

(30) Comment submitted by James Santory, Director, Environmental Health and Safety, Calgon Carbon Corporation, EPA-HQ-OAR-2002-0058-2956. *See also* EPA's Response to Public Comment's on EPA's National Emission Standards for Hazardous Air Pollutants for Major Source Industrial Commercial Institutional Boilers and Process Heaters, EPA-HQ-OAR-2002-0058-3289, at 288.

Response: The EPA disagrees that the source of the 40 microgram per cubic meter mercury fuel specification limit is not objective or scientific. While we agree that HAP concentrations in gaseous fuels can and do fluctuate, we believe that the 40 microgram per cubic meter limit is appropriate. Uncontrolled mercury emissions data provided for natural gas combustion show, when converted back to a fuel concentration using a Method 19 fuel factor, that all of the natural gas combusted was below the 40 microgram per cubic meter threshold for mercury content.

Commenter Name: Peter Pagano

Commenter Affiliation: American Iron and Steel Institute (AISI)

Document Control Number: EPA-HQ-OAR-2002-0058-3490-A1

Comment Excerpt Number: 19

Comment: Scientific data on this subject actually suggests that a much higher content threshold is appropriate. Mercury content in natural gas varies depending on where it is captured.³¹ For example, mercury concentrations for Midwest and Eastern U.S. pipeline natural gas can be as high as 100 and 440 ug/m³, respectively, well above the specification in the definition. Another study in the literature lists the mercury concentrations for Midwestern and Eastern U.S. pipeline natural gas ranging between 1 to

100 ug/m³ and 19 to 440 ug/m³, respectively³²

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 10

Comment: EPA should examine the 40 µg/m³ mercury criteria for process gases to qualify as Gas 1. As stated in the detailed comments being submitted by the American Coke and Coal Chemicals Institute (ACCCI), there are several regions where natural gas has a higher mercury content than 40 µg/m³. The threshold neither represents natural gas mercury content nor constitutes a specification for the natural gas industry.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3490-A1, excerpt 18.

Commenter Name: Paul Noe

Commenter Affiliation: American Forest & Paper Association (AF&PA) et al.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 132

Comment: We question using a mercury content of 40 µg/m³ as the criterion to determine Gas 1 eligibility. The mercury specification should properly reflect all available data indicating the highest measured concentrations in natural gas and refinery gas, the two gaseous fuel types that EPA has declared "clean gas." Data provided by ACCCI and AISI in their comments indicate that mercury concentrations are found in natural gas well above the 40 µg/m³ threshold that EPA uses in the rule to define "clean gas."

Response: See the response to comment EPA-HQ-OAR-2002-0058-3490-A1, excerpt 18.

Commenter Name: Shannon S. Broome

Commenter Affiliation: Auto Industry Forum (AIF)

Document Control Number: EPA-HQ-OAR-2002-0058-3512-A1

Comment Excerpt Number: 20

Comment: *If EPA Persists in Listing Landfill Gas in the Gas 2 Category and Subjecting It to the Demonstration Mechanism, EPA Should Still Make a Categorical Determination to Automatically Classify Landfill Gas as an "Other Gas 1 Fuel."*

As noted above, LFG is equivalent to Gas 1 fuels NG and RG in the relevant emission measures, abundant data show Hg levels for LFG as consistently, substantially below the “other Gas 1 fuel” specification limit for Hg, and compelling policy reasons support classifying LFG as a Gas 1 fuel. If, however, EPA fails to list LFG in that category and, instead, persists in listing LFG as a Gas 2 that can qualify for the Gas 1 category only through the demonstration mechanism, then EPA should make a categorical determination that LFG qualifies as an “other Gas 1 fuel.” AIF, therefore, recommends EPA modify § 63.7521(f) as follows:

To demonstrate that a gaseous fuel other than natural gas or refinery gas qualifies as an other gas 1 fuel, as defined in § 63.7575, you must conduct a fuel specification analysis for mercury . . . except as specified in paragraph (f)(1) through (3) of this section.

(1) You are not required to conduct the fuel specification analyses in paragraphs (g) through (i) of this section for natural gas, or refinery gas or landfill gas.

Boiler MACT Reconsideration Proposal, 76 Fed. Reg. at 80,633 (strikethrough reflecting suggested deletions; underline reflecting suggested additions).

Response: EPA disagrees that landfill gas should be exempted from the gas specification. EPA does not discount that several data sources suggest that landfill gas has similar HAP characteristics and emission profiles as natural gas and refinery gas. However, emissions data reported to EPA suggest that landfill gas has the potential to exhibit higher HAP emissions than natural gas or refinery gas. EPA believes that the mercury limit of 40 micrograms per cubic meter is an appropriate measure of HAP concentrations in gaseous fuels, and that the combustion of fuels with a higher mercury content exhibits the significant potential for environmental harm. Thus, EPA has not provided an exemption from the fuel specification for landfill gas in the final rule.

Commenter Name: Kerry Kelly

Commenter Affiliation: Waste Management (WM)

Document Control Number: EPA-HQ-OAR-2002-0058-3681-A2

Comment Excerpt Number: 10

Comment: If EPA fails to list LFG in the Gas 1 category despite the abundant data showing that LFG mercury levels are substantially below the Gas 1 fuel specification limit for mercury, then EPA should provide a categorical determination for LFG. The categorical determination that LFG qualifies as an other gas 1 fuel should be granted based on available published data, including EPA’s own reports, that shows LFG meets the other Gas 1 fuel specification limit of 40µg/m³. We therefore recommend §63.7521(f) be modified as follows:

§63.7521(f) To demonstrate that a gaseous fuel ~~other than natural gas or refinery gas~~ qualifies as an other gas 1 fuel,.....except as specified in paragraph (f)(1) through (3) of this section.

(1) You are not required to conduct the fuel specification analyses in paragraphs (g) through (i) of this section for natural gas ~~or~~, refinery gas or landfill gas.

Commenter Name: Shannon S. Broome
Commenter Affiliation: Auto Industry Forum (AIF)
Document Control Number: EPA-HQ-OAR-2002-0058-3512-A1
Comment Excerpt Number: 13

Comment: In the reconsideration proposal, EPA proposes to eliminate the H₂S specification but would retain the Hg specification for a fuel to qualify in the Gas 1 category. As explained in detail below, AIF supports the elimination of the H₂S specification but believes that retention of the Hg specification, at least as to LFG, is unnecessary and inappropriate based upon the technical information before the Agency and that the proposal discourages the beneficial use of LFG (a gas formerly flared at the landfill) in boilers and process heaters. Instead, the proposed rule will create barriers to using LFG, a renewable fuel, and lead companies that have sought to put LFG to beneficial use to move back toward exclusive use of NG. This will result in combustion of neglected LFG by the landfills that will:

- increase emissions to the environment overall since the landfill gas must still be burned or flared,
- waste a valuable fuel source further depleting NG reserves, and
- run counter to EPA's policies and programs for encouraging the beneficial use of LFG.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3512-A1, excerpt 20.

Commenter Name: Edward W. Repa
Commenter Affiliation: National Solid Wastes Management Association (NSWMA)
Document Control Number: EPA-HQ-OAR-2002-0058-3539-A1
Comment Excerpt Number: 3

Comment: NSWMA does not agree with EPA that Hg is a better indicator of HAP. From Table 2, the concentrations of Hg in both NG and RG are greater than LFG. As with H₂S, EPA is holding LFG to a high standard than a Gas 1 fuel and the agency has not demonstrated that a correlation exists between Hg and HAP

Response: See the response to comment EPA-HQ-OAR-2002-0058-3512-A1, excerpt 20.

Commenter Name: William C. Herz
Commenter Affiliation: The Fertilizer Institute (TFI)
Document Control Number: EPA-HQ-OAR-2002-0058-3448-A1
Comment Excerpt Number: 7

Comment: The purge gas should not require testing to determine the mercury concentration and a comparison to the 40 micrograms/cubic meters limit in the regulations since the purge gas stream is merely unreacted natural gas purged from the ammonia loop section. Utilization of this purge gas not only makes the plant more efficient but also reduces the release of pollutants from these systems.

Response: Only gases other than natural gas, refinery gas, and gaseous fuels subject to another subpart of part 63 are required to test to determine mercury concentration. The purge gas would not be required to be tested if it is unreacted natural gas.

Commenter Name: Paul G. Page

Commenter Affiliation: AK Steel Corporation

Document Control Number: EPA-HQ-OAR-2002-0058-3457-A2

Comment Excerpt Number: 7

Comment: It is not clear from the definition of "other gas 1 fuel" how this considerable variability and complication in fuel mixture, sampling point, and mercury concentration should be addressed. If EPA does not exempt "process gases that otherwise would be flared" directly from the definition of "waste heat boiler," then AK Steel believes the Agency needs to significantly revise the definition of "other gas 1 fuels" to incorporate additional protocols on the methods to demonstrate compliance under such variable circumstances.

Response: EPA has revised the definition of waste heat boilers, but that edit does not incorporate waste heat boilers using gases that would otherwise be flared. Refer to the chapter of this response to comment document under the Legal/Applicability section on waste heat boilers. For a discussion of other methods added to demonstrate compliance with the other gas 1 fuel specification, refer to comment EPA-HQ-OAR-2002-0058-3490-A1, excerpt 22 under the chapter Appropriateness of Gas Specification.

Commenter Name: Peter Pagano

Commenter Affiliation: American Iron and Steel Institute (AISI)

Document Control Number: EPA-HQ-OAR-2002-0058-3490-A1

Comment Excerpt Number: 20

Comment: Moreover, natural gas companies do not have to comply with quality specifications themselves, including mercury specifications. EPA's own documents reveal that mercury removal in many natural gas plants is optional and depends on the amount of mercury in feeds, whether aluminum heat exchangers are utilized, and whether downstream customers have mercury specifications³³ According to publicly available information from the Federal Energy Regulation Commission ("FERC"), there also are no mercury limits or thresholds imposed on natural gas in FERC gas tariffs. The absence of a mercury specification for natural gas and the aforementioned data mean that the proposed mercury limit of 40 ug/m³ either should be eliminated or increased substantially. The threshold neither represents natural gas mercury content nor constitutes a specification for the natural gas industry.

[Footnote]

(33) Mercury in Petroleum and Natural Gas: Estimation of Emissions from Production, Processing, and Combustion, EPA/600/R-01-066 (September 2001) [See DCN EPA-HQ-OAR-2002-0058-3490-A2 for attachment]

Response: The EPA disagrees a lack of mercury specification data for natural gas should lead to the limit being eliminated or increased. Units burning natural gas are not subject to the gaseous

fuel specification, and thus the lack of a precedent for mercury content in natural gas does not apply to this rule. For discussion on requests for the 40 microgram per cubic meter limit to be increased, please see the response to comment EPA-HQ-OAR-2002-0058-3490-A1, excerpt 18.

Commenter Name: Lorraine Gershman

Commenter Affiliation: American Chemistry Council (ACC)

Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1

Comment Excerpt Number: 32

Comment: ACC members support the Gas 1 opt-in provision for gases other than natural gas and refinery gas proposed by EPA. We agree with EPA's proposed definition of "other gas 1 fuel" and the mercury content criteria. Additionally, ACC believes that additional criteria such as Btu content and organic HAP content are not needed or appropriate since some process gases have lower Btu content than natural gas (e.g., hydrogen), or higher organic HAP than natural gas (e.g., some chemical process gases), but are still clean burning (i.e., result in HAP emissions that are not feasible to measure).

Response: The EPA thanks the commenter for their support.

Commenter Name: Elizabeth McMeekin

Commenter Affiliation: PPG Industries, Inc

Document Control Number: EPA-HQ-OAR-2002-0058-3778-A1

Comment Excerpt Number: 7

Comment: PPG agrees with EPA's proposed mercury content criteria, and we believe that additional criteria such as Btu content and organic HAP content are not appropriate. Some process *gases*, such as hydrogen, may have lower Btu content than natural *gas*, or higher organic HAP than natural *gas*, but are still as clean burning as natural gas.

Response: The EPA thanks the commenter for their support.

Commenter Name: Shannon S. Broome

Commenter Affiliation: Auto Industry Forum (AIF)

Document Control Number: EPA-HQ-OAR-2002-0058-3512-A1

Comment Excerpt Number: 14

Comment: AIF urges EPA to revisit its proposed specifications. Moreover, AIF urges the Agency to recognize the importance of minimizing liability for users of LFG and not impose certification requirements on content of the gas that are not within the control of the certifying entity.

Response: EPA disagrees that the rule provides a disincentive to combust landfill gas. If a source combusts landfill gas, and the fuel demonstrates compliance with the mercury gas

specification limit, the source is classified as a unit designed to combust other gas 1 fuels and is subject to the same work practices as units burning natural gas or refinery gas. EPA believes this creates incentives for units to switch to the combustion of gaseous fuels, including landfill gas, that likely meet the mercury gas specification limit.

Commenter Name: Robert D. Bessette

Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 8

Comment: As set forth in its Petition for Reconsideration and Comments on the Proposed Rule, there is no rational reason to not provide similar regulatory treatment for gaseous fuels that have similar constituents and emissions impacts as natural gas. In response to EPA's question whether additional parameters should be included in the Gas 1 fuel specification, CIBO urges that no additional criteria should be included because there is no rational basis for these to be added.

Response: The EPA agrees with the commenter, and no additional parameters have been added to the gas specification.

Commenter Name: Robert D. Bessette

Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 12

Comment: To the extent that landfill gas is categorized as neither Gas 1 nor given a categorical exemption from the fuel specification mechanism, EPA should change the fuel specification mechanism and allow for alternative testing and certification measures. In the proposed Reconsideration Rule, a Gas 2 unit can secure Gas 1 treatment by: (1) certifying that the fuel will "never" exceed the Hg specification of 40 mm/m³, or (2) conduct monthly testing of the fuel. *Id.* at 80,641-42. Rather than certifying that a fuel will "never" exceed the Hg specification, a unit should have to certify that, based on available data, it is reasonably unlikely that the fuel will not exceed the Hg specification. Additionally, if a unit elects the testing option, the frequency of testing should be reduced if the unit's prior tests show consistent compliance with fuel specifications. Additionally, EPA should expand the allowable test methods listed in the *Boiler MACT Reconsideration Proposal*, 76 Fed. Reg. at 80,666 (Table 6) to include the allowable methods used to gather the Hg data that affected facilities supplied to EPA in response to the Section 114 requests (EPA Methods 29, 30A, or 30B at 40 CFR part 60).

Response: The EPA has revised the rule language to provide for a tiered testing frequency, based on the results of the initial fuel specification results. Refer to 63.7540(c) for this revised testing frequency. This should remove the concerns of the commenter regarding certification of never exceeding the fuel specification. Regarding allowing additional test methods, refer to comment EPA-HQ-OAR-2002-0058-3490-A1, excerpt 22 under the chapter Appropriateness of Gas Specification.

17Z. Other Gas Specification Comments

Commenter Name: Shannon S. Broome

Commenter Affiliation: Auto Industry Forum (AIF)

Document Control Number: EPA-HQ-OAR-2002-0058-3512-A1

Comment Excerpt Number: 25

Comment: The compliance benchmark for Hg in gas fuels other than NG or RG is flatly inconsistent with compliance approaches used to demonstrate compliance with emission limits and work practice standards. It unfairly subjects all other gaseous fuels other than NG or RG to a fuel specification that the Gas 1 fuels are not even required to address in the most cursory manner. It suggests that even one aberrant or anomalous fuel measurement, would function as sufficient basis for failing to demonstrate the Hg specification is met and subjecting the unit to Gas 2 limits. This conflicts with the compliance demonstration methods presented elsewhere in the same reconsideration proposal, including in § 63.7520(e), in § 63.7522, and in § 63.7530. All of these fuel analysis-based compliance methods involve performing some type of statistical data analysis of multiple fuel samples. Moreover, the certification option is inconsistent with the very definition of "other Gas 1 fuel," which states that such fuel "*does not* exceed the maximum concentration of 40 micrograms/cubic meters of mercury." *Boiler MACT Reconsideration Proposal*, 76 Fed. Reg. at 80,653. The definition does not discuss future events, nor should it, and, therefore, it is unreasonable based on this definition to impose a certification as to future conditions as a compliance tool.

For these reasons, there should be no certification option. At a minimum, EPA should amend the compliance method for demonstrations that gaseous fuels other than NG or RG qualify as a Gas 1 fuel to ensure that it is consistent with these other approaches. As a corollary, to the extent EPA retains a certification option, EPA should provide that companies can make the certification based on an initial fuel specification analysis that shows Hg content below the specification level or based on contractual terms with the landfill that require the LFG to be below the level. Otherwise, companies that are unwilling to use LFG if they would be subject to Gas 2 limits may simply opt not to continue combusting LFG. And EPA must ensure comparison to a single maximum value reported among a group of samples does not determine compliance (or more importantly, non-compliance).

Response: The EPA has revised the rule language to provide for a tiered testing frequency, based on the results of the initial fuel specification results. Refer to 63.7540(c) for this revised testing frequency and 63.7530(g) for the certification revisions. This should remove the concerns of the commenter regarding certification of never exceeding the fuel specification.

Comment Excerpt Number: 14

Comment: The "never exceed" specification for mercury in gas fuels other than natural gas or refinery gas is more stringent than typical compliance demonstration methods such as for emission limits and work practice standards. For example, we are not aware of any other

circumstance in which EPA has required a facility to certify to future compliance with work practice standards, or to certify the contents of future emissions tests or analyses. Likewise, the certification requirement included in the proposed Boiler MACT Reconsideration Rule is inconsistent with the very definition of "other gas 1 fuel", which states that such fuel "does not exceed the maximum concentration of 40 micrograms/cubic meters of mercury." (76 FR 80653). The definition does not discuss future events (nor should it), and therefore it is unreasonable based on this definition to impose a requirement to certify future conditions as a compliance tool in this case. Such requirement unfairly subjects all gaseous fuels other than natural gas or refinery gas to a fuel specification standard that these two Gas 1 fuels are not required to even address in the most cursory manner.

Comment Excerpt Number: 24

Comment: Even if the Hg constituents in the fuel consistently test far below the specification, the absolute formulation of the certification could be read in the future to potentially impose liability on the source not only for gas that exceeds the specification but also for a "false certification," should the highly unlikely circumstance outside of the representative's control arise in which the constituents of a purchased fuel like LFG exceed the regulatory specification. Further, it is simply substantively unreasonable to impose the term "never" as a qualification to limit testing obligations in this case, since certifications under Section 112 and Title V are intended to be based on information and belief formed after reasonable inquiry. *See, e.g.*, 40 C.F.R. § 70.5(c).

Comment: *AIF's Comments on the Monthly Testing Option*

If a fuel's gas constituents "could vary above the [fuel] specification," then, under the proposed regulations, monthly testing is required. *See id.* EPA should revise this option for several reasons. First, EPA fails to provide any explanation as to why other options beyond monthly sampling as to each individual facility could not reliably demonstrate compliance with the Hg fuel specification limit. As conveyed in the discussion of the categorical determination approach outlined above, EPA could allow for the performance of a one-time, fuel specification compliance study, performed following applicable EPA sampling guidance, for fuel types like LFG, *i.e.*, for use of the fuel across all facilities. By including a representative number of facilities and collecting numerous samples, such a study could reliably characterize the variability of Hg concentrations so as to obviate the need for monthly testing. With respect to

LFG, as discussed elsewhere in these comments, the numerous published studies that have evaluated Hg in LFG provide a sufficient database for demonstrating compliance with the Hg fuel specification limit. However, as the reconsideration proposal does not address this type of study, AIF recommends that EPA revise it to incorporate this approach as an option for classification as an "other Gas 1 fuel."

Response: EPA disagrees with the commenter about developing a facility-specific representative testing value. Process and combustion conditions can vary between facilities and therefore EPA has determined that each facility should conduct the test. However, EPA has adjusted the testing frequency for the fuel specification for facilities that conduct an initial fuel specification and demonstrate their emissions are at or below the specification as discussed in Refer to 63.7540(c) of the final rule.

Comment Excerpt Number: 5

Comment: EPA should afford companies the option of using the results of a representative fuel analysis from another similar affected facility to demonstrate that the fuel qualifies as "other gas 1" fuel in accordance with § 63.7521, and other applicable subparts. Similar to relying on the fuel provider to demonstrate fuel quality, if a company can demonstrate that the fuel used at a second facility is comparable to that of previously analyzed fuel at a first affected facility, then the company should not have to test the fuel at the second facility. Implementing this practice could reduce testing requirements, while maintaining the regulatory intent for companies to address fuel quality.

Comment: Dow supports EPA's proposed rule revisions of 40 CFR 63.7521(g)(2)(iii) which rightfully addresses the situation where multiple boilers and process heaters are fueled by a common fuel stream. Sampling to determine compliance with the mercury fuel specification can be done at a common point of gas distribution.

Response: The EPA thanks the commenter for their support.

Commenter Name: Russell A. Wozniak

Commenter Affiliation: The Dow Chemical Company

Document Control Number: EPA-HQ-OAR-2002-0058-3449-A1

Comment Excerpt Number: 13

Comment: EPA should modify the proposed rule at 40 CFR 63.7521(h) regarding the number of fuel samples to provide more flexibility.

EPA's proposed rule states that: "You must obtain a single fuel sample for each fuel type according to the sampling procedures listed in Table 6 for fuel specification of gaseous fuels."

EPA should modify the final rule to allow the owner/operator to obtain multiple samples of gas for mercury analysis to provide a reliable average when determining whether or not a gas fuel stream will meet the specification of 40 micrograms per cubic meter. In many cases, our approach to sampling and analysis is that samples are taken either in duplicate or triplicate. EPA should allow the option of averaging the results of multiple samples in order to determine the concentration of mercury present in the fuel gas stream(s). The following changes are recommended to 40 CFR 63.7521(h):

You must obtain, at a minimum, a single fuel sample for each fuel type according to the sampling procedures listed in Table 6 for fuel specification of gaseous fuels. The owner/operator may obtain more than one fuel sample according to the sampling procedures listed in Table 6 for fuel specification of gaseous fuels and may average the results of all fuel samples when determining the mercury concentration of a fuel.

Response: EPA disagrees with allowing an average Hg level be the basis for comparison to the other gas 1 fuel specification. The intent of the fuel specification was to have a level at which gases comparable with natural gas and refinery gas mercury contents could qualify for a work practice standard in lieu of emission limits. This comparison must be consistent and should not cover a fuel that is sometimes containing mercury levels higher than the 40 microgram/m³ specification. If this standard is not consistently met the fuel does not qualify as an other gas 1 fuel type. The EPA did allow for sources to voluntarily continue to collect mercury data in 63.7540(c)(4) for a subsequent 12 month period in order to allow a source to switch from the unit designed to burn gas 2 subcategory to the unit designed to burn other gas 1 fuel subcategory as long as the mercury data supports this switch in subcategories.

Commenter Name: Russell A. Wozniak

Commenter Affiliation: The Dow Chemical Company

Document Control Number: EPA-HQ-OAR-2002-0058-3449-A1

Comment Excerpt Number: 14

Comment: If the owner/operator is subject to monthly sampling requirements for mercury to demonstrate that the criteria for other gas 1 fuels is met, EPA should clarify how an individual sample > 40 micrograms/cubic meter will be handled.

Proposed 40 CFR 63.7530(g) requires monthly testing for mercury content if the gas constituents could vary above the specification. However, EPA's rule does not address situations where one or two samples perhaps over the course of a year may have a mercury content > 40 micrograms per cubic meter. In order to avoid a situation where one or two "high" sample results occur over the course of a year, EPA should allow the Dow Chemical Comments Page 7 Docket EPA-HQ-OAR-2002-0058

owner/operator to calculate an annual average (based on the monthly sample results from a 12 month period) to determine whether or not the off-gas fuel is meeting the mercury specification of less than 40 micrograms per cubic meter.

Response: EPA has revised the language at 63.7540(c) to explain what steps should be taken if the initial gaseous fuel specification shows mercury levels in exceedance of the 40 microgram per cubic meter limit. Each affected unit burning this gaseous fuel is not a part of the unit designed to burn gas 1 subcategory, and must be in compliance with the emission and operating limits for the appropriate subcategory. These sources may elect to conduct additional monthly sampling while complying with the emission and operating limits to demonstrate that the gaseous fuel qualifies as an other gas 1 fuel. If 12 consecutive monthly fuel samples are at or below the 40 microgram per cubic meter limit, each affected unit can elect to switch back into the unit designed to burn gas 1 subcategory. Monthly fuel samples must continue to be conducted, and the unit may elect to remain in the unit designed to burn gas 1 subcategory until a fuel sample exceeds the 40 microgram per cubic meter limit.

For a response to the request for multiple fuel samples and an annual average be included in the gaseous fuel specification, please see comment EPA-HQ-OAR-2002-0058-3449-A1, excerpt 13.

Commenter Affiliation: Waste Management (WM)

Document Control Number: EPA-HQ-OAR-2002-0058-3681-A2

Comment Excerpt Number: 21

Comment: Per §63.7521(h), you must obtain a single fuel sample for each fuel type. Table 6 requires the owner/operator or fuel supplier to measure mercury concentration in the fuel sample (emphasis added) and convert to units of ug/m³. The proposed fuel specification demonstration apparently ensures that even one aberrant or anomalous fuel measurement, even if it is not valid, would be sufficient basis for failing to demonstrate the mercury fuel specification is met. This sampling requirement is inconsistent with compliance methods presented elsewhere in the proposed Boiler MACT Reconsideration Rule, specifically in §63.7530, which directs that the arithmetic average mercury concentration in each fuel type should be used and also provides an equation for calculating a 90 percent upper confidence limit fuel concentration from sample data (referred to in the rule as the “90th percentile confidence level”⁵). The fuel analysis based compliance method involves performing some type of statistical data analysis of multiple fuel samples. At a minimum, the approach used to demonstrate that a gaseous fuel qualifies as an other Gas 1 fuel should be consistent with compliance methods provided elsewhere in the proposed Boiler MACT Reconsideration Rule and standard EPA statistical guidance (e.g., EPA’s 2006 report, Data Quality Assessment: Statistical Methods for Practitioners. EPA QA/G-9S. EPA/240/B-06/003). We recommend that the proposed Boiler MACT reconsideration Rule be amended to ensure that compliance will not be determined based on one sample or by comparison to a single maximum value reported among a group of samples.

[Footnote]

(5) The equation provided for calculating a “90th percentile confidence level” to compare to emission limits (Eq. 10 at 76 FR 80641) does not appear to reflect EPA statistical guidance, for

example, as provided in EPA's 2006 report, Data Quality Assessment: Statistical Methods for Practitioners. EPA QA/G-9S. EPA/240/B-06/003.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3449-A1, excerpt 13.

Commenter Name: Kerry Kelly

Commenter Affiliation: Waste Management (WM)

Document Control Number: EPA-HQ-OAR-2002-0058-3681-A2

Comment Excerpt Number: 18

Comment: WM recommends the EPA modify the certification requirements and testing frequency in §63.7530(g) as follows: (g) If you elect to demonstrate....If the mercury constituents in the gaseous fuels ~~will never~~ do not and are not reasonably expected to exceed the specification included in the definition, you will include a signed certification with the Notification of Compliance Status that the initial fuel specification test meets the gas specification outlined in the definition of other gas 1 fuels. The Notification of Compliance Status may include other relevant data or measurements that supports the certification that the mercury constituents are not reasonably expected to exceed the specifications ~~If your gas constituents could vary above the specification, you will~~ If your initial fuel specification test does not meet the gas specification outlined in the definition of other gas 1 fuels or would otherwise be reasonably expected to vary above the specification, then you must follow Gas 2 subcategory requirements or you may conduct monthly testing according to the procedures in §63.7521(f) through (i) and §63.7540(c) and maintain records of the results of the testing as outlined in §63.7555(g). Where 12 consecutive monthly samples demonstrate that the fuel meets the specification for mercury for the other gas 1 subcategory, you may decrease fuel specification testing frequency to annually.

Response: The language at 63.7530(g) has been revised. All units burning gaseous fuels other than natural gas refinery gas that may qualify as an other gas 1 fuel must conduct the initial fuel specification analysis if classification in the gas 1 category is desired. For fuels for which the initial specification analysis demonstrates compliance with the mercury specification limit, the requirement for a signed Notification of Compliance Status was retained.

The testing frequency at 63.7540(c) has been modified since the December 23, 2011 proposed rule to include the following provision:

- (1) If the mercury concentration resulting from the initial fuel specification analysis is equal to or less than half of the 40 microgram per cubic meter limit, no further sampling is required.
- (2) If the initial test shows that the mercury concentration is between half and 75% of the 40 microgram per cubic meter limit, you must conduct semi-annual sampling. If any semi-annual sample exceeds 75% of the limit, you must return to monthly sampling until 12 consecutive months of sampling show mercury levels at or below 75% of the limit.
- (3) If the initial test shows that the mercury concentration is greater than 75% of the limit, you must conduct monthly sampling. If 12 consecutive months show mercury levels below 75% of the limit, you may switch to semi-annual fuel sampling.

Comment: We recommend the EPA modify the certification requirements and testing frequency in §63.7540(c) as follows: (c) If you elected to demonstrate that the unit meets the specification for mercury for the other gas 1 subcategory and you cannot submit a signed certification under § 63.753045(g) because the constituents ~~could exceed~~ exceeded the specification, you must follow Gas 2 subcategory requirements or conduct monthly fuel specification testing of the gaseous fuels, according to the procedures in § 63.7521(f) through (i). Where 12 consecutive monthly samples demonstrate that the fuel meets the specification for mercury for the other gas 1 subcategory, you may decrease fuel specification testing frequency to annually.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3681-A2, excerpt 18.

Commenter Name: Peter Pagano
Commenter Affiliation: American Iron and Steel Institute (AISI)
Document Control Number: EPA-HQ-OAR-2002-0058-3490-A1
Comment Excerpt Number: 26

Comment: EPA proposes that a gas 1 fuel can be certified based on process knowledge confirmed by a single fuel sample mercury analysis. Absent that certification, monthly fuel samples are required to verify gas 1 eligibility. This is impractical because a single sample with elevated mercury could recategorize a source from gas 1 to gas 2 and impose new generic emission limits that cannot immediately be met. The specification analysis should instead be based on two or more fuel samples taken and analyzed prior to the calendar year(s)³⁸ for which the certification would be effective. The average mercury content over those samples would be used to determine if the fuel meets the gas 1 mercury specification. Averaging over multiple fuel samples mitigates the effect of uncharacteristic spikes in the mercury content of process gases. If all valid data are below the specification, the fuel should be deemed certified gas 1 and no further fuel samples should be required unless the fuel type has changed. Otherwise, the fuel specification mercury sampling and testing would occur again in advance of the next period for which the gas 1 certification would be effective. This process offers sources some notice and time to plan if they determine that a process gas can no longer meet the gas 1 fuel specification.

[Footnote]

(38) AISI encourages EPA to extend this period of gas 1 certification to facilitate longer term planning in the industry. EPA has used a three year period to assess eligibility thresholds that could subject a unit to significantly different regulatory obligations. *See* 40 CFR 72.6(b)(4)(i) (rendering a cogeneration unit subject to the Acid Rain program if it contributes more than 113 of its output capacity to the grid for sale averaged over any three calendar years.)

Response: For discussion on changes to the sampling frequency for the gaseous fuel specification, please see comment EPA-HQ-OAR-2002-0058-3681-A2, excerpt 18. For

discussion on requests for additional fuel samples to be included and averaged as a part of the fuel specification, please see comment EPA-HQ-OAR-2002-0058-3449-A1, excerpt 13.

Comment Excerpt Number: 16

Comment: The Boiler MACT Rule should not preclude subsequent testing to demonstrate compliance with the fuel specification where the results of the initial fuel specification demonstration did not meet the gas specification outlined in the definition of other gas 1 fuels. In this case, a subsequent initial test followed by periodic testing, such as monthly sampling, to validate initial fuel specification demonstration results could be required. The proposed Boiler MACT Reconsideration Rule states that if “12 consecutive monthly fuel analyses demonstrate compliance, you may request decreased fuel analysis frequency by applying to the EPA.” (76 FR 80631). We recommend the Agency also include a reduced testing frequency, such as annually or bi-annually where 12 consecutive monthly samples demonstrate that the fuel meets the gas specification outlined in the definition of other gas 1 fuels.

Comment Excerpt Number: 27

Comment: In the alternative, EPA fails to provide any explanation as to why it does not allow, at the facility-specific level, an equivalent, one-time fuel specification analysis, performed following applicable EPA sampling guidance, for demonstrating compliance with the Hg fuel specification limit. The absence of such an option is inconsistent with other compliance requirements in the proposed reconsideration rule, including performance stack tests annually and tune-ups annually, biennially or every five years. Consistent with those compliance requirements, in the alternative, EPA should amend the reconsideration rule to allow each facility to qualify a fuel as an "other Gas 1 fuel," if the initial fuel specification analysis demonstrates Hg concentration a certain percentage below the specified limit.

Response: The testing frequency at 63.7540(c) has been revised. If the initial gaseous fuel specification analysis shows a mercury concentration at or below half of the 40 microgram per cubic meter limit, no further fuel sampling is required. EPA believes that, at mercury levels this low, it is highly unlikely that the mercury concentration of the fuel will ever fluctuate above the 40 microgram per cubic meter limit, and thus further testing is not necessary. For more discussion on changes to the sampling frequency for the gaseous fuel specification, please see comment EPA-HQ-OAR-2002-0058-3681-A2, excerpt 18.

Comment Excerpt Number: 21

Comment: *To the Extent that Landfill Gas (or Any Gaseous Fuel) May Qualify as Gas 1 Only Through the “Other Gas 1 Fuel” Specification, EPA Should Finalize the Proposed Elimination of the H2S from the Specification Because H2S is Not Directly Related to Potential HAP from the Combustion of Gaseous Fuel.*

As noted above, EPA proposes to revise the fuel specification analyses requirements for the demonstration mechanism. *See id.* at 80,609, 80,641. Specifically, EPA reexamined the fuel specification and concluded that (1) the H2S fuel specification from the final rule does not provide a direct indication of potential HAP from combustion of gaseous fuel and (2) the key contaminant for demonstration of comparability from a HAP perspective is Hg. *See id.* Upon reexamination, then, EPA proposes to eliminate the H2S fuel specification and use an “other Gas 1 fuel” specification based only on an Hg level in the gaseous fuel of 40 µg/m³, *i.e.*, the same level as EPA included in the final rule of March 21, 2011. *See id.* Under this proposal, LFG (and other gaseous fuels besides NG and RG) still would initially fall into the Gas 2 fuel category but could now qualify as an “other Gas 1 fuel” with merely a demonstration of not exceeding the previously published Hg limit of 40 µg/m³. *Boiler MACT*, 76 Fed. Reg. at 15,639.

As articulated above, AIF urges EPA to automatically classify LFG as a Gas 1. If, however, EPA retains the demonstration mechanism and still classifies LFG (and/or other gaseous fuels) in the Gas 2 category, AIF supports the proposed elimination of H2S from the fuel specification, *i.e.*, EPA’s proposed “other Gas 1 fuel” specification based solely on a Hg concentration of 40 µg/m³. AIF concurs with EPA that the H2S fuel specification from the final rule does not provide a direct indication of potential HAP from the combustion of gaseous fuel. Moreover, as stated in AIF’s prior comments, the prior formulation of the demonstration mechanism arbitrarily and capriciously required LFG to meet an H2S emission limit of 4 ppmv or less for classification as a Gas 1 even while the regulations allowed RG emissions of up to 162 H2S and still automatically treated RG as a Gas 1. If EPA elects to retain the demonstration mechanism as the method for LFG (and other gaseous fuels) to attain “other Gas 1 fuel” classification, AIF, therefore, supports the proposed elimination of the H2S fuel specification.

Response: The EPA thanks the commenter for their support of the removal of the H2S limit from the gaseous fuel specification analysis. The decision to exclude the H2S limit has been retained in the final rule.

The EPA disagrees that landfill gas should automatically qualify as a gas 1 fuel. Emissions data reported to EPA show that uncontrolled mercury emissions from landfill gas, when converted back to a gaseous fuel concentration, can fluctuate above and below the 40 microgram per cubic meter limit. For this reason, landfill gas has not been defined as a gas 1 fuel, and units combusting landfill gas may elect to demonstrate that the fuel qualifies as an other gas 1 fuel by conducting the fuel specification analysis.

Commenter Affiliation: Auto Industry Forum (AIF)

Document Control Number: EPA-HQ-OAR-2002-0058-3512-A1

Comment Excerpt Number: 28

Comment: In the alternative, EPA fails to provide any explanation as to why it does not allow a gradual, performance-based reduction in the monthly testing frequency as facilities obtain successive positive results as to a particular fuel. As an example, if a source reports less than a certain percentage of the Hg fuel specification for several consecutive months (*e.g.*, less than 80% of the 40 µg/m³ level), the regulations could provide for an automatic reduction in testing frequency to every other month; then, after a certain duration of continued positive testing, the frequency would decrease to every six months, and so on. There is no rational basis to indefinitely require monthly testing when a fuel regularly tests well below the Hg fuel specification for qualifying as an "other Gas 1 fuel." EPA has utilized such compliance flexibility in other contexts. *See, e.g.*, 40 C.F.R. § 63.1161 (NESHAP for Steel Pickling, Subpart CCC; EPA allows the permitting authority to approve an alternative schedule for performance testing that allows testing less frequently than annually); 40 C.F.R. § 63.1543(e) (NESHAP for Primary Lead Smelting, Subpart TTT; EPA allows less-frequent testing when facilities demonstrate consistent compliance with the standards); 40 C.F.R. § 265.1057(c)(1) (Subpart BB of the Resource Conservation and Recovery Act ("RCRA") Regulations, valves in gas/vapor service; EPA permits sources to monitor valves for leaks less frequently if a leak is not detected for two successive months and allows sources to skip quarterly leak detection periods if a low percentage of valves are leaking). Consistent with those regimes, in the alternative, EPA should finalize a gradual, performance-based reduction in the monthly testing frequency for the "other Gas 1 fuel" specification as facilities obtain successive positive results as to a particular fuel.¹⁷

[Footnote 17: Moreover, to the extent EPA retains any form of the monthly testing option, it should more clearly articulate to facilities how the monthly testing option works, *e.g.*, if a facility tests below the "other Gas 1 fuel" specification level one month but then above the specification level the next month, whether it can, then, test back into the Gas 1 category the succeeding month with a test result below the specification level.]

Response: See the response to comment EPA-HQ-OAR-2002-0058-3681-A1, excerpt 18.

Commenter Name: Shannon S. Broome

Commenter Affiliation: Auto Industry Forum (AIF)

Document Control Number: EPA-HQ-OAR-2002-0058-3512-A1

Comment Excerpt Number: 22

Comment: *As to the "Other Gas 1 Fuel" Specification, EPA Should Amend the Certification Option to Make It More Workable and Amend the Monthly Testing Option to Allow for Additional Flexibility.*

Even with the proposed elimination of H₂S, the "other Gas 1 fuel" specification does not provide a viable avenue for relieving LFG (and other gaseous fuels in the Gas 2 category) of the regulatory burdens associated with unnecessarily stringent emission limits, sampling, and testing.

In its current form, the demonstration mechanism still creates a significant disincentive for companies to purchase and use LFG as a renewable fuel alternative to NG. It provides facilities using fuels in the Gas 2 category and seeking to qualify those fuels for classification in the Gas 1 category with a choice between a certification or monthly testing. Specifically, proposed § 63.7530(g) states:

If you elect to demonstrate that a gaseous fuel meets the specifications of an other gas 1 fuel as defined in §63.7575, you must conduct an initial fuel specification analyses according to §63.7521(f) through (i). If the mercury constituents in the gaseous fuels will *never exceed the specification* included in the definition (40 ug/cm) you will include a signed certification with the Notification of Compliance Status that the initial fuel specification test meets the specification outlined in the definition of other gas 1 fuels. If your gas constituents could vary above the specification, you will conduct *monthly testing* according to the procedures in §63.7521(f)-(i) and §63.7540(c) and maintain records of results of the testing as outlined in §63.7555(g).

Boiler MACT Reconsideration Proposal, 76 Fed. Reg. at 80,641 (emphasis added). As indicated in this proposed regulatory language, the certification option requires the fuel user to sign a certification, based on the results of an initial fuel specification analysis according to § 63.7521(f)-(i), that the gaseous fuel will *never* exceed the regulatory fuel specification. *See id.* The alternative, if the gas constituents in the fuel could vary, is conducting *monthly testing* per § 63.7521(f)-(i) and keeping the requisite, corresponding records. *See id.* EPA proposes retaining these provisions in the same form as promulgated in the final rule of March 21, 2011, however, with the elimination of the H₂S fuel specification, affected sources now would only need to make a certification or conduct the monthly testing as to the Hg constituents. *See id.*

AIF objects to the language of the certification requirement as unworkably absolute and inconsistent with other compliance approaches in the Boiler MACT, and to the alternative of monthly testing as onerous and, as applied to LFG, not supported by the consistently low concentrations of Hg from available analyses.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3681-A1, excerpt 18.

Commenter Name: Shannon S. Broome

Commenter Affiliation: Auto Industry Forum (AIF)

Document Control Number: EPA-HQ-OAR-2002-0058-3512-A1

Comment Excerpt Number: 23

Comment: *AIF's Comments on the Certification Option*

The absoluteness of the certification option EPA imposes – a promise that LFG will *never* exceed the Hg specification – is problematic because it asks the *user* of the gas to certify what will occur in the future based on actions the user does not control. A facility's responsible official may well conclude that he or she cannot guarantee the future given the absolute language, even though there is no reasonable expectation that Hg content will exceed the specification level. EPA should revise the language and/or clarify it to be clear that initial tests below the 40 µg/m³ level are sufficient to make the certification (or some percentage of that level, *e.g.*, if the initial test is less than 80% of the 40 µg/m³ level, a facility is not required to do

testing). Such an approach would provide an objective criterion for facilities to know whether or not they are required to conduct periodic testing.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3681-A1, excerpt 18 for discussion on changes to the sampling frequency for the gaseous fuel specification. For discussion on landfill gas and the request for it to be classified as a gas 1 fuel, please see comment EPA-HQ-OAR-2002-0058-3512-A1, excerpt 21.

Comment: The certification requirements in proposed §63.7530(g) state: “If you elect to demonstrate that a gaseous fuel meets the specifications of an other gas 1 fuel as defined in §63.7575, you must conduct an initial fuel specification analyses according to §63.7521(f) through (i). If the mercury constituents in the gaseous fuels will never exceed the specification included in the definition (40 ug/cm) you will include a signed certification with the Notification of Compliance Status that the initial fuel specification test meets the specification outlined in the definition of other gas 1 fuels. If your gas constituents could vary above the specification, you will conduct monthly testing according to the procedures in §63.7521(f)-(i) and §63.7540(c) and maintain records of results of the testing as outlined in §63.7555(g).” This provision would appear to require a certification that LFG “will never exceed the specification limit for mercury.” Such a certification, relating to unknown future conditions, is overly burdensome, impractical and unworkable. A facility designated representative cannot sign such a certification without taking an undue legal/fiduciary risk, even for a highly unlikely circumstance that is out of the representative’s control. Such certification is inconsistent with RCRA and Clean Air Act NSPS, NESHAP and Title V operating permit certification requirements, which allow for certifications to be based on all credible evidence, generator knowledge, and which provide for certifications based on generator or operator knowledge, information, belief. While it can be demonstrated that a gaseous fuel consistently meets the mercury specification through all currently available data sets (as shown above with respect to LFG), it is unnecessary and impossible to demonstrate that a gaseous fuel will never exceed such specification in the future, especially where the content of future analyses and data sets cannot be known.

Response: For discussion on changes to the sampling frequency for the gaseous fuel specification, please see comment EPA-HQ-OAR-2002-0058-3681-A2, excerpt 18. For discussion on landfill gas and the request for it to be classified as a gas 1 fuel, please see comment EPA-HQ-OAR-2002-0058-3512-A1, excerpt 21.

Comment Excerpt Number: 2

Comment: If the final rule does not allow LFG to be a "gas 1" fuel, changes to the "other gas 1" requirements are necessary. The reconsideration allows LFG to be categorized as "other gas 1" if

it is certified that the LFG "will never exceed the specification limit for mercury". DSWA finds it unlikely that any entity would execute a certification with such rigid language. We suggest that the language should be changed to reasonably account for the possibility of factors beyond the entity's control. This could be accounted for via an engineering report that would explain the remote likelihood of an increase in the mercury content of LFG.

The alternative to certification is monthly lab analysis. The required frequency of testing is onerous. An annual or semiannual test is sufficient to determine mercury levels present in gas.

Response: For discussion on changes to the sampling frequency for the gaseous fuel specification, please see comment EPA-HQ-OAR-2002-0058-3681-A2, excerpt 18. For discussion on landfill gas and the request for it to be classified as a gas 1 fuel, please see comment EPA-HQ-OAR-2002-0058-3512-A1, excerpt 21.

Commenter Affiliation: Waste Management (WM)

Document Control Number: EPA-HQ-OAR-2002-0058-3681-A2

Comment Excerpt Number: 15

Comment: The only alternative to this onerous certification requirement provided in the proposed Boiler MACT Reconsideration Rule is monthly testing of gaseous fuels to demonstrate compliance with the gas specification. This testing requirement is not supported by the consistently low levels of mercury from all available LFG analyses. Accordingly, in the case of LFG, the Initial Fuel Specification Analysis is sufficient to demonstrate Other Gas 1 status. Section 63.7530(g) states that you will conduct monthly testing if your gas constituents could vary above the specification. In addition, §63.7540(c) requires monthly fuel specification testing be conducted at each facility if a signed certification stating mercury fuel specification limit will never be exceeded cannot be submitted. As discussed above, it is unreasonable and inconsistent with other Federal Rules to require such certification. The requirement to conduct monthly testing is also unreasonable and inconsistent with other compliance requirements in the proposed Boiler MACT Reconsideration Rule (i.e., annual performance stack test, annual or biennial tune-ups). The proposed Boiler MACT Reconsideration Rule should allow, at the facility-specific level, a one-time certification, performed following applicable EPA sampling guidance, rather than monthly monitoring to demonstrate compliance with the mercury fuel specification limit.

Response: For discussion on changes to the sampling frequency for the gaseous fuel specification, please see comment EPA-HQ-OAR-2002-0058-3681-A2, excerpt 18. For discussion on landfill gas and the request for it to be classified as a gas 1 fuel, please see comment EPA-HQ-OAR-2002-0058-3512-A1, excerpt 21.

Commenter Name: Kerry Kelly

Document Control Number: EPA-HQ-OAR-2002-0058-3681-A2

Comment Excerpt Number: 11

Comment: To the extent that LFG or any gaseous fuel may only qualify for Gas 1 categorization through a fuel specification, WM requests that EPA revise the specification to

ensure that it is established in a manner that will include LFG that is managed in accordance with existing CAA requirements as discussed above. For example, the Landfill MACT requires that LFG be routed to a treatment system that processes the gas for subsequent sale or use as fuel; this requirement would be an appropriate and adequate specification for demonstrating that LFG may be combusted as a Gas 1 fuel.

Response: For discussion on the request for landfill gas to automatically be classified as a gas 1 fuel, please see comment EPA-HQ-OAR-2002-0058-3512-A1, excerpt 21. Comments pertaining to correlating this rule with other MACT rules are outside the scope of this comment response document.

Document Control Number: EPA-HQ-OAR-2002-0058-3681-A2

Comment Excerpt Number: 20

Comment: We recommend the EPA modify the certification requirements and testing frequency in §63.7555(g) as follows: (g) If you elected to demonstrate that the unit meets the specification for mercury for the other gas 1 subcategory and you cannot submit a signed certification under § 63.753045(g) because the constituents ~~could exceed~~ exceeded the specification, you must follow Gas 2 subcategory requirements or maintain monthly and/or annual records of the calculations and results of the fuel specification for mercury in Table 6.

This approach is consistent other NESHAP requirements such as 40 CFR Part 63, Subpart N (40 cfr 63.344); Subpart GGG (see 40 CFR 63.1250). See also 40 CFR 261.10 (use of generator knowledge to certify to regulatory characteristics of materials)

Response: The EPA has updated the recordkeeping requirements for the sources demonstrating compliance with the fuel specification. The edits do not exactly reflect the requests of the commenter, but EPA agrees that the wording needed to be revised to be consistent with the frequency of the fuel sampling required under 63.7540(c).

Other Petitioner Issues Not Granted Reconsideration

112A. Allow Health-Based Compliance Alternatives for HCl, Mn, and Acid Gases [DENIED PETITIONER ISSUE]

Commenter Name: Randall D. Quintrell

Commenter Affiliation: Georgia Paper & Forest Products Association

Document Control Number: EPA-HQ-OAR-2002-0058-3451-A1

Comment Excerpt Number: 2

Comment: Allowing a health-based option, particularly for HCl, would benefit solid fuel units among the industrial boiler fleet. Under the current MACT proposal, those facilities would be required to install pollution control equipment at an estimated average capital cost of \$1 million per affected unit and incur additional annual operating costs of \$2 million per unit, *without*

realizing a commensurate improvement in public health protection. The health-based emissions limitations established in the 2004 MACT rule were developed under rigorous standards that protect public health with an ample margin of safety. EPA can and should set health-based standards that are clearly and unequivocally allowed by the Clean Air Act.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Commenter Name: Peter Pagano

Document Control Number: EPA-HQ-OAR-2002-0058-3490-A1

Comment Excerpt Number: 37

Comment: Health-based compliance options should be available based on site-specific demonstrations.

EPA has the discretion to include a health-based compliance option for hydrochloric acid and manganese because they are threshold pollutants for which scientists have determined a level below which adverse health effects are not observed. EPA included a health-based compliance option in the original Boiler MACT rule, but has excluded it in the proposed rule. Given the significant cost of this rule and burden on U.S. businesses, EPA should exercise all of its options to provide site-specific flexibility. To the extent a facility can prove that its emissions, when considered with the emissions in the area, do not produce concentrations at or across their fence line in excess of the health-based threshold for HCL or manganese, they should be able to avoid the unnecessary costs of controlling those emissions.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Comment Excerpt Number: 9

Comment: First, we urge EPA to adopt health-based compliance alternatives for HCl and manganese under section 112(d)(4) of the Clean Air Act in order to provide environmental health benefits while avoiding extreme costs to the industry. Biomass contains very small amounts of HCl and the proposed numerical standards will require expensive technological adjustments that provide very little benefit to public health or the environment. In addition, EPA has long recognized that manganese is emitted from many facilities in amounts that do not expose anyone in surrounding population to concentrations above the established health thresholds and therefore the emissions do not pose a significant risk to the surrounding population.²⁹ Providing an alternative health-based approach will ensure that high compliance costs are not imposed on the industry unless commensurate health benefits are provided.

Comment Excerpt Number: 12

Comment: Weyerhaeuser continues to urge EPA to reverse its position and provide health-based compliance alternatives for HCl and for manganese. When the original Boiler MACT was promulgated in 2004, it included "Health Based Compliance Alternatives" (HBCA) as emissions limitations for HCl and manganese. Weyerhaeuser found these alternatives would have been a significant cost reduction factor that still met the CAA goals of reducing health and environmental risk. At that time we intended to employ the HBCA for one or both of the target HAPs at about one-third of our then-existing portfolio of mills. We refer EPA to our discussion of this approach in our comments on the June 2010 proposed rule (see docket ID EPA-HQ-OAR-2002-0058-2797) and incorporate those comments by reference.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Comment: EPA Should Adopt a Health-Based Emission Limit for HCl

EPA has long recognized its authority to adopt health-based emission limits (11 HBELs") pursuant to CAA § 112(d)(4). Section 112(d)(4) authorizes EPA to consider, "[w]ith respect to pollutants for which a health threshold has been established . . . such threshold level, with an ample margin of safety, when establishing emission standards under [112(d)]." Congress's intent in including section 112(d)(4) was to avoid setting HAP emission limits that go well beyond what is needed to protect the public. In formulating this section of the CAA, Congress recognized that 11 [f]or some pollutants a MACT emissions limitation may be far more stringent than is necessary to protect public health and the environment."4 As a result, Congress included section 112(d)(4) as an alternative standard setting mechanism for HAPs "where health thresholds are well-established . . . and the pollutant presents no risk of other adverse health effects, including cancer... ."5

In the 2004 Boiler MACT rule, EPA determined that the MACT floor limits established for HCl were in some cases more stringent than necessary to protect public health, and established an HBEL as a compliance alternative for solid fuel-fired boilers. The HCl limits EPA found more stringent than necessary were 0.02 lb/mmBtu and 0.07 lb/mmBtu for new and existing units, respectively.6

Since that time, EPA has continued to impose even more stringent HCI limits on solid fuel-fired boilers. In the March 2011 Rule, EPA imposed an HCI limit of 0.035 lb/mmBtu on existing units. Despite recommendations and numerous comments from the regulated community (including the Small Business Advisory Review Panel), EPA declined to include an HBEL in that rule. In the Proposed Rule, EPA has proposed an HCI limit that is *more than 30% more stringent* than the March 2011 rule and *almost 70% more stringent* than the 2004 rule for solid fuel-fired units. These significantly more stringent limits only bolster support for EPA's initial 2004 determination and the recommendations of the Small Business Advisory Review Panel ("SBA Review Panel"). EPA has articulated no explanation for abandoning its 2004 approach or ignoring the advice of the SBA Panel. A final rule that does not include an HBEL option would be unsupportable.

Document Control Number: EPA-HQ-OAR-2002-0058-3685-A2

Comment Excerpt Number: 4

Comment: Adoption of an HBEL for acid gases would significantly reduce this cost burden for small entities by allowing them to meet emission limitations that are protective of human health and the environment without spending millions on unnecessary control equipment and operating costs. Under both the RFA and the Unfunded Mandates Reform Act ("UMRA"), EPA is obligated to consider the costs of its rules on small government entities and to analyze the costs of alternative regulatory approaches. EPA has not done so. EPA never analyzed the significant costs that might be avoided by offering an HBEL option for HCI, despite the fact that the SBA Review Panel's number one recommendation was adoption of an HBEL.¹¹ Instead, EPA vaguely asserted a lack of information and implementation issues that do not exist. In the final March 2011 rule, EPA cited the "potential environmental impacts and cumulative impacts of acid gases on public health."¹² EPA performed a thorough analysis of the HBEL alternative in 2004, and concluded it could establish an HBEL that was protective of human health and the environment with an ample margin of safety. Furthermore, the 2004 HBEL alternative required each source wishing to use the HBEL to perform a site-specific risk analysis to ensure that the public would be adequately protected.

[Footnote¹¹: EPA properly analyzed the costs savings in 2004, and determined it would save approximately \$2 billion in unnecessary control costs.]

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: Douglas A. McWilliams

Document Control Number: EPA-HQ-OAR-2002-0058-3685-A2
Comment Excerpt Number: 5

Comment: EPA further attempted to justify its exclusion of an HBEL option by citing the co-benefits of collateral non-HAP emission reduction that would occur under the technology-based limitation. Specifically, EPA cited reductions in SO₂, non-condensable PM, and other non-HAP acid gases.¹³ The Clean Air Act does not permit EPA to consider non-HAP collateral emission reductions in setting standards. Section 112(d)(2) provides an express list of factors that EPA may consider in setting section 112(d) standards. That list includes "the cost of achieving such emission reduction, and any *non-air quality* health and environmental impacts and energy requirements." (emphasis added). This list does not include consideration of non-HAP air quality benefits, which are likely to be minimal at best. In the coming years, many of these sources will be required to reduce SO₂ and PM emissions because of other regulatory requirements, such as the revised NAAQS standards. It would be unreasonable for EPA to base its refusal to include an HBEL on reductions in pollutants that are already managed by other programs. EPA cannot support its refusal to properly analyze the HBEL option under the RFA and UMRA by citing non-existent "potential" impacts and air quality benefits that are likely to occur with or without the Boiler MACT rule.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Document Control Number: EPA-HQ-OAR-2002-0058-3685-A2
Comment Excerpt Number: 7

Comment: It Would Be Arbitrary for EPA to Disregard Its Prior Adoption of Health-Based Emission Limits

When EPA first promulgated the Boiler MACT rule in 2004, it included HBELs for HCl and manganese. These standards required a site-specific risk assessment to demonstrate that emissions from the site were low enough to protect human health with an ample margin of safety. The standards also required actual emission testing to verify emission rates used in the risk assessment, and required sources to include relevant site parameters such as stack height and fence locations in its Title V operating permit.¹⁴ These standards required accountability, and were more than adequate to protect human health and the environment without forcing struggling small entities to invest millions in unnecessary control equipment. EPA and the Department of Justice vigorously defended these HBELs in the final 2004 rule and in the ensuing litigation. EPA dedicated 17 pages of its brief to explaining why its HBELs complied with the requirements of section 112(d)(4). In that brief, EPA acknowledged making the following determinations: (1) both HCl and manganese have reference concentrations and have not been shown to be carcinogenic, (2) the HBELs provided an ample margin of safety, (3) "health-based standards would not reduce the HAP-related health benefits from the rule because only those

facilities with emissions that did not pose a health risk would qualify for the alternative standards," (4) it is inappropriate to consider potential cumulative risks until the residual risk stage of the NESHAP process, and (5) "the potential collateral benefits of controls were not a proper reason to impose control costs under the HAPs program on facilities with HAP emissions that did not pose a public health risk." EPA argued that each of these positions was reasonable, in accord with the law, and entitled to deference. EPA has offered no explanation for its about-face on this issue.

Although EPA has discretion in setting HBELs, "a reasoned explanation is needed for disregarding facts and circumstances that underlay or were engendered by [a] prior policy." *FCC v. Fox Television Stations, Inc.*, 129 S. Ct. 1800, 1810 (2009). EPA has offered no explanation for its change in position, or even acknowledged its prior defense of HBELs in the 2004 Boiler MACT rule. In particular, the two main arguments EPA relies upon for refusing to establish an HBEL for HCl- the concern over cumulative risks and collateral benefits- are *directly contrary* to the conclusions EPA reached in items (4) and (5) above. EPA's failure to acknowledge its prior determination and failure to explain why it has raised as questions issues that previously were resolved render its decision not to propose HBELs arbitrary and capricious.

[Footnote14: See 69 Fed. Reg. at 55227-28.]

114A. Definition of Natural Gas Curtailment [DENIED PETITIONER ISSUE]

Commenter Name: Russell A. Wozniak

Commenter Affiliation: The Dow Chemical Company

Document Control Number: EPA-HQ-OAR-2002-0058-3449-A1

Comment Excerpt Number: 31

Comment: EPA should further clarify the definition of "Period of gas curtailment or supply interruption".

The definition of “Period of gas curtailment or supply interruption” should be revised to also incorporate scenarios that are beyond the control of the facility that “restrict” the supply of gas fuels to a site in such a manner that the type of fuel used by some on-site boilers would need to be changed for a short period of time. The proposed definition could be interpreted to mean that the only conditions that would meet this definition are those where the gas supply to the site is completely stopped or halted.

Therefore, EPA should consider adding “or restricted” to the first sentence in the definition as follows:

means a period of time during which the supply of gaseous fuel to an affected facility is halted or restricted for reasons beyond the control of the facility.

In addition, many contractual agreements are possible for supplying gas fuel to a site and EPA should clarify that the use of back-up fuel is allowed under certain situations where the supply of gas fuel is restricted to a site under a purchase contract agreement to the extent that a very high cost or penalty would be involved for continued gas use under certain situations. Thus, the first sentence of the definition could be further amended as follows:

means a period of time during which the supply of gaseous fuel to an affected facility is halted or restricted for reasons beyond the control of the facility or due to the terms of a contractual agreement with a supplier of gas fuel that allows gas curtailment or supply interruption.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 125

Comment: When disparity between overall supply and overall demand threatens the integrity of the pipeline transportation system, interruptible supply contracts are curtailed first generally by

Operational Flow Orders (or similar contractual requirements by another name) issued to users under their supply contract terms. These orders do not generally involve physically blocking the supply pipeline,⁵⁵ but rather an evaluation after the fact of possible non-contractually compliant use during the curtailment period and the institution of a fine or penalty that can be assessed as high as 10 or so times the contract gas sales price. Payment of a penalty due to unauthorized natural gas usage during an Operational Flow Order is regularly not considered an increase in the cost or unit price of natural gas or a surcharge due to market supply/demand fluctuations. The contracts and user requirements are to protect the integrity of the pipeline system and allow its operation in compliance with FERC requirements.

The current definition could be interpreted to mean that if a company contracts for interruptible natural gas supply, where the interruption could either mean the supply is halted by the utility/FERC regulated pipeline or the facility must switch fuels to avoid contractual fines, the use of backup liquid fuel during periods of high residential/critical infrastructure demand would not constitute curtailment unless the utility/FERC-regulated pipeline actually physically halts the entire supply of gas to the facility.

[Footnote 55: More drastic response such as blocking service lines generally is not considered unless more drastic curtailment situations warrant. This is not typical practice in the experience of many small manufacturers. In limited supply areas Operational Flow Order restrictions and curtailment may happen multiple times a year for interruptible supply users. In some regions even this level of curtailment is infrequent.]

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Commenter Name: Robert D. Bessette

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 63

Comment: In certain regions of the country, firm service contracts are no longer available and interruptible service is the only option for small manufacturing sites. When disparity between overall supply and overall demand threatens the integrity of the pipeline supply system, interruptible supply contracts are curtailed generally by Operational Flow Orders (or similar contractual requirements by another name) issued to users under their supply contract terms. These orders do not generally involve physically blocking the supply pipeline¹⁴, but rather an evaluation after the fact of possible non-contractually compliant use during the curtailment period and the institution of a fine or penalty that can be assessed as high as 10 or so times the contract gas sales price. Payment of a penalty due to unauthorized natural gas usage during an OFO is not considered an increase in the cost or unit price of natural gas or a surcharge due to market supply/demand fluctuations. The contracts and user requirements are to protect the physical integrity of the system and allow its operation in compliance with FERC or state regulations.

Example contract language from actual contracts for supply reinforce these points and should be helpful in understanding curtailment scenarios.¹⁵

The current definition could be interpreted to mean that if a company contracts for interruptible natural gas supply, where the interruption could either mean the supply is halted by the utility/FERC regulated pipeline or the facility must switch fuels to avoid contractual fines, the use of backup liquid fuel during periods of high residential/critical infrastructure demand would not constitute curtailment unless the utility/FERC regulated pipeline actually physically halts the entire supply of gas to the facility.

[Footnote 14: More drastic response such as blocking service lines generally is not considered unless more drastic curtailment situations warrant. This is not typical practice in the experience of many small manufacturers. In limited supply areas, Operational Flow Order restrictions and curtailment may happen multiple times a year for interruptible supply users. In some regions even this level of curtailment is infrequent.]

[Footnote 15: Examples of gas supply contract language: Curtailment "- a critical period in which natural gas transportation service provider issues an Operational Flow Order (OFO). The OFO is required to prevent physical damage to or to maintain the integrity and safe operations of the provider's natural gas pipeline system. *If a penalty for ignoring an OFO is assessed*..... The payment or increase in cost or unit price of natural gas for unauthorized gas usage during an OFO shall under no circumstances be considered as giving the buyer the right to violate OFOs nor shall such payment be considered a substitute for any other supply remedy available. This increase in cost or unit price of natural gas is not considered a surcharge." Moreover, helpful websites include: <http://www.ferc.gov/industries/gas/gen-info.asp> - FERC website on natural gas regulations

<http://www.ingaa.org/cms/143.aspx> - Link explaining how natural gas pipelines are regulated]

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: Robert D. Bessette

Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 64

Comment: Most LDC's/FERC regulated pipelines do not have automatic shutoff capability, but rather they rely on customers taking appropriate action to reduce gas use when needed for meeting high demand or for system integrity requirements. Therefore, due to the inclusion of the word "halted" in the current definition, we are concerned that the only conditions that would meet the definition are those where the gas supply to the facility is completely stopped beyond the control of the facility. Contracts for interruptible service and the inaccessibility of firm service in some regions leave a user only a limited choice – "either use backup liquid fuel during periods of natural gas curtailment, manufacturing operations cease or violate contractual restrictions under strict penalties".

If the definition of curtailment is not revised to include contractual orders whose supply is halted or restricted due to an OFO (Operational Flow Order), interruptible supply users have but no option other than to cease operations during periods of gas curtailment and suffer the economic consequences. If that is EPA's intent, the extremely high cost to manufacturers from this result

has not been assessed. Such a cost impact would have severe effects on the US economy, with its harshest effects falling on smaller manufacturers. EPA did and directly affect small It is our belief that such

Comment: The first sentence of the definition for NG curtailment restricts the allowance for liquid firing to only periods when the supply of natural gas is "halted." A total halting of natural gas is highly unusual, rather gas supplies are typically reduced to a point where they are inadequate to maintain operations. At that point liquid firing may be employed (where the capability exists) to keep at least the most critical operations going. Thus the word "halted, must be replaced with "halted or limited to a level inadequate to maintain current operations."

Comment: EPA has proposed to amend the definition of period of natural gas curtailment (76 Fed. Reg. 80536). The definition would be amended to read as follows:

"Period of gas curtailment or supply interruption means a period of time during which the supply of gaseous fuel to an affected facility is halted for reasons beyond the control of the facility. The act of entering into a contractual agreement with a supplier of natural gas established for curtailment purposes does not constitute a reason that is under the control of a facility for the purposes of this definition. An increase in the cost or unit price of natural gas due to normal market fluctuations not during periods of supplier delivery restriction does not constitute a period of natural gas curtailment or supply interruption. On-site gaseous fuel system emergencies or equipment failures also qualify as periods of supply interruption when the emergency or failure is beyond the control of the facility."

We appreciate EPA's movement on this matter, but additional clarification is still needed. The current definition is unclear and problematic, particularly as it relates to typical requirements of interruptible gas supply contracts such as those often in place at industrial facilities. Many manufacturing companies that utilize natural gas-fired boilers and process heaters operate under contractual supply agreements with local utilities and natural gas suppliers. These entities often utilize FERC-regulated natural gas pipelines to transport natural gas supply from point of

production to the consuming manufacturing facilities. Utilities and natural gas pipelines offer limited "firm supply" contracts and "interruptible supply" contracts, as appropriate, under FERC regulations to ensure the integrity of the natural gas pipeline transportation system and to maximize service according to defined user priorities for a given supply. Hospitals for example are critical users and are afforded high priority. Interrupting or "curtailing" service is required by FERC to ensure the integrity of the pipeline system. Contracts for supply define the terms of that curtailment. Interruptible service may involve lower gas prices than firm service prices because the higher priority commands a higher price. In many areas firm service is no longer available and interruptible service is the only option for manufacturing sites.

Comment Excerpt Number: 144

Comment: THE DEFINITION OF NATURAL GAS CURTAILMENT

EPA has proposed to amend the definition of period of natural gas curtailment as follows:

Period of gas curtailment or supply interruption means a period of time during which the supply of gaseous fuel to an affected facility is halted for reasons beyond the control of the facility. The act of entering into a contractual agreement with a supplier of natural gas established for curtailment purposes does not constitute a reason that is under the control of a facility for the purposes of this definition. An increase in the cost or unit price of natural gas due to normal market fluctuations not during periods of supplier delivery restriction does not constitute a period of natural gas curtailment or supply interruption. On-site gaseous fuel system emergencies or equipment failures qualify as periods of supply interruption when the emergency or failure is beyond the control of the facility. (76 Fed. Reg. 80536)

This definition presents a major concern for industry because the term "halted" is too restrictive and may be interpreted to interfere with existing contractual obligations. Many manufacturing companies that use natural gas fired boilers and process heaters operate under contract supply agreements with local utilities, often at reduced cost to the company, in exchange for either the utility's ability to curtail the supply or a facility's commitment to switch fuels when regional demand by residential or other critical users (e.g., hospitals) is high. Critical regional demand is frequently a function of inclement weather when residential and medical facilities require more gas than normal, thus limiting the amount of gas available to industrial customers. However, most gas suppliers do not have automatic shutoff capability so they rely on industrial customers to reduce gas use when needed.

Comment Excerpt Number: 145

Comment: The current definition can be read to severely penalize facilities that contract for interruptible natural gas, which is the most common method of industrial gas curtailment. Interpreted literally, the current definition of curtailment includes only periods when the utility physically halts the entire supply of gas to a facility. As discussed, that is not even possible for most gas supply circumstances.

Given the many contractual arrangements possible, ACC requests that EPA modify the rule to clarify it does not intend to restrict the ability of natural gas consumers to obtain the most appropriate gas purchasing contract arrangement for their purposes. In addition, please clarify that EPA will allow use of backup liquid fuel firing under those situations where the supply of natural gas is restricted to affected facilities under a purchase contract arrangement to the extent that a very high cost or penalty would be involved for continued natural gas use at pre-restriction levels.

ACC suggests the following revision to the definition: *"Period of gas curtailment or supply interruption means a period of time during which the supply of gaseous fuel to an affected facility is halted or restricted for reasons beyond the control of the facility or due to the terms of a contractual agreement with a supplier of natural gas that allows gas curtailment or supply interruption. An increase in the cost or unit price of natural gas due to normal market fluctuations that does not occur during periods of supplier delivery restriction does not constitute a period of natural gas curtailment or supply interruption. Restriction of supply by a natural gas supplier under a contractual order (e.g., operational flow order under a user's interruptible supply contract) does constitute a period of natural gas curtailment. On-site gaseous fuel system emergencies or equipment failures also qualify as periods of supply interruption when the emergency or failure is beyond the control of the facility."*

The definition needs to be consistent between the area source and major source rules.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Comment Excerpt Number: 126

Comment: Most utilities/FERC regulated pipelines do not have automatic shutoff capability, but rather rely on customers taking appropriate action to reduce gas use when needed. Therefore, due to the inclusion of the word "halted" in the current definition, we are concerned that the only conditions that would meet the definition are those where the gas supply to the facility is completely stopped beyond the control of the facility.

Given the many contractual arrangements possible, we request that EPA clarify that the Agency does not intend to restrict the ability of natural gas consumers to obtain the most appropriate gas purchasing contract arrangement for their purposes. In addition, please clarify that EPA will allow use of backup liquid fuel firing under those situations where the supply of natural gas is restricted to affected facilities under a purchase contract arrangement.

We suggest the following revision (see underlined text) to the definition:

"Period of gas curtailment or supply interruption means a period of time during which the supply of gaseous fuel to an affected facility is halted or restricted for reasons beyond the control of the facility or due to the terms of a contractual agreement with a supplier of natural gas that allows gas curtailment or supply interruption. An increase in the cost or unit price of natural gas

due to normal market fluctuations that does not occur during periods of supplier delivery restriction does not constitute a period of natural gas curtailment or supply interruption. Restriction of supply by a natural gas supplier under a contractual order (e.g., operational flow order under a user's interruptible supply contract) does constitute a period of natural gas curtailment. On-site gaseous fuel system emergencies or equipment failures also qualify as periods of supply interruption when the emergency or failure is beyond the control of the facility."

The definitions in both the Boiler MACT and GACT rules should be consistent.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: Robert D. Bessette

Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 65

Comment: We request that EPA clarify that the Agency does not intend to restrict the ability of natural gas consumers to obtain the most appropriate gas purchasing arrangement for their purposes, while at the same time complying with FERC or State regulations. In addition, EPA should clarify that EPA will allow use of backup liquid fuel firing under those situations where the supply of natural gas is restricted to affected facilities under a purchase contract arrangement.

The revised text does not account for the many contractual arrangements possible, and the definition should be amended so that it does not restrict the ability of natural gas-fired units to obtain the most appropriate gas purchasing contract arrangement for their purposes. In addition, EPA should revise the text to allow use of backup liquid fuel firing under situations where the supply of natural gas is restricted to affected facilities under a purchase contract arrangement to the extent that a very high cost or penalty would be involved for continued natural gas use at pre-restriction levels.

We suggest the following revisions to the definition in the Proposed Reconsideration Rule:

"Period of gas curtailment or supply interruption means a period of time during which the supply of gaseous fuel to an affected facility is halted or restricted for reasons beyond the control of the facility. ~~The act of entering into or due to the terms of~~ a contractual agreement with a supplier of natural gas ~~established for curtailment purposes does not constitute a reason that is under the control of a facility for the purposes of this definition. that allows gas curtailment or supply interruption or due to the terms and conditions of a tariff or supply rate offered by the local utility provider that allows curtailment or supply interruption.~~ Restriction of supply by a natural gas supplier under a contractual order (e.g., operational flow order under an interruptible supply contract) does constitute a period of natural gas curtailment or supply interruption. An increase in the cost or unit price of natural gas due to normal market fluctuations ~~not~~ that does not occur during periods of supplier delivery restriction does not constitute a period of natural gas curtailment or supply interruption. On-site gaseous fuel system emergencies or equipment failures ~~may~~ also qualify as periods of supply interruption when the emergency or failure is beyond the control of the facility."

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 61

Comment: CIBO commented on EPA’s earlier definition of natural gas curtailment and explained its legal and factual deficiencies. In response to comments and in the Proposed Reconsidered rule, EPA did not address the critical compliance obstacle that this definition creates.

EPA’s Proposed Reconsideration makes these amendments to the definition in the Final March 2011 Rule of period of natural gas curtailment:

Period of gas curtailment or supply interruption means a period of time during which the supply of ~~natural gas~~[gaseous fuel](#) to an affected facility is halted for reasons beyond the control of the facility. The act of entering into a contractual agreement with a supplier of natural gas established for curtailment purposes does not constitute a reason that is under the control of a facility for the purposes of this definition. An increase in the cost or unit price of natural gas [due to normal market fluctuations not during periods of supplier delivery restriction](#) does not constitute a period of natural gas curtailment or supply interruption. [On-site gaseous fuel system emergencies or equipment failures may qualify as periods of supply interruption when the emergency or failure is beyond the control of the facility.](#)

76 Fed. Reg. 80653 (redline edits indicate changes to the Final Rule). EPA’s revisions on reconsideration do not address the significant concerns raised by sources. This definition continues to present a major compliance concern for industry because the term "halted" is too restrictive and may be interpreted to interfere with existing contractual obligations. The bottom line for sources is that under this narrow definition of curtailment, ordinary gas supply circumstances will result in Gas 1 sources being re-defined out of the Gas 1 category, if they make sensible market-based decisions regarding fuel availability and pricing impacts.

This definition is apparently written to protect firms whose supply is downstream of a Local Distribution Company (LDC). Users downstream of a LDC can indeed have their supply restricted or halted when the needs of users exceed the LDC’s available supply. In such a scenario, residential users, hospitals and others would be given priority and an industrial company would be shut off. In that simple case, the industrial source must burn its alternate fuel. However, most curtailments are not that simple, and instead reflect complex supply and demand circumstances that EPA does not account for in its simplistic approach to curtailments.

The proposed definition does not address the range of gas supply arrangements and would likely create confusion and eliminate routine cost-effective use of gas purchase contract arrangements. Such impacts would extend beyond EPA authority and implicate state and FERC regulatory authority. The range of gas supply arrangements can include purchase from an LDC under state jurisdiction or purchase from a gas supplier that transports the supply on a interstate/intrastate gas pipeline system under FERC jurisdiction. Purchased transportation can be firm (a consumer

contracts for a specific amount of transport capacity) or interruptible (a consumer can be interrupted by the transporting entity at the transporting entity's will), or a combination of firm and interruptible. Because a site must pay a cost for firm transportation whether the gas is actually purchased or not, many large natural gas consumers utilize contracts that incorporate a combination of firm and interruptible supply contracts to optimize transportation costs in light of variation in natural gas demand.

Normally, with purchase of firm transportation, the risk of curtailment limits a firm's delivery amount to the firm transport capacity purchased (or the firm's daily nomination, whichever is less). Curtailment typically occurs when demand is unusually high, for example, with very cold weather.

Firm transport customers are normally only subject to curtailment to less than their firm capacity when the transporter suffers a force majeure situation (e.g., a compressor station failure, pipe failure), or the supply is significantly disrupted (e.g. a major hurricane in the Gulf of Mexico).

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 33

Comment: The second sentence of the definition is "The act of entering into a contractual agreement with a supplier of natural gas established for curtailment purposes does not constitute a reason that is under the control of a facility for the purposes of this definition." This sentence appears to be making it clear that interruptible supply contracts are allowed and natural gas reductions as a result of such contracts would be an acceptable reason for firing liquid. However, the wording of the second sentence is totally unclear and should be revised to "Natural gas curtailments due to the terms of a contractual agreement with a supplier of natural gas that allows gas curtailment or supply interruption are considered periods of curtailment beyond the control of the facility."

Interruptible supply agreements are important, not only because they save money for facilities, but because they allow utilities to provide gas to critical users (e.g., residences, hospitals) when regional gas supplies are short (e.g., during hurricanes). This definition must be clear that such agreements are allowed and curtailments due to these agreements are an acceptable basis for liquid firing. If that is not the case, EPA must outline all of the implications of disallowing such agreements on the public, public health, emergency response, etc. and incorporate those impacts and the added costs of converting facilities to non-interruptible supply contracts into the rule supporting analysis and provide that information for notice and comment.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Comment Excerpt Number: 62

Comment: In the case of interstate/intrastate gas transportation contracts, there are provisions under which a customer hypothetically could buy natural gas in excess of its contractual firm transportation amount during a curtailment. However, penalties in pipeline tariff agreements, regulated by FERC, can be significant and are intended to make the a violation of curtailment so painful as effectively to prohibit a consumer from attempting to defy the curtailment order. As examples, one interstate pipeline tariff cites a \$15 per Dekatherm penalty on top of Henry Hub prices, effectively quadrupling the cost of natural gas and another interruptible user reports an even higher \$30 per Dekatherm penalty. The penalties of unauthorized natural gas usage during a curtailment are imposed to ensure pipeline system integrity and are not considered a unit cost increase for the price of natural gas. In contrast, for firms purchasing gas from a LDC there is little or no ability to buy supply as customers are required to honor the curtailment order. If they do not, the customer is subject to huge penalties for amounts taken above the contract quantity and pipeline system integrity can be compromised.

For interruptible service, or for that portion of a supply contract that is interruptible, transportation of natural gas on both interstate/intrastate pipelines and local distribution systems would be "halted" or "restricted" under Operational Flow Order (OFO) conditions (or pre-OFO conditions). Because many large consumers of natural gas utilize contracts that combine firm and interruptible transportation, an OFO represents an unpredictable constraint on a firm's ability to operate its plant at optimal levels. For those firms whose natural gas supply contracts consist entirely of firm delivery, this would be an infrequent event such as a Force Majeure. Many small manufacturing sites such as those subject to GACT also operate under purely interruptible service contracts. Frequency of curtailment under an OFO varies but on system's that are supply/capacity limited curtailment may run from zero to multiple events per year based on actual overall supply/distribution capacity versus actual overall demand.

Comment Excerpt Number: 31

Comment: The definition of "period of gas curtailment or supply interruption" is unclear and does not provide relief for all reasonable situations and thus needs to be revised.

EPA has proposed the following definition of period of gas curtailment or supply disruption as follows.

Period of gas curtailment or supply interruption means a period of time during which the supply of gaseous fuel to an affected facility is halted for reasons beyond the control of the facility. The act of entering into a contractual agreement with a supplier of natural gas established for curtailment purposes does not constitute a reason that is under the control of a facility for the purposes of this definition. An increase in the cost or unit price of natural gas due to normal market fluctuations not during periods of supplier delivery restriction does not constitute a period of natural gas curtailment or supply interruption. On-site gaseous fuel system emergencies or equipment failures qualify as periods of supply interruption when the emergency or failure is beyond the control of the facility.

In this definition the term “beyond the control of the facility” is used repeatedly to narrow what special cases are allowed. However, this phrase is arbitrary and unclear and puts facilities at risk of violations based on the whim of a regulator or citizen. Since EPA claims through their affirmative defense language that essentially all malfunctions are preventable, it is unclear they would consider any emergency or equipment failure to be beyond the control of the facility. Even loss of natural gas because of a pipeline rupture might not qualify, since EPA claims under the affirmative defense provisions that an event is not a malfunction if the event could “have been prevented through careful planning, proper design or better operation and maintenance practices” or stemmed “from any activity or event that could have been foreseen and avoided, API/AFPM Comments on Proposed BPH NESHAPs, CISWI and NHSM Rules Page 22 “ The phrase “beyond the control of the facility” is arbitrary and unclear and should be deleted.

[Footnote 11: See proposed §63.7501(a)(1)(ii) and (iii).]

Document Control Number: EPA-HQ-OAR-2002-0058-3500-A1

Comment Excerpt Number: 46

Comment: UARG does not object to a requirement to report data that are necessary to determine compliance, or are otherwise useful to the Agency. UARG also does not object to electronic reporting of those data. However, UARG does object to codification of vague and inadequately defined reporting requirements. Where EPA has proposed to require reporting of “performance test data” and “relative accuracy test audit data,” UARG understands those terms to refer to information already required to be reported under Subpart DDDDD. For example, when performance tests are conducted using reference methods specified in Subpart DDDDD, those promulgated methods specify what results must be reported. Similarly, when relative accuracy test audits are conducted, the applicable performance specification identifies what must be reported. To the extent additional data are needed to support compliance, EPA must specify those data in the rule. If EPA simply required the reporting of those existing data in a reasonable electronic format, UARG would not object. Unfortunately, EPA does not. EPA requires ERT.

EPA asserts that ERT clearly states what must be reported. However, ERT is not a rule. ERT is only a “tool” for reporting information as required by rule. ERT has not undergone rulemaking, or review under the PRA. EPA cannot use ERT to define what must be reported. That must be specified in the rule so that affected facilities have the opportunity to review and provide comment on the scope of the substantive reporting requirement. EPA’s outreach to stack testing companies regarding the content of ERT is not a substitute for rulemaking. Unfortunately, one need look no further than the ERT user manual to see that EPA is attempting to use ERT to establish new substantive reporting requirements. For example, no “test data” may be entered into ERT until a Test Plan has been created in ERT. Section 63.7520(a) does require development of a test plan according to § 63.7(c), which in turn requires submission of the plan “if requested.” But EPA has not formally requested submission of such test plans,²⁰ or limited the ERT Test Plan to information required under § 63.7(c). *See, e.g.*, Electronic Reporting Tool (ERT) Users Guide Version 3.1 June 2009 at 3 (describing the expanded process descriptions required so that “ERT can be used to develop and report emission factors”). A more thorough audit of ERT and its user manual undoubtedly would reveal many other examples of newly created substantive reporting requirements. Notably, neither ERT nor its user manual contain a single regulatory citation to identify the source of the substantive reporting requirement. The first step in making ERT legal is to identify for each data input a rule requiring reporting of that information.

[Footnote]

(20) Neither Subpart DDDDD, nor § 63.7(c), appear to anticipate that EPA would require that a test plan be submitted and approved prior to every performance test. Instead, after a notification of performance testing is submitted, EPA must request submission of the plan for that test.

Comment: Any electronic report used to satisfy federal reporting requirements also must meet the requirements of the Cross-Media Electronic Reporting Rule, codified at 40 C.F.R. Part 3, including the requirement that the document include a valid electronic signature, as defined in the rule. EPA has made no attempt to explain how ERT, CEDRI, or WebFIRE meet this requirement. UARG also is concerned regarding the ability of ERT to satisfy other criteria EPA deems necessary for valid electronic reporting, including whether (i) each electronic signature was a valid electronic signature at the time of signing; (ii) the electronic document cannot be altered without detection at any time after being signed; and (iii) each signatory had the opportunity to review in a human readable format the content of the electronic document that he or she was certifying to, attesting to, or agreeing to by signing. *See, e.g.,* 40 C.F.R. § 3.2000(b)(5). In UARG's experience, ERT satisfies none of these criteria. Especially troublesome is the inability of the responsible official to prevent revision of the information in ERT at or after the point of submittal. EPA cannot require sources to submit data using a mechanism that does not satisfy its own requirements for such submissions. Promises by EPA that these issues will be addressed by the time reports must be submitted are not sufficient to satisfy EPA's obligations under the CAA to provide notice and opportunity for comment at the time of proposal.

Comment Excerpt Number: 48

Comment: UARG does not agree with EPA's unsupported assertion that the information required to be submitted under ERT to WebFIRE will benefit EPA and sources by improving emission factors. EPA has yet to explain in any detail how the process of emission factor development from performance test and 30-day rolling average CEMS and CPMS data submitted to WebFIRE will work. In its comments on the ANPR, UARG expressed concerns about the process EPA described and objected to any attempts to mandate submission of reports before EPA had more completely explained its plans, completed any necessary rulemakings, and made operational its website. UARG reiterates those points here. EPA should reserve the question of mandatory reporting to WebFIRE until it has resolved the questions raised in the ANPR.

Comment: DHEC has serious reservations about facilities reporting to the EPA through the Central Data Exchange (CDX). Our concerns center around data quality and the burden of requiring facilities to submit reports to both the state, as the Delegate Agency, and to the EPA.

DHEC is encouraged by the prospect of integrating a streamlined approach to electronic submission of data, however the EPA must consider how this proposal would assure data quality and how it would impact the reporting burden on facilities. These issues should be addressed prior to moving forward. Until these concerns are addressed, DHEC has significant reservations regarding the EPA's effort to have data submitted directly to the CDX.

DHEC takes seriously our responsibility to ensure the quality of data submitted by facilities, and notes that routine requests are made for facilities to correct, revise, or supplement the data after initial submission and review. It does not appear that the data submitted through the CDX will be reviewed or revised. This will lead to inaccurate data being relied on for future use or public viewing. This would create a significant issue for public trust and transparency as well as potentially provide invalid data for future environmental permit decisions.

Comment: In §63.7550(j), EPA proposes to require submission of parametric operating data to WebFire on a quarterly basis. Purdue University's Wade Utility Plant boilers are currently CAIR affected units for ozone season NO_x emissions. This program requires quarterly submission of emissions data to the Clean Air Markets Division via ECMPS. The process for collecting, preparing, quality assuring, and submitting this data for CAIR compliance is burdensome and, due to staff time constraints, requires the assistance of contractors specifically skilled in the preparation and submission process. To require submission of parametric monitoring data electronically would add tremendous burden and cost to Purdue's existing reporting scheme for Part 75, a program that currently costs the University \$25,000/year for data QA, data submission, and data acquisition and handling system support. As well, the state regulatory agency is unable to accept data electronically resulting in duplicative reporting with little environmental benefit.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Comment Excerpt Number: 139

Comment: Alternative reporting mechanisms should be specified, since exclusive use of EPA's new and unproven Compliance and Emissions Data Reporting Interface and the limited ERT puts sources at risk due to failures of this unproven system. Timing of these submissions should be coordinated with the periodic reports.

1. Proposed §63.7550(j) requires periodic reports of operating parameter daily averages and that those reports be submitted using the Compliance and Emissions Data Reporting Interface, or CEDRI, which is accessed through the EPA's Central Data Exchange (CDX). However, this system has only been put into production as of the first of 2012 and is clearly unproven in regards to its reliability and accuracy. It is highly unlikely to be reliable for periodic report use for much longer than the compliance time for this rule and EPA should provide the normal paper reporting as an alternate until some future time when electronic periodic reporting is 100% proven, if this requirement is finalized. It is unreasonable to put sources at risk of violations (late reporting) because of EPA reporting tool issues or availability. A 100% reliable alternative to using the unproven CEDRI system must be made available.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Comment Excerpt Number: 140

Comment: In §63.7550(h), (i) and (j), the rule proposes to require performance test results be submitted using the Agency's Electronic Reporting Tool (ERT). While we disagree with most of the claims stated in the preamble for the benefits of this system and believe it will add additional stack testing costs, we understand that its use for performance test results is now essentially a fait accompli. Our recent experience using the ERT for Component IV of the Refinery ICR shows that there are many problems and difficulties in trying to use the ERT and that this requirement increases burdens and puts facilities at significant risk of deviations because the ERT is unable to accept this information.

EPA has recognized this problem in the recently promulgated revisions to part 60 subpart Db. §60.46b(j)(14)⁵², where it states "Only data collected using test methods compatible with ERT are subject to this requirement to be submitted electronically into EPA's WebFIRE database." Unfortunately, this sentence falls short in addressing the entire problem, because it does not indicate how to submit the information that the ERT cannot accept or how EPA will match up information that is split between the ERT submission and what we presume would be a paper submission. Nor is it clear that the cost and burden estimates supporting this rulemaking reflect the duplication that will be occurring

Thus, clarifications are needed to make this requirement more practical and to prevent violations due to ERT issues. We recommend 1) EPA incorporate the sentence quoted in the previous paragraph from §60.46b(j)(14) into §63.7550(h), (j) and (i); and 2) EPA be specific about how to submit any information that the ERT does not accept.⁵³

[Footnote 52: 77 Fed. Reg. 9460 (February 16, 2012)]

[Footnote 53: We note that EPA has currently proposed amendments (77 Fed. Reg. 1130, January 9, 2012) to most stack test methods that will change many commonly used stack test

methods if those amendments are finalized. It is unclear how promptly the ERT can be revised to handle such changes.]

Comment Excerpt Number: 142

Comment: Proposed §63.7515(g) requires reporting of performance tests and associated operating parameter information within 90 days after completing the test. For facilities with many BPH requiring stack tests, managing the submission of this large number of reports in paper versions to the State and in electronic and paper versions to EPA (since the ERT does not accept all of the information required) imposes large unnecessary burdens. It would be much more efficient for sources and for regulators if this information could be accumulated and submitted with the periodic report. Thus, we request that §63.7515(g) be revised to require reporting of subsequent performance test and associated required information, including ERT submissions, on the same schedule as applies to periodic reports (i.e., January 31 or July 31 for the six month calendar periods ending December 31 and June 30, respectively).

Comment Excerpt Number: 15

Comment: Public records for monitoring and compliance with emissions limits. The Lung Association recommends that the records and reports of monitoring and compliance measures for emissions limits be made easily and readily accessible to the public. The public has an established right to know about the emissions of toxic substances. For 25 years, EPA has required companies to make public information on toxic chemicals released into the community through the Toxic Release Inventory (TRI). We support a system similar to TRI, where facilities are required to report toxic emissions to the database and make data relating to those emissions available online.

EPA should require boiler operators to publicly disclose and report all monitoring data and compliance documentation—including with required work practices standards—and submit those data reports to EPA for public access online. These would include data and results from performance tests of facilities and emissions that occur during malfunctions of boiler equipment. Communities have a right to know what toxic air pollutants are emitted by boilers and incinerators, the quantities of each type of pollutant being emitted, when those emissions are occurring, particularly when the emissions exceed limits set by EPA.

115C. Modify Gas Curtailment Notifications [DENIED PETITIONER ISSUE]

Commenter Name: Lorraine Gershman

Commenter Affiliation: American Chemistry Council (ACC)

Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1

Comment Excerpt Number: 146

Comment: In addition, the requirement to notify EPA within 48 hours when oil is burned in a gas-fired unit due to curtailment is burdensome and unnecessary. Section 63.7545 requires facilities to submit a notice of natural gas curtailment of supply interruption when an alternate fuel is burned within 48 hours of the curtailment declaration. This notification requirement is an unnecessary burden on facilities, and it has the potential to result in numerous reporting violations. It should be sufficient for facilities to keep records of such events, make them available upon request, and summarize any such periods in the semi-annual compliance reports required by the rule.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Commenter Name: Shannon S. Broome
Commenter Affiliation: Auto Industry Forum (AIF)
Document Control Number: EPA-HQ-OAR-2002-0058-3512-A1
Comment Excerpt Number: 42

Comment: In the final rule, EPA imposed an additional obligation on operators of Gas 1 units during periods of NG curtailment or supply interruption. In the newly proposed 40 C.F.R. § 63.7545(f), EPA required these Gas 1 unit operators to provide notification of their use of an alternative, non-Gas 1 fuel within 48 hours of the commencement of such periods. *See Boiler MACT*, 76 Fed. Reg. at 15,679, 15,685.

In its petition for reconsideration and subsequent comments, AIF advocated for the elimination of this requirement and recommended that EPA modify any notification requirements to comport with the 6-month reporting deadlines under Title V. *See* 40 C.F.R. § 70.6(c) (including the notification as to a NG curtailment from the previous 6-month period in the Title V semi-annual report of required monitoring). AIF made this suggestion because of its concerns regarding the feasibility of EPA imposing on facilities such a short timeframe for notification and the fact that backup fuels are allowed by existing permits, rendering this requirement unnecessary.

In the proposal, § 63.7545(f) continues to contain this requirement. *See Boiler MACT Reconsideration Proposal*, 76 Fed. Reg. at 80,646. Further, EPA does not explain why it did not include this issue in the preamble or otherwise acknowledge this subject as one as to which AIF petitioned for reconsideration.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: Shannon S. Broome
Commenter Affiliation: Auto Industry Forum (AIF)
Document Control Number: EPA-HQ-OAR-2002-0058-3512-A1
Comment Excerpt Number: 43

Comment: AIF reiterates the position conveyed in its petition for reconsideration and subsequent comments: EPA should eliminate this requirement. It simply is not feasible to impose on facilities such a short timeframe for notification. EPA has previously stated that, as "curtailments are an unlikely event, so the burden of this requirement should be minimal." EPA's Responses to Public Comments on *Boiler MACT*, Vol. 2, Comment Excerpt No: 6 (Mar. 21, 2011), Document Control No: EPA-HQ-OAR-2002-0058-2894.1. The fact that such a situation may occur only infrequently, however, does not change the severity of the burden on a facility, including those owned and/or operated by AIF members, when it does occur. EPA, therefore, should eliminate the notification requirement.

In the final rule, EPA sought to justify it as functioning to "ensure that only those units that qualify as Gas 1 units remain in the Gas 1 subcategory." *See id.*, Vol. 1, at p. 895, Document Control No: EPA-HQ-OAR-2002-0058-3289. This concern, however, does not justify a 48-hour notification requirement—the selection of that notification timeframe is arbitrary and capricious; EPA fails to explain how its stated concern supports imposing 48 hours as the timeframe for the

requisite notification. If EPA elects to retain the requirement, it can still clearly achieve its stated goal by receiving any information regarding NG curtailment in Title V reports. There is no rational basis to add to facilities' monitoring burdens when Title V already requires them to report NG curtailments from the previous 6 months in their semi-annual reports of required monitoring. If it elects to retain the notification requirement, therefore, EPA should amend it to operate consistently with the timeframe of Title V's reporting regime for required monitoring, relying on reporting of changes in the semi-annual report of required monitoring, rather than imposing a 48-hour notification requirement.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: Shannon S. Broome

Commenter Affiliation: Auto Industry Forum (AIF)

Document Control Number: EPA-HQ-OAR-2002-0058-3512-A1

Comment Excerpt Number: 44

Comment: Moreover, EPA fails to provide a rational basis as to why, even in light of its stated concern, it should require any notification when facilities, in instances of NG curtailment, merely burn backup fuels. When facilities burn backup fuels, notification is unnecessary because existing permits allow the burning of backup fuels. Burning a backup fuel is not like burning a new fuel. At most, then, if EPA elects to retain the notification requirement, it should restrict the requirement to circumstances where, during instances of NG curtailment, facilities burn a fuel that was not previously identified in a permit. There is, otherwise, no rational basis for it.

Therefore, EPA should eliminate the notification requirement of alternative fuel use during NG curtailment. In the alternative, EPA should amend the timeframe of § 63.7545(f) to one that is consistent with Title V's semi-annual report of required monitoring. Moreover, EPA should only require facilities to report when they burn a new fuel, *i.e.*, one that was not previously identified or allowed under their Title V permit.

Commenter Affiliation: Merck and Co., Inc

Document Control Number: EPA-HQ-OAR-2002-0058-3546-A2

Comment Excerpt Number: 1

Comment: In the current proposal, the EPA allows gaseous fuel boilers and process heaters to burn liquid fuel for periodic testing, maintenance, or operator training, not to exceed a combined total of 48 hours during any calendar year, unless there is a gas curtailment or other supply emergency. In order to maintain the ability for a dual fuel boiler to burn liquid fuel during emergencies, it is necessary to properly train operators to switch fuels safely, while maintaining proper combustion practices, thus minimizing emissions. The current annual testing and tuning alone may take up to 48 hours. A 72 hour period would provide a more adequate timeframe to complete these activities safely and ensure boilers are running proficiently in the event of a fuel switch. The emissions from the operation of the boiler for up to 24 hours more per year on liquid fuel would be negligible. However, this small addition of time to the limit on liquid fuel burning would allow for training of personnel so that they can safely operate boilers on the back-up fuel in the event of an emergency, and enable the performance of maintenance that may be required for efficient on-going operation of the boiler.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Comment: Our comments on the NHSM rule are brief. As with the Boiler MACT reproposal, we fully support the comments submitted by AF&PA, NCASI, and individual member companies of GPFPA, and include them by reference as part of our comments here.

First and foremost, the underlying principal in any consideration of a waste and non-waste is the concept of "discard", a concept clearly laid out in RCRA. If a secondary material is not discarded, even though it may be used or reused for a secondary purpose, it is not a waste. The rule could be that simple! The angst that has been caused by the current NHSM rule and reproposal, which served to muddy the waters so much that many facilities do not yet know whether or not their units are boilers or CISWI units, is unnecessary.

Non-discarded materials commonly used as fuels include, but are not limited to, recycled paper rejects (e.g., *ace* rejects), wastewater residuals, broken and scrap paper that is not recyclable, pulping residuals, sawdust and wood trim (resinated and non-resinated), and off-spec product. Each of these materials has value as fuel and is being used to offset the use of fossil fuels, thus reducing costs, greenhouse gas emissions, and dependence on foreign oil. As such, the use of these materials as fuel furthers the goals of other EPA, and DOE, programs. Facilities should not have to "prove" that a useful, non-discarded material is a non-waste; rather a material that is not discarded and is used on site, or that is purchased and treated as a commodity regardless of what it is, should be presumed to be a non-waste, and only if certain conditions are met, should there be any question about its status as a non-waste or waste. For example if a source pays an operator to have a material burned for it, then the value as a fuel would appear to be insufficient for commerce and the burning might be disposal; that circumstance could be a condition for a "waste" classification.

EPA should expand its list of non-waste materials to include all the materials mentioned above, as well as other materials commonly used as fuels in other industries, to include all materials that are currently and/or have historically been used as fuels, and EPA should revise its proposed approach from materials being presumptive waste with the facility having to prove differently. To do otherwise will unavoidably relegate useful fuels to the "waste" category and will necessarily require that these be replaced with either a fossil fuel or other biomass fuel, increasing operating costs with no benefit to the environment.

Response: This comment pertains to the Identification of Non-Hazardous Materials That Are Solid Waste and it is out of scope for this boiler rulemaking. Provided the commenter has submitted this comment to the Identification of Non-Hazardous Materials That Are Solid Waste rulemaking docket, the response to this comment will be provided there.

Comment: Many of the Maine Mills operate multi-fuel boilers to provide steam for processes. The Mills have undertaken great efforts to recover the heat value of a wide variety of secondary materials in these boilers. For example, most of the Mills burn WWTR from their wastewater treatment facilities, waste paper, cardboard and tire-derived fuel- all of which serve to displace a commensurate amount of biomass wood chips and/or fossil fuels, and preserve landfill capacity. EPA's definition of non-hazardous secondary materials, even with the proposed amendments, may jeopardize the Maine Mills' ability to continue to beneficially reuse these types of materials as fuels in these units unless they comply with the more stringent CISWI standards.

Response: This comment pertains to the Identification of Non-Hazardous Materials That Are Solid Waste and it is out of scope for this boiler rulemaking. Provided the commenter has submitted this comment to the Identification of Non-Hazardous Materials That Are Solid Waste rulemaking docket, the response to this comment will be provided there.

Comment Excerpt Number: 3

Comment: MPPA appreciates that EPA has acknowledged that on a mill-by-mill basis, WWTR probably meets the legitimacy criteria and can be managed as a non-waste fuel. However, there remains a lack of certainty in this status. To clarify the issue, MPPA and its members urge EPA to list pulp and paper mill wastewater treatment plant residuals categorically as a non-waste. Most Maine Mills operate boilers that are specifically designed to handle a variety of fuels; few boilers are designed to burn just traditional fuel. Over the years, the industry has recognized the benefit of burning secondary materials - particularly those generated on-site- because they are derived from on-site processes and many have characteristics similar to traditional fuel, particularly the biomass used to produce pulp and paper products.

Mills do not usually burn just one type of fuel at any one time. Bark and biomass fuel may be the primary fuel, but it is supplemented by others -- both traditional and alternative. This is done in order to meet the energy needs of the mill - but also to address best management of the boiler as well as air quality requirements. If the biomass fuel is wet, a boiler may need to burn more fossil fuels or alternative fuels with high heat content to boost heat value; if the boiler is burning too hot, the addition of fuel WWTR enables the mill to regulate temperature and improve combustion.

WWTR may also be burned because it has the best fuel value for the price. All of these decisions are based on the cost of energy and the energy demand of the mill at the time. Boiler conditions, fuel availability, energy needs, air quality requirements, as well as costs are all considered when the energy manager and boiler operators determine the right mix of fuel to burn on any given day.

As a result, the quantities of different types of fuels burned over the course of a year differ. This means that the mill may not burn 100 percent of the available fuel generated during that year. Not all WWTR can be burned. Not all biomass fuel can be burned. The fact that only a percentage of a secondary material generated by the industry is used for fuel does not negate its value as fuel. It reflects the realities of running a boiler where economic and operating conditions change from day to day, even hour to hour.

EPA needs to clarify that the Mill's WWTR may be fired in mill boilers without triggering applicability of CIS WI. Secondary materials have been an important alternative fuel used safely by the Maine mills for many years. In fact, most of the Maine mills' multi-fuel boilers, their fuel handling equipment, mill wastewater treatment systems and other ancillary equipment were designed to combust these fuels, particularly WWTR. Use of these fuels reduces reliance on purchased biomass and/or fossil fuels and provides an avenue to beneficially reuse the materials. In light of the greater stringency of the CISWI regulation, mills are likely to landfill these materials instead of recovering their fuel value if these materials are considered solid waste for purposes of Boiler MACT/CISWI. The cost to the Maine mills to dispose of these materials and to replace the heat value with natural biomass or fossil fuels would be in the tens of millions of dollars. B. Responses to EPA's Questions Concerning WWTR.

In the preamble (p 80484), EPA raises a number of questions concerning the management of the pulp and paper mill WWTR and asks for additional information about the amount and contamination of the WWTR. The MPP A Mills offer the following responses.

1. How is WWTR used as fuel integrated into the industrial production process?

As described above, the energy manager at a mill will determine the approximate amount of different types of fuels needed to obtain the most energy under the best operating conditions. WWTR solids are generated through a dewatering process, then handled and stored in segregated areas to prevent contamination; it is directed toward the biomass fuel piles using loaders or directly to combustion using dedicated fuel handling and conveying equipment, or towards other uses. This decision is based on whether the mill's boiler is designed and permitted to burn WWTR and the amount is determined by the energy demands on that particular day.

2. Steps taken industry-wide to ensure that WWTR is consistently used as a legitimate fuel and is not discarded.

Just as mills do not use all of the same traditional fuel, mills do not always use WWTR as a fuel. Decisions regarding the use of WWTR as a fuel is undertaken at the mill level, depending on the energy and fuel needs of the boilers, the availability of fuels, and the quality of the WWTR generated at the particular mill. Some Maine mills burn all or more than 80 percent of the WWTR that is generated. Some mills have determined that the capital needed to support use of WWTR as fuel is more than the cost of using alternative fuels, and therefore have chosen not to burn the WWTR.

However, the bottom line is that those that burn WWTR for its energy value do so because the material is valuable to that mill.

All mill WWTR should not be classified as waste just because a portion of the fuel happens to be managed for agricultural purposes or landfilled. At Maine facilities, the WWTR is handled as a

valuable fuel up until the point there is a decision to discard it. WWTR at Maine facilities where it is combusted is managed to consistently generate a fuel with valuable heat content. It is segregated, handled, and stored to prevent contamination. At one mill, it is run through a dryer to increase its heat content.

3. What is the amount of WWTR burned as fuel?

In 2011, members of MPPA burned over 75,000 dry tons of WWTR. As examples, Lincoln combusts 100% of its WWTR, Verso mills combusts >80%, while Sappi mills combust > 60%.

4. Clarify what factors determine when WWTR is burned as fuel as opposed to being land applied or disposed.

As described above, a variety of factors go into determinations when a mill will burn WWTR rather than managing it in some other fashion. First and foremost, mills try to reuse as much from the mill as possible - back in the process, to other products, to other uses (such as for fuel), and only at last resort to disposal. The decisions are based on the type of boiler at the particular mill, the type of WWTR generated, the cost of other fuels (both traditional and alternative) in the area of the mill, and the operating conditions of the boiler. Some boilers are not designed to burn WWTR - just as some mills cannot burn coal or natural gas -- so the mill uses other fuels.

There is no one scenario for all Maine mills. However, WWTR that is burned for energy is used because it is a good fuel. The fact that not all WWTR is burned does not negate the value of the material to those mills that have chosen to use it as a fuel.

5. More data on contaminant levels - particularly chlorine and metals. A number of Maine's Mills have submitted extensive data to EPA regarding the chlorine and metal levels in their WWTP residuals in response to EPA information requests.

6. What steps has the industry taken to ensure the quality of pulp and paper mill WWTR when used as a fuel is consistent with that of fuel product? Every pulp and paper mill that generates WWTR does so as part of their compliance with Clean Water Act requirements. The strategies that each mill uses to meet those requirements differ depending upon the type of product, the location of the mill, and the specific standards established by EPA and the respective states. However, in every instance, mills clean wastewaters prior to discharge, thus creating primary and a variety of secondary WWTR, all which capture fibers. Furthermore, the question of whether the quality of the WWTR is appropriate for a particular mill is based on how it is dewatered, handled, stored, and conveyed, as well as boiler design. As such, there are some boilers designed to burn it; others cannot. Maine boilers that burn WWTR are designed to burn WWTR as a fuel.

7. What are the standard practices used to ensure WWTR has meaningful heating value? The overwhelming majority of pulp and paper mills remove water from WWTR prior to managing it in any way. Belt and screw presses are most commonly used in the industry. (e.g., one Verso mill uses screw presses for primary WWTR and a belt press for secondary WWTR, one Verso mill uses a belt press for combined primary and secondary WWTR and Verso uses a rotary dryer using recycled boiler exhaust). In all instances, the goal is to raise the solids content- and thus Btu value.

8. When shipped, how are WWTR managed?

None of the MPPA Mills send their WWTR off-site for purposes of burning as is. WWTR is sent off-site when it is being used by other entities to produce another product used for other purposes (land application, use as landfill cover), or for final disposal. WWTR is shipped by truck or rail in containers.

Comment: *Clarification of Criteria for Biomass or Bio-based Fuels and Non-hazardous Solid Waste:*

The treatment of biomass found in the three final NESHAPS rules created uncertainty whether urban biomass would be treated as a biomass fuel or a solid waste subject to the CISWI rule.

While this clarification is found in the CISWI reconsideration rule, the applicability to the Area Source and Major Source reconsideration rules are understood. GRU supports the clarification and believes that the clarification will remove a barrier to expanding the use of several promising biomass fuel sources.⁴

[Footnote]

(4) FR Vol. 76. No. 247, p. 80474 December 23, 2011 *"Specifically, we are proposing to make the following revisions and additions to the definition: (1) Explicitly acknowledge that the list of biomass materials is not exclusive by adding the phrase, "including, but not limited to '"; (2) revise the category 'forest-derived biomass' to include " agricultural biomass"; (3) add hogged fuel, wood pellets, and untreated wood pallets as examples of forest-derived biomass; (4) add the category of "urban wood" and provide examples, including tree trimmings, stumps, and related forest-derived biomass from urban settings ...)*

Response: This comment pertains to the Identification of Non-Hazardous Materials That Are Solid Waste and it is out of scope for this boiler rulemaking. Comment: *EPA bases its rules on incorrect assumptions about contamination levels in waste wood.*

EPA paints a rosy picture of how it is possible to render a "clean" fuel stream from C&D. EPA's March 2011 document "Identification of non-hazardous secondary materials that are solid waste" states that when C&D is sorted, painted wood is removed. This is not the case. Painted and contaminated wood is routinely burned.

For instance, the picture below is from the Palmer Renewable Energy (MA) facility's application to the Massachusetts Department of Environmental Protection.¹ The facility actively lobbied against any requirement to sort material to remove painted wood, stating "a specific sorting step for painted wood would result in losses of wood with no lead, losing the opportunity for safe beneficial use of this material".² When we interviewed the plant manager at New England Recycling, the main facility where Palmer would get its wood, he informed us that the "positive pick" process did not remove painted wood from the line. The majority of the wood they sort there is sent to Maine for burning. The picture below clearly shows painted wood in the debris pile from a Maine facility.

The wood in the picture above is described as "clean". The description of the picture is as follows: *"The second facility is Commercial Paving & Recycling Company (CPRC), which operates "wood recycling" operations at the City of Portland Riverside Facility and at CPRC's Scarborough Facility. At these sites, C&D wood is primarily received in a pre-sorted condition. CPRC only accepts pre-sorted, "clean" C&D wood and prohibits plastics, treated woods, non-combustibles, fines (dirt, wallboard, sawdust, roofing materials), asbestos, and metals from the wood storage piles (see Figure 2-7)."*

The "Evergreen Community Power" facility in Reading PA is a synthetic minor source for BACT (we could not ascertain its status with regard to HAPs). A Department of Energy report on the facility³ states that its fuel consists of *"forest industry waste, shredded construction wood waste, and demolition debris. The 'mulch' is mostly wood product, but there are significant amounts of paper, plastic and foreign debris."* The typical fuel composition is shown below.

Comparison with traditional fuels for C&D should be restricted to virgin biomass

EPA states that in determining whether a NHSM meets the legitimacy criteria, its contamination level must be compared to that of a traditional fuel. EPA explicitly states that a facility can compare the contamination level of construction and demolition debris and other wood waste to contamination levels in coal, even if the facility is not permitted to burn coal.

Page 80471:

2. Contaminant Legitimacy Criterion for NHSM Used as Fuels The 2011 NHSM final rule codified three self-implementing legitimacy criteria that NHSM must meet in order to be considered a non-waste fuel when burned in a combustion unit (40 CFR 241.3(d)(1)(i)-(iii)). One of these criteria focused on comparing levels of contaminants contained in the NHSM to levels of those constituents found in traditional fuels. Specifically, the contaminant legitimacy criterion for fuels was finalized as follows: "The non-hazardous secondary material must contain contaminants at levels comparable in concentration to or lower than those in traditional fuels which the combustion unit is designed to burn. Such comparison is to be based on a direct comparison of the contaminant levels in the non-hazardous secondary material to the traditional

fuel itself.” 40 CFR 241.3(d)(1)(iii). The existing language provides flexibility for persons to make comparisons on a contaminant- by-contaminant basis or on a group of contaminants-by-group of contaminants basis in determining what constituents to compare. The phrase “traditional fuels which the combustion unit is designed to burn” also provides the flexibility to choose among multiple fuel options.

This old language did not catch our attention in the previous version of the rule, because it never occurred to us, when talking about C&D, that the "traditional fuel" used for comparison could be anything other than biomass.

Industry groups have expressed concern that the regulatory language does not clearly reflect the EPA’s intent. 9 The EPA agrees that the regulatory language can be revised to better reflect the EPA’s intent in implementing the contaminant legitimacy criterion. Therefore, the Agency is proposing to revise this criterion to read, “The non-hazardous secondary material must contain contaminants or groups of contaminants at levels comparable in concentration to or lower than those in traditional fuel(s) which the combustion unit is designed to burn. In determining which traditional fuel(s) a unit is designed to burn, persons can choose a traditional fuel that can be or is burned in the particular type of boiler, whether or not the combustion unit is permitted to burn that traditional fuel. In comparing contaminants between traditional fuel(s) and a non-hazardous secondary material, persons can use ranges of traditional fuel contaminant levels compiled from national surveys, as well as contaminant level data from the specific traditional fuel being replaced. Such comparisons are to be based on a direct comparison of the contaminant levels in both the non-hazardous secondary material and traditional fuel(s) prior to combustion.” We are taking comment on how this revised contaminant legitimacy criterion would apply to specific fuels.

This is a disaster for new biomass electric plants that are area sources and also overwhelmingly synthetic minor sources for BACT. Under this rule, they would be permitted to wood with contamination levels far above clean biomass, particularly since EPA specifies it is acceptable to use "**ranges** of traditional fuel contaminant levels" for purposes of comparison (not averages or medians). This opens the door to comparing biomass/C&D contaminant levels with the *highest* contaminant levels found in coal. In the face of such a collapse of protection at the federal level, states wishing to protect themselves against C&D burning will be forced to enact new regulations, such as Massachusetts is already doing, in response to the Palmer Renewable Energy proposal to burn C&D which was shown to be so fatally flawed.

This should not be permitted. Clean untreated wood is the obvious "traditional" fuel to which C&D should be compared. C&D wood should not contain contaminants at levels higher than found on average in virgin biomass. This is particularly important for pellet manufacture, since pellets are burned not only in commercial and institutional boilers, such as those found in schools, but also in domestic pellet burners.

EPA must require testing of contaminant levels in fuels

On page 80477, EPA states the following:

Two other issues have arisen during implementation of the 2011 NHSM final rule that, while not leading to specific regulatory changes in today’s proposal, still merit discussion. The first issue

is that contaminant legitimacy criterion determinations do not require testing contaminant levels, in either the NHSM or an appropriate traditional fuel. Persons can use expert or process knowledge to justify decisions to rule out certain constituents.

EPA must require testing for contamination. C&D as a waste fuel is extremely variable. "Slugs" of contaminated wood move through sorting facilities at various times. Particularly given the large amount of material that is going to be generated as abandoned and foreclosed housing is torn down, the potential for liberating vast amounts of lead and other urban toxics, to say nothing of arsenic and chromium from pressure-treated wood, has never been higher. Facilities burning this contaminated material tend to be located in urban areas that already have high levels of air toxics. The Evergreen facility in Reading PA is a good example – it was built (with \$39 million in Stimulus funds) in a county (Berks) that is not only out of attainment with the ozone NAAQS, but also with the lead NAAQS (hard to do, considering it is an order of magnitude lower than it used to be). The region where the plant was built is also an environmental justice area. The facility is burning whatever comes through its door, with waste imported from all over the region, including New Jersey.

The potential for C&D fuel to emit toxics used to be taken seriously by EPA; for instance, in 2010 an ethanol company in Minnesota was fined \$120,000 for burning wood contaminated with lead-based paint and arsenic preservatives in its biomass gasification unit.⁴ With the proposed rule, EPA is removing any hope of regulating contaminants from the biomass power industry. Fuel won't be tested, and emissions won't be regulated, especially given the number of large biomass facilities that claim to be "area" sources.

Definition of "clean" cellulosic biomass has become too expansive

EPA is proposing to modify the definition of "clean" cellulosic biomass. Page 80470:

Clean Cellulosic Biomass The EPA is proposing to revise the definition of "clean cellulosic biomass" to list additional examples of biomass materials that are appropriately included within this definition....

.... Thus, the EPA is proposing to revise the definition of "clean cellulosic biomass" as follows: "Clean cellulosic biomass means those residuals that are akin to traditional cellulosic biomass, including, but not limited to: agricultural and forest-derived biomass (e.g., green wood, forest thinnings, clean and unadulterated bark, sawdust, trim, tree harvesting residuals from logging and sawmill materials, hogged fuel, wood pellets, untreated wood pallets); urban wood (e.g., tree trimmings, stumps, and related forest-derived biomass from urban settings); corn stover and other biomass crops used specifically for the production of cellulosic biofuels (e.g., energy cane, other fast growing grasses, byproducts of ethanol natural fermentation processes); bagasse and other crop residues (e.g., peanut shells, vines, orchard trees, hulls, seeds, spent grains, cotton byproducts, corn and peanut production residues, rice milling and grain elevator operation residues); wood collected from forest fire clearance activities, trees and clean wood found in disaster debris, clean biomass from land clearing operations, and clean construction and demolition wood. These fuels are not secondary materials or solid wastes unless discarded. Clean biomass is biomass that does not contain contaminants at concentrations not normally associated with virgin biomass materials..

Comments on bolded terms:

1. **Hogged fuel.** "Hogging" refers to the process of shredding material. Just because material has been shredded does not make it clean. This description of a process does not belong in this list, which otherwise consists of material fuel sources.
2. **Wood pellets.** Like hogging, pelletizing can be done to almost any material. Wood pellets can be made from any kind of wood. The definition should specify "wood pellets made from virgin biomass materials".
3. **Byproducts of ethanol natural fermentation processes.** This is a discarded waste product and does not deserve the appellation "clean". What is the standard of "virgin biomass" to which is being compared?
4. **Clean wood found in disaster debris.** This again refers indirectly to a process (the process by which standing wood is knocked down in a disaster such as a tornado). This adds nothing to the list that is not already there (i.e., all the "clean" kinds of materials that could be found in disaster debris are already listed).
5. **Clean construction and demolition wood.** This should not be in here, because operationally, this material is discarded by definition. Further, the majority of this material can in no way be considered "clean".

Asbestos should be included as a regulated contaminant

EPA states on page 80475:

Also, we are proposing to exclude from the definition of contaminants those pollutants in the CAA sections 112(b) and 129(a)(4) lists that we do not expect to find in any NHSM.... Fine mineral fibers are excluded because they are releases from the manufacturing and processing (not combustion) of non-combustible rock, glass, or slag into mineral fibers.

Asbestos is commonly found in construction and demolition debris. Asbestos particles in smoke are deadly. Sorting procedures at C&D sorting facilities commonly attempt to remove material that looks like it contains asbestos, but by nature this material can end up in the "fines". The description⁵ of the sorting procedure at a C&D sorting facility in Massachusetts demonstrates why asbestos contamination (and contamination by lead, mercury, and other toxics) is common:*NER accepts mixed C&D waste and separates out ferrous and non-ferrous metals, aggregate (asphalt, brick, concrete (ABC)), OCC (cardboard), plastics (Nos. 1 and 2), gypsum, wood and fines. The mixed C&D is dumped onto the tipping floor where it is inspected for presence of unacceptable materials (hazardous materials, municipal solid waste, and suspect asbestos containing materials). A grapple sorts out large bulky items (large aggregate, bulky insulation or plastics, and large gypsum/wallboard), roughly crushes remaining items and feeds a conveyor to a trommel screen where approx. 1/2 inch fines are removed. The remaining materials move via conveyor onto the sorting line, where some 20 pickers manually remove ABC OCC, metals, and wood. The wood is thus picked off the line by a positive sort.*

Excluding mineral fibers from regulation explicitly ignores the possibility of such contamination in C&D. Asbestos should be a regulated contaminant. [Footnote 1: Palmer Renewable Energy

Comment: AIF Supports the Result That Thermal Sand Recycling Not Be Subject to the CISWI Rule and Urges a Similar Result for Recovered Paint Solids as well as Other Appropriate Revisions to the Final Rule.

A. Classification of Thermal Sand Recycling: EPA Should Finalize the Proposed Definition for “Foundry Sand Thermal Reclamation Unit.”

In the preamble to the final NHSM Rule, EPA asserted, for the first time, that it considered foundry sand recycled on-site using a thermal sand reclamation (“TSR”) unit and reused in the same process loop a “solid waste,” thereby making TSR units subject to CAA Section 129’s emission standards. *See CISWI and NHSM Rules*, 76 Fed. Reg. at 15,519. This statement was the first instance in a publicly available document where EPA suggested that TSR units could become subject to the CISWI Rule as “solid waste.” In its petition for reconsideration and subsequent comments, AIF commented that EPA’s statement was arbitrary and contradictory to the CAA, and urged EPA to reconsider and revise it. AIF explained that, under EPA’s line of reasoning, a host of processes not previously contemplated by EPA could become regulated under the CISWI Rule. EPA’s statement, likewise, runs contrary not only to the purposes of the CAA as set forth in Section 101(c),³⁶ AIF explained, but also to EPA’s policy to promote reducing, reusing and recycling, *see* 74 Fed. Reg. 41, 46 (Jan. 2, 2009). AIF articulated that EPA’s line of reasoning would promote increased sand mining, the purchase of virgin sands for the casting industry, and require the disposal, in landfills, of huge volumes of foundry sand, rather than its recycling and reuse. Accordingly, AIF requested EPA to reconsider its determination and clarify that (1) foundry sand being recycled is not a “solid waste” and (2) TSR units are not solid waste incineration units subject to the requirements in the CISWI Rule (either 2000 version or 2011 version).

In the proposal, EPA concludes that TSR units are parts reclamation units as defined in the 2000 CISWI Rule (“unit[s] that burn coatings off parts (e.g., tools, equipment) so that parts can be reconditioned and reused”) because TSR units are “parts reclamation units” that are on foundry sand, which allows re-use of the sand. *CISWI and NHSM Rules Reconsideration Proposal*, 76 Fed. Reg. at 80,463. EPA solicits comment on the proposed definition of TSR units, *see id.*, and elects not to propose standards for TSR units on the basis that it does not currently have emissions data for TSR units and regulation of such units is not required to comply with its CAA § 112(c)(6) obligation. *See id.*

EPA proposes to define “foundry sand thermal reclamation unit” as:

a type of part reclamation unit that removes coatings that are on foundry sand, [and] not an incinerator, waste-burning kiln, an energy recovery unit or a small, remote incinerator under this subpart.

Id. at 80,502. EPA then proposes to define a “burn-off oven” as:

any rack reclamation unit, part reclamation unit, or drum reclamation unit. A burn-off oven is not an incinerator, waste-burning kiln, an energy recovery unit or a small, remote incinerator under this subpart.

Id. Based on these definitions, then, TSR units would not be regulated under the CISWI Rule because EPA has determined that it will not regulate burn-off ovens under the regulation.³⁷ *See, e.g., id.* at 80,460. While AIF does not believe that TSR units qualify as CISWI units more generally, it also agrees that TSR units should not be subject to CISWI requirements because they significantly reduce landfill through reuse, such units are numerous and there are a lack of emissions data available for them. Just like burn-off ovens, these are activities that EPA should create policies to encourage, rather than discourage by regulating them under CISWI.³⁸

Accordingly, consistent with its prior submittals on this issue, AIF supports both EPA’s clarification that TSR units are not incinerators and its proposed definition of “foundry sand thermal reclamation unit” in that it results in TSR units not being subjected to the CISWI rule requirements.³⁹ [Footnote 36: “A primary goal of this chapter is to encourage or otherwise promote reasonable Federal, State, and local government actions, consistent with the provisions of this chapter, for pollution prevention.” CAA § 101(c); 42 U.S.C. § 7401(c).]

[Footnote 37: In fact, TSR units have never been contemplated as falling within the CISWI program since its inception. The purpose of a TSR unit is neither to “combust” the sand, nor to reduce the volume of the sand, nor to generate heat for reuse. The purpose is simply to reuse the sand in the making of new sand cores and molds. EPA never intended to include these types of processes in the CISWI Rule.]

[Footnote 38: EPA also noted it was not required to include such units to comply with their Section 112(c)(6) obligations to identify categories of sources of pollutants to assure that sources accounting for not less than 90 percent of the aggregate emissions of each such pollutant are subject to Section 112 standards. *See CISWI Rule*, 76 Fed. Reg. at 15,708, 15,734. To the extent Section 112(c)(6) is relevant, the same rationale applies to TSR units.]

[Footnote 39: For the reasons explained in its petitions for rulemaking and reconsideration, AIF does not agree that TSR units are incinerators even should they not fall within the definition of parts reclamation units and our support for the proposed definition should not be interpreted as conceding this point. However, since its members would not be affected by the rule given the proposed definition, AIF supports the exclusion (albeit on different grounds).

Comment: Classification of Recovered Paint Solids: EPA Should Adopt an Exclusion from the CISWI Rule for Recovered Paint Solids Collected from Automobile Assembly Plants that are Combusted for Energy Recovery.

In its petition for reconsideration and subsequent comments, AIF called upon EPA to clarify that the regulations consider recovered paint solids collected from automobile assembly plant painting operations a non-hazardous secondary material, *i.e.*, NHSM, not a “solid waste” subject to the CISWI Rule. AIF conveyed to EPA that such recovered paint solids are not hazardous but, instead, serve as a valuable commodity and are managed as similar valuable commodities such as scrap tires combusted as alternative fuels. Rather than promote energy recovery from these materials, AIF commented, classifying recovered paint solids in the CISWI Rule not only would increase the amount of paint solids diverted to landfill, including by facilities owned and/or operated by AIF members, but also increase the use of fossil fuels due to the fuels that facilities would need to burn instead of recovered paint solids. Accordingly, AIF advocated for EPA to adopt an exclusion from the CISWI Rule for recovered paint solids collected from automobile assembly plants.

The proposal fails to respond to or even discuss AIF’s petitions and comments. Accordingly, here, AIF reiterates both its concerns about the classification of recovered paint solids and its recommended revisions. In the final reconsideration rule, EPA should clarify that recovered paint solids collected from automobile assembly plant operations, categorically, are not a “solid waste” subject to the CISWI Rule but, rather, a non-hazardous secondary material under the NHSM Rule. Several rational bases support such action. First, recovered paint solids collected from automobile assembly plant operations are not hazardous materials. On the basis of test burns, for example, state regulators have already determined that the combustion of paint solids is acceptable. Second, they serve a legitimate energy recovery function because they are regarded as a valuable commodity in that they provide a beneficial use as a fuel, with similar BTU value to coal. Facilities contract with the automotive companies, AIF’s members included, to accept recovered paint solids for use as fuel, like coal, in coal-fired boilers. Recovered paint solids are managed similar to coal and mixed prior to combustion. They have attributes comparable to scrap tires, which EPA proposes to classify as non-wastes, in large part, because contractual

arrangements exist whereby, in lieu of automotive companies discarding them, combustors receive scrap tires for use as fuel. *See, e.g., id.* at 80,476. Since the purpose of burning recovered paint solids “is not to destroy or discard them, as they are clearly considered and managed as a valuable commodity to the manufacturing process,” EPA should classify them as non-waste, just as EPA proposes to classify resinated wood. *Id.* at 80,483.

EPA should promote the energy recovery inherent in the use as fuel of recovered paint solids collected from automobile assembly plants. Classifying these materials in the CISWI Rule would only increase the amount of materials diverted to landfill, including by facilities owned and/or operated by AIF members. Moreover, it would increase the use of fossil fuels because facilities would need to burn fossil fuels instead of recovered paint solids. In the final reconsideration rule, therefore, EPA should classify as non-hazardous secondary material paint solids collected from automobile assembly plants that are burned for energy recovery. As a corollary, EPA should exclude recovered paint solids from the CISWI Rule.

Response: This comment pertains to the Identification of Non-Hazardous Materials That Are Solid Waste and it is out of scope for this boiler rulemaking. Comment: Fail to list important biomass materials as fuels. Important biomass materials such as paper recycling residuals, pulping sludge, wood construction debris and railway ties are still not listed as fuels, which creates great uncertainty for the businesses that rely on them. The failure to list such materials as fuels means that the boilers burning such fuels could be regulated under the onerous and stigmatizing incinerator standards. Alternatively, those materials could end up being sent to landfills, rather than being used to produce energy—a bad result for jobs and the environment.

Response: This comment pertains to the Identification of Non-Hazardous Materials That Are Solid Waste and it is out of scope for this boiler rulemaking. Comment Excerpt Number: 4

Comment: The NHSM rule is of critical importance to NAFO’s members because it determines whether the co-products associated with biomass production processes are considered fuels subject to the Major Source rule or solid waste subject to the more stringent CISWI rule when combusted for energy. The combustion of biomass residuals for energy is an important

component of the production processes for many of NAFO members' customers. Other customers rely on these materials as valuable co-products which can be sold for energy production by third parties. Yet experience has shown that classifying these materials as "solid waste" ensures that they will not be combusted for energy due to the high costs of compliance with CISWI standards. Rather than attempting to meet the more stringent limits, facilities will simply switch to other fuels that are subject to the less stringent Major Source rule standards.

The NHSM rule promulgated by EPA in March 2011 suffers from a number of flaws that will harm NAFO members and prevent the use of many clean, renewable secondary materials for biomass energy production. First, the definition of clean cellulosic biomass lacked sufficient clarity, creating uncertainty whether certain types of biomass were considered clean cellulosic biomass and could be combusted for energy without triggering CISWI requirements. Second, the rule improperly classified many traditional biomass fuels as solid waste despite their long history of use as valuable fuel products. Third, the limited access to complicated petitioning processes failed to provide adequate redress for regulated entities (and their suppliers) when the default rules classified their biomass fuel supplies as solid waste.

The proposed rule includes a number of revisions that will have a positive impact on NAFO's members and appropriately encourage the use of biomass secondary materials as valid traditional fuels. As described below, NAFO generally supports EPA's proposed changes, but believes that additional changes are needed to accurately reflect the historic role of biomass secondary materials as traditional fuels.

A. EPA Must Not Exceed Its RCRA Authority by Seeking to Regulate Biomass Energy Feedstocks That Have Not Been Discarded

EPA's authority over secondary materials is limited to material that has been discarded. Under RCRA, only material that has been "discarded" meets the definition of "solid waste." *See Ass'n of Battery Recyclers v. EPA*, 208 F.3d 1047, 1051 (D.C. Cir. 2000) ("Congress unambiguously expressed its intent that 'solid waste' (and therefore EPA's regulatory authority) be limited to materials that are 'discarded' by virtue of being disposed of, abandoned, or thrown away."). The D.C. Circuit has also established the transfer of a co-product from a generator to a third party does not create a presumption that the material has been discarded because firms may prefer to transfer biomass co-products to third parties who can use them more efficiently. *Safe Food and Fertilizer v. EPA*, 350 F.3d 1263, 1268 (D.C. Cir. 2003) ("As firms have ample reasons to avoid complete vertical integration, . . . firm to firm transfers are hardly a good indicia of a 'discard' as the term is ordinarily understood." (citation omitted)). As such, if a material is a valuable product or industrial input, and handled as such, EPA cannot regulate it under RCRA.)

As described above, biomass provides a clean, renewable, alternative to fossil fuels and represents an important part of the Administration's clean energy policy. In order to support and further that policy, EPA must adopt regulations that support existing biomass energy facilities and encourage the development of new biomass energy facilities, whether they rely on traditional biomass fuels or, through ingenuity, develop new energy opportunities for biomass co-products. Any presumption that biomass co-products are discarded waste products is inconsistent with this objective and, as described below, we urge EPA to avoid such presumptions in its regulations. While a policy of encouraging biomass energy would be most consistent with the Administration's goals, EPA must not take positions that are in conflict with that goal. At a

minimum, EPA must adopt a neutral policy that does not presume biomass materials are discarded solid waste.

Accordingly, we urge EPA to interpret its RCRA authority narrowly to ensure that the materials it seeks to regulate have actually been discarded. Any material that is treated by generators or their customers as a valuable fuel feedstock and is actually combusted for energy production has not been discarded and thus is outside of EPA's authority under the NHSM rule. It is irrelevant whether the material is a traditional or newly developed fuel or whether the fuel is combusted by the generator or by a third party. In any case, biomass materials with value as energy feedstocks are not discarded and should not be subject to EPA's authority under RCRA or the more stringent CISWI emissions limitations.

B. Definition of "Clean Cellulosic Biomass," 40 C.F.R. § 241.2

NAFO believes that all trees and all other materials taken from the forest are "clean" cellulosic biomass and supports EPA's conclusion that clean cellulosic biomass materials are traditional fuels and thus are not solid waste when burned for energy. NAFO supports EPA's decision to clarify the definition of clean cellulosic biomass by including more comprehensive examples of secondary materials that qualify as clean cellulosic biomass. However, we believe that additional steps can be taken to provide greater clarity to the rule and greater assurance to regulated entities that additional forest products qualify as clean cellulosic biomass and will not be considered solid waste.

NAFO agrees with EPA's conclusion that the list of materials included in the clean cellulosic biomass definition should not be considered exhaustive and supports EPA's addition of the phrase "including, but not limited to" in the definition. 76 Fed. Reg. at 80,470. This change will provide regulated entities with the assurance that unlisted materials will not be categorically considered to be solid waste and provide them with the flexibility to alter fuel mixes and incorporate traditional fuels that are not explicitly listed in the definition of clean cellulosic biomass without fear of becoming subject to the more stringent CISWI emissions standards.

In NAFO's comments on the June 4, 2010 Proposed NHSM rule, we suggested adding clarity to the forest derived biomass portion of cellulosic biomass definition.²¹ We appreciate EPA's explanation on page 173 in its "Responses to Comments Document for the Identification of Nonhazardous Secondary Materials That Are Solid Waste Rulemaking (February 2011)," posted at EPA-HQ-RCRA-2008-0329 on March 21, 2011: "Under the final rule, forest-derived biomass, including green wood, forest thinnings, clean and unadulterated bark and tree harvestings residuals, is considered an alternative traditional fuel. The categories would encompass dead trees and wood residues." NAFO also supports EPA's decision to include "hogged fuel, wood pellets, untreated wood pallets[, and] urban wood (e.g. tree trimmings, stumps, and related forest-derived biomass from urban settings)" and "byproducts of ethanol natural fermentation processes" within the definition clean cellulosic biomass. This expanded definition, along with EPA's response to NAFO's comments, will provide assurance to the entities that produce and combust these traditional biomass energy fuels and appropriately encourages their use clean, renewable fuels.

However, we urge EPA to provide greater clarity by removing from the final rule the caveat that "Clean biomass is biomass that does not contain contaminants at concentrations not normally

associated with virgin biomass materials." 76 Fed. Reg. 80, 529. Despite EPA's efforts to provide an expansive definition of clean cellulosic biomass that accurately reflects the wide range of biomass feedstocks that have traditionally been used as fuels – and thus have not been discarded – this final requirement suggests that these traditional fuels must still satisfy the legitimacy criteria discussed in section II.E in order to avoid being classified as solid waste. It also perpetuates EPA's erroneous interpretation of its authority under RCRA, which is expressly limited to discarded material and does not encompass traditional fuels. This definition of clean cellulosic biomass will be of little value to regulated entities if they are required to complete the NHSM regulatory process and demonstrate compliance with the legitimacy criteria even if the biomass fuels they combust are explicitly included in the definition of clean cellulosic biomass. Thus in addition to removing this confusing sentence, we urge EPA in the preamble to the final rule to clarify that the feedstocks explicitly listed in the definition of clean cellulosic biomass are traditional fuels that are not subject to EPA's RCRA authority over discarded materials, whether combusted by generators or by third parties.

C. Administrative Petition Process for Non-waste Determinations for Non-Generators, 40 C.F.R. § 241.3(c)

Despite the additional clarity provided by the revised definition of clean cellulosic biomass, many biomass materials used as fuels are not listed and must instead be considered on a case-by-case basis. For borderline cases, the administrative petition process – which currently presumes that all biomass co-products combusted by entities other than generators are solid waste – offers a means to obtain assurance that EPA will consider the material to be a fuel and not solid waste. NAFO supports EPA's efforts to streamline and add flexibility to the petition process, but believes that additional steps can be made to make the process consistent with the law and more workable in practice.

The proposed rule clarifies a number of features that streamline and add flexibility to the administrative petition process. NAFO agrees with EPA that any interested person – including forest owners – should be able to initiate the petition process. It also agrees that petitions should be allowed for entire classes of combustors rather than requiring a case-by-case analysis. These clarifications will encourage all members in the biomass supply chain to promote their products and co-products as clean, renewable fuels and promote the development of new markets for biomass materials. However, NAFO believes that these benefits could be achieved more efficiently by allowing for nation-wide petitions for classes of combustion units rather than requiring separate petitions for each EPA region.

NAFO also believes that the administrative petition process could be further streamlined by not seeking public comment on every individual petition. By filing an administrative petition, a petitioner is not seeking to change EPA's regulatory program or create new legal rights or obligations. Instead, the administrative petition process provides an opportunity for a petitioner to obtain in advance agency concurrence, based on sound science, with respect to the classification of a particular feedstock under existing regulations. In this respect, the administrative petition process differs from the categorical non-waste determination discussed below, where EPA makes changes the regulatory status of certain secondary materials that are reflected in the Code of Federal Regulations. Because the public – through this rulemaking process – has an opportunity to provide input on EPA's regulations, there is no need to provide a

second opportunity for public comment when those regulations are applied by EPA in specific contexts through the administrative petition process.

While EPA's proposed changes are beneficial, NAFO believes that additional changes could further streamline and provide greater flexibility to the administrative petition process. First EPA should adopt a more flexible approach to evaluating petitions, recognizing – as it does in the categorical non-waste determination process – that fuels should not be considered solid waste, even if they do not meet each of the legitimacy criteria. Second, EPA should not distinguish between secondary materials combusted by generators and third parties. The current default rule presuming that secondary materials combusted by third parties are solid waste ignores the fact that third parties have traditionally combusted biomass material for energy and discourages the development of new markets for clean, renewable biomass co-products and is not consistent with Congressional intent in RCRA that EPA only has authority over material that has been discarded. Instead, EPA should permit non-generators to make the same self-determination as generators that their secondary material fuels are not solid waste. Under this approach, the administrative process would still play a valuable role in providing assurance to all regulated entities in borderline cases.

D. Categorical Non-Waste Determinations for Specific NHSM, proposed 40 C.F.R. § 241.4

NAFO supports EPA's adoption of its recommendation to categorically classify resinated wood as non-waste.²² As described more fully in our previous comments, resinated wood residuals have been used as a traditional fuel source since the 1950s²³ and we applaud EPA's recognition of this traditional fuel source. NAFO also urges EPA make full use of the proposed categorical non-waste determination process and aggressively consider categorical determinations for other traditional fuels.

As explained in our previous comments, there are a number of traditional biomass fuels that may not qualify as clean cellulosic biomass under the strict criteria included in the current. Nevertheless, these secondary materials have a long history of use as energy feedstocks and should not be classified as solid waste. Among these traditional fuels are construction and demolition debris; pulp and paper wastewater residues, which consist largely

of biomass (wood fiber); paper recycling residuals; and certain treated woods, such as creosote-treated railroad ties. We concur with the analyses submitted by the American Forest & Paper Association in support of a categorical non-waste determination for pulp and paper wastewater residues (pulp and paper sludge) and for construction debris. NAFO supports EPA's proposed Categorical Non-Waste Determination Process as a means to exclude these traditional fuel products from the definition of solid waste and to provide regulated entities with the necessary assurances that their combustion will not trigger more stringent CISWI emissions limits.

To determine whether a non-hazardous secondary material should be granted a categorical non-waste determination, EPA must focus primarily on whether the secondary material has been discarded or whether it is treated as a co-product with value as an energy feedstock because, as described above, EPA's regulatory authority over secondary material is limited to material that is discarded. *See Ass'n of Battery Recyclers*, 208 F.3d at 1051 While consideration of other factors such as the legitimacy criteria may aid EPA in making that determination, EPA should make clear in the final rule that secondary material will qualify as non-waste if the petitioner can

demonstrate that it has not been discarded, but is used instead as a fuel source by the generator or third parties.

To this end, NAFO supports EPA's proposal to add flexibility to the petition and review process for making categorical determinations. First, NAFO supports EPA's proposal to apply the categorical determinations to all combustors and not merely to generators of secondary materials. This approach appropriately recognizes the many circumstances in which generators have treated their secondary materials as valuable co-products and developed markets for their combustion for energy by third parties. Second, NAFO supports EPA's proposal to allow any person to file a categorical determination petition with EPA. In doing so, EPA appropriately recognizes that other entities besides the generator and combustor have an interest in properly categorizing traditional fuels as non-waste and in developing new opportunities to utilize biomass secondary materials as raw materials in other industrial processes. Third, NAFO supports EPA's decision to balance the legitimacy criteria with other factors. Many traditional fuels have a long history of use for energy combustion, but may not meet each of the legitimacy criteria. By balancing the legitimacy criteria with other factors, EPA can take a more flexible approach that can emphasize historic uses of biomass secondary material and respond to new markets as they develop.

E. Legitimacy Criteria, 40 C.F.R. § 241.3(d)

NAFO also supports EPA's proposals to incorporate additional flexibility to the legitimacy criteria applied to NHSM. As explained in our earlier comments, the legitimacy criteria are unnecessarily stringent and will inappropriately exclude some NHSM that are validly reused as energy feedstocks.²⁵

While the proposed rule makes a several improvements, the legitimacy criteria remain unnecessarily stringent.

First, NAFO agrees with EPA's proposal to provide regulated entities with the flexibility to apply the legitimacy criteria to individual contaminants or entire classes of contaminants as appropriate. This change will provide greater flexibility to accurately compare the environmental and health impacts of NHSM and traditional fuels. Second, NAFO supports EPA's proposal to permit comparisons to any traditional fuel that could be combusted in the unit. Again, this added flexibility offers a better opportunity to compare the environmental and public health impacts of NHSM and the traditional fuel alternatives that could be combusted in their place.

However, NAFO continues to disagree with EPA's decision to place more stringent requirements on legitimacy criteria for NHSM than it does for hazardous materials. First, EPA should recognize that some traditional fuels do not meet each of the legitimacy criteria and permit balancing of the legitimacy criteria – as it proposes to do under the categorical non-waste determination process – instead of requiring strict compliance with each criterion. Second, rather than limiting NHSM to those with "contaminants at levels comparable to or lower than those in traditional fuels," 40 C.F.R. § 241.3(d)(1)(iii), EPA should adopt the standard traditionally applied to hazardous materials where contaminants cannot be present "at levels that are significantly elevated from those found in analogous products." 40 C.F.R. § 260.43(c)(2)(ii). There is simply no justification for applying more stringent standards for secondary materials that are non-hazardous than for those that are hazardous.[Footnote 21: NAFO NHSM RuleComments,at 3-4.]

Comment: As anticipated, EPA has addressed several significant elements of the March 2011 Final NHSM rule, which have the effect of reclassifying sources between the incinerator and boiler categories and among subcategories in each rule. Even during the development of and comment period on the Proposed Reconsidered NHSM rule, EPA issued three interpretive letters that directly affected subcategory populations. 76 Fed. Reg. 80473. Among the sources whose classifications were directly affected are CIBO members. And EPA went on to propose other significant changes in the fuel definition that must be accounted for by sources in their compliance plans. Even publishing the Final Reconsidered NHSM rule, however, will not fully determine the status as waste or NHSM of many materials currently being used as fuel, and that rule provides a petition process to make those determinations. Sources that are unsure about the status of their materials will petition EPA for determinations of the status of their materials, and on the basis of those determinations, the sources will then know whether their continued use of those materials will classify the source as an incinerator or boiler. CIBO has urged EPA to establish a timeline for completion of the initial round of waste/fuel determinations, although the Proposed Reconsidered NHSM Rule does not indicate a date-certain by which sources will have final decisions regarding the status of their materials.

Comment: While the EPA has fixed some of the problems with the proposed Boiler Maximum Achievable Control Technology (MACT) rule compared with previous versions of the rule, I still have many concerns. One step in the right direction was the secondary non hazardous materials rule that will decide under which rule a boiler is operated; however, there should be a way to make the majority of these determinations without EPA involvement. Since the Wisconsin

Department of Natural Resources already does an overly thorough job, this is a particularly frustrating issue in Wisconsin. There may be a few cases where a determination from EPA is needed, but this requirement creates an unnecessary burden on the company, the fuel supplier, and the EPA. Companies should be able to make decisions on their own with clear criteria. It should be possible for companies to keep records of how and why they made their determinations. Companies would be required to keep this information available if questions arise in the future. As an example, the small paper mill that I work at will need to have two determinations made. The two fuels are unique, but both are mainly wood. Having some sort of threshold set up that says that if something is 90% of a traditional fuel with the remaining material not falling under the RCRA rules would be one suggested method. Another example that comes to mind is for facilities with anaerobic digesters that are burning the biogas that is generated. Since the majority of the biogas is methane with carbon dioxide making up the majority of the difference, the biogas should be regulated similar to natural gas under the Boiler MACT rule.

Comment: Solid Waste Definition

- In its August 2, 2010 comments, Masco addressed the definition of "solid waste" in EPA's parallel rulemaking, "Identification of Non-Hazardous Secondary Materials That Are Solid Waste", proposed rule (75 Fed. Reg. 31844, June 4, 2010). EPA explained the purpose of its parallel ("NHSM") rulemaking as follows:

The meaning of "solid waste" as defined under RCRA is of particular importance since it will determine whether a combustion unit is required to meet emissions standards for solid waste incineration units issued under section 129 of the Clean Air Act (CAA) or emissions standards for commercial, industrial, and institutional boilers issued under CAA section 112.

- Masco biomass-fueled boilers combust wood or resinated wood material generated from the manufacture of cabinetry. Masco commented that such wood fuels, which are either combusted or sold to other manufacturers for use as fuel, are not solid waste and therefore the NHSM rule (and by implication, the Boiler MACT and CISWI2 rules) should be clarified to ensure that combustion of such solid wood fuels would not subject the boiler to regulation as an incinerator under the CISWI or Boiler MACT rules. Masco is pleased to note that EPA essentially agrees, and has clarified in the parallel rulemaking, that such "clean wood" or "resinated wood" solid fuels are generally not solid waste for purposes of the NHSM rule or the Boiler MACT and CISWI rules. See 76 Fed. Reg. 15459.

- Nevertheless, the NHSM rule provides that resinated wood must still satisfy certain "legitimacy criteria" in order to maintain its status as a solid fuel rather than a solid waste. See 76 Fed. Reg. 15459. Masco continues to believe that resinated wood should be treated as any other traditional fuel and therefore be fully and specifically exempt from further regulation, including the "legitimacy criteria" imposed by the NHSM final rule.

Response: This comment pertains to the Identification of Non-Hazardous Materials That Are Solid Waste and it is out of scope for this boiler rulemaking. Comment Excerpt Number: 2

Comment: The Pennsylvania Chamber supports a holistic approach to the fuel versus waste determination that considers historical purposes and uses of the combustion material, rather than narrow application of one or a few legitimacy criteria.

In the proposed revised definition of solid waste materials, EPA has proposed listing certain (biomass) materials that will be simply designated as non-waste in the definition, regardless of their status under the legitimacy criteria. In addition, EPA proposed more flexibility in the application of the legitimacy criteria, insofar as EPA applies the criteria, after the rules are finalized, when making a categorical determination for a particular fuel that would apply to all sources burning that fuel. The Pennsylvania Chamber supports this proposed approach to the fuel vs. waste determination, which will reduce the instances where the rule that applies to an individual boiler hinges on a specific consideration under the legitimacy criteria, (e.g., whether the material is generated on or off site). The Pennsylvania Chamber urges EPA to clarify in the final rules that this holistic approach will also be applied when making unit-specific fuel versus waste determinations. Such an approach will more accurately distinguish between those materials which have been discarded and are truly being burned as waste from materials which have the characteristics of a legitimate fuel, but may not satisfy all of the legitimacy criteria, which of necessity are designed to cover a broad range of circumstances.

Response: This comment pertains to the Identification of Non-Hazardous Materials That Are Solid Waste and it is out of scope for this boiler rulemaking. Provided the commenter has submitted this comment to the Identification of Non-Hazardous Materials That Are Solid Waste rulemaking docket, the response to this comment will be provided there.

Comment: API urges EPA to reaffirm the status quo and promulgate a final NHSM Rule under which EPA presumes that non-hazardous secondary material (NHSM) that is burned for energy recovery or used as an ingredient in a combustion unit is not a waste. Starting from that presumption, EPA can then use the NHSM Rule to identify wastes. However, that is not the framework of the current NHSM Rule. That rule starts from the presumption that all NHSM that are combusted are wastes, and then identifies conditions under which NHSM may be identified as non-waste. The FRRC comments in docket EPA-HQ-RCRA-2008-0329 (incorporated by reference) explain the following main points in detail:

- The NHSM proposal exceeds EPA's authority under RCRA. There are major flaws in the contaminant legitimacy criterion, categorical determinations that a material is a non-waste fuel, and the proposed rulemaking petition process.
- The proposal is arbitrary and capricious under the administrative procedure act because: o EPA has no record to support its determination that most NHSM that are combusted are wastes; and
- EPA has provided no rationale to support its presumption that almost all NHSM combustion constitutes disposal.
- EPA should establish the presumption that most NHSM is not a waste when combusted for energy recovery or for use as an ingredient.
- EPA must correct earlier misstatements regarding the status of certain categories of NHSM and make other clarifications. o EPA's statements on gaseous fuels are inconsistent with its acknowledgement that gas that is not contained in a container is not a waste.
- EPA's statements on thermal treatment are inconsistent with its recognition that destruction of a contaminant is not dispositive evidence of discard and that materials that are being continuously used in an industrial process are not discarded, even when reclaimed.
- EPA treatment of ingredients as waste is illogical and inconsistent with RCRA.
- EPA's statements on off-specification used oil are inconsistent with RCRA.

The FRRC comments on the NHSM proposal explain how EPA's NHSM rule undermines the basis for the Boiler NESHAP and CISWI Rules, and other NESHAP standards. Section 129 of the Clean Air Act provides that a unit that is a commercial and industrial solid waste incinerator is subject to the CISWI Rule, and no other NESHAP standards. 42 U.S.C. 7429(h)(e). If a unit combusts solid waste, it is a CISWI unit. The NHSM Rule is intended to provide the basis for distinguishing between CISWI units and other combustion units by identifying what material is a solid waste when combusted. Unfortunately, the proposed revisions to the NHSM Rule do not add the clarity and certainty needed by both EPA and the regulated community to determine what units are CISWI units and what units are subject to other MACT standards.

- **Comment:** Our four integrated pulp and paper mills have a total of five solid fuel-fired boilers which would be regulated under the "wet biomass stokers" subcategory. These boilers principally burn clean biomass (bark and wood residues) but also burn other NonHazardous Secondary Materials (NHSM) such as urban wood, wastewater treatment residuals, tire derived fuel, and cross tie derived fuel. Our biomass boilers also burn other incidental NHSM such as used oil and recycled paper residuals for fuel. Thus, there is the potential that our biomass stoker boilers could become Commercial Industrial Solid Waste Incinerators (CISWI) with their historical fuel mix, depending on how EPA decides the "fuel vs. solid waste" issue. Boise has previously provided comments on the proposed NHSM rule (August 2, 2010, submitted to rradocket@epa.gov) and supports the current comments on the NHSM rule re-proposal submitted by AF&PA and NCASI.

Response: This comment pertains to the Identification of Non-Hazardous Materials That Are Solid Waste and it is out of scope for this boiler rulemaking. Provided the commenter has submitted this comment to the Identification of Non-Hazardous Materials That Are Solid Waste rulemaking docket, the response to this comment will be provided there.

Comment: FUEL TO WASTE SWITCHING PROVISIONS

ACC has long advocated the need for combustion units that intermittently burn solid waste to be able to move between §129 and §112 as applicable, and included comments on this issue in our submissions on both the proposed CISWI rule and the 2010 Proposed Boiler Rule . ACC does not support the fuel switching requirements that EPA promulgated in the final CISWI rule and believes EPA exceeded its statutory authority in the approach it took. In this reconsideration, EPA requests comment "on the fuel switching provisions included in the final CISWI rule, particularly on whether the provisions should include further clarification on the timeline and regulatory requirements of a fuel switch. Additionally, we are soliciting comment on an alternative time period for switching frequency (e.g., 12 months)." 76 Fed. Reg. 80458-80460 (Dec. 23, 2011). ACC appreciates the opportunity to submit comments again on this important issue and hope that EPA will seriously consider finalizing the approach advocated below.

Response: This comment pertains to the CISWI rulemaking, and it is out of scope for this boiler rulemaking. Provided the commenter has submitted this comment to the CISWI rulemaking docket, the response to this comment will be provided there.

Comment: *EPA Should Abandon its Proposed Fuel-Switching Requirements for Regulating Sources that Intermittently Combust a Solid Waste Because EPA Lacks Authority Under §129 to Regulate these Units as CISWI When They Are Not Burning a Solid Waste.*

Some ACC members operate units that intermittently combust a solid waste generated on-site from manufacturing operations. These units switch between burning a traditional fuel and solid waste fuel as needed. ACC appreciates EPA's attempt to address fuel-switching and acknowledge that it presents some unique regulatory issues as these units move from being regulated under §129 as CISWI to being regulated under §112 as boilers, and vice versa. *See* 76 Fed. Reg. 80458–60. However, ACC believes that the approach EPA has chosen to address such fuel switching is contrary to the plain language of §129 and unlawful.

EPA's proposed approach is that “[u]nits that cease combusting solid waste remain subject to CISWI for at least 6 months after solid waste is added to the combustion chamber. After 6 months, sources must either comply with any applicable section 112 standards or, if they intend to combust solid waste in the unit in the future, opt to remain subject to CISWI.” *Id.* at 80501 (to be codified at 40 C.F.R. §60.2265). The proposed definition of CISWI unit in § 60.2265 reads in relevant part “any distinct operating unit of any commercial or industrial facility that combusts, *or has combusted in the preceding 6 months*, any solid waste.” (Emphasis added).

The requirement that sources remain subject to CISWI for 6 months after their last combustion of solid waste is unlawful. Section 129(g)(1) defines solid waste incineration unit, in relevant part, as “a distinct operating unit of any facility which *combusts* any solid waste material.” (Emphasis added). Congress did not say “which combusts, *or has combusted in the preceding 6 months*, any solid waste,” or more generally, “which *recently combusted* any solid waste material.” Instead, Congress chose the present tense “combust” to express its clear intent to regulate only units currently combusting solid waste. EPA must “give effect to the unambiguously expressed intent of Congress” under step 1 of the *Chevron* test. *See Chevron USA v. NRDC*, 467 U.S. 837, 842-43 (1984). Since Congress was clear in its intent to only regulate solid waste incineration units *currently* combusting waste, EPA's expansion of the definition of CISWI to regulate units that *have* burned waste in the past but have stopped is illegal.

Similar reasoning applies to EPA's proposal in §60.2145(a)(4) that a CISWI unit give EPA 30-days' notice prior to the effective date of a fuel switch from a waste to a non-waste fuel. This prior notice requirement also continues to illegally regulate the unit under § 129 after it has ceased burning waste. For example, a unit that stops combusting waste on January 1st and notifies EPA of its waste-to-fuel switch on that same date would continue to be regulated as a CISWI until January 31st. As stated above, this is an impermissible expansion of §129 requirements to a unit not combusting waste material. *See Chevron*, 467 U.S. at 842-43.

Response: This comment pertains to the CISWI rulemaking, and it is out of scope for this boiler rulemaking. Provided the commenter has submitted this comment to the CISWI rulemaking docket, the response to this comment will be provided there.

Commenter Affiliation: American Chemistry Council (ACC)

Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1

Comment Excerpt Number: 149

Comment: *EPA's 6-month Requirement Could Illegally Subject Units that No Longer Burn Solid Waste to § 112 and 129 Standards Simultaneously.*

Under §129(h)(2), Congress limited EPA's authority to regulate CISWI units by stating that "no solid waste incineration unit subject to performance standards under [CISWI – sections 111 and 129] shall be subject to standards under [NESHAP – section 112]." The recent ruling from the D.C. Circuit Court of Appeals highlighted the mutual exclusivity of §112 and §129. In *Portland Cement Ass'n v. EPA*, 2011 U.S. App. LEXIS 24577, at *12 n.2 (D.C. Cir. Dec. 9, 2011) the court notes that some cement kilns would be regulated under NESHAP and other cement kilns combusting solid waste "...would be subject to standards under the CISWI rules rather than under the NESHAP rules, since the two regimes are mutually exclusive. *See also, NRDC v. EPA*, 489 F.3d 1250, 1256 (D.C. Cir. 2007). The reconsidered CISWI proposal would subject some units that should be subject to regulation under §112 (e.g., boilers), when and because they are combusting traditional fuels, to both §129 and §112 emission limits because of their intermittent combustion of solid waste.

For example, the Boiler MACT rule applies to an ICI boiler or process heater, as defined in 40 C.F.R. §63.7575, that is a major source of hazardous air pollutants. 40 C.F.R. §63.7485. The Boiler MACT states in §63.7575 that a unit "combusting solid waste . . . is *not* a boiler." In other words, as soon as a major source unit subject to §129 regulation stops burning solid waste, it would be a combustion unit regulated by the Boiler MACT §112 standards. But under EPA's fuel-switching approach, the unit would continue to be a "solid waste incinerator," subject to §129 standards for at least 6 months after the unit stops burning waste. This 6-month overlap between the start of Boiler MACT applicability and the end of CISWI applicability is impermissible because it would subject a unit to both §129 and §112 standards in violation of those sections of the CAA and D.C. Circuit case law.

Fortunately, there is precedent for a fuel switching provision that is both lawful and workable, and would assure that a combustion unit is subject to either the CISWI or the Boiler MACT rule requirements at all times, but not to both simultaneously. The fuel switching provisions in the 2005 NESHAP for Hazardous Waste Combustors ("HWC MACT") have been in place for many years and are operating successfully. *See* 40 C.F.R. §§63.1200 et seq., 63.1206(b)(ii) & 63.1209(q). The HWC MACT allows units that intermittently combust hazardous waste to comply with either Subpart EEE, some other subpart promulgated under §112 or §129, depending on whether the unit is combusting hazardous waste. 40 C.F.R. §63.1206(b)(ii).⁴² In relevant part, the emission standards and operating requirements set forth in the HWC MACT do *not* apply "when hazardous waste is not in the combustion chamber" and the unit's compliance with other §112 or 129 requirements has been documented. *Id.*

The HWC MACT requires that if the unit is going operate under different modes of operation, the owner/operator must establish operating parameter limits for each mode. Additionally, the owner/operator must document in the operating record when the unit changes a mode of operation and begins complying with the operating limits for an alternative mode of operation. In order to operate under otherwise applicable requirements promulgated under §§112 or 129, the owner/operator must specify the otherwise applicable requirements as a mode of operation in its Documentation of Compliance; its Notification of Compliance; and its Title V permit application. These requirements include the otherwise applicable requirements governing emission standards, monitoring and compliance, notification, reporting and recordkeeping. *See* §63.1209(q)(1).

ACC recognizes that hazardous waste combustion units, unlike solid waste combustion units, are exempted from the definition of “solid waste incineration unit” in §129(g) so EPA is not *required* to regulate these units under § 129. Nonetheless, if EPA can offer regulatory flexibility for units that intermittently combust *hazardous* waste, it should certainly do the same for units that intermittently combust non-hazardous solid waste.

The regulatory approach taken in the HWC MACT could easily be adapted and applied permissibly under §129. This would ensure that when combusting a solid waste the unit is regulated under §129, and when combusting a traditional fuel it is regulated under §112. One of these strict regulatory regimes would be applicable at all times, there would be no regulatory gaps and no confusion as to which set of requirements apply and the burden would be on the owner/operator to ensure that it is in compliance with one of these regulatory regimes at all times.

[Footnote 42: When hazardous waste is not in the combustion chamber (i.e., the hazardous waste feed to the combustor has been cut off for a period of time not less than the hazardous waste residence time) and you have documented in the operating record that you are complying with all otherwise applicable requirements and standards promulgated under authority of sections 112 (e.g., 40 CFR part 63, subparts LLL, DDDDD, and NNNNN) or 129 of the Clean Air Act in lieu of the emission standards under §§ 63.1203, 63.1204, 63.1205, 63.1215, 63.1216, 63.1217, 63.1218, 63.1219, 63.1220, and 63.1221; the monitoring and compliance standards of this section and §§ 63.1207 through 63.1209, except the modes of operation requirements of § 63.1209(q); and the notification, reporting, and recordkeeping requirements of §§ 63.1210 through 63.1212.]

Comment Excerpt Number: 56

Comment: Coating Operation Control Devices: AIF Supports EPA’s Clarification and Confirmation that the CISWI Rule Does Not Apply to Burning Gaseous Materials Associated with Coating Operations; EPA Should Reinstate the Definitions of “Contained Gaseous Material” and “Solid Waste” for Clarity.

The NHSM Rule, issued contemporaneously with the CISWI Rule, purported to outline which secondary materials are classified as “solid waste” for purposes of determining whether the CISWI Rule may apply to units that combust those materials. In response to comments on the proposal for the NHSM Rule requesting a definition of “contained gas” consistent with its prior interpretation under the RCRA, EPA made certain statements that raised questions as to whether EPA was revising its long-standing interpretation that gas in pipelines is not a “contained gas” and thus not “solid waste” under RCRA. *See Responses to Comments Document on NHSM Rule*, at p. 213-14 (March 21, 2011), Docket Control No: EPA-HQ-RCRA- 2008-0329-1837. Although AIF noted that the definition of “CISWI unit” makes a distinction between the CISWI unit and the attached control device, AIF requested clarification from EPA that emissions streams from the various processes ducted to control devices, including those utilized by facilities owned and/or operated by AIF members, are not “solid waste,” *i.e.*, the air pollution control unit is *not* a “CISWI unit.” A May 13, 2011, letter from Suzanne Rudzinski, Director of EPA’s Office of Resource Conservation and Recovery, to Mr. Timothy Hunt, American Forest and Paper Association, set forth that EPA’s statements in the NHSM Response to Comments did “not change any previous EPA positions” and that EPA’s “previous statements and interpretations remain effective.” Docket No. EPA-HQ-RCRA-2008-0329-1854 (“Rudzinski Letter”). Based on that letter, AIF understood that the CISWI Rule does not apply to control units (and associated equipment)⁴⁰ that transport and burn captured gas, and that the gaseous materials combusted in the course of coating operations are not “solid wastes” under RCRA. AIF requested that EPA confirm this interpretation and clarify it in regulatory language. In the proposal, EPA acknowledges that the Rudzinski Letter caused confusion about whether EPA was changing its prior interpretation regarding the burning of gaseous materials and whether or not

such burning constitutes the treatment of a solid waste by burning. *See CISWI and NHSM Rules Reconsideration Proposal*, 76 Fed. Reg. at 80,472-73. Accordingly, EPA now clarifies that which it set forth in the Rudzinski Letter: EPA is not changing any of its prior interpretations; those prior interpretations remain effective on the issue of whether “contained gaseous material” is a solid waste. *See id.* Specifically, EPA restates that “burning of gaseous material, such as in fume incinerators (as well as other combustion units, including air pollution control devices that may combust gaseous material) does *not* involve treatment or other management of a solid waste as defined in RCRA section 1004(27).” *Id.* at 80,473 (emphasis added).

AIF appreciates and supports EPA’s clarification and confirmation in the proposal that the CISWI Rule does not apply to the burning of gaseous materials associated with coating operations. The proposal, however, still leaves several questions unanswered.

First, as conveyed in the reconsideration proposal, the regulations do not include a definition of “contained gaseous material.” While that definition is presently found at 40 C.F.R. §§ 60.2265 and 60.2875, the CISWI Rule as finalized on March 21, 2011, appeared to remove these definitions. *See CISWI Rule*, 76 Fed. Reg. at 15,761 (noting an amendment to § 60.2265 by, among other things, removing the definition of “contained gaseous material”); *id.* at 15,782 (same as to § 60.2875). The reconsideration proposal does not include any statements confirming or re-affirming the removal of the definitions. As a corollary, nor does it include any statements explicitly confirming that the definitions will remain part of the regulations or making any correction as to the apparent removal of the definitions in the CISWI Rule as finalized on March 21, 2011. EPA’s clarification and confirmation in the reconsideration proposal that the CISWI Rule does not apply to the burning of gaseous materials associated with coating operations suggests to AIF that EPA intended for the reconsideration proposal to reinstate the definitions of “contained gaseous material” into the CISWI Rule. To carry out that intent, however, EPA must actually reinstate those definitions into regulatory provisions of the final reconsideration rule. AIF urges EPA to take that action.

Second, reinserting the definition of “contained gaseous material” would not, by itself, resolve the concern in the regulatory community as to gas in pipelines being regulated as a “contained gaseous material” and thus as a “solid waste” under RCRA. This is because the reconsideration proposal does not appear to reverse the removal of the definition of “solid waste” from the CISWI Rule at § 60.2265. Without reinstating the definition of “solid waste,” the regulations cannot give effect to the definition of “contained gaseous material” (assuming EPA reinstates it) because “contained gaseous material” does not appear elsewhere in the CISWI Rule. Despite not appearing the definitions section, the term “solid waste” does appear in the following definitions in the reconsideration proposal: “[CISWI] unit,” “energy recovery unit,” “incinerator,” “small, remote incinerator,” “solid waste incineration unit,”⁴¹ and “waste-burning kiln.” *See CISWI and NHSM Rules Reconsideration Proposal*, 76 Fed. Reg. at 80,501-03. Each of these definitions as proposed modifies the term “solid waste” with reference to how the Administrator defines the term at 40 C.F.R. § 241. *See id.* At 40 C.F.R. § 241, the regulations set forth that “[s]olid waste means the term solid waste as defined in 40 CFR 258.2.”⁴² 40 C.F.R. § 241.2. The definition there is equivalent to the definition of “solid waste” that was deleted

from the CISWI Rule in the final rule of March 21, 2011.⁴³ *See* 40 C.F.R. § 258.2; *see also* 68 Fed. Reg. 57,518, 57,551 (Oct. 3, 2003) (comparable definition of “solid waste” in the CISWI Rule as then-finalized). This formulation of the definition derives from the definition of “solid

waste” in the Solid Waste Disposal Act at 42 U.S.C. § 6904(27), *i.e.*, RCRA § 1004(27). Without EPA reinstating the definition of “solid waste,” then, it would appear that a reinstated definition of “contained gaseous material” would control interpretation of the term “solid waste” in the CISWI Rule. To promote clarity across the CISWI and NHSM Rules, as well as understanding in the regulated community, however, EPA should reinstate the definition of “solid waste” into the CISWI Rule.⁴⁴

Reinstating both the “contained gaseous material” and “solid waste” definitions is necessary, given the uncertainty created by EPA in its response to comments on the NHSM Rule. As noted above, EPA states in the reconsideration proposal that it did not intend to create this uncertainty or change any of its previous positions regarding contained gas. *See CISWI and NHSM Rules Reconsideration Proposal*, 76 Fed. Reg. at 80,472-73. To that end, EPA conveys that the “burning of gaseous material, such as in fume incinerators (as well as other combustion units, including air pollution control devices that may combust gaseous material) does not involve treatment or other management of solid waste (as defined in RCRA section 1004(27)).” *Id.* The only way EPA can adequately give effect to its representations is reinstating the definitions of “contained gaseous material” and “solid waste.”

As a corollary, EPA must clarify that the CISWI Rule does not apply to the combustion of LFG, either when combusted for control or as fuel in a boiler, *i.e.*, the combustion of LFG is not a “contained gaseous material” and, therefore, it is not a “solid waste” and not regulated under the CISWI Rule. LFG is not a “solid waste” because, even if it considered to have been derived from “solid waste,” it is a newly generated material that has never been discarded. EPA should add clarifying language to that effect in the CISWI and NHSM Rules.⁴⁵

[Footnote 40: *E.g.*, regenerative thermal oxidizers used in coating operations.]

[Footnote 41: Note that there appears to be a typographical error in the proposed regulatory language for this definition such that it only includes the term “solid” where it appears that it should read “solid waste.”]

[Footnote 42: According to the regulations accompanying that definition, § 241 does not define “solid waste”; rather, they “identif[y] the requirements and procedures for the identification of solid wastes.” 40 C.F.R. § 241.1 (purpose).]

[Footnote 43: The definition reads as follows: *Solid waste* means any garbage, or refuse, sludge from a wastewater treatment plant, water supply treatment plant, or air pollution control facility and other discarded material, including solid, liquid, semi-solid, or contained gaseous material resulting from industrial, commercial, mining, and agricultural operations, and from community activities, but does not include solid or dissolved materials in domestic sewage, or solid or dissolved materials in irrigation return flows or industrial discharges that are point sources subject to permit under 33 U.S.C. 1342, or source, special nuclear, or by-product material as defined by the Atomic Energy Act of 1954, as amended (68 Stat. 923). *Id.* § 258.2.]

[Footnote 44: As an alternative, AIF requests that EPA clarify whether AIF correctly understands EPA’s intent as to “contained gaseous material” and “solid waste” in the CISWI Rule. ;

[Footnote 45: The Boiler MACT Reconsideration Proposal already implies that EPA takes this position in that it includes LFG in the definition of “gaseous fuel” at the proposed § 63.7575. *See*

Boiler MACT Reconsideration Proposal, 76 Fed. Reg. at 80,652. Moreover, EPA's own outreach program recognizes LFG as a fuel. *See LMOP, supra.*]

Comment: The NAM agrees with the EPA's decision not to apply the proposed incinerator MACT standards to small "burn-off ovens." 76 Fed. Reg. 80,460. In addition to the reasons identified by the EPA, it is not appropriate to categorize burn-off ovens as incinerators, as most burn-off ovens are not actually combusting material. Instead they use lower temperature processes such as melting or pyrolysis and are specifically designed to avoid flaming conditions, which would damage the parts being cleaned.

Comment: If the PM and mercury limits remain roughly as proposed for existing sources,⁴⁰ few sources will desire to be regulated under section 129. Most sources will argue that they get a "meaningful" contribution to the overall combustion process from what they burn. This will increase the level of disagreement over whether a material is a waste and may result in fewer sources burning waste materials. Some sources (with low CO levels) might find it in their interests to assert that they are incinerators rather than energy recovery units. Thus, the definitions of "solid waste" and "incinerator" may matter to a number of sources. EPA should also consider its proposed MACT rules in light of BACT determinations for similarly situated units and explain why emission limitations deemed "available" as BACT are orders of magnitude more stringent than the ("maximum achievable") MACT standards. A review of EPA's RACT/BACT/LAER clearinghouse reveals a number of BACT decisions for cement kilns that are far more stringent than EPA's proposed limits.⁴¹ In addition, EPA's control technologies guidelines for cement kilns,⁴² published under section 108 of the CAA, document the existence of cost-effective retrofit technologies available for control of SO₂ and NO_x in cement kilns. EPA seems to assume either that there are no cost-effective controls for these pollutants at cement kilns or that the CAA does not require MACT limits to be based on these controls. EPA should explain its rationale in greater detail and set forth a basis for any final decision it makes. EPA should review each of its proposed MACT limits to ensure that they reflect the application of maximum achievable technology, not merely the MACT floor. In addition, it would seem that

MACT should be more stringent than either GACT or BACT. Accordingly, MACT limits for cement kilns for SO₂ and NO_x should be at least as stringent as BACT limits for such units.

Moreover, the performance demonstrated by the best performing units suggests that existing sources, if equipped with MACT level technology, would be capable of far better performance than suggested by EPA's rules. Similarly, we note the very significant differences in the MACT limit that EPA applies to smaller units at area sources compared to similar units at major sources. Since the MACT limits for those units are presumed to meet the statutory effectiveness tests for MACT controls, unless the cost per ton for similar units at area sources is substantially different it would seem that the test is met at those sources as well.

[Footnotes]

(40) NO_x and SO₂ limitations under section 129 may also discourage combustion of solid waste. This issue can be addressed by EPA when it adopts emission limitations for large industrial units under Phase II of its Transport Rules.

(41) Many of these decisions are for new units, but are based on technologies suitable for retrofit (albeit at somewhat greater cost).

Comment Excerpt Number: 18

Comment: EPA seeks comment on the provisions included in the final CISWI rule regarding changing fuels being combusted and thereby changing the status of a unit as an incinerator or boiler, particularly on whether the provisions should include further clarification on the timeline and regulatory requirements of a fuel switch. Additionally, EPA is soliciting comment on an alternative time period for switching frequency. 76 FR 80460.

CIBO opposes EPA's prescriptive approach to boiler or incinerator status. This constrained approach is not necessary to ensure compliance with the applicable standards. Instead, the constraints result in EPA governing economic decisions related to supply and demand, and deprive regulated sources the flexibility to make sound economic decisions related to their operations.

Response: This comment pertains to the CISWI rulemaking, and it is out of scope for this boiler rulemaking. Provided the commenter has submitted this comment to the CISWI rulemaking docket, the response to this comment will be provided there.

Comment: The practical effects of the regulation are far-reaching. For example, if a facility burns a waste /fuel mix, which is typical, and is operating under the CISWI regulations, if for some reason the waste component of their fuel supply becomes unavailable, solid fuel boilers (e.g., coal) would not be able to meet the emission requirements under CISWI (e.g. sulfur dioxide) and would have to shut down operations (or find an alternate source of energy) until they are permitted to switch back to an appropriate standard for their solid fuel. Many waste streams are not available year round and their supply is dependent upon production schedules at other entities. Also, a facility may inadvertently burn a material that is a waste or later becomes classified as a waste, and might be forced to shut down or operate under the CISWI regulations for six months during periods while no waste is being burned. This presents an additional and significant risk to attempting to burn alternative fuels. Another complication is that many units do not fire solid waste until the unit is started up and at steady state.

To remedy these damaging effects, a provision should be added that allows a facility to elect to either (1) comply with CISWI at all times or (2) comply with CISWI while burning solid waste but comply with otherwise applicable standards under section 112 of the Clean Air Act while not burning solid waste. The Hazardous Waste Combustor MACT (see 40 CFR 63.1206(b)(1)(ii) and 63.1209(q)) provides a helpful referent.

This will also alleviate another problem caused by the EPA's decision that work practice standards are not adequate for the regulation of sources during their startup and shutdown periods. Because EPA has stated it cannot use work practice standards during periods of startup and shutdown, compliance with CO emission limits along with other parameters such as sorbent loading in spray dryer absorbers will be very problematic. EPA should resolve this problem by allowing sources that encounter these issues to elect to comply with section 112 standards during all times that solid waste are not being combusted or, alternatively, during just the startup and shutdown periods.

If a source elects one of these options, it would have to conduct all necessary performance testing and establish continuous compliance monitoring systems and recordkeeping systems to comply with both the section 129 (CISWI) and the section 112 rules. Facilities can easily document which mode of operation they are in (by tracking solid waste feed rates) and readily show compliance with the applicable standard. There are no compliance assurance issues with allowing this flexibility, as sources are able to demonstrate during what periods solid waste is in the combustor.

Comment Excerpt Number: 3

Comment: We are pleased that the preamble to the proposed Commercial and Industrial Solid Waste Incineration (CISWI) rule indicates the rule is being modified to clarify which biomass fuels (i.e. waste wood from forest harvesting) are not solid waste. However, the rule amendment could make this more explicit by specifically listing these materials as fuels.

A key consideration when assessing whether a material meets the legitimacy criteria is determining whether the material has been "discarded". The regulated community would benefit by either adding a definition of "discarded" that is not ambiguous or by issuing a Clarification

Letter explaining how this determination will be made by the Agency. This is especially important when considering the status of materials collected through programs designed to divert useful materials from landfill disposal that can otherwise be processed into legitimate fuels or feedstock.

While acknowledging efforts to ensure expeditious review of petitions to the regional director for a non-waste determination, we believe the value of the opportunity for public comment outweighs the burden of a thirty day delay in completing the petition process. We are pleased that EPA proposed to segregate coal fired energy recovery units from other nonhazardous waste, biomass based energy recovery units under the CISWI rule. This segregation will provide much more appropriate alignment of hazardous air pollutant emission limits with the type of fuel.

Comment Excerpt Number: 9

Comment: 1. Definition of Contained Gaseous Material.

At pg 80463 the reconsideration proposal states that EPA is "not changing its historical interpretation of what gases could be considered to be solid waste (Le., a 'contained gas')." In that same discussion EPA states that it has added back into CISWI the definition of "contained gaseous material." When we looked we could not find the definition in the regulatory text. Unless we missed it, it appears that EPA missed adding the definition back into regulatory text of the reconsideration proposal.

2. Contained Gas Policy for Regulated Gas Streams Combusted in a Boiler

With respect to EPA's historical interpretation of contained gas, Alyeska reviewed the RCRA documents that it is aware of that embody that interpretation and the CISWI response to comments. We are still concerned that a narrow reading of the contained gas interpretations and the response to comments may limit its application to fume incinerators (Le., air pollution control devices). We also are still concerned that EPA has not assured industry that gas that arises from

. an air pollution control device, or that is captured through a control device such as a vapor recovery system, that is then routed to and combusted in a boiler will not be considered a nonhazardous secondary material, unless it passes the burdensome legitimacy criteria. In the proposed Boiler rule on page 80652 there is a definition of "gaseous fuel" that includes process gases, which under that rule a facility should be able to rely upon to describe their combusted gas a fuel. However, in the CISWI rule there is no such definition or similar discussion. We refer you to the following response to comments for the earlier final CISWI rule, specifically the bolded text:

Comment [3b-B-4]:

Contained Gas --A limited number of commenters indicated that the final rule should contain a definition of "contained gaseous material." The statutory definition of solid waste includes "solid, liquid, semisolid or *contained gaseous material.*" 42 U.S.C. § 6903(27) (emphasis added). EPA has interpreted the term "contained gaseous material" to include gases in containers, but not gases flowing through pipes to combustion units. Under the June 4, 2010 Comments Document -NHSM Rule proposed revisions to the CISWI rule, the existing definition of solid waste will be removed, and the rule will rely upon the proposed definition of solid waste here (proposed 40 C.F.R. Part 241).

The commenters state that the preamble language in the proposed rule could be read to suggest that gaseous fuels are to be included in the Part 241 definition of solid waste. In discussing which traditional fuels are to be used for comparison purposes in applying the legitimacy criterion concerning contaminants, the proposed rule says:

"For example, if the boiler burns fuel oil, the level of contaminants to be compared would be the level of contaminants in fuel oil or other liquid traditional fuels that is or can be burned in such unit, while *for gas-fired boilers, the level of contaminants in the non-hazardous secondary material fuels would be compared to natural gas.*"

The commenter assumes that EPA does not intend to regulate gaseous fuels through this rule or otherwise under CAA section 129. Consistent with the statutory definition of solid waste and with EPA's approach in the 2000 CISWI rule, EPA should make clear that "contained gaseous material" is only meant to cover gas in a container when that container and its contents are combusted.

EPA's response: As a preliminary matter, EPA wishes to correct certain misconceptions in these comments. First, we wish to make it clear that the statement regarding secondary material fuels replacing natural gas in gas-fired boilers only refers to fuels that are secondary materials. It does not refer to a situation in which a gas-fired boiler can use, for example, refined fuel oil EPA is aware that fuel oil and gas may be used interchangeably in some boilers. The preamble statement, however, only applies to a secondary material, not a product fuel. Since on specification used oil is considered an alternative "traditional fuel," it would not be considered a secondary material.

Next, EPA also acknowledges that this rule does not apply to vented gas that is in no way contained and simply goes into the atmosphere. We are not dealing with whether such vented gases are subject to the definition of solid waste. Vented gas simply will not be used as a secondary material in any gas-fired boiler and thus, is not part of this rulemaking; nor is EPA reopening any rules regarding such vented gases.

Further, EPA is not considering viewpoints regarding how it regulates gases under the hazardous waste regulations -specifically, whether gases in pipelines are contained. The Agency needs to evaluate whether the non-hazardous secondary gaseous material that will be used as substitutes in gas-fired boilers are solid wastes, or not, under the statutory definition. EPA's determination in this rule is based on the plain language of the statute. This leads EPA to the situation covered in this rule. In the first place, we are unable to find any Agency reasoning supporting previous EPA

interpretations that only gases in containers may be considered "contained.» Based on the facts of this case, EPA cannot see how gaseous secondary material that is generated in any particular system and is somehow sent to a gas-fired boiler, even through a pipeline, can be considered an "uncontained gas." This el'en assumes that "uncontained gas" is not covered under the definition of solid waste, which EPA does not concede in this rulemaking. This would mean that a clean gas-fired boiler could still burn under CAA 112 secondary material that is handled through a seriously leaking pipeline, has little to no real fuel value, and is full of dirty contamination, simply because the material is not a "contained gas" under the definition of solid waste. EPA rejects any such formulation.

EPA appears to provide greater assurances later in the preamble when it refers to the letter to American Forest and Paper Association, 80473. Here EPA states that the burning of gaseous material in a combustion units, not limited to air pollution control devices is not an a form of treatment or other management of solid waste. This certainly is helpful. Nonetheless this is a very important issue and one we would like as much certainty as possible about. The boilers at the Valdez Marine Terminal burn vapors (gases) generated from storage tanks and the loading of tankers. These vapors consist predominately of hydrocarbon vapors and a limited amount of stack gas from the tankers and the boilers that is used as an inert gas for these vapor collection systems. We wish to utilize the control device exemption in Boiler MACT. but arc concerned that EPA may in turn classify the vapors as solid waste or at least require that we must demonstrate the vapors are non-traditional fuels through the legitimacy criteria.

Logically, it makes sense that a boiler that acts as a control device under some other part, in our case marine loading and organic liquid distribution MACTs, should be exempt from CISWI. Indeed as we discussed above Boiler MACT provides an exemption for boilers used as control devices provided the gases contribute more than 50% of the boiler's heat input. To eliminate this confusion and future compliance and Title V permitting risks it would be ideal ifEPA simply created an exemption from CISWI for air pollution control devices and boilers and process heaters that are used as control devices under Parts 63, 61 and 60. Alternatively, EPA could as a matter of interpretation make such a statement in the preamble or response to comments.

3. Exclusion of Cyclonic Burn Barrels, Soil Treatment Units, Laboratory Analysis Units and Space Heaters from CISWI

Alyeska strongly supports the retention of the exemptions for cyclonic burn barrels, soil treatment units, laboratory analysis units, and space heaters. Since the function and operation of these types of units is fundamentally different than incinerators contemplated under the Act, Alyeska supports EPA's decision to exclude them from CIS WI.

4. Alyeska Supports the Comments of the Alaska Oil and Gas Association (AOGA)

Alyeska is a member of AOGA and strongly supports AOGA's comments.

Response: This comment pertains to the CISWI rulemaking, and it is out of scope for this boiler rulemaking. Provided the commenter has submitted this comment to the CISWI rulemaking docket, the response to this comment will be provided there.

1C. Out of Scope: Area Source Boilers

Commenter Name: Michael Bradley

Commenter Affiliation: The Clean Energy Group

Document Control Number: EPA-HQ-OAR-2002-0058-3495-A1

Comment Excerpt Number: 11

Comment: In general, the Clean Energy Group supports the changes EPA made to the area source rule between the proposed and final rules.

Startup and Shutdown

EPA proposes to revise the work practice standards for startup and shutdown to include a definition of startup and shutdown as well as to standardize requirements. Startup would be defined as the period between no combustion and 25 percent load, and shutdown would be between 25 percent load and no combustion. EPA requests comment on the need for and an appropriate duration limit for startup and shutdown periods during which numeric emission limits do not apply. The Clean Energy Group agrees with the need for a definition of startup and shutdown in light of the final rule's use of work practices for these periods. However, rather than 25 percent load, which may be inappropriate for many units, we recommend EPA alter the definition of startup to reflect unit-specific considerations, such as defining the end of startup as when the unit reaches the minimum safe operating load or when compliance with Title V emission limits is reached. Similarly, EPA could define shutdown as the period of time from when a unit reduces load with the intent to shut down and ends with the cessation of combustion of fuel. This would avoid defining as "shutdown" those circumstances where units may need to operate at a level below 25 percent, but above the minimum safe operating load.

In this way, EPA would utilize definitions already incorporated into existing air quality operating permits. Typically, these definitions are jointly established by the responsible air permitting authorities and the individual facility because startup and shutdown periods are somewhat unique to each boiler design. Below the unit-specific "normal operating mode" is when startup and shutdown requirements should apply. We recommend that EPA not numerically define startup and shutdown in the final rule, and instead defer to the definitions contained in currently active air quality operating permits issued by local and/or state air permitting agencies.

Additionally, EPA proposed to require that new boilers with heat input capacity greater than 10 MMBtu per hour that are biomass-fired or oil-fired must comply with work practice standards to minimize the boiler's startup and shutdown periods following the manufacturer's recommendations, or the manufacturer's recommendations for a unit of similar design. As noted above, we recommend revising the definition of startup and shutdown to allow for individual unit variation.

Synthetic Area Sources

Partially as a result of this rulemaking, we expect that many sources will seek to qualify as area sources if they are able, including through permit limitations. For example, an oil-fired unit that is currently a major source may reduce permitted potential to emit (PTE) through a permit limit on quantity of oil combusted. Particularly during the upcoming time period when existing area

source units are subject to requirements, while major source units are not, clarification on the timing of notification and compliance demonstration requirements is necessary. In the area source rule, § 63.11225(a)(2) states that "As specified in § 63.9(b)(2), you must submit the Initial Notification no later than 120 calendar days after May 20, 2011 or within 120 days after the source becomes subject to the standard." However, EPA proposes to amend § 63.11210(g) to clarify the compliance demonstration requirements for units that switch subcategories as the result of a physical modification or fuel switch. We request clarification as to which requirement governs newly-limited synthetic area sources, and specifically when notification requirements are due.¹ If § 63.11210(g) is intended to include synthetic area sources, we recommend EPA revise the language of § 63.11210(g) to clarify (1) that permit limits are included, and (2) the 180 days to demonstrate compliance includes units that switch from the major source rule to the area source rule. For example, the text could read (bold denotes additions and strikethroughs deletions):

(g) For affected boilers that switch fuels, or make a physical modification to the boiler, or take a permit limit that results in the applicability of a different subcategory or boiler NESHAP (e.g., a boiler that was previously subject to the major source rule at Subpart DDDDD), you must demonstrate compliance within 180 days of the effective date of the fuel switch, OF physical modification, or permit limit consistent with § 63.11225(g).

However, if § 63.11210(g) is not intended to include area sources created through permit conditions, we recommend that § 63.11210(g) clarify that the shorter timeline in § 63.9(b)(2) governs these sources. For example,

(g) For affected boilers that switch fuels or make a physical modification to the boiler that results in the applicability of a different subcategory, you must demonstrate compliance within 180 days of the effective date of the fuel switch or physical modification consistent with § 63.11225(g). However, if you become newly-subject to Subpart JJJJJ as the result of a permit condition (e.g., as a synthetic area source), you must comply with the requirements of § 63.9(b)(2).

Revisions to Initial Tune-up Requirement

EPA proposes that all existing boilers would have two years (by March 21, 2013) to demonstrate initial compliance. However, we do not expect the majority of sources to be able to take advantage of this proposed flexibility due to the timing of the proposal. The final rule requires area sources to complete this requirement by March 21, 2012, which is just one month after comments for these proposals close. As we do not expect EPA to complete review of comments and finalize the rule in one month, if EPA intends to finalize this change, the Agency should immediately issue a 90-day stay notice under Clean Air Act section 307(d)(7)(B).² Alternatively, we understand EPA is considering issuing a No Action Assurance letter, stating that the Agency would not enforce this provision. Either way, we expect this change will not provide the intended flexibility for the vast majority of sources that seek to ensure compliance with the final rule.

There are many instances where boiler operation may be too irregular to qualify as seasonal use, but run infrequently enough that a tune-up would be due while the unit is not operational, including at nuclear facilities. The final area source rule states that boilers due for a tune-up while they are not operating are not required to run the boiler only for the tune-up. Boilers in these situations would be required to conduct the tune-up within one week of startup. It does not

appear that the proposed reconsideration seeks to alter this provision; however, the Clean Energy Group expresses support for and encourages EPA not to alter this common-sense provision that eliminates unnecessary boiler operation and associated emissions. One week in which to complete the tune-up is reasonable and in line with state requirements (see, for example, New Jersey's code at 7:27-19.4(c), which allows seven days from initial operation for boilers not running when combustion adjustments are due).

Title V Implications

The final rule exempts all area sources from Title V permitting as a result of this rule. In other words, this rule alone would not trigger Title V requirements for an area source. The proposed rule required Title V permits for major sources of HAPs that became area sources by installing controls after 1990. However, EPA determined in its review of the record that it lacked sufficient information to distinguish these sources from other area sources. Thus, in the final rule, EPA is no longer requiring any units to obtain Title V permits as a result of this rule. Sources would need a Title V permit if they are subject to Title V for another reason. The Clean Energy Group supports this decision, which will allow both permitting authorities and covered sources to focus on the larger emitters, allowing for more efficient and effective emissions reductions.

Additional Subcategories

EPA proposes to create a new subcategory for seasonally-operated boilers, which would be subject to a tune-up requirement every five years after the initial tune-up prior to the compliance date. EPA also proposes to exempt temporary boilers, as was done in the final rule for major sources. We agree that temporary boilers should be exempted from both rules. We also support the creation of the seasonally-operated boiler subcategory, which, like many of the changes, will reduce requirements on boilers that operate infrequently or otherwise are likely to be insubstantial sources of HAPs. EPA proposes that seasonal boilers would include boilers that undergo "a shutdown for a period of at least 7 consecutive months (or 210 consecutive days) due to seasonal market conditions." However, many seasonal boilers are subject to separate regulatory requirements that they be officially available for longer periods. For example, in New York City and other cities in colder climates, heating is required to be available from October 1 to May 31. Other jurisdictions may have differing seasons depending on local needs. Thus, we recommend that EPA consider a wider range of seasonal definitions, or allow for a three-year rolling average of actual months of operation, without requiring a permit limit restricting months of availability.

Clarification of Applicability and Implementation Requirements

EPA proposes to amend the natural gas curtailment definition to clarify that it does not include normal market price fluctuations but would include on-site emergencies and equipment failures and is applicable to all gaseous fuels. This seems to be a clarification of rather than a change to the final rule, which we support.

Compliance Monitoring Flexibility

We support EPA's proposed revisions to compliance monitoring, including the use of CO CEMS, a 30-day rolling average for parameter monitoring and demonstrating compliance with operating

limits, and decreasing the tune-up requirement for small (<5 MMBtu/year) units to every five years, with the initial tune-up by the compliance date.

[Footnote 1: We have contacted Office of Air Quality Planning and Standards (OAQPS) and the Office of Enforcement and Compliance Assurance (OECA) with this question.]

[Footnote 2: The preamble to the proposed reconsideration states that if "the Agency has not taken final action on the initial compliance date for tune-ups prior to the date (March 21, 2012) for initial compliance, we could stay the effectiveness of the rule for 90 days, as allowed under CAA section 307(d)(7)(B), so that the Agency could complete reconsideration" (76 FR 80535, emphasis added). This statement on the compliance deadline is ambiguous.]

Document Control Number: EPA-HQ-OAR-2002-0058-3502-A1

Comment Excerpt Number: 1

Comment: ACA generally supports the following proposed changes in the Area Source Boiler rule:

1. Proposal to exempt temporary boilers;
2. Proposal to require an initial tune-up by March 21, 2014 and revision to the requirement for subsequent tune-ups only for oil-fired boilers equal to or less than 5 MMBtu/hr. to tune-up once every five years; however, EPA should extend the deadline for the initial tune-up to three years from promulgation of the March 2011 final rule in order to allow companies adequate time to complete the initial tune-ups and also to harmonize rule compliance dates for existing sources;
3. Revised definition of natural gas curtailment to clarify that a curtailment does not include normal market fluctuations in the price of gas that are not associated with periods of supplier delivery restrictions; however, the term "halted" may be interpreted to interfere with existing contractual obligations and therefore is too restrictive. ACA recommends that EPA incorporate the language changes suggested by the American Chemistry Council (ACC);
4. Revised averaging time from 12-hour average times to 30 days in order to address variability;
5. EPA's decision not to require Title V permits for area source boilers;
6. Proposal to exclude electric and residential boilers from the rule;
7. Proposal that process heaters are excluded from the definition of boilers;
8. Clarification that the emission limits in Table 1 do not apply during periods of startup and shutdown; EPA should, however, clarify that the operating limits set forth in Table 3 do not apply during startup and shutdown as well.

Commenter Affiliation: Northeast States for Coordinated Air Use Management (NESCAUM)
Document Control Number: EPA-HQ-OAR-2002-0058-3506-A1
Comment Excerpt Number: 3

Comment: NESCAUM urges the EPA to create a new subcategory for biomass electric utility steam generating units (EGUs) of 25 MW or greater and establish emissions standards for these units at a *MACT* level of control consistent with how EGUs powered by other fuels are regulated. Though most types of EGUs have a separate *MACT* rule regulating them, EGUs that burn biomass fuel do not. Therefore, biomass EGUs with emissions below the major source threshold will be regulated as area source boilers, which is an inappropriate classification. There are many such sources that fall into this subcategory; in the NESCAUM region alone, at least a dozen facilities fall into this category and are subject only to area source requirements.

Response: This comment pertains to the area source boiler rulemaking. Provided the commenter has submitted this comment to the area source boiler rulemaking docket, the response to this comment will be provided there.

Comment Excerpt Number: 4

Comment: Unlike the major source boiler rule, the area source rule has created categories that are too large, and include a broad variety of boiler types that are not comparable. The current and proposed requirements for existing and new biomass boilers with heat input higher than 30 MMBtu/h do not adequately address the potential impacts and reductions that could be achieved by these very large units captured under the area source rule. Therefore, the NESCAUM states urge that the EPA develop a subcategory for biomass EGUs of 25 MW or greater that include appropriate emission limits and testing requirements as required for similar sized units firing liquid fuels and coal.

Comment: NESCAUM is providing numerical emissions limits typical of individual permitted biomass EGU sources in New Hampshire (specifically, for PSNH Schiller and Pinetree Power, Tamworth) and Massachusetts (based on the Renewable Portfolio Standard) as a possible basis for emission limits for national implementation. NESCAUM suggests the limit of 0.1 pounds per MMBtu (lb/MMBtu) for CO and 0.012 lb/MMBtu for PM. NESCAUM notes that these limits are contingent on the biomass being clean and uncontaminated (rather than wood waste fuel).

Comment: In the area source boiler rule reconsideration (76 FR 80538, Section IV.M. "Title V Permitting Requirements"), the EPA is proposing to retain the existing language at 40 CFR 63.11194(e) to exempt area source boilers from the requirement to obtain a Title V permit. The

EPA is proposing this exemption for all area source boilers: both “natural” area sources, i.e., sources that have potential to emit below the major source threshold without any control technologies; and “synthetic” area sources that avoided a major source determination because of installed control technology or instituted work practices to reduce emissions. The EPA requested comment on this exemption in light of a petition filed by the Sierra Club (Docket ID: EPA-HQ-OAR-2006-0790-2359) to reconsider the EPA’s decision to grant this exemption.

The existing language of 40 CFR 63 Subpart JJJJJ clearly states that an area source is exempt from the requirement to obtain a Title V permit irrespective of how or when the source became an area source subject to the subpart. We agree with the proposal to maintain this exclusion from Title V permitting. Facilities subject to Title V permitting requirements have additional administrative and financial burdens, and subjecting facilities to Title V permitting requirements solely because of previous source emissions will not result in further air quality benefits so long as clear and enforceable area source permits or regulatory limits are in place.

More importantly, retaining an exemption from Title V permitting requirement will create an incentive for major sources to reduce emissions below the major source threshold (10 or 25 tons per year) and thereby avoid the Title V permitting requirements. This source category (i.e., boiler units) is particularly likely to benefit from the incentive to avoid Title V because units in this category are not typically the units that cause the source to be major. Those sources that are major will be more likely to reduce emissions below the major source threshold through fuel switching or installation of control technologies in order to avoid Title V requirements. Therefore, NESCAUM recommends that the EPA retain the exemption for area source boilers from Title V permitting requirements when appropriate so as to not place unnecessary effort upon these sources and encourage enforceable emission reductions.

Comment: In its reconsideration of the final rule for area sources, the EPA proposes emission limits for biomass-fired boilers with heat input capacity between 10 and 30 MMBtu/h and over 30 MMBtu/h (76 FR 80548, Table 1 to Subpart JJJJJ of Part 63—Emission Limits). The NESCAUM states are concerned that failing to establish numeric emission limits for biomass-fired boilers between 1.6 MMBtu/h and 10 MMBtu/h will result in greater HAP emissions from sources in this category in the northeast region, and this may have detrimental impacts on sensitive population groups. According to a Biomass Energy Resource Center (BERC) database on small wood-fired boilers, most (95 of 150, or 63 percent) of the small wood boilers in the nation are installed at schools or hospitals.¹ The US Forest Service’s “Fuels for Schools” program has identified schools and hospitals as prime candidates to switch to biomass fuels. According to an analysis by BERC, in Wisconsin alone there are 200 to 300 schools using natural gas boilers that could economically and feasibly switch to biomass boilers.² Also

according to BEREC (2008), 30 percent of school children in Vermont attend schools heated with wood-fired boilers, yet only a handful of those boilers are required to meet an emission limit or undergo a single performance test. With the potential large increase in the use of small biomass boilers, NESCAUM anticipates significant emissions from these sources.

Comment: NESCAUM requests that the EPA create a new subcategory and establish emission limits for smaller biomass units. Small institutions like schools and hospitals are increasingly installing new, smaller biomass that are cleaner (e.g., those with multistage combustion) that do not need additional control technologies to avoid major source classification. A study by the New York State Energy Research and Development Authority (NYSERDA) found that high efficiency units can achieve an emissions performance level less than 0.1 lb/MMBtu without the use of any control device. Another study looking at biomass boilers installed under the Fuels for Schools program found that the range of performance varied significantly from 0.15 lb/MMBtu to 0.9 lb/MMBtu for a variety of biomass boilers. The EPA has not performed an adequate analysis to determine if a baseline performance standard should be required for all biomass boilers. Furthermore, the EPA has announced its intent to develop an emission standard for residential biomass boilers. If an emission standard is feasible for residential biomass boilers, it highlights not only the feasibility of emissions standards for small industrial, commercial, and institutional boilers, but the necessity of regulation so as not to create a void for these emission sources.

Comment: In its reconsideration of the final area source rule, the EPA is proposing to create a new subcategory for seasonally operated boilers. Boilers in this subcategory would be required, under an amended 40 CFR 63.11223, to complete a tune-up every five years instead of every two years, as required by non-seasonal boilers (76 FR 80534-5). The proposed definition of a seasonal boiler is:

Seasonal boiler means a boiler that undergoes a shutdown for a period of at least 7 consecutive months (or 210 consecutive days) due to seasonal market conditions. This definition only applies to boilers that would otherwise be included in the biomass subcategory or the oil subcategory.

NESCAUM is concerned that this seasonal boiler definition creates an opportunity for facilities with boilers used as heating units during the heating season to claim that they are “seasonal units,” although that is not the EPA’s stated intent. Boilers operating from November through March (i.e., that are shut down between April and October) might qualify as seasonal units under the proposed language and operate under the reduced tune-up requirements. Therefore, NESCAUM does not support the creation of a seasonal use category.

NESCAUM proposes that the EPA create a “limited use” subcategory that would serve to fulfill EPA’s intent to include facilities that are used on a more limited basis than units operated year-round. The limited use subcategory would be similar to the limited use subcategory described in the major source rule (76 FR 80609), specifically applying to units operating less than 10 percent of the hours in a year. This has the benefit of being consistent with the major source rule approach, and similar boilers would be treated the same way in different categories.

Comment: *Demonstrating Compliance with the Work Practice and Management Practice Standards under the Area Source Rule*

In its reconsideration of the final area source rule (76 FR 80540), the EPA is proposing to require that boiler tune-ups use the same type of fuel that provided the majority of the heat input to the boiler over the previous year. This closes a potential loophole for boilers that have the capability of burning multiple types of fuel to circumvent emissions limits by burning cleaner fuel for the compliance demonstration but burning dirtier fuel under typical operation. NESCAUM supports this change because it will create clearer tune-up protocols for regulators and regulated entities and reduce emissions.

Comment: In its area source rule reconsideration, the EPA proposed to amend 40 CFR 63.11196 to specify that all existing boilers subject to the tune-up requirement would have two years (by March 21, 2013) in which to demonstrate initial compliance, instead of one year to demonstrate initial compliance. In addition, the EPA requested comment on whether the initial compliance period for the tune-up requirement should be extended to three years (i.e., until March 21, 2014) (76 FR 80535).

Compliance with the March 21, 2012 deadline is logistically challenging for area sources and tune-up technicians given the short timeline, large universe of sources, and unfamiliarity with requirements under this rule. Therefore, NESCAUM supports extending the compliance period for the initial tune-up requirement to three years, until March 21, 2014.

Comment: NESCAUM supports efforts to have facilities conduct energy assessments in order to identify cost-effective, energy conservation measures on boilers larger than 1.6 MMBtu/h. NESCAUM agrees with the specific requirements and clear language for what constitutes an energy assessment, which NESCAUM had commented on previously. To ensure that energy assessments lead to tangible improvements in energy use and emissions, NESCAUM encourages the EPA and the states to work with facilities to implement cost-effective improvements identified in the energy assessment. Furthermore, NESCAUM recommends that the EPA work with agencies to establish clear guidelines as to what constitutes a cost-effective energy efficiency improvement.

Comment: EPA Should Expand the Current Seasonal Subcategory or Create a Separate Subcategory for Agricultural, Seasonal Boilers In the reconsideration of the area source Boiler rule, EPA acknowledged that it is appropriate to treat boilers that are operated on a seasonal basis differently from boilers that run continuously all year long. Boilers that run on a partial schedule have less overall environmental impact and can often tie their use to seasonal agricultural production. Boilers located at sugarbeet processing facilities fall into such a seasonal use category because they are only used for a finite agricultural season. The average use is less than 32 weeks, during which sugarbeets are being processed into granulated sugar. Over eighty percent of the boilers at sugarbeet processing facilities operate eight months or less per year. The USBSA recommends that EPA build upon the differentiation for seasonal sources already present in the reconsideration of the area source rule to either include such boilers in the seasonal subcategory or create a separate subcategory for seasonal, agricultural boilers that are located in remote locations and tied to the production of a crop. EPA has broad authority to subcategorize sources, and therefore, the agency is strongly supported in creating an agricultural, seasonal boiler subcategory. Indeed, expanding or creating an additional subcategory is an effective way to avoid unnecessarily costly emissions standards while still effectively protecting human health. The Clean Air Act (CAA) requires that EPA publish a list of “all categories and subcategories of major sources and area sources” of HAP.⁵ In creating such a list, EPA is required to be consistent with the categories created for New Source Performance Standards (NSPS) and Prevention of Significant Deterioration (PSD) programs, only “to the extent practicable.” Indeed, the statute gives EPA significant discretion in the creation of additional subcategories “as appropriate.” No other place in section 112 of the CAA speaks to or limits EPA’s abilities to create subcategories when appropriate. Courts also have found that the agency’s ability to subcategorize sources is quite broad and is limited only by the general reasonableness to which all agencies must adhere.⁶ In addition, EPA itself has acknowledged that it should address the creation of subcategories on an “as appropriate” basis, with the understanding that “each HAP emitting industry presents its own unique situation and facts to be considered.”⁷ EPA already has created subcategories based on use and on geography,⁸ and thus such additional subcategories would simply be an expansion of what the agency already has done, using the same rationale.

Expanding the existing seasonal subcategory or creating a new subcategory for seasonal boilers located in agricultural areas where sugarbeets are grown is an appropriate addition to the Boiler Rules because it supports differential regulation based on the actual impact of these boilers. In the case of the boilers used in sugarbeet processing, the intermittent nature of the use as well as the agricultural location of the boilers reduces the need to require the controls that would be necessary for a boiler operating in a more densely populated area with year-round use. By instituting management practices standards for such boilers, EPA will ensure that human health is adequately protected while also reducing the need for expensive controls that are not cost-effective because of the limited nature of the boiler use.

Comment Excerpt Number: 2

Comment: The affected boilers used to process sugarbeets are located in agricultural areas of the United States (MI, MN, ND, NE, MT, ID, CO, WY) away from large population centers (see Attachment A). Sugarbeet processing facilities are located near the agricultural fields where the sugarbeets are grown in order to minimize transportation, and thus concerns about HAP emissions from these boilers are minimal and such facilities pose a lower risk to public health. Because of the agricultural and seasonal nature of the sugarbeet processing facilities, there is significant justification for EPA to distinguish such boilers when finalizing the Boiler Rules. EPA has previously made distinctions between appropriate controls in areas that are heavily populated and those that are in remote areas when establishing requirements under section 112, such as in the Oil and Gas MACT. In making such distinctions, the agency has acknowledged the differential impacts that can occur from area sources that are located near population centers and near many other sources of HAP. Conversely, in sparsely populated areas where there are few sources of HAP, health impacts from these HAP emissions are greatly reduced. The section of the CAA that addresses area sources, in particular, is heavily focused on population centers. CAA section 112(k)(1) requires a finding that “emissions of hazardous air pollutants from area sources that may individually, or in the aggregate, present significant risks to public health in urban areas.” It is appropriate, therefore, and consistent with section 112(k) for EPA to regulate those sources located in agricultural areas, especially those classified as area sources, differently from sources located in more densely populated urban centers. Furthermore, expansion of the seasonal subcategory to include these boilers is in keeping with the other subcategories established in the Boiler Rules. EPA already has created subcategories based on geographical distinctions in the Boiler Rules. The rules currently have continental and non-continental subcategories, and distinctions based on the non-urban nature of the source stem from the same logic already being employed by the agency. EPA has broad discretion to subcategorize based on the agricultural locations of the boilers used for processing sugarbeets and doing so would be an appropriate balancing of economic and environmental concerns.

Comment Excerpt Number: 3

Comment: In addition to the remote nature of the USBSA members’ boilers, such boilers are used only on a seasonal basis. Because the boilers are tied to the production of an agricultural product, they are used only during the season for processing sugarbeets into granulated sugar. There is no other market for sugarbeets other than being processed into granulated sugar, and the sugarbeets must be processed in a timely manner such that they do not spoil. Once the yearly harvest of sugarbeets has been processed, the boilers at such facilities cease to operate until the next harvest is received. The limited use nature of the boilers further supports either adding them to the current seasonal subcategory or creating a separate subcategory, because the overall

emissions impact of such boilers is low. Over eighty percent of the boilers run for eight months or less a year. It is appropriate for the agency to take these lower levels of operation for agricultural boilers into account and to either add them to the existing seasonal use subcategory or create a new subcategory to reflect their unique characteristics.

Comment Excerpt Number: 4

Comment: Management Practices

As these comments demonstrate, it is appropriate for EPA to either add boilers at sugarbeet processing facilities to the seasonal subcategory or create a separate area source subcategory for those boilers. Because of the agricultural-based locations and consequent lower emissions impacts of such boilers, as well as the challenging economic circumstances surrounding many such agriculture processing facilities, USBSA requests that EPA create a management practices standard for such sources. EPA has the discretion to create management practices standards under CAA section 112(d)(5) for area sources to reduce HAP emissions. As currently written, the reconsidered rule would require that sugarbeet processing facilities undergo significant physical modification in order to comply with the emission limits. These facilities would have a very difficult time meeting the standards especially considering that appropriate technology may not be readily available, is extremely costly, and has unknown reliability, and there is limited time for implementation. Therefore, there is a strong rationale for adopting management practices for a seasonal subcategory of boilers located away from concentrated urban centers. Management practices would provide for environmental protection while avoiding burdensome regulations that negatively impact the United States' agricultural industry and do not provide meaningful environmental and public health benefits. USBSA suggests that EPA adopt management practices for agriculturally-based seasonal boilers that include actions such as employing good combustion practices on a boiler-specific basis, creating and carrying out operations and maintenance plans for individual boilers, periodic tuneups of the boilers, and a periodic maintenance inspection. There also may be other suitable management practices, and USBSA looks forward to working with the agency to determine appropriate work practices for agricultural, seasonal boilers.

Comment Excerpt Number: 61

Comment: 45Th purpose of this submission is to provide EPA with some information relevant to the boiler and waste rules applicability to biomass burners, using a fairly comprehensive database of recently issued air permits to characterize current trends in the industry. We wish to demonstrate to EPA that the boiler and waste rules as currently conceived are opening the door to far greater pollution, and more toxic pollution, from the biomass energy sector than is necessary, given the technologies available for emissions control and the reasonable presumption that the public should have that "clean" biomass fuel burned as renewable energy does not consist of toxic waste. We submit these comments in support of legal comments from Earthjustice, and also on our own behalf. As part of our own submission, we are attaching comments we submitted on the "beneficial use determination" for a facility in Massachusetts, Palmer Renewable Energy, that proposed to burn construction and demolition debris.

We compiled a database of permits for biomass facilities issued in the last four years. All are power producers.

There are 67 new and re-permitted facilities in the database.

Of these 21 are existing facilities that are expanding their existing biomass capacity or adding a biomass boiler; 46 are new facilities. Some of the new facilities have now been withdrawn but were included in the permit database as examples of contemporary permitting practices.

Not every permit or application specifies the type of boiler. Of the ones that are specified, 31 are fluidized bed boilers; 26 are stokers. There are no examples of some of EPA's categories, e.g. "dutch ovens" or "biomass fuel cells".

Major/minor status of facilities in the database

For the purposes of BACT determination/criteria pollutants, regarding major/minor status:

- 1) 3 are not specified
- 2) 22 are major sources.
- 3) 42 are minor sources. Of these, 29 are synthetic minors.

For the purposes of MACT determination/HAPs,

- 1) 7 facilities do not specify whether they are major or area sources (most of these are modifications to add a biomass boiler or expand capacity at an existing facility, and permits do not always specify whether these facilities are currently major sources for MACT).
- 2) 9 facilities are major sources
- 3) 44 facilities are "area" sources.

Synthetic area sources for HAPs – our definition

Of the 44 area source facilities, 32 are what we characterize as "synthetic" minor sources. By this we mean:

- 1) the permit either specifies little information about actual HAPs emission rates, but specifies that the facility will emit "less than" 25 tons of all HAPs and less than 10 tons of any HAP.
- 2) Or, the permit/application does add up emissions of HAPs with specific emission rates, and miraculously comes in just under 25 tons (it is common for HAPs to sum to 24.9 tons).
- 3) Or, the permit/application selectively uses a mix of AP-42 emission factors, NCASI emission factors, and other industry-provided emission factors to estimate HAPs emission rates, with a sum that comes in just under 25/10 tons. In some cases, NCASI and other industry emission rates are used that are orders of magnitude lower than AP-42 rates. Often the AP-42 rates that are supplanted with industry data are graded "A" for data reliability. Very few if any permits/applications provide justification for using something other than the AP-42 rates.

Comment Excerpt Number: 63

Comment: *Facilities burning construction and demolition waste (C&D)*

There are at least 16 facilities in the database that plan to burn construction and demolition waste. Some of these specify that only "clean" C&D can be burned. In our review of permits and applications, we found only one fuel sorting study. We analyzed this study and found it to be utterly deficient in terms of the statistical approach used to characterize contamination in the fuel stream (we have attached this analysis). Most if not all facilities with permits allowing burning of C&D do not specify a fuel testing plan; the permits generally say "no burning of treated wood" with no verification provisions.

Of the 16 facilities that plan to burn C&D 11 are minor sources that will not go through BACT; 7 are synthetic minors for BACT (by "synthetic minor", we mean facilities with a potential to emit that is greater than 250 tons of a criteria pollutant, but the permit caps emissions at 250 tons).

10 are area sources for HAPs, and thus will be regulated under the area source rule. Of these, 9 are "synthetic" area sources (see above for our definition of a synthetic area source for HAPs).

Comment: *The significance of the waste definition in the context of the area source rule*

We provide comment on the use of non-hazardous secondary materials such as C&D below. Here we note that the area source rule and the definition of biomass (which will now encompass a great deal of material that would ordinarily be considered "waste") are interlinked in an important way. As EPA loosens restrictions on what can be defined as "biomass" instead of "waste", there will be an increasing number of large facilities burning potentially contaminated material, but since many are considered "area" sources, they will only be regulated for PM, not other pollutants that are regulated under the major source MACT rule.

Comment: The EPA is proposing to amend 40 CFR 63.11196 to specify that all existing boilers subject to the tune-up requirement would have two years (by March 21, 2013) in which to demonstrate initial compliance, instead of one year to demonstrate initial compliance. The EPA requested comment on whether the initial compliance period for the tune-up requirement should be extended to three years. 76 Fed. Reg. 80,535.

For many of the same reasons discussed above, the NAM recommends that this compliance period should be extended to three years. *See* 76 Fed. Reg. 15579, Table 4 (identifying 183,000 existing area source boilers). Combining a potential shortage of environmental engineers with the long range planning required for testing and work at facilities, it will be difficult to schedule and complete the testing needed to comply with the tune-up requirements in time to meet a two year deadline, particularly for facilities with multiple boilers.

Comment Excerpt Number: 45

Comment: EPA has also requested public comment on whether the compliance date for boiler tuneups for area sources should be extended to March 2013, as EPA is currently proposing, or if the compliance date should be extended to March 2014. To be consistent with the initial compliance date for boiler tune-ups at major sources, EPA should extended the compliance date for area sources to March 2014. Although the tune-up requirements do not appear overly burdensome, affected sources will still need sufficient time to determine what needs to be included in the tuneup protocol, when to schedule the initial tune-up, and to develop the reporting protocol that needs to be submitted to EPA or to the delegated state or local agency. Further, there appears to be no reason why the smaller area sources should not have the full three years to comply that is currently afforded to major sources. Extending the compliance date for tune-ups would also allow extra time for states to identify and provide outreach and compliance assistance to area source facilities. This assistance is very important, because many of these sources have had little prior experience in understanding and complying with complex air regulations. EPA is not providing states additional funding to implement these new standards. Having sufficient time before the compliance deadline to assistance affected area sources will help ease the implementation burden for states and will almost certainly minimize violations after the compliance date.

Document Control Number: EPA-HQ-OAR-2002-0058-3527-A2

Comment Excerpt Number: 29

Comment: The finalized MACT rule for area sources does not distinguish between limited use boilers separate from boilers used in regular service. EPA is proposing under the reconsideration to create a separate subcategory for "seasonally" operated boilers which do not run for at least 7 months out of the year. This requirement is based on operation of agricultural oriented processing of crops such as in the sugar cane industry. These boilers under the finalized MACT are subject to tune-ups every two years. EPA is now proposing that seasonal boilers be subject to tune-ups every five years.

The Department supports aligning the frequency of tune-ups across sources to be proportional to their operation. We believe EPA's finding that sources operating less frequently are subject to a more restrictive requirements and more costs than regularly operated sources on the same tune-

up schedule. However, we believe the proposed definition of seasonally operated boilers does not adequately address the different sources which are not in regular season through the year. One example, especially in northern climates, is space heating boilers (non-residential) which operate less than half of the year. Other types of applications certainly exist throughout the different commercial and industrial facilities.

The Department suggests that EPA create a "limited use" subcategory similar to the major source boiler rule. This subcategory can define limited use units based on total operating hours or percent operation during the year. The definition, if necessary, could further require that operation must occur in consecutive months and with more than four consecutive months of non-operation.

Instead of establishing a separate seasonal or limited use subcategory, EPA may want to consider allowing an alternative schedule for all tune-ups under the Area source rule. Under this schedule, the rule can simply require tune-ups based on the total of 12, 24, or 60 operating months to reflect the annual, biennial, and five year tune-up requirements affecting different sources. The Department acknowledges that the number of months allowed may need to be adjusted to reflect the average operation time of sources subject to the primary requirements.

A separate option we believe EPA should consider is allowing sources which install and operate a CO/O₂ CMS trim system to perform tune-ups once every four years. This form of combustion trimming basically tunes the boiler on a continually basis and is superior to periodic tune-ups. Therefore a "tuneup" is only required on a schedule necessary to inspect mechanical systems and the boiler burners. Under this approach sources would not have to track seasonal or limited operating in qualifying for an alternative schedule.

Comment: EPA is proposing to create a subcategory of "Temporary" boilers which are exempt from boiler MACT requirements. EPA proposed a definition where a boiler does not qualify as temporary if it is onsite for more than 12 months.

The Department supports EPA's approach to exempting boilers used in such circumstances. However, there may be cases where construction schedules extend beyond a year. For example, if a facility is replacing multiple boilers. The Department feels that an allowance needs to be made for non-permanent boilers which may be on site longer than 12 months. EPA stated an expectation that temporary boilers are typically less than 10 mmBtu/hr and primarily oil or gas fired. The primary MACT or GACT requirement for these boilers would be to perform a tune-up. A simple approach that addresses both time constraints and the tune-up requirement is to allow that any temporary boiler, remaining on site longer than 12 months, is exempt from MACT requirements if the boiler is operated using an oxygen trim system. The Department feels that

this approach ensures that the boiler has the same good standard operating equipment in place that is reasonably expected for any gas or oil fired boiler. This exemption also addresses that the same boiler will be operated again much like a limited use or regularly operated boiler – just on another site.

Comment: The finalized MACT rule required many sources to perform tune-ups within a year of rule promulgation. In the reconsideration, EPA is proposing to extend the requirement to within two years of rule promulgation. The Department supports extending the compliance schedule for the initial tune-up requirement. However, the Department requests that EPA consider extending the schedule to within three years of rule promulgation. At a minimum EPA should consider extending the compliance deadline to three years for any source installing CO/O₂ CMS trim systems to continuously tune the boiler system.

The Department acknowledges that the Clean Air Act requires implementation of MACT requirements as expeditiously as practicable. However, we believe EPA needs to consider that the major source ICI and EGU rules are being implemented on the same or similar time frame as the area source rule. These rules will require the same resources and vendors for tune-ups and energy assessments as needed by sources subject to the area rule. Another factor is that many sources will be addressing multiple emission requirements ranging from multiple pollutant emission limitations to a minimum of a tune-up and energy assessment. Further, the tune-up requirements currently have no lower threshold in place for the size of solid fuel fired unit affected at an area source. Clearly, the area source will apply to sources which are being regulated to this degree for the first time. In fact, we firmly believe that significant time will be required to even identify all of the affected sources. We believe that without a clear assessment of the entire affected pool of sources or the interaction between the multiple MACT rules that EPA needs to be prudent in establishing compliance deadlines. Lastly, EPA needs to consider that portions of the rule are still under reconsideration, including the schedule for tune-up requirements. EPA had identified such areas would be under reconsideration and cannot anticipate that significant sources have moved forward in the compliance. For all of these reasons the Department encourages EPA to utilize the full 3 years allowed under the Clean Air Act with a compliance date of March 21, 2014.

The Department requests for EPA to consider an extended compliance schedule for sources installing a CO/O₂ trim system. This is an alternative compliance option the Department is proposing in lieu of the current frequency of tune-ups (refer to discussion of CO monitoring). Basically, sources can have the alternative to use a CO/O₂ CMS trim system to operate continuously at good combustion conditions; i.e. continuously tuning the boiler. We believe this approach is more beneficial to both the source and ensures continuous emissions improvement.

At a minimum, we request that sources installing such equipment be allowed the full 3 year compliance timeframe.

The Department feels that EPA should consider extending the compliance date for energy assessments under the rule to 4 years after promulgation. The energy assessment requirement is basically a "secondary" requirement. For some utilities results of the energy assessment may provide enough benefit to aid in meeting requirements under the output based emission limitations. We believe facilities will self-identify this potential and move ahead with energy assessments and improvements in the 3 year compliance time-frame. EPA followed this concept in not requiring implementation of assessment results. However, larger sources will likely have to focus first on implementing primary emission controls or optimize the boiler combustion to ensure meeting the emission limitations. For these sources the energy assessment is a secondary measure with results implemented only if cost-effective. We believe that such facilities should be able to pursue the energy assessment on a time-frame which is most beneficial to them in both meeting rule requirements and applying resources. Once again EPA should also consider here that available vendors and resources will be needed in meeting both the area and major source rules. These resources should be most readily available to sources for which the assessment will help meet emission limitations. For these reasons we believe that the compliance date for energy assessments should be four years from rule promulgation, especially since implementation of energy assessment results is voluntary.

Comment: *1. CO CEMs monitoring:* Under the finalized rule sources are required to demonstrate compliance with CO emission limitations through annual stack testing. EPA is proposing in the reconsideration that sources, as an alternative, can demonstrate compliance with CO emission limitations using a certified CO CEMs. This is because some sources already have a CO CEMs monitoring system in place.

The Department supports allowing use of a CO CEMs for demonstrating compliance with applicable CO emissions limitations. However, the Department believes that sources should also be allowed to perform parametric monitoring and continuous tune combustion using a CO/O₂ continuous monitoring and trim system (CMS). This CO/O₂ CMS trim system option can provide for stack testing every two years instead of annually.

The Department believes that EPA should consider that many sources already have in place and operate CO analyzer systems in order to operate their boilers at good combustion conditions. This type of system is usually operated along with O₂ monitoring to create a CO/O₂ trim system for the boiler. A number of sources in Wisconsin's ozone non-attainment areas, including coal stokers, glass furnaces, and lime kilns, are currently required to operate CO/O₂ trim systems

under a combustion optimization requirement. We believe that EPA should consider that these systems can be correlated to absolute CO values during periodic stack testing and provide a better continuous demonstration of compliance versus monitoring oxygen alone. EPA already acknowledges that O2 trim systems are superior to parametric monitoring of O2 alone. From this perspective using a CO continuous monitoring system (non-CEMs) is a higher level yet of parametric monitoring and provides better assurance of actual CO emission levels. In addition, based on our experience, CO is a more sensitive parameter to use than O2 in tuning a source for good combustion (see discussion in major source comments under "oxygen monitoring"). For these reasons, when a source is operating a CO/O2 CMS trim system we believe that stack testing on an annual basis is not necessary. The CO CMS will identify relative changes in CO while the overall system ensures better continuous combustion and greater emission reductions than achieved by O2 monitoring. Therefore, we believe that stack testing should only be required on a biennial basis for sources utilizing a CO/O2 CMS trim system.

EPA is proposing a similar approach in allowing a PM CMS in place of a PM CEMs requirement under the major source MACT rule. This shows that a non-certified monitoring system can be specified and expected to yield quality data and can be a less costly option than a CEMs system but still provide better compliance and emission results than a stack test approach.

2. Oxygen monitoring: The finalized rule requires sources to determine an O2 concentration level during stack testing which is consistent with meeting the CO emission limitation. The source is then required to continuously monitoring O2 concentrations according to part 60 requirements as parametric monitoring for compliance. In the reconsideration, EPA is proposing that instead of requiring O2 monitoring that a source can perform parametric monitoring using an oxygen analyzer continuous monitoring and combustion trim system.

The Department supports the use of an oxygen CMS trim system instead of CEMS oxygen monitoring. We believe this approach provides continuous tuning of combustion which will result in overall lower emissions levels as compared to monitoring to comply with a single O2 concentration value. We also recommend that EPA allow for use of a CO/O2 CMS trim system with biennial stack testing as previously discussed.

Comment: The EPA in the finalized rule determined that 30-day averaging of parametric monitoring parameters is appropriate to account for variability. EPA is requesting comment on this finding.

The Department supports EPA's conclusion that 30-day averaging of parametric parameters is appropriate. The Department requests that EPA clarify and ensure the rule language allows a source to use instantaneous or un-averaged value in showing compliance with the set parameter

value. We are aware that equipment such as excess oxygen monitors is currently in place to monitor and record the instantaneous value. Instead of replacing this equipment or creating additional work to compile the data some sources simply plan to demonstrate that excess oxygen always remains below the targeted value. This option should be clearly allowed under the current rule language as this approach is more restrictive than using the averaged parametric values.

Comment: Tune-up Work Practices

1. Oil fired boilers < 10 mmBtu/hr: The finalized rule provides that oil fired boilers < 10 mmbtu/hr are subject to a biennial tune-up requirement. In the reconsideration, EPA is proposing that oil-fired boilers should be subject to tune-ups every five years with an initial compliance date of March 21, 2014.

The Department supports using the full available time allowed under the Clean Air Act in setting the initial compliance date of March 21, 2014 (refer to comments on initial compliance schedule). EPA's rationale that large numbers of small sources at a source may be affected resulting in logistical issues is correct.

We believe that EPA's rationale is not limited to just oil-fired boilers and for just area sources. The same complexity exists for all small boilers < 10 mmBtu/hr. Sources may have a mix of small boilers affected under the area rule: biomass, coal, and oil. We are particularly concerned with added complexity for biomass fired boilers where sources may not be currently regulated therefore adding a different logistical issue. The complexity of logistics is not limited to only small boilers. Traditional industrial sources with small boilers will also likely have large boilers subject to tuning and emission limits. It is difficult to distinguish logistic issues and complexity between sources with multiple small boilers and sources with a mix of small and large boilers. Using EPA's rationale, the tune-up compliance date for all boilers and process heaters regardless of size should be no sooner than March 21, 2014.

The Department believes that this same issue applies to boilers under the Major Source Rule and should be appropriately considered by EPA.

2. Conducting Initial Tune-ups at New Sources: EPA is proposing under the reconsideration that new sources will not be subject to an initial tune-up. Their reasoning is that a tune-up is inherent to starting a new source.

The Department agrees that a tune-up and full optimization of combustion will occur during startup operations of a boiler. In fact, this process is likely to take some time during shakedown of the unit operations. Clearly, optimization and tuning of the combustion may be conducted by

the boiler vendor or a different contractor than may be normally employed for a regular tune-up. In many respects this startup process may involve personnel with more complete knowledge of the system and the intended operation points of the boiler. For this reason, the Department believes it is still important for results of the tuning process be recorded. This initial start-up information provides the basis and bench-marks for measuring the effectiveness of ensuring tune-ups. Comparisons to this base information will also identify whether there are significant changes in the system and identify if other actions are needed to maintain good combustion. In fact, we would expect that a tune-up would occur any time there is a major change in equipment affecting combustion.

Therefore we recommend that EPA require an initial recording of tuning set points be recorded no later than 60 days of when full and continuous operational levels are demonstrated.

3. Clarification of Tune-up monitoring: Currently, tune-ups require measurement of oxygen and carbon monoxide concentrations in the flue gas. In discussions with potentially affected sources and equipment providers it is apparent that there is confusion whether combustion analyzer measurements are sufficient or if oxygen measurements need to be taken following 40 CFR part 60 methods for stack testing. We request that EPA clearly specify the acceptable approaches and methods in quantifying combustion gas concentrations for purposes of a

3. Small Biomass boilers and process heaters: With respect to biomass boilers < 10 mmBtu/hr the Department requests that EPA clarify tune-up requirements. The rule currently suggests that tuning steps or measure be followed as applicable or specified by the manufacturer. However, the rule also indicates that if steps are not specified for that unit that measures are to be followed as specified by manufacturers of similar units. This approach will result in confusion and potential differences in applying the tune-up requirements. Specifically, as biomass boilers become smaller it is more likely that there will be less ability to adjust combustion air accordingly or even to expect that same combustion settings should remain the same between firings. This latter point becomes especially apparent for boilers which are manually fired or operated on a single load basis. In addition, for smaller boilers it is more likely that fuels will vary more in type and quality. For these reasons we believe that at some level small boilers simply may not be tunable in the sense the rule requires – establishing a single tuned set point. As units become smaller it may even be technically challenging to obtain correct combustion gas readings or correctly adjust combustion gases. Therefore we ask EPA to provide rule language which clarifies that a source does not have to perform combustion gas measurements or flue gas adjustments if technically infeasible. We suggest that for such sources the rule specify best practices of firing clean, un-wetted fuels with visual inspection for good combustion characteristics for boilers < 5 mmBtu/hr or for boilers which are manually loaded.

Preferred Approach – The Department agrees with EPA that all boilers should operate following good combustion practices in order to minimize toxic emissions. However, the Department does not feel that biomass boilers smaller than 10 mmBtu/hr have been sufficiently characterized in order to proscribe technically sound requirements. This is particularly true with no lower threshold for applicability. For oil and natural gas fuels, the boiler components and fueling methods are fairly similar regardless of size. But for smaller biomass boilers we believe, as previously discussed, that there will actually be more variability in combustion configurations, the ability to adjust combustion air, and in fuel quality as boilers decrease in size. EPA needs to also consider that certain boilers are configured and intended to operate under

smoldering conditions most of the time until heat is called for from the unit. Finally without a clear characterization of small biomass units, we feel that EPA cannot even adequately determine what sources are likely to be considered an area source.

For this reason we request that EPA define a lower threshold for biomass boiler applicability under the area source rule at this time. We also believe the same threshold should be applied in the major source rule as well. The Department suggests that this threshold, at a minimum, should be no lower than 5 mmBtu/hr. At this time we do not have a technical basis for determining an appropriate lower applicability threshold. This speaks to our lack of information for biomass boilers at this time. The suggestion is solely based to match the threshold at which tune-ups for oil fired boilers go from a two to five year requirement.

Comment: GACT emission limits for Biomass and Oil-Fired Boilers

The Department supports that all biomass boilers and oil-fired boilers smaller than 10 mmbtu/hr should be subject to limitations no more stringent than GACT instead of a MACT based requirement. EPA has appropriately determined that these boilers are not needed under MACT to address 90% of the urban toxic emissions. In addition, smaller biomass fired sources vary greatly in combustion configuration where one MACT requirement may not be technically appropriate. Finally, based on the definition of "biomass" under the non-hazardous secondary materials rule, these sources will have minimal emissions compared to the source categories regulated under MACT. The Department supports a good work practices under GACT for biomass and oil-fired sources.

Comment Excerpt Number: 37

Comment: Consolidated Carbon Monoxide, Tune-up, and Stack testing Requirements

Many of the Department's comments are formulated from a common basis. The Department believes that there is significant opportunity, in context of the issues open for comment, to achieve the same or better environmental results and reduce compliance cost by allowing CMS parametric monitoring for PM, Hg and CO and O₂ monitoring for good combustion. One basic benefit in pursuing an alternative compliance demonstration is better parametric monitoring and stable combustion conditions which will allow for stack testing on a biennial schedule. This is very important for sources in reducing compliance cost and aligning stack testing with current Wisconsin stack testing requirements.

Although not providing absolute certified values, a CMS system which directly monitors the regulated pollutant ensures better overall environmental results as compared to an annual stack test. EPA has basically followed this premise in proposing the use PM CEMs, CO CEMs and Hg CEMs as an alternative in demonstrating compliance. EPA has also shown with the proposal of a PM CMS and oxygen trim systems for parametric monitoring that they believe quality monitoring can be standardized without requiring full CEMs certification. In this approach CMS data is correlated to the periodic stack test for each source and ensures ongoing compliance. The CO CMS is also correlated to good combustion over different loads with the source required to continuously trim the system to good combustion when operating. Because of the obvious higher value of operating direct pollutant CMS systems the Department suggest that biennial stack testing be allowed in place of annual stack when operating such a system. The Department also believes that monitoring of other operating parameters is not required when directly monitoring the pollutant of interest with a CMS.

The Department also believes that stack testing can be allowed on a biennial schedule for sources with emission limitations the sources are operating a positive control system for the pollutant in question. Specific cases we have identified where we believe biennial stack testing applies under positive control systems are as follows. The Department proposes that a CO CMS and good combustion trim system is positive control in reducing all organic toxics including dioxin and furans. EPA is proposing that particulate is a combustion based pollutant. Under this approach we believe that a source operating with good combustion (CO CMS) and ESP or fabric filter systems is a positive control system for both PM and non-mercury metals. In this case the source should be able to monitor the necessary parameters and stack test every two years for PM or metals. The Department also believes this approach constitutes an option equal to a PM CMS

compliance demonstration. The Department believes that a similar approach and biennial stack testing schedule can be taken for mercury controlled by activated carbon injection and for hydrogen chlorides controlled by either dry or wet scrubbing. To simplify this option, EPA can allow a source to demonstrate a correlation between the pollutant of interest and the positive control measure. If necessary this correlation can be approved by the delegated authority.

The Department also suggests EPA consider that a CO CMS system with good combustion trim requirements basically constitutes continuous tuning of the source. Along with biennial stack testing the CO CMS trim system is checked every two years. Under this monitoring approach, the Department believes that tune-ups are only necessary every four years. This schedule coincides with the time frame EPA suggests for inspecting burners and other boiler system equipment.

Commenter Name: Bart Sponsellar

Commenter Affiliation: Wisconsin Department of Natural Resources

Document Control Number: EPA-HQ-OAR-2002-0058-3527-A2

Comment Excerpt Number: 38

Comment: For source categories that do not have emission limitations, such as oil and gas boilers or boilers smaller than 10 mmBtu/hr, the MACT rule requires that tune-ups be performed every two years. These sources should have the alternative to install and operate a CO/O₂ CMS trim system with tune-ups conducted on a four year schedule. This provides the same alternative as proposed for the larger sources subject to emission limitations.

Lastly, this proposed schedule for CO, PM, and tune-ups is premised on the CO/O₂ trim system and a two year stack test schedule. A three or four year tune-up and stack test schedule could be considered for sources which implement a neural network system in operating the boiler system. This approach is adopted under in the finalized EGU MACT rule. The default requirement is for EGU boilers to undergo tune-ups every 36 months or 3 years. However the rule allows EGU sources with a neural network system in place to perform tune-ups on a four year cycle. To put a neural network system in place a source is typically tested intensively with computer fluidized modeling performed to determine optimum conditions for operating the boiler. The Department feels that a source which is optimized and operated to this level can be placed on a three or four year stack test schedule at a minimum for PM and CO emissions and for tune-ups.

Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 16

Comment: In addition, EPA is proposing to create a new subcategory for seasonally operated boilers. For these seasonally operated boilers, EPA is proposing to require a tune-up every five years (following the initial tune-up). Seasonally operated boilers would be defined as follows:

"Seasonal boiler means a boiler that undergoes a shutdown for a period of at least 7 consecutive months (or 210 consecutive days) due to seasonal market conditions. This definition only applies to boilers that would otherwise be included in the biomass subcategory or the oil subcategory."

We support the addition of a seasonal boiler subcategory. These boilers are used in seasonal agricultural operations or for comfort heat and typically operate only about 100 days per year, so the number of hours actually operated over a 5-year period is much less than a boiler in normal operation. Therefore, a 5-year tune-up frequency for these units is appropriate and is comparable to the tune-up frequency required for units that operate continuously.

However, this subcategory should also cover units that only operate during short periods of high electricity demand in the summer and for semi-annual capacity testing requirements. Because of the semi-annual testing required by the electric utility, the units will not meet the proposed criterion of being completely shut down for 7 consecutive months, but would otherwise be considered seasonal units and their limited operation is consistent with EPA's intent when developing this subcategory. Therefore, EPA should revise the definition of seasonal boiler to allow intermittent operational testing (e.g., up to 15 days) during the 7 month period. This would allow biomass or oil units at area sources that have availability requirements to ensure that the unit is available on short notice.

Comment Excerpt Number: 2

Comment: Masco supports EPA's decision to regulate biomass boilers based on "generally available control technologies or management practices" ("GACT"). EPA's June 4, 2010 proposed rule would have imposed standards for biomass-fueled area source boilers based on "maximum achievable control technology" ("MACT"). EPA has invited comment on the final area source standards based on GACT instead of MACT. The use of GACT is authorized in this case under Clean Air Act §112(d)(5). Moreover, as EPA acknowledges, only coal fired area source boilers are needed to account for the 90 percent requirement set forth in Clean Air Act §112(c)(6) for polycyclic organic matter ("POM ") and mercury (76 Fed. Reg. 80537). Accordingly, it is not reasonable or necessary to regulate biomass boilers based on MACT.

Commenter Name: Jennifer Youngblood
Commenter Affiliation: National Tribal Air Association
Document Control Number: EPA-HQ-OAR-2002-0058-3667-A2
Comment Excerpt Number: 26

Comment: The Association appreciates EPA's protection of health and environment of communities by controlling the emission of hazardous air pollutants from area sources. However, there is some concern that in Section VII(F) of the Federal Register notice it states "This proposed rule does not have Tribal implications as specified in Executive Order 13175". This language causes concern that even though the reconsideration may have potential impacts to Tribal Communities, it appears that that is not an issue being addressed. The Association wished to thank EPA's Office of Air Quality Planning and Standards for the outreach conducted to educate Tribes on this reconsideration.

Since many Tribes are now using biomass boilers and the U.S. Department of Energy is promoting Biomass energy resources in their Tribal Energy Program as an alternative energy source, the proposed Rule appears to place compliance schedules for the units on Tribal governments.² The Association also recognizes that language regarding residential boilers used in single family and multi-family residences is being included to indicate that these units should not be subject to subpart JJJJJ. Many of these units are used in Tribal housing and if regulated fully, may cause an undue fiscal cost to Tribal Housing Authorities, thus impacting Tribes. The Association is pleased that the Rule addresses this in a proposed amendment to 40 CFR 63.11195.

The Association would like to take this opportunity to provide EPA with our comments and recommendations regarding the need for EPA to clearly integrate Tribes in the implementation of the Rule and other EPA reconsiderations regarding the Rule. To assist EPA in gaining a better

understanding on our views regarding this reconsideration, the Association has bolded and italicized its recommendations below to distinguish them from our general comments.

Tribal-Related Issues about the Rule

EPA's policy is to work with Tribes on a government-to-government basis in implementing the NESHAP. This reconsideration contains provisions which clearly have the potential to impact Tribal Nations. These are the establishment of standards for biomass and oil-fired area source boilers based on generally available control technology, the proposal of a new subcategory for seasonally operated boilers and establishing GACT Emission Limits for biomass boilers. The Association is in agreement in two areas that may have Tribal implications. These areas are exemption for temporary boilers and adding residential boilers to the list of boilers not subject to subpart JJJJJ. This reconsideration of the Rule seeks to clarify language of the NESHP.

The Association seeks clarification on steps that alternative energy resources funders can include when working with Tribal governments who wish to move to biomass energy resources.

Standards for Area Source Boilers, GACT and Costs

To determine GACT, EPA looks at methods, practices and techniques that are commercially available and appropriate for use by the sources in the category. A consideration of the economic impacts on sources in the category and the technical capabilities of those operating and

maintaining the emissions control systems is another piece to this determination. Tribes may have limited resources to conduct increased maintenance on these units. The Association understands that in the reconsideration Federal Register notice, EPA states that *“these amendments will not increase the costs for the final rule but will result in a decrease in the burden on small facilities as a result of the reduction on the frequency of conduction tune-ups for seasonal boilers and small (equal or less than 5 MMBtu/hr) boilers.”* The definition included in the notice on page 89542 foot note 3, defines small entities under 13 CFR 121.201 to include small businesses, small organizations and small governmental jurisdiction. It may be implied that Tribes are included in this but a clarification of this definitional language should include how Tribes fall into this amendment language.

The Association recommends that EPA conduct more clear and concise outreach with Tribes to facilitate understanding of the maintenance schedule of biomass boilers and to work with other federal Agencies which fund Tribal energy programs. Further, the Association would like to see clarification of language as to the role of Tribes in relationship to the “small entity” definition in 13 CFR 121.201.

Document Control Number: EPA-HQ-OAR-2002-0058-3671-A2

Comment Excerpt Number: 4

Comment: A number of our members have expressed support for the creation of the seasonally-operated boiler subcategory, which, like many of the changes, will reduce requirements on boilers that operate infrequently or otherwise are likely to be insubstantial sources of HAPs. However, EPA proposes that seasonal boilers would include boilers that undergo "a shutdown for a period of at least 7 consecutive months (or 210 consecutive days) due to seasonal market conditions." Seasonal changes affect differing parts of the US. The seven month shutdown period benefits only facilities in the southern part of the country. The definition should be based upon differing regional climate conditions to allow for northern seasonal variances or shortened to five month shutdown criteria.

Comment: The Pennsylvania Chamber supports EPA's proposal to extend by 365 days the compliance date of the initial tune-up for new and reconstructed sources. However, we urge EPA to harmonize this extension with the definition of new/reconstructed sources by resetting the proposal date for defining such sources from June 2010 to the re-proposal date of December 2011. This will allow more reasonable lead time for covered sources to factor changes reflecting those revisions into construction plans.

Comment: III. Area Source Proposal Comments

1. Many of our wording and clarification suggestions relative to the major source rule apply to the areas source rule as well and should be incorporated into that rule.

2. The temporary boiler exemption should be clarified.

Proposed §63.11195(h) exempts temporary boilers from the area source proposal. Temporary boiler is defined in proposed §63.11237 as follows.

Temporary boiler means any gaseous or liquid fuel boiler that is designed to, and is capable of, being carried or moved from one location to another by means of, for example, wheels, skids, carrying handles, dollies, trailers, or platforms. A boiler is not a temporary boiler if any one of the following conditions exists:

- (1) The equipment is attached to a foundation.
- (2) The boiler or a replacement remains at a location for more than 12 consecutive months. Any temporary boiler that replaces a temporary boiler at a location and performs the same or similar function will be included in calculating the consecutive time period.
- (3) The equipment is located at a seasonal facility and operates during the full annual operating period of the seasonal facility, remains at the facility for at least 2 years, and operates at that facility for at least 3 months each year.
- (4) The equipment is moved from one location to another in an attempt to circumvent the residence time requirements of this definition.

Paragraph (2) of this definition excludes a boiler or a replacement that "remains at a location for more than 12 consecutive months." And further specifies that "Any temporary boiler that replaces a temporary boiler at a location and performs the same or similar function will be included in calculating the consecutive time period."

The second sentence language creates a problem because there is no time period associated with the replacement. It is not unusual for a temporary boiler to be used for short periods during turnarounds or other maintenance activities that recur several years apart. Under the proposal, these boilers would not be considered temporary, because each boiler replaces the previous one and performs the same function, even though there is a multi-year gap between the occurrences. We believe that replacements that occur after a gap of at least one year should not be considered consecutive for the purposes of this definition and the language of paragraph (2) should be revised to reflect that situation.

3. Only a design or Operations and Maintenance Plan requirement should apply to liquid fired boilers with a design heat duty of <10 MMBTU/hr.

Under this proposal, liquid-fired boilers of <5MMBTU.hr duty require tune-ups every five years. As discussed in Comment II.3.B, relative to gas and light liquid-fired BPH at major sources, even an every five year tune-up is not justified and we recommend a design practice or Operations and Maintenance Plan work practice instead.

Instead of the proposed five year tune-up, a design practice requiring the boiler to be designed to fire liquids or an Operations and Maintenance Plan work practice, such as incorporated into the Engine NESHAP should be required. Item 9 of Table 6 of part 63 subpart ZZZZ addresses the parallel situation for small and limited use engines. It requires that the owner/operator follow a work practice and demonstrate continuous compliance by "(i) operating and maintaining the stationary RICE according to the manufacturer's emission-related operation and maintenance instructions; or (ii) develop and follow your own maintenance plan which must provide to the extent practicable for the maintenance and operation of the engine in a manner consistent with good air pollution control practice for minimizing emissions."

4. The residential boiler exemption should be extended to similar boilers providing comfort heat and hot water for similarly sized offices and other spaces. 1. On page 80616 of the major source proposal 54 , EPA states:

Residential Unit Exemption. During the initial phases of implementation of the area source boiler rule, stakeholders requested clarification from the EPA on the applicability of the area source rule to residential boilers, particularly those units at individual residences located at institutional facilities. The EPA's intent was not to cover such units, and during reconsideration, the EPA is amending the area source rule accordingly.

Since a residential boiler is defined as a boiler providing only comfort heat and/or hot water for up to four residential units, we believe a boiler providing comfort heat and/or hot water for an office, workroom, control room, or similar space of similar size⁵⁵ should also be exempted. Such small boilers, whether firing gas or liquid, have miniscule emissions and there is no environmental or health basis for imposing any requirements on such small emission sources.

5. Our comments in Section II.8 above on the major source proposal also apply to the malfunction and affirmative defense requirements in the area source proposal.

6. Comments on the Energy Assessment Requirements

A. The energy assessment requirement is not justified and should be deleted.

The proposal to impose a facility-wide energy assessment through this rulemaking is not practical, overstates benefits, understates costs, and is not authorized by the CAA. Since the energy assessment requirement impacts units other than BPH in a facility by including energy consuming systems, this rulemaking expands this BPH rulemaking to many other source categories. The Agency's authority under section 112 of the CAA for that expansion is unclear at best.

There is no basis to claim any benefits for the energy assessment requirement since 1) larger area sources typically have already performed extensive energy assessments and installed those projects with high economic returns that make sense from a safety, reliability, operability and capital management perspective, 2) smaller area sources have neither the expertise or wherewithal to execute such assessments, and 3) the proposal separately requires BPH tune-ups, EPA's claimed main source of energy assessment benefits⁵⁶ .

For smaller area sources, cost might be reasonable if they could avail themselves of the proposed 8 hour and 24 hour limit on assessment hours, but there is no chance of any benefits in those cases, since 8 and 24 hours is inadequate to meet the assessment requirements as outlined in Table 2 or to certify compliance (See the following comment).

Nothing in the proposal or proposal preamble addresses 1) the legality of imposing this requirement on sources outside the regulated source category (i.e., steam consumers), 2) how this assessment is linked to HAP emissions, the legal basis for this rulemaking (which are miniscule from light liquid fired equipment), 3) how equipment reliability, safety, and operability are to be protected, or 4) the real costs of the proposal.

B. The revisions to the definition of "energy assessment" to allow EPA to incorrectly claim a reduced energy assessment cost do not accomplish that goal and the true cost should be reflected in the beyond-the-floor analysis and the Information Collection Request or EPA must change the energy assessment requirements to match the time allowed. Other clarifications to the definition are also needed.

1. On page 80615 of the major source proposal preamble EPA states; "We have revised the definition of "Energy assessment" to change the maximum time from 1 day to 8 technical hours and from three days to 24 technical hours. This would allow sources to perform longer assessments at their discretion." All this change does is revise the criterion for when the violation occurs (i.e., it is now a violation if you fail to meet all the energy assessment criteria in Table 357 because to do so would require more than 8 hours or 24 hours, rather than 1 day or 3 days.). Nothing in the proposed energy assessment definition relieves sources from the Table 3 requirements for energy assessment content if they cannot complete the assessment in the specified time. In fact, proposed §63.11214(c) requires that a facility certify in the NCS that "the energy assessment was completed according to Table 2 to this subpart and is an accurate depiction of your facility." Thus, sources have no discretion whether or not to spend more time and it is false for EPA to assume the 8 and 24 hour limits have any meaning or to rely on those limits for the burden and cost analyses.

The Table 2 requirements involve significant technical work and thus will always require more than the 8 or 24 hours specified by EPA for facilities less than 1 trillion BTU per year. Thus, to avoid violating §63.11214(c) sources will always expend more than 8 or 24 hours. EPA needs to include a realistic time estimate in the record for the energy assessment and justify the real costs as required by section 112(d) of the CAA and provide that justification to the Office of Management and Budget and to the public, rather than setting artificial and unrealistic time limits to justify reduced cost estimates for this arbitrary requirement.

2. The definition is unclear whether the energy assessment applies to just boilers or to both boilers and process heaters. Since the size criterion (i.e., facility boiler and process heater energy consumption) is based on both boilers and process heaters, we would assume the proposed definition means the assessment must deal with both steam and process heat. However, the area source rule only deals with boilers and thus there is no basis for evaluating process heaters or process heat consumers. If the energy assessment requirements are finalized, the area source energy assessment must be limited to boilers and steam consumers. The definition wording, as exemplified in Item 4 below, should be clarified on this point.

3. Each of the three paragraphs in the definition call for evaluating "the boiler system and any energy use system" accounting for at least a specified percentage of the energy output. "Output" is a meaningless term related to consumers and that word should be changed to "production or consumption."

4. For example, to be clearer Paragraph 3 of the energy assessment definition should read as follows.

(3) In the Energy assessment for facilities with affected boilers and process heaters using greater than 1.0 trillion Btu per year, the boiler system and any energysteamuse system accounting for at

least 20 percent of the energysteamoutputproduction or consumption will be evaluated to identify energysteamsavings opportunities.

Paragraphs 1 and 2 of the proposed definition should be changed accordingly

C. Energy assessor qualification requirements should be generalized.

Proposed §63.11237 defines qualified energy assessor as follows. Qualified Energy Assessor means:

(1) Someone who has demonstrated capabilities to evaluate energy savings opportunities for steam generation and major energy using systems, including, but not limited to:

(i) Boiler combustion management.

(ii) Boiler thermal energy recovery, including

(A) Conventional feed water economizer.

(B) Conventional combustion air preheater, and

(C) Condensing economizer.

(iii) Boiler blowdown thermal energy recovery.

(iv) Primary energy resource selection, including

(A) Fuel (primary energy source) switching, and

(B) Applied steam energy versus direct-fired energy versus electricity.

(v) Insulation issues.

(vi) Steam trap and steam leak management.

(vii) Condensate recovery.

(viii) Steam end-use management.

(2) Capabilities and knowledge includes, but is not limited to:

(i) Background, experience, and recognized abilities to perform the assessment activities, data analysis, and report preparation.

(ii) Familiarity with operating and maintenance practices for steam or process heating systems.

(iii) Additional potential steam system improvement opportunities including improving steam turbine operations and reducing steam demand.

(iv) Additional process heating system opportunities including effective utilization of waste heat and use of proper process heating methods.

(v) Boiler-steam turbine cogeneration systems.

(vi) Industry specific steam end-use systems.

There are at least two major problems with this definition. First, as written, this definition requires a single person to have all of the capabilities and experience listed. Such a person likely does not exist. For instance, people who specialize in boiler combustion management will likely have no experience with condensate recovery or industry specific steam end use systems. If instead of a single person, the definition is meant to apply to a team (as most energy assessments require) that is not reflected in the time, burden or cost estimates used for this rule. Secondly, the definition requires expertise and experience that will not be needed. For instance, the definition requires process heater and process heat expertise, even though the area source proposal only applies to boilers and, therefore, only steam use. Similarly, most facilities do not have boiler-steam turbine cogeneration systems, yet they cannot employ an assessor who lacks that experience.

We recommend the definition be revised to the following.

Qualified Energy Assessor or Assessors means a person or persons who have demonstrated capabilities to evaluate energy savings opportunities for steam generation and major steam using systems, as applicable to the facility.

D. If the energy assessment requirement is finalized, the Table 2 Item 10 allowance for use of past energy assessments, must be amended to waive energy assessor approval and qualifications requirements.

Proposed Item 2 of Table 10 lists the elements that must be addressed in the energy assessment. In the introductory paragraph it states "An energy assessment completed on or after January 1, 2008, that meets or is amended to meet the energy assessment requirements in this table, satisfies the energy assessment requirement." However, to be acceptable an energy assessment must have been performed by an assessor approved by the Administrator and that assessor or team of assessors must have met all of the requirements in the proposed qualified energy assessor definition. As discussed in the previous comment, the energy assessor definition is unreasonably restrictive and it is virtually impossible that an existing assessment was done by a team that met all those specific requirements. Further, the assessor or assessors for a past assessment certainly were not approved by the Administrator. Thus, the allowance to use existing assessments, which we requested and fully support, is not usable in practice. A sentence needs to be added to Table 2 Item 10 that waives the energy assessor definition and approval where an existing assessment is being used to meet the energy assessment requirement.

E. If the energy assessment is finalized, the modifications discussed above must be made to make the hour limits meaningful. The certification language required for the NCS and §63.11214(c) also need to be modified to reflect the hour limits and to clarify that the assessment is a snapshot.

1. Proposed §63.11214(c) requires that the NCS certify that "an energy assessment of the boiler and its energy use systems was completed according to Table 2 to this subpart and is an accurate depiction of your facility." If the 8 hour and 24 hour limits on the energy assessment for facilities producing < 1 trillion BTU/year are made meaningful, most sources in those production ranges will not have completed energy assessments, since that amount of time is inadequate to

even get started. Thus, those sources will be unable to sign the proposed certification wording. For those sources alternate wording must be provided. We suggest the following be provided as an alternate certification.

This facility has expended at least 8 or 24 technical hours, as applicable, towards evaluating steam production and consumption efficiencies.

2. Proposed §63.11214(c) must also be revised to clarify that the facility is only certifying to the accuracy of the information used in the assessment as a snapshot. Since the assessment is a onetime requirement, the certification should indicate that it is only an accurate depiction of the facility at the time of the assessment, thereby removing any suggestion that a new assessment is needed if the facility changes.

F. If the energy assessment is finalized, the following clarifications are needed to the definition of energy assessment.

1. The definition of energy assessment has three categories based on facility heat input, but then requires that the assessment address "energy use systems." There is no basis for expanding the assessment beyond producers and users of steam or heat provided by boilers and process heaters subject to this rule (e.g., electricity users, imported steam users) and therefore the term "energy system" should be replaced with "steam and process heat consumers."

2. Each of the three paragraphs in the energy assessment definition call for evaluating "the boiler system and any energy use system" accounting for at least a specified percentage of the energy output. As in the previous item, the term "energy" is unclear and should be changed to "steam." Additionally "output" is a meaningless term related to consumers and that word should be changed to "production or consumption." Finally, it should be clarified the percent is the percent of the facility total steam production or consumption, as applicable.

3. For example, to address the above concerns, Item 3 of the energy assessment definition should be revised to read as follows.

(3) Energy assessment for facilities with affected boilers using greater than 1.0 TBtu per year, the boiler system(s) and any onsite energysteamuse system accounting for at least 20 percent of the affected boiler(s) energysteamoutputproduction or consumption, as applicable, at the facility will be evaluated to identify energysteamsavings opportunities.

Similar revisions to Items 1 and 2 of the energy assessment definition are also needed.

7. The compliance timing for boilers that stop burning solid waste must be clarified and it should be clarified that only when it is intended to permanently cease burning solid waste does the CISWI unit become subject to the appropriate NESHAP rule.

1. Proposed §§60.2145(a)(2) and (3), and 60.2710(a)(2) and (3) and the proposed definitions of CISWI unit specify that a unit that has been subject to CISWI remains subject for 6 months after ceasing to combust solid waste. On the other hand, §63.11196(d) of this proposal states:

(d) If you own or operate an industrial, commercial, or institutional boiler or process heater and would be subject to this subpart except for the exemption in §63.11195(b) for commercial and

industrial solid waste incineration units covered by part 60, subpart CCCC or subpart DDDD, and you cease combusting solid waste, you must be in compliance with this subpart on the effective date of the switch from waste to fuel.

"Effective date" is unclear in this context and should be clarified by specifically referencing the provisions of the CISWI rules that identify this effective date as being the date identified by the source for the transition from the CISWI rule to the area source rule and not the date the source ceases to burn solid waste or the effective date of the part 63 subpart JJJJJ rule.

2. Proposed §63.11196(d) deals with compliance timing for boilers and process heaters that have been subject to the CISWI rule, but stop firing solid waste and thus become subject to this major source rule instead. The language of this paragraph needs to be clear that this transition only occurs if the unit is stopping solid waste burning permanently. As currently wording, a temporary stoppage (which happens frequently at CISWI) units would appear to make this rule applicable rather than CISWI.

3. Citing process heaters in proposed §63.11196(d) is incorrect since the area source NESHAP only applies to boilers.

To address these issues (1 through 3) we suggest the following revision to §63.11196(d).

(d) If you own or operate an industrial, commercial, or institutional boiler and would be subject to this subpart except for the exemption in § 63.11195(b) for commercial and industrial solid waste incineration units covered by part 60, subpart CCCC or subpart DDDD, and you intend to permanently cease combusting solid waste, you must be in compliance with this subpart on the effective date of the switch from waste to fuel part 60 subparts CCCC or DDDD to this subpart as identified under the provisions of §§60.2145(a)(2) and (3), or §§60.2710(a)(2) and (3).

8. We support the use of Generally Available Control Technology (GACT) to set the PM limit for new oil-fired boilers at area sources, but the GACT model (NSPS Dc) only establishes a numeric limit for boilers burning fuels with greater than 0.5 % sulfur and EPA should follow that example in this rulemaking.

EPA finalized a PM emission limit in the existing final BPH NESHAP based on GACT58 for new oil-fired area source boilers and is soliciting comment on the level at which the limit was set. In this proposal, EPA stated⁵⁹ :

For the purposes of regulating PM from new boilers, we concluded that the GACT standards should consist of numeric emission limits for units with heat input capacities greater than 10 million Btu per hour or greater because these new units will be subject to the new source performance standard (NSPS) emission limits for PM, and the NSPS will require PM emissions testing. For units with capacity less than 10 million Btu per hour, GACT does not include a numerical emission limit because of technical limitations of testing PM emissions from boilers with small diameter stacks.

We agree with EPA's rationale to base these limits on GACT versus MACT. Basing the limit on NSPS Subpart Dc is justified, as EPA has recently reviewed that NSPS60 and determined that a PM limit of 0.030 lb/MMBTU (see 40 CFR 60.43c(c)) is appropriate. However, NSPS Dc

provides an exemption from the PM limit for units burning low-sulfur fuel at § 60.43c (e)(4), as follows.

an owner or operator of an affected facility that commences construction, reconstruction, or modification after February 28, 2005, and that combusts only oil that contains no more than 0.50 weight percent sulfur or a mixture of 0.50 weight percent sulfur oil with other fuels not subject to a PM standard under §60.43c and not using a post-combustion technology (except a wet scrubber) to reduce PM or SO₂ emissions is not subject to the PM limit in this section.

Therefore, to reflect GACT, EPA should include a similar sulfur criterion in the area source NESHAP in applying the new source boiler PM limit. Boilers firing liquid fuels containing < 0.5 wt. % sulfur should only be subject to the work practice requirement to maintain a record that the liquid fuel fired contains < 0.5 wt. % sulfur. Such a work practice is justified since the low sulfur content indicates low PM emissions and thus meets the CAA §112(h) criteria of being infeasible to measure. [Footnote 54: 76 Fed. Reg. 80598 (December 23, 2011)]

[Footnote 55: 6000 square feet is our estimate of the square footage of a typical four unit residence, but EPA may have data to allow specifying a heat duty, which would be a preferential way of defining the exclusion (i.e., Residential boiler means a boiler providing only comfort heat and/or hot water firing up to ___ MMBTU/hr.)]

[Footnote 56: In originally proposing the energy assessment requirement, EPA stated at 75 Fed. Reg. 32026 (June 4, 2010) "The Department of Energy has conducted energy assessments at selected manufacturing facilities and reports that facilities can reduce fuel/ energy use by 10 to 15 percent by using best practices to increase their energy efficiency. Many best practices are considered pollution prevention because they reduce the amount of fuel combusted which results in a corresponding reduction in emissions from the fuel combustion. The most common best practice is simply tuning the boiler to the manufacturer's specification."]

[Footnote 57: Table 2, Item 10 of the proposal states "The energy assessment must include" [emphasis added] and then lists eight elements, some of which are major technical efforts.]

[Footnote 58: 76 Fed. Reg. 15574 (March 21, 2011)]

[Footnote 59: 76 Fed. Reg. 80537 (December 23, 2011)]

[Footnote 60: 72 Fed. Reg. 32759 (June 13, 2007) and 74 Fed. Reg. 5091 (January 28, 2009).]

Comment: Comments on the Area Source Rule

Tune up date delay and stay

We are requesting EPA stay the effective date of the rule for 90 days as allowed under Clean Air Act section 307(d)(7)(B), so that the EPA can complete its reconsideration process and finalize the area source rule. EPA has requested comment on delaying the compliance date for the tune up work practice until March 21, 2013 or March 21, 2014. Maine DEP supports delaying the compliance date for this regulation until May 21, 2014. Maine DEP continues to receive several calls each month from sources just becoming aware of this regulation. Most Maine boiler owners have informed us they already perform tune ups to maximize their units' efficiency during Maine's cold winters, but not all tune up technicians perform tune ups as prescribed in the proposed rule. Several boiler owners had their boilers tuned this summer, but under the proposed rule would be required to do another costly tune up to fit the EPA prescribed method.

Modified Tune up procedure

Maine DEP disagrees with the removal of the tune up requirement for new boilers. EPA should require a modified tune up for new sources that focuses on the optimization of boiler efficiency. EPA should also allow for sources to request approval for modified tune up procedures from the delegated authority, similar to mechanisms provided in EPA's rules regarding stack testing and monitoring. Portions of EPA's tune up procedure as proposed in the regulation are not applicable to biomass boilers. EPA should use the boiler tune up definition provided in the Major Source Boiler MACT for biomass units. *"Tune-up", as defined in the proposed Major Source Boiler MACT rule, means "adjustments made to a boiler in accordance with procedures supplied by the manufacturer (or an approved specialist) to optimize the combustion efficiency."*

Seasonal boiler EPA proposed a definition for seasonal boilers with a less rigorous tune up schedule for these boilers. EPA should instead provide an exemption for "limited use" boilers in the Area Source boiler rule, consistent with the Major Source Boiler MACT.

Units switching from natural gas to another fuel should not be considered new units 40 CFR 63.11194 (d) states: *A boiler is a new affected source if you commenced fuel switching from natural gas to solid fossil fuel, biomass, or liquid fuel after June 4, 2010.*

We have many boilers manufactured and installed with fuel switching capabilities. Treating them as "new" when they are operated as originally designed does not make sense, and is inconsistent with the Major Source Boiler MACT.

EPA should establish a straight forward heat input exemption for the major source and area source boiler rules

Maine DEP supports EPA's intent to exempt small residential sized boilers. Unfortunately, the final hot water heater definition was complicated and difficult for implementing agencies and boiler technicians to understand, making applicability determinations very difficult. The proposed addition of the 1.6 MMBtu/hr threshold makes implementation more straightforward. However, Maine DEP believes this should be used as an overall applicability threshold for all types of boilers and fuels. If EPA retains the hot water heater exemption, EPA should include biomass in the definition as follows, "hot water heater means a closed vessel with a capacity of no more than 120 U.S. gallons in which water is heated by combustion of gaseous, liquid, *or biomass* fuel and hot water is withdrawn for use external to the vessel. Hot water boilers (i.e. not

generating steam) combustion gaseous, liquid fuel, or *biomass* with a heat input capacity of less than 1.6 million Btu per hour are included in this definition."

Comment: We Reiterate Our Strong Support for the DOE-USDA Technical Assistance Program

We are extremely gratified to hear of EPA's forthcoming collaboration with the Departments of Energy and Agriculture to help facilities "develop compliance strategies, such as combined heat and power that are cleaner, more energy efficient, and that can have a positive economic return for the plant over time."²³ This kind of technical support is critical to help regulated entities understand and comply with the regulatory process. Moreover, because industrial facilities only replace their boilers every 15 to 20 years, the Rule creates a narrow window of opportunity to make substantial improvements to these systems. The Technical Assistance program leverages the Boiler MACT by enabling facilities to take advantage of these investment points. Our organizations and businesses are eager to lend support to EPA during this process.

We assume that the fact that this program was not mentioned in the December Rule is not a reflection of EPA's regard for the program and remain hopeful that it will be fully supported and funded by the Agency. We remain happy to work with the Administration to lend support to this initiative and to alert our networks of the opportunity. We look forward to collaborating with you as this effort moves forward and hope that you will identify ways that we can help popularize the program among regulated entities.

[Footnote 23: US EPA, Fact Sheet: "EPA Boiler Standards: Department of Energy and Department of Agriculture Technical Assistance for Boiler Operators and Owners (<http://www.epa.gov/airquality/combustion/docs/20110221doefs.pdf>).]

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.
