Research Triangle Park, NC**

FOREWORD

This document provides EPA's responses to public comments on EPA's Proposed National Emission Standards for Hazardous Air Pollutants for Major Sources: Industrial, Commercial, and Institutional Boilers and Process Heaters.

EPA published a notice of reconsideration and proposed amendments of the standards applicable to industrial, commercial, and institutional boilers and process heaters in the Federal Register on December 23, 2011 (76 FR 80598). EPA received comments on these proposed rules via mail, e-mail, and facsimile. Copies of all comments submitted are available at the EPA Docket Center Public Reading Room and are also available electronically through <http://www.regulations.gov> by searching Docket ID EPA-HQ-OAR-2002-0058.

This document provides the verbatim text of comments extracted from the original letter. For each comment, the name and affiliation of the commenter, the document control number (DCN) assigned to the comment letter, and the number of the comment excerpt is provided. In some cases the same comment excerpt was submitted by two or more commenters by submittal of a form letter prepared by an organization. Rather than repeat these comment excerpts for each commenter, EPA has listed the comment excerpt only once and provided a list of all the commenters who submitted the same form letter in a table at the end of the document.

EPA's responses to comments are generally provided immediately following each comment excerpt. However, in instances where several commenters raised similar or related issues, EPA has provided a single response after the first comment excerpt in the group and referenced this response in the other comment excerpts.

Parallel with this rulemaking effort are three separate, but related rulemakings that may be of interest to stakeholders. These three rules are: *National Emission Standards for Hazardous Air Pollutants for Area Source Industrial/Commercial/Institutional Boilers* (Docket ID: EPA-HQ-OAR-2006-0790); *Identification of Non-Hazardous Secondary Materials That Are Solid Waste* (Docket ID: EPA-HQ-RCRA-2008-0329); and *Standards of Performance for New Stationary Sources and Emission Guidelines for Existing Sources: Commercial and Industrial Solid Waste Incineration Units* (Docket ID: EPA-HQ-OAR-2003-0119).

Given the identical proposal dates, and the related nature of these other rules, many commenters submitted comments to this rulemaking docket that were specific to one of these related rulemakings. Some commenters submitted a single DCN with comments on all four rules while others submitted a separate DCN specific to each rule. Many commenters submitted identical comments to all of these dockets. In order to reduce duplicative comments, this document flags comments associated with any of the above three related rulemakings as out-of-scope comments for this response to comment document. To the extent that the commenter submitted these comments to the appropriate rulemaking document, responses have been developed in the response to comment documents for each of these related rulemakings. For this reason, EPA encourages the public to read the other response to comment documents prepared for these three other rulemakings as they may contain topics relevant to these other rulemakings.

Legal and Applicability Issues

2A. Authority for Emission Credits

Commenter Name: Jessica Bridges

Commenter Affiliation: United States Clean Heat & Power Association (USCHPA)

Document Control Number: EPA-HQ-OAR-2002-0058-3501-A1

Comment Excerpt Number: 23

Comment: We are supportive of this use of emission credits obtained from energy conservation measures.

Response: The EPA thanks the commenter for their support.

Commenter Name: Myra Reece

Commenter Affiliation: South Carolina Department of Health and Environmental Control

Document Control Number: EPA-HQ-OAR-2002-0058-3629-A2

Comment Excerpt Number: 2

Comment: The EPA Should Provide A Clear Process To Determine Acceptability Of Benchmarks

Section 63.7533 requires facilities opting to use the emission credit approach to establish an emissions benchmark from which emission reduction credits may be generated. Credits are generated by the difference between the benchmark that is established for each affected boiler, and the actual energy demand reductions from energy conservation measures implemented after January 1, 2008. According to the proposed rule, the benchmark shall be determined by using the most representative, accurate, and reliable process available for the source.

The EPA does not provide specific parameters to determine what constitutes an acceptable benchmark. However, the October 10, 2010, EPA guidance document titled “Available and Emerging Technologies for Reducing Greenhouse Gas Emissions from Industrial, Commercial, and Institutional Boilers” states that “the U.S. EPA’s ENERGY STAR Program has developed benchmarking tools that establish best-in-class for specific industrial sectors” and encourages industry to use these tools.

DHEC requests that the EPA provide in the rule the acceptable benchmarks in order to establish a level playing field for all facilities using this compliance approach, and to minimize the resources required by the delegated agencies to review and approve the NOCS. In addition to updating the rule, we believe the EPA should develop and make available guidance examples demonstrating the implementation of the emission credit compliance option.

Response: We believe that the benchmark, as used in the rule, can be easily determined. Benchmark is defined in the rule as:

Benchmark means the fuel use for a boiler or process heater for the one-year period before the date that an energy demand reduction occurs, unless it can be demonstrated that a different time period is more representative of historical operations.

Benchmarking under the EPA's ENERGY STAR is more difficult because it involves determining energy output and energy use, whereas in 63.7533, the requirement is to benchmark the fuel use of the affected boiler which can be easily determined. In terms of guidance on calculating energy credits, the Department of Energy has prepared guidance which has been posted to the EPA's Boiler MACT webpage.

Commenter Name: Myra Reece

Commenter Affiliation: South Carolina Department of Health and Environmental Control

Document Control Number: EPA-HQ-OAR-2002-0058-3629-A2

Comment Excerpt Number: 3

Comment: DHEC also requests that the EPA clarify how to assign emission credits generated from process efficiencies that might well affect more than one boiler or process heater. Should emission credits be dedicated to a single boiler or process heater?

Response: As part of the required Implementation Plan that the source must develop and submit for approval, the source is to identify the affected boiler to which the emission credits will be applied, and to document all uses of energy from the identified affected boiler. It is the only improvement made to systems using energy from the identified affected boiler.

Commenter Name: Ahmed Idriss, Capital Power Corporation

Commenter Affiliation: CPI USA North Carolina (CPI NC)

Document Control Number: EPA-HQ-OAR-2002-0058-3524-A1

Comment Excerpt Number: 8

Comment: CPI NC is confused by the EPA's decision to grant energy credits for steam-output based emission limits but not electricity output-based emission limits. Such a position creates an unfavorable market bias against facilities that do not produce steam, making such facilities less economic to run. Further, it does not provide incentive for such facilities to make modifications leading to energy efficiencies.

CPI NC recommends the Proposed Rule be amended to also provide energy credits for electricity output-based emission limits.

Response: We agree that the emission credit provision should be available for the electricity output-based emission limits. When section 63.7533 was promulgated in the March 2011 final rule, the output-based limits were only in terms of steam output. In the December 2011 reconsideration proposal, the steam output-based limits were also listed in terms of Mwh output, but 63.7533(a) was inadvertently not revised. In the final rule, 63.7533(a) has been revised to read "If you elect to comply with the alternative equivalent output-based emission limits ..."

2B. Waste Heat Boilers and Process Heaters

Commenter Name: Russell A. Wozniak

Commenter Affiliation: The Dow Chemical Company

Document Control Number: EPA-HQ-OAR-2002-0058-3449-A1

Comment Excerpt Number: 35

Comment: EPA should revise the definition of Boiler to clearly exclude all waste heat boilers from coverage under this regulation.

The last sentence in the proposed definition of "Boiler" says that waste heat boilers that use only natural gas, refinery gas, or other gas 1 fuels for supplemental fuel are excluded from this definition. In addition, EPA should also exclude waste heat boilers that are fueled with gas 2 fuels in the rare case that a gas 2 fuel is used as supplemental fuel in a waste heat boiler. Table 3 of EPA's Miscellaneous Proposed Technical Corrections describes this change as "Revise the definition of waste heat boiler to clarify that the definition includes fired and unfired waste heat boilers", which leads one to believe that all waste heat boilers should be excluded from the regulation.

EPA should replace the last sentence of the proposed new definition of Boiler with the text from the March 21, 2011 final rule, which reads: "Waste heat boilers are excluded from this definition". This change would better reflect the intent of EPA which is to exempt these types of units from coverage under this MACT rule.

Response: The change suggested by the commenter is being incorporated into the final rule. Waste heat boilers was first proposed to be exempted from the Boiler MACT in the original 2003 proposal. The rationale (see 68 FR 1669) was that the proposed rule did not regulate emissions from combustion units with waste heat boilers, unless such units would otherwise be subject to the proposed rule. Waste heat boilers and heat recovery steam generators are not a boiler as defined in the rule and were never part of the source category because waste heat boilers do not combust fuel. Waste heat boilers are heat exchangers that do not have their own firebox but use the heat of hot waste gases from industrial (e.g., thermal oxidizers, kilns, furnaces) or power equipment (e.g., gas turbine, engines) to generate steam. The definition of "Waste heat boiler" in the final rule has also been revised to clarify what is meant by "fired and unfired." Duct burners, which are mounted in a duct or discharging into a duct, are sometimes used to increase the temperature of the hot exhaust gas from a combustion turbine to increase electricity output from a combined cycle gas turbine system.

Commenter Name: Russell A. Wozniak

Commenter Affiliation: The Dow Chemical Company

Document Control Number: EPA-HQ-OAR-2002-0058-3449-A1

Comment Excerpt Number: 36

Comment: The last sentence in the proposed definition of "Process Heater" says that Waste heat process heaters that use only natural gas, refinery gas, or other gas 1 fuels for supplemental fuel are excluded from this definition. In addition, EPA should also exclude waste heat process heaters that are fueled with gas 2 fuels in the rare case that a gas 2 fuel is used as supplemental

fuel in a waste heat process heater. Table 3 of EPA's Miscellaneous Proposed Technical Corrections describes this change as "Revise the definition of waste heat process heater to clarify that the definition includes fired and unfired waste heat process heaters", which leads one to believe that all waste heat process heaters should be excluded from the regulation.

EPA should replace the last sentence of the proposed new definition of Process Heater with the following text:

"Waste heat process heaters are excluded from this definition".

This change would better reflect the intent of EPA which is to exempt these types of units from coverage under this MACT rule.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3449-A1, excerpt 35.

Commenter Name: Paul G. Page

Commenter Affiliation: AK Steel Corporation

Document Control Number: EPA-HQ-OAR-2002-0058-3457-A2

Comment Excerpt Number: 1

Comment: In the proposed Reconsideration Rule, it appears that EPA understands our concerns and is seeking to implement sound policy by exempting process gas-fired units, albeit with qualifications, from the Boiler MACT. To that end, EPA has proposed the following exemption criteria:

- Blast furnace gas-fired boilers or process heaters that receive 90 percent or more of their total annual gas volume from blast furnace gas;
- Waste heat boilers that use only natural gas, refinery gas, or other gas 1 fuels for supplemental fuel;
- Waste heat process heaters that use only natural gas, refinery gas, or other gas 1 fuels for supplemental fuel;
- Any boiler or process heater that is part of the affected source subject to another NESHAP in 40 C.F.R. part 63; and
- Any boiler or process heater that is used as a control device to comply with another subpart of part 60, 61 or 63, provided that at least 50 percent of the heat input to the boiler or process heater is provided by the gas stream that is regulated under another subpart.

While AK Steel supports these exemptions and EPA's effort to provide them, they are limited in their scope and benefit. As a practical matter, AK Steel is uncertain as to how we can verify the applicability of these exemption criteria to our process operations without further clarification from EPA.

Response: The EPA thanks the commenter for their support. Several of the exemption in 63.7491 have been revised to better clarify the scope of the exemption. See the response to comment EPA-HQ-OAR-2002-0058-3449-A1, excerpt 35 regarding changes to waste heat boiler exemption.

Commenter Name: Paul G. Page
Commenter Affiliation: AK Steel Corporation
Document Control Number: EPA-HQ-OAR-2002-0058-3457-A2
Comment Excerpt Number: 4

Comment: At one of AK Steel's facilities, the Company utilizes four waste heat boilers. Each waste heat boiler is associated with a corresponding slab reheat furnace and receives waste heat from that slab reheat furnace as a component of its heat input. The waste heat boilers only operate when their associated slab reheat furnace is operating so at all times they are truly functioning as waste heat boilers. The waste heat boilers combust blended coke oven gas as a supplemental fuel.

Prior to the proposed Reconsideration Rule, these waste heat boilers were exempt without qualification. Under the proposed Reconsideration Rule, the waste heat boilers are only exempt if their supplemental fuel meets the "other gas 1 fuel" criteria.

Response: See response to comment EPA-HQ-OAR-2002-0058-3449-A1, excerpt 35.

Commenter Name: Peter Pagano
Commenter Affiliation: American Iron and Steel Institute (AISI)
Document Control Number: EPA-HQ-OAR-2002-0058-3490-A1
Comment Excerpt Number: 2

Comment: It appears in the Reconsidered Rule that EPA understands our concerns and is seeking to implement sound policy by exempting units used to control process gases from the Boiler MACT. To that end, EPA has exempted, with qualifications, the following:

- Blast furnace gas fuel-fired boilers or process heaters that receive 90 percent or more of their total annual gas volume from blast furnace gas
- Waste heat boilers that use only natural gas, refinery gas, or other gas 1 fuels for supplemental fuel,
- Waste heat process heaters that use only natural gas, refinery gas, or other gas I fuels for supplemental fuel,
- Any boiler or process heater that is part of the affected source subject to another NESHAP in 40 C.F.R. part 63; and
- Any boiler or process heater that is used as a control device to comply with another subpart of part 60, 61 or 63, provided that at least 50 percent of the heat input to the boiler or process heater is provided by the gas stream that is regulated under another subpart.
- While we strongly support these exemptions and EPA's efforts, they fall short of encouraging the continued beneficial reuse of process gases by the iron and steel industry.

Response: The EPA thanks the commenter for their support. Several of the exemptions in 63.7491 have been revised in the final rule to better clarify the exemption. See the response to comment EPA-HQ-OAR-2002-0058-3449-A1, excerpt 35.

Comment: Clarification regarding supplemental fuel in the definitions of "boiler" and "process heater" also is necessary.

As currently written, the use of coke oven gas in a waste heat boiler/process heater could negate the exclusion. The definitions of "boiler" and "process heater" exclude only waste heat boilers and waste heat process heaters "that use only natural gas, refinery gas, or other gas I fuels for supplemental fuel. " The preamble further clarifies that these units can include supplemental burners as long as those burners combust only gas 1 fuels, up to 50% of their heat input, without voiding the exclusion. Because coke oven gas may not meet the current proposed definition of a gas I fuel, coke oven gas may not be able to be used in a waste heat boiler or process heater without voiding the exclusion.

As discussed in our previous comments,¹³ this makes no sense and is contrary to EPA's intended goals in promulgating the rule. Coke oven gas is an efficient fuel that can replace natural gas as a supplemental fuel. The coke oven gas will be combusted elsewhere if not used in a boiler or process heater, so there is no environmental benefit to excluding it from use in one of these units. EPA should not discourage the use of coke oven gas in a waste heat boiler or process heater just because the supplemental fuel contains a process gas other than natural gas, refinery gas, or a gas 1 fuel.

Comment Excerpt Number: 121

Comment: EPA is proposing to amend the definition of boiler and process heater to clarify that waste heat boilers and process heaters are not covered by the Boiler MACT.

ACC appreciates the clarification that waste heat boilers are not covered, and support the exemption for waste heat boilers with supplemental burners. The last sentence in the proposed definition of "Boiler" states that waste heat boilers that use only natural gas, refinery gas, or other gas 1 fuels for supplemental fuel are excluded from this definition. EPA should also exclude waste heat boilers that are fueled with gas 2 fuels in the rare case that a gas 2 fuel is used as supplemental fuel in a waste heat boiler. Preamble Table 3, which lists EPA's Miscellaneous Proposed Technical Corrections, describes this change as "Revise the definition of waste heat

boiler to clarify that the definition includes fired and unfired waste heat boilers," which leads one to believe that all waste heat boilers should be excluded from the regulation.

EPA should replace the last sentence of the proposed new definition of boiler with the text from the Final Boiler Rule, which reads: "Waste heat boilers are excluded from this definition." (See 76 Fed. Reg. 15686.) EPA should similarly change the definition of process heater. This change would better reflect the EPA's intent to exempt these types of units from coverage under this MACT rule. In addition, although the preamble text cited above mentions a 50 percent heat input cutoff for supplemental burners, this criteria is not included in the boiler or process heater definitions, and it is unclear as to the necessity or the basis of such criteria. ACC comments again that all waste heat boilers and all waste heat process heaters should clearly be excluded from this rule.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3449-A1, excerpt 35.

Document Control Number: EPA-HQ-OAR-2002-0058-3547-A2

Comment Excerpt Number: 4

Comment: Clarification regarding supplemental fuel in the definitions of "Boiler" and "Process Heater" is also necessary. As currently written, the use of coke oven gas in a waste heat boiler/process heater would negate the exclusion. The definitions of "boiler" and "process heater" exclude only waste heat boilers and waste heat process heaters "that use only natural gas, refinery gas, or other Gas 1 fuels for supplemental fuel." The preamble further clarifies that these units can include supplemental burners as long as those burners combust only Gas 1 fuels, up to 50% of their heat input, without voiding the exclusion. Coke oven gas, however, is neither a natural gas, refinery gas, nor Gas 1 fuel. Its use in these units, therefore, would void the exclusion.

ACCCI raised concerns about this issue in our comments on the original rule and we repeat those concerns here. It makes no sense to discourage the use of coke oven gas in a waste heat boiler or process heater just because the supplemental fuel contains a process gas other than natural gas, refinery gas, or a Gas 1 fuel. Coke oven gas is an efficient fuel that can replace natural gas as a supplemental fuel. The coke oven gas will be combusted elsewhere if not used in a boiler or waste heat boiler, so there is no environmental benefit to excluding it from use in a boiler. In fact, coke oven gas will most likely be combusted in a flare, which is less efficient than a boiler or waste heat boiler and will result in increased emissions to the environment based on this reduced efficiency.

In summary, we urge EPA to modify the definitions "waste heat boiler" and "waste heat processor" to include those units designed to use process gases as fuel. We also request clarification that coke oven gas can be used in a supplemental burner in a waste heat boiler or process heater without voiding the exclusions.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3449-A1, excerpt 35.

Commenter Name: Paul G. Page
Commenter Affiliation: AK Steel Corporation
Document Control Number: EPA-HQ-OAR-2002-0058-3457-A2
Comment Excerpt Number: 6

Comment: If the definition of "waste heat boiler" is not revised to properly include the use of process gases, then further revisions will be necessary to clarify the "supplemental fuel" provisions of the exemption.

For example, in order to meet the "other gas 1 fuel" criteria, the "fuel" must have a mercury concentration less than 40 $\mu\text{g}/\text{m}^3$. The fuel combusted in AK Steel's waste heat boilers is a mixture of coke oven gas combined with natural gas diluted with air. The natural gas is diluted with air to bring its heating value to a comparable level with the coke oven gas (around 500 BTu/cf). This mixed gas is then supplemented with natural gas, as needed based on pressure, depending on the waste heat boiler's output requirements and the coke oven gas availability. Accordingly, the ratio of the fuel components as combusted in the waste heat boilers is continually changing. Therefore, the "fuel" is constantly changing depending on the operational variables, including boiler output requirements and coke oven gas availability.

AK Steel has also identified significant variability on mercury concentration in coke oven gas. AK Steel collected three samples of the coke oven gas prior to mixing over a three-day period and the results were 126.674 $\mu\text{g}/\text{m}^3$, 40.827 $\mu\text{g}/\text{m}^3$, and 24.006 $\mu\text{g}/\text{m}^3$. Notwithstanding these results, AK Steel presumes that the mixed fuel as combusted is below the 40 $\mu\text{g}/\text{m}^3$ exemption criteria threshold. However, AK Steel is unable to sample the mixed fuel as combusted at this time to confirm that, thus further complicating the analysis.

Comment: Waste Heat Units Using Gas 1 Fuels Are Not Boilers or Process Heaters

EPA amended the proposed definition of "process heater" to exclude "waste heat process heaters that use only natural gas, refinery gas, or other gas 1 fuels for supplemental fuel." The VI supports the revised definition, which mirrors the definition for "boiler." EPA also clarified that waste heat boilers and process heaters may use Gas 1 fuels for supplemental fuel and still remain outside the requirements of Subpart DDDDD. However, VI does not support EPA's clarification that waste heat boilers with supplemental Gas 1 firing greater than 50% would become regulated boilers. As EPA states in the final rule preamble (Page 15617 of 3/21/10 final rule), all waste heat boilers should be exempted to encourage use of these energy saving devices and ensure valuable fuel gases are used for energy recovery rather than wasted.

The VI supports these exclusions because it would be inappropriate to apply emission standards for traditional boilers and process heaters to waste heat boilers and process heaters, which have a

substantially different configuration and therefore have substantially different emission profiles and require substantially different emission controls. Furthermore, waste heat boilers and process heaters provide a significant energy efficiency and pollution prevention opportunity over conventional units. Waste heat units burn less fuel than conventional units, resulting in lower overall emissions.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3449-A1, excerpt 35.

Commenter Name: Erika Frank

Commenter Affiliation: Calgon Carbon Corp.

Document Control Number: EPA-HQ-OAR-2002-0058-3680-A2

Comment Excerpt Number: 1

Comment: Generally, Calgon Carbon supports the waste heat exemption from the Major Source Boiler Rule because it encourages the use and re-use of heat and steam, which in turn reduces fossil fuel combustion and conserves valuable energy at industrial facilities. However, the scope of the waste heat boiler exemption remains unclear. When the Major Source Boiler Rule was finalized in March 2011, EPA removed any limitation on the amount of heat provided by supplemental burners in order to be considered a "waste heat boiler." EPA deleted the 50 percent criterion that appeared in a prior version of the rule, and also indicated in the comment response document that EPA was modifying the definition of waste heat boiler to include "all waste heat boilers instead of considering only those units with 50 percent or more of their waste heat." EPA further indicated in the comment response document that "[a]ll waste heat boilers have been exempted from [the March 2011 final rule], regardless of the heat input contribution from duct burners or other sources." In contrast, the preamble to the December 2011 proposed revisions seems to once again impose a 50 percent criterion. In the December 2011 preamble, EPA explained that waste heat boilers "can include supplemental burners as long as those burners combust only Gas 1 fuels, up to 50 percent of their heat input." This language appears to reintroduce the 50 percent criterion. This is especially confusing because EPA did not propose to revise the actual text of the regulatory provisions in this regard, and EPA did not otherwise indicate intent to reinsert the 50 percent criterion into the definition of either "boiler" or "waste heat boiler." Please reaffirm that all waste heat boilers and process heaters are exempt from the Major Source Boiler Rule, regardless of the heat input contribution from duct burners or other sources. We also request that EPA make the following changes to the December 2011 proposed definition of "waste heat boiler":

Waste heat boiler means a device that recovers any amount of normally unused energy and converts it to usable heat, regardless of the heat input contribution from supplemental burners and other sources. A waste heat boiler can include supplemental burners that use only natural gas, refinery gas, or other gas 1 fuels. Waste heat boilers are also referred to as heat recovery steam generators. This definition includes both fired and unfired waste heat boilers.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3449-A1, excerpt 35.

Document Control Number: EPA-HQ-OAR-2002-0058-3808-A1

Comment Excerpt Number: 1

Comment: Although EPA has attempted to clarify the applicability of the rule to duct burners installed in waste heat boilers, there is still a discrepancy between the information provided in Section K2 of the preamble (page 80616) and the information provided in the definition of “Boiler” on page 80650 that warrants further clarification. While the preamble language states that “ We also are clarifying that waste heat boilers and process heaters can include supplemental burners as long as those burners combust only Gas 1 fuels, up to 50 percent of their heat input”, the definition of boiler does not seem to mention the same heat input restriction: “Waste heat boilers that use only natural gas, refinery gas, or other gas 1 fuels for supplemental fuel are excluded from this definition.” Please confirm that “all fired waste heat boilers that use only natural gas, refinery gas, or other gas 1 fuels for supplemental fuel” are exempt from the major source boiler MACT rule regardless of the duct burner heat input rate.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3449-A1, excerpt 35.

Comment Excerpt Number: 136

Comment: EPA is proposing to amend the definition of boiler and process heater to clarify that waste heat boilers and process heaters are not covered by the Boiler MACT.

We appreciate the clarification that waste heat boilers are not covered, and support the exemption for waste heat boilers with supplemental burners. However, we request that EPA revise the definitions to exclude the limitation on the fuels that may be burned in supplemental burners on waste heat boilers to qualify for the exemption. In addition, although the preamble text cited above mentions a 50 percent heat input cutoff for supplemental burners, this criterion is not included in the boiler or process heater definitions, and we are unclear as to the necessity for or the basis of it.

Response: The EPA thanks the commenter for their support. See the response to comment EPA-HQ-OAR-2002-0058-3449-A1, excerpt 35.

Commenter Name: Barry Christensen

Commenter Affiliation: Occidental Chemical Corporation (OCC)

Document Control Number: EPA-HQ-OAR-2002-0058-3477-A1

Comment Excerpt Number: 7

Comment: OCC supports the exclusion of *all* gas-fired waste heat boilers (WHBs) from the final rule. The proposed revision limits the exclusion to units using only natural gas, refinery gas, or other gas 1 fuels. Use of WHBs provides a significant energy efficiency and pollution prevention opportunity over conventional units because they burn less fuel, which results in lower overall emissions. Therefore, these energy saving units should be encouraged by EPA’s regulations and not restricted, as explained on preamble page 15617 of the final rule.

For example, several OCC sites utilize onsite cogeneration steam turbine facilities which operate with waste heat boilers and a common stack. These WHBs are generally referred to as heat recovery steam generators, or HRSGs. Some of these HRSGs are capable of being supplementally-fired with natural gas and/or hydrogen gas (a gaseous co-product) and consequently are currently classified as Gas 2 sources. Generally it is not possible to separate the combustion turbine emissions (or those from any other primary source) from those associated with the HRSG due to their integrated design and single exhaust stack configuration. Therefore, a regulation that contains emission limitations for supplementally-fired waste heat boilers is not practical because it is not possible to operate the WHBs without the turbines or any other fired source to conduct compliance testing. In this case, these WHBs should be regulated under the National Emission Standards for Hazardous Air Pollutants for Stationary Combustion Turbines (40 CFR Part 63, Subpart YYYY), if at all, rather than the Boiler and Process Heater MACT standard. Another similar example includes units subject to the Hazardous Waste Combustion MACT where WHB's are often used. Therefore, emissions from all combustion units with supplementally-fired waste heat boilers are most appropriately regulated by the applicable standards for the primary combustion source and should be expressly excluded from this proposed rule for major source boilers.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3449-A1, excerpt 35.

Commenter Name: Richard Krock

Commenter Affiliation: The Vinyl Institute

Document Control Number: EPA-HQ-OAR-2002-0058-3526-A1

Comment Excerpt Number: 19

Comment: Measuring emissions from these units would also be impracticable because of their varying operation and their integration into other fired units. For example, some VI members utilize onsite cogeneration facilities with steam turbines with waste heat boilers. These waste heat boilers are generally referred to as heat recovery steam generators (HRSGs). Some of these HRSGs are capable of being supplementally-fired with natural gas and/or hydrogen gas (or other gaseous co-products). Generally, it is not possible to separate the combustion turbine emissions (or those from another primary source) from those associated with the HRSG. Thus, measuring emissions for supplementally-fired waste heat boilers is not practicable because it is not possible to operate the waste heat boilers without the turbines or other fired source to conduct compliance testing.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3449-A1, excerpt 35.

Commenter Name: Richard Krock

Commenter Affiliation: The Vinyl Institute

Document Control Number: EPA-HQ-OAR-2002-0058-3526-A1

Comment Excerpt Number: 20

Comment: These waste heat boilers may be regulated under other MACT standards, which would also exclude them from regulation under the Boiler MACT. Indeed, in an earlier version of the Boiler MACT that was later vacated by the U.S. Court of Appeals for the District of Columbia Circuit on other grounds, EPA was clear on this point: "emissions from a combustion

unit with a waste heat boiler are regulated by the applicable standards for the particular type of combustion unit.”³⁰ The VI agrees that emissions from combustion units with supplementally-fired waste heat boilers are most appropriately regulated by the applicable standards for the primary combustion source.

Commenter Affiliation: Calgon Carbon Corp.

Document Control Number: EPA-HQ-OAR-2002-0058-3680-A2

Comment Excerpt Number: 2

Comment: If EP A is indeed reintroducing the 50 percent criterion, then the relevant definitions (i.e., "boiler," "process heater," "waste heat boiler," and "waste heat process heater") should be revised so that the delineation of heat input to a unit utilizing waste heat is based on an annual average. Such a revision would promote both clarity and consistency, as several definitions in the March 2011 final rule are already based on the annual heat input to the unit, including, for example, "blast furnace gas fueled boiler or process heater," "unit designed to burn gas 2 (other) subcategory," and "unit designed to burn coal." If EPA intends to reintroduce the 50 percent criterion, we request that EPA make the following alternative changes to the December 2011 proposed definition of "waste heat boiler":

Waste heat boiler means a device that recovers normally unused energy and converts it to usable heat. A waste heat boiler can include supplemental burners that use only natural gas, refinery gas, or other gas 1 fuels. up to 50 percent of their heat input on an annual average. Waste heat boilers are also referred to as heat recovery steam generators. This definition includes both fired and unfired waste heat boilers.

Response: We disagree with the commenter's suggestion on how to revise the definition of waste heat boiler. See the response to comment EPA-HQ-OAR-2002-0058-3449-A1, excerpt 35 on how the definition is being revised.

Commenter Name: Barry Christensen

Commenter Affiliation: Occidental Chemical Corporation (OCC)

Document Control Number: EPA-HQ-OAR-2002-0058-3477-A1

Comment Excerpt Number: 9

Comment: The preamble page 80616 states, “We also are clarifying that waste heat boilers and process heaters can include supplemental burners as long as those burners combust only Gas 1 fuels, up to 50 percent of their heat input.” At the same time, the definition of rated heat input excludes “heat input provided by preheated combustion air, recirculated flue gases, or exhaust gases from other sources such as gas turbines, internal combustion engines, kilns, etc.” Therefore, we seek clarification regarding what is the exact method of calculation concerning the

50% limit mentioned in the preamble – i.e. as total rated heat input or just the fuel fired heat input. This preamble clarification, which is not in the proposed rule, may make most natural gas fired WHBs subject to the rule, which is contrary to the definition of boiler and process heater, which excludes them. As noted above, it is not possible to separate turbine emissions from HRSG emissions to do stack sampling, so even Gas 2 fired WHB units cannot be stack sampled.

Response: The reference to the 50% limit has been deleted. See the response to comment EPA-HQ-OAR-2002-0058-3449-A1, excerpt 35.

Commenter Name: Matthew Todd

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 18

Comment: Waste heat boilers that use only natural gas, refinery gas or other gas 1 fuels are excluded from the definitions of boiler and process heater. Since proposed §63.7491(i) excludes control devices, gases subject to other part 63 subparts or part 60, 61 or 65 subparts should also be allowed to be combusted in a waste heat boiler or process heater without making that waste heat system a boiler or process heater. Under the proposed definitions combustion of any such gas would negate the waste heat exception and sources would therefore be discouraged from recovering the energy from such regulated gases in waste heat boilers or process heaters.

Response: A waste heat boiler, or heat recovery steam generator, is an enclosed device without fuel combustion. The heat input to the unit is the hot exhaust gas from industrial and power equipment. The temperature of the incoming exhaust gas is sometimes increased by the use of a duct burner located upstream from the waste heat boiler. Also, the incoming hot gas may be the exhaust from a thermal oxidizer used to treat off-gases. We agree with the commenter and the definition of "boiler" and "process heater" have been revised in the final rule to excluded all waste heat units from those definition because a waste heat boiler does not meet the definition of a boiler since it is not an enclosed device using controlled flame combustion.

Commenter Name: Erika Frank

Commenter Affiliation: Calgon Carbon Corp.

Document Control Number: EPA-HQ-OAR-2002-0058-3680-A2

Comment Excerpt Number: 3

Comment: EPA should clarify that in the context of waste heat boilers, the term "supplemental burners" means burners that introduce fuel directly into the combustion unit where the heat recovery is also located. Burners that introduce fuel in an upstream combustion unit (e.g., incinerator, thermal oxidizer, or afterburner) are part of the upstream combustion unit that is not a "boiler" because it has no heat recovery. Subsequent recovery of the waste heat in a downstream unit does not render the upstream combustion unit a "boiler."

Response: The definition of "Waste heat boiler" has been revised in the final rule to clarify that a "waste heat boiler" is a boiler without its own firebox (i.e., internal burners) which uses the heat of hot exhaust gases from industrial or power (e.g., gas turbine) equipment to generate

additional steam. The temperature of the exhaust gas to the waste heat boiler is increased in some cases by the installation of burners (i.e., duct burners) in the duct upstream from the waste heat boiler.

Comment: Please clarify if liquid fuel burned for periodic testing not to exceed a combined total of 48 hours during any calendar year or during periods of gas curtailment or gas supply emergencies would also be included in this exemption of “all fired waste heat boilers that use only natural gas, refinery gas, or other gas 1 fuels for supplemental fuel.”

Response: The exemption has been revised to remove the criteria of the type of fuels used for supplement. See the response to comment EPA-HQ-OAR-2002-0058-3449-A1, excerpt 35.

Commenter Name: Monica Lopes
Commenter Affiliation: NAES Corporation
Document Control Number: EPA-HQ-OAR-2002-0058-3808-A1
Comment Excerpt Number: 3

Comment: The proposed area source Boiler MACT rule seem to exclude all fired and unfired waste heat boilers from the definition of boiler, regardless of the type of fuel fired in the duct burners. Please clarify EPA’s rationale for not making the same exclusion under the major source Boiler MACT rule since these duct burners are typically installed after gas turbines, do not operate independently of the gas turbines, and therefore, their emissions will be combined with the gas turbine emissions thus making it difficult for facilities to demonstrate compliance with the limits that apply only to the duct burners, regardless of the type of fuel fired in the duct burners.

Commenter Affiliation: The Alliance for Industrial Efficiency
Document Control Number: EPA-HQ-OAR-2002-0058-3683-A2
Comment Excerpt Number: 7

Comment: We Commend EPA for Exempting Waste Heat Process Heaters from the Standards.

In the December rule, EPA clarifies that waste heat process heaters are not subject to emissions limits.²² We are grateful for this exemption, as waste heat process heaters are essentially heat exchangers that capture heat from waste gas and convert it into heat or hot water to support an industrial process. EPA has encouraged this energy efficiency improvement by exempting such waste heat process heaters from the emissions standards of the Industrial Boiler MACT. We urge the Agency to retain this exemption in the final rule.

[Footnote 22: 76 Fed. Reg. at 80616 (“...waste heat process heaters, like waste heat boilers, are not subject to the standards. Petitioners are correct that the EPA intended to exempt waste heat process heaters from the rule, and the EPA is amending the definition of process heater to exclude waste heat process heaters. We also are clarifying that waste heat boilers and process heaters can include supplemental burners as long as those burners combust only Gas 1 fuels, up to 50 percent of their heat input.”).]

Response: The EPA thanks the commenter for their support.

100A. Waste Heat Boiler and Process Heater

Commenter Name: Paul G. Page
Commenter Affiliation: AK Steel Corporation
Document Control Number: EPA-HQ-OAR-2002-0058-3457-A2
Comment Excerpt Number: 5

Comment: AK Steel supports EPA's efforts to exempt waste heat boilers from the Boiler MACT requirements, but believes that the Agency needs to broaden the definition of "waste heat boiler" to include process gases that otherwise would be flared. AISI and ACCCI have provided comments for EPA to accomplish that, including proposed new definitions. AK Steel fully supports those comments and recommends that EPA give them serious consideration as they will resolve potential complex exemption applicability determinations and compliance uncertainty.

Response: We thanks the commenter for their support to exempt waste heat boilers. The exemption has been revised to exempt all waste heat boilers which are actually heat exchangers generating heat from hot exhaust gases generated by other combustion units.

Commenter Name: Paul G. Page
Commenter Affiliation: AK Steel Corporation
Document Control Number: EPA-HQ-OAR-2002-0058-3457-A2
Comment Excerpt Number: 8

Comment: If the coke oven gas cannot be combusted as a supplemental fuel in the waste heat boilers, then the alternative is for AK Steel to flare the coke oven gas and to combust natural gas in the waste heat boilers. This alternative is not beneficial to anyone, and only serves to increase emissions to the environment.

Response: The definition of a waste heat boiler is a heat exchanger generating steam from hot off-gases (i.e., waste heat) from a combustion unit located at the facility. A waste heat boiler does not have its own combustion system. The rule has been revised to exempt all waste heat boilers because they are not part of the source category.

Commenter Name: Peter Pagano

Commenter Affiliation: American Iron and Steel Institute (AISI)

Document Control Number: EPA-HQ-OAR-2002-0058-3490-A1

Comment Excerpt Number: 1

Comment: As explained in AISI's Initial Comments on the original proposed rule, iron and steel manufacturing is an energy-intensive industry that extensively utilizes process gases and waste heat to offset fossil fuel consumption. The iron and steel industry can handle its process gases—notably blast furnace gas, coke oven gas, and basic oxygen furnace off gas—in one of two ways: either flare them or otherwise utilize them as fuels to meet environmental and safety requirements.

Utilizing process gases in a boiler or process heater is the environmentally preferred option for three reasons. First, controlling process gases in a boiler or process heater allows the recovery of energy that otherwise would be wasted. By capturing process gases, routing them to boilers and process heaters that require heat, and moving the point of combustion to those units, previously unused energy and wasted heat are put to work. Second, this practice helps reduce overall emissions in steel manufacturing facilities. When process gases are used as fuel in boilers and process heaters, they offset the use of fossil fuels in those units, thereby eliminating greenhouse gases, criteria pollutants, and HAP emissions associated with those fuels. Finally, process gases are more efficiently combusted in a boiler than when flared. Flaring is exposed to wind and other elements that may interfere with complete combustion. Supplemental fuel at a flare typically is limited to the pilot light and is not available to help ensure a stable flame, which further interferes with efficient combustion. As reflected in EPA's emission factors, flares are less efficient than boilers at controlling organic compounds.⁴ For these reasons, encouraging the iron and steel industry to control process gases by combusting them in boilers or process heaters is environmentally preferred to flaring them, which is the only other option.

[Footnote]

(4) See EPA, AP-42 at 1.403, 12.5-4 (citing EPA's Flare Efficiency study, EPA-600/2-83-052).

Response: We agree that there is an environmental benefit to combusting regulated gases in a boiler instead of flaring them. Thus, we have revised the definition of "gaseous fuel" in the final rule to clarify that regulated off gases are not included in the definition. Therefore, if a boiler combusted a combination of regulated off gases and natural gas, the boiler would be considered to be in the Gas 1 subcategory.

Comment: The definitions of waste heat boiler and process heater should be amended so that units combusting process gases for control are exempt from the Boiler MACT.

The clearest way to effectuate these exemptions would be to revise the definitions of "waste heat boiler" and "waste heat process heater" to include process gases used in the iron and steel industry. To the extent that process gases either specifically already are exempt or otherwise regulated when combusted, utilizing them in a boiler or process heater should not result in increased regulation. We again propose that EPA amend the definitions of "waste heat boiler" and "waste heat process heater" to exempt process gas-fired units at iron and steel facilities from the Boiler MACT. This would be the most succinct amendment to effectuate the objective of efficient and environmentally preferable combustion of process gases in boilers and process heaters.

In the Proposed Rule, a "waste heat boiler" is defined as "a device that recovers normally unused energy and converts it to usable heat. Waste heat boilers are also referred to as heat recovery steam generators. This definition includes both fired and unfired waste heat boilers." The definition of "waste heat process heater" similarly "means an enclosed device that recovers normally unused energy and converts it to usable heat. Waste heat process heaters are also referred to as recuperative process heaters. This definition includes both fired and unfired waste heat process heaters." In the same way that EPA does not intend to regulate waste heat boilers or process heaters under the Boiler MACT, it also does not intend to regulate units controlling process gases in the iron and steel industry. By way of example, blast furnace gas-also a process gas recovered in the iron and steel industry-is exempt under the rule. We, therefore, propose that the definition of waste heat boiler and waste heat process heater be amended by adding the language in bold to the respective definitions:

Waste heat boiler means a device that recovers normally unused energy or process gas that otherwise would be flared and converts it to usable heat

Waste heat process heater means an enclosed device that recovers normally unused energy or process gas that would otherwise be flared and converts it to usable heat. ...

These changes, like previous alterations to these definitions, would reflect that EPA does not intend to regulate units combusting process gases.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3457-A2, excerpt 11 regarding the revision to the definition and exemption for waste heat boiler.

Comment: Whereas the MATS require that performance stack testing be conducted quarterly, this frequency is not warranted for smaller units regulated under this rule. Rather testing should be done as is currently required in Title V operating permits.

Response: Compliance testing to demonstrate compliance with the emission limits is generally required on an annual basis.

Commenter Name: Paul G. Page

Commenter Affiliation: AK Steel Corporation

Document Control Number: EPA-HQ-OAR-2002-0058-3457-A2

Comment Excerpt Number: 11

Comment: If EPA maintains the Boiler MACT provisions as they are currently proposed and if AK Steel decides to operate the waste heat boilers as they currently are, then the waste heat boilers would be subject to Gas 2 requirements. However, AK Steel doubts that compliance with the stipulated emission limits for Gas 2 sources would be achievable for these units. The standards presume emissions from only one source, but the waste heat boilers have emissions from the combustion of supplemental fuel from the boilers as well as fuel from the slab reheat furnaces, as the exhaust gases from both of these sources are discharged through the same exhaust stack. Since the two sources operate in tandem, EPA would need to establish a subcategory for waste heat boilers of this type to include the emissions from their source of waste heat if EPA is intent on regulating these sources as the rule is currently written. It would not be appropriate to conduct a stack test on the waste heat boiler without the slab reheat furnace operating because that would not be indicative of normal operations and, in that scenario, it would no longer be a waste heat boiler. Accordingly, AK Steel encourages EPA to give serious consideration to clarifying the exemption for waste heat boilers, preferably through the revision to the definition of "waste heat boiler" by including "process gas that otherwise would be flared" to provide optimal clarity.

Response: The exemption for waste heat boilers in the final rule has been revised to clarify that all waste heat boilers, whether with supplement firing or not, are exempt from the rule. Waste heat boilers are heat exchangers and do not meet the definition of "boiler" in the rule nor were considered part of the source category.

Comment Excerpt Number: 137

Comment: The definitions of "waste heat boiler" and "waste heat process heater" should expressly include the use of waste heat from process gases that would otherwise be flared. Flares waste heat and energy and recovering that wasted heat and energy in a boiler or process heater adds no new emissions to the atmosphere. Boilers and process heaters tend to be more efficient and, therefore, produce less of the HAP emissions attributable to incomplete combustion than

would be produced at a flare. Also, using process gases displaces fossil fuels that would otherwise contribute additional emissions to the atmosphere and deplete limited energy resources. Waste heat boilers are exempt because they offer energy efficient use of otherwise wasted heat and energy – which is precisely what happens when the point of process gas combustion is moved from a flare to a boiler or process heater.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3490-A1, excerpt 1.

Document Control Number: EPA-HQ-OAR-2002-0058-3547-A2

Comment Excerpt Number: 3

Comment: The current definitions of these terms evolved from considerations of what EPA intended not to regulate under the Boiler MACT. Initially, all units that combust solid waste were exempt. EPA then expanded the rule to cover boilers and process heaters that combust solid waste but are exempt, by statute, from section 129 incinerator rules because they are qualifying small power producers or cogeneration units that combust a homogenous waste stream. EPA intended the change to be in line with its goal to set emissions standards for all boilers and process heaters that are not solid waste incineration units subject to regulation under section 129. The proposed rule included a definition of waste heat boiler that excluded units with supplemental burners that are designed to supply 50 percent or more of the total rated heat input capacity. EPA subsequently removed the criteria that 50 percent of total rated heat input capacity had to be from waste gases to qualify as a “waste heat boiler” and revised the final definition to include all waste heat boilers.

Based on these considerations, a “waste heat boiler” is defined as “a device that recovers normally unused energy and converts it to usable heat. Waste heat boilers are also referred to as heat recovery steam generators. This definition includes both fired and unfired waste heat boilers.” “Waste heat process heater” is similarly defined and are also referred to as recuperative process heaters.

In the same way that EPA did not intend to regulate waste heat boilers or process heaters under the Boiler MACT, it also did not intend to regulate units controlling process gases in the steel and coke industry. We, therefore, propose that the definition of waste heat boiler and waste heat process heater be amended by adding the following language in bold to the respective definitions:

Waste heat boiler means a device that recovers normally unused energy or process gas that otherwise would be flared and converts it to usable heat. . . .

Waste heat process heater means an enclosed device that recovers normally unused energy or process gas that would otherwise be flared and converts it to usable heat. . . .

These changes, like previous alterations to these definitions, would reflect that EPA does not intend to regulate units combusting process gases.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3490-A1, excerpt 1.

2C. Exempted NESHAP Control Devices

Commenter Name: Paul G. Page

Commenter Affiliation: AK Steel Corporation

Document Control Number: EPA-HQ-OAR-2002-0058-3457-A2

Comment Excerpt Number: 9

Comment: EPA has indicated that it does not intend to regulate further boilers and process heaters that combust process gases, which are regulated under 40 C.F.R. Parts 60, 61, and 63. Since the combustion of coke oven gas is regulated by another NESHAP (40 C.F.R. 63.307, Subpart L), AK Steel believes that EPA's intention is to exempt the combustion of coke oven gas-fired boilers and process heaters under this exemption provision. AK Steel supports that approach. However, AK Steel contends that the qualification for the exemption which EPA has proposed should be revised.

The exemption qualification criteria in the proposed Reconsideration Rule specifies that at least 50 percent of the heat input to the boiler must be provided by a "regulated gas stream." In other words, the majority of the gas stream, or fuel as combusted, must be regulated by Parts 60, 61, or 63 to be exempt from the Boiler MACT. Although all coke oven gas sent to a boiler or process heater from a coke oven gas recovery plant is "regulated," other process gases (regulated or not) as well as natural gas may also comprise the boiler's gas stream and potentially "dilute" the ratio of "regulated" to "unregulated" gas sufficiently to negate this exemption or maintain it so close to the 50% threshold as to cause uncertainty.

AK Steel's facility with the four waste heat boilers, as described above, provides a direct example of the need to revise these exemption criteria. The total volume of coke oven gas is being diverted to 4 "control devices" (waste heat boilers) instead of one flare. The coke oven gas is blended with diluted natural gas prior to combustion, with additional natural gas used as needed for increased boiler demand. The ratio of coke oven gas to natural gas usage by volume per waste heat boiler oscillates around 50% for each fuel. This creates unacceptable regulatory uncertainty.

However, the critical point is that the total coke oven gas volume is combusted in a "control device" which is more efficient than the flare and, subsequently provides improved environmental benefit. It should not make any difference whether the total volume of regulated gas is combusted in four control devices or one. In addition, it should not make any difference whether the regulated gas is combusted in a fuel blend at a ratio less than or greater than 50% since all of the coke oven gas is being combusted. Accordingly, compliance with the intent of the exemption is being achieved since all of the regulated gas, coke oven gas in this case, is being combusted, which is the requirement of the Subpart L standard at 40 C.F.R. § 63.307.

The fact that a gas stream, as combusted, going to a boiler or process heater may contain less than 50% of a specific regulated gas should not be the deciding factor for these exemption criteria. The 50% threshold serves no useful purpose and may provide an unintended consequence of determining whether it is more cost-effective for AK Steel to flare coke oven gas and burn natural gas in our waste heat boilers.

Response: The exemption listed in 63.7491(i) is for a boiler, or process heater, that is used as a control device. Waste heat boilers are not by definition, in the final rule, a "boiler" because waste heat boilers are not enclosed devices using fuel combustion. Waste heat boilers, or heat recovery steam generators (HRSG), are heat exchangers generating steam from the incoming hot exhaust gas from industrial (e.g., thermal oxidizers, kilns, furnaces) or power (e.g., combustion turbine, engine) equipment. Duct burners, which are mounted in a duct or discharging into a duct, are sometimes used to increase the temperature of the hot exhaust gas from a combustion turbine to increase steam production in a HRSG to increase electricity output from a combined cycle gas turbine system.

Coke oven gas that is required to be controlled by another NESHAP or NSPS and is controlled by flaring or by a thermal oxidizer (e.g., afterburners) and then the hot off gas is routed to a waste heat boiler would not be subject to the rule. Coke oven gas that is required to be controlled and routed to a boiler or process heater for control is, in the final rule, an exempted gas. In the final rule, the definition of gaseous fuel has been revised to clarify that off gases regulated by another standard under parts 60, 61, 63, or 65 are exempt from this definition. However, a boiler combusting these regulated off gases is only exempted if the regulated off gases account for at least 50% of the heat input to the boiler. If less than 50%, the boiler is subject to the rule and is in the subcategory based on the fuel being combusted with the regulated off gases.

The 50% criteria for the exemption has been clarified in the final rule to be 50% of the average annual heat input during any 3 consecutive calendar years. To clarify, if 50 percent of the fuel is not regulated by another standard, the combustion unit is subject to the Boiler MACT.

Commenter Name: Paul G. Page

Commenter Affiliation: AK Steel Corporation

Document Control Number: EPA-HQ-OAR-2002-0058-3457-A2

Comment Excerpt Number: 10

Comment: AK Steel contends that the exemption qualification criteria should be that all of the regulated process gas be combusted in a "control device" at least as efficient as a flare, independent of its concentration as combusted. The fuel ratios established for our combustion units are done-so to enhance efficiency which in turn reduces emissions. Therefore, AK Steel respectfully suggests that EPA revise this exemption by adding language to it which would stipulate that boilers and process heaters (including waste heat boilers and process heaters unless they are exempted elsewhere) that combust a gas stream which includes coke oven gas that is regulated under Part 61, is therefore exempt from the Boiler MACT requirements.

Response: We disagree with the comment to exempt any boiler or process heater combusting any amount of coke oven gas from the rule. See the response to comment EPA-HQ-OAR-2002-0058-3457-A2, excerpt 9 regarding revisions being made to the final rule to clarify this exemption.

Commenter Name: Peter Pagano

Commenter Affiliation: American Iron and Steel Institute (AISI)

Document Control Number: EPA-HQ-OAR-2002-0058-3490-A1

Comment Excerpt Number: 6

Comment: AISI requests express clarification in the rule or preamble that a coke oven gas-fired boiler is a control device pursuant to one or more of these parts and that coke oven gas is a "gas stream that is regulated under Mother subpart" as that phrase is used in the above exemption. Indeed, coke oven gas is regulated in a number of different subparts. For example, coke oven emissions vented through a bypass/bleeder stack must be flared or vented to an alternative control device. See 40 C.F.R. 63.307, Subpart L. Subpart L also limits leaks from offtake systems and collecting mains, which collect coke oven gas from the ovens.

Coke oven gases are processed in a byproduct recovery plant, after which generally about 40 percent is used to underfire the coke ovens and the remainder is available for use as a fuel elsewhere in the plant. See Subpart L of Part 61 (40 C.F .R. 61.130-61.139) regulates benzene emissions from coke oven gas processing systems in a byproducts recovery plant. Under art 61, Subpart L, all process vessels, which must be enclosed and whose openings must be sealed, vent the coke oven gas to a collection and distribution system where the benzene in the gas must be recovered or destroyed.¹⁷

Some iron and steel facilities, however, recover benzene in their byproducts plant before they send coke oven gas to a boiler or flare. In these instances, Part 61 may not regulate the clean coke oven gas leaving the byproducts plant. Nonetheless, this clean coke oven gas is sent to a boiler or process heater for beneficial reuse; or, alternatively, sent to a flare for combustion before it is released to the atmosphere. Although Subpart L requires a properly operated flare or an alternate system (approved by the Administrator) that achieves 98% destruction of the coke oven gas vented to the system, it is not clear whether a boiler combusting this clean coke oven gas would be considered a "control device" used to comply with Subpart L since the combustion, in these instances, occurs on clean coke oven gas. Since all boilers achieve 98% combustion efficiency when properly maintained and operated, EPA may use the Reconsidered Rule to impose an annual tune-up obligation as the sole requirement and approve the boiler as an alternate system under 40 C.F.R. § 63.307, which would clearly subject the coke oven gas-fired boiler to the MACT standard in Part 61, Subpart L. Here is an instance where "dirty" coke oven gas is exempt because it is subject to Subpart L, but "clean" coke oven gas may not be exempt. To address this potential gray area, AISI asks that EPA add a sentence to the exemption to also expressly exclude clean coke oven gas-fired boilers and process heaters.

[Footnote]

(17) 40 C.F.R. § 61.132(a)(2).

Response: See the response to comment EPA-HQ-OAR-2002-0058-3457-A2, excerpt 9. The final rule has been revised to exempt off-gases that are regulated under another part 63 standard. Therefore, a boiler, or process heater, that combust regulated off-gases would be classified in a subcategory based on the fuel combusted in combination with the regulated off-gas. For example, if the regulated off-gas was combusted in combination with national gas, the unit would be in the Gas 1 subcategory, If the off-gas is combusted in combination with coal, the unit would be in one of the coal subcategories.

Commenter Name: Peter Pagano
Commenter Affiliation: American Iron and Steel Institute (AISI)
Document Control Number: EPA-HQ-OAR-2002-0058-3490-A1
Comment Excerpt Number: 7

Comment: AISI also seeks clarification regarding how this exemption is applied to mixed gas streams. Currently, the proposed exemptions in the Reconsidered Rule depend on whether at least 50 percent of the heat input to the boiler is provided by a "regulated gas stream." This means that the majority of a gas stream must be regulated by Parts 60, 61, or 63 to be exempt from the Boiler MACT. Even if all coke oven gas sent to a boiler or process heater from a coke byproduct plant is considered "regulated," other gases that are not regulated may be mixed into the fuel gas system that may "dilute" the ratio of "regulated" to "unregulated" gas sufficiently to negate the exemption. For instance, blast furnace gas often is mixed with coke oven gas at integrated iron and steel mills when process gases are combusted in a boiler. Blast furnace gas is excluded from the Boiler MACT definition of gaseous fuel because of its low HAP content. When blast furnace gas is unavailable, natural gas may be used to supplement the fuel source. Ironically, if more than 50 percent of the heat input for a control device was from blast furnace gas and/or natural gas, the coke oven gas-fired boiler could lose its exemption. This is an unnecessary limitation of the exemption.

AISI, therefore, requests that EPA amend the proposed exemption to allow for all process gases (otherwise regulated or not) to count towards the 50 percent applicability threshold. The fact that a gas stream going to a boiler or process heater may contain less than 50% of a specific regulated gas does not diminish the environmental benefit of encouraging the use of process gases. The 50% threshold serves no useful purpose and may provide an unintended consequence that harms rather than benefits the environment.¹⁸

[Footnote]

(18) The threshold percentages for qualifying for exemptions throughout the rule (*e.g.*, as an otherwise regulated unit under parts 60, 61, or 63; as a blast furnace gas fuel-fired unit; or as a gas 1 unit) raise multiple compliance issues. The Reconsidered Rule does not explain how an operator can demonstrate compliance with an exemption or the rule when its unit may be exempt at one point in time because it meets a percentage threshold, but later no longer qualifies under that exemption. This would cause units to be covered intermittently by the Boiler MACT. We urge EPA to clarify how it intends to deal with these compliance issues. We propose that EPA exclude both blast furnace gas and natural gas from the calculation if the boiler meets the gas I tune-up requirement. *See also supra*, at 8 (discussing "compliance conundrum").

Response: See the response to comment EPA-HQ-OAR-2002-0058-3457-A2, excerpt 9. We agree that the 50% criteria in the exemption needs clarification. We have revised the exemption criteria to allow all regulated and exempted process gases to count towards 50%.

Commenter Name: Dan F. Hunter
Commenter Affiliation: ConocoPhillips Company
Document Control Number: EPA-HQ-OAR-2002-0058-3689-A2
Comment Excerpt Number: 3

Comment: ConocoPhillips agrees with an exemption for BPH used as a control device to comply with another subpart. However, the 50% threshold is arbitrary and should be removed as a criterion within the exemption. This exemption should apply to any BPH used as a control device to comply with another subpart regardless of the percent heat input. There are at least two reasons for this:

1. In the BPH as a control device exemption, EPA does not specify an averaging time (e.g., 50% heat input on an annual basis) so the safe course for facilities that might be close to that 50% threshold will be to assume that any excursions below 50% heat input will disqualify one from the exemption. This, of course, causes the installation of more fuel burning equipment (e.g., thermal oxidizer).

2. Consider a BPH used as a control device in tank loading, subject to the Organic Liquid Distribution MACT. In this scenario, the BPH receives gases pushed out of the tank(s) and burns them in the course of electrical power generation. Initially, the gases recovered and routed to the BPH represent more than 50% of the total BPH heat input. But over time, the facility throughput will vary. Market forces and natural production declines will cause this variation. So there will be periods, possibly very extended, when throughput is insufficient to generate enough gas to be more than 50% of the heat input necessary for facility power generation. Similarly, after periods of extended decline, market upswings or whatever else might increase throughput could push the heat input back above 50%. So could a facility's exemption status vary from year to year? We do not believe this is intended nor do we believe this is a sound regulatory approach.

This is an issue with the exemption rooted in a real situation that heat input averaging periods will not solve. The periods of variability could last years. In addition, establishing another heat input threshold, say 20 or 80%, will also not solve the issue. The correct solution must be to eliminate the heat input threshold altogether thereby encouraging the continued use of the BPH as a control device. Otherwise, it is inescapable that additional fuel burning unit(s) will be installed.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3457-A2, excerpt 9. The 50% criterion has been clarified in the final rule. To clarify, the exemption can vary from year to year if the average annual heat input during any 3 consecutive calendar years from the regulated off-gas drops below 50%.

Commenter Name: Peter Pagano

Commenter Affiliation: American Iron and Steel Institute (AISI)

Document Control Number: EPA-HQ-OAR-2002-0058-3490-A1

Comment Excerpt Number: 5

Comment: The exemptions for boilers and process heaters used as devices to comply with standards issued under 40 C.F.R. Parts 60, 61, or 63 should be expanded to include all process gases.

EPA has indicated that it does not intend to regulate further boilers and process heaters that are fed by process gases otherwise regulated under 40 C.F.R. Parts 60, 61, and 63. AISI supports EPA's approach but believes that further clarification and expansion of the proposed exemption is needed to avoid creating conflicts with existing regulatory obligations and imposing

disincentives to the efficient combustion of all process gases. The expanded exemptions are necessary to encourage iron and steel manufacturers to send process gases to boilers instead of to less efficient flares. Sources would be dissuaded from combusting process gases in boilers if those sources had to comply with the Boiler MACT.¹⁵

The Reconsidered Rule appropriately would exempt from the Boiler MACT, "Any boiler or process heater that is used as a control device to comply with another subpart of this part [(part 63)], or part 60, or part 61 of this chapter provided that at least 50 percent of the heat input to the boiler or process heater is provided by the gas stream that is regulated under another subpart." Part 60 sets new source performance standards ("NSPS") for new or modified stationary sources, including new boilers, and controls organic pollutants, and Parts 61 and 63 set national emission standards for hazardous air pollutants ("NESHAP"). AISI supports EPA's proposal to exclude from the Boiler MACT those boilers and process heaters that serve as control devices under one of these parts. The exclusion specifically would address AISI's concern that process gases that must be flared are not subject to additional costs of control when they are combusted in a boiler or process heater. The proposed language in the exemption, however, must be expanded to address the process gases generated by the iron and steel industry.

Document Control Number: EPA-HQ-OAR-2002-0058-3547-A2

Comment Excerpt Number: 1

Comment: Boilers and Process Heaters Using Coke Oven Gas Should Be Exempt from the Boiler MACT

EPA has indicated that it does not intend to regulate further boilers and process heaters that are fed by process gases otherwise regulated under 40 CFR Parts 60, 61, and 63.⁴ ACCCI supports EPA's approach but believes that further clarification and expansion of the proposed exemption is needed to avoid conflicts with existing regulatory obligations and imposing disincentives to the efficient combustion of all process gases. The proposed exemptions are necessary to encourage coke manufacturers to send coke oven gas to boilers instead of to less efficient flares. Sources would be dissuaded from combusting process gases in boilers if those sources had to comply with the Boiler MACT.

The Reconsidered Rule appropriately would exempt from the rule boilers and process heaters used as controls to comply with Parts 60, 61, and 63. Pollutants controlled under any of these parts are more efficiently controlled in a boiler than a flare. For example, coke oven gas combustion currently is regulated by another NESHAP (40 CFR 63.307, Subpart L). Coke oven gases are processed in a byproduct recovery plant, after which about 40 percent is used to underfire the coke ovens and the remainder is available for use as a fuel elsewhere in the plant. Subpart L of Part 61 (40 C.F.R. 61.130- 61.139) regulates benzene emissions from coke

byproduct recovery plants. Under Subpart L, process coke oven gas may be sent to an enclosed combustion device (e.g., boiler) in a closed-vent system or sent to flare, if proper controls are achieved. The overall control system in the byproduct plant must be designed and operated for no detectable emissions, as indicated by a benzene instrument reading of less than 500 ppm above background and visual inspections.⁵ Any fugitive gases from the system must be captured and sent to a control device.⁶ If a boiler is used as a control device for Subpart L purposes, it must be designed and operated to reduce volatile HAP emissions vented to it with an efficiency of 95 percent or greater or to specified levels.

Commenter Name: Bruce A. Steiner

Commenter Affiliation: American Coke and Coal Chemical Institute (ACCCI)

Document Control Number: EPA-HQ-OAR-2002-0058-3547-A2

Comment Excerpt Number: 2

Comment: Utilization of process gases in boilers is a superior control option to flaring under existing regulations. As explained above, elements causing unstable flames reduce a flare's efficiency relative to a boiler. As reflected in EPA's emission factors, flares are less efficient than boilers for controlling organic compounds. Boilers therefore are a means of reducing organic pollutant emissions to a much greater degree than what a flare would emit. EPA recognizes that the Boiler MACT unnecessarily would overlap with these regulations, and potentially dissuade facilities from sending process gases and waste heat to boilers and instead encourage flaring. Flaring also results in the loss of valuable energy. By capturing process gases and moving their point of combustion to a boiler, previously unused energy is converted to usable heat. At coke plants operated by integrated iron and steel producers and at stand-alone coke plants, approximately 60 percent of off gases from coke ovens are recovered and combusted for their waste heat in a boiler or process heater. Process gases thus are used as an alternative fuel, reducing the need to burn fossil fuels and further curtailing overall emissions. EPA, therefore, correctly encourages the continued use of combustion controls by exempting boilers and process heaters that comply with Parts 60, 61 or 63.⁷

ACCCI strongly supports these exemptions, but believes that certain clarifications are needed and that the exemptions should be expanded to cover boilers and process heaters fired by coke oven process gases, which are regulated under Parts 60, 61 and/or 63. Currently, the proposed exemptions in the Reconsidered Rule depend on whether at least 50 percent of the heat input to the boiler is provided by a "regulated gas stream." This means that the majority of a gas stream must be regulated by Parts 60, 61, or 63 to be exempt from the Boiler MACT. Although all coke oven gas sent to a boiler or process heater from a coke byproduct plant is "regulated," other process gases (regulated or not) may also comprise the boiler's gas stream and potentially "dilute" the ratio of "regulated" to "unregulated" gas sufficiently to negate the exemption. If

sending coke oven gas to a boiler would subject the source to the Boiler MACT, the industry's practical response instead would be to flare the gas. ACCCI, therefore, requests that EPA amend the proposed exemption to allow for all process gases (otherwise regulated or not) to count towards the 50 percent applicability threshold. The fact that a gas stream going to a boiler or process heater may contain less than 50% of a specific regulated gas does not diminish the environmental benefit of encouraging the use of process gases. The 50% threshold serves no useful purpose and may provide an unintended consequence that harms rather than benefits the environment.

Response: We agree that utilization of process gases in boilers is a superior control option to flaring. See the response to comment EPA-HQ-OAR-2002-0058-3457-A2, excerpt 9.

Commenter Name: Matthew Todd

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 16

Comment: We support EPA's proposal to exempt BPH used as control devices for VOC, provided that at least 50% of the heat duty for the unit is derived from regulated streams, but request revisions to §63.7491(i) and the definitions of boiler and process heater to clarify this exemption.

1. As EPA concludes, recovery of energy from gas streams combusted for compliance with regulations reduces overall emissions versus having to provide those energy needs from fuel combustion and thus should be encouraged. This obvious and significant pollution prevention position is independent of whether the combustion is of HAP, VOC or, as is typical, both. Thus, EPA is correct in including streams regulated under part 60, as well as parts 61 and 63 in the exemption. However, some combustion control requirements are set in part 65 subparts B through G (the SOCOMI Consolidated Air Rule) and EPA is currently working to transfer many other combustion control requirements from parts 60, 61 and 63 to part 65 through the Uniform Standards effort (part 65 subparts H through M). Although applicability of the control requirements will still be maintained in parts 60, 61 and 63, we recommend including part 65 in the exemption language to avoid future confusion over whether the exemption applies or not when the combustion control is specified in part 65, rather than parts 60, 61, or 63.

2. Proposed §63.7491(i) defines which BPH are being exempted as follows.

(i) Any boiler or process heater that is used as a control device to comply with another subpart of this part, or part 60 or part 61 of this chapter provided that at least 50 percent of the heat input to the boiler or process heater is provided by the gas stream that is regulated under another subpart.

Proposed §63.7491(i) needs to be clarified to be clear how the 50% heat input requirement is applied. We see three issues with this wording that need clarification. First, it needs to be clear that the heat input from all regulated streams is summed for the 50% test. Second, it should be made clear that the heat duty for a regulated stream is based on its total heat content, not just the heat content of the regulated species (i.e., for a part 63 regulated streams it is not just the HAP heat duty that counts, for a part 60 stream it is not just the VOC heat duty that counts). Finally, it

should be clarified that the 50% test is on an calendar annual average basis, since there will be times (e.g., normal stream variability or when a unit producing a regulated stream is out-of-service for maintenance) when the 50% criteria is not met on an instantaneous or even daily basis.

3. To address these concerns (1 and 2 above) we suggest the following revisions to the proposed §63.7491(i) language.

(i) Any boiler or process heater that is used as a control device to comply with another subpart of this part, or part 60 or part 61 or part 65 of this chapter provided that at least 50 percent of the heat input to the boiler or process heater, as a calendar annual average, is provided by the gas streams that areis regulated under another subparts. For gas streams regulated under other subparts, the entire heat input of the streams are summed when determining their heat input contribution, not just the heat input from the regulated species in the streams.

Response: The EPA thanks the commenter for their support. We agree that clarification of the exemption is needed and have revised the exemption in the final rule similar to that suggested by the commenter to include part 65.

Commenter Name: Mark Anthony

Document Control Number: EPA-HQ-OAR-2002-0058-3684-A2

Comment Excerpt Number: 4

Comment: Alyeska supports determining the heat input on an annual average basis that is a further described as a rolling 12-consecutive month period. First, this approach is consistent with how annual averages are used in most EPA and state programs. For example, the Terminal's existing permit requirements to meet state SIP permit limits are based on this approach. Second, this approach seems logical because it provides for seasonal variability or other short term circumstances when regulated gas streams may be limited or the heat content of the gas changes. However, on an annual average the gas streams do contribute more than 50% of the heat input to the boilers. Since Alyeska believes it is EPA's intent to promote the usage of on-site gas over other off-site fuels, such as liquid or solid fuels, which result in additional emissions, an annual basis would be beneficial and would not penalize a facility during the short periods the 50 . percent criteria couldn't be met.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3457-A2, excerpt 9 for clarifications on 50% heat input.

Commenter Name: Mark Anthony

Commenter Affiliation: Alyeska Pipeline Service Company

Document Control Number: EPA-HQ-OAR-2002-0058-3684-A2

Comment Excerpt Number: 3

Comment: We are uncertain about how the exemption may practicably terminate for a boiler that is utilizing this exemption. If a boiler has been operating under the exemption at § 63.7491 (i) by burning over 50 percent gaseous fuel on a heat input basis from regulated gas streams and

the regulated gas stream drops below 50% on an annual average (see comment below) how soon would the boiler have to meet the emission standards of the rule? Depending upon circumstances, a drop in the regulated gas stream heat input usage may not be foreseeable or avoidable. Gas streams that arise from processes may appear to be forecastable, but unforeseeable economic conditions or other events may change the supply of the underlying commodity that generates the gas stream. This in turn may result in a rapid unforeseeable diminishment in the gas stream volume and corresponding heat input to the boiler. If a facility has to retrofit boilers with emission controls sufficient time must be allowed to reasonably allow for the changes to be made. Therefore, Alyeska proposes that EPA clarify this obligation and provide a reasonable time for installation of controls to the boilers. Based upon our review of the timeframe to make such a change at least three years will be needed after a boiler no longer qualifies for the exemption criteria to put in place the controls, monitoring and other requirements necessary to meet the rule's compliance obligations.⁴

[Footnote]

(4) We supported 5 years for the initial compliance period for Boiler MACT, but recognize that later in the life of a boiler that a 3 year timeframe may be achievable if transitioning from the control device exemption to full Boiler MACT compliance, including the addition of controls. There will be considerable national experience developed by contractors to install controls and companies that utilize the exemption will have some anticipation and understanding of what Boiler MACT compliance looks like at these later dates.

Response: The commenter raises an interesting concern regarding the exemptions in 63.7491. 63.7495 (When do I have to comply with this subpart?) does not address the situation when an exempted boiler or process heater changes the manner of operation such that the unit is no longer exempt. 63.7495(c)(2) states that "Any existing boiler or process heater at the existing source must be in compliance with this subpart within 3 years after the source becomes a major source." We have revised 63.7495 to add a similar compliance time for units that change such that they are no longer exempted under 63.7491(i).

Commenter Name: Lorraine Gershman

Commenter Affiliation: American Chemistry Council (ACC)

Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1

Comment Excerpt Number: 119

Comment: ACC supports the proposed exemption from applicability to this rule in § 63.7491(h) for those boilers and process heaters that are specifically listed as an affected source in another standard under 40 CFR Part 60, 61, or 63. There are several existing NESHAPs that include boilers and process heaters within the scope of the affected source through different language. Some of the NESHAPs that include boilers and process heaters within the definition of "affected source" when used as a control device are Subparts JJJ, OOO, PPP, U. ACC requests that EPA provide specific identification of all applicable NESHAPs wherein boilers and process heaters used as control devices under those subparts are considered part of that affected source and thereby not subject to Subpart DDDDD. Having EPA provide this specificity will avoid confusion and minimize permitting time and effort associated with applicability determinations.

Response: We agree that providing specific identification of all applicable NESHAPs wherein boilers and process heaters used as control devices under those subparts are considered part of that affected source and thereby not subject to Subpart DDDDD will avoid confusion and minimize permitting time and effort associated with applicability determinations. We also agree that boilers and process heaters that are used as a method of compliance, used as a control device, in Subparts JJJ, OOO, PPP, U. are within the definition of affected source for those subparts. The exemption in 63.7491(h) has been revised in the final rule to specifically list these subparts.

Commenter Name: Lorraine Gershman

Commenter Affiliation: American Chemistry Council (ACC)

Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1

Comment Excerpt Number: 120

Comment: Similarly, gases that are combusted in a boiler or process heater used as a control device for any NESHAP should be specifically excluded from the definition of other gases (Gas 2). Combustion devices should not be subject to multiple NESHAP, and use as a control device should be considered the primary purpose for combustion of Gas 2 streams in this case.

EPA could specifically revise proposed § 63.7491(h) to include the combustion units, combustion unit exhaust streams, and process vent gas streams covered under another MACT as follows: *§63.7491(h) Any boiler, process heater, combustion unit, combustion unit exhaust stream, or process vent gas stream that is specifically listed as an affected source in another standard(s) under 40 CFR part 63.*

These process gas streams should also be exempt from the fuel sampling requirements, particularly gases that do not contain metals.

Response: We agree that exhaust streams should not be subject to multiple NESHAPs. The definition of "Gaseous fuels" in the final rule has been revised to indicate that off-gases regulated by another standard are excluded from the definition. Therefore, these regulated off-gases would be exempt from the fuel sampling requirement. Boilers and process heaters burning these regulated off-gases would be subject to the rule based on the type of fuel being combusted in combination with the regulated off-gases, unless the regulated off-gases account for more than 50% of the heat input to the boiler or process heater.

Commenter Name: Matthew Todd

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 17

Comment: Additionally, we request EPA discuss in the preamble or at least the response to comments the meaning of the term "provided by gas streams that are regulated under another subpart." Our understanding is that this term means that where the control of a gas stream is required under another subpart (e.g., Marine Vessel Loading NESHAP, RMACT 1, NSPS Kb or

GGGa, part 61 subpart FF), and that stream is routed to a boiler or process heater for the purpose of achieving the required control, then it is a regulated stream as that term is used here.

Response: We agree that clarification is needed. A definition of "Regulated gas stream" has been added to the final rule.

Commenter Name: Mark Anthony

Commenter Affiliation: Alyeska Pipeline Service Company

Document Control Number: EPA-HQ-OAR-2002-0058-3684-A2

Comment Excerpt Number: 2

Comment: Along with API and its members Alyeska thanks EPA for modifying the exemption to cover regulated gas streams under Parts 60 and 61. We also support API's additional requests for changes to help clarify the exemption.

Like all facilities that have regulated gas streams that are combusted as fuel in boilers subject to this standard it is very important that we clearly understand the application of this exemption. API's comments and requests for clarifying changes will do that. In addition, Alyeska asks EPA to provide some discussion in the preamble to the final rule or in the response to comments to provide further certainty about this exemption. Our concern is that the current record on this exemption is sparse as to how it might actually apply at specific facilities. Currently the only example, and it is a complex one, is the Norbord Industries comment and EPA's **Response:**

Norbord stated: "Many facilities exhaust process gases from other sources through the combustion chamber of a boiler or process heater. Does the standard apply to all or a portion of the exhaust? At one Norbord facility a portion of the process gases passing through the combustion unit is PCWP MACT regulated, and another portion of the gases passing through is from a kiln. Additionally, greater than 50% of the heat input to the boiler/process heater is from the kiln and dryers. At the very least wouldn't the boiler/process heater be considered a waste heat boiler?"

EPA responded as follows:

"EPA has modified the exemption to remove the phrase 'specifically listed' and replaced with 'part of the affected source' in order to address the concerns of the commenter. Further we added another exemption to allow for situations where the boiler serves as the control device for another MACT-regulated process where at least 50% of the heat input comes from the regulated process."

We realize there are statements by EPA in the preamble to the proposed rule reinforcing the benefit of the exemption. 76 FR 80615~ 80616. However, what is less certain is how the exemption will effectively apply. For example, at the Valdez Marine Terminal vapors are collected and controlled as described above under 40 CFR 63 Subparts Y and EEEE. Our understanding is that these collected vapors are a regulated gas stream for purposes of the exemption. Further, the collected vapors are used as fuel in the boilers, and meet the definition of a "gaseous fuel" under § 63.7575. The exemption also requires that the boiler perform as a control device to comply with another subpart. Subpart Y's emissions standard requires that a vapor collection system connect to an air pollution control device. Air pollution control device

for purposes of Subpart Y expressly includes boilers. Boilers are used at the VMT as control devices. Under Subpart Y, large boilers above a certain size are not required to satisfy emissions testing, monitoring and performance criteria that the thermal oxidizers must meet. EPA made that decision in the Subpart Y rulemaking because of the inherent combustion efficiency of boilers and the pollution prevention benefits of burning vapors for fuel in lieu of diesel or other fuels in the boilers. That is well documented in the rulemaking history. As you know EPA established this practice with the HON and it has properly been added to many MACT standards. It is our understanding that the VMT boilers when used in this manner are used as a control device to comply with another subpart and therefore satisfy this requirement of the control device exemption.

We believe the same is true for OLD MACT (Subpart EEEE) at the VMT. Subpart EEEE, requires regulated vapors to be collected and routed to either to 1) a dedicated air pollution control device, or 2) a fuel gas system followed by a combustion device. At the VMT, the dedicated control devices are thermal oxidizers; the combustion devices receiving regulated vapors via the fuel gas system are boilers (serving as control devices).

We would appreciate some discussion by EPA to confirm our understanding of the scope of this exemption to circumstances like ours where boilers receiving regulated gases via a vapor collection system and/or fuel gas system serve as control devices.

Response: We agree that clarification is needed. See the response to comment EPA-HQ-2002-0058-3510-A1, excerpt 120.

Commenter Name: Robert D. Bessette

Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 59

Comment: EPA recognizes that Boiler MACT affected sources are utilized to combust process off-gases required by other subparts of 40 CFR Part 63 and has included language in §63.7510(a)(2)(ii) and in §63.7521(f)(2) to exempt these process off-gases from the periodic fuel analysis requirements and Gas 1 fuel specification requirements.

CIBO agrees with EPA's determination on these process gases. CIBO also agrees with EPA's determination that fuel analysis for chloride is not required for gases and that operators are not required to conduct the mercury fuel specification analyses for gaseous fuels that are natural gas, refinery gas, or otherwise subject to another subpart of part 63.

However EPA should extend the exemptions for not conducting fuel specification analysis and periodic fuel analysis to process gases that are regulated under Parts 60 and 61. Specifically, §63.7510(a)(2)(ii) and §63.7521(f)(2) should be amended with the addition of the bold language to read as follows:

§63.7510(a)(2)(ii) When natural gas, refinery gas, other gas 1 fuels are co-fired with other fuels, you are not required to conduct a fuel analysis of those fuels according to § 63.7521 and Table 6 to this subpart. If gaseous fuels other than natural gas, refinery gas, or other gas 1 fuels are cofired with other fuels and those gaseous fuels are subject to another subpart of this part, **to**

part 60, or to part 61 you are not required to conduct a fuel analysis of those fuels according to § 63.7521 and Table 6 to this subpart.

§63.7521(f)(2) You are not required to conduct the fuel specification analyses in paragraphs (g) through (i) of this section for gaseous fuels that are subject to another subpart of this part, **to part 60, or to part 61.**"

EPA has already extended the exemption to boilers and process heaters serving as control devices for controlling gaseous streams subject to Part 60 or Part 61 as noted in §63.7491(i).

Response: We agree and 63.7521(f)(2) in the final rule has been revised.

Commenter Name: Matthew Todd

Comment Excerpt Number: 160

Comment: Proposed §63.7545(f) imposes a reporting requirement associated with units that are designed to burn "gaseous fuel subject to another subpart of this part." As we have commented elsewhere, gaseous fuels subject to parts 60, 61 and 65 subparts should also be exempted from rule requirements along with gaseous fuels subject to part 63 subparts, thus we believe this phrase in §63.7545(f) should be revised to "gaseous fuel subject to another subpart of this part or a subpart of part 60, 61 or 65."

Response: We agree and 63.7545(f) has been revised in the final rule to be consistent with other revisions being made to address the issue of regulated off-gases.

Commenter Name: Timothy Serie

Commenter Affiliation: American Coatings Association (ACA)

Document Control Number: EPA-HQ-OAR-2002-0058-3502-A1

Comment Excerpt Number: 11

Comment: ACA generally supports the following proposed changes in the Boiler MACT rule:

Exemption for any boiler or process heater that is used as a control device to comply with standards issued under part 60, part 61, or part 63 of the CAA (provided that at least 50% of the heat input to the boiler is provided by a gas stream that is subject to the standards under those parts)

Response: The EPA thanks the commenter for their support.

Commenter Name: Shannon S. Broome

Commenter Affiliation: Auto Industry Forum (AIF)

Document Control Number: EPA-HQ-OAR-2002-0058-3512-A1

Comment Excerpt Number: 52

Comment: EPA Should Finalize the Proposed Extension of the Exemption to Parts 60 and 61.

EPA proposes exempt from the Boiler MACT those units that facilities use as control devices to comply with the standards of part 60, part 61 or part 63 of the CAA, provided that "at least 50 percent of the heat input to the boiler is provided by the gas stream that is regulated under another subpart." *Boiler MACT Reconsideration Proposal*, 76 Fed. Reg. at 80,615-16. In the final rule, EPA had merely promulgated this exemption in the part 63 context, however, it now proposes to extend the exemption to parts 60 and 61 because of their respective relevance to the NESHAP program. *See id.* EPA, therefore, proposes to revise accordingly the provision at § 63.7491(i) that enumerates the boilers and process heaters not subject to the Boiler MACT. *See id.* at 80,628.

AIF supports extending the exemption to cover units required by parts 60 and 61 in addition to part 63 of the CAA and to units used as integral to control devices. Consider, for example, boilers used as part of VOC control devices for the purpose of desorbing the VOC that is adsorbed onto a carbon bed or wheel, such that the VOC can be concentrated and routed to a thermal oxidizer. Without the use of the boiler, this VOC control system would be extremely inefficient and require much larger thermal oxidizers and waste more NG in the destruction of VOC. Therefore, EPA should finalize its proposed amendment to the exemption for units serving as control devices.

Response: The EPA thanks the commenter for their support.

Comment Excerpt Number: 23

Comment: Proposing to exempt any boiler or process heater used as control device to comply with standards issued under part 60, 61, or 63 of the CAA, provided that at least 50% of heat input to boiler is provided by gas stream subject to standards under those parts.

NC DAQ concurs with EPA's proposed approach on this issue.

Response: The EPA thanks the commenter for their support.

2D. Exempted Residential boilers

Commenter Name: Pamela Lacey

Commenter Affiliation: American Gas Association (AGA)

Document Control Number: EPA-HQ-OAR-2002-0058-3672-A2

Comment Excerpt Number: 4

Comment: AGA appreciates EPA's proposal to exempt "residential boilers" meaning boilers" used in a dwelling containing four or fewer family units, to provide heat and/or hot water" from the major source rule. This would cover natural gas-fired furnaces and water heaters in dwellings

located at a university campus, military base or other institutional facility. However, we had thought the 2011 final rule would also exclude these residential-style appliances *wherever they are located* at a major source, including for example at a small office building or trailer at a utility service center or a small lab where the appliances are used to provide heat or hot water – and not just when located in a dwelling. While performing tune-ups once every five years will make this more workable, our members are concerned that keeping track of reporting for hundreds of small units that heat 100 gallons of water or less could be very burdensome. We question the utility of this paperwork burden and urge EPA to exempt these very small units regardless of where they are located.

Response: The rule does contain an exemption for "residential type" hot water heaters that are located at industrial, commercial, and institutional facilities, because such heaters are not part of the listed source category. Hot water heaters are defined in the rule as gas or liquid units with a capacity of less than 120 gallons of water. Therefore, the hundreds of small units that heat 100 gallons of water or less mentioned by the commenter would be exempt.

Commenter Name: Arthur N. Marin

Commenter Affiliation: Northeast States for Coordinated Air Use Management (NESCAUM)

Document Control Number: EPA-HQ-OAR-2002-0058-3506-A1

Comment Excerpt Number: 8

Comment: Inclusion of Boilers at Industrial, Commercial, and Institutional in the Residential Exemption under the Area Source Rule [Note: Same exemption proposed in Major Source Rule.]

The EPA is proposing to include large boilers at dwellings at industrial, commercial, and institutional facilities in the list of exemptions in the area source rule. Specifically, the EPA proposes to define a residential boiler according to the following definition.

Residential boiler means a boiler used in a dwelling containing four or fewer family units to provide heat and/or hot water. This definition includes boilers used primarily to provide heat and/or hot water for a dwelling containing four or fewer families located at an institutional facility (e.g., university campus, military base, church grounds) or commercial/industrial facility (e.g., farm) (76 FR 80548).

NESCAUM believes that almost all residential units will be exempted under the proposed reconsidered boiler definition, which specifies that units with heat inputs of 1.6 MMBtu/h and larger are subject to the rule (these units are much larger than a typical residential boiler). Hot water heaters below that threshold will be exempt. Therefore, by creating a duplicative exemption for residential units does not achieve additional environmental benefits, but does exempt some industrial, commercial, and institutional sources that should be subject to control. This change in definition would allow some significant sources to circumvent the rules. NESCAUM believes that sources should be regulated based on the size and emission potential of the unit, not the type of facility in which it resides.

Response: We disagree that the exemption for residential boilers is a duplicative exemption to the exemption for hot water heaters. The source categories covered by the boiler area source rule are industrial boilers located at area source facilities and institutional and commercial boilers located at area source facilities. Residential boilers are thus not covered by the rule, as they are

not part of the listed source category. We added the exemption for residential boilers to clarify that fact since applicability questions were raised by regulatory agencies and regulated facilities regarding boilers located at residences at institutional (military bases, universities) and commercial (farms) facilities. The exemption for hot water heaters pertains to heaters or boilers generating hot water. The exemption does not cover boilers generating steam for heating. Therefore, both exemptions are appropriate.

Commenter Name: Matthew Todd

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 22

Comment: Since a residential boiler is defined as a boiler providing only comfort heat and/or hot water for up to four residential units, we believe a boiler providing comfort heat and/or hot water for an office, workroom, control room, or similar space of similar size⁶ should also be exempted. Such small boilers, whether firing gas or liquid, have miniscule emissions and there is no environmental or health basis for imposing any requirements on such small emission sources. [Footnote 6: 6000 square feet is our estimate of the square footage of a typical four unit residence, but EPA may have data to allow specifying a heat duty, which would be a preferential way of defining the exclusion (i.e., Residential boiler means a boiler providing only comfort heat and/or hot water firing up to __ MMBTU/hr.)]

Response: See the responses to EPA-HQ-OAR-2002-0058-3506-A1, excerpt 8 and EPA-HQ-OAR-2002-0058-3672-A2, excerpt 4 for discussion.

Commenter Name: Arthur N. Marin

Commenter Affiliation: Northeast States for Coordinated Air Use Management (NESCAUM)

Document Control Number: EPA-HQ-OAR-2002-0058-3506-A1

Comment Excerpt Number: 9

Comment: In our region, there are many historically single unit residences that have been subdivided into several condominiums or apartments. The specification of a number of units as the threshold for exemption from the rule creates a situation where similar residences with similar boilers will be treated differently. In the extreme case, if an unusually large and heavily emitting unit were to reside in a 1-3 unit dwelling at an institution (e.g., a university), it would be appropriate to regulate that unit under this rule. That scenario is extremely unlikely given the proposed boiler definition in the reconsidered rule. The number of units a building is subdivided into does not have a bearing on the size or emissions of the boiler.

Therefore, the exemption for dwellings at industrial, commercial, and institutional boilers should be deleted from the final rule. NESCAUM suggests that the EPA abandon this approach for exempting residential units, and instead rely solely on the exemption for units below a unit-size threshold to exempt residential units.

Response: We disagree that the exemption should be deleted - See the response to comment EPA-HQ-OAR-2002-0058-3506-A1, excerpt 8. The boilers and process heaters source category

includes commercial facilities like apartment buildings and condominiums, but not single family residences. However, we do recognize that a single family residence could be subdivided into more than 4 living units. The definition of "residential boiler" in the final rule have been revised to include historically single unit residences that have been subdivided into several condominiums or apartments.

Commenter Name: Matthew Todd

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 21

Comment: EPA should finalize the proposed clarifications to the residential boiler exemption, but should extend the exclusion to small office or similar boilers.

EPA proposes some clarifications of what BPH are considered residential units and thus are exempt from the proposed rule. In particular, the revisions make clear that the exemption applies even if the unit is in a residence that is located at an institutional, commercial, or industrial site, for instance a residence at a farm or a university. This clarification is important and appropriate and should be finalized.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3672-A2, excerpt 4 for discussion.

Commenter Name: Heather Parent

Commenter Affiliation: Maine Department of Environmental Protection

Document Control Number: EPA-HQ-OAR-2002-0058-3691-A2

Comment Excerpt Number: 11

Comment: While Maine DEP supports exempting small units from the Major Source Boiler MACT, we recommend combining and simplifying the definitions of hot water heater and residential boiler to further clarify which units will be exempt from the rule. EPA should apply a heat input capacity threshold and remove the ambiguous language in the definition. Maine DEP also recommends that the exemption apply to all units under a certain size regardless of the type of fuel that is fired in the unit (i.e., gaseous, liquid, and solid fuel fired under a certain capacity should be exempt).

Response: The EPA thanks the commenter for their support. As for combining the two definitions, see the response to comment EPA-HQ-OAR-2002-0058-3506-A1, excerpt 8. The definition of "hot water heater" in the final rule has been revised to include biomass in the type of fuel included in the definition.

Commenter Name: Jessica Bridges

Commenter Affiliation: United States Clean Heat & Power Association (USCHPA)

Document Control Number: EPA-HQ-OAR-2002-0058-3501-A1

Comment Excerpt Number: 18

Comment: EPA has proposed that residential boilers be exempted from the major source and the area rule and is proposing to define residential boiler as follows:

Residential boiler means a boiler, used in a dwelling containing four or fewer family units, to provide heat and/ or hot water. This definition includes boilers used primarily to provide heat and/or hot water for a dwelling containing four or fewer families located at an institutional facility (e.g., university campus, military base, church grounds) or commercial/ industrial facility (e.g., farm).

Congress encouraged exploration of the use of small-scale combined heat and power in residential heating appliances in EPACT (2005) Section 923.⁹

USCHPA is cognizant that advances in residential micro-combined heat and power technology have led since 2005 to the installation more than 120,000 systems in residences globally. These systems function with the heat/or hot water system. The description above aptly applies to these installations. We recommend that the definition be modified by the insertion of the words "and/or as part of a residential combined heat and power system" after the words "hot water".

Residential boiler means a boiler, used in a dwelling containing four or fewer family units, to provide heat and/ or hot water and/oras part of a residential combined heat and power system. This definition includes boilers used primarily to provide heat and/or hot water for a dwelling containing four or fewer families located at an institutional facility (e.g., university campus, military base, church grounds) or commercial/industrial facility (e.g., farm).

[Footnote]

(9) 42 USC § 16213 - MICRO-COGENERATION ENERGY TECHNOLOGY

Response: We agree with the commenter and have revised the definition of residential boiler to include language for "residential combined heat and power system."

Comment Excerpt Number: 2

Comment: Under the reconsidered area source rule, the EPA proposes to change the definition of hot water heaters (76 FR 80547), which are exempted from the area source rule requirements. The proposal creates a clear line to define hot water heaters exempt from the rule as units with heat input capacity below 1.6 million British thermal units per hour (MMBtu/h). NESCAUM supports the change in definition with regard to the 1.6 MMBtu/h heat input threshold. [Note: The same change was made in the major source rule.]

Response: The EPA thanks the commenter for their support.

Commenter Name: Tangela Niemann

Commenter Affiliation: Texas Commission on Environmental Quality (TCEQ)

Document Control Number: EPA-HQ-OAR-2002-0058-3594-A3

Comment Excerpt Number: 1

Comment: The TCEQ supports the proposed new exemptions for temporary and residential boilers to clarify the rule and exempting sources with insignificant emissions.

Response: The EPA thanks the commenter for their support.

2E. Comparable Fuels

Commenter Name: Lorraine Gershman

Commenter Affiliation: American Chemistry Council (ACC)

Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1

Comment Excerpt Number: 122

Comment: ACC appreciates EPA's clarification in the preamble that boilers and process heaters firing comparable fuels (secondary materials that have properties similar to fuel oil) are covered under the Boiler MACT and not under the hazardous waste combustor MACT. It is appropriate to treat units burning comparable fuel as liquid units. 76 Fed. Reg. 80616. ACC requests that EPA provide this clarification in the regulatory text with reference to specifications provided in 40 CFR 261.38.

Response: The EPA has provided this clarification in the final rule. The definition of "Liquid fuel" has been revised to include "comparable fuels as defined under 40 CFR 261.38."

Commenter Name: Vickie Woods

Commenter Affiliation: Division of Air Quality, North Carolina Department of Environment and Natural Resources (NCDENR)

Document Control Number: EPA-HQ-OAR-2002-0058-3663-A2

Comment Excerpt Number: 24

Comment: Section 261.38 states hazardous secondary materials (i.e., spent materials, sludges and byproducts) -with fuel value and whose hazardous constituent levels are comparable to those found in fuel oil that could be burned in their place -- are not solid wastes and hence not hazardous wastes under RCRA Subtitle C. These materials are called comparable fuels. EPA clarifies units burning comparable fuels are covered by the Boiler MACT.

NC DAQ supports this definition and clarification of comparable fuels.

Response: The EPA thanks the commenter for their support.

2Z. Out of Scope: Legal and Applicability Issues

Commenter Name: John V. Corra, Director

Commenter Affiliation: State of Wyoming Department of Environmental Quality

Document Control Number: EPA-HQ-OAR-2002-0058-3435-A1

Comment Excerpt Number: 4

Comment: Wyoming suggests the addition of a small boiler and process heater exemption. The exemption of boilers and process heaters less than 2 MMBtu/hour will somewhat alleviate the recordkeeping and tracking burden on both the State and industry.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Commenter Name: Randall D. Quintrell

Comment Excerpt Number: 1

Comment: This proposed rule imposes hazardous air pollutant (HAP) emissions limits that are much tighter than needed to protect human health and the environment.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Commenter Name: Traylor Champion

Commenter Affiliation: Georgia-Pacific LLC (GP)

Document Control Number: EPA-HQ-OAR-2002-0058-3465-A1

Comment Excerpt Number: 21

Comment: GP is requesting that EPA consider exempting from these regulations units that have a heat input of less than 5.0 MMBtu/hr. These units are typically listed as insignificant activities in a Title V permit and HAP emissions are essentially zero. An example of a unit that will be unnecessarily regulated is a propane vaporizer. These units are simply small propane burners that are used to indirectly heat propane such that it is vaporized from a liquid to gas for use in larger burner systems. To require routine tune-ups is unnecessary and overly burdensome to the regulated community. While this example provided is a very small unit (less than 0.15 MMBtu/hr), it demonstrates the burden placed on the regulated community with no corresponding environmental benefits.

GP requests that EPA establish a minimum applicable size criterion that would exempt very small sources for which regulation would achieve limited environmental benefit while imposing unnecessary and excessive regulatory burden.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Commenter Name: David L. Meeker

Commenter Affiliation: National Renderers Association (NRA)

Document Control Number: EPA-HQ-OAR-2002-0058-3476-A1

Comment Excerpt Number: 9

Comment: The Boiler MACT includes the following definition for Other Gas 1 fuel under §63.7575:

Other gas 1 fuel means a gaseous fuel that is not natural gas or refinery gas and does not exceed the maximum concentration of 40 micrograms/cubic meters of mercury.

The mercury content for defining a fuel as Other Gas 1 instead of Gas 2 identifies a representative "threshold" for a significant HAP content (mercury) for a fuel (Gas 1) that is not subject to an emissions limitation. If an "other" gas fuel does not meet the definition of an Other Gas 1 fuel, the unit is classified as a Gas 2 (other) fuel.⁸ A maximum concentration of 40 µg/m³ for the mercury content in Other Gas 1 fuel is equivalent to 2.5e-06 lb/MMBtu mercury emission factor assuming a heating value of 1,000 Btu/scf.

Processed fats are not gaseous fuels, but the mercury content in the processed fats samples was below a 5 ppbw detection limit. Even if we assume that the mercury was present at this detection limit of 5 ppbw, and we apply a conservative heating value of 17,000 Btu/lb, this is approximately 3.0e-07 lb/MMBtu – an order of magnitude less than the EPA-defined threshold for natural gas-equivalency. Since Gas 1 units are subject to work practice standards under the Boiler MACT, the NRA has demonstrated the mercury (metal HAP) content identified in various types of processed fats samples analyzed is similar (or less than) in mercury content to Other Gas 1 fuel, and should be similarly regulated (work practice standards).

[Footnote 8: New and existing Gas 2 (other) units are subject to emissions limitations for PM, CO, HCl, mercury, and dioxin/furans as defined in Tables 1 and 2 to NESHAP Subpart DDDDD, respectively.]

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Commenter Name: David L. Meeker

Commenter Affiliation: National Renderers Association (NRA)

Document Control Number: EPA-HQ-OAR-2002-0058-3476-A1

Comment Excerpt Number: 11

Comment: The rendering industry routinely monitors processed fats for the presence of acid gas HAP-forming constituents, specifically chlorinated pesticides and polychlorinated biphenyls (PCBs). The U.S. Food and Drug Administration (FDA) considers any rendered product contaminated with pesticides/PCBs as adulterated under the Food Drug and Cosmetic Act if they exceed tolerances established by the FDA or EPA (40 CFR Part 180). The testing of these products to verify compliance is an integral part of the industry's Good Manufacturing Practices (GMP). The GMP varies from one NRA member to another and includes, but is not limited to, the following:

- Testing each production run before it is released for sale;
- Testing each load prior to shipment;
- Testing a weekly composite sample of each type of processed fat produced; and
- Periodic, or spot, testing.

Each year NRA members test several thousand samples of processed fats for the presence of the chlorinated pesticides and PCBs as a GMP to assure compliance with tolerances established by the FDA or EPA. Three of the aforementioned processed fats samples (Yellow Grease No. 1, Poultry Grease, and Tallow No. 1) were also analyzed using ASTM D 4327 and indicated no detected chloride content.⁹ The methods used for chlorinated pesticide testing are also recognized by the World Health Organization (WHO) as an approved method for the screening of dioxins and dioxin like substances and therefore the referenced test results also indicate these compounds are not typically present in processed fats.

Compared to natural gas from the EPA Emissions Database, the maximum chlorine content in 12 natural gas fuel samples analyzed is 82 ppmw. For 340 petroleum-based liquid fuel samples analyzed, the maximum chlorine content is 1,260 ppmw.¹⁰

The NRA considers these GMP practices and results of monitoring processed fats for chlorinated pesticides and PCBs as demonstrating that acid gas HAP-forming constituents are insignificant. Due to insignificant content of chlorinated compounds (based on separate FDA requirements for the industry) in the processed fats prior to combustion, the NRA believes the correlation to insignificant acid gas HAP emissions from boilers burning processed fats is direct. Any acid gas HAP emissions result from the actual chlorinated compound content in the fuel source combusted and are not produced by combustion due to insignificant levels of chlorinated compounds in the fuel source. Without high content of acid gas HAP-forming constituents in processed fats due to industry quality requirements, boilers burning processed fats do not emit significant acid gas HAP emissions. Therefore, similar to Gas 1 units, these processed fat-fired

boilers should also be subject to work practice standards and not an HCl emissions limitation under the Boiler MACT.

[Footnote 9: Detection level or threshold is 10 ppm for ASTM D 4327.]

[Footnote 10: The petroleum-based liquid fuels includes No. 6 fuel oil, No. 2 distillate, diesel fuel, fuel oil, biodiesel, No. 4 fuel oil, and No. 5 fuel oil, as identified in the EPA Emissions Database.]

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Commenter Name: David L. Meeker

Commenter Affiliation: National Renderers Association (NRA)

Document Control Number: EPA-HQ-OAR-2002-0058-3476-A1

Comment Excerpt Number: 12

Comment: EPA is required to establish emission standards for organic HAP emissions (compliance with the Boiler MACT demonstrated using CO surrogate pollutant for subject subcategories). Organic HAP emissions, such as polycyclic organic compounds (POCs) (as 7-PAH and referred to as polycyclic organic matter [POM]) and ethylene dioxide, are due to incomplete combustion of fossil fuels and solid vegetable matter that contains lignin and cellulose. Processed fats contain triglyceride mono, di, and free fatty acids. Acrolein (or 2-propenal) can be formed when processed fats fuel is burned due to decomposition of the triglyceride glycerin backbone. However, this is not a cyclic compound and therefore does not meet the definition of a POC (or POM). As such, the pollutant generation of these organic HAP from processed fats combustion is analogous to natural gas combustion. EPA previously found that these emissions were insignificant from natural gas combustion, and a similar argument can be made for processed fats fuel combustion. Therefore, similar to Gas 1 units, these processed fat-fired boilers should also be subject to work practice standards and not a CO emissions limitation under the Boiler MACT.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Commenter Name: Barry Christensen

Commenter Affiliation: Occidental Chemical Corporation (OCC)

Document Control Number: EPA-HQ-OAR-2002-0058-3477-A1

Comment Excerpt Number: 8

Comment: OCC requests clarification of how industrial cogeneration units, both turbines and HRSGs, are affected by this revised rule. Our prior understanding took into consideration that EPA intended for these industrial cogeneration units to be subject to the Subpart YYYYY Turbine MACT Standard and not covered by this rule. However, the exclusion in the proposed rule expressly addresses only EGUs that sell more than one third of their power to the grid. Therefore, we would appreciate language in the final rule that reiterates EPA's previously stated intent, which we are relying upon, that all EGUs, including EGUs that sell less than 1/3 of their

power to the grid, are exempt from the final boiler MACT rule. As stated previously, our turbines operate with HRSGs and are potentially subject to this rule.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Commenter Name: Peter Pagano

Commenter Affiliation: American Iron and Steel Institute (AISI)

Document Control Number: EPA-HQ-OAR-2002-0058-3490-A1

Comment Excerpt Number: 10

Comment: Fuel averaging across multiple units should be allowed as a means of qualifying as a Blast Furnace Gas Fuel-Fired Boiler/Process Heater.

As noted above, while AISI strongly supports a BFG exemption, the exemption requires revision to further effectuate facility-wide emission reductions and operational flexibility. Because multiple boilers, at times, operate together as a system to produce steam, AISI believes it is most appropriate to allow fuel averaging across multiple units for the BFG exemption to apply. In such situations, based upon the gas piping network and the availability of BFG, some boilers are always first to receive BFG while others may continue to be supplemented by other fuels, such as natural gas. In such instances, the use of BFG across the units is not necessarily equal which could result in some boilers firing well over 90%, by volume, of BFG, while other boilers may be firing less than 90% by volume, with an average over the multiple boilers exceeding 90%. If the BFG exemption were not to apply across multiple units, it could act as a disincentive for the continued beneficial reuse of BFG on certain individual boilers, which could result in BFG unnecessarily being flared.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Commenter Name: Peter Pagano

Commenter Affiliation: American Iron and Steel Institute (AISI)

Document Control Number: EPA-HQ-OAR-2002-0058-3490-A1

Comment Excerpt Number: 28

Comment: AISI is concerned that carbon monoxide standards in the Boiler MACT are too stringent to accommodate the full range of low-NOx technology that will be needed to meet the next generation of regulatory requirements applied to the variety of sources facing NOx control requirements. EPA should excuse affected sources from the CO emission limits when they can demonstrate that these limits conflict with an applicable NOx control requirement. Regular tune-ups should be sufficient to ensure that the boiler is optimizing combustion efficiency within the constraints of its low-NOx technology.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Commenter Name: Peter Pagano
Commenter Affiliation: American Iron and Steel Institute (AISI)
Document Control Number: EPA-HQ-OAR-2002-0058-3490-A1
Comment Excerpt Number: 29

Comment: In the iron and steel industry, low-NO_x process gases are also used to meet NO_x control requirements particularly during ozone seasons. *See e.g.*, 326 IAC 10-3 (Indiana rule requiring at least 50% blast furnace gas during the ozone season to meet NO_x control requirements). While blast furnace gas is exempt from the Boiler MACT definition of gaseous fuel, and boilers using 90% blast furnace gas or more are expressly excluded from Boiler MACT, mixed gas units that include some blast furnace gas with other process gases may still be subject to CO emission limits under the gas 2 fuel subcategory. Blast furnace gas is a low-NO_x fuel that can be added to mixed gas as a NO_x control strategy. However, since CO is one of the primary constituents of blast furnace gas, AISI members may not be able to control NO_x using this process gas without violating the stringent Boiler MACT CO emission limits. EPA should exempt affected boilers and process heaters from the CO emission limits when they are using blast furnace gas and are not otherwise exempt.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Commenter Name: Peter Pagano
Commenter Affiliation: American Iron and Steel Institute (AISI)
Document Control Number: EPA-HQ-OAR-2002-0058-3490-A1
Comment Excerpt Number: 36

Comment: EPA should clarify that an affected unit that cogenerates steam and electricity could be subject to the Boiler MACT, and not the MACT for Electric Utility Steam Generating Units, when the unit supplies less than one-third of its potential electric output capacity *on an annual average basis*.

Electric Utility Steam Generating Units ("EGUs") are not subject to the Boiler MACT rule because they have their own EGU MACT rule. Cogeneration units can be caught between the two rules with applicability determined based on whether the unit supplies more than one-third of its potential electric output capacity to a utility power distribution system (the "grid") for sale. Unfortunately, the CAA and the EGU MACT have been silent on the period of time to be used to determine whether more than one third of potential electric output capacity has been sent to the grid. AISI encourages EPA to use the Boiler MACT final rule to clarify its intent to use an annual averaging period for this calculation as EPA did when applying this same threshold to cogeneration units under the Acid Rain program. This will support use of cogeneration systems to reduce energy cost, support energy efficiency initiatives and environmental benefits.

Cogeneration units improve energy efficiency by utilizing steam for an industrial purpose while also generating electricity. AISI members are large energy consumers and they are constantly looking for ways to improve energy efficiency and reduce energy costs. Cogenerating electricity from waste heat and steam in our industry has been, and will continue to be, a focus of capital investment that reduces cost while improving the environment. In most instances, the facility

operating the cogeneration system has sufficient appetite for the electricity generated that only a minor amount is sent to the grid. However, there are circumstances when sending more than one-third of potential electric output capacity to the grid is consistent with our Nation's goals of energy efficiency and grid reliability. EPA can accommodate these circumstances by clarifying that "one-third of its potential output capacity" is to be determined on an annual average basis consistent with the CAA Acid Rain provisions.

By connecting to the grid, cogeneration units have the opportunity to contribute to the reliable distribution of electricity. Concerns regarding grid stability have been debated recently as costly environmental regulations force many older units to shutdown. As our national base load capacity decreases, distribution systems increasingly will need to rely on backup power supplies during high demand periods to sustain a reliable grid. Cogeneration systems have unused capacity that can be tapped for that back up system. The Boiler MACT rule should not force a cogeneration unit into the EGU MACT rule merely because it utilizes that backup capacity to support the electricity grid in times of high demand.

Local generation capacity also must be called upon when regional electricity distribution is interrupted. As we witness during significant regional blackouts, local generation can provide the necessary electricity to keep hospitals and other essential services operating. Cogeneration units should not face a new regulatory regime by sharing their unused capacity (above one-third of each unit's potential output) to respond appropriately to demand for local generation. We cannot know how long such episodes may last. The simple solution would be to clarify that a cogeneration unit may consider its output on an annual average basis to determine if it has contributed more than one third of its potential electric output capacity to the grid.

Cogeneration units could also provide a benefit to energy consumers by providing additional supply during peak usage periods. By providing additional supply to the grid as prices start to increase, cogeneration units contribute to price stability and mitigate the economic burden of high electric costs during periods when supply is otherwise constrained. This produces benefits throughout the economy and helps energy intensive industries compete in the global market.

Finally, as the iron and steel industry and others are considering new investments in cogeneration technology, the return on investment is critical to deploying limited capital. The return on investment is quicker, and capital is more likely to be invested, if the cogeneration unit can provide more electricity to the grid during peak demand periods that command a higher price per kW-hour. EPA can encourage energy efficiency investments, reduce the peak cost of electricity, and take an important step to improve grid reliability by establishing an annual average as the basis for determining if a unit is providing more than one-third of its potential electric output capacity to the grid. The Clean Air Act definition of "Electric Utility Steam Generating Unit" does not preclude an annual averaging period. Clean Air Act Section 112(b)(8) states in pertinent part, "A unit that cogenerates steam and electricity and supplies more than one-third of its potential electric output capacity and more than 25 megawatts electrical output to any utility power distribution system for sale shall be considered an electric utility steam generating unit." Congress did not specify the method by which to calculate the fraction of a cogeneration unit's potential electric output capacity supplied to the grid. EPA has the implied authority to add a reasonable calculation method to implement Congress' intent. When EPA faced this same situation under the Acid Rain program, it issued a rule that allowed a cogeneration unit to evaluate its electric output on an annual average basis over three years to determine if it met the

one-third threshold for the cogeneration exemption. *See* 40 CFR 72.6. Like Section 112(b), the Acid Rain portion of the Clean Air Act defined the utility unit in reference to one-third of potential output capacity without specifying an averaging period. *See* 42 U.S.C. 7651a(17). EPA utilized its inferred authority to set an annual average calculated over three years for the Acid Rain program; and EPA should do the same under the Boiler MACT rule.

The EGU MACT is currently silent on the averaging period, like the Clean Air Act. This does not preclude EPA from using the Boiler MACT to clarify an averaging period and to express its intention that the silence in the EGU MACT be interpreted consistent with the express clarification in the Boiler MACT rule. This has important benefits for grid reliability, energy price stability, and it creates an incentive for energy efficiency that produces significant environmental benefits. We urge you to place a special emphasis on these measures because they simultaneously improve energy efficiency and reduce emissions while producing high quality distributed power generation. Cogeneration and waste heat recovery can be a superior substitute for power produced from inefficient conventional electric power generation.

Comment Excerpt Number: 3

Comment: There is a Strong Congressional Policy Favoring Innovation in Emission Control Technology. The Supreme Court has summarized the point in *Chem. Mfrs. Ass'n v. Natural Res. Def. Council, Inc.*, 470 U.S. 116, 155-56, 105 S.Ct. 1102, 1123 (1985).

The legislative history [of the CAA] also makes clear why Congress found it so important that the standards be set for "categories" of dischargers, and not for individual dischargers. Congress intended to use the standards as a means to "force" the introduction of more effective pollution control technology. Thus, Congress directed EPA to establish BPT levels by reference to "the average of the best existing performance by plants of various sizes, ages, and unit processes within each industrial category." 118 Cong.Rec. 33696 (1972) Leg. Hist. 169 (Sen. Muskie). In establishing BAT levels, it directed EPA to look at "the best performer in an industrial category." 118 Cong.Rec. 33696 (1972) Leg.Hist. 170. By requiring that the standards be set by reference to either the "average of the best" or very "best" technology, the Act seeks to foster technological innovation. 118 Cong.Rec. 33696 (1972) Leg.Hist. 170. See generally La Pierre, Technology-Forcing and Federal Environmental Protection Statutes, 62 Iowa L.Rev. 771, 805-829 (1977); Note, Forcing-Technology: The Clean Air Act Experience, 88 Yale L.J. 1713 (1979).

Similarly in order to encourage the use of innovative multi-pollutant control technologies and other innovative technologies, EPA in the final EGU NSPS rule, 40 C.F.R. Part 60, provided for commercial demonstration permits to a limited number of EGU operators that deployed innovative multi-pollutant control technologies and other innovative technologies. As EPA explained in its proposal for the EGU rule:

[T]o encourage the continued development of new technologies that show promise in achieving levels of performance comparable to those of existing technologies, but at lower cost or with other offsetting environmental or energy benefits, special provisions are needed which encourage the development and use of new technologies, while ensuring that emissions will be minimized. 76 Fed. Reg. at 25,068-69.

Commenter Name: N.W. Bernstein & Associates, LLC

Commenter Affiliation: Eco Power Solutions (USA) Corporation

Document Control Number: EPA-HQ-OAR-2002-0058-3499-A1

Comment Excerpt Number: 6

Comment: There is a strong Congressional policy favoring the adoption and employment of new technology such as Eco Power's COMPLY 2000® technology, and EPA has recognized and sought to accommodate that need in the EGU Rule. The benefits of multipollutant removal technology are not only that it achieves multi-pollutant control and reduces CO₂ emissions by between 10% and 15% without sequestration, but it also avoids the collateral harm to the environment caused by conventional emission control technology. So for example, Eco Power's COMPLY 2000® is at least as effective as conventional wet flue gas desulfurization (WFGD) for SO₂ and selective catalytic reduction (SCR) for NO_x.⁵ Unlike WFGD, however, Eco Power's technology does not increase CO₂ emissions (*see* Available and Emerging Technologies for Reducing Greenhouse Gas Emissions From Coal-Fired Electric Generating Units, Office of Air and Radiation, US Environmental Protection Agency, October 2010, p. 23) and unlike WFGD, it does not significantly increase water usage (EPA Draft BACT GHG Guidance, p. 41, fn. 99). Additionally the water pollution problems created by WFGDs have been widely reported in the news media (*see* Attachment 2 to these comments, "Cleansing the Air at the Expense of Waterways," The New York Times, October 13, 2009). In contrast to WFGDs, COMPLY 2000® consumes and discharges smaller amounts of water due to the nature of its process and, as noted above, reduces CO₂ by 10% - 15% without sequestration. EPA should spell out these reasons in detail in justifying its rescission of the Boiler Rule in its entirety.

[Footnote]

(5) In its study of Applicability and Feasibility of NO_x and SO₂ and PM Emissions Control Technologies for Industrial, Commercial and Institutional Boilers (ICI) the Northeast States for Coordinated Air Usage Management (NESCAUM November 2008 revised January 2009) assumed higher than 90% NO_x reduction for SCR (NESCAUM Sec. 3.1 at 3-2) and 90% - 95% SO₂ removal for WFGD but only 70% - 90% for dry scrubbers (NESCAUM Sec. 3.6 at 3-12). NESCAUM did not provide comparative data for mercury reduction. As noted above, Eco Power's COMPLY 2000® achieves greater reduction in all of the above pollutants.

Comment: Exemption for Temporary Boilers in the Area Source Rule [Note:Same exemption proposed in Major Source Rule.]

The EPA is proposing to amend the area source rule at 40 CFR 63.11195 by adding temporary boilers to the list of boilers not subject to regulation (76 FR 80535). This change would make the major and area source rules' treatments of temporary boilers consistent. In justifying this change, the EPA indicated that temporary boilers are typically located on site for less than a year and are not included in the facility's operating permit. The EPA defined a temporary boiler as:

Temporary boiler means any gaseous or liquid fuel boiler that is designed to, and is capable of, being carried or moved from one location to another by means of, for example, wheels, skids, carrying handles, dollies, trailers, or platforms. A boiler is not a temporary boiler if any one of the following conditions exists:

(1) The equipment is attached to a foundation.

(2) The boiler or a replacement remains at a location for more than 12 consecutive months. Any temporary boiler that replaces a temporary boiler at a location and performs the same or similar function will be included in calculating the consecutive time period.

(3) The equipment is located at a seasonal facility and operates during the full annual operating period of the seasonal facility, remains at the facility for at least 2 years, and operates at that facility for at least 3 months each year.

(4) The equipment is moved from one location to another in an attempt to circumvent the residence time requirements of this definition.

Comment Excerpt Number: 30

Comment: *EPA Could Extend the Work Practice Approach Used for Gas 1 to Include Distillate Oil Fired Units*

Response: EPA has proposed work practice standards for certain existing units. The proposed work practice standard would include the implementation of a tune-up program. In order to further incentivize the use of clean fuels, EPA should extend the work practice standard to cover ultra-low sulfur distillate oil-fired units. EPA has established the MACT floors for liquid-fired units based on fuels that have low sulfur, chloride, and mercury content. As a result, the MACT

floors are based on fuel characteristics and not on consideration of emission controls employed by the units (in fact, the light liquid floor units have no emission controls). Considering this, EPA should not impose controls on boilers that burn a clean liquid fuel such as distillate fuel with low sulfur, chloride, and mercury content. In many cases it is difficult, if not impossible, to design emissions controls for such low contaminant levels, since the levels in the oils are already below detection levels.

Commenter Name: Lorraine Gershman

Commenter Affiliation: American Chemistry Council (ACC)

Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1

Comment Excerpt Number: 33

Comment: ACC reiterates its strongly-held view that work practices are appropriate for units burning other process gases as previously noted, and for the reasons below:

- Many petrochemical and chemical process gases have HAP emissions at the ultra-low levels of natural gas. Measuring these ultra-low levels of HAP emissions is not possible using existing methods.
- Integrated chemical plants typically use process gases as fuels from processing areas as fuels in boilers and process heaters. The use of these fuels is critical to maintaining energy efficiency at these sites. Based on the extremely low numeric standards proposed for units designed to burn Gas 2 fuel in both the original proposal and in this reconsideration proposal and the uncertainty surrounding the efficacy of expensive add-on controls, many facilities would be forced to use these process gases in a non-optimal manner, such as routing this fuel to flares or other combustion sources at the site, and replacing the lost fuel value by burning more natural gas. Forcing this switch is contrary to the nation's goal of reducing fossil fuel use and encouraging use of alternate energy sources (especially landfill gas).
- Facilities with process gas-fired units are very concerned over the feasibility of ensuring continuous compliance with such low Gas 2 limits.

Comment: NACAA has reviewed EPA's Response to Comments submitted in the 2011 rulemaking. We recognize that responding in detail to the many thousands of comments received in that rulemaking would be an enormous undertaking. As a consequence, however, EPA has not provided a meaningful response to most of the comments submitted by NACAA. This makes it difficult to advance the issues that carry forward from that rulemaking to the present activity.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Commenter Name: Bart Sponsellar
Commenter Affiliation: Wisconsin Department of Natural Resources (DNR)
Document Control Number: EPA-HQ-OAR-2002-0058-3527-A1
Comment Excerpt Number: 8

Comment: The Department believes that EPA does not have the information to characterize and regulate smaller biomass boilers. We believe there is considerable variability in small biomass boiler design, operation, and fuel quality and it is even questionable if these sources can be tuned according to the rule. We suggest that EPA suspend regulating boilers smaller than 5 mmBtu/hr under this rulemaking and proceed with collecting the necessary information. This threshold is suggested simply because EPA determined that below this size it is appropriate to reduce the tune-up frequency for oil boilers. In many cases we believe the contaminant content of biomass will be closer to oil than to coal fuels for these small sources.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Commenter Affiliation: Wisconsin Department of Natural Resources
Document Control Number: EPA-HQ-OAR-2002-0058-3527-A2
Comment Excerpt Number: 10

Comment: The Department's preferred approach is to establish work practices for all biomass dedicated sources and all pollutants. This conclusion is based on the fact that the content of fuel based pollutants including chlorides, mercury, and non-mercury metals will vary greatly between specific biomass sources and even vary based on the environmental conditions to which the biomass is exposed. Therefore conditions at one source cannot be expected to always be true for other sources in the subcategory. The Department suggests that a biomass source should be subject to only a work practice limit if the material is clean or virgin material and has not been exposed to pathways for contamination by the pollutants in question. Appropriate work practices may include material handling practices and operating particulate control equipment. If the biomass is not deemed clean, the source should be subject to alternative emission limitations as proposed based on the biomass subcategory floor determinations.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Commenter Name: Bart Sponsellar

Commenter Affiliation: Wisconsin Department of Natural Resources

Document Control Number: EPA-HQ-OAR-2002-0058-3527-A2

Comment Excerpt Number: 11

Comment: The Department suggests a work practice with alternate emission limitation by subcategory, can also be applied in the case of carbon monoxide emission requirements [at biomass units]. We believe the CO emission data for biomass also shows that concentrations related to good combustion will vary significantly by each biomass fuel type and also the quality of the fuel over time. To some extent variability could be controlled by specifying fuel parameters such as moisture content. But the Department believes such parameters must be determined by each source. The more practical approach to achieving good combustion is to require continuous CO and O2 emissions monitoring and trimming of combustion air according to a good combustion plan. This approach is much more effective in maintaining good combustion while burning variable fuels as compared to a single stack test while burning optimal fuels. Therefore, the Department believes that a combustion monitoring system of a CO and O2 analyzer system (non-CEM) is an appropriate carbon dioxide work practice requirement representing good combustion for biomass sources. As an alternative, a source can demonstrate compliance with the annual stack test emission limitation.

Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 4

Comment: Under basic principles of due process and administrative law, EPA has an obligation to provide the public with a reasonable opportunity to comment on proposed rules. Specifically, Congress requires EPA to give the public “a reasonable period . . . of at least 30 days” in which to comment on “any regulation” promulgated under the CAA.⁹ By the clear terms of the CAA, Congress indicates that 30 days is the minimum time necessary to give the public a reasonable opportunity to evaluate a proposed rule and provide adequate feedback to the Agency. Thus, a comment period meeting the statutory 30-day minimum would be reasonable for a single, ordinary proposed rule. Here, EPA has violated the clear terms of the CAA and deprived sources of a means to adequately protect their interests and rights in the administrative and judicial processes by providing 60 days of comment for four complex interrelated rules.

Under reconsideration, the rules are no less complex than when they were first proposed in June 2010. A 60-day comment period is particularly inadequate given their complexity, breadth of applicability, and economic impact. EPA has added data on reconsideration for 300 additional sources that must be reviewed and sources face the pressures of sorting complex data and developing thorough comments that address very technical issues. Although EPA released the

signed rule proposals almost one month prior to their publication in the Federal Register, it did not provide the majority of the supporting documentation for the proposed rules until publication on December 23, 2011, just two days before the holidays, effectively shortening the comment period. The four proposed rules under reconsideration make for an enormously broad and costly proposal, which would have a significant economic impact across numerous and diverse sectors of the US economy, with the boiler MACT rule alone imposing capital costs of more than \$5 billion and affecting nearly 200,000 sources, according to EPA. 76 Fed. Reg. 80622.

This economic impact alone, which CIBO estimates to be over \$14 billion,¹⁰ requires a comment period sufficient to ensure thorough consideration of the proposed rules. CIBO joined with 26 other entities and trade associations, representing tens of thousands of affected sources, to ask EPA to extend the comment period by 30 days and explaining in detail why the extra 30 days was needed and justified.¹¹ On February 14, 2011, just seven days before the comments were due, EPA denied the request.

Sources have done the best under the circumstances to develop thoughtful comments on their concerns and the specific requests for comment EPA made in the four rules, and where necessary or appropriate, and where time permitted, to compile data to support its positions. [Footnote 9: CAA §307; 42 U.S.C. § 7607(h) (2006).]

Commenter Name: Robert D. Bessette

Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 15

Comment: EPA should promulgate a *de minimis* exemption, not merely a work practice standard, for small boilers and process heaters of up to 10 MMBtu/hr or less. *Alabama Power Co. v. Costle*, 636 F.2d 323, 400 (D.C. Cir. 1979), clearly establishes EPA's authority to fashion *de minimis* and administrative necessity exemptions. In addition to the logistical issues involved with shutting down multiple small units in a facility at the same time, there is the considerable cost involved with performing the tune-ups. This significant cost produces only minimal corresponding reductions in HAP emissions. Tune-ups required under the current final and proposed rules will have only a limited effect on the HAP emissions from these small units. At least one CIBO member facility has estimated the cost of performing biennial tune-ups at \$20,000 per ton and quintennial tune-ups at \$8,000 per ton. The tune-up requirement results in a disproportionate expense in a very small portion of industry-wide HAP emissions.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Commenter Name: Robert D. Bessette
Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)
Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1
Comment Excerpt Number: 17

Comment: Because some units, depending on their fuel, may be defined and therefore regulated as either section 112 boilers or section 129 incinerators, the regulations governing the process of changing source status affects both boilers and incinerators. EPA addresses this issue in the definitions section of the CISWI rule. This issue should be addressed and cross-referenced in the boiler MACT rule as well.

Comment Excerpt Number: 25

Comment: In order to further incentivize the use of clean fuels, EPA should extend the tune-up work practice standard to cover ultra-low sulfur distillate oil-fired units. EPA has established the MACT floors for liquid-fired units based on fuels that have low sulfur, chloride, and mercury content. As a result, the MACT floors are based on fuel characteristics and not on consideration of emission controls employed by the units (in fact, the light liquid floor units have no emission controls). Considering this, EPA should not impose controls on boilers that burn a clean liquid fuel such as distillate fuel with low sulfur, chloride, and mercury content. In many cases it is difficult, if not impossible, to design emissions controls for such low contaminant levels, since the levels in the oils are already below detection levels.

Comment Excerpt Number: 4

Comment: Due to the extensive nature of the proposed revisions to the rule, Westlake asks EPA to extend the comment period for this rulemaking. Westlake needs additional time to evaluate the MACT floor determination as it pertains to the emission limits for liquid fuels, and time to study the proposed CO limits and the impacts on our low-NOx burner equipped boilers. This specific topic is a major concern for owners of ICI boiler and process heaters located in ozone nonattainment areas that are affected by NOx Reasonably Available Control Technology regulations.

Document Control Number: EPA-HQ-OAR-2002-0058-3539-A1

Comment Excerpt Number: 7

Comment: EPA has regulated HAP emissions from boilers and other LFG destruction equipment under various sections of the Clean Air Act. These include New Source Performance Standards and Maximum Achievable Control Technology Standards (e.g. boilers) for landfill gas. These standards adequately control HAP emissions. The proposed rule imposes additional emission limits on control devices and constitutes an impermissible duplication of emission limits under Section 112 of the Clean Air Act. In addition, the proposed boiler rules would result in fuel switching from LFG to fossil fuels that increases greenhouse gas emissions and criteria pollutants.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Commenter Affiliation: Texas Commission on Environmental Quality (TCEQ)

Document Control Number: EPA-HQ-OAR-2002-0058-3594-A3

Comment Excerpt Number: 2

Comment: The EPA should include an exemption for electric boilers similar to the exemption proposed for 40 CFR 63 Subpart JJJJJ for boilers at area sources.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Commenter Name: Tangela Niemann

Commenter Affiliation: Texas Commission on Environmental Quality (TCEQ)

Document Control Number: EPA-HQ-OAR-2002-0058-3594-A3

Comment Excerpt Number: 3

Comment: The TCEQ is concerned at the lack of a size exemption in the rule. While the emission standards and performance testing requirements in the rule only apply to units with a capacity of 10 million British thermal units per hour (MMBtu/hr) or greater, units less than 10 MMBtu/hr are still subject to certain requirements such as the periodic tune-up provisions and the energy assessment. Despite petitioners' subsequent requests for a *de minimis* size exemption, the current proposed rule revisions only change the frequency of the tune-up requirements for small units equal to or less than 10 MMBtu/hr. The EPA did not provide any rationale for denying petitioners' requests for including a size exemption in the current proposed revisions other than to indicate that "the EPA disagrees that small boilers should be exempt from the rule..." (76 FR 80614). However, in the March 21, 2011, *Federal Register* publication of the

final rule for 40 CFR 63 Subpart JJJJJ for the area source boiler NESHAP rule (76 FR 15568), the EPA's response to comments regarding a *de minimis* heat input level appears to indicate that the EPA believes that Federal Clean Air Act (FCAA), Section 112 mandates establishing standards (numeric limits or work practices) for all sources in the category or subcategory and that the EPA is prohibited from providing a size-based exemption. It is counter-intuitive for the EPA to argue that it may provide an exemption for boilers within a category based on limited use at the site (i.e., the current proposed temporary boiler exemption) yet a permanent boiler within the same category cannot be exempted based on limited size. Additionally, the EPA has already incorporated certain size-based criteria in other exemptions via the definitions used for those exemptions. The definition of *hot water heater* includes a maximum size of 120 gallons capacity that serves as a sized-based exemption for all hot water heaters 120 gallons or less. Similarly, the proposed addition of hot water boilers less than 1.6 MMBtu/hr to the definition of a *hot water heater* also establishes a sized-based exemption threshold.

The potential HAP emissions from such small units, particularly the natural gas-fired units, is significantly less than other units that are currently exempt from 40 CFR 63 Subpart DDDDD or that EPA has proposed exemptions for with the current rulemaking. As an example, the TCEQ points to one facility located in Texas that is listed in the appendices of the EPA's Technical Support Document (TSD) entitled *Revised (November 2011) Methodology for Estimating Cost and Emissions Impacts for Industrial, Commercial, Institutional Boilers and Process Heaters - National Emission Standards for Hazardous Air Pollutants – Major Source*. The facility is identified as being a major source of HAP subject to the rule with two 0.02 MMBtu/hr natural gas-fired boilers and one 5 MMBtu/hr process heater. Using the EPA's only emission data from the TSD document, the total HAP emissions from the two 0.02 MMBtu/hr natural gas-fired boilers combined is approximately 2 pounds per year. The total reduction in HAP emissions from these boilers as a result of applying the EPA tune-up requirement is 0.3 ounces per year. The EPA's own cost analysis data in the technical support document shows that the fuel savings for performing the tune-up requirements on the two small boilers is \$7 per year each, while the annualized costs for performing the tune-up requirements is \$2,875 for each boiler. Applying the tune-up requirements of 40 CFR 63 Subpart DDDDD to such small units is not cost-effective by any reasonable interpretation. The TCEQ encourages the EPA to incorporate a *de minimis* size-based exemption threshold into the final rule to eliminate burdensome and unnecessary requirements on owners and operators of small boilers and process heaters that have such insignificant emissions.

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 1

Comment: As is obvious from the number of issues we and others have identified and the history of this rulemaking, these rules are very complex and difficult to understand and comment upon. Thus, we were extremely disappointed that the Agency failed to provide adequate time to comment. Many of the issues we have identified could not be dealt with in any but a superficial way as a result of the short 60 day comment period. While the draft rules were available a few weeks before Federal Register publication, none of the critical supporting documents were available until after publication, preventing the most productive use of that, albeit short, extra time. In an effort to learn from this experience, we recommend and request that EPA make supporting documents available in the docket at the same time the draft is released. Furthermore, we request EPA to seriously consider all of our and others comments and not ignore the majority of them because of a rush to finalize these rules.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Commenter Name: Richard D. Garber

Commenter Affiliation: Boise Inc.

Document Control Number: EPA-HQ-OAR-2002-0058-3686-A2

Comment Excerpt Number: 8

Comment: Inadequate Time was Provided to Industrial Sources for Review and Comment on the December 23, 2011 Boiler MACT and Related Rules.

On December 23, 2011, the EPA published three notices proposing four new rules to reconsider and/or amend the March 21, 2011 final Boiler rules under the Clean Air Act (CAA) and the Resource Conservation and Recovery Act (RCRA): the major-source National Emission Standards for Hazardous Air Pollutants (NESHAPs) for industrial, commercial and institutional boilers and process heaters under CAA § 112 (Boiler rule); the area-source NESHAPs for industrial, commercial and institutional boilers under CAA § 112 (Area Source rule); and the New Source Performance Standards (NSPS) and emission guidelines for commercial and industrial solid waste incinerators under CAA § 129 and Non-hazardous Secondary Materials (NHSM) rule- under the RCRA defining "solid waste" to demarcate applicability under CAA § 112 and § 129 between boilers and solid waste incinerators (CISWI and NHSM rule).

As EPA is well aware, the proposed rules have raised an unprecedented number of complex issues in determining the appropriate MACT floors for these very large, diverse source categories. The simultaneous proposal of the rules greatly complicates the analysis of whether the standards can be achieved by affected sources. A large percentage of sources must first apply a complex set of factors under the NHSM rule to each material they combust, to determine whether EPA is likely to consider the material a waste or a fuel. If the materials would be considered *solid waste*, the source combusting those materials would be considered an *incinerator*, and it must then consider the applicability and achievability of the *CIS WI* standards. On the other hand, if under the NHSM rule, the materials are characterized as *fuel*, the source combusting those materials would be considered a *boiler*, and the source must then consider the applicability and potential achievability of the *Boiler rule* (for a major source) or *Area Source rule* (for a non-major source).

When EPA initially proposed these rules for comment on June 4, 2010, EPA provided for 60 days of comment. As multiple entities explained in letters to EPA at that time, 60 days is inadequate for sources to review voluminous data and EPA's analysis and to assess the achievability and impact of all four rules on the full range of affected sources at each facility.

In response to our request on the initial rule, EPA provided additional time for comments. Now on reconsideration, the rules are no less complex, EPA has added data that must be reviewed for 300 additional sources, and sources face the same pressures of sorting complex data and

developing thorough comments that address very technical issues. Although requesting a public hearing would have extended the comment period, we decided our time was better spent in developing comments. There is an extensive amount of data within the docket that takes many hours to sort through in order to produce thorough comments. Also, because EPA only allowed a few weeks, during the holidays, for review of the four proposals before the hearing would have been held, there was effectively less time to sort data in advance of a hearing. We were doubtful that we could have produced enough specific information to have a meaningful discussion by that date. For all these reasons, rather than use a procedural tool to achieve an extension, we decided to seek, in a straightforward fashion, additional time to prepare comments.

Understanding that EPA has made public commitments for an accelerated process to complete these rules, we only asked for 30 additional days for the Boiler MACT, CISWI and NHSM rules. We did not expect to need additional time for comment on the Area Source rule. EPA has an obligation to provide the public with a reasonable opportunity to comment on proposed rules. We have identified many issues with the proposed rules, but the lack of an extension has resulted in less time to fully develop our arguments and detailed justification for each of our comments.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Commenter Name: Richard D. Garber

Commenter Affiliation: Boise Inc.

Document Control Number: EPA-HQ-OAR-2002-0058-3686-A2

Comment Excerpt Number: 9

Comment: We are very concerned that EPA is not leaving itself sufficient time to evaluate the substantive comments including new data, make appropriate revisions, and finalize within a couple of months after an important interagency review process. Cutting corners and rushing major rules such as these to the Federal Register greatly increases the chance of errors and oversights that would either make it vulnerable under court review or require further modifications after promulgation. That does not serve the public or the Agency well.

Commenter Name: Dan F. Hunter

Commenter Affiliation: ConocoPhillips Company

Document Control Number: EPA-HQ-OAR-2002-0058-3689-A2

Comment Excerpt Number: 1

Comment: In §63.7485, you are subject to Subpart DDDDD if you own or operate an industrial, commercial, or institutional boiler or process heater that is located at a major source of HAPs, as defined in §63.2 or §63.761 (Subpart HH, NESHAPs from Oil and Natural Gas Production Facilities). This reference to another subpart, tying the definitions of "major source" together rather than incorporate the applicable regulatory text in each specific subpart, has created an unnecessarily complex situation; one where the result is revisions in one rule subsequently triggering the applicability of another; specifically, proposed changes to Subpart

HH will, if finalized, subject our facilities to Subpart DDDDD. In the case of Subpart DDDDD, EPA proposed significant revisions to requirements for both area and major sources. At the time, the definition of major source for oil and natural gas production facilities was not being proposed for revision. Therefore, owners/operators of oil and natural gas production facilities reviewed and provided comment based on their source status at the time (i.e., area sources reviewed the area source requirements and major sources reviewed and commented on the major source requirements). EPA did not provide any indication that they intended to propose a future change to the major source definition found in Subpart HH and there was no reason to foresee EPA would change such a critical definition that has been used since 1999 and is important for determining the area versus major source requirements for oil and natural gas production facilities. But EPA has not opened §63.7485 during this public comment period for the proposed rules. We thus find ourselves suddenly subject to a rule with which the applicability is closed to our comment. ConocoPhillips hopes EPA recognizes the procedural issues that have occurred as a result of the timing for each regulatory proposal and believes the proper remedy is for EPA to adopt the major source definition originally in DDDDD; i.e., copy the text of the §63.761 major source definition, prior to the proposed changes to that definition in 2011, into DDDDD. In addition, we request EPA's ongoing consideration of this concern with the regulatory structure in future rulemaking.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

100B. Exemption for All Gas-Fired Units [DENIED PETITIONER ISSUE]

Commenter Name: Matthew Todd

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 40

Comment: We strongly support EPA's conclusion that the CAA 112(h) criteria are met and therefore design, equipment, work practice, or operational requirements are the appropriate and legal means of meeting the requirements of CAA section 112(d)(2) for D/F emissions, for the Gas 1 and Limited-Use subcategories and for smaller boilers and process heaters (i.e., <10 MMBTU/hr).

Response: The EPA thanks the commenters for their support.

100C. Natural Gas-Fired Water Heaters [DENIED PETITIONER ISSUE]

Commenter Name: Shannon S. Broome

Commenter Affiliation: Auto Industry Forum (AIF)

Document Control Number: EPA-HQ-OAR-2002-0058-3512-A1

Comment Excerpt Number: 31

Comment: In its petition for reconsideration and subsequent comments, AIF asked EPA to reconsider the merits and disadvantages of imposing the work practice standard because

emissions from the units to which it applies are insignificant and to eliminate the biennial tune-up requirements for those units as well as for NG-fired hot water heaters with capacity greater than 120 U.S. gallons. AIF articulated that, contrary to EPA's claim that it lacks authority to exempt such units altogether from the final work practice standard, nothing in the cases on which EPA relied overruled *Alabama Power Co. v. Costle*, 636 F.2d 323, 400 (D.C. Cir. 1979), which clearly establishes EPA's authority to fashion *de minimis* and administrative necessity exemptions. AIF noted that EPA's approach of subjecting those small units to work practice standards, including biennial tune-ups, is extremely burdensome and costly without providing for corresponding, significant emission-reduction benefits. EPA's approach, AIF commented, would actually create incentives for facilities to switch from NG-fired water heaters to electric water heaters, which are far-less energy efficient. Therefore, AIF urged EPA to reconsider its decision not to exempt NG-fired boilers and large hot water heaters with heat input capacities of 10 MMBtu/hr or less from the infeasible and minimally beneficial work practice standards EPA promulgated. Consistent with that comment, AIF advocated for the elimination of biennial tune-up requirements on NG-fired hot water heaters with capacity greater than 120 U.S. gallons, given the extreme burdens imposed and the lack of emission-reduction benefits.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: Shannon S. Broome

Commenter Affiliation: Auto Industry Forum (AIF)

Document Control Number: EPA-HQ-OAR-2002-0058-3512-A1

Comment Excerpt Number: 32

Comment: *Under Alabama Power, EPA Appropriately Proposes to Change the Definition of "Hot Water Heater" to Include Those Combusting Gaseous or Liquid Fuel with a Heat Input Capacity of Less Than 1.6 MMBtu/hr.*

As noted above, the reconsideration proposal modifies the definition of "hot water heater" to include hot water boilers that combust gaseous or liquid fuel and that have a heat input capacity measuring less than 1.6 MMBtu/hr. Hot water heaters are not subject to the Boiler MACT, so EPA's proposal functions as a *de minimis* exemption for those types of hot water boilers. AIF supports the proposed change to the definition because the administrative (and economic) burdens of regulating those types of small, NG-fired hot water boilers – which include those hot water boilers for the showers that assembly workers use to clean up after their shifts – are excessively burdensome without a meaningful, corresponding benefit in terms of reducing HAP emissions. Given those factors, EPA clearly has the authority to finalize its proposal under *Alabama Power Co. v. Costle*, 636 F.2d 323, 360-61, 400 (D.C. Cir. 1979).²⁰ *Alabama Power's* essential holding relevant to this context is that agencies like EPA have the authority to issue *de minimis* exemptions as a rational approach for relieving severe administrative (and economic) burdens that blind adherence to the literal terms of a statute would otherwise create.²¹ *See* 636 F.2d at 360-61, 400.

Under *Alabama Power*, EPA has the inherent power to overlook trifling matters, such as the *de minimis* HAP emissions, to the extent such emissions are even measurable, from these types of small, NG-fired hot water boilers. *See id.* at 360-61. As the D.C. Circuit emphasized in *New York*

v. EPA, 444 F.3d 880, 888 (D.C. Cir. 2006), and as the U.S. Supreme Court held in *Wisc. Dep't of Rev. v. William Wrigley, Jr., Co.*, 505 U.S. 214, 231 (1992), the *de minimis* doctrine is a legal principal that forms part of the established background against which all statutes are enacted. Agencies, therefore, may diverge from the plain meaning of the statute as far as is necessary to avoid its futile application.²² See *New York*, 444 F.3d at 888.

[Footnote 20: Moreover, nothing in the statute compels EPA to regulate every possible emission point at a major source. *Alabama Power* simply provides additional justification for EPA's action here.]

[Footnote 21: EPA has indicated that it believes the literal terms of the statute compel it to regulate these sources. While AIF does not concede that the literal terms require regulation of these small units, to the extent they do, *Alabama Power's* *de minimis* authority still would be available.]

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Comment Excerpt Number: 33

Comment: Section 112 "permits" *EPA* to issue this *de minimis* exemption. See *EDF v. EPA*, 82 F.3d 451, 466 (D.C. Cir. 1996). As the *EDF* court explained, the availability of a *de minimis* exemption depends on whether Congress has not been "extraordinarily rigid" in drafting a statute; if it has not, then there is an implication of the agency's authority to provide such an exemption, if "the burden of regulation yield[s] a gain of trivial or no value." *Id.* (quoting *Alabama Power*, 636 F.2d at 360-61) (internal quotation marks omitted).

Section 112 sets forth that EPA "shall publish, and shall from time to time, but no less often than every 8 years, revise ... a list of all categories and subcategories of major sources and area sources." CAA § 112(c)(1); 42 U.S.C. § 7412(c)(1). It then directs EPA to "establish emission standards under subsection (d)" as to those categories and subcategories. CAA § 112(c)(2); 42 U.S.C. § 7412(c)(2). Subsection (d) directs EPA to "promulgate regulations establishing emission standards for each category or subcategory of major sources and area sources of [HAPs] listed for regulation pursuant to subsection (c)." CAA § 112(d)(1); 42 U.S.C. § 7412(d)(1). Critically, it then proceeds to state the following:

Emissions standards promulgated under this subsection and applicable to new and existing sources of [HAPs] shall require the maximum degree of reduction in emissions of [HAPs] subject to this section (including a prohibition on emissions, where achievable) that the Administrator, taking into consideration the cost of achieving such emission reduction, and any non-air quality health and environmental impacts and energy requirements, determines is achievable for new or existing sources in the category or subcategory to which such emission standard applies, through application of measures, processes, methods, systems or techniques ...

CAA § 112(d)(2); 42 U.S.C. § 7412(d)(2). The framework of this statutory scheme, then, permits EPA to define the units within the source categories and subcategories it is regulating in such a way as to exclude or exempt those units whose emission of HAPs is *de minimis*. This is because the CAA directs EPA to promulgate emission standards that require regulated sources to achieve a maximum degree of reduction in emission of HAPs but it expressly permits EPA to take into consideration the cost of achieving that reduction. It cannot be said that the statutory scheme is so extraordinarily rigid that it does not contemplate a potential *de minimis* exemption where the burden of regulation would yield a gain of trivial or no value, particularly considering “the cost of achieving such emission reduction.” CAA § 112(d)(2); 42 U.S.C. § 7412(d)(2).

The EDF decision supports the *de minimis* exemption for which AIF advocates because, there, the D.C. Circuit upheld EPA’s definition of the CAA’s prohibition of federal activities that do not conform to SIPs as exempting or excluding those federal activities that would produce either no or a trivial level of emissions. *See* 82 F.3d at 466. Beyond AIF’s arguments about the regulatory burden – on EPA, state agencies that must include the requirements in Title V permits and conduct enforcement of such requirements, and regulated entities that must comply with them – of including small, NG-fired hot water boilers within the scope of the Boiler MACT, therefore, there is a rational basis for EPA to find that HAPs from those units, to the extent such emissions are even measurable, are *de minimis*. As EPA has the authority to make that finding, it has the corresponding authority to finalize the proposed revision to the definition of “hot water heater” and AIF supports EPA finalizing that proposed revision.

100D. Natural Gas and Oil Hot Water Systems Smaller than 10 MMBtu/hr [DENIED PETITIONER ISSUE]

Commenter Name: Shannon S. Broome

Commenter Affiliation: Auto Industry Forum (AIF)

Document Control Number: EPA-HQ-OAR-2002-0058-3512-A1

Comment Excerpt Number: 34

Comment: *Alabama Power Also Supports a De Minimis Exemption for Small, Natural Gas-Fired Hot Water and Process Heaters with Heat Input Capacities of Up to 10 MMBtu/hr or Less.*

EPA should finalize a *de minimis* exemption from the Boiler MACT for small, NG-fired hot water and process heaters with heat input capacities of 10 MMBtu/hr or less. AIF recommends that EPA further change the definition of “hot water heater” to include any hot water boilers with heat input capacities of 10 MMBtu/hr or less and exclude from the definition of “process heater” any NG-fired process heaters with heat input capacities of 10 MMBtu/hr or less.

In its response to comments as to the proposed rule for the Boiler MACT final rule of March 21, 2011, EPA argued that it lacks the authority to issue a *de minimis* exemption as to emission standards established under Section 112. *See* Response to Comments on *Boiler MACT*, Vol. 1, at p. 339, Document Control No: EPA-HQ-OAR-2002-0058-3289. In making that argument, EPA

cited to the statutory language of Section 112(d) and case law from the D.C. Circuit that it described as requiring EPA to set emission standards for *all* HAP emitted from a source. EPA contended that this requirement precludes it from establishing a *de minimis* threshold below which HAP emitted by a source would not be regulated. EPA cited to the following cases:

- *Sierra Club v. EPA*, 479 F.3d 875, 883 (D.C. Cir. 2007) (“EPA has a ‘clear statutory obligation to set emission standards for each listed HAP,’ which does not allow it to ‘avoid setting standards for HAPs not controlled with technology.’” quoting *Nat’l Lime Ass’n v. EPA*, 233 F.3d 625, 634 (D.C. Cir. 2000) (“*Nat’l Lime II*”).
- *NRDC v. EPA*, 489 F.3d 1364, 1371 (D.C. Cir. 2007) (holding that EPA must establish emission standards for listed HAP emitted from a category, citing the *Sierra Club* and *Nat’l Lime II* decisions).

In its petition for reconsideration and subsequent comments, AIF pointed out that nothing in those cases overruled Judge Leventhal’s decision for the Court in *Alabama Power*, which, as described above, clearly establishes EPA’s authority to exempt *de minimis* situations and create exemptions based on administrative necessity. Had the Court intended to overrule *Alabama Power* in its subsequent decisions, it surely would have been more clearly. EPA fails to address this contention in the reconsideration proposal, instead merely stating that it disagrees with commenters that advocate for a *de minimis* exemption for small units. *See Boiler MACT Reconsideration Proposal*, 76 Fed. Reg. at 80,616.

As articulated above, the position previously argued by AIF was sound, and EPA failed to substantively respond to it in the reconsideration proposal. EPA has the authority to promulgate a *de minimis* exemption as to small hot water and process heaters, and any other source for which the burdens of regulation would be high and the emission-reduction benefits would be insignificant. This is not a context where the best performers use no emission control technology, *see Sierra Club*, 479 F.3d at 883; *Nat’l Lime*, 233 F.3d at 633, nor where the mechanism being advocated is EPA promulgating a risk-based subcategory, *see NRDC v. EPA*, 489 F.3d at 1368-71. Moreover, none of those cases disturbed or much less *considered* the essential holding of *Alabama Power*, *i.e.*, that agencies like EPA have the authority to issue *de minimis* exemptions as a rational approach for relieving severe administrative (and economic) burdens that blind adherence to the literal terms of a statute would otherwise create. *See* 636 F.2d at 360-61, 400. EPA appears to concede as correct AIF’s reading of the case law and EPA’s authority under the CAA in that it now proposes to change the definition of “hot water heaters” in a way that effectively creates a *de minimis* exemption for hot water boilers with heat input capacities of less than 1.6 MMBtu/hr.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Document Control Number: EPA-HQ-OAR-2002-0058-3512-A1

Comment Excerpt Number: 35

Comment: Accordingly, consistent with its authority under *Alabama Power*, EPA should finalize a *de minimis* exemption for small, NG-fired hot water and process heaters with heat input capacities of 10 MMBtu/hr or less. The work practice standards for these types of small and clean units, even with EPA's proposed reduction in tune-up frequency for certain units, remain infeasible from the standpoint of administration and cost, and provide minimal, if any, HAP emission reductions. In the experience of AIF members, tuning of NG-fired hot water and process heaters with heat input capacities of 10 MMBtu/hr or less has a limited effect on combustion efficiency, so the work practice standards only create additional burden without any corresponding, meaningful benefit in terms of HAP reductions.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Document Control Number: EPA-HQ-OAR-2002-0058-3512-A1

Comment Excerpt Number: 36

Comment: Providing support for the conclusion that a *de minimis* exemption is appropriate for these small units, one automotive facility currently spends an estimated \$40,000 annually to perform safety inspections on the various gas burners and gas trains in the facility. Almost all of these inspected burners are under 10 MMBtu/hr input and the vast majority of inspected units are between 1.6 and 5 MMBtu/hr. The facility projects that the additional cost for the tune-ups proposed in § 63.7540(10) could be of a similar magnitude. The present, annual cost of safety inspections does not include the myriad of small heaters less than 1.6 MMBtu/hr scattered throughout the plant as to which no inspections are currently required or performed. Without a *de minimis* exemption, many more of these small heaters would require tune-ups, which would further increase the cost impact on plant maintenance budgets with only a small reduction of HAP emissions.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: Shannon S. Broome

Document Control Number: EPA-HQ-OAR-2002-0058-3512-A1

Comment Excerpt Number: 37

Comment: For example, a typical, well-tuned 10 MMBtu/hr burner emitting HAPs at the rate published in EPA's AP-42 NG emissions factor tables²³ would emit around 160 pounds of HAP per year. Even the most poorly-tuned unit of this size (which is unlikely to be encountered) could only emit HAPs at twice the rate of a well-tuned unit. A facility with twenty poorly-tuned 10 MMBtu/hr burners could collectively emit HAP at a rate of about 1.6 ton per year in excess of a well-tuned unit. Therefore, using the typical costs noted above, the cost of biennial inspections for such units would effectively cost at least \$12,500 per ton of HAP abated.²⁴ Similarly, inspections on a five-year schedule for twenty 10 MMBtu/hr burners would cost at least \$25,000 per ton abated. A hypothetical facility operating two 100 MMBtu/hr boilers and three 12

MMBtu/hr boilers, in addition to the twenty 10 MMBtu/hr burners in the example above, would be spending around 50% of its tune-up budget on the smallest units to minimize 8% of its HAP emissions due to biennial tune-up requirements. AIF believes that units are generally not "poorly tuned," so the cost per ton, in fact, will be dramatically higher than even estimated here.

[Footnote 23: U.S. EPA, *Compilation of Air Pollutant Emission Factors*, Table 1.4-3, "Emission Factors for Speciated Organic Compounds from Natural Gas Combustion," available at <http://www.epa.gov/ttn/chief/ap42/ch01/final/c01s04.pdf>.]

[Footnote 24: If one assumes a more typical tuning profile, the cost per ton would be more akin to \$12,500 to \$25,000 per ton.]

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Comment Excerpt Number: 38

Comment:

Moreover, because such units do not generally deteriorate over time in any meaningful way, EPA's approach, as articulated above, could actually increase emissions because it creates incentives for facilities to switch from NG-fired water heaters to electric water heaters, which are far-less energy efficient.²⁵ Facilities retaining their small NG-fired hot water and process heaters, which EPA has acknowledged sometimes number in the hundreds in a single facility, *see Boiler MACT Reconsideration Proposal*, 76 Fed. Reg. at 80,614, would face a large recordkeeping burden to track the compliance requirements and complete annual compliance certifications.

[Footnote 25: In part, the loss in energy efficiency would result from the electricity that would power those replacement electric heaters coming from coal-fired power plants, instead of from the NG supply that now powers the small units.]

Comment Excerpt Number: 39

Comment: And facilities would incur additional cost to account for such units as part of the Boiler MACT's one-time energy assessment, assuming EPA retains it in the final reconsideration rule.

These burdens would result from EPA's failure to promulgate a *de minimis* exemption because the majority of SIPs exclude these small units from permit-to-install regulations, *i.e.*, they are not presently listed in facilities' Title V permits due to their insignificance, and such units are, likewise, not covered by the scope of the industrial boiler NSPS, *see* 40 C.F.R. § 60.40c(a). There is no rational basis for EPA to not finalize the Boiler MACT consistent with those other regulatory programs. As the HAP emissions of small NG-fired hot water and process heaters with heat input capacities of 10 MMBtu/hr or less are insignificant and the consequent administrative burdens from subjecting them to the Boiler MACT are high, EPA should fashion a *de minimis* exemption to exclude them.²⁶ *See Alabama Power*, 636 F.2d at 360-61, 400.

[Footnote 26: To the extent that EPA decides not to fashion a *de minimis* exemption for NG-fired hot water and process heaters with heat input capacities of 10 MMBtu/hr or less, in the alternative, it should promulgate a *de minimis* exemption for such units at a cutoff of 5 MMBtu/hr or less, consistent with EPA's recognition of such a cutoff as the dividing line for less-frequent tune-ups in the reconsideration proposal. *See Boiler MACT Reconsideration Proposal*, 76 Fed.Reg. at 80,614. To the extent EPA does not promulgate such a *de minimis* exemption, in the alternative, it should issue a NG-fired *de minimis* exemption for NG-fired process heaters at the same cutoff of less than 1.6 MMBtu/hr it already proposed for hot water boilers. *See id.* at 80,652.]

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: Robert D. Bessette

Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 13

Comment: CIBO sought reconsideration, of the definition of "hot water heaters," which are excluded from the Boiler MACT Rule. CIBO said "EPA should expand the definition to include natural gas or distillate fuel oil fired circulating hot water systems no larger than 10MMBtu/hr heat input that are used for domestic (e.g., washroom, cafeteria) or space heating purposes. This would eliminate the need to spend time or effort on units with insignificant emissions."

On Reconsideration, EPA defined hot water heater to include "Hot water boilers (i.e., not generating steam) combusting gaseous or liquid fuel with a heat input capacity of less than 1.6 million Btu per hour." 76 Fed. Reg. 80,652.

CIBO supports the revised definition and the the 1.6 MMBtu/hr limit on the definition EPA could exclude sources with larger capacities and still have no environ consequences..

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

100F. Blast Furnaces [DENIED PETITIONER ISSUE]

Commenter Name: Paul G. Page

Commenter Affiliation: AK Steel Corporation

Document Control Number: EPA-HQ-OAR-2002-0058-3457-A2

Comment Excerpt Number: 2

Comment: The Boiler MACT exempts blast furnace gas-fired boilers and process heaters with the qualification that the unit receives 90% or more of its total annual gas volume from blast furnace gas. AK Steel assumes that this qualification is based on an annual usage rate, but EPA has not specified that in the qualification language and needs to make clear how to determine the 90% threshold. AK Steel further assumes that units capable of qualifying for this exemption are expected to meet these criteria under normal operating conditions. However, blast furnaces periodically are shutdown for extended maintenance outages during which time blast furnace gas is unavailable and supplemental fuel must be used. AK Steel strongly supports the exemption, but we request clarifying language in the exemption to differentiate between periods of blast furnace gas curtailment and normal operations.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: Paul G. Page

Commenter Affiliation: AK Steel Corporation

Document Control Number: EPA-HQ-OAR-2002-0058-3457-A2

Comment Excerpt Number: 3

Comment: Without clarifying language in the exemption, the 90% provision creates a compliance dilemma. One of our facilities currently uses fuel oil as a supplemental fuel for its blast furnace gas-fired boilers. Under normal operations, the facility can clearly demonstrate compliance with the 90% exemption qualification provision. However, AK Steel is concerned that if the facility is required to verify this "compliance status" with the exemption qualification on an annual basis, some given year could conceptually demonstrate that the facility does not qualify for the exemption. For example, if the blast furnace were to be shutdown for an extended maintenance outage or due to reduced customer demand, but the boilers were still needed for some minimal output such as comfort heating, then the exemption qualification demonstration may not be as certain as under normal operating conditions. Under this scenario even on an annual basis, the percentage of fuel oil usage would significantly increase and the percentage of blast furnace gas would significantly decrease. If the outage took place in January through March of the year, AK Steel would not know whether it met the exemption qualification until January of the following year and by that time normal operations would be in place. Assuming the facility did not meet the 90% exemption criteria for this hypothetical year, under the current proposed rule, the blast furnace gas-fired boilers would become liquid-fired boilers. However, it would not be possible for the facility to demonstrate compliance with the liquid-fired boiler requirements when they would be operating as blast furnace gas-fired boilers under normal process operations by the time the determination was made.

AK Steel believes that EPA simply overlooked this potential situation and does not intend to regulate blast furnace gas-fired boilers or process heaters under this scenario. Therefore, we encourage EPA to clarify the exemption criteria language for a blast furnace gas-fired boiler or process heater to stipulate that if it meets the 90 percent threshold during normal operations, then the unit will retain its status as a blast furnace gas-fired boiler independent of the volume of supplemental fuel it uses during periods of blast furnace gas curtailment. EPA should also take into consideration that it is to our economic advantage to use as much blast furnace gas as possible, whenever possible, and to minimize the use of supplemental fuel.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Commenter Name: Peter Pagano

Commenter Affiliation: American Iron and Steel Institute (AISI)

Document Control Number: EPA-HQ-OAR-2002-0058-3490-A1

Comment Excerpt Number: 8

Comment: Once a boiler unit qualifies as a "Blast Furnace Gas Fuel Fired Boiler," that status should apply and not change even during times of blast furnace gas curtailment.

The Boiler MACT exempts blast furnace gas fuel- fired boilers and process heaters provided that the unit receives 90 percent or more of its total annual gas volume from blast furnace gas. Units capable of qualifying for this exemption must meet these criteria under normal operating conditions. However, for various operating reasons, iron and steel plants are susceptible to blast furnace gas curtailment periods, during which time sufficient blast furnace gas is not available to produce the plant's required steam or electricity normally generated by the blast furnace gas-fired boilers, and supplemental fuel must be used. AISI strongly supports the exemption, but we request clarifying language on the distinction between periods of blast furnace gas curtailment and normal operations.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Commenter Name: Peter Pagano

Commenter Affiliation: American Iron and Steel Institute (AISI)

Document Control Number: EPA-HQ-OAR-2002-0058-3490-A1

Comment Excerpt Number: 9

Comment: The 90 percent provision creates a compliance conundrum. For example, blast furnace gas-fired boilers may use fuel oil as a supplemental fuel. Because the current Reconsidered Rule only contemplates backward-looking qualifications, iron and steel facilities must determine at the end of the year whether a unit used blast-furnace gas 90 percent of the time on average, inclusive of blast furnace gas curtailment periods. If a unit did not meet the criteria as determined after the fact, it is impossible to retroactively demonstrate compliance with the liquid-fuel requirements after the unit was operated as a blast-furnace gas boiler. We, therefore, seek clarifying language that if a unit qualifies as a blast furnace gas fuel-fired boiler or process heater because it meets the 90 percent provision during normal operations, it should be able to

retain its status as a blast furnace gas fuel-fired boiler even if it uses a supplemental fuel during periods of blast furnace gas curtailment.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

100G. Exhaust Used in Direct-Fired Process Heaters [DENIED PETITIONER ISSUE]

Commenter Name: Traylor Champion

Commenter Affiliation: Georgia-Pacific LLC (GP)

Document Control Number: EPA-HQ-OAR-2002-0058-3465-A1

Comment Excerpt Number: 23

Comment: Since these integrated systems serve multiple purposes, this gives rise to the potential regulatory applicability question as to whether operation of these systems results in the indirectly-heated portion of the drying system and the thermal oil system exhaust being subject to the requirements of the Boiler MACT rule as a process heater in addition to the PCWP MACT requirements. The pollutants generated from the drying process and the pollutants generated from the combustion process are part of the same exhaust stream which is ultimately exhausted to the atmosphere at a single location. Since integrated wood-fired heat sources which also provide a relatively small amount of indirect heat to a thermal oil heater or boiler are relatively common in the composite wood products manufacturing industry, this issue was anticipated during the rulemaking process for both the PCWP and the vacated Boiler MACT rules.

Accordingly, the term *Process Heater* as proposed in the current Boiler MACT rule is defined as “an enclosed device using controlled flame, and the unit’s primary purpose (*emphasis added*) is to transfer heat indirectly to a process material (liquid, gas, or solid) or to a heat transfer material for use in a process unit, instead of generating steam. Process heaters include units heating hot water as a process heat transfer medium. Process heaters are devices in which combustion gases do not come into direct contact with process materials.” The combustion gases involved in indirect heat transfer for the more typical integrated heat sources are routinely re-combined with the heat source exhaust and direct-fired into the drying process where they come into direct contact with the process materials, so their exclusion from the definition is very clear. For the two GP facilities, however, the fact that a portion of the hot air to the drying process is indirectly heated and the fact that the exhausts from the indirectly heated hot oil units are not sent through the drying system has resulted in some confusion over their appropriate categorization. As noted above, the Wellons Energy System combustion gases at these facilities normally come in direct contact with the rotary strand dryers’ process materials (process exhaust gases from the drying process). Accordingly, their design, function, and emission characteristics are vastly different from boilers or process heaters as defined under the Boiler MACT rule. As such, we believe these units are more appropriately covered under the PCWP MACT given that their primary purpose is to support the operations that are covered under that rule in both serving as the heat source required for the drying process and as the control device for the pollutants generated in the drying process.

The applicability determination for the two GP units would be made less complicated if EPA incorporated the statement contained in the preamble into the proposed rule definition of a process heater. In the statement, EPA states that in this proposed rule, “process heaters are defined as units in which the combustion gases do not directly come into contact with process material or gases in the combustion chamber (e.g. indirect fired)”. However the definition only contains the term “process material” but does not include the term “gases” which should be added to the definition. With this change, it would be clear that these systems’ incorporation of all the drying process gases into the integrated wood-fired heat source prevented their classification as “process heaters”. Furthermore, since all pollutants generated from these operations are exhausted to the atmosphere via a single location under normal operations, it would be impossible to segregate the pollutants generated from the source that could potentially be subject to Boiler MACT requirements from the sources that are covered under PCWP MACT requirements. Additionally based on the above-described facility-specific operational conditions at these facilities, GP has already addressed the operation of these integrated systems as part of the overall PCWP MACT compliance program. [See submittal for process flow diagram]

GP urges EPA to:

- b. Include in the preamble to the final rule a determination that Wellons Energy Systems are clearly regulated under the PCWP MACT and not under Boiler MACT, as discussed above.
- c. Revise the proposed definition of process heater in §63.7575 to include the preamble language of “gases” as discussed above. The revised definition should read as follows:

“Process heater means an enclosed device using controlled flame, and the unit’s primary purpose is to transfer heat indirectly to a process material (liquid, gas, or solid) or to a heat transfer material for use in a process unit, instead of generating steam. Process heaters include units heating hot water as a process heat transfer medium. Process heaters are devices in which combustion gases do not come into direct contact with process materials or contain process exhaust gases.”

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

MACT Floor Analysis

3A. MACT Floor Methodology: Statistical Procedure for CO

Commenter Name: John M. Cullen

Commenter Affiliation: Masco Corporation

Document Control Number: EPA-HQ-OAR-2002-0058-3661-A2

Comment Excerpt Number: 4

Comment: EPA proposes to use a 99% upper prediction limit (“UPL”) for CO MACT floor analysis. Masco disagrees with EPA’s decision to use a 99% percent confidence interval versus a 99.9% interval as original proposed. Carbon monoxide emissions have a high degree of variability by comparison to other pollutants and a source is compelled to certify compliance

with the CO limit over all operating conditions except startup and shutdown. EPA's CO MACT floor should account for such variability to the extent reasonably possible. Masco submits that the rationale for the 99.9% confidence interval in the March 21, 2011 Boiler MACT rule remains valid.

Response: For the reasons outlined in the preamble to the December 23, 2011 proposed reconsideration of the rule (See 76 FR 80614), EPA has elected to retain the 99% UPL in its calculation of emissions variability for all subcategories. In addition, EPA is establishing alternative CO limits for those subcategories for which EPA has sufficient data to establish such limits.

Commenter Name: M.L. Steele

Commenter Affiliation: CraftMaster Manufacturing, Inc.

Document Control Number: EPA-HQ-OAR-2002-0058-3814-A1

Comment Excerpt Number: 8

Comment: In its data variability analysis USEPA lowered the CO confidence coefficient from 99.9% to 99% to be consistent with other pollutants. CraftMaster's 15 years of experience with CO GEM's on a biomass-fired unit indicates that the variability of CO is not like other pollutants and we believe the higher confidence coefficient for CO is justified. CO emissions can vary significantly and quickly due to load swings and changes in fuel characteristics such as moisture content, bulk density, etc.

Response: See the response to EPA-HQ-OAR-2002-0058-3661-A2, excerpt 4.

Comment: In the recent MACT Floor memo (ERG 2011b), the revised floor analysis included an important difference from the analysis conducted for the March 2011 final Boiler MACT rule. The revised memorandum stated "Statistical variability was incorporated using the 99% UPL for CO (a change from the 99.9% UPL that was used for CO in the final rule), in order to be consistent with the UPL statistic selected for the other regulated pollutants." In the final rule preamble, EPA concluded "In this final rule, we have determined that 99 percent UPL is appropriate for fuel based HAP and a 99.9 percent UPL is appropriate for combustion dependent HAP (i.e., CO)." Also, "For CO, EPA considered both quantitative and qualitative comments received during the public comment period on how CO emissions vary with load, fuel mixes and other routine operating conditions. After considering these comments EPA determined that a 99.9 percent confidence level for CO would better account for some of these fluctuations." The significantly higher variability associated with emissions of CO from an industrial boiler as compared to HCl, Hg, filterable particulate matter, and total selected metals is well documented, and a higher level of confidence limit assigned to the UPL for CO is appropriate. The need to be consistent with the UPL statistic for the other regulated pollutants is not relevant. In cases where additional Method 10 tests were obtained for boilers already identified as best performers, the variability among tests and test runs was seen to be very large. Furthermore, analysis of CO

CEMS data confirm that a limit based on the 99% UPL does not adequately reflect variability in CO emissions even during periods of steady operation at relatively high loads. NCASI firmly believes that UPLs with 99.9% confidence limits are necessary and appropriate to address the documented variability of CO emissions from industrial boilers, especially boilers burning biomass fuels.

Response: For a response to the claim that a 99.9% confidence interval is preferred over a 99% confidence interval for CO emissions due to inherent variability, see comment EPA-HQ-OAR-2002-0058-3661-A2, excerpt 4. The EPA disagrees that the need to be consistent with confidence intervals for the other regulated pollutants is irrelevant because emission limits for all pollutants must be met simultaneously; identical confidence intervals between pollutants does not allow the emission limits for any of the regulated pollutants to take precedence over the others.

The commenter did not provide the analysis conducted on CO CEMS data based on a 99% UPL, thus EPA cannot respond to the claim that the 99% UPL does not adequately reflect variability in CO emissions even during periods of steady operation at relatively high loads.

Comment: Selection Of Confidence Level For CO

EPA is proposing to revise the CO MACT floor analysis to use a 99 percent confidence interval as opposed to a 99.9 percent confidence interval to determine the UPL.

ACC does not agree with EPA's justification in using a 99 percent confidence interval "for consistency's sake." Carbon monoxide emissions have a much greater degree of variability than other pollutants, and EPA is requiring sources to certify compliance with the CO limit under all operating conditions except startup and shutdown. Therefore, EPA's CO MACT floor should account for variability to the maximum extent possible. The small amount of data used in EPA's analysis is not representative of the range of expected operations and true variability that is expected from the best performers. The emissions data used to set the CO limit is based on stack testing performed during maximum load conditions, only providing a snapshot of the day-to-day operations of each source.

EPA cited several reasons why it used a 99.9 UPL to set the CO MACT floor in the preamble to the Final Boiler Rule, including fuel moisture content after a rain event, elevated moisture in the air, and fuel feed issues or inconsistency in the fuel. (76 Fed. Reg. 15628.) The reasons are still valid now, and therefore, EPA should retain the use of the 99.9 UPL for calculating CO limits in its reconsidered final rule.

Response: For a response to the claim that the same confidence interval is not required for all regulated pollutants, please see EPA-HQ-OAR-2002-0058-3505-A1, excerpt 19. For a response to the claim that a 99.9% confidence interval is a better choice to account for inherent variability of CO emissions, please see comment EPA-HQ-OAR-2002-0058-3661-A2, excerpt 4. EPA

acknowledges that emissions of CO are inherently more variable than emissions of the other regulated pollutants, but EPA also believes that the 99% UPL appropriately accounts for the variability in emissions of all of the regulated pollutants.

Comment: EPA is proposing to revise the CO MACT floor analysis to use a 99 percent confidence interval as opposed to a 99.9 percent confidence interval to determine the UPL. We do not agree with EPA's rationale for reverting to a 99 percent confidence interval. EPA states (76 Fed. Reg. 80614).

We do not agree with the justification to use a 99 percent confidence interval for consistency's sake. Carbon monoxide emissions have a much greater degree of variability than other pollutants and a source must certify compliance with the CO limit over all operating conditions except startup and shutdown; therefore, EPA's CO MACT floor should account for variability to the maximum extent possible. The small amount of data used in EPA's analysis is not representative of the range of expected operations and true variability that is expected from the best performers. The emissions data used to set the CO limit are based on stack testing performed during maximum load conditions, only providing a snapshot of the day-to-day operations of each source.

The reasons for using a 99.9 UPL for setting the CO MACT floor cited in the preamble to the March 2011 Boiler MACT rule remain valid: *76 Fed. Reg. 15628*. Therefore, EPA should retain the use of the 99.9 percent UPL for calculating CO limits.

Response: For a response to the claim that the same confidence interval is not required for all regulated pollutants, please see comment EPA-HQ-OAR-2002-0058-3505-A1, excerpt 19. For a response to the claim that a 99.9% confidence interval is a better choice to account for inherent variability of CO emissions, please see comment EPA-HQ-OAR-2002-0058-3661-A2, excerpt 4.

Commenter Affiliation: Pennsylvania Department of Environmental Protection (DEP)

Document Control Number: EPA-HQ-OAR-2002-0058-3507-A1

Comment Excerpt Number: 13

Comment: In the final rule, the EPA selected the use of a 99.9 percent confidence interval for calculating the MACT floor for CO emissions, which was challenged by a petitioner requesting reconsideration of this selection given the fact that the EPA used a 99 percent confidence interval for all of the other emission limits in the final rule. The petitioner pointed out that if the data are highly variable, the 99 percent confidence interval should adequately reflect the variability of emissions (e.g. variability during startup and shutdown events) as well as for the data sets of the other pollutants. Therefore, EPA has proposed to use a 99 percent confidence level for CO in order to maintain a consistent methodology in the development of the MACT floors for other pollutants, and because optional CO CEMS-based limits have also been proposed that would allow sources additional flexibility in meeting the requirements of the proposed rule.

The DEP believes that it is important to be consistent in the development of the MACT floors for all of the pollutants and therefore agrees with the EPA for using the same 99 percent confidence level in setting the CO emission limit.

Response: EPA appreciates the commenter's support for the use of the 99% UPL. For a response to the claim that the same confidence interval is not required for all regulated pollutants, please see comment EPA-HQ-OAR-2002-0058-3505-A1, excerpt 19. For a response to the claim that a 99.9% confidence interval is a better choice to account for inherent variability of CO emissions, please see comment EPA-HQ-OAR-2002-0058-3661-A2, excerpt 4.

Comment Excerpt Number: 8

Comment: The proposed CO limits continue to ignore the reality of CO control among the diverse universe of boilers being regulated, even with subcategorization; the documented limited benefit of CO control below a threshold of 300 ppmv (provided in other's comments) for control of organic HAP; and the adverse affects of operating a unit to minimize CO to low levels, which for example include increased NOx emissions and lower boiler efficiency, requiring increased fuel use for the same output. The proposed limits should be adjusted to reflect the true boiler operating variability, particularly with load following units; and the inverse relationship with nitrogen oxides, a pollutant of high concern. For some subcategories, the CO limits proposed remain unachievable, in large part because EPA has not taken into account the true variability of even the best performing units and has proposed using a 99 percent confidence interval instead of 99.9% on one of the most highly variable emissions, one that is a surrogate and is not even a HAP. EPA should revert to its position in the preamble to the March 2011 rule in this regard, and maintain the 99.9% UPL, and it should not require CO limits less than 300 ppmv as a surrogate for HAP control for any boiler units.

Response: EPA acknowledges the relationship between CO and NOx emissions. In its calculation of CO MACT floor emission limits, EPA investigated the relationship between reported CO and NOx emissions for each of the top performing units. Certain CO tests were disqualified from MACT floor calculations on the premise of high NOx emissions. Further detail on the relationship between CO and NOx and how it affected the CO emission limitations can be found in the memo entitled, "Revised MACT Floor Analysis for the Industrial, Commercial, and Institutional Boilers and Process Heaters NESHAP" in the docket.

EPA disagrees with setting CO emission limitations no lower than 300 ppmv given the volume of reported CO emissions testing and continuous emissions monitoring data reported below this threshold. In addition, preliminary data from surrogacy testing conducted at EPA's Multi-pollutant Control Research Facility show a downward trend in PAH emissions with decreasing CO emissions below 300 ppm. A presentation entitled "Hazardous Air Pollutant (HAP) Emissions Testing in the EPA Pilot-Scale Combustion Research Facility" which presents this preliminary data can be found in the docket.

For a response to the claim that a 99.9% confidence interval is a better choice to account for inherent variability of CO emissions than a 99% confidence interval, please see comment EPA-HQ-OAR-2002-0058-3661-A2, excerpt 4.

Comment: EPA's MACT Floor Methodology is Flawed

AMP has expressed concern with EPA's MACT floor methodology in its previous comments, and suggested ways EPA could remedy those issues to calculate MACT floors that are both achievable and supportable. EPA has failed to take steps within its discretion to help set achievable emission limits that can be met by all units subject to this rulemaking- including small municipal utilities. AMP asks that EPA take this final opportunity to rectify the persistent

flaws in its MACT floor methodology and adopt *achievable* emission limits as the Clean Air Act requires.

Response: The methodology for establishing the MACT floor is outside the scope of this reconsideration with the exception of a few discrete items related to the methodology that EPA specifically requested comment on in its December 23, 2011 proposal. EPA solicited and responded to comments regarding the statistical analysis used to develop the alternative CO CEMS-based emission limitations. Please see the responses to those comments, as well as the memo titled, "CO CEMS MACT Floor Analysis (May 2012) for the Industrial, Commercial, and Institutional Boilers and Process Heaters NESHAP" in the docket for discussion on the changes in methodology for the alternative CO CEMS-based emission limits. For discussion on the request for a 99.9% UPL in lieu of a 99% UPL, please see comment EPA-HQ-OAR-2002-0058-3661-A2, excerpt 4.

Comment: Some boilers determined by EPA to be best performers for CO based on 3 one hour average stack test runs were also equipped with CEMs for CO, either permanently as in the case of the biomass FBC units at GATemple InlandRome and ALIPCourtland, or temporarily as in the case of the biomass stoker unit at MSGPNewAugusta. An analysis of the hourly average CEM data for these units shows that several three hour block averages would have exceeded the currently proposed 3 hour average 99% UPL limits of 370 ppm for biomass FBCs and 790 ppm for biomass stokers at 3% O₂. Thus even a best performing boiler is likely to have some 3-hour average CO concentrations above a 99% UPL value.

Response: The alternative CO CEMS-based limits referenced by the commenter are ten day rolling averages and not three hour block averages. The ten day averaging period is designed to address concerns regarding variability such as that in this comment.

3B. MACT Floor Methodology: Non-Continental Liquid

Commenter Name: Matthew Todd

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 63

Comment: Since the non-continental liquids subcategory has less than 30 units, the PM emission limitation must be calculated based on the procedures typical of such subcategories.

The proposal establishes a numerical emission limit for filterable PM of 0.0080 lb per MMBTU of heat input for new, reconstructed, and existing BPH. These limits were established based on data provided by non-continental sources since the March 21, 2011 rule was promulgated using the EPA's paradigm for subcategories that contain more than 30 units.

However, with the shutdown of the HOVENSA refinery in February 2012²³, this subcategory contains less than 30 units and the normal EPA approach to establishing a limit for such a subcategory is to use the average of the available test data and then adjust statistically for variability. The test data for this subcategory confirms there is considerable variability between non-continental BPH, which reflects the differences in the fuels such units must feed (i.e., fuels produced in their own refining operations) and the different burner designs that result from having to have the capability to burn both liquid and gaseous fuels. The Tesoro boiler can burn either liquid or gaseous fuels, but not at the same time; while the Chevron process heater can fire both liquid and gaseous fuels in the same burners at the same time. The Tesoro boiler also uses burners that were designed to minimize opacity while the Chevron source has newer burners designed to minimize NO_x formation. Therefore, there are important technical differences that account for some of the observed variability in the available test results. It is critical that the variability reflected in the test reports be appropriately addressed in developing the PM limitation for the less than 30 unit non-continental liquids subcategory.

Applying the same approach to variability to these non-continental liquid subcategory units as was done for the continental liquids subcategory, and as described in ERG's floor memo results in a calculated upper prediction limit (UPL) of 0.36 lb per MMBTU of heat input at a 99% confidence level. The calculation of these recommendations is shown in Attachment 1 [see submittal for Attachment 1. PM Variability Calculations] in the same format used by EPA in the floor analysis for other <30 unit subcategories. Basing the PM standard on this calculated UPL is a reasonable approach for EPA to use in addressing the variability of PM emissions from these specific units. The reasonableness of this PM limit is supported by a recent Chevron test result of 0.22 lb/MMBTU (Attachment 3) [see DCN EPA-HQ-OAR-2002-0058-3677-A3 Attachment 3. Chevron, Kapolei, Hawaii, PM Boiler Stack Test Results]. Although the recent Chevron test was done for operation information purposes and was not an official test, the results support the reasonable outcome of this EPA variability calculation procedure.

[Footnote 23: On Wednesday, January 18, 2012, HOVENSA announced its refinery will be shutting down operations over the next 3 week period. HOVENSA will continue to operate the marine terminal as an oil/product storage and distribution facility. All refinery specific processing units will be shutdown. As a 525,000bpd facility, HOVENSA operated 23 oil-burning heaters and boilers. As an oil/product storage and distribution facility HOVENSA will most likely operate one boiler which could potentially burn oil.]

Response: EPA acknowledges that the HOVENSA refinery in St. Croix has shut down, and the inventory of major source industrial, commercial, and institutional boilers and process heaters has been updated accordingly. With the closure of this facility, EPA agrees that there are less than 30 applicable boilers or process heaters designed to burn liquid fuels located in non-continental states or territories. The 99% UPL for all regulated pollutants for the non-continental liquid units have been recalculated based on the reduced number of units in the subcategory, and following the procedures outlined in the memorandum titled "MACT Floor Analysis for the Industrial, Commercial, and Institutional Boilers and Process Heaters NESHAP - Major Source" located in the docket. The recalculated UPLs incorporate all additional emissions testing data provided to EPA during the comment period.

Commenter Name: Matthew Todd

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 66

Comment: Since the non-continental liquids subcategory has less than 30 units, the CO emission limitation must be calculated based on the procedures typical of such subcategories.

As noted previously, the non-continental liquids subcategory will have less than 30 units. Thus in accordance with Section 112(d)(3)(B) of the CAA, the CO standard for existing sources should be based on the best performing 5 sources for which the Administrator has emissions information. Consistent with ERG's MACT floor memo and its CO measurement error memo, the calculated 99% UPL for CO based on all of the individual runs for the top performing three sources with CO stack test data available (Chevron's F-5103 and Tesoro's SG1102 and SG1103) results in approximately 140 ppm CO at 3% O₂. The calculation of these recommendations is shown in Attachment 2 [see DCN EPA-HQ-OAR-2002-0058-3677-A4 CO Variability Calculation] in the same format used by EPA in the floor analysis for other <30 unit subcategories.

Response: For a response to the comment that, due to the closure of the HOVENSA refinery in St. Croix, there are now fewer than 30 non-continental liquid units and MACT Floors should be adjusted accordingly, see comment EPA-HQ-OAR-2002-0058-3677-A2, excerpt 63.

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 64

Comment: The top ranked BPH used in establishing the PM emission limits for this subcategory is the Tesoro boiler SG-1102. However, the test data for that unit was obtained with the unit operating at 40% of load (representative of typical operations for that particular boiler). Operation at low load does not provide PM results that represent the high rate operation that is the usual basis for performance tests and that is typical for other BPH in the subcategory. Low load operation results in increased residence time as compared to full load operations and could result in lower PM_{2.5}. Coen Company, a major burner manufacturer, has provided the following graph [see submittal graph of Boiler PM Emission Factors vs. Load %] 26 illustrating the significant impact of load. The chart uses data from one boiler on the East Coast firing heavy fuel oil that has 2% Sulfur, 0.15% Ash, and 5% Asphaltene. The PM was measured by EPA test method 5 with filter box at 250°F.

In consideration of the best performing source for establishing the PM standard for new sources in the non-continental liquid subcategory, it is important to note that the fuel for the top ranked unit (Tesoro's SG-1102) is specific to the Tesoro refinery and cannot be reasonably purchased or obtained by other sources in the subcategory. In addition, this test was performed at 40% of maximum load and, as discussed above, such operation could result in PM emissions less than

expected at higher loads. Consistent with the HCl MACT floor for new boilers designed to burn liquid fuel, the Hg MACT floor for new boilers designed to burn solid fuel, and the CO MACT floor for new fluidized bed boilers designed to burn biomass, and as described in ERG's previously-cited memo (page 24), we request that EPA utilize the next lowest emissions as the basis for the floor calculations. Using the second lowest test average for the PM MACT floor for new non-continental liquid BPH results in 0.078 lb per MMBTU, based on the calculated 99% UPL. The calculation of these recommendations is shown in Attachment 1 [see DCN EPA-HQ-OAR-2002-0058-3677-A3 Attachment 1. PM Variability Calculation] in the same format used by EPA in the floor analysis for other <30 unit subcategories.

[Footnote 25: The carbon burnout mechanism from oil combustion is very complex. In general, the carbon loss is strongly influenced by furnace residence time. For example, the furnace may be designed for 0.5 seconds residence time at maximum firing conditions. When this furnace is operating at 50% of maximum load, the residence time would be almost doubled. This enables carbon particles to spend more time in hot zone and help burn better.]

[Footnote 26: Private communication (E-Mail), Vijay Mandayam, Director, Combustion System Group, Coen Company, Inc. to Clay Freeberg, Chevron Corporation, February 1, 2012.]

Response: EPA disagrees that the low-load PM emissions testing data should be disregarded. Emissions from low load operations are incorporated in the MACT floor analysis for multiple subcategories (for example, Suspension Burners designed to combust biomass/bio-based solids). EPA also disagrees that the test should be disregarded on the premise of site-specific fuel; several facilities located in non-continental states or territories combust site-specific fuel, and disregarding tests combusting site-specific liquid fuel for all applicable non-continental boilers would minimize the available emissions testing data for the subcategory. EPA has incorporated the additional emissions testing data submitted by Tesoro for the top performer. The variability between the previously reported and new emissions testing data have resulted in a less stringent PM emission limitation for boilers designed to combust liquid fuel located in non-continental states or territories.

Commenter Name: Matthew Todd

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 68

Comment: Test data from Tesoro's SG1102 may not represent the CO emissions achieved in practice for other non-continental liquids subcategory BPH. In addition to the performance test being conducted on the unit at 40% load, the fuel consumed during the test is specific to the Tesoro refinery and cannot be reasonably used by other sources in the subcategory. As such, we request that EPA utilize the next best source to determine the CO floor for new sources, or Chevron's F-5103 unit, which results in a new source standard of 51 ppm CO at 3% O₂. The calculation of these recommendations is shown in Attachment 2 [see DCN EPA-HQ-OAR-2002-0058-3677-A4 Attachment 2] in the same format used by EPA in the floor analysis for other <30 unit subcategories.

Response: For a response to the comment that Tesoro's boiler SG1102 test data are not representative of other non-continental liquid units due to low-load operation and site-specific fuel, please see comment EPA-HQ-OAR-2002-0058-3677-A2, excerpt 64. EPA has incorporated additional CO emissions testing data for the top performer into the recalculation of the 99% UPL for the subcategory. The variability between the previously reported and new emissions testing data resulted in an increased CO emission limitation for boilers designed to combust liquid fuel located in non-continental states or territories.

3C. MACT Floor Methodology: Non-Detect Values

Commenter Name: James Pew

Commenter Affiliation: Earthjustice, Clean Air Council, Partnership for Policy Integrity

Document Control Number: EPA-HQ-OAR-2002-0058-3511-A1

Comment Excerpt Number: 14

Comment: EPA exacerbated these problems with the approach to “non-detect” test results that it took in 2010. That approach continues to be unlawful and arbitrary for all the reasons given in the 2010 comments, which are incorporated by reference as if fully stated herein and reiterated with respect to the agency’s 2011 final rule and reconsideration proposal. 2010 Comments at 22.

Now, EPA further exacerbates the other flaws in its variability analysis by arbitrarily assuming that individual sources’ actual emission level are three times higher (*i.e.*, worse) than an arbitrarily selected “method detection level”(MDL) whenever their emissions fell below this level. That bizarre assumption follows a series of decisions that were unlawful, arbitrary, or both. First, EPA itself encouraged sources to report tests below method detection levels by advising them during the data collection phase that they did not need to use specific (or even adequate) criteria for testing and assuring them that the agency would address the absence of precise data in its rulemaking. As a result of EPA’s stated willingness to accept data that were not precise, many sources used testing methods that were not precise and that yielded non-detect results at emission levels that could have been precisely measured had these sources chosen to use more precise testing methods – which are available and have been available for many years. Second, EPA now claims that any test below the mean detection level for all the alleged best sources in every subcategory – a level the agency now dubs the “representative detection level” or “RDL” – is a non-detect, whether that test really is a non-detect or not. Third, for all of the alleged non-detect results, EPA simply fills in a fictional replacement value equal to 300% of the RDL, unless that number would be lower than the floor. Nowhere does the agency offer any explanation for its apparent assumption that the 99% UPL it applies to each source’s emission test results does not already fully account for that source’s variability. Further EPA uses this 300% multiplier even though it does not and cannot provide any rational basis for assuming that all test results below the RDL actually reflect emission levels 300% higher than the RDL (even assuming *arguendo* that that they are higher than the RDL at all). All the agency offers on that subject is a conclusory assertion that multiplying the RDL by three approximates a 99% UPL for a data set of seven or more values, without either supporting that claim or explaining why it is even relevant. For these reasons alone, EPA’s floors do not reflect the best sources’ actual emission levels and are unlawful and arbitrary. Moreover, it is arbitrary – and amounts to a sabotage of the rule – for EPA to encourage sources to submit imprecise emissions data and then

use the resulting imprecision in the data it receives as an excuse to grossly inflate the emission standards.

Response: The commenter is incorrect that EPA's test method specifications during the ICR data collection encouraged the collection of data below the detection level. During the data collection request, we specified sampling times and/or volumes where appropriate. These times/volumes were calculated to provide reasonable assurance of detecting compounds that were present. EPA manual testing methods are designed to be conducted over an hour of sampling, but may be conducted with extended testing times to collect additional sample volume and provide for increased measurement sensitivity. Our guidance to ICR respondents for reporting pollutant emissions used to support floor development has been to require them to provide test-specific method detection limit (MDL) values in the reports. Also, in accordance with our guidance, source owners are to identify emissions data which were measured below the MDL and report those values as equal to the MDL determined for that test. This is done to provide for minimum pollutant concentrations when evaluating the emission floor, otherwise the measured concentration values as reported in the testing were used in calculating the floor.

Not all test reports that include instrumental test method data included test-specific MDL values. In cases where the report does not include test-specific MDL data measured with an instrumental test method, the test-specific MDL values were determined using the reported calibration span values. The EPA accounted for the effect of measurement imprecision in calculating a floor using a database that includes reported MDL data by first defining an MDL value that is representative of the data to be used in establishing the floor or emissions limit. This value is termed the representative method detection limit (RDL). The second step in the process was to calculate three times the RDL and compare that value to the calculated floor or emissions limit. The value of 3* RDL is necessary to gauge the performance test methods' level of quantitation, or that point at which the test method begins to return values within expected levels of confidence. The EPA recognizes that values between the method detection limit and the level of quantitation have more uncertainty than values at or above the level of quantitation, therefore we make this determination to provide a value to the floor setting decision process that describes the level of quantitation for the compliance determination method. If 3*RDL was less than the calculated floor or emissions limit calculated from the upper prediction limit (UPL), we concluded that measurement variability was adequately addressed and the calculated floor or emissions limit was not adjusted. If, on the other hand, the value equal to 3*RDL was greater than the floor value or emission limit, we concluded that the calculated floor or emission limit does not account entirely for measurement uncertainty, and the value equal to 3*RDL was substituted for the adjusted floor or emissions limit (i.e., increasing the floor to be equal to 3*RDL). This adjusted value ensures measurement uncertainty is adequately addressed in the floor or the emissions limit and that the test method used to determine compliance with the emission standard will be appropriate for quantitative determination of emissions concentrations at, and above, the level of the emission standard.

Originally, the floor was calculated by multiplying individual tests by a factor of three when the result was below the RDL. This methodology has been corrected in the final rule to the standard methodology described above.

See the memo from Peter Westlin to Docket EPA-HQ-OAR-2002-0058, April 10, 2012, for further information on floor determination for instrumental test methods.

Comment: The first step in any scientifically sound measurement process is to ensure that the procedures employed are sufficiently precise to determine meaningful differences. In response to questions from industry as to whether they should extend sampling periods to ensure more precise results, EPA advised them that they did not need to and that the agency would address it the final rulemaking. EPA defines the method detection limit as, "the minimum concentration of a substance that can be measured and reported with 99% confidence that the analyte concentration is greater than zero and is determined from analysis of a sample in a given matrix containing the analyte." Where the "adjusted" average emissions of the top 12 percent is "near" the method detection level, EPA now proposes¹⁰ to increase the calculated average so that the floor is not less than 300 percent of the detection level. To justify this increase EPA observes that when measurements are near the detection level the measurement uncertainty can be as high as (+/-) 40 percent, while such uncertainty is reduced to (+/-) 15 percent if the measured value is three times (300 percent) the detection level. However, since such measurement uncertainties are necessarily part of the overall variability determined in step one of EPA's procedure, there is no need or basis to substitute this arbitrary figure for the actual emission data that the statute requires be used. Additionally, it also makes no technical sense to introduce a known error of 300 percent in the MACT floor in order to avoid a possible error of 25 percent¹¹ in any individual measurement. This step constitutes yet one more bias in favor of allowing higher levels of HAP emissions. In this rulemaking EPA proposes to compound this error by "adjusting" the detection level reported by the laboratory in accordance with established protocols, even where EPA has no information that the detection levels reported by the laboratory are incorrect.

[Footnotes]

(10) EPA employed this technique in the cement kiln New Source Performance Standard rule.

(11) This is the difference between the potential error at the detection level and that at three times the detection level.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3511-A1, excerpt 14.

We disagree with the commenter assertion that EPA, knowing many results would be at or below detection limits if it only required sample periods of one hour per run, responded to industry that the sources need not extend sample periods to ensure more precise results. In fact, enclosure 1 to the ICR letter requesting testing stated the methods and sampling times or volumes. For example, for sampling for metals, it was stated that EPA Method 29 be used and to collect a minimum volume of 4.0 cubic meters or have a minimum sample time of 4 hours per run. For dioxins/furans, enclosure 1 specified that EPA Method 23 be used and to collect a minimum volume of 2.5 cubic meters or have a minimum sample time of 4 hours per run.

Comment: In the December 23, 2011 proposal EPA explained that to establish the stack test-based emission standards for different pollutants, EPA followed the following procedure:

1. EPA utilized the data obtained from two different ICRs and any additional data provided by source operators to identify the best performing sources for each source subcategory and for each pollutant.
2. Using the data for the best performers, EPA calculated the 99 percent UPL for each pollutant and source subcategory.
3. The above calculated values were compared to three times the representative detection limit (RDL) for each pollutant, and the emission standards were set at the higher of the UPL or the three times RDL value.
4. EPA calculated the RDL for each pollutant by averaging the detection limits for that pollutant as reported by the best performing sources in all subcategories.

We support EPA's decision to multiply the representative detection limit by three to determine the lowest level at which the emission standard for any pollutant could be set.

Response: The EPA thanks the commenter for their support for multiplying the representative detection limit by three.

Comment: Several EPA Method 10 CO concentration measurements for boilers in the Boiler MACT floors for various subcategories are at the low end of the range of the span gas concentration used to calibrate the Method 10 analyzer. In a January 20, 2011 EPA memo (EPA 2011a) Peter Westlin addressed some of the concerns with Method 10 measurement uncertainty at low concentrations. By way of an example, the memo explains how a calibration span value of 25 ppm results in an instrumental detection level of 0.9 ppm. The memo then states "Consistent with the methodology we applied for non-instrumental methods, discussed in section C of this memorandum, where we established limits no less than three times the MDL, this estimated measurement error value of about 1 ppmv would translate to a limit of 3 ppmv...One outcome of this assessment is recognition that the site-specific estimated measurement errors in some cases may be higher than some of the reported levels. Therefore, for each emission test used in the MACT floor calculations we substituted the site-specific estimated measurement error for reported values below those values in order to ensure the quality of the data used to set the floors."

In the 2009 ICR, EPA specified that all measurements below the method detection limit should be reported as being equal to the detection limit. Using such reported values, EPA identified the best performing sources in each subcategory and then calculated the UPL for each pollutant for each subcategory. The UPL estimated from these data was compared to three times the representative detection level (RDL) for each pollutant. The RDL for each pollutant was determined using the average detection limit achieved by the best performing sources which constituted the floor. The most recent procedure for calculating RDLs is detailed in a November 17, 2011 memo by Peter Westlin (EPA 2011b).

EPA then compared the UPL value to three times the RDL value for each pollutant. If $3 \times \text{RDL}$ was greater than the calculated UPL, the $3 \times \text{RDL}$ value became the emission standard in place of the UPL value.

NCASI believes the procedures followed by ERG (2011a) to determine when to replace a reported Method 10 CO concentration with the estimated measurement error (EME) prior to calculating the UPL were not consistent with the Westlin guidance. ERG replaced any concentration (at 3% O₂) less than three times the EME with three times the EME. First, it seems the actual CO concentration at stack O₂ should have been compared to the EME since the CO concentration measured by the analyzer is at stack O₂, not 3% O₂. Second, the measured CO concentration should be compared to the EME, rather than three times the EME. Only values below the EME should be set to the EME. Furthermore, a comparison of the calculated UPL with three-times the EME value, which would represent the quantitation limit (QL) of the instruments used at the sources constituting the floor, was never carried out to see if the UPL needed to be replaced by this estimate (although for CO the UPLs were invariably much higher than the QLs).

Response: We have revised the CO floor to account for several errors in the initial calculation. For those tests where oxygen concentrations in the stack were known, the comparison was revised to a stack oxygen basis instead of an oxygen corrected basis. Due to data limitations, the oxygen conditions at the stack were not known for all cases, and in these instances, the comparison was made to the oxygen adjusted values. In the revised analysis, we have corrected the error identified by NCASI by replacing any concentration less than the method detection limit (MDL) with the MDL instead of three times the MDL. Also, the revised UPL equations in the final rule were compared to the three times MDL value.

For further information on how the CO floor was set, see comment EPA-HQ-OAR-2002-0058-3511-A1, excerpt 14.

Comment: The following is a summary of how the 99% UPLs change when the 3 x EMEs are replaced by the respective EME values for various boiler and fuel categories. [See submittal for Table] The 99.9% UPLs are also provided since we believe the 99.9% UPL is more appropriate for determining CO limits. Note that reported concentrations were used when the value at 3% O₂ was above the EME but less than 3 times the EME. The EPA emission database does not contain the stack O₂ concentrations measured during each sampling run, so the comparison to the EME was made with CO concentrations adjusted to 3% O₂. Time did not allow for review of the original sampling reports for the best performers to obtain the CO concentrations measured in the stack to compare to the EMEs.

Response: For a response to issues with the UPL calculation and estimated CO measurement error being compared to measured emissions corrected to 3% oxygen, see comment EPA-HQ-OAR-2002-0058-3505-A1, excerpt 20. For a response to using the 99% UPL for CO instead of the 99.9% UPL, see comment EPA-HQ-OAR-2002-0058-3661-A2, excerpt 4 under the chapter for Methodology: Statistical Procedure for CO.

Comment Excerpt Number: 36

Comment: In the proposed calculations of MACT floors for CO for biomass sources EPA significantly alters the reported data to account for what it styles as “measurement span errors.” This appears to be double counting of variability, since any random errors in the measurement system will be reflected in the variability of the resulting data. Moreover, the method relies on the highest reported values of computed errors rather than an average of those errors.

Response: We agree that variability is accounted for in the measurement data. Data is only adjusted when the floor value falls below three times a reliable method detection limit. For a response to issues with the methodology of setting the CO floor and adjusting the database for variability, see comment EPA-HQ-OAR-2002-0058-3511-A1, excerpt 14. For a response to issues with methodology used to develop the estimated measurement error for CO, see comment EPA-HQ-OAR-2002-0058-3505-A1, excerpt 20.

Comment: EPA should indicate in the final Boiler rule that when calculating TSM emissions based on Method 29 test results or fuel analysis data, if individual metals are non-detect for all 3 test runs or fuel samples, emissions of those metals should be counted as zero.

Response: We believe that when calculating total selected metals emissions based on Method 29 test results or fuel analysis data, if individual metals are below the detection limit, emissions of those metals should be counted at the detection limit. Our process for setting the floor includes consideration of these data at the detection limit and our floor limits are set to be a minimum of 3x this value. EPA method 29 provides for different detection limits for each metal analyte, and when using method 29 to quantify a single analyte, using the detection limit associated with that single analyte would be appropriate. Ergo, when evaluating the data set for TSM we recognize the overall TSM detection limit as the sum of the detection limits of the associated TSM metals. As such, we feel it is appropriate for sources to report data as emitted at the amount of the detection limit as this will not cause a noncompliance issue for the source and this provides incentive for sources to choose better performing testers and labs. We have added language to the final rule to address this issue.

Comment Excerpt Number: 64

Comment: It is not appropriate to treat detection level limited data for purposes of establishing regulatory limits in the same manner as detected values because the uncertainty²² associated with measurements near or below the method detection limits is too high. In setting the standards in this rulemaking, EPA has acknowledged that the emission limit should not be set below the capability of the applicable test method. ACC supports EPA's decision to multiply the method detection limit by three to approximate the representative detection limit for each pollutant. [Footnote 22: Uncertainty here refers to the statistical expression of measurement error, such as defined in ASME Performance Test Code 19.1, rather than an inference of something which is unknown.]

Response: The EPA thanks the commenter for their support of multiplying the method detection limit by three.

For a response on how detection level limited data is handled in establishing floor values, see comment EPA-HQ-OAR-2002-0058-3511-A1, excerpt 14.

Commenter Name: Paul Noe

Commenter Affiliation: American Forest & Paper Association (AF&PA) et al.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 52

Comment: In response to EPA's reconsideration of the Boiler MACT and CISWI standards, NCASI submitted extensive comments to EPA which noted that (1) source emission testing has three components, namely source sampling, sample recovery, and sample analysis, (2) the errors associated with sample collection and recovery are much greater than those associated with sample analysis, and (3) to determine the source test method detection and quantitation limit, EPA procedures must account for the variability associated with source sampling and sample recovery.

These issues were also identified in an ASME report entitled "Reference Method Accuracy and Precision (ReMAP), Phase 1," which examined the precision of selected EPA source emission test methods. The report, which is referenced in the December 23, 2011 EPA proposal, makes several important points: (1) there are both random errors and systematic errors (bias in the measurement process), (2) "the magnitude of random errors associated with extraction and recovery of the sample from the stack might be expected to vary in proportion to stack concentrations," and (3) "estimation of method precision must be based on data from special tests where multiple sampling trains are used simultaneously to determine the stack pollutant concentration." In its proposal, EPA has ignored these issues and considered only the precision of laboratory analytical measurements in establishing method RDLs. We urge EPA to carefully evaluate the method quantitation limited-related issues raised by NCASI in its July 15, 2011 comments and the comments submitted in response to the December 23, 2011 proposal.

We believe that consideration of these issues will result in higher RDL values for several of EPA's reference test methods and will raise the emission standards for many source categories.

We are, however, concerned that EPA's approach in calculating the representative detection limits for various pollutants by averaging the detection limits achieved by the best performers is based only on partial information on method detection limits and is, consequently, incorrect and needs to be modified.

Response: We agree with the commenter that there are errors associated with the extraction and recovery of the samples from the stack. We believe that the calculation of the floor by the upper predictive limit takes into account variability in the operation and emissions of the source. To ensure measurement variability is adequately addressed, when there are undetectable measurements, we compare the calculated floor against three times the representative method detection limit (RDL), or the associated level of quantitation of the test method. If the floor is less than three times the RDL, we adjust the floor level to three times the RDL so that measurement variability is sufficiently addressed.

We disagree with the commenter that this adjustment of three times the RDL does not properly account for the random measurement errors addressed in the ASME study, which also includes errors associated with laboratory analysis.

Comment Excerpt Number: 1

Comment: The following provides clarification that the detection limits on dioxin/furan testing commonly reporting with stack test results reported by Advanced Industrial Resources (AIR) reflect the analytical detection limits as opposed to the overall detection limits of the stack test methods themselves. AIR always attempts to minimize variability on the emissions results associated with actual sampling events but it should be understood that there is not attempt to quantify those factors in reporting of detection limits.

Prior to conducting a sampling event, AIR attempts to estimate a source's expected pollutant emission concentration and exhaust gas stream volume (dry, standardized) in order to determine the sample volume and duration necessary to obtain a detectable quantity of pollutant in the collected samples. However, ultimately, the detectable limit reported is defined within the analysis process. Therefore, when reporting emission results, the final quantity reported by the analysis process, whether it is an actual measured quantity or the analytical detection limit, establishes whether or not the value reported (i.e., emission ate) is above or below a detectable level.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3521-A1, excerpt 52.

Document Control Number: EPA-HQ-OAR-2002-0058-3505-A1

Comment Excerpt Number: 9

Comment: The issues related to test method detection limits were identified in an ASME report (Lanier and Hendrix 2001) entitled "Reference Method Accuracy and Precision (ReMAP), Phase 1," which examined the precision of selected EPA source emission test methods. The report, which is referenced in the December 23, 2011 EPA proposal, makes several important points: (1) there are both random errors and systematic errors (bias in the measurement process), (2) "the

magnitude of random errors associated with extraction and recovery of the sample from the stack might be expected to vary in proportion to stack concentrations,” and (3) “estimation of method precision must be based on data from special tests where multiple sampling trains are used simultaneously to determine the stack pollutant concentration.” Using the data presented in the ReMAP study, NCASI determined the quantitation limits, which are essentially the same as 3 x RDLs, for various EPA source test methods. The results of this analysis were described in detail in the July 15, 2011 letter to Brian Shrager (Attachment 4) and are summarized in Table 3. [See submittal for Table 3 and Attachment 4] The ReMAP study also provides data on the detection limits for select metals when using EPA Method 29. All these data may be useful to EPA in establishing the RDL values for the entire method as opposed to the analytical component of the test method.

Response: In developing RDL values for these data the EPA used MDL values from the ICR test reports themselves. ReMAP data was not included in that evaluation. The EPA feels the ICR specific data set better addresses matrix interferences and the specific compliance determination method affecting this source category.

Commenter Affiliation: National Council for Air and Stream Improvement, Inc. (NCASI)

Document Control Number: EPA-HQ-OAR-2002-0058-3505-A1

Comment Excerpt Number: 8

Comment: We are concerned that EPA has misinterpreted the method detection limit data submitted with emission test results and thus has reached incorrect conclusions regarding test method RDL values. As NCASI explained in its letter to Brian Shrager of EPA [See submittal for Attachment 4], source emission testing has three components, viz., source sampling, sample recovery, and sample analysis; the errors associated with sample collection and recovery are much greater than those associated with sample analysis; and to determine the source test method detection and quantitation limit, EPA procedures must account for the variability associated with source sampling and sample recovery in addition to the variability associated with sample analysis. However, as shown in Attachment 3, testing companies do consider errors associated with sample collection and recovery in determining method detection limits. [See submittal for Attachment 3]

Comment: NON-DETECT DATA

In setting limits under this rule, EPA has attempted to ensure that they are not set at less than 3 times a "representative detection limit" or RDL.³⁹ Therefore, EPA has not set out procedures for handling non-detect data obtained from fuel analyses or stack testing. The RDL was determined based on only the laboratory analysis data from the top performing units, and does not take into

account the error associated with sampling procedures. ACC has not had adequate time to evaluate all of the limits against what our members typically experience as non-detect levels from the companies used by our members. However, ACC requests that EPA include a provision in the rule that states if a facility does a stack test or fuel analysis using the appropriate methods and procedures set out in the rule and obtains a result that is labeled as non-detect but is above the emission limit, the source has 60 days to retest and demonstrate that emissions or fuel constituents are below the standard.

[Footnote 39: 76 Fed. Reg. 80611.]

Response: We believe that it is appropriate to use the detection limit value for determining compliance when data is analyzed below the detection limit. The detection limit provides reasonable assurance of compliance because we have set the emission floor no lower than 3x the RDL for the compliance test method. This means that reporting at the method detection level will not create a compliance issue for the source and it provides incentive to the source to select a tester and laboratory who will conscientiously evaluate their detection level prior to conducting the source test and determine appropriate pre-test goals for a target detection level. We have added language to the final rule to address this issue.

While we understand ACC's concerns, we do not feel that it is appropriate to include a provision for allowing retesting when the detection limit causes an exceedance of the standard. While the facility may certainly choose to retest or may be required to do so by the regulating authority, we do not feel that this provision is appropriate for the rule. We expect facilities, testers, and laboratories to use best practices to obtain detection levels that are reasonably low enough to show compliance with the emission standard.

For a response to error associated with sampling procedures, see comment EPA-HQ-OAR-2002-0058-3521-A1, excerpt 52.

Document Control Number: EPA-HQ-OAR-2002-0058-3505-A1

Comment Excerpt Number: 6

Comment: EPA has assumed that the procedure used by different testing companies to establish the analytical method detection limit is correct and follows a methodology established by EPA. This issue is significant because, in its air emission testing methods, EPA has not defined a methodology for determining the air emission test method detection limits. Consequently, many testing companies rely upon water methods for determining their analytical method detection limits. However, this is not the case for all testing companies. For example, in its Revised Assessment of Detection and Quantitation Approaches (EPA 2004) applicable to test methods used for water analysis, method detection limit is defined as 3.14 times the standard deviation of seven replicate analyses of very low level samples. While some laboratories used this practice, as shown in Table 2, one testing company reported its replicate analysis standard deviation as the detection limit instead of multiplying it by 3.14 [See submittal for Table 2 and Attachment 3].

Response: While we do not require sources to follow a specific methodology for determining method detection limits, we have provided instruction for, and advise sources to use EPA Method 301, section 15 as the standard methodology for determining method detection limits. Where sources have not used Method 301 procedures, we have asked that they provide the scientific basis for their technique. Many of the data used to develop the RDL values were from labs who used this methodology for determination of their detection limit.

Document Control Number: EPA-HQ-OAR-2002-0058-3505-A1

Comment Excerpt Number: 10

Comment: Further support for the need to utilize the detection limit for the entire test method is found in the results of a recent study aimed at examining the performance of PM CEM on a multi-fuel boiler. During this study simultaneous PM tests on the stack were carried out with two separate EPA Method 5 sampling trains. The results of these simultaneous tests, which are summarized in Table 4 and are described in detail in Attachment 1, show that when simultaneous Method 5 tests were carried out at a multi-fuel boiler, the unbiased standard deviation of the duplicate measurements calculated according to the protocol used in the ReMAP study was estimated to average 1.5 mg/dscm. [See submittal for Attachment 1] As compared to the 1.5 mg/dscm standard deviation in the above study, the standard deviation of quarterly replicate weighings of beakers, summarized in Table 1, shows a standard deviation of 0.6 mg at a tare weight of 103 gm. [See submittal for Table 1] When multiplied by 3.14 as per EPA methodology (EPA 2004), this would give an RDL of 5 mg for Method 5 whereas the laboratory test-based method would give an RDL of 2 mg for Method 5.

Response: We have used our published level of quantitation for particulate matter data of 1.0 mg. This detection limit accounts for the systematic error from the inherent blank in Method 5. See EPA Method 5I for a discussion on PM detection limits and level of quantitation. For a

response to the validity of the 2004 EPA guidance for determining method detection limits and how it pertains to this rulemaking, see comment EPA-HQ-OAR-2002-0058-3505-A1, excerpt 6. For discussion on the ReMAP study, see comment EPA-HQ-OAR-2002-0058-3521-A1, excerpt 52.

Comment: EPA should audit the procedure used by laboratories/testing companies to ensure that a consistent method is used to determine the method detection limit.

Response: While we do not require sources to follow a specific methodology for determining method detection limits, we have provided and advised sources to use EPA Method 301, section 15, as the standard methodology for determining method detection limits. The National Environmental Laboratory Accreditation Conference (NELAC) Institute (TNI) works to foster generation of environmental data of known and documented quality. Laboratories may apply to TNI for accreditation, and some state agencies require laboratories generating data to be accredited in order to for the data to be acceptable. Even if a state does not require laboratories to be accredited, as the delegated authority for enforcing the rule, the state agency or regional office has the right to audit testers and laboratories and all of the procedures used, including the development of method detection limits.

Comment: In describing the procedure for calculating the RDL, in the November 17, 2011 memo EPA has stated that “By limiting the data set to those tests used to establish the floor or emissions limit (i.e., best performers), we believe that the result is representative of the best performing testing companies and laboratories using the most sensitive analytical procedures.” If EPA believes this to be true, what is EPA’s rationale for further adjusting these values downward by taking an average of the detection limits reported by the nation’s “best performing testing companies and laboratories using the most sensitive analytical procedures”? We believe that EPA’s own conclusion would lead to using the highest detection limit achieved by the best performing testing companies as the method RDL. We also note that such an interpretation is too restrictive and EPA should use 90 or 95th percentile of the method detection limit data to set method RDL values as described in NCASI’s July 15, 2011 letter [See submittal for Attachment 4].

Response: In determining the representative method detection limit (RDL), we averaged the detection limits achievable in the data set used to set the floor. In doing this we are basing the detection limit of the test method on data representative of a pool of labs available to sources and testers who conscientiously target low detection levels from this source category. Selecting the highest detection limit merely makes allowances for the poorest lab results, a factor we wish to

avoid when setting emission floors. Moving forward to future testing efforts we want sources and their testers to make informed assessments of detection limit needs when conducting performance tests. By basing the RDL on a pool of lab data we provide a reasonable assessment of what can be detected by a cross section of testers and labs. We have accounted for measurement variability by multiplying the RDL by three when comparing it the floor's upper predictive limit and we compare this 3xRDL value with our 99% UPL value that accounts for source operational variability. When we base the floor data on the higher of these two numbers we feel that we have adequately addressed variability in the floor data set.

Comment Excerpt Number: 4

Comment: Even if the Agency is reluctant to develop a work practice standard for organic HAP emissions from all IB subcategories, it should, at the very least, examine the available organic test data for each subcategory to determine the percentage of measurements below the method detection limit as well as a level three times the method detection limit - the point at which EPA has stated that emissions can be accurately measured. Extensive testing during the EGU MACT rulemaking of organic emissions from coal fluidized bed units, pulverized coal units and oil-fired units showed the vast majority of these organic measurements were below the method detection limit and/or three times that level. Coal- and oil-fired IBs of similar designs should have similar emission profiles because the equipment is designed based on the same scientific principles.

Response: We did not compute a 3*RDL limit for organic HAP in the proposed rule. Setting a standard for organic HAP is outside the scope of this reconsideration action.

Comment Excerpt Number: 6

Comment: It does appear that the particulate matter emission limits in the rule were set considering the likely detection limit of the stack testing procedure; however, it does not appear that the precision of the test method was considered. Precision is a function of the repeatability of a procedure and is the determining factor of the detection limit. As referenced in 40 CFR 136, Appendix B, Definition and Procedure for the Determination of the Method Detection Limit, the proper procedure to determine the MDL would involve seven simultaneous stack tests with statistical analysis for the seven results. While focused primarily on water analysis, the methods presented in Part 136, Appendix B, were designed for applicability to a broad variety of physical and chemical methods. Following this methodology would be very expensive and likely possible for only large rectangular stacks where seven simultaneous samples could be taken without undue interference from adjacent test probes.

Presumably, because of the difficulty and expense in performing such an analysis for numerous source types, the EPA published a discussion of error sources for particulate matter stack tests in 1974 that could be relied upon in lieu of inadequate MDL data. The EPA document is "Administrative and Technical Aspects of Source Sampling for Particulates" (EPA 450/3-74-047, August 1974, Office of Air and Waste Management, Office of Air Quality Planning and Standards, Research Triangle Park, NC 27711), Chapter 8. The discussion provides a summation of the possible errors of measurement of each portion of the testing protocol and concludes that the maximum error of a given particulate test is 15% with a probable error range of 10%. The conclusions were based on the assumption that 200 mg of residue would be collected, which was the norm for the time. However, changing the weight of the residue to a smaller amount (10 mg) more reflective of modern test levels is not anticipated to impact the percent error significantly.

A discussion of error is not the same nor should it be substituted for a properly determined MDL. However, the error analysis does point out an issue with the proposed MACT emission limits for particulate matter. A 10% error range means that the result of the analysis has only one significant figure. Therefore, a result of 0.028 lb/MMBtu should only be reported as 0.03 lb/MMBtu. Failure to round the result properly could result in the appearance of a violation where one may not have occurred and take away necessary flexibility to address potential test errors.

Response: The Laxton 1990 Memo (Emissions Measurement Center Technical Information Document 024) provides the guidance related to the handling of significant figures throughout the calculation of emissions floors and the use of two significant figures for emission limits. As such the emission limit of 0.028 lb/MMbtu may be expressed and appropriately reported as 2.8E-02 lb/MMbtu.

For a response to treatment of measurement error, see comment EPA-HQ-OAR-2002-0058-3521-A1, excerpt 52.

Comment Excerpt Number: 143

Comment: In setting the Boiler MACT standards, EPA has acknowledged that the emission limit should not be set below the capability of the applicable test method. However, EPA did not use the widely accepted definition of method detection limit, which is based on the capabilities of multiple commercial laboratories to analyze a sample and identify the presence of a chemical above the “noise” level. In its place, EPA coined a new term, “representative method detection limit” (RDL) to define a measurement method detection limit which is based on the laboratory detection limits reported for the tests with the lowest emissions. This erroneous methodology resulted in estimating D/F detection limits that are over 100 times lower than those regularly achieved by commercial laboratories, based on an analysis documented in previous comments by AF&PA and the National Council for Air and Stream Improvement (NCASI).²⁰

The detection limit of an analytical method is commonly defined as the lowest concentration that can be distinguished from replicate blanks. The quantitation limit of a method is defined as the smallest concentration of the substance which can be measured with an acceptable level of uncertainty. Detection limits and quantitation limits are defined in a scientific, non-arbitrary manner in various widely-published peer-reviewed consensus guidelines²¹ and EPA documents. Quantitation limits of test methods have great significance when measuring very low concentrations of pollutants. In practice, reported values below the method’s quantitation limit should not be treated as real values.

The majority of a federal advisory committee on method detection and quantitation limits recommended that the quantitation limit of a test method should be based on the 95th percentile of what is being achieved by the commercial laboratories.²² Using this approach and rounding up the quantitation limit to a single digit, as EPA has done for floor setting, would result in a D/F TEQ quantitation limit of 0.2 ng/dscm based on analytical procedures alone. However, using the results of the ASME ReMAP study,²³ which evaluated the precision of Method 23D/F stack testing measurements, a D/F TEQ quantitation limit of 0.27 ng/dscm is derived, which addresses the uncertainty of all of the test method components.

[Footnote 20: The National Council for Air and Stream Improvement is an independent, non-profit research institute that focuses on environmental topics of interest to the forest products industry. Established in 1943, NCASI is recognized as the leading source of reliable data on environmental issues affecting this industry.]

[Footnote 23: Lanier, W.S. and Hendrix, C.D. Final Report--Reference Method Accuracy and Precision (ReMAP): Phase 1 Precision of Manual Stack Emission Measurements, ASME International, Washington, D.C. (2001).]

Response: We did not propose numerical emission limits for dioxins/furans in this rule. The final rule will not be changed to add numerical emission limits. Dioxins/furans standards are based on a work practice to conduct a boiler or process heater tune-up.

3D. MACT Floor Methodology: Output based standard (Alternative) - Boiler Efficiency Analysis

Commenter Name: James Pew

Commenter Affiliation: Earthjustice, Clean Air Council, Partnership for Policy Integrity

Document Control Number: EPA-HQ-OAR-2002-0058-3511-A1

Comment Excerpt Number: 48

Comment: Although EPA did not collect out-put emissions data or set output-based floors, the agency proposes to offer sources the option of complying with output-based emission standards. Specifically, EPA proposes to allow sources to meet standards that are converted from the floors it did set with a pre-determined conversion factor. Facilities that currently have relatively low efficiency would be unlikely to choose to meet the output-based standards because they would likely be more stringent than the standards EPA actually sets. Facilities with relatively high efficiencies, however, would likely choose to use the output-based standards because they would be less stringent.

EPA's output based standards do not reflect either the maximum degree of reduction that is achievable or the actual performance of the relevant best units. Had EPA calculated output based floors (properly), such floors would reflect the superior performance of the more efficient boilers. Moreover, EPA would have been forced to recognize that superior design and efficiency are themselves means by which cleaner sources achieve better emission levels. Because EPA did not set output based floors, however, the optional-output based standards do not purport to meet the Clean Air Act's floor requirements. Indeed, converting from EPA's standards to output-based standards could not possibly work without information highly specific to each individual source that chose to use it. But EPA does not require such information – choosing instead to offer a pre-determined conversion factor– and if the agency did require it, the option of using output-based standards would hold no allure for industry because it would not provide a compliance option less stringent than the floors EPA set.

Response: We disagree with the commenter that alternative output based standards do not reflect the actual performance of the relevant best performing units. Contrary to the commenter's assertion, EPA did in fact require output information specific to the best performing units and did not use a pre-determined conversion factor. The output-based limits are in fact based on data collected from the best performing units, as explained in the memorandum "Development of Alternate Equivalent Output-Based Emission Limits for Boilers and Process Heaters located at Major Source Facilities" (Docket ID No. EPA-HQ-OAR-2002-0058-3275). In the memo, we describe the process in the development of the alternate output-based emission limits that are equivalent to the MACT floor determinations for boilers and process heaters. First, we conducted an effort, under authority of section 114 of the Clean Air Act, to obtain steam/output data (flow, temperature, and pressure) for the test period corresponding to the reported emission data from

the best performing units comprising the proposed MACT floor pool. In determining alternate equivalent output-based emission limits, we determined for each of the best performing units the boiler efficiency for each of the boilers having available steam/output data. We determined the average boiler efficiency factor for each subcategory from the individual best performing units in that subcategory by calculating the average efficiency of this group. We applied the average boiler efficiency factor for each particular subcategory to the MACT floor (lb/million Btu heat input) emission limits for that particular subcategory to develop the alternate output-based emission limits. (The average subcategory specific boiler efficiency was revised based on a more appropriate approach for calculating boiler efficiency - See Docket ID No. EPA-HQ-OAR-2002-0058-3376)

The alternate output-based emission limits were proposed to encourage energy efficiency. The output-based limits are equivalent in stringency to the MACT floor because a unit operating at the average boiler efficiency of the best performing units will emit the identical mass (pound/hour) of HAP emissions complying with either the input-based limits or the output-based limits. Further, a unit operating at a boiler efficiency greater than the average boiler efficiency of the best performing units would emit less HAP on a mass-basis if complying with the input-based limits because the unit is combusting less fuel to generate the same output.

Commenter Affiliation: Pennsylvania Department of Environmental Protection (DEP)

Document Control Number: EPA-HQ-OAR-2002-0058-3507-A1

Comment Excerpt Number: 4

Comment: The EPA has proposed several changes to the output-based provisions in the reconsidered rule to address issues raised regarding boiler efficiency for this compliance option. The boiler efficiency calculation has been revised to include the heat (energy) associated with the feedwater. The DEP supports the revised output-based standards compliance option opportunity provided for existing boilers. The DEP agrees with the revision to the efficiency calculation and believes that the revised equation will result in more realistic boiler efficiencies or output-based standards.

Response: The EPA thanks the commenter for their support.

Commenter Name: Jessica Bridges
Commenter Affiliation: United States Clean Heat & Power Association (USCHPA)
Document Control Number: EPA-HQ-OAR-2002-0058-3501-A1
Comment Excerpt Number: 1

Comment: Changes to the Boiler Efficiency calculation to facilitate output-based standards are appropriate. EPA should also consider the authoritative data contained in the Energy and Environmental Analysis report from 2005 that is a boiler industry survey putting efficiency rates at approximately 78% (averaging black liquor fired, coal, and natural gas-fired systems.) It is available on the American Boiler Manufacturers Association website.⁶

[Footnote]

(6) http://www.abma.com/ICI_Boiler_Population_Characterization.pdf

Response: The EPA thanks the commenter for their support of the revisions to the output-based standards.

The 2005 Energy and Environmental Analysis report data is not appropriate for converting the MACT floor limits from an input basis to an output basis because it does not present the boiler efficiency of the best performing units that represent the MACT floor. However, the report does support the revised approach for calculating the actual boiler efficiency of the best performing units. That is, the recalculated boiler efficiencies included the heat (energy) associated with the feedwater which was initially disregarded resulting in efficiencies that were unrealistically high.

Commenter Name: Mary Sullivan Douglas
Commenter Affiliation: National Association of Clean Air Agencies (NACAA)
Document Control Number: EPA-HQ-OAR-2002-0058-3525-A1
Comment Excerpt Number: 39

Comment: NACAA has long supported the general notion of output-based standards as a way to encourage energy efficiency and mitigate emissions of air pollutants. However, unlike the EGU sector, determining energy efficiency improvements from a variety of industrial processes is a complex task that EPA has not yet addressed. Moreover, EPA has not developed the MACT floors using net output-based data and is not proposing to promulgate mandatory output-based MACT limits. Rather, it has converted the results of MACT data for sources selected as best

performing units on an input-basis and proposes to offer sources the option of complying with either the input-based limits or the converted limits. In addition, the uncertainties associated with past and future determinations of the unit's net heat rate are larger than potential efficiency gains that may result from adoption of output-based standards for existing units using common factors. NACAA believes that the most significant effect of offering existing sources the option of output-based standards based on a pre-determined conversion factor will be a reduction in the effectiveness of the rule, rather than any measureable improvement in efficiency of existing or new sources.

Response: For a response to issues with the conversion factor approach used to develop output-based standards, please see comment EPA-HQ-OAR-2002-0058-3521-A1, excerpt 48.

EPA disagrees that output based standards are inappropriate for the boilers and process heaters source category. In particular, we disagree that that the option of complying with output-based standards will be a reduction in the effectiveness of the rule, which the commenter claims will occur because the standards are based on a pre-determined conversion factors. The conversion factors are based on actual output data from the same units that EPA determined were the best performers and therefore used to calculate the input based MACT floor limits. Compliance with the alternate output-based emission limits are based on actual output data from the affected unit, not on determination of the unit's heat rate. The alternate output-based emission limits are considered equivalent to the input-based emission limits because the mass emissions (pounds per hour) will be equivalent from a unit complying with either limit.

Commenter Name: Mary Sullivan Douglas

Commenter Affiliation: National Association of Clean Air Agencies (NACAA)

Document Control Number: EPA-HQ-OAR-2002-0058-3525-A1

Comment Excerpt Number: 40

Comment: For existing units, the principal effect of an "optional" output-based standard would be to establish a class of "winners" that qualify for lower emission rates based on their currently existing condition, rather than providing an incentive to reduce emissions. Since facilities with low efficiencies (high heat rates) may elect to comply with the input-based limit, the only "losers" in this process are the members of the public who are subjected to higher emissions of HAPs than would otherwise be the case. For this reason EPA should not allow an output-based standard as an option for existing sources to employ, but should set standards based on net output emissions data. This could be accomplished at the next review of the standard, as required by the CAA every eight years and discussed below.

Response: We disagree that the alternate output-based standards will subject the public to higher emissions of HAP, see the response to comment EPA-HQ-OAR-2002-0058-3525-A1, excerpt 39. The purpose of the alternate output-based standards is to encourage energy efficiency. A source may determine that improving its boiler efficiency may be more cost effective in complying with the Boiler MACT than installing or upgrading its control equipment. Operating at improved efficiency will better the public even more since increase efficiency results in lower fuel consumption and reduction of all emissions, not just HAP emissions.

Commenter Name: Mary Sullivan Douglas
Commenter Affiliation: National Association of Clean Air Agencies (NACAA)
Document Control Number: EPA-HQ-OAR-2002-0058-3525-A1
Comment Excerpt Number: 41

Comment: Opportunities for improvement in the heat rate of existing sources are relatively small. In addition, many efficiency improvement options, such as soot removal, are not permanent and require ongoing maintenance to sustain improved performance. Before proceeding in this area EPA should develop a record that would enable accurate measurement and determination of sustainable efficiency improvements. The record in this rulemaking is not sufficient to establish such procedures.

Response: Compliance with the alternate output-based standards are no less stringent than with the heat input emission limits, see the response to comment EPA-HQ-OAR-2002-0058-3525-A1, excerpt 39. Whatever improvements are made in boiler efficiency they will need to be maintained for the source to comply on a continuous basis.

Document Control Number: EPA-HQ-OAR-2002-0058-3683-A2
Comment Excerpt Number: 3

Comment: We Commend EPA for Modifying the Output-Based Compliance Option So that More Facilities Can Benefit.

While the original Proposed Rule included numerous provisions to encourage greater efficiency of regulated boilers, it failed to provide for an output-based emission standard. As EPA has recognized in other contexts, output-based regulations “encourage[] energy efficiency and clean energy supply, such as combined heat and power (CHP), by relating emissions to the productive output of the process rather than the amount of fuel burned.”⁶ EPA largely corrected this oversight in the March 2011 Rule by providing an output-based standard as an alternative compliance mechanism. Therein, EPA recognized that this alternative standard “provide[s] a regulatory incentive to enhance unit operating efficiency and reduce emissions.” Unfortunately, the February Rule included some minor errors, which limited the efficacy of the output-based standard. These errors are corrected in the December Rule.

We commend EPA for making modest improvements to the output-based standard to make this provision more effective.

103G. MACT Floor Methodology: HCl - Fuel Variability

Commenter Name: James Johnson

Commenter Affiliation: United States Beet Sugar Association (USBSA)

Document Control Number: EPA-HQ-OAR-2002-0058-3508-A1

Comment Excerpt Number: 5

Comment: In the reconsideration of the Boiler Rules, EPA has failed to introduce standards that sufficiently take into account the inherent variability in operations. Variability is a known part of operations at facilities with industrial boilers. While the utilization of the upper prediction limit (UPL) does allow for some variability based on stack tests, there are meaningful differences between the results of stack tests, which are conducted at full-load, steady-state operations and

real-world operations where fluctuations in operational conditions are the norm. The emission limits in the Boiler Rules consider testing variability but do not reflect operational variability. The D.C. Circuit has held that variability, particularly in emission controls, must be accounted for when setting MACT standards.¹¹ According to the D.C. Circuit, the CAA's statutory requirements for setting the MACT floor authorize EPA to set a standard which reflects what the best performing units can achieve under "the worst reasonably foreseeable circumstances."¹² To account for the worst reasonably foreseeable circumstances, EPA is required to estimate the variability associated with all factors that impact a source's emissions, including operational and fuel factors.¹³

USBSA supports EPA's exercise of discretion to account for variability in the standard but recommends that the emission limits also reflect operational and fuel variability in addition to the UPL. EPA properly chose to consider variability in its setting of the MACT floor but did not consider all the sources of operational variability that could be reflected in the standards. EPA should include these other factors to develop more achievable standards.

[Footnote]

(11) See *Cement Kiln Recycling Coal. v. EPA*, 255 F.3d 855 (D.C. Cir. 2001).

(12) *Sierra Club v. EPA*, 167 F.3d 658, 665 (D.C. Cir. 1999).

(13) *Nat'l Lime Ass'n v. EPA*, 627 F.2d 416, 443 (D.C. Cir. 1980).

Response: The EPA thanks the commenter for their support of accounting for variability in setting standards. The EPA agrees with the commenter's assertion that the solid fuel limits only represented testing variability and not operational variability. For this reason, EPA believes it is necessary to establish fuel variability factors (FVF) for the Hg and HCl limits for the solid fuel subcategory. The Hg and HCl MACT floor emission limitations in the final rule have each been multiplied by an FVF, which EPA believes fully accounts for operational variability.

Commenter Name: Stephen E. Woock

Commenter Affiliation: Weyerhaeuser Company

Document Control Number: EPA-HQ-OAR-2002-0058-3523-A1

Comment Excerpt Number: 9

Comment: This technical feasibility concern may be diminished if EPA adjusts its proposed solid fuel subcategory mercury limit based on fuel variability. We believe EPA may have inaccurately evaluated the re-proposed limit by failing to include the variability of the mercury in solid fuels combusted by individual units beyond the amounts present during the performance tests of the selected top performers. For example, at one of our mills the supplier specifications for delivered coal in April 2011 had a mean of 0.07 ppm with a 95% percentile of 0.13 ppm. This single example of nearly two-fold factor can translate directly to variations in emission levels over short periods of time and impact the ability to demonstrate compliance during performance tests where the margin of compliance is narrow due to technology concerns raised above. We refer EPA to the detailed AF&PA et al. and CIBO comments which address incorporating a fuel variability factor (FVF) to ensure the limits are achievable and the NCASI comments which highlight technical aspects of fuel variability factor approaches.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3508-A1, excerpt 5.

Commenter Affiliation: American Forest & Paper Association (AF&PA) et al.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 69

Comment: Another issue to consider is whether the fuel quality among top performers is representative of the fuel quality among all units, i.e., whether the range of pollutant concentrations observed within the fuels in the top performers encompasses the range of "all possible" concentrations. Since the MACT floor units are such a small percentage of the total number of boilers in that subcategory, it is unlikely that the range is fully represented. This would be an important factor to ensure that the standards being developed are achievable, especially in the case of "fuel-based pollutants."

Response: See the response to comment EPA-HQ-OAR-2002-0058-3508-A1, excerpt 5.

Commenter Name: Randall D. Quintrell

Commenter Affiliation: Georgia Paper & Forest Products Association

Document Control Number: EPA-HQ-OAR-2002-0058-3451-A1

Comment Excerpt Number: 3

Comment: The proposed emission limits for mercury and hydrogen chloride do not reflect the effects of fuel variability within each type of fuel class, a factor that is often beyond the control of the operator. Fuel supply availability and cost are important factors that EPA has not appropriately factored in to these decisions, leaving boiler operators in an untenable situation when fuel variability could cause non-compliance, even though the required technology has been installed.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3508-A1, excerpt 5.

Comment Excerpt Number: 26

Comment: Fuel flexibility is an important factor in the operation of many industrial facilities, and fuel cost is usually one of the top three costs of doing business. Many facilities have committed to a single solid fuel, such as coal, but other facilities burn a mixture of fuels. EPA should set limits for HCl and Hg for solid fuel-fired units that ensure the maximum number of sources can achieve the limits and that do not disadvantage users of any one particular fuel.

EPA has the discretion and should include a fuel variability factor in the MACT floor analysis for the solid fuel subcategory HCl and Hg limits so fuel pollutant content variability among the top performers is adequately considered. This approach would make achievability of these standards more viable, while reflecting the real world operational and fuel variability that boilers experience.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3508-A1, excerpt 5.

Comment: The Application of Some Fuel Variability Factors (FVFs) May Be Appropriate for HCl and Hg Emission Limits Once EPA Establishes Separate Subcategories for Coal and Biomass Boilers

In the MACT Floor Memos for both the Final Boiler Rule⁸ and the Reconsideration Proposal⁹, EPA made the following statement:

For existing solid fuel units, EPA reviewed the fuel variability in the UPL calculations prior to multiplying the results by the FVF. In the case of the solid fuel subcategory the fuels used in the top performing boilers varied widely, including coal, petroleum coke, tire-derived fuel, as well as several types of biomass fuel. Based on the heterogeneous make up of the best performing units, we determined that the UPL calculation alone considered sufficient variability in fuel types from best performing units and it was unnecessary to incorporate additional fuel variability through the use of a FVF.

Once EPA separates biomass and coal units into subcategories, it needs to re-evaluate the variability represented by the upper prediction limit (UPL) calculation. It should follow the procedures from the Final Boiler Rule MACT Floor Memo where both the recommended (combined solid units) and the alternative (separate coal and biomass) datasets are evaluated and determine whether or not FVFs should be applied. What EPA will find is that the datasets have significantly less heterogeneity and FVFs may be appropriate. [Footnote 8: EPA-HQ-OAR-2002-0058-3273]

[Footnote 9: EPA-HQ-OAR-2002-0058-3387]

Response: For the reasons specified in the preamble to the March 21, 2011 final rule notice (76 FR 15608), EPA has retained a solid fuel subcategory for HCl and Hg. However, EPA has implemented a fuel variability factor (FVF) for the HCl and Hg solid fuel limits for the final rule. For discussion of the solid fuel FVF, please see comment EPA-HQ-OAR-2002-0058-3508-A1, excerpt 5.

Comment Excerpt Number: 10

Comment: Application of some Fuel Variability Factors (FVFs) may be appropriate for HCl and Hg emission limits once EPA establishes subcategories for coal and biomass boilers.

Discussion: In the MACT Floor Memos for both the final rule (memo dated January 4, 2011) and the reconsideration proposal (memo dated November 2011), EPA made the following statement:

For existing solid fuel units, EPA reviewed the fuel variability in the UPL calculations prior to multiplying the results by the FVF. In the case of the solid fuel subcategory the fuels used in the top performing boilers varied widely, including coal, petroleum coke, tire-derived fuel, as well as several types of biomass fuel. Based on the heterogeneous make up of the best performing units, we determined that the UPL calculation alone considered sufficient variability in fuel types from best performing units and it was unnecessary to incorporate additional fuel variability through the use of a FVF.

Once EPA separates biomass and coal units into subcategories, it needs to re-evaluate the variability represented by the UPL calculation. It should follow the procedures from the final rule MACT Floor Memo where both the recommended (combined solid units) and the alternative (separate coal and biomass datasets) are evaluated and determine whether or not FVFs should be applied. What EPA will find is that the datasets have significantly less heterogeneity and FVFs may be appropriate.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3510-A1, excerpt 22.

Document Control Number: EPA-HQ-OAR-2002-0058-3525-A1

Comment Excerpt Number: 24

Comment: EPA takes the result of its 99th percentile UPL calculation and applies a second variability factor, what it styles as a “fuel variability factor,” to determine the overall variability to apply to a “best performing unit.” This constitutes double counting and should not be permitted. This double counting occurs because fuel variability is part of, and in many instances the major part of, the test-to-test variability that forms the basis of the 99th percentile UPL calculation. In the case of the liquid-fired Hg limit, EPA applied a “Fuel Variability Factor” to the 99th percentile UPL to further increase its proposed MACT floor to 2.6×10^{-5} lb/MMBtu. EPA applies this factor, not because the data respecting the Hg fuel variability of the best units showed that the variability was too large, but because it was, in EPA’s view, too small. EPA acknowledged that, for solid-fuel units, the variability in the amount of a pollutant in the fuel would be reflected in the emissions performance of the units but decided that “[f]or existing and new liquid fuel units, the fuels making up the best performing units demonstrated less variability in their composition and type, and there were a smaller pool of available test runs. EPA determined that an additional fuel variability factor was necessary in these cases.” EPA’s added emission factor makes only a slight (5 percent) difference in that case, but, if applied to solid fuel-fired units, would increase the standard by an order of magnitude.²²

[Footnote]

(22) Memorandum, Eastern Research Group to Shrager, B, USEPA, *Revised MACT Floor Analysis (November 2011) for the Industrial, Commercial, and Institutional Boilers and Process Heaters National Emission Standards for Hazardous Air Pollutants – Major Source*, November, 2011 (“MACT Floor Memo”) Appendix C-4-(a)(i). p. 7.

Response: EPA disagrees that the fuel variability factor (FVF) constitutes double-counting of variability. The 99% UPL accounts for testing variability, while the FVF accounts for

operational and fuel variability between sources. EPA believes both types of variability should be accounted for when establishing emissions standards.

Commenter Name: Mary Sullivan Douglas

Commenter Affiliation: National Association of Clean Air Agencies (NACAA)

Document Control Number: EPA-HQ-OAR-2002-0058-3525-A1

Comment Excerpt Number: 8

Comment: EPA then multiplies these results by a fuel variability factor to establish the final number that it uses to calculate the floor. This fuel variability factor is also different for different units, and so, again, the unit with the lowest single test result is not necessarily the “best performer” as used in EPA’s calculations.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3525-A1, excerpt 24.

Document Control Number: EPA-HQ-OAR-2002-0058-3511-A1

Comment Excerpt Number: 15

Comment: Not satisfied with grossly overstating sources’ actual emissions through its 99% UPL and treatment of non-detect levels, EPA also applies a second variability factor that it describes as a “fuel variability factor.” But any variability in sources’ emissions that is caused by variations in fuel is already accounted for – and indeed, grossly overstated – by the 99% UPL. Adding a second variability factor to account for variability that has already been accounted for once overstates variability and results in overestimates of individual sources’ performance and, therefore, yields floors that do not reflect the best sources’ performance. Remarkably, EPA adds a fuel variability factor where the data showing fuel variability is, in EPA’s opinion, too small. Inflating the alleged emissions achieved by sources based on alleged variability that the agency cannot even identify is arbitrary itself, and reveals that the agency is simply adjusting the numbers to reach more lenient standards that it evidently prefers to the standards required by the Clean Air Act.

Response: EPA disagrees that the fuel variability factor (FVF) constitutes double-counting of variability. In this case, we applied the UPL to assess source variability. Specifically, the MACT floor limit is an upper prediction limit (UPL) calculated with the Student’s t-test using the TINV function in Microsoft Excel®. The Student’s t-test has also been used in many other EPA rulemakings to account for variability. A prediction interval for a future observation is an interval that will, with a specified degree of confidence, contain the next (or some other pre-specified) randomly selected observation from a population. In other words, the prediction interval estimates what the upper bound of future values will be, based upon present or past background samples taken. The UPL consequently represents the value which we can expect the mean of future observations to fall below within a specified level of confidence, based upon the results of an independent sample from the same population. Therefore, if we were to randomly select a future test condition from any of these sources, we can be 99 percent confident that the reported level will fall at or below the UPL value. Use of the UPL is appropriate in this

rulemaking because it sets a limit any single or future source can meet based on the performance of the MACT floor sources data pool. This formula uses a pooled variance (in the s^2 term) that encompasses all the data-point to data-point variability of the best performing sources comprising the MACT floor pool for each HAP. EPA also received comments claiming that this final rule raises the (perceived) quandary voiced by Judge Williams in his concurring opinion in Brick MACT where an achieved level of performance for purposes of CAA section 112(d)(3) results in a standard which is unachievable under CAA section 112(d)(2) because it is too costly or not cost-effective. Brick MACT, 479 F. 3d at 884-85. EPA is of course mindful of the repeated admonitions from the D.C. Circuit that MACT floors must reflect achieved performance of the best performing units, that HAP content of process inputs (raw materials and fuels) must be accounted for in ascertaining sources' performance, and that EPA cannot consider costs in ascertaining the level of the MACT floor. See, e.g., Brick MACT, 479 F. 3d at 880-81, 882-83; NRDC v. EPA, 489 F. 3d 1364, 1376 (D.C. Cir. 2007) ("Plywood MACT"); see also Cement Kiln Recycling Coalition v. EPA, 255 F. 3d 855, 861-62 (D.C. Cir. 2001) ("achievability" requirement of CAA section 112 (d)(2) cannot override the requirement that floors be calculated on the basis of what best performers actually achieved). EPA is also mindful of the need to account for sources' variability (both due to control device performance and variability in inputs) in assessing sources' performance when developing technology-based standards. See, e.g., Mossville Environmental Action Now v. EPA, 370 F. 3d 1232, 1242 (D.C. Cir. 2004); National Lime I, 627 F. 2d 416,433-34(D.C. Cir. 1980). EPA has carefully developed data for each standard, assessing both technological controls and HAP inputs from fuel in doing so, to accurately measure both which performers are best and what their performance is.

The MACT floors reflect a reasonable estimate of what the best performing sources will achieve over time. Each of the floors considers the impact of non-technology factors, notably HAP inputs in fuels, on the source's emissions. For mercury and HCL, the standards reflect 30 days of data from the best performing sources for all fuel inputs (which was collected from boilers and process heaters as part of the ICR), reasonable estimates of control device performance, plus a reasonable statistical methodology to account for variability (including variability of HAP content from fuel inputs). The 30-day fuel variability data show that boiler performance for the source categories at issue (based only on short term stack test data) does not necessarily reflect the different fuel inputs that were used outside the short term sampling period. Therefore the short term stack test data alone are not necessarily indicative of long term emissions performance. Based on the 30 day fuel input data from the best performing sources, it was observed that the mercury and chlorine levels varied significantly at the best performing sources over the 30 day period. Fuels combusted within a short term three hour test would be expected to be fairly consistent in their levels of mercury and chlorine, but the 30 days of data provided by industry in response to EPA's ICR data collection show significant variations in levels of these pollutants from the fuel that is combusted by boilers and process heaters over longer periods of time. In light of this, we applied the fuel variability factor to reflect the variation of HAP from fuel inputs. The FVF accounts for fuel variability between sources using long term fuel measurement data that represent inherent natural variations in fuel usage at the best performing units over time. The FVF is the average of the individual FVF that were calculated for each best performing unit using the mercury and chlorine content of samples collected over a 30 day period. The FVF was used in conjunction with the 99% UPL to characterize long-term

variability due to technological controls and fuel characteristics. The results are MACT floors which reasonably estimate the performance over time of the best performing sources.

Comment Excerpt Number: 37

Comment: EPA has provided no rationale for selecting the maximum emission factor in a group of tests in developing its fuel variability factors. Other examples of an upward bias can be found in EPA's calculation process³⁷ including: (1) exclusion of test results where the result provided is "zero" or "non-detect," but the detection limit is not provided, and (2) failure to include homogeneous waste material combusted by some biomass boilers in the fuel variability analysis (EPA argued that such data should be excluded because it is not a representative material for other boilers in the biomass subcategory).

[Footnote]

(37) The rounding process employed by EPA can increase MACT floor results significantly. The other biases we mention are unlikely to have a large impact on the MACT floor. The use of log-normal statistical procedures may or may not result in lower MACT limits than would otherwise be the case, but is technically justified where nonnormal distributions are observed.

Response: The EPA did not select the maximum in developing the fuel variability factors. Given that the solid fuel category does exhibit some heterogeneous fuel make-up amongst the top performing units, the EPA adopted the average fuel variability ratio for each pollutant instead of the maximum fuel variability ratio. This average value was selected to not overestimate fuel variability for a subcategory that has a mix of biomass, coal, and other solid fossil stack test data factored into the 99% UPL calculations, but it recognizes that some additional fuel variability is present in the best performing units that may not be represented by the stack test data alone.

Commenter Affiliation: MeadWestvaco Corporation (MWV)

Document Control Number: EPA-HQ-OAR-2002-0058-3493-A1

Comment Excerpt Number: 3

Comment: MWV believes that EPA has established a series of requirements that are more stringent than necessary to satisfy the requirements of the MACT floor which represents the average of the top 12 % in specific subcategories. EPA needs to take additional steps to better account for performance variability of the identified top performers. This can be accomplished by considering fuel variability in setting the proposed emission limits. EPA has not included fuel variability factors for HCl or mercury for the solid fuel subcategory but has included a fuel factor for HCl and mercury in the liquid unit subcategory. EPA should collect fuel variability data for all top performers to ensure that the analysis is complete. EPA should also determine whether the fuel variability adjustment adequately captures the variability of all types of fuels that could be fired by boilers in each of the subcategories. Variability will lead to more appropriate standards

for both new and existing units. A more complete evaluation of variability will lead to more achievable emission levels while providing adequate protection to health and the environment.

Response: The EPA agrees with the commenter's assertion that fuel variability should apply to all regulated fuel subcategories, including solid fuel. The Hg and HCl MACT floor emission limitations in the final rule have each been multiplied by an FVF, which EPA believes fully accounts for operational variability. EPA would have incorporated any new fuel variability data received during the public comment period into the FVF analysis, but no new data were received.

Commenter Affiliation: American Forest & Paper Association (AF&PA) et al.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 66

Comment: The solid fuel subcategory HCl and Hg limits must incorporate a fuel variability factor (FVF) to ensure the limits are truly achievable and account for variations in fuel pollutant content across the fuels burned by the top performing units that make up the solid fuel subcategory floor.

While EPA has included an FVF for Hg and HCl for the liquid fuel subcategory MACT floors, a similar analysis has not been included for the solid fuel category MACT floors in the re-proposal. As outlined in the ERG MACT floor memo, in the case of the solid fuel subcategory, EPA concluded that the range of fuels used in the top performing boilers varied widely and included coal, petroleum coke, tire-derived fuel, as well as several types of biomass fuel. Given this heterogeneous make-up of the best performing units, EPA concluded that the UPL calculation alone represented sufficient fuel variability and that it was unnecessary to incorporate additional fuel variability through the use of a FVF. We do not believe that fuel heterogeneity, by itself, accounts for the range of pollutant concentrations that could exist within those fuels. For instance, the range of pollutant concentrations observed within these fuels during the performance tests may not be representative of the range of "all possible" concentrations. Furthermore, "intra-unit" variability in fuel pollutant concentrations may not have been addressed adequately by considering only the limited performance tests. For these reasons, we recommend the following:

- EPA should collect additional fuel variability data for all top performers to ensure that the fuel analysis data covers the entire range of possible concentrations.
- EPA should also determine whether the fuel variability adjustment adequately captures the variability of all types of fuels that could be fired by boilers in each of the subcategories. As EPA has previously stated, fuel switching is not an appropriate mandate for this rule, so the limits should be achievable for boilers burning the full ranges of coals and fuel oils.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3493-A1, excerpt 3.

Commenter Name: Douglas A. McWilliams

Commenter Affiliation: American Municipal Power

Document Control Number: EPA-HQ-OAR-2002-0058-3685-A2

Comment Excerpt Number: 31

Comment: EPA also failed to include a fuel variability factor for HCl or Hg for solid fuel-fired units. EPA states that this was unnecessary due to the variety of fuels represented in the top 12 percent, but this ignores the purpose of the variability analysis: to ensure that emission limits are achievable in practice. Each of the fuels represented in the top 12 percent is variable in itself, and EPA has not accounted for this in its analysis. Capturing variability is particularly important for coal-fired units, because variability in coal quality occurs within individual seams and within one unit's supply, which may come from different sources. EPA's testing did not account for this difference in fuel quality. However, EPA may look to other sources for emissions information related to the variability of coal content among coal rank and regions and apply this information to improve the variability data for the top performers.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3493-A1, excerpt 3.

Commenter Name: Ashok K. Jain

Commenter Affiliation: National Council for Air and Stream Improvement, Inc. (NCASI)

Document Control Number: EPA-HQ-OAR-2002-0058-3505-A1

Comment Excerpt Number: 15

Comment: NCASI agrees with EPA's rationale regarding the applicability and use of Fuel Variability Factors (FVF) to better account for changes in Hg and HCl concentrations in fuels over time. This rationale is especially pertinent given that Hg and HCl are classified as "fuel-based pollutants" in this rulemaking. However, EPA has not considered the use of FVFs in proposing the emission limits for Hg and HCl in the solid fuel subcategory. As outlined in the Singleton Memorandum (Singleton 2011), in the case of the solid fuel subcategory, EPA concluded that the range of fuels used in the top performing boilers varied widely and included coal, petroleum coke, tire-derived fuel, as well as several types of biomass fuel. Given this heterogeneous make-up of best performers, EPA concluded that the UPL calculation adequately represented fuel variability and that it was unnecessary to incorporate additional fuel variability through the use of a FVF.

It is true that performance tests, conducted across all best performers in the fuel category, may indeed reflect emissions under a wide range of possible pollutant concentrations in fuels. Additionally, the UPL calculations take into account "intra-unit" emission and test-run variability. However, they do not directly account for unit-specific variability in fuel pollutant concentrations nor do they reflect the range of pollutant concentrations that could exist within these fuels. Any representation of these ranges would be purely coincidental and dictated by the prevailing pollutant concentrations during the performance tests. The following points are pertinent:

Across all best performing facilities, the range of pollutant concentrations observed in the fuels during the course of the performance tests may not encompass the range of "all possible" concentrations that could be measured in these fuels at these locations. For any given best performer, the range of pollutant concentrations observed in the fuels during the course of

limited performance tests may not encompass the range of “all possible” concentrations that could be measured at that facility.

This variability in pollutant concentrations can be adequately accounted for only by quantifying FVFs for each source that is a best performer. This is especially true for fuel-based pollutants. For these reasons, we recommend that the EPA should collect additional fuel variability data for all top performers to ensure that the fuel analysis data covers the entire range of possible concentrations.

Response: EPA agrees with the commenter. A fuel variability factor (FVF) has been applied to the solid fuel subcategory MACT floor emission limitations in the final rule. Additional fuel variability data were welcomed during the public comment period, but no data were received.

Commenter Name: Ashok K. Jain

Commenter Affiliation: National Council for Air and Stream Improvement, Inc. (NCASI)

Document Control Number: EPA-HQ-OAR-2002-0058-3505-A1

Comment Excerpt Number: 16

Comment: NCASI has carried out an analysis of Fuel Variability Data among the top performing boilers in the solid fuel subcategory using the procedures laid out in the Singleton Memorandum (Singleton 2011). The *fuelspecific* approach outlined in the Singleton memo involves the following:

- Variability ratios are calculated for all top performers in the solid fuel subcategory. The entire dataset of ratios, calculated for every fuel analysis data point reported for all best performers, is assumed to be normally distributed.
- Outliers from this dataset of ratios are removed by applying the empirical rule to the entire dataset and removing all ratios that do not fall within three (3) standard deviations of the mean of all the ratios for the solid fuel subcategory.
- After the outliers are removed, the maximum ratio in the new dataset becomes the FVF for the solid fuel subcategory.

In the original proposal, this outlier analysis was carried out both on a *fuel-specific basis* (all calculated ratios from all best performers in the solid fuel subcategory combined into one dataset) and a *unit-specific basis* (outlier analysis carried out on variability ratios calculated for each unit on the best performer list).

However, the *fuel-specific basis* was concluded to be more appropriate for this analysis. The reasoning (also provided in the Singleton Memo) was that the fuel variability is based on a range of fuel types identified to be from a set of best performing units in a subcategory and not for fuels specific to any single unit.

Hg and HCl FVFs for the solid fuel subcategory, calculated using the approach detailed above, are provided in the Table below. [See submittal for table] Additionally, the variability ratios among the best performers in the biomass subcategory have also been analyzed in order to calculate Hg and HCl FVFs.

The above analysis, carried out using the methodology outlined by EPA in the original rulemaking, indicates that the variability in Hg and HCl concentrations in the fuel is an important component and should be incorporated into the applicable emission limits.

Response: EPA agrees with the commenter's assertion that fuel variability factors (FVF) should be applied to the Hg and HCl emission limitations for the solid fuel subcategory. In the final rule, the Hg and HCl MACT floor emission limits for solid fuels have been multiplied by an FVF.

Commenter Name: Paul Noe

Commenter Affiliation: American Forest & Paper Association (AF&PA) et al.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 67

Comment: NCASI conducted an analysis of fuel variability data among the top performing boilers in the solid fuel subcategory using the procedures laid out in the ERG MACT floor memo. This procedure (a) calculates variability ratios for all top performers in the solid fuel subcategory and (b) utilizes the empirical rule, on all calculated ratios within the solid fuel subcategory, to identify and remove potential outliers. As outlined in the ERG MACT Floor Memo, this outlier analysis was carried out both on a fuel-specific basis (all calculated ratios from best performers in the solid fuel subcategory combined into one dataset) and a unit-specific basis (outlier analysis carried out on variability ratios calculated for each unit on the best performer list). However, the fuel-specific basis was concluded to be more appropriate for this analysis. The FVFs calculated using this approach are provided in the table below and demonstrate that both biomass and coal have a significant amount of variability in chloride and mercury content. The data show that an adjustment of the calculated 99 UPLs by at least a factor of 2 is warranted.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3505-A1, excerpt 16.

Commenter Name: Ashok K. Jain

Commenter Affiliation: National Council for Air and Stream Improvement, Inc. (NCASI)

Document Control Number: EPA-HQ-OAR-2002-0058-3505-A1

Comment Excerpt Number: 17

Comment: NCASI has carried out the above analysis in order to be consistent with the approach outlined in the Singleton memo. However, it is worthwhile to point out that the approach has its limitations as it pertains to outlier identification and elimination. The following are worth identifying:

- The dataset of variability ratios associated with all best performers in the subcategory is frequently not normally distributed. The empirical rule may therefore not be applicable for outlier identification (eliminating outlier values that are not within three SDs of the mean of all computed ratios).
- Two key criteria for confirming outliers are (1) does a graphical observation of the data including the outlier(s) confirm that it is an outlier? and (2) when data normality is assumed to identify outliers, are the remaining data without the outlier(s) normally distributed? On

both these points, a review of the Hg and HCl FVFs for the solid fuel subcategory shows that these criteria were not satisfied.

- The empirical rule, when applied on a *fuel-specific basis* (on the larger dataset of all best performers), may incorrectly identify some variability ratios as outliers. For instance, if a subset of best performing units have a higher level of variability in fuel pollutant concentration, this information may be lost as part of the *fuel-specific* outlier identification procedure. In such cases, the empirical rule may also have to be applied on a *unit-specific basis* to reconfirm outliers.

Outlier elimination using the empirical rule on a *fuel-specific basis* therefore has the potential to *underestimate* the FVFs. Given the above limitations, it is also worthwhile to consider alternative approaches to calculating FVFs and eliminating the limitations of an unconfirmed outlier analysis. These include:

- Estimating either the 90 or 95% UPL of all variability ratios in a subcategory, using a methodology consistent with the type of data distribution, or Employing non-parametric statistics (e.g., the 90 or 95% Chebyshev UPLs) when the dataset is not represented by any particular type of distribution.

Response: Based on our consideration of the suggested alternative approaches, we have not changed our approach to estimating FVF.

102D. MACT Floor Methodology: Minimum CO Levels

Commenter Name: Robert D. Bessette

Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 33

Comment: EPA itself has already reached the conclusion that forcing CO emissions below 100 ppm does not force organic HAP emissions to ultra-low levels in the Hazardous Waste Combustor NESHAP rulemaking. As the Agency states at 70 FR 59462 (October 12, 2005):

"We explained at proposal why the carbon monoxide standard of 100 ppmv and the hydrocarbon standard of 10 ppmv are appropriate floors. See 69 FR at 21282. The floor level for carbon monoxide of 100 ppmv is a currently enforceable Federal standard. Although some sources are achieving carbon monoxide levels below 100 ppmv, it is not appropriate to establish a lower floor level because carbon monoxide is a conservative surrogate for organic HAP. Organic HAP emissions may or may not be substantial at carbon monoxide levels greater than 100 ppmv, and are extremely low when sources operate under the good combustion conditions required to achieve carbon monoxide levels in the range of zero to 100 ppmv. (See also the discussion below regarding the progression of hydrocarbon oxidation to carbon dioxide and water). As such, lowering the carbon monoxide floor below 100 ppmv may not provide significant reductions in organic HAP emissions. Moreover, it would be inappropriate to establish the floor blindly using a mathematical approach—the average emissions for the best performing sources—because the best performing sources may not be able to replicate their emission levels (and other sources may not be able to duplicate those emission levels) using the exact types of good combustion

practices they used during the compliance test documented in our data base. This is because there are myriad factors that affect combustion efficiency and, subsequently, carbon monoxide emissions. Extremely low carbon monoxide emissions cannot be assured by controlling only one or two operating parameters."

CIBO agrees that CO is an appropriate surrogate for organic HAP, but we believe HAP emissions are minimized at levels well above the 3 to 10 ppm CO limits proposed for Gas 2 and liquid boilers. At CO levels below about 100 ppm, differences in organic HAP emissions are negligible. Where achievable emission limitations for organic HAP that properly reflect source category and unit variability are derivable from representative data, CO should continue to be used as the compliance surrogate for organic HAP. However, the CO limits should reflect the fact that the organic HAP concentration becomes insensitive to CO level below some value (e.g., 100 ppm).

For coal units, EPA reached a similar conclusion in the recently finalized MATS rule. Many coal-fired boilers emit CO in the range of 50-100 ppm while emitting less than 1 ppm THC. This fact is supported by EPA's boiler ICR databases. Thus, a boiler required to reduce CO to meet the numerical standard could install an oxidation catalyst with no evidence that VOC will be reduced since there is little emitted to begin with.

Response: We agree that CO is an appropriate surrogate for organic HAP. Based on the concern raised by the commenter, and others, that there is a CO level below which organic HAP emissions/destruction are negligible, we conducted an evaluation to determine whether there is a minimum CO level below which there is no further benefit in organic HAP reduction/destruction. We first evaluated the relationship between CO and formaldehyde using the available data obtained during the rulemaking. Formaldehyde was selected as the basis of the CO-organic HAP comparison because it was the most prevalent organic HAP in the emission database and a large number of paired tests existed for CO and formaldehyde. A plot of the paired data showing the relationship between CO and formaldehyde emissions confirms that CO is an appropriate surrogate for organic HAP. The plot shows decreasing formaldehyde emissions with decreasing CO emissions down to CO levels around 300 ppm. The relationship between formaldehyde and CO emissions at levels below 150 ppm, however, suggested that at these low CO levels, CO is not a good surrogate for formaldehyde emissions/destruction because the overall CO-formaldehyde data show either no further reduction or an increase in formaldehyde emissions. In assessing the correlation between CO and formaldehyde, formaldehyde levels appear at their lowest when CO emissions are in the range of 130 to 300 ppm. At CO levels lower than 130 ppm, formaldehyde emissions appear to increase. The lower end of this range, 130 ppm, was therefore used as the minimum CO emission limit for a subcategory if the calculated 99% UPL was less than 130 ppm.

Minimum CO emission limits were assigned to the coal fluidized bed, pulverized coal, heavy liquid, light liquid, non-continental liquid, and gas 2 subcategories for both existing and new sources. The new source coal stoker CO emission limit was also assigned to the minimum value of 130 ppm.

Comment: It is well established that CO is harder to combust than the volatile HAPs that might be emitted by industrial boilers and other similar combustion sources. In this respect, CO actually is a conservative surrogate for volatile HAPs from industrial boilers because measured CO emissions can rise up to a certain point without a corresponding increase in volatile HAP emissions. As mentioned in the previous section, studies have shown that volatile HAP emissions remain extremely low at measured CO levels of up to about 100 ppm.

Thus, while it is certainly possible to reliably measure CO to levels well below 100 ppm, EPA would be justified in setting the IB MACT CO limits at no lower than 100 ppm because lower values would not result in demonstrably lower volatile HAP emissions. This squares with DC Circuit precedent on the use of surrogates because the court has held that EPA may use surrogates as long as the Agency can establish a necessary relationship between emissions of the surrogate and emissions of the underlying HAPs. There is nothing in that precedent that demands that the relationship must be linear. In the case of CO and volatile HAP emissions from industrial boilers, credible data show that the relationship is highly nonlinear at low levels. It would be rational and in keeping with court precedent for EPA to set a CO standard that reflects this nonlinear relationship.

Comment: Carbon monoxide is the most common product of incomplete combustion (PIC), and because of its associated chemical kinetics, is one of the most difficult PICs to oxidize completely. As such, CO emissions have historically been used as an indicator of the quality of the combustion process. The concept is that low CO emissions would equate to negligible emissions of other organic compounds. While this is true in general, the mechanisms by which CO is formed and destroyed in the combustion process are different than for other organics.³³ As such, in cases where other organic compounds have been completely oxidized, CO concentrations may still be elevated. While the tendency is to think that further reductions in CO emissions will improve the quality of the combustion, and in turn minimize emissions of other organic compounds, this is not necessarily true. Instead, forcing CO emissions lower and lower ends up over- constraining the combustion process, producing negative impacts on other air quality concerns, such as NOX emissions, without documented improvements in emissions of organics past a certain level of CO emissions reduction. Because the chemical kinetics make CO far more difficult to oxidize than other organic compounds, it is not necessary to drive CO emissions toward zero to obtain a corresponding minimization of organic emissions.

[Footnote 33: For example, we understand conversion of CO to CO₂ occurs at much higher temperatures than does oxidation of C (in coal or complex organics) or CH₄. CH₄ may burn at around 500 degrees F and carbon in coal at around 800 to 1000 degrees F, but CO converts most

readily around 1800 degrees F. CO as an intermediary in a flame zone likely will see temperatures in excess of 3000 degrees F and convert readily, while CO that carries from the flame zone (such as in the vortex adjacent to pulverized coal burner tips) to near the furnace wall at about 600 degrees would not oxidize but would rise along the furnace wall, never seeing sufficient temperature to ignite and exit as CO in the fuel gas. This is a primary phenomenon contributing to CO emissions levels in the 0 to 100 ppm range. Low loads and transient loads sub-optimize the time, temperature, and turbulence factors contributing further to un-combusted CO. These operational realities have less influence on organics than on CO because of the thermodynamic properties outlined.]

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 51

Comment: EPA has justifiably used a CO standard as a proxy for organic destruction for over 20 years. However, it is well established that CO is harder to combust than the volatile HAPs that might be emitted by industrial boilers and other similar combustion sources. In this respect, CO actually is a conservative surrogate for volatile HAPs from industrial boilers because measured CO emissions can increase to a certain point without a corresponding increase in volatile HAP emissions. As mentioned in the previous section, studies have shown that volatile HAP emissions remain extremely low at measured CO levels of up to about 100 ppm.

The first EPA regulation to set a carbon monoxide (CO) standard for combustion was the "Burning of Hazardous Waste in Boilers and Industrial Furnaces" (56 Fed. Reg. 7134, February 21, 1991) under the Resource Conservation and Recovery Act (RCRA).

In that rule EPA set a CO standard of 100 ppmv. EPA chose that limit because their research indicated that while CO was a good surrogate for the destruction of organics, the validity of that surrogacy broke down at CO levels of approximately 400 ppmv. Based on EPA's authority under RCRA to establish standards that are protective of human health and the environment, the Agency established a 100 ppmv standard as protective.

The Agency later justifies a 100 ppmv standard at 70 Fed. Reg. 59462 (October 12, 2005) for the hazardous waste combustion NESHAP.

Thus, while it is certainly possible to reliably measure CO to levels well below 100 ppm, EPA would be justified in setting the Industrial Boiler MACT CO limits for fossil fuel-fired units no lower than 100 ppm because lower values would not result in demonstrably lower volatile HAP emissions but will create intractable compliance problems. This squares with DC Circuit precedent on the use of surrogates because the court has held that EPA may use surrogates as long as the Agency can establish a necessary relationship between emissions of the surrogate and emissions of the underlying HAPs. There is nothing in that precedent that demands that the relationship must be linear. In the case of CO and volatile HAP emissions from boilers, credible data show that the relationship is highly nonlinear at low levels. It would be rational and in

keeping with court precedent for EPA to set a CO standard that reflects this nonlinear relationship.

Comment: Strict CO levels will not result in greater reduction of emissions of other organic compounds. CIBO has heard from vendors that they cannot guarantee many of the coal, liquid, and gas CO limits. In addition, some of our members with top performing units equipped with sophisticated combustion control like over-fired air, cannot say with certainty that they will meet the limits 100% of the time. CO varies significantly with load and fuel quality to the point that some of the units EPA is relying on to set the MACT floors cannot comply all year round.

Carbon monoxide is the most common product of incomplete combustion (PIC), and because of its associated chemical kinetics, is one of the most difficult PICs to oxidize completely. As such, CO emissions have historically been used as an indicator of the quality of the combustion process. The concept is that low CO emissions equate to low emissions of other organic compounds. While this is true in general, the mechanisms by which CO is formed and destroyed in the combustion process are different than for other organics. As such, in cases where other organic compounds have been completely oxidized, CO concentrations may still be elevated. While the tendency is to think that further reductions in CO emissions will improve the quality of the combustion, and in turn minimize emissions of other organic compounds, this is not necessarily true. Instead, forcing CO emissions lower and lower ends up over-constraining the combustion process, resulting in other air quality concerns, without achieving corresponding reductions in emissions of organics.

Document Control Number: EPA-HQ-OAR-2002-0058-3454-A1

Comment Excerpt Number: 1

Comment: Based on EPA research, the Agency cannot justify setting a MACT-floor emission standard for CO at a level less than approximately 400 ppmv.

In the proposed rule, EPA offers some changes to the CO standard that is being used as a surrogate for organic HAP emissions and proposes a second, alternative CO standard based on CO CEMS data. 76 Fed. Reg. at 80,611, and 80,614. As the Agency knows, based on D.C. Circuit Court of Appeals precedent, EPA may use non-HAP surrogates as long as the Agency can establish a necessary relationship between emissions of the surrogate and emissions of the underlying HAPs. EPA has justifiably used a CO standard as a proxy for organic destruction for over 20 years.

The first EPA regulation to set a carbon monoxide (CO) standard for combustion was the "Burning of Hazardous Waste in Boilers and Industrial Furnaces" (56 Fed. Reg. 7134, February 21, 1991) under the Resource Conservation and Recovery Act (RCRA). In that rule EPA set a CO standard of 100 ppmv. EPA chose that limit because their research indicated that while CO was a good surrogate for the destruction of organics, the validity of that surrogacy broke down at CO levels of approximately 400 ppmv. Based on RCRA's authority to establish standards that are protective of human health and the environment, EPA established a 100 ppmv standard as protective.

Response: We disagree that the Agency cannot justify setting a MACT floor emission standard for CO at a level below 400 ppmv. We do agree that CO is an apparent surrogate for organic HAP and, based on analysis of paired CO-formaldehyde data, there appears to be a CO threshold level which varies depending on boiler type and fuel but these levels are below 400 ppmv. See the response to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 33 for a discussion on establishing minimum CO emission limits.

Comment Excerpt Number: 2

Comment: As the Agency knows, the first stage of thermal decomposition of organic compounds is to form smaller organic compounds (commonly called products of incomplete combustion or PICs). These PICs rapidly decompose to CO – a non-HAP organic not subject to regulation under the CAA MACT program. The second stage of combustion is to oxidize CO to CO₂. The CO to CO₂ step is the rate controlling step because CO is more difficult to oxidize than the other intermediate products of combustion. Given enough time under steady state conditions, all measurable amounts of the organics are destroyed and the CO and CO₂ come into equilibrium. The levels of CO at this equilibrium point depend upon the temperature and the amount of excess air in the combustion chamber. However, since conditions in a combustor are never in equilibrium because additional fuels are being added and gases are being exhausted, the Agency had to decide what levels of CO will guarantee that the organics have been destroyed and they are no longer a threat to human health and the environment – the primary regulatory question for RCRA regulation.

EPA attempted to answer this question in a series of studies to support the BIF rule. The Agency found that there was a correlation between the destruction removal efficiency of organics in the combustion process and CO above 400 ppmv but below this value, the relationship between CO and destruction of organics becomes more complicated. This makes sense since the rate limiting step is not the destruction of hydrocarbon but the oxidation of CO to CO₂. This is illustrated by data comparing benzene emissions to CO concentration (data from Graham, J.L., D.L. Hall, and B. Dellinger, "Laboratory Investigations of Thermal Degradation of Mixtures of Hazardous Organic Compounds," *Envi. Sci. Technol.*, Vol. 20, No. 7, pp 703-710, July 1988, cited in "Guidance on PIC Controls for Hazardous Waste Incinerators," Volume 5 of the Hazardous Waste Incineration Series, EPA/530-SW-90-040, April 1990). This graph [see EPA-HQ-OAR-2002-0058-3454-A2.pdf] shows that the below about 400 ppmv CO, the benzene concentrations are essentially flat and at a very low concentrations. Above these values, the benzene

concentrations may be higher. EPA concluded from this information that CO was a conservative indicator for organics – an important technical policy decision because it meant that below a certain level of CO, one can be assured that organic destruction is adequate. Complete destruction may occur above that level but it is not guaranteed. To add an additional level of safety to this conservative estimate, the Agency chose to set the CO standard at 100 ppmv. From the data, it can be seen that the Agency could just have well selected 200 ppmv or any value up to about 400 ppmv.

Response: See the responses to comments EPA-HQ-OAR-2002-0058-3454-A1, excerpt 1 and EPA-HQ-OAR-2002-0058-3534-A1, excerpt 33.

Commenter Name: Melvin E. Keener

Document Control Number: EPA-HQ-OAR-2002-0058-3454-A1

Comment Excerpt Number: 3

Comment: In the MACT program, EPA is charged with the responsibility to develop emission standards that reflect the maximum degree of reduction in emissions of hazardous air pollutants being achieved by the best performers. According to EPA studies, therefore, all facilities emitting less than 400 ppmv are best performers. There is no reason to distinguish between them. EPA understands this concept because in the boiler and CISWI ICR, the Agency states "Agency research suggests that at CO levels below 100 ppm, CO concentration is no longer an accurate indicator of organic HAP control." (ICR No. 2286.11, OMB Control No. 2060-0616).

CRWI asserts that requiring a combustor to operate below a specified threshold will not result in any additional destruction of organics because there is little or none left to destroy. Thus, EPA is not justified in lowering the CO level to lowest observed level. As a non-HAP surrogate, CO must be judged based on the relationship it has to the regulated HAP. According to EPA research, any combustor with CO emissions below 400 ppmv, has destroyed virtually all organics and should all be considered as top performers. Therefore, setting a CO standard below approximately 400 ppmv is unnecessary and unlawful.

Response: See responses to comments EPA-HQ-OAR-202-0058-3454-A1, excerpt 1 and EPA-HQ-OAR-2002-0058-3534-A1, excerpt 33.

Comment Excerpt Number: 58

Comment: CO is not a reliable surrogate for organic HAP oxidation below 100 ppm and there is, therefore, no basis for establishing emission limitations below that level.

Carbon monoxide is the most common product of incomplete combustion (PIC), and because of its associated chemical kinetics, is one of the most difficult PICs to oxidize completely. Thus, CO emissions are often used as a surrogate for more easily oxidized species, such as organic

HAPs. However, at lower CO levels this association breaks down because once all of the organic compounds have been completely oxidized the CO concentration is no longer an indicator of organic HAP oxidation.

EPA itself has already reached this conclusion in the Hazardous Waste Combustor NESHAP rulemaking. As the Agency states at 70 FR 59462 (October 12, 2005):

We explained at proposal why the carbon monoxide standard of 100 ppmv and the hydrocarbon standard of 10 ppmv are appropriate floors. See 69 FR at 21282. The floor level for carbon monoxide of 100 ppmv is a currently enforceable Federal standard. Although some sources are achieving carbon monoxide levels below 100 ppmv, it is not appropriate to establish a lower floor level because carbon monoxide is a conservative surrogate for organic HAP. Organic HAP emissions may or may not be substantial at carbon monoxide levels greater than 100 ppmv, and are extremely low when sources operate under the good combustion conditions required to achieve carbon monoxide levels in the range of zero to 100 ppmv. (See also the discussion below regarding the progression of hydrocarbon oxidation to carbon dioxide and water). As such, lowering the carbon monoxide floor below 100 ppmv may not provide significant reductions in organic HAP emissions. Moreover, it would be inappropriate to establish the floor blindly using a mathematical approach—the average emissions for the best performing sources—because the best performing sources may not be able to replicate their emission levels (and other sources may not be able to duplicate those emission levels) using the exact types of good combustion practices they used during the compliance test documented in our data base. This is because there are myriad factors that affect combustion efficiency and, subsequently, carbon monoxide emissions. Extremely low carbon monoxide emissions cannot be assured by controlling only one or two operating parameters.

CO is an appropriate surrogate for organic HAP at higher CO levels and for fuels that could generate significant levels of organic HAP, but we believe HAP emissions are minimized at levels well above the 3 to 18 ppm CO limits proposed for Gas 2 and liquid boilers. At CO levels below about 100 ppm, differences in organic HAP emissions are negligible. Thus, the surrogacy argument is not valid below 100 ppm and EPA should not set a CO numerical emission limit below that level.

Response: We agree that the surrogacy argument appears to be not valid below some CO level which appears to be dependent on the boiler type and fuel. See the response to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 33 for further discussion on identifying and establishing minimum CO level..

Commenter Name: Robert D. Bessette

Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 32

Comment: Some boilers only produce significant CO when they are experiencing load variations. All of the testing that is being used to establish the floor was conducted at steady high load conditions. A boiler may have very low CO emissions at steady high load, but significant CO emissions as the load varies. As such, the CO data used to establish the floor may not be

representative of normal boiler operation and a low CO limit may not be achievable by even the top performers under all operating scenarios, including operation at loads less than 100%.

CIBO sought the input of a leading supplier of burners for gas- and liquid-fired boiler applications to determine what CO emission guarantees would be provided for their installations. For applications for Gas 1 category fuels, the CO emission guarantee is generally 50 ppmvd (@ 3% O₂). For ultra-low NO_x burner applications, the CO emissions often exceed 50 ppmvd up to 50% load. For liquid-fired applications, the supplier offers a CO emissions guarantee of 100 ppmvd (@ 3% O₂), for loads ranging from 25% to 100%. Gas 2 sources have a greater variety of emissions characteristics due to the differences in fuel composition, which makes control of excess air more difficult. Most of these other gases tend to be lower heating value than natural gas or refinery gas and burn at lower flame temperatures. They are also commonly limited on the pressure that is available, therefore there is not as much flexibility on how the gases are injected and mixed in the burner. With these factors the potential for CO emissions tends to be higher on these gases than for natural gas or refinery gas. The supplier's default CO guarantee is 400 ppmvd (@ 3% O₂) at loads from 25-100% for Gas 2 fuels. Given the right furnace conditions, the guarantee may be as low as 100 ppm. CO guarantees are only provided on a "steady state" basis, since as burners change load the fuel-air ratio changes until the controls can react and the system stabilizes. If a boiler is equipped with CEMS and operates in a load- following mode, the transient conditions may generate CO levels that would inflate the 30-day rolling average.

Response: EPA agrees with the commenter that boilers may exhibit relatively lower CO emissions during periods of steady high loads and that emissions testing is typically conducted during these periods. EPA has implemented minimum CO emission limits of 130 ppm for all subcategories for which the calculated 99% UPL is less than 130 ppm. The CO emission limit for existing Gas 2 boilers in the final rule is significantly less stringent than the proposed limit of 4 ppm, and EPA believes this mitigates any concerns with low CO emissions correlating to periods of steady high loads exhibited during emissions testing.

Commenter Name: Stephen E. Woock

Commenter Affiliation: Weyerhaeuser Company

Document Control Number: EPA-HQ-OAR-2002-0058-3523-A1

Comment Excerpt Number: 8

Comment: We believe the re-proposed mercury limit for existing units of 3.1 lbs/TBtu, which would be more stringent than that finalized in March 2011, may be unachievable for multi-fuel units that burn biomass and coal without substantially impacting coal use, in essence forcing fuel switching. Use of activated carbon to control mercury emissions is highly uncertain for this type unit given the existence of biomass char already present in the combustion chamber and flue gas and the presence of other acid gas control technology.

Response: EPA has recalculated the mercury emission limitation for boilers and process heaters in the solid fuel subcategory. The resultant emission limitation is less stringent than the limit in the March, 2011 final rule due to the number of best performing sources being reduced from 40 to 39. The permanent closure and reclassification of several sources led to fewer overall sources

with mercury testing data. The EPA ICR Database contains several tests reported as co-firing coal and biomass for which the 3-run average is demonstrating compliance with the mercury emission limitation for solid units. EPA does not agree that this emission limitation will substantially impact coal use or force fuel switching for multi-fuel units. EPA believes that the less stringent limit provides added flexibility to overcome the uncertainty of activated carbon injection when paired with acid gas control technology for these multi-fuel units.

3F03. MACT Floor Results: Existing Coal – Fluidized Bed

Commenter Name: Dell Majure

Commenter Affiliation: Kimberly-Clark Corp.

Document Control Number: EPA-HQ-OAR-2002-0058-3692-A2

Comment Excerpt Number: 3

Comment: The CO emission limit from stack tests for coal-fired FB boiler is 56 ppmv @ 3 % O₂ is derived from CO values from two boilers "IAADM CornProcessingCR" and "ILCornProductsInt" of which both fire bituminous coal. K-C believes that these boilers may not have a FBHE due to the coal sources in the area they are located. K-C has contacted these facilities to confirm this fact, but has not received a response.

There is a fundamental difference between the reference unit and K-C's FBHE boiler. The Chester FBHE boiler cannot operate firing coal with only 9 % ash content because there is not enough ash too facilitate the conductive heat exchange with the furnace tubes and FBHE. By comparison, the design for the K-C FB boiler with its integral FBHE design requires a minimum fuel ash content of 20 – 25 %. This demonstrates a fundamentally different design than a coal-fired FB without a FBHE.

Therefore, the boiler used to establish the CO CEM emission limit is not of the same design or CO emission rates as a coal-fired FB boiler with a FBHE. In addition, the same is true for the CO stack test emission limit assuming that those boilers do not have a FBHE.

Response: EPA agrees with the fundamental design differences between a traditional fluidized bed boiler and a fluidized bed with an integrated heat exchanger, and separate subcategories have been established for these differing designs. An integrated heat exchanger allows a fluidized bed boiler to combust lower-quality coal (i.e., coal with a lower heating value), producing different combustion-related HAP emission characteristics than a fluidized bed boiler without an integrated heat exchanger. The CO CEMS-based and CO stack test-based emission limits have been recalculated for each of these combustor designs.

Commenter Name: Mark D. Pettegrew

Commenter Affiliation: PolyOne Corporation

Document Control Number: EPA-HQ-OAR-2002-0058-3513-A1

Comment Excerpt Number: 1

Comment: In addition to supporting VI's comments, PolyOne Corporation provides its own comments. Our Henry, Illinois facility operates a fluidized bed coal fired boiler that was installed in the mid 1980s. The boiler design and installation was influenced by the state government of

Illinois, as an economic boost to the state economy. This fluidized boiler design was specified because it would allow an Illinois company to burn Illinois coal which is inherently higher in sulfur and chlorine content. EPA's proposed limits for hydrogen chloride (HCl) cannot be met by continuing to burn Illinois coal without installing an expensive emission control device to meet the limit, or retrofitting the boiler and sourcing non-local coal, adversely impacting reliability and cost of our fuel source. We ask that USEPA reconsider the limits for HCl which will permit the continued economic viability of local fuel for this boiler.

Response: The EPA notes that the commenter does not suggest that the boiler is designed in a manner that would prevent HCl controls from being installed on the unit. Instead the comment points to the cost of installing these controls. First, section 112(d) does not permit EPA to take cost into consideration when establishing MACT floor limits. Further, the EPA did not subcategorized boiler types according to the cost to control pollutants from each subcategory, but rather based on differences in the class, type, and size of units. The EPA has evaluated the HCl emissions from the best performing solid fuel boilers and has finalized the emission limits based on the data available to the EPA. The EPA has also incorporated a fuel variability factor for HCl at solid fuel boilers in response to comments to better address fuel variability among best performing units.

3F04. MACT Floor Results: Existing Coal – Pulverized Coal

Commenter Name: Paul Noe

Commenter Affiliation: American Forest & Paper Association (AF&PA) et al.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 46

Comment: EPA proposes to set the CO limit for pulverized coal (PC) boilers at 41 ppm based on 3-hour stack test data from only a small percentage of the population. Vendors will not guarantee this level of performance. There are 188 PC boilers in EPA's database, EPA collected CO stack test data for only 41 units and only 5 units set the floor. With a favorable coal fineness distribution and fairly steady, high-rate load a PC boiler could be optimized to a very low CO emission level (maybe even 41 ppm). This approach (but not necessarily the 41 ppm numerical limit) is good for units that are base loaded close to their maximum capacity rating. Load following ("swing") boilers will seldom achieve the combination of fuel fineness, air control, and flame shape required to produce these low CO emissions because the demand dynamics of the steam system won't allow the boiler controls to find the ideal conditions. Safe boiler operation dictates that anytime boiler load changes, the air supply leads on load increase and lags on load decrease.

This is to ensure that there is never a fuel-rich mixture being introduced into the furnace that could result in an explosion. This safety concern overrides any attempt by an O2 trim controller to drive the air supply to the absolute ideal concentration for both CO and NOX reduction as load changes. Fortunately, the primary CO three hour performance test and longer term average oxygen monitoring provision requirements work in harmony with this safety concern. Because oxygen increases will lead fuel increases in increasing load scenarios and fuel decreases will lead oxygen decreases in decreasing load scenarios, sufficient oxygen for good combustion and safety will always be present, even though CO may increase at low levels as noted earlier.

Response: The CO MACT floor emission limitations for all subcategories have been recalculated based on new data or corrected data since the December, 2011 proposed reconsideration of the rule. The Pulverized Coal CO emission limit is now less stringent than the limit in the proposed rule. Three of the five units comprising the top performing CO emitters for this subcategory were reported as load-following units, and the CO test averages for these units demonstrate compliance with the revised emission limitation. EPA therefore disagrees that load-following units will have difficulty demonstrating compliance with the CO emission limitation for this subcategory.

Commenter Name: Dirk J. Krouskop

Commenter Affiliation: MeadWestvaco Corporation (MWV)

Document Control Number: EPA-HQ-OAR-2002-0058-3493-A1

Comment Excerpt Number: 4

Comment: MWV believes that requirements for certain subcategories remain unachievable. Specifically, we are concerned that the carbon monoxide (CO) standards for pulverized coal boilers are not achievable for many units. MWV is concerned that EPA believes that compliance with these standards is largely a function of combustion only. While combustion is a major factor, these emissions are also a function of boiler geometry, size and residence time. MWV believes that it is possible to implement various control strategies and air system improvement which will lower CO emissions, but not to the levels EPA proposes. MWV believes that EPA should look more closely at either additional subcategories for coal fired units or, as described in other areas of these comments, account, more fully for variability.

Response: For a response on achievability of CO standards for existing pulverized coal boilers, see comment EPA-HQ-OAR-2002-0058-3521-A1, excerpt 46. Specifically for Pulverized Coal boilers, 70 percent of the units in this subcategory for which emissions data were provided demonstrated compliance with the emission limitation in at least one 3-run test (as seen in the memo titled "MACT Floor Analysis for the Industrial, Commercial, and Institutional Boilers and Process Heaters NESHAP" in the docket). Given the number of boilers that reported emissions in compliance with the emission limitation, EPA disagrees that control strategies will be unable to reduce CO emissions for other units and also disagrees that further subcategorization of Pulverized Coal boilers is warranted. The commenter provided no specific information to support any further subcategorization.

Commenter Name: Samuel H. Bruntz

Commenter Affiliation: Alcoa Power Generating, Inc.

Document Control Number: EPA-HQ-OAR-2002-0058-3755-A1

Comment Excerpt Number: 10

Comment: Alcoa - Warrick performed Method 10 tests on one of its pulverized coal industrial boilers pursuant to a Section 114 request. The test results indicated that, on the test day, the proposed short term limit was met. Those tests may not have reflected potential operating conditions, such as mills that may not have been operating at peak performance. In addition, at the time of the Section 114 tests, Alcoa-Warrick was not subject to Best Available Retrofit Technology (BART) requirements for NOx emissions from its industrial boilers. BART will

require compliance with a low NOx burner emission limit of 0.38 lb./mm Btu that becomes effective in 2013. Based on available information for these burners, Alcoa- Warrick projects that it will be unable to comply with the proposed CO emission limit for pulverized coal fired boilers, once it implements the changes needed to comply with the BART emission limit for NOx, and requests that the proposed emission limit be increased to 150 ppm.

Response: For a response on the general achievability of CO standards for existing pulverized coal boilers, see comment EPA-HQ-OAR-2002-0058-3521-A1, excerpt 46. The relationship between CO and NOx emissions for the top performing CO emitters was evaluated for each subcategory. The MACT floor emission limit for Pulverized Coal boilers is calculated from a mixture of tests which exhibit both high and low NOx emissions, and EPA believes the variability between these tests results in an appropriate emission limitation for the subcategory. Several Pulverized Coal boilers are demonstrating compliance with the CO emission limitation while simultaneously demonstrating compliance with the 0.38 lb/MMBtu BART requirement for NOx (see the memo titled "MACT Floor Analysis for the Industrial, Commercial, and Institutional Boilers and Process Heaters NESHAP" in the docket). EPA therefore disagrees that units will be unable to demonstrate compliance with both emission limitations.

Comment Excerpt Number: 2

Comment: Review of the boiler MACT survey database and specifically Appendix B-4b: Unit Rankings for CO from Pulverized Coal 9 /Solid Fossil Fuel Units (Recommended Option), leads MSU to believe that the units that were used to set the floor are not representative units for MSU's boilers. To begin, MSU's PC boilers are equipped with low nitrogen oxide (NOx) burners (LNBS) and selective non-catalytic reduction (SNCR) controls to comply with NOx standards during the ozone season. NOx and CO have an inverse relationship when it comes to combustion properties. By reducing NOx emissions through control, MSU's CO emissions are higher than units not equipped with similar control. Of the five (5) units used to set the MACT floor for pulverized coal (PC) boilers, only one (1), the highest emitting in the floor, is equipped with low NOx burners and none of the units have SNCR. Therefore, MSU's boilers are not similar to those used to set the floor.

Response: EPA evaluated the relationship between CO and NOx emissions for all top performers. The ratio of reported NOx to CO emissions for several of the top performers in the Pulverized Coal subcategory is on the same level as reported for the Michigan State University boilers (where NOx emissions are less than five times higher than CO emissions). The EPA disagrees with the commenter that the design of pollution control equipment such as low NOx burners and SNCR should influence the subcategories established under this rule.

Comment Excerpt Number: 3

Comment: When the limitations were set in this proposed reconsidered rule, they were set for units greater than or less than 250 million British thermal units per hour (MMBtu/hr) of heat input. Review of Appendix B-4b, shows that the second lowest emitting source operates at 163 MMBtu/hr and the 6th ranked unit operates at 209 MMBtu/hr. MSU's boilers are all rated above the 250 MMBtu/hr threshold and should not be required to meet the same emission threshold that is met by smaller units.

Response: The MACT floor emission limitations for all subcategories have been revised since the December, 2011 proposed reconsideration of the rule. For the CO MACT floor emission limit for Pulverized Coal units, three of the 5 units comprising the top 12 percent have a maximum rated heat input capacity of greater than 250 MMBtu per hour. The remaining two units have a capacity below 100 MMBtu per hour. EPA believes that the large size range of the units comprising the top 12 percent mitigates the commenter's concerns.

For response to issues with NO_x control differences between MSU boilers and other top performing pulverized coal boilers, see comment EPA-HQ-OAR-2002-0058-3674-A2, excerpt 2.

Comment: The emissions data for CO from each of the best performing units was obtained from 3 consecutive 1-hour stack tests, which are typically performed at maximum or normal operating loads and do not account for startups and shutdowns. U.S. EPA obtained actual CO CEMS data from two coal-fired units and noted that CO emissions from these units did not vary at loads below the design capacity. As such, the proposed CO emission limit encompasses all operating loads and does not include periods of startup and shutdown.

Response: The EPA acknowledges this comment.

Comment Excerpt Number: 7

Comment: EPA's proposed reduction of the CO limits for existing pulverized coal boilers is of particular concern. The CO limit in the final rule when using stack testing is 160 ppm; the proposed limit drops to 41 ppm, both corrected to 3% oxygen. Our existing PC boilers have been configured to minimize NO_x formation in the furnace for compliance with Section 308 of the CAAA Regional Haze Rule for prevention of visibility impairment in Class I areas. The proposed CO limit will require excess oxygen levels in the furnace to be increased significantly which will create a fuel-lean condition; this will be detrimental to the effectiveness of the existing controls that inhibit NO_x formation.

Response: For the reasons listed in the preamble to the March, 2011 final rule, EPA believes that oxidation catalysts may be used to reduce CO emissions without increasing emissions of

NOx. The installation and operation of an oxidation catalyst would allow sources to reduce their CO emissions without significantly impacting boiler operating parameters (such as excess air) because the catalyst treats the effluent gas from the boiler instead of being placed in the combustion chamber. Control costs for oxidation catalysts were factored into EPA's cost analysis. Further, EPA has implemented minimum CO emission limits of 130 ppm for all subcategories for which the calculated 99% UPL is less than 130 ppm. EPA believes the less stringent limit and the applicability of oxidation catalysts mitigate the commenter's concerns about significantly altering existing operating conditions.

Document Control Number: EPA-HQ-OAR-2002-0058-3453-A1

Comment Excerpt Number: 8

Comment: Compliance with the proposed CO limit will require substantial modifications to the fuel-air management systems on our boilers and may ultimately require add-on emission control equipment to capture the NO, generated from the fuel-lean combustion requirements. As a practical matter, it seems contrary to good regulatory management by proposing a CO limit which promotes formation of NOx, a long-established NSPS criteria pollutant and regulated as a precursor pollutant for visibility and deposition impairment in Class I areas.

Response: For response to CO limits for existing pulverized coal boilers necessitating increased excess oxygen and creating fuel-lean scenarios, see comment EPA-HQ-OAR-2002-0058-3453-A1, excerpt 7.

3F06. MACT Floor Results: Existing Biomass – Fluidized Bed

Commenter Name: Gretchen Brewer

Commenter Affiliation: PT AirWatchers

Document Control Number: EPA-HQ-OAR-2002-0058-3825-A1

Comment Excerpt Number: 2

Comment: For fluidized bed, biomass fuel cells, and biomass hybrid suspension grate, the limits for existing units should be adjusted down to the same level as for new units.

Response: EPA disagrees that existing source emission limits should be adjusted downward to be identical to the new source emission limitation for the same subcategory. The commenter provides no rationale for such an approach.

Commenter Name: Gretchen Brewer

Commenter Affiliation: PT AirWatchers

Document Control Number: EPA-HQ-OAR-2002-0058-3825-A1

Comment Excerpt Number: 1

Comment: The gap between existing unit and new unit standards for the following three control technologies are excessive, especially as compared with the difference for other technologies listed.

- Fluidized bed - existing @ 0.11 lb/MMBtu ; new @ 0.0098 lb/MMBtu
- Biomass Fuel cells - existing @ 0.033 ; new @ 0.011 lb/MMBtu
- Biomass Hybrid suspension grate - existing @ 0.44 ; new @ 0.026 lb/MMBtu

Response: The MACT floor emission limits for these subcategories have been recalculated. Due to the reclassification of units in the major source boiler and process heater inventory, the Biomass Fuel Cell emission limitation for filterable PM for existing sources is now less stringent than the limit in the December, 2011 proposed reconsideration of the rule. The Fluidized Bed and Hybrid Suspension/Grate filterable PM emission limits remained unchanged. The existing source limits for these units are calculated based on the variability of the emissions data from the top 12% of the emitters in the subcategory, as per the requirements of the Clean Air Act. Further, the CAA requires that new source MACT floor limits be based on the emissions performance of the best performing similar source, and that existing source floor limits be based on the average emissions performance of the best performing 12 percent of sources in the subcategory, and EPA has calculated floor limits according to the requirements of the Act. Moreover, EPA does not believe the gap between the existing and new source limits are excessive. For response to the request that emission limits for existing Fluidized Bed units, biomass Fuel Cells, and biomass Hybrid Suspension/Grate units should be adjusted downward to be at the same level as the new source emission limits, please see comment EPA-HQ-OAR-2002-0058-3825-A1, excerpt 2.

3F08. MACT Floor Results: Existing Biomass – Suspension Burner

Commenter Name: Mark Weiss

Commenter Affiliation: Reciprocal Energy Company

Document Control Number: EPA-HQ-OAR-2002-0058-3658-A2

Comment Excerpt Number: 2

Comment: We believe that the data used to set parameters for CO emissions within the Major Source Rule raises questions about the methodology for data acquisition and its application in the Rule. I am referring specifically to the data points and resulting limits for both the 3-hour and ten day test for CO.

The standard for CO is posted as: Existing—Biomass Suspension Burner.... 58 PPM or CEMS 1,400 PPM. It is unclear if they were recorded with fossil fuel supported flames. 58 PPM of CO is not achievable in most, if not all, suspension combustion applications using field-processed biomass. A typical suspension combustion power plant in Europe will operate at or below 200-300 PPM of CO. Low firing rates will typically produce higher CO readings.

Response: EPA has recalculated the CO MACT floor emission limitation for this subcategory. The resultant limit is less stringent than the limit in the December, 2011 proposed reconsideration of the rule. EPA believes that all suspension combustion applications should be able to demonstrate compliance with the final rule limitation since all top performer 3-run test averages are demonstrating compliance with the revised limit (see the memo titled "MACT Floor

Analysis for the Industrial, Commercial, and Institutional Boilers and Process Heaters NESHAP" in the docket).

Commenter Name: Mark Weiss

Commenter Affiliation: Reciprocal Energy Company

Document Control Number: EPA-HQ-OAR-2002-0058-3658-A2

Comment Excerpt Number: 5

Comment: The required testing is designed for long, steady full fire. Many applications do not allow for steady state full fire. These "load following" applications minimize fuel consumption/emissions but the testing protocols are not applicable to these installations, by type.

Response: The CO MACT floor emission limitation for Suspension Burners designed to combust biomass or bio-based solid fuel was calculated from the emissions of a load-following boiler. Moreover, some of the load-following units are currently meeting the CO limit (see the memo titled "MACT Floor Analysis for the Industrial, Commercial, and Institutional Boilers and Process Heaters NESHAP" in the docket). EPA therefore disagrees that load-following units will have difficulty demonstrating compliance with the testing requirements and emission limitations in the rule.

Commenter Name: Mark Weiss

Document Control Number: EPA-HQ-OAR-2002-0058-3658-A2

Comment Excerpt Number: 7

Comment: Size matters. Small boilers (under 100,000 pounds of steam per hour) used primarily for thermal can have higher CO levels given turn down requirements. These applications can play a vital role in reducing dependency on fossil fuels and over-all emissions.

Response: The CO MACT floor emission limit for Suspension Burners designed to combust biomass or bio-based solid fuels is calculated from the emissions of a boiler rated at less than 100,000 pounds of steam per hour. EPA acknowledges the comment that small boilers play a vital role in reducing the dependency on fossil fuels and overall emissions.

Commenter Name: M.L. Steele

Commenter Affiliation: CraftMaster Manufacturing, Inc.

Document Control Number: EPA-HQ-OAR-2002-0058-3814-A1

Comment Excerpt Number: 9

Comment: CO MACT Limit for Suspension Burner biomass subcategory. The proposed limit of 58 ppm_{dvc} is unrealistic and must be questioned. We base this statement on the following points:

a) The limit does not remotely compare to any of the other biomass subcategories. The next lower limit is four times higher.

b) The limit is based on test data from only one source.

- c) CraftMaster's experience with a combination suspension-fired and stoker-fired biomass unit is that CO is higher when firing in suspension yet the CO limit for stokers is 13 times higher than the proposed suspension limit.
- d) The CO MACT limit for Suspension burners is not consistent with the CO GEMs MACT limit for the same subcategory. While the CO MACT limit is the lowest, the CO GEMs MACT limit of 1400 ppm_{dvc} is the highest of all the biomass subcategories.
- e) Was the biomass fuel fired during the stack test process-specific or representative of that used by the entire subcategory?
- f) Was any co-firing of other fuels occurring during the stack test?
- g) Is the relatively small size (40 MMBtu per hour) of the unit tested representative of the entire subcategory?
- h) What were the combustion conditions (%excess air, etc.) during the CO stack test and are they transferrable to the entire subcategory?

Response: EPA has revised the CO MACT floor emission limitation for Suspension Burners designed to combust biomass or bio-based solids since the December, 2011 proposed reconsideration of the rule. The revised emission limit is less stringent than in the proposed rule. The revised CO CEMS MACT emission limit is also less stringent than was proposed.

Given the limited amount of available emissions data from units in this subcategory, the emission limit is still calculated from the emissions from a single unit. This is consistent with the language of section 112(d)(2), which requires that MACT floor limits be calculated based on the best performing twelve percent of units "for which the Administrator has emissions information[.]" not the best performing twelve percent of units in the entire subcategory. In some cases, as in this case, where EPA lacks emissions information for all units in the subcategory, the floor limit must therefore be established based on fewer than the top twelve percent of all such units. The top performing unit reported four separate 3-run emissions tests, each of which is combusting at least 90 percent plywood generated on-site. One of the tests co-fires natural gas, which accounts for approximately 5 percent of the heat input during the test. However, the best-performing test reported by the facility combusts 100 percent plywood.

The average design capacity for all major source boilers and process heaters in the Suspension Burner subcategory is 56 MMBtu per hour and the median design capacity for the subcategory is 40 MMBtu per hour. For this reason, EPA believes that the size of the top performer (40 MMBtu per hour) is an accurate representation of the entire subcategory. Finally, EPA believes that the commenter's concerns regarding differences in the combustion conditions of the top performer test data are addressed by the CO limit in today's final action, which is less stringent than the proposed limit.

Comment Excerpt Number: 7

Comment: CO MACT Floors and Limits for biomass subcategories

The CO MACT limits for the "Suspension Burners" and "Dry Stokers" subcategories are based on only one stack test in each subcategory. This limited sample size simply cannot be indicative of the emissions being achieved by the average of the best performing 12% of units in the source category. Per USEPA's data these subcategories contain 47 (Suspension) and 74 (Dry Stokers) units. Then the number of units in the top 12% would be 6 and 9 for the Suspension Burners and Dry Stokers subcategories, respectively. Test data is available to USEPA for 6 units in each subcategory but USEPA considers only one test on one unit in each subcategory to establish the MACT limits. Ironically, if the source categories had contained fewer units (< 30) USEPA would be required to include test data from a greater number (5) of units in the MACT Floor average.

We believe USEPA is pre-mature in issuing any firm limit for an entire source category based on test data from a single unit.

Response: For a general response to issues with the Suspension Burner CO emission limitation being calculated from the emissions data from a single unit, please see comment EPA-HQ-OAR-2002-0058-3814-A1, excerpt 9. Consistent with other rulemakings, the top 12 percent of units in a subcategory applies to the number of units with available test data and not the total number of units in the subcategory. In subcategories for which EPA has emissions information for only 6 units, a single unit represents the top 12 percent when rounding up to the nearest whole number.

3F09. MACT Floor Results: Existing Biomass – Hybrid Suspension/Grate

Commenter Name: Responsible Citizens

Commenter Affiliation: John Smith

Document Control Number: EPA-HQ-OAR-2002-0058-3531-A1

Comment Excerpt Number: 2

Comment: In the December 2011 proposed rule, EPA introduced a new biomass boiler subcategory (the hybrid suspension/grate boiler). The PM limits on this new subcategory are more than 10 times more lenient than the limits on other biomass boilers. The CO limit (3900 ppm) is 100 times more lenient than other biomass units. Even though EPA describes this new subcategory as being developed for the small number of bagasse-fired boilers, the definition of the subcategory makes it very easy for a large majority of biomass boilers that fire non-dry fuel to be categorized in the hybrid suspension/grate subcategory. EPA MUST place more restrictions on the boilers that fall under this category. Otherwise the result will be a majority of grate-based biomass boilers being categorized under this dubious subcategory. Many of these existing units are already subject to NSPS standards for PM (0.10 lb/MMBtu), so it is inexplicable that EPA would roll out a PM MACT standard four times greater than the NSPS. And that the CO standard would be 100 times greater than the levels many of these units already operate at.

Response: EPA has revised the CO MACT floor emission limitation for Hybrid Suspension/Grate units designed to combust biomass or bio-based solid fuels. The revised emission limit is more stringent than the limit in the December, 2011 proposed reconsideration of the rule. EPA has revised the definition of the Hybrid Suspension/Grate subcategory such that

only the intended Hybrid Suspension/Grate biomass combustors meet the definition of the subcategory.

3F10. MACT Floor Results: Existing Wet Biomass – Stoker/Sloped Grate/Other

Commenter Name: John S Williams

Commenter Affiliation: Maine Pulp & Paper Association (MPPA)

Document Control Number: EPA-HQ-OAR-2002-0058-3466-A1

Comment Excerpt Number: 6

Comment: CO Standards are problematic.

The new CO limits are particularly problematic for stoker boilers burning wet biomass¹ (such as those at the S.D. Warren Somerset, Lincoln Paper & Tissue, Verso Paper and Old Town Fuel & Fiber mills). Boiler adjustments and costly combustion air reconfigurations (which are not even physically possible on some older boilers) are not likely to be sufficient for some biomass stoker boilers to meet the CO limits. Further, CO catalysts which convert CO to CO₂ (a greenhouse gas) and which typically cost over one million dollars may get poisoned, making them ineffective.

The Boiler MACT CO limits would necessitate combinations of emission controls that would have adverse effects on each other, and even then are unachievable for certain biomass boilers at Maine mills.

Response: EPA has revised the CO MACT floor emission limitation for Stokers/Sloped Grate/Other units designed to combust wet biomass fuel. The revised emission limitation is less stringent than the limit in the December, 2011 proposed rule, and EPA believes that the commenter's concerns regarding the potential impacts of different control technologies on each other are addressed by the revised limit. Approximately 78 percent of the units in this subcategory with CO emissions data reported at least one test that is demonstrating compliance with the revised CO emission limit.

3F11. MACT Floor Results: Existing Dry Biomass – Stoker/Sloped Grate/Other

Commenter Name: Bill Lane

Commenter Affiliation: American Home Furnishings Alliance (AHFA)

Document Control Number: EPA-HQ-OAR-2002-0058-3676-A2

Comment Excerpt Number: 2

Comment: We have some concerns about the specific criteria and requirements for the dry biomass subcategory. Most importantly, we are very concerned that the emission standard for carbon monoxide (CO) from existing boilers (250 ppm corrected to 3% oxygen) is not representative of the best performing boilers that belong in the subcategory. According to the EPA database, the MACT floor determination that produced this limit is based on the emissions data from the Algoma hardwood facility located in Algoma, Wisconsin. It is our understanding that this facility is a synthetic minor facility. AHFA believes that the facility should not be

considered in the MACT floor analysis because as a HAP minor source it is not part of the kiln-dried biomass subcategory for the major source Boiler MACT.

Response: EPA agrees that the Algoma Hardwood facility located in Algoma, Wisconsin is a synthetic minor source of HAP emissions, and has been reclassified as such in the EPA ICR Databases. As such, the emissions data from this source have been excluded from the calculation of MACT floor emission limits.

Commenter Name: Bill Lane

Commenter Affiliation: American Home Furnishings Alliance (AHFA)

Document Control Number: EPA-HQ-OAR-2002-0058-3676-A2

Comment Excerpt Number: 3

Comment: We are aware that very little CO emission data were available for calculation of the MACT floor in the kiln-dried biomass boiler subcategory. The lack of data for CO and other target pollutants strongly suggests that additional time for source evaluation is warranted prior to finalizing the MACT floor for this subcategory. Although insufficient time was available for a thorough evaluation of existing sources, the AHFA initiated an ongoing CO test program with the objective of identifying the magnitude and range of previously unknown CO emissions in the kiln-dried biomass subcategory. Preliminary results demonstrate sizeable variability within the subcategory, with CO measurements @3% oxygen ranging from 211 ppm to nearly 35,000 ppm. We are concerned that this high level of variability in such a small subcategory is not adequately accounted for in the current floor calculation method employed by EPA.

Response: EPA is required to establish MACT floor levels based on emissions limits achieved by sources for which emissions information is available to the Administrator. The MACT floor emission limitations were calculated from available emissions data in the EPA ICR Databases. EPA acknowledges that CO emissions can fluctuate greatly from units combusting biomass or bio-based solid fuels. The commenter did not provide enough information relative to the CO emissions data from kiln-dried biomass combustion ranging from 211 to 35,000 ppm to allow the data to be incorporated into the EPA ICR Databases.

3F12. MACT Floor Results: Existing Liquid

Commenter Name: Paul Noe

Commenter Affiliation: American Forest & Paper Association (AF&PA) et al.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 45

Comment: We have heard from numerous vendors that they cannot guarantee many of the liquid and gas CO limits. Low-NOX burner (LNB) designs for gas-fired boiler applications manipulate the stoichiometry within the flame to minimize NOX formation. These designs establish a fuel-rich zone for the initial phase of combustion, and then add air at a later stage in the outer regions of the flame. In the initial phase, there is not sufficient oxygen available to form significant amounts of NOX, and in the secondary phase, the flame is much cooler, which also inhibits NOX formation. However, these burners often operate with CO emission up to 10 ppmvd in the upper part of the load range. At mid loads, the CO begins to increase near 50

ppmvd, and at low loads, it may exceed 100 ppmvd. Older or "first generation" low NOX burners are reported to generate even higher levels of CO for a given NOX reduction. These low-NOX burners will not be able to achieve CO emissions as low as the 4 ppmvd levels proposed by EPA, and many older existing units will not be able to achieve a CO limit below 100 ppmv. As EPA is on the verge of establishing a lower ozone standard, many more facilities will likely be installing low-NOX burners. Further, specifying CO limits below those needed to achieve good combustion and organic HAP destruction levels is expected to result in facilities having to replace many existing LNB currently in service.

Response: EPA investigated the relationship between CO and NOx for the top performer emission tests by calculating a NOx-to-CO ratio for all tests where NOx data were available. High ratios suggest that low levels of CO are achieved at the expense of elevated NOx emissions. For existing source floor calculations, EPA believes that the variability in emissions of all top performers accounts for the cases where CO emissions are minimized by increasing NOx emissions. Several of the top performing CO emitters have low NOx burners installed and exhibit both low CO and low NOx emissions. EPA acknowledges that emissions of CO and NOx can affect one another, but believes that the presence of units with low NOx burners exhibiting low CO and low NOx emissions, as well as the resultant variability of the units comprising the top 12 percent, mitigates any concerns that liquid-fired combustion units with low NOx burners will be unable to demonstrate compliance with the CO emission limitations for liquid-fired units in the rule.

Commenter Name: Mary Sullivan Douglas

Commenter Affiliation: National Association of Clean Air Agencies (NACAA)

Document Control Number: EPA-HQ-OAR-2002-0058-3525-A1

Comment Excerpt Number: 25

Comment: EPA's proposed limits for Hg emissions from liquid-fired boilers reveal the magnitude of EPA's decisions respecting (1) the level of precision to be employed in conducting emission testing and fuel analysis, (2) determining variability of "best" sources with insufficient data, (3) "pooling" variance among different sources where there is no reason to believe that each of those sources has the same amount of variability, and (4) determining the UPL based on emission data where the source is not "in compliance."

Distillate oil (#2 oil) is commonly understood to contain far less Hg than coal or biomass; while residual oil (#6 oil) contains somewhat less Hg than solid fuels. EPA's existing source MACT floor is based on a series of test results from ten sources combusting four different types of oil.²³ Six sources submitted the results of a single compliance test and four sources submitted 41 fuel analyses. The arithmetic average of these results is 3.70×10^{-7} lb/MMBtu and the standard deviation is 3.07×10^{-7} lb/TBtu, suggesting that a reasonable MACT floor would be in the range of $1.0 - 1.5 \times 10^{-6}$ lb/MMBtu (a variability factor of 300 to 500 percent).²⁴ EPA's earlier UPL calculation led to the final rule MACT standard of 3.4×10^{-6} lb/MMBtu – a variability factor of over 900 percent. EPA's newly proposed statistical procedure results in a proposed UPL of 2.49×10^{-5} , using the same data. This number is more than 100 times the arithmetic average of the data and more than 100 times the standard deviation of the data set²⁵.

As a consequence, of the 71 sources for which EPA has data, only four sources will have to reduce emissions.

[Footnotes]

(23) MACT Floor Memo, Appendix C-4-(a)(i).

(24) A somewhat higher limit may be appropriate as many of the reported results were below detection limits, thereby constraining the variability that would have been demonstrated by more precise analyses. This effect is offset by the fact that the arithmetic average would be lower with more precise analyses, but the degree to which these factors offset is not known.

(25) Sources routinely maintain, and EPA agrees, that fuel variability is so small that sources only have to conduct new fuel analyses when they change suppliers.

Response: The mercury MACT floor emission limitation for liquid-fired units has been revised since the December, 2011 proposed reconsideration of the rule. The revised limit is more stringent than the proposed limit because of an error in the 99% UPL calculated for the proposed rule; mercury emissions from non-continental liquid boilers were inadvertently disregarded from the calculation of the 99% UPL at proposal, but were added to the calculation of the revised 99% UPL for the final rule. The more stringent limit requires more liquid-fired boilers to reduce mercury emissions than the proposed limit. As was done for the proposed rule, the mercury MACT floor emission limit for liquid-fired combustion units was computed from emissions data from both distillate and residual fuel oils.

EPA acknowledges that distillate oil and residual oil contain differing and varying levels of mercury content. However, the 99% UPL calculation was not changed for liquid-fired sources because the best performing sources contain emissions data from both distillate and residual oil (see the memo titled, "MACT Floor Analysis for the Industrial, Commercial, and Institutional Boilers and Process Heaters NESHAP" in the docket). Since the 99% UPL is calculated on data from both distillate and residual fuel oils, EPA believes the 99% UPL appropriately accounts for the variation in mercury content between the two fuels.

Commenter Affiliation: National Association of Clean Air Agencies (NACAA)

Document Control Number: EPA-HQ-OAR-2002-0058-3525-A1

Comment Excerpt Number: 26

Comment: As Table 1 demonstrates, many of the characteristics of the data for the liquid fuel-fired subcategory are similar to those in the solid fuel-fired subcategory and yet EPA's proposed

MACT floor for liquid fuel-fired boilers is nearly ten times higher than the proposed limit for solid fuel-fired units. [See submittal for Table 1] Charts 2 and 3 demonstrate the impact of EPA's determination of variability on the effectiveness of the rule. [See submittal or Charts 2 and 3] The average of the top 12 percent (lowest test value) in each case is well below 1.0×10^{-6} lb/MMBtu. If EPA had set the limit for coal-fired units at that level, approximately 25 percent of the subcategory would meet the limit and the balance would be required to take some steps to reduce emissions. At the proposed level of 3.1×10^{-6} lb/MMBtu, while the gross emitters would

have to take steps to comply, approximately two thirds of the units in the subcategory would not need to reduce emissions. For the oil-fired subcategory, only four of 71 units would have to reduce emissions at all; the proposed limit is five times higher than the emission rate of the fifth highest emitting unit in the subcategory.

These results do not appear to be consistent with EPA's obligation to set MACT floors at levels that represent the average of the performance of the top 12 percent.

NACAA attempted to discern why EPA's procedure generated such different results when the overall distribution of the Hg emissions data for coal and oil-fired units was so similar. The largest single reason for this vast difference appears to be a simple error in importing the data – EPA incorporates the emissions data for HCl instead of Hg into its UPL calculation.²⁶ With the correct data, EPA's 99th percentile UPL calculation yields a MACT floor of 4.58×10^{-7} lb/MMBtu.

[Footnote]

26 The error can be found in MACT Floor Memo, Appendix C, Worksheet "C-4(a)(iv)&C-4b(iv)" which is then carried over into Worksheet "C-4(a)(ii)."

Response: The mercury MACT floor emission limitation for liquid-fired units has been revised since the December, 2011 proposed reconsideration of the rule. The revised limit is more stringent than the limit in the proposed rule. The revised 99% UPL is still greater than 1.0×10^{-6} lb/MMBtu, but EPA believes that since the limit is more stringent than the limit in the proposed rule it correlates to a fair mixture of sources that will be required to reduce emissions and those which will not. For a response to the claim that only 4 units were required to reduce emissions to demonstrate compliance with the proposed limit, please see comment EPA-HQ-OAR-2002-0058-3525-A1, excerpt 25.

3F13. MACT Floor Results: Existing Heavy Liquid

Commenter Name: Dakota Gasification Company Great Plains Synfuels Plant

Commenter Affiliation: David W. Peightal

Document Control Number: EPA-HQ-OAR-2002-0058-3424

Comment Excerpt Number: 2

Comment: In previous comments, DGC requested that EPA evaluate DGC's stack test results and re-evaluate the variability of carbon monoxide emissions. DGC does not combust No. 6 fuel oil. DGC combusts byproduct fuels, residual type oils. This is similar to EPA's comment to the non-continental liquid units' discussion as far as type of combustion fuels. The stack test results from DGC demonstrated the variability in CO emissions. DGC's test run result for testing CO demonstrated that CO emissions at DGC's GPSP varied from 0.67 ppm to 187.11 ppm. These are one-minute values corrected to 3% Oz. In addition, EPA did not adequately address the inverse relationship with CO emissions versus NOx emissions management, which causes competing issues such as efficiency versus minimizing NOx emissions for permit compliance and may not leave a window to operate effectively. Operating parameters required to achieve 10 ppm CO emissions where EPA has not demonstrated that a 10 ppm CO limit is a true indicator of complete combustion of organic HAPs. DGC requests EPA to re-evaluate the proposed basis of

having a 10 ppm limit or an 18 ppm limit with an averaging time of 10 days for heavy liquid units that combust residual type fuels or other byproducts of heavy liquid fuels.

Response: The facility's emissions data have been incorporated into the EPA ICR Databases. EPA acknowledges that the units at the facility combust process-specific liquid fuels with similar characteristics to residual fuel oil. However, the heat input data reported for the emissions testing show that approximately half of the heat input from the test was obtained from these residual-type liquid fuels; the remaining heat input came from gaseous fuel. Thus, given the procedures outlined in the memo entitled, "Revised MACT Floor Analysis (May 2012) for the Industrial, Commercial, and Institutional Boilers and Process Heaters NESHAP" in the docket, the reported emissions data do not qualify for consideration in the calculation of the MACT floor emission limitations since the test data do not correlate with the combustion of at least 90% heavy liquid fuel.

For a response to the claim that EPA should evaluate the relationship between CO and NO_x emissions, please see comment EPA-HQ-OAR-2002-0058-3521-A1, excerpt 45 under the chapter for Existing Results: Liquid.

EPA disagrees that separate limits are justified for units combusting process-specific residual-type liquid fuels. Reported emissions from process-specific residual-type liquid fuels are comparable to emissions data from traditional residual fuel oil.

Commenter Name: Sarah E. Amick

Commenter Affiliation: Rubber Manufacturers Association (RMA)

Document Control Number: EPA-HQ-OAR-2002-0058-3503-A1

Comment Excerpt Number: 6

Comment: EPA is proposing a stringent set of emission limits for light and heavy liquid fuel boilers that are, in many cases, not based on the use of any technology. In many cases, light and heavy liquid fuel boilers are achieving low emission rates not due to use of any particular technology, but due to the mix of fuels being fired (which sometimes includes fuels with pollutant contents below the limits of detection) or other unit specific characteristics that are not transferable to other sources. Facilities are limited in the fuels that their boilers can fire by design, cost, permits, and fuel availability. EPA should not set limits for hundreds of liquid fuel boilers based on data from a few boilers in which the specific mechanisms resulting in lower emissions are not fully understood and that are not available to all units in the subcategory.

Response: The EPA disagrees that co-fired units are providing a downward bias to the MACT floor emission limitations for the Heavy and Light Liquid subcategories. The only pollutant for which the top 12 percent comprises a co-fired test is the CO MACT floor emission limitation for the Heavy Liquid subcategory. However, as seen in the memo titled "MACT Floor Analysis for the Industrial, Commercial, and Institutional Boilers and Process Heaters NESHAP" in the docket, there are several tests in this subcategory from units which reported they are combusting 100 percent residual oil and are demonstrating compliance with the CO emission limit in the rule.

3F15. MACT Floor Results: Existing Non-Continental Liquid

Commenter Name: Christopher Coleman

Commenter Affiliation: HOVENSA LLC. , Hess Corporation

Document Control Number: EPA-HQ-OAR-2002-0058-3673-A2

Comment Excerpt Number: 7

Comment: The API and AFPM comments both discuss the proposed limits for CO and PM. HOVENSA supports the view that the CO limit should be based on longer term data where that is available and that using a short 3 hour period is particularly inapt for oil fired units. This is primarily because of the need to switch fuels, but is also because of variability in the fuel gas system that is amplified in island refineries because of the absence of natural gas. See HOVENSA's comments on Proposed BPH MACT, pages 16 and 21-28. HOVENSA also supports the position taken by API and NFPM that a CO limit of 51 ppmv for a performance test is appropriate, based on the data available.

Response: EPA disagrees that longer than a 3-hour testing period should be required for non-continental units designed to combust liquid fuels. Several of the top performing CO and PM tests from these units were conducted during a 3-hour testing period, proving that a longer testing period is not necessary to determine compliance with the emission limitations in the rule. Further, EPA has implemented minimum CO emission limits for all subcategories for which the calculated 99% UPL is less than 130 ppm. For these reasons, EPA believes that the concern of non-continental liquids not being able to demonstrate with CO emission limits due to fuel variability is mitigated.

Commenter Name: Christopher Coleman

Commenter Affiliation: HOVENSA LLC. , Hess Corporation

Document Control Number: EPA-HQ-OAR-2002-0058-3673-A2

Comment Excerpt Number: 8

Comment: HOVENSA strongly supports the API and NFPM position on PM limits for non-continental units and the optional use of TSM. We concur that HOVENSA's units should be removed from the subcategory since they have been shut down, thus reducing the units in the category to below 30 sources. However, even if that were not so, using a single source to set the MACT floor makes no statistical sense and simply cannot be viewed as a fair view of the variability in operation between the tested Tesoro and Chevron units. This is underscored by the point that the Tesoro test was conducted at 40% load with a low PM but higher NOx emitting burner design. API and NFPM included manufacturer data that demonstrated that PM emissions are much lower at this load level. This data is confirmed by EPA's own compilation of emissions factors information for fuel oil combustion.

"Boiler load can also affect filterable particulate emissions in units firing No. 6 oil. At low load (50 percent of maximum rating) conditions, particulate emissions from utility boilers may be lowered by 30 to 40 percent and by as much as 60 percent from small industrial and commercial units."

Source: AP-42 Emissions Factors Chapter 1-3 Fuel oil Combustion, Section 1.3.3.1.

Accordingly, HOVENSA concurs that the API/AFPM .36 lbs/MMBTU is an appropriate emissions limit.

Response: For responses to the closure of the HOVESNA refinery in St. Croix and its effect on the non-continental liquid floors, as well as the desired PM emission limit of 0.36 lb/MMBtu for non-continental units, please see comment EPA-HQ-OAR-2002-0058-3677-A2, excerpt 63 under the chapter for Methodology: Non-Continental Liquid. For response to claim that low load operation causes higher PM emissions, please see comment EPA-HQ-OAR-2002-00583677-A2, excerpt 64 under the chapter for Methodology: Non-Continental Liquid.

Commenter Name: Lisa Barry

Commenter Affiliation: Chevron Corporation

Document Control Number: EPA-HQ-OAR-2002-0058-3687-A2

Comment Excerpt Number: 2

Comment: EPA's proposed PM limit for island oil-fired units of 0.008 lb/MMBtu is unrealistically close to the limit for gas-fired units. Since it is much easier to achieve low PM with gas than liquid, EPA's island limit is not logical or fair for heavy oil island boilers and heaters. We are concerned that the large cost could adversely affect the economic viability of our Hawaii refinery. The Clean Air Act requires different consideration when setting emission limits for subcategories with less than 30 units. With the island subcategory now under 30 units total (due to the cessation of refining operations by Hovensa in the Virgin Islands), EPA should comply with the Clean Air Act and re-calculate the emission limit based on the best five units, not the single lowest measurement that was taken at 40% load. Such low load greatly increases residence time, causing fuller combustion and lower PM, but it does not represent normal operation for other units. We note that the proposed PM limit for some biomass units is as high as 0.44 lb/MMBtu.

Response: EPA has revised the MACT floor emission limitations for all subcategories since the December, 2011 proposed reconsideration of the rule. The revised PM emission limit for non-continental units designed to combust liquid fuel is less stringent than the proposed limit, and is also less stringent than the PM limit for units designed to combust Gas 2 fuel. For a response to the closure of the HOVESNA refinery in St. Croix and its effect on the non-continental liquid floors, please see comment EPA-HQ-OAR-2002-0058-3677-A2, excerpt 63 under the chapter for Methodology: Non-Continental Liquid. For a response to the claim that low load operation causes higher PM emissions, please see comment EPA-HQ-OAR-2002-00583677-A2, excerpt 64 under the chapter for Methodology: Non-Continental Liquid.

Commenter Name: Lisa Barry

Commenter Affiliation: Chevron Corporation

Document Control Number: EPA-HQ-OAR-2002-0058-3687-A2

Comment Excerpt Number: 3

Comment: With the closure of the Hovensa refinery, the island subcategory now has less than 30 units total. Therefore, EPA should re-calculate the CO emission limit based on the best five units, not the single lowest unit. API/AFPM's comments today include a limit calculation using EPA's common method and the available island CO data that shows the island CO limit actually

should be approximately 210 ppm (3-hour, 3% O₂), which is much higher than EPA's proposed limit of 18 ppm. Also, the recent final NESHAP for electric generating oil-fired units has no CO limit, even though the units are similar to ours. We believe that EPA should strive to provide more equitable treatment across sectors.

Response: For response to the closure of the HOVESNA refinery in St. Croix and its effect on the non-continental liquid floors, please see comment EPA-HQ-OAR-2002-0058-3677-A2, excerpt 63 under the chapter for Methodology: Non-Continental Liquid. The revised CO emission limits using the new dataset are shown in the final rule. EPA disagrees with removing CO emission limits in order to maintain consistency with 40 CFR Part 63 Subpart UUUUU. While the units are similar to electric generating units, they are not identical. Further, CO is regulated as a surrogate for organic HAP, which poses a significant threat to the environment and human health. With many more sources subject to this rule compared to Subpart UUUUU, organic HAP emissions cannot be ignored.

Commenter Affiliation: Tesoro Companies, Inc

Document Control Number: EPA-HQ-OAR-2002-0058-3630-A2

Comment Excerpt Number: 1

Comment: *Non- Continental Liquid Subcategory Emission Limits*

Although the re-proposed 40 C.F.R. 63 Subpart DDDDD has improved certain compliance options and emission limits, there remains a great deal of uncertainty whether it will be feasible for the Kapolei Refinery to meet the re-proposed "non-continental liquid subcategory" standards on a consistent basis. This is because those re-proposed standards were developed based on source test data from very few {2 -3} of the sources within the "non-continental liquid subcategory." In addition, some of the sources were tested during a specific operating regime. The uncertainty regarding the ability to routinely meet the re-proposed emission limits, and the potential costs of changing operations or adding controls in order to meet the re-proposed limits, is a large concern for Tesoro. The API/AFPM comment letter provides recommendations, consistent with methods used by EPA, for addressing the limited source test data and potential for variability when setting the emission limits for the non-continental liquid subcategory. The API/AFPM comment letter also provides suggested revised limits for the non-continental liquid subcategory.

Response: For a response to the claim that using data from few sources to set an emission limit for the Non-Continental Liquid subcategory is not appropriate, as well as a response to the claim that specific operating regimes have an effect on emissions, please see comment EPA-HQ-OAR-2002-0058-3673-A2, excerpt 63. EPA has recalculated the MACT floor emission limitations for all subcategories since the December, 2011 proposed rule. For non-continental units designed to combust liquid fuels, the emission limits for CO and PM are less stringent than those in the proposed rule, which should address the commenter's concerns about the achievability of the proposed limits.

3F16. MACT Floor Results: Existing Gas 2 (Other Process Gases)

Commenter Name: Russell A. Wozniak

Commenter Affiliation: The Dow Chemical Company

Document Control Number: EPA-HQ-OAR-2002-0058-3449-A1

Comment Excerpt Number: 8

Comment: Dow requests that the CO emission limit for Units designed to burn gas 2 (other) gases of 4 ppmv, dry corrected to 3% O₂, be revised to at least 20 ppmvd at 3% O₂ in order to accommodate limitations in the analytical methodology as well as to not make the CO emission requirement contradictory to other emission requirements.

The current proposed CO level (4 ppmv @ 3% Oxygen) for Units designed to burn gas 2 (other) gases is at a level that challenges the repeatability of the required method (Method 10). A paper submitted to EPA by the National Council for Air and Stream Improvement (NCASI) 1 makes several references to Method 10 regarding the ability to provide quantifiable CO data at levels below 10 ppmv. This observation puts into question the datasets used to develop the operating limit due to CEMs being calibrated against Method 10 as well as the determination that 4 ppmv is a quantifiable value in determining compliance. An additional challenge is the requirement to correct measured CO values to 3% oxygen while maintaining a minimum demonstrated oxygen level. Operating at higher excess air levels (oxygen levels) is a typical means to reduce CO levels. Typically the facility, during a demonstration test required by the rule may set a 4% oxygen level during the test that then becomes an operating limit. During normal operations the facility may operate at 7% O₂ in order to avoid drifting below the 4% compliance limit. Incorporating the oxygen correction factor required by the rule would make the 4 ppmv corrected equivalent to a 3 ppmv measured. The result is a 25% reduction in the measured value, further challenging the analytical method.

[Footnote]

1. National Council For Air and Stream Improvement, Inc. Southern Regional Center Letter of July 15, 2011, addressed to Mr. Brain Shrager, Energy Strategies Group (C205-01), Sectors Policies and Program Division, US Environmental Protection Agency, Research Triangle Park, NC 27711.

Response: EPA disagrees that emissions below 20 ppm measured following the procedures of Method 10 are unrepeatable or inaccurate. Several facilities reported Method 10 tests to the EPA ICR Databases for which CO emissions are below 20 ppm. Several individual units reported multiple CO tests under the 20 ppm threshold. However, EPA has implemented minimum CO emission limits of 130 ppm for all subcategories for which the calculated 99% UPL was less than 130 ppm. EPA believes these minimum CO emission limits mitigate the concerns identified in the NCASI letter to EPA dated July, 2011.

Commenter Name: Russell A. Wozniak

Commenter Affiliation: The Dow Chemical Company

Document Control Number: EPA-HQ-OAR-2002-0058-3449-A1

Comment Excerpt Number: 10

Comment: The proposed CO level raises the question of the performance requirement demanded by the specification. Under the HWC MACT rule, a destruction efficiency of 99.99% is required. Allowing for a generic VOC as a feed, the 4 ppmv CO requirement calculates to a greater than 99.997% destruction efficiency. Using the same oxygen correction factors (3%), a 99.99% destruction efficiency is equivalent to a CO concentration of 16 to 18 ppmv.

Response: EPA has imposed a minimum CO emission limit of 130 ppm for all subcategories for which the calculated 99% UPL was lower than this level. EPA believes the minimum CO emission limit mitigates the commenter's concerns since the minimum CO emission limit of 130 ppm corresponds to a destruction efficiency of much lower than 99.997%.

3G01. MACT Floor Results: New Solid

Commenter Name: James Pew

Commenter Affiliation: Earthjustice, Clean Air Council, Partnership for Policy Integrity

Document Control Number: EPA-HQ-OAR-2002-0058-3511-A1

Comment Excerpt Number: 67

Comment: Of the 26 facilities in our database that list HCl emission rates, rates range from 0.00083 to 0.02 lb/mmbtu. There are 36 facilities in the database that list some kind of acid gas control, such as trona injection, trona plus wet scrubber, pulverized limestone injection, dry scrubber, etc. Not all of these specify an actual emission rate however. Many permits that are synthetic area sources for HAPs simply specify that HCl emissions are capped at less than 10 tons per year, and they basically promise that they will keep adding sorbent until they reduce the emission rate to an acceptable level.

For facilities that do list rates, the red dots in the graph designate rates at facilities that will use of some kind of acid control. [See submittal for graph.]

Response: The EPA acknowledges this comment.

Commenter Name: Pat Dennis

Commenter Affiliation: Archer Daniels Midland Company

Document Control Number: EPA-HQ-OAR-2002-0058-3670-A2

Comment Excerpt Number: 4

Comment: The HCl limit for new solid fuel boilers will likely not be achievable for coal fired boilers without resorting to exorbitant control measures. The HCl solid fuel floors appear to be dominated by biomass combusting boilers. EPA should not group biomass boilers with coal boilers for HCl due to the general lack of chloride content of biomass and the widely varying chloride content found in coal. The lack of chloride in biomass indicates nothing about the ability to control HCl in a coal fired boiler. The HCl limit for existing boilers will likely not be achievable for fluidized bed boilers burning coal with any significant chloride content.

Response: In the final rule, the HCl MACT floor emission limits for both existing and newly constructed solid fuel boilers and process heaters are equivalent. Approximately 44 percent of the solid fuel HCl emitters in the EPA ICR Databases reported at least one test that is in

compliance with the limit in the final rule. Many of these tests are combusting coal or other solid fossil fuels. EPA acknowledges that some biomass fuels have lower emissions of regulated HAP than other solid fuels, but disagrees that the HCl limits are unachievable for new coal-fired boilers since many existing coal-fired boilers are already demonstrating compliance with the limit (as shown in the memo titled "MACT Floor Analysis for the Industrial, Commercial, and Institutional Boilers and Process Heaters NESHAP" in the docket). EPA believes that the 99% UPL accounts for the variability of chloride content of coal and biomass fuels.

3G03. MACT Floor Results: New Coal – Fluidized Bed

Commenter Name: Robert D. Bessette

Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 29

Comment: In the Reconsidered Boiler MACT Rule, EPA proposes to retain the final standard of 0.0011 lb/MMBtu, but to split the units into subcategories. As CIBO indicated in its Petition for Reconsideration of the Final Boiler MACT Rule, the PM limits finalized for new solid fuel-fired boilers are unachievable. Newer coal-fired units do not come close to meeting the standards.

CIBO believes that the limits are skewed based on data from one of the units relied on to set floor, which is not representative of units in the category. The boiler that set the solid fuel floor for PM, designated as IA Archers Daniels Midland Des Moines is a small bubbling bed boiler burning low ash coal and equipped with an oversized baghouse. The baghouse is designed for greater than nameplate boiler capacity whereas the boiler typically operates at less than nameplate capacity. As such, its extremely conservative design is not representative of the community of solid fuel boilers. The data from that boiler should not be relied on, as it is outlier data from a unit equipped with controls that are not considered standard for the unit.

Response: EPA has revised the PM MACT floor emission limitations for all subcategories since the December, 2011 proposed reconsideration of the rule. The revised PM limit for new Fluidized Bed units designed to combust coal or other solid fossil fuels is less stringent than the limit in the proposed rule due to corrections made to the reported emissions for the best performing source.

EPA disagrees that the top performer should be disregarded from the new source PM MACT floor emission limit for this subcategory. EPA agrees that the oversized baghouse is a conservative design from an emissions standpoint, but other sources are not prevented from installing a similar oversized control. An oversized baghouse only provides a greater PM removal, and does not correlate to any technical reason for the emissions data to be invalidated. Further, given that section 112(d) was intended as a technology-forcing provision that would result in application of the best emission reduction technologies, it would be inconsistent with the purpose of section 112 to ignore a source simply because it is using a technology that reduces emissions beyond what other sources are achieving. This is particularly true for new sources, where Congress required the MACT floor to be no less stringent than the best performing similar

source, since new sources should be able to design and construct units taking into account the application of control technologies needed to meet emissions standards.

Commenter Name: Pat Dennis

Commenter Affiliation: Archer Daniels Midland Company

Document Control Number: EPA-HQ-OAR-2002-0058-3670-A2

Comment Excerpt Number: 2

Comment: In the Reconsidered Boiler MACT Rule, EPA proposes to retain the final new source PM standard of 0.0011 lb/ MMBtu for fluidized bed boilers. This limit is not achievable for new fluidized bed boilers. ADM believes that the limit is skewed based on data from one of its own units relied on to set the floor, which is not representative of units in the category. The boiler that set the solid fuel floor for PM, designated as IAArchersDanielsMidlandDesMoines is a small bubbling bed boiler burning low ash coal and equipped with an oversize baghouse. The baghouse is designed for greater than pennitted heat input capacity. As such, its extremely conservative design is not representative of the community of solid fuel boilers. The data from that boiler should not be relied on, as it is outlier data from a unit equipped with controls that are not considered standard for the unit. ADM has started up five large CFB boilers since 2008. The filterable PM emissions from these boilers approximated 0.0040 lbs/mmbtu from the initial compliance demonstrations. Based on this experience, a limit of 0.010 lbs/mmbtu would be much more achievable for new well-controlled fluidized bed boilers.

Response: For response, see DCN EPA-HQ-OAR-2002-0058-3534-A1, Excerpt No. 29.

Commenter Name: Pat Dennis

Commenter Affiliation: Archer Daniels Midland Company

Document Control Number: EPA-HQ-OAR-2002-0058-3670-A2

Comment Excerpt Number: 3

Comment: The ADM unit referenced above, IAArchersDanielsmidlandDesMoines, would not meet the proposed TSM limit for new or existing boilers. Also, ironically, the fluidized bed unit that set the floor for the TSM limit, ILPolyOne, would not meet the new source fluidized bed limit for filterable PM. This is not a logical outcome and EPA should ensure that the MACT limits are achievable by the best controlled sources. In the case of the new source filterable PM for fluidized bed boilers and the TSM limits, they are not.

Response: In the final rule, EPA has established a single PM emission limitation (and TSM alternative) for all units designed to combust coal or other solid fossil fuels. The resultant TSM alternative limit is less stringent than the limit for new Fluidized Bed units designed to combust coal or other solid fossil fuels in the December, 2011 proposed reconsideration of the rule.

Reported emissions data from ILPolyOne to the EPA ICR Databases show that the Fluidized Bed unit at the facility is demonstrating compliance with the revised new source TSM alternative limit in the final rule as well as both the revised existing source PM and TSM limits in the final rule. Reported emissions data from IAArchersDanielsMidlandDesMoines show that the Fluidized Bed unit at the facility is demonstrating compliance with both the new and existing source revised PM emission limits in the final rule. Since compliance with TSM limits can be

demonstrated as an alternative to compliance with the PM limits, EPA believes the less stringent emission limits in the final rule mitigate the commenter's concerns about the achievability of the limits.

3G05. MACT Floor Results: New Biomass – Dutch Oven/Pile Burner

Commenter Name: Mary Sullivan Douglas

Commenter Affiliation: National Association of Clean Air Agencies (NACAA)

Document Control Number: EPA-HQ-OAR-2002-0058-3525-A1

Comment Excerpt Number: 38

Comment: EPA's proposed standards are also highly sensitive to the decisions to exclude clean sources without sufficient basis and to retain highly variable results that are more properly treated as outliers. This is especially true in EPA's new source MACT floor calculations. By way of example, for one new source subcategory³⁸, the source had been tested twice, for a total of six runs. Results from five of the six runs were low and consistent; but the results of the sixth run were 100 times greater than any of the other five runs. Since this result is outside the 99th percent confidence level of the rest of the data set, under EPA's methodology it should have been excluded. EPA retained this value and the result is an extremely high new source MACT floor calculation.

[Footnote]

38 Biomass Dutch Oven Filterable PM.

Response: EPA has revised the PM emission limitation for Dutch Ovens/Pile Burners combusting biomass or bio-based solid fuels since the December, 2011 proposed reconsideration of the rule. The revised PM emission limit for this subcategory is more stringent than the proposed limit. EPA disagrees that the single run for the previous top performer should be disregarded because the test reports for both emissions tests were reviewed and no issues were found with the testing methodology. However, additional emissions data provided during the public comment period have resulted in a different combustion unit being the top performer for this subcategory. The average emissions for the new top performer are seven times lower than the previous top performer, and there is significantly less variability in the emission values across all test runs, resulting in a more stringent 99% UPL. For further detail on the calculation of the MACT floor emission limit for this subcategory, please see the memo titled, "MACT Floor Analysis for the Industrial, Commercial, and Institutional Boilers and Process Heaters NESHAP" in the docket.

3G10. MACT Floor Results: New Wet Biomass – Stoker/Sloped Grate/Other

Commenter Name: James Pew

Commenter Affiliation: Earthjustice, Clean Air Council, Partnership for Policy Integrity

Document Control Number: EPA-HQ-OAR-2002-0058-3511-A1

Comment Excerpt Number: 65

Comment: All new and re-permitted facilities in our database use either a baghouse or ESP for PM control. These technologies are assumed capable of removing >99% of PM; baghouse removal rates of 99.9% and above are sometimes promised in air permits.

Not every permit specifies a separate emission rate for filterable PM versus total PM. For those in the database that do (there are 19 of them), values range from 0.0075 to 0.03 lb/mmbtu. In the graph [see submittal for graph], red dots designate bubbling fluidized bed boilers or circulating fluidized bed boilers; blue dots designate stokers. Given the similarity of the emission rates, it is not clear why EPA has designated such a large difference in the between the new unit standard for "wet" stokers (0.029 lb/mmbtu) and BFB's (0.0098 lb/mmbtu). These units appear to be using the same technologies and achieving the same emissions rates for PM.

Response: MACT floor emission limits for new sources were calculated from the emissions performance of the best-performing similar source as reported in the EPA ICR Databases. No enforceable permit limit constraints were considered in the calculation of these emission limits because permit limits which have not been verified through performance testing are not sufficiently reliable to use as a basis for identifying best performing units. This is supported by the commenter's own statements "are sometimes promised in air permits" and "appear to be achieving." Further, the commenter did not submit their database, so we are unable to determine if any of these permitted units have actually been constructed or whether they may already be in EPA database. While EPA acknowledges that Stokers and Fluidized Bed units combusting biomass fuel may be using similar controls, the emission limitations reflect the variability of actual emissions data reported to EPA. Pursuant to section 112(d)(3), the MACT floor must be based on the best performing sources for which the Administrator has emissions information. However, EPA has also analyzed the appropriateness of going beyond the floor for the new source PM emission limits and it has determined that in several instances it is cost effective to go beyond the floor to the level of the boiler NSPS (0.03 lb/mmBtu) for new sources in cases where the MACT floor emission limit is less stringent than this value. Refer to the preamble and the memorandum "Beyond the Floor Technology Analysis for Major Source Boilers and Process Heaters (Revised August 2012)" for a discussion of the rationale to select a beyond the floor level of control for new source PM emission values.

Commenter Name: James Pew

Commenter Affiliation: Earthjustice, Clean Air Council, Partnership for Policy Integrity

Document Control Number: EPA-HQ-OAR-2002-0058-3511-A1

Comment Excerpt Number: 69

Comment: EPA presents CO limits in units of ppm, not lb/mmbtu as they are usually specified in emissions permits. We back calculated what EPA's CO limits were in terms of lb/mmbtu (heat input basis) by reversing the formula that EPA provides for estimating output-based limits from input-based limits, and applying this to EPA's output-based limits provided in the major source rule. [See submittal for table of lb/mmbtu CO rates.]

All the facilities in our database are classified as stokers (wet) or FB.

In our database, there are 50 facilities with permits that specify a CO emission rate, which range from 0.027 to 0.6 lb/mmbtu. CO is very hard to control in biomass burners, but nonetheless,

most facilities still claim they will control it using "good combustion practices". There are 9 facilities (marked in red on the graph below) that state they will use an oxidation catalyst for CO control. [See submittal for graph.] Many facilities that do not proposed to use an oxidation catalyst nonetheless are permitted at CO emission rates similar to those promised at facilities that do use a catalyst.

The stoker and fluidized bed categories are the types of boilers found in the permit database. There is a big difference in the new unit CO emission rates between stoker and fluidized bed boilers in EPA's rule. The graph below suggests that the stokers with the very lowest CO rates do tend to be fluidized bed units. [See submittal for graph.] However, there are a number of BFB's that are permitted with CO emission rates considerably lower than the limit of 0.19 lb/mmbtu that EPA has proposed. Further, while stoker units do appear to be using oxidation catalysts to achieve the lowest rates, there are some stokers that are not proposing to use oxidation catalysts that will achieve a CO rate comparable to a BFB. The bottom line: EPA's new source performance standards for stokers and BFB's do not appear to represent anything close to the best/lowest rates.

Response: For general discussion on Stoker and Fluidized Bed emissions being similar for biomass and/or bio-based solid fuel combustion, please see comment EPA-HQ-OAR-2002-0058-3511-A1, excerpt 65. The MACT floor emission limits for this rule were calculated from top performer emissions data reported in the EPA ICR Databases. No external data nor any enforceable permit limits were considered in the calculation of the emission limits. In fact, both the best performing units for CO emissions in the wet biomass stoker and biomass fluidized bed subcategories used to establish the MACT floor have CO emissions lower than the lowest permitted CO limits listed in the comment for those types of boilers. The commenter did not submit the actual database that they refer to: so we are unable to determine if any of these units have actually been constructed or whether we may already have data and information on any in the EPA database. Further, the summary information show that even within the permitted new units there is considerable variation which we account for in our MACT floor analysis on the best performing unit.

3G11. MACT Floor Results: New Dry Biomass – Stoker/Sloped Grate/Other

Commenter Name: James Pew

Commenter Affiliation: Earthjustice, Clean Air Council, Partnership for Policy Integrity

Document Control Number: EPA-HQ-OAR-2002-0058-3511-A1

Comment Excerpt Number: 74

Comment: The floor for new stokers burning kiln-dried wood in the rule is 0.32 lb/mmbtu; EPA's own AP-42 document shows filterable PM10 emissions of 0.36 lb/mmbtu for dry wood combusted with no emissions controls. The AP-42 document further shows that use of just a mechanical collector (which relies on centrifugal force to spin out large particles) reduces the emissions to 0.3 lb/mmbtu for dry wood. [See submittal for AP-42 excerpt table.]

Response: EPA first notes that the final rule PM limit for new stokers burning kiln-dried biomass is 0.03 lb/mmBtu, based on EPA's beyond-the-floor analysis. Further, this rule regulates emissions of total filterable PM, of which PM10 represents only a portion of the total

emission profile. Emissions of PM10 characterize only those particles for which the diameter is less than 10 microns. Total filterable PM emissions are known to contain particles with diameters both larger and smaller than 10 microns.

3G14. MACT Floor Results: New Light Liquid

Commenter Name: Robert D. Bessette

Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 23

Comment: In its Petition for Reconsideration, CIBO stated that the CO limit in Boiler MACT for oil fired units was unachievable. The CO limits are still unachievable in some cases and these standards do not meet the CAA requirement that they be achievable by existing units.

Response: The EPA acknowledges this comment. The CAA requires that the emission limits be no less stringent than the average emission limitation achieved by the best performing 12% of units in the subcategory for existing units and the emission control achieved by the best controlled similar source for new units. The CO emission limits are based on CO levels achieved by the best performing units.

3H. Beyond-the-Floor: TSM8 at Existing Fuel Cells

Commenter Name: James Pew

Commenter Affiliation: Earthjustice, Clean Air Council, Partnership for Policy Integrity

Document Control Number: EPA-HQ-OAR-2002-0058-3511-A1

Comment Excerpt Number: 50

Comment: New and modified sources subject to section 165 must install “the best available control technology” (BACT) for a number of criteria pollutants regulated under the CAA. There is nothing in the plain text of the CAA or its legislative history that suggests that Congress intended the maximum achievable control technology, which applies to emissions of highly toxic and carcinogenic pollutants, to be less stringent than the best available control technology, which applies to criteria pollutants. Indeed, for new sources it is clear that Congress intended MACT to be at least as stringent as the lowest achievable emission rate (LAER), which is generally recognized as being more stringent than BACT. Significantly, EPA fails to set standards based on the degree of reduction that can be achieved through the use of fabric filters, electrostatic precipitators, wet scrubbers, and other control technologies that the agency has identified as BACT, even though the agency has necessarily determined that these technologies are both technologically and economically achievable. EPA’s apparent position that control technologies that have been employed for decades for control of criteria pollutants are not achievable within the meaning of § 112 effectively reads the central component of section 112 – its requirement for MACT standards – out of the statute.

Response: As the commenter is aware, all standards established pursuant to section 112 of the CAA must reflect MACT, the maximum degree of reduction in emissions of air pollutants that the Administrator, taking into consideration the cost of achieving such emissions reductions, and

any nonair quality health and environmental impacts and energy requirements, determines is achievable for each category. The CAA specifies that MACT for new boilers and process heaters shall not be less stringent than the emission control that is achieved in practice by the best-controlled similar source, as determined by the Administrator, which EPA has defined as the lowest emitting source in this rulemaking, with an appropriate consideration of variability. This minimum level of stringency is the MACT floor for new units. However, EPA may not consider costs or other impacts in determining the MACT floor. EPA must exercise its judgment, based on an evaluation of the relevant factors and available data, to determine the level of emissions control that has been achieved by the best controlled similar source under variable conditions. The DC Circuit Court of Appeals has recognized that EPA may consider variability in estimating the degree of emission reduction achieved by best-performing sources and in setting MACT floors. *See Mossville Env'tl Action Now v. EPA*, 370 F.3d 1232, 1241–42 (DC Cir 2004) (holding EPA may consider emission variability in estimating performance achieved by the best-performing source and may set the floor at level that best-performing source can expect to meet “every day and under all operating conditions”).

We disagree that we failed to set standards based on the degree of reduction that can be achieved through the use of fabric filters, electrostatic precipitators, wet scrubbers, and other control technologies that the agency has identified as BACT. In all cases, the emission limits for new sources in the final rule are based on the best controlled similar source which is defined as the lowest emitting. The analysis of the cost of achieving those limits is in fact based on the control technologies cited by the commenter. Moreover, BACT determinations cannot be compared to a MACT standard that is established based on the best performers for each subcategory nationwide, since BACT determinations are specific to individual units. Further, section 112(d)(3)(A) states that in determining the best performing 12 percent of existing units, sources that are achieving lowest achievable emission rate (LAER) should be excluded. Nevertheless, in the June 4, 2010 proposal, we did consider various regulatory options more stringent than the MACT floor level of control for both existing units (75 FR 32026) and new units (75 FR 32029). In this final amended rule, we reviewed the emission levels that became less stringent since the March 2011 final rule in order to assess whether a beyond-the-floor option was technically achievable and cost effective. See memorandum “Beyond the Floor Technology Analysis for Major Source Boiler and Process heaters (revised August 2012)” in the docket.

Comment Excerpt Number: 49

Comment: On reconsideration, EPA is proposing to revise its standards, but again fails to set or even consider limits reflecting the maximum degree of reduction that can be achieved through the use of control technology. Instead, EPA only adopts “beyond the floor” limits where its flawed calculation procedure leads to new source MACT floors (allegedly based on the best performing unit) that are less stringent than existing source MACT floors (allegedly based on the top 12 percent). However, even in these circumstances, EPA does not evaluate available technologies and establish limits reflecting the degree of reduction that can be achieved. EPA merely employs what it styles “beyond the floor” authority to raise the new source MACT limit to be equal to the existing source limit. EPA’s failure to set standards reflecting the maximum

achievable degree of reduction in emissions and its failure even to consider standards based on the use of available control measures such as fabric filters, wet scrubbers, activated carbon injection, and switching to cleaner fuels is unlawful and arbitrary.

Response: For response to the claim that EPA has failed to set or consider limits reflecting the maximum degree of reduction that can be achieved through the use of control technology, please see comment EPA-HQ-OAR-2002-3511-A1, excerpt 50.

As the commenter is aware, the EPA must consider cost, non-air quality health and environmental impacts, and energy requirements in connection with any standards that are more stringent than the MACT floor (beyond-the-floor controls). EPA's beyond the floor analysis did evaluate these factors in determining whether it was appropriate to establish more stringent standards. Moreover, while section 112(d) allows existing source MACT floor limits to be less stringent than new source limits, the Agency interprets this provision as precluding the new source limits from being less stringent than the existing source limits. Thus, it is appropriate to set the new source limit to be no less stringent than the existing source limit.

3Z. Out of Scope - MACT Floor Analysis

Commenter Name: Regina Hopper

Commenter Affiliation: America's Natural Gas Alliance (ANGA)

Document Control Number: EPA-HQ-OAR-2002-0058-3444-A1

Comment Excerpt Number: 1

Comment: ANGA submitted comments (dated August 23,2010) to EPA regarding the proposed ICI Boiler MACT Rules, as well as comments (dated July 15,2011) regarding the Agency's reconsideration of the final ICI Boiler MACT Rules. We resubmit, in their entirety, both sets of comments for the Agency's consideration.

We are deeply concerned that EPA has failed to incorporate in its analyses the recent, best available data and information regarding technology, the state of the natural gas market and natural gas infrastructure and in particular the dramatic expansion in the supply of domestic natural gas since 2007, in determining the cost-effectiveness of using natural gas as a fuel choice for boilers and process heaters.

ANGA believes that this rule, like other rules promulgated by the Agency, should reflect the use of the best data and science that is available, and the ongoing reconsideration presents an opportunity for EPA to do so. We therefore reiterate our request that the Agency look more closely at the comments that we have submitted previously, and the data and information underlying those comments, as it reconsiders the ICI Boiler MACT Rules, and requests that it look specifically at the issues identified in those comments as part of its broader reconsideration of the entire rule.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Commenter Name: Regina Hopper

Comment Excerpt Number: 2

Comment: Even if EPA, after conducting an appropriate analysis using the best available data, does not revise its conclusion to establish a revised beyond-the-floor standard that considers use of natural gas as an appropriate control technology, some owners and operators may find that converting to natural gas-based generation is a cost-effective compliance strategy. As set forth in our comments, ANGA is concerned that EPA cited excessive cost and supply constraints as the basis for its current conclusions without rigorous review of the most recently available data. Therefore, it is very important that EPA, at a minimum, recognize and put forth accurate assumptions associated with natural gas availability and costs so that the public as well as owners and operators of boilers are not misled by inaccurate and misleading information disseminated by the Agency.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Commenter Name: Regina Hopper
Commenter Affiliation: America's Natural Gas Alliance (ANGA)
Document Control Number: EPA-HQ-OAR-2002-0058-3444-A1
Comment Excerpt Number: 3

Comment: In comments dated August 23, 2010, regarding the proposed ICI Boiler MACT Rules, we, along with the American Gas Association (AGA), specifically requested that the Agency take into consideration the most recent and best science, information and data with respect to fundamental issues such as the significantly lower level of HAP emissions from natural gas-fired boilers and the ability of the industry to provide natural gas to ICI boilers in light of current natural gas supply and infrastructure conditions (see pages 9-14 of ANGA's August 23, 2010 comments, which are attached, for a summary and discussion of these issues). We note that AGA has filed comments on the Boiler MACT reconsideration and we hereby endorse those comments, dated July 5, 2011.

Based on our review of the ICI Boiler MACT Rules, and the Response to Comments document, we are very disappointed that EPA failed to consider the dramatic expansion in the supply of domestic natural gas since 2007. We encourage the Agency, as part of this reconsideration process, to consider and incorporate in its analyses the recent, best available data as well as the potential cost-effectiveness implications this abundant supply would have on the choice to use natural gas as a fuel for boilers and process heaters. The Agency response to comments¹ fails to provide any explanation as to how the Agency considered or incorporated the best available data in its final proposal. The Agency's entirely conclusory statement, and the absence of such an explanation or incorporation of the data in revised analyses, raises concerns as to whether the standard set by the Agency in the final rule is based on best available data or supported by the administrative record.

[Footnote]

(1) "EPA has reviewed the camp/ex details cited by the commenter, such as the country's pipeline and storage network capacities. However, the EPA decision that fuel switching is inappropriate remains unchanged"

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Comment: Emission limits and MACT floor methodology.

EPA proposes to make changes to a number of emission limits, including the Hg limits, as well as making some minor adjustments to their floor setting methodologies. See *e.g.*, 76 Fed. Reg. at 80610 – 80614. When doing so, CRWI suggests that EPA take note of the D.C. Circuit Court of Appeals most recent MACT related decision, *Portland Cement Association v. EPA* (D.C. Cir. 2011) in which Judge Brown wrote a compelling concurrence questioning the Agency's reliance on a previous case, *Sierra Club v. EPA*, 479 F.3d 875, 883 (D.C. Cir. 2007), (also known as *Brick MACT*) for support of EPA's "lowest emission" floor-setting methodology.

In *Brick MACT* the court seemed to uphold the concept that EPA was justified in using the lowest levels emanating from a source to set the regulatory limits, regardless of how that level was achieved. However, in doing so, as Judge Brown notes, the *Brick MACT* court erroneously interpreted a prior decision (*National Lime Association v. EPA*, 233 F.3d 625, 631 – 633, D.C. Cir. 2000) (also known as *NLA II*) relating to the Portland Cement MACT.

In that case, the court held that EPA could not refuse to set standards because sources did not use air pollution control technology to control emissions. Later in the opinion, when deciding a challenge from the National Lime Association ("NLA"), the court rejected NLA's argument that particulate matter ("PM") was not a proper surrogate for setting a standard and wrote the language that prompts EPA's erroneous interpretation. The *NLA II* court noted that controlling PM actually controls hazardous air pollutant ("HAP") metals stating:

According to the NLA, this methodology requires the agency to set a floor of "no control" for HAP metals because no cement plant intentionally controls HAP metals; metal emissions are controlled only incidentally by controls placed upon PM. The EPA's response is the correct one: "cement plants actually *are* controlling HAP metals[,] intentionally or not. *Id.* at 640.

Thus, the *NLA II* court was not saying that control does not matter. Instead, the court was explaining that *as long as control is being achieved*, intent to control does not matter. Therefore, if a source is controlling one pollutant and that control also limits another pollutant, the Agency can consider the performance data for that second pollutant as well. Thus, EPA may not use just any emissions data to select best performers. It must be emissions data for pollutants that are being controlled.

Judge Brown makes the same conclusion. In her concurrence she notes:

Sierra Club [*Brick MACT*] relied on our holding in *National Lime Ass'n v. EPA*, 233 F.3d 625, 640 (D.C. Cir. 2000), that the CAA does not require "that [the] achievement . . . be the product of a specific intent." But I do not read *National Lime* to have held that the achievement need not be the product of *any* intent. Instead, context reveals that the *National Lime* Court was referring to emissions of one sort that are "controlled only incidentally by controls placed upon" another sort of emission. *Id.* The incidental control of one emission as the result of controlling another still certainly counts as an "achievement" of emission control. But the Court did not state—or even imply—that emissions levels determined by inputs alone count as an "achievement" of emission control within the meaning of the statute.

Thus, Judge Brown cast considerable doubt on the astuteness of the *Brick MACT* panel's analysis of prior cases. Continuing on, Judge Brown declared that:

Our holding in *Sierra Club* was a self-inflicted wound, and the result of a series of interpretive leaps that I simply cannot follow. I regret that we have ignored Congress's wishes and made life more difficult—for industry and its employees, for EPA, and for ourselves.

CRWI, therefore, urges EPA to avoid perpetuating this "self-inflicted" wound, and to avoid putting too much credence in the *Brick MACT* decision.

Comment: The limits established in the March 2011 final rule and proposed in this reconsideration rulemaking for industrial boilers burning biomass are a substantial improvement relative to the original (May 2010) proposed rule. In comments submitted in response to the May 2010 proposal, several technical issues associated with the methodology used in setting the MACT standards were identified that EPA has considered and improved upon in the March 2011 final rule and this reconsideration proposal with more reasonable PM limits and additional subcategorization of biomass units. Nevertheless, we remain concerned that the revised limits will inhibit the combustion of biomass in the future and could discourage companies from combusting biomass over more traditional fossil fuels, making it increasingly difficult for companies to meet RPS and GHG requirements and/or reduction goals. The cost of adding controls for biomass could be extensive, potentially inhibiting the development of new biomass facilities.

Comment: EPA should ensure that affected sources can comply with any imposed obligations under the boiler MACT.

EPA must reconcile the fact that carbon monoxide standards may not be achievable for units required to use low nitrogen oxide-burner technology.

The proposed CO emission limits included in the MACT floor do not adequately account for the effect of low NO_x technology on CO emission rates. Existing low-NO_x burner (LNB) technology relies on lower burner temperatures to suppress NO_x formation, which often increases the CO emission rate. While some LNB applications can be managed to simultaneously minimize CO, many cannot. Burning additional natural gas or other fossil fuels in an afterburner to control CO does not solve the problem because these fuels contribute NO_x to the exhaust stack putting the source at risk of violating the applicable NO_x limit. With the increased use of low-NO_x technology in response to evolving environmental regulations under the Cross State Air Pollution Rule (CSAPR), Regional Haze, NAAQS (e.g., NO₂, Ozone, PM_{2.5}), NSPS, etc., demonstrating compliance with CO limits in Boiler MACT may increasingly conflict with other Clean Air Act requirements.

Comment: Good combustion practice (GCP) consists of operating a combustion or incineration device at high enough temperature, with adequate residence time, and allowing for good mixing with oxygen. GCP will minimize the formation of products of incomplete combustion (PICs). The US EPA has historically approached the control of PICs by regulating combustion efficiency rather than mandating emission limits for PICs. One method by which combustion efficiency is traditionally judged is by monitoring the level of carbon monoxide (CO) in the combustion flue gases.

In general, when burning fossil fuels in boilers, a level of 100 to 200 ppm CO in the flue gas is believed to be achievable and consistent with GCP. However, in the forest products industry (FPI) the burning of wood or wood-derived fuels, by themselves or in combination with other fossil fuels, involves very different combustion conditions than the burning of fossil fuels alone. The high moisture content typical of most wood-derived fuels requires a larger than usual area of refractory surface to dry the fuel before combustion. Sufficient secondary air must be supplied over the fuel bed to burn the volatiles that account for most of the combustible material in the fuel. Further, the air should not be so excessive as to cool the combustion flame (which also results in increased CO and PICs). As a result of these differences, well operated biomass boilers have significantly higher levels of CO than well operated fossil fuel-fired boilers.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Comment: *EPA Is Justified In Using Emissions Data From Five Sources To Determine The Existing Source MACT Floor For Subcategories With More Than 30 Sources Where Emissions Information On Less Than 30 Sources Are Available*

The above tables point out that in several cases, EPA is using less than 5 sources to set MACT floors. EPA has explained that it is using the top 12 percent of sources for which data are available where there are more than 30 sources in a subcategory. EPA should use no fewer than 5 sources in setting the MACT floor for any source category – regardless of the number of sources in the category or subcategory. The language of § 112(d)(3)(A) shows that Congress clearly expected enough emissions information to be available for categories or subcategories with 30 or more sources so that more than 5 sources would be used in selecting the top 12%. It makes no sense for Congress to specify a minimum number of sources, i.e. 5, for source categories or subcategories with less than 30 sources, but allow EPA to establish standards based on less than 5 sources for larger source categories. Using no less than 5 sources at all times would comport with the clear intention of Congress.

ACC also notes that the word "sources" as used in the last clause of §§ 112(d)(3)(A) and (B) is ambiguous and, therefore, susceptible to reasonable interpretation by the Agency. As EPA explains in the preamble, the word "sources" might be construed to refer to all sources in the given category or subcategory. However, the word "sources" in the first clause of §§ 112(d)(3)(A) and (B) clearly refers to the sources for which EPA has emissions information. Notably, the second use of the word "sources" in § 112(d)(3)(A) also clearly is a reference to sources for which EPA has emissions information. So, it is reasonable to conclude that Congress intended the word "sources" to have a consistent meaning for all purposes under these provisions. In other words, the reference "30 or more sources" at the end of § 112(d)(3)(A) and "fewer than 30 sources" at the end of § 112(d)(3)(B) reasonably should be construed as a reference to sources for which EPA has emissions information. This interpretation allows for EPA to naturally reconcile the application of §§ 112(d)(2)(A) and (B) such that the number of sources for which EPA has emissions information in a given category or subcategory dictates whether § 112(d)(2)(A) or (B) should apply.

Document Control Number: EPA-HQ-OAR-2002-0058-3511-A1

Comment Excerpt Number: 18

Comment: The Courts have said in *dicta* that in developing standards for new sources based on the performance of a single unit, it may be reasonable for EPA to set MACT limits that reflect the performance of emission units "under most adverse circumstances which can reasonably be expected to recur." This suggestion has been adopted by EPA and is well known to industry. For most pollutants the most adverse circumstance is full load operation of the unit and most compliance testing is done at 90 to 100 percent of full load operation. In its instructions to industry EPA did not require sources to test under less stringent conditions and was clear that it intended to use the results to establish MACT floors. EPA did not supervise the testing. Under these circumstances it would seem reasonable to assume that sources, who are in the best position to determine those "representative" operating conditions that would produce the highest emissions have, in fact, done so and submitted data reflecting the most adverse circumstances that can reasonably be expected to occur. For this reason, we believe that before EPA assigns any additional factor for adverse operating conditions, it should produce some objective basis, such as a showing that a particular test or set of tests was conducted under less stringent conditions, for determining that any additional adjustments are appropriate.

Response: We disagree with the assumption that sources would conduct tests under operating conditions reflecting the most adverse circumstances that can reasonably be expected to occur. Most data obtained during the ICR process were the results of compliance tests conducted to show compliance with permit conditions, and sources are unlikely to conduct such testing under the most adverse conditions since they would want emissions to be as low as possible to ensure that compliance is demonstrated. Even under the tests specifically required by the ICR, facilities would be reluctant to operate under conditions that are more adverse than the required testing at typical operating load, because to test at adverse conditions would require the facility to perhaps detune the control device and boilers, which could result in emissions that violate their operating permits. In addition to the emission test data, we required that facilities record and report the following process information taken during the 30 day period before, at the time of, and during, the emissions test: Heat input; fuel composition and feed rate; steam output; emissions control devices in use during the test; control device operating or monitoring parameters (including, as appropriate to the control device, flue gas flow rate, pressure drop, scrubber liquor pH, scrubber liquor flow rate, sorbent type and sorbent injection rate), and process parameters (such as oxygen). This was to ensure that we were aware of both the boiler and control device operation during the test and how it related to normal operation for the boiler and control device. Also, we had multiple tests from many of the best performers. Most of the facilities tested as part of the ICR had previously submitted test results. The multiple test results from these units show variability. However, we identified the best performers based on the single lowest 3-run test average and used the other test results to account for variability. Furthermore, the commenter did not provide any information to support its assertion that the most adverse conditions were used in testing.

Commenter Name: James Pew

Commenter Affiliation: Earthjustice, Clean Air Council, Partnership for Policy Integrity

Document Control Number: EPA-HQ-OAR-2002-0058-3511-A1

Comment Excerpt Number: 19

Comment: There is nothing to suggest that the Court intended an all out assault on compliance testing when it suggested that MACT limits should reflect the most adverse circumstances that

can reasonably be expected to occur. For several decades EPA has held out "reference method" compliance testing as the gold standard of environmental protection. EPA tells us that just one test every year, or every 5 years, is "sufficient to assure compliance" with pollution limits needed to protect public health. This is because its reference method testing is so accurate and the test conditions are so severe. In its enforcement actions EPA routinely defeats industry arguments about what a test result might have been and enforces based on the average of the three runs of a reference method test. When a defendant argues that a violation might be a "false positive", EPA's lawyers respond that in other matters there might just as well be "false negatives", where a dirty source has a serendipitous result and the Courts have ruled that a single result of a reference test is sufficient to characterize the emissions performance of the unit and establish a violation. Now, when convenient, EPA throws its carefully designed reference method tests under the bus and asserts that plant performance is so variable that emissions on any given day might be 100 times greater than demonstrated in a compliance test. The actual result of the reference method test of best performing unit(s) plays no meaningful part in EPA's MACT floors. EPA's proposed floors are based on calculations of what test results might have occurred at a given unit. Yet, for every unit in the top 12 percent whose emissions would increase on retesting there is another unit whose emissions would decrease. For this reason, the average of the top 12 percent would not change appreciably if the entire group were to be tested and retested. EPA should accept the results of reference testing for standard setting purposes, just as it does for compliance purposes.

We note that the Court has also raised a concern that standard setting and enforcement be consistent. Thus, to the extent that EPA utilizes statistical and other tests and assumptions in standard setting so as to ensure continuous compliance, it should apply those same tests and assumptions in the enforcement of those standards. Under EPA's proposed methodology, sources should be required to demonstrate, based on test results, fuel variability factors, instrument errors and scale errors, that the 99th percentile of their UPL is less than the standard adopted by EPA.

Because the flaws identified in the 2010 Comments and above show that EPA unlawfully and arbitrarily misrepresents the actual performance of individual sources, the agency's new source floors – which must reflect the emission level achieved by the single best performing source – are unlawful and arbitrary. EPA's misrepresentation of individual sources' performance also renders its floors for existing sources unlawful and arbitrary.

Response: EPA disagrees with the commenter that it interpreted compliance testing used to set the MACT floors inappropriately. This particular comment is referencing earlier concerns about EPA's use of a fuel variability factor and adjustments to data reported below detection levels in order to develop a standard that reflect a level achieved "under most adverse circumstances which can reasonably be expected to recur." EPA recognizes the importance of reference method testing in setting emission standards. However, EPA also identified other variations in best performers when looking at fuel variability (See response to comment under the HCl-Fuel Variability chapter DCN: EPA-HQ-OAR-2002-0058-3511-A1, excerpt number 15) and data reported below detection limit, especially in cases where the measurements made during the reference test methods were approaching the limits of detection of these methods (See responses to comments in Chapter Methodology: Non-Detect Values).

Comment: EPA Could Endorse a Petition Process for Unit-Specific CO Limits for Units That Cannot Implement Cost-Effective Modifications to Comply

In its comments, the Council of Industrial Boiler Owners ("CIBO") requests that EPA include in the final rule a provision allowing CO emissions limitations to be determined by state permitting authorities on a case-by-case basis. This provision would be available for boilers and process heaters that cannot attain the final rule CO emission limit without major unit redesign, oxidation catalyst addition with associated stack gas reheat and increased fuel usage, exceedance of an applicable NOX standard, or derating the unit. We concur with this recommendation.

EPA has broad authority to create subcategories and to distinguish among classes, types, and sizes of sources within a source category or subcategory. These authorities would even enable EPA to establish a subcategory for an individual source or a standard for an individual source within a category or subcategory, provided the Agency had a rational basis for establishing such a subcategory or standard. CIBO's recommended case-by-case approach to setting CO standards for certain individual sources is imminently reasonable and would be a proper exercise of such authority.

The essence of CIBO's argument is that certain individual sources are fundamentally different from most other sources in the industrial boiler source category with regard to CO emissions. As CIBO points out, CO emissions depend on unique boiler characteristics and it is simply not possible for certain boilers to meet a CO standard that is based on the performance of other boilers that do not share those unique characteristics. CIBO also points out that such incompatibilities are revealed, for example, when a particular boiler cannot meet the CO standard without fundamentally redesigning the unit or without derating the unit. In such cases, EPA reasonably can conclude that the particular boiler is fundamentally different and, therefore, a boiler-specific standard is reasonably justified.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Commenter Name: Roger Martella
Commenter Affiliation: National Alliance of Forest Owners (NAFO)
Document Control Number: EPA-HQ-OAR-2002-0058-3519-A1
Comment Excerpt Number: 8

Comment: With respect to the remaining emissions limits included in the proposed Major Source (and CISWI) rule, NAFO urges EPA to consider both the necessity of imposing stringent emissions limits on biomass boilers from a public health perspective as well as the impact that expensive control technology will have in discouraging the use of this clean, renewable, and climate-beneficial energy source. While EPA's proposed emissions limits represent in some

cases an improvement over current standards, they do not go far enough in correcting the flaws in the current rule.

NAFO supports EPA's proposal to impose less stringent emissions standards on new biomass boilers. This proposal remains consistent with EPA's legal obligations under section 112 of the Clean Air Act, while removing compliance-based barriers to bioenergy development. With the exception of mercury, which is discussed above, the proposed emissions limits for new boilers represent a marked improvement over current standards and, at a minimum, we urge EPA to adopt these standards.

Nevertheless, in order to properly reflect the health and climate benefits of biomass and provide proper incentives for the continued development of this important source of energy, EPA must make additional modifications beyond its current proposals. Therefore, we reiterate and incorporate herein our previous comments urging alternative and less stringent emissions limitations for biomass boilers and incinerator units.²⁸

Comment: We urge EPA to adopt more reasonable emissions limits for CO and PM that are less stringent and less costly, but still achieve statutory requirements. Again, the costs required to meet the proposed emissions limits are unreasonably high in comparison to the public health and environmental benefits that will accrue. EPA can encourage, rather than discourage, the use of clean, renewable biomass fuels by imposing less stringent standards that will still comply with EPA's statutory mandates under the Clean Air Act ensure that high compliance costs are not imposed on the industry unless commensurate health benefits are provided.

Comment: Although we believe that a full load CO stack test followed by 30-day average oxygen monitoring is a workable compliance approach for many large industrial boilers with sophisticated combustion control systems (e.g., automated oxygen trim systems), more flexible approaches are needed to accommodate a certain subset of sources. In addition to the proposed adjustments to the CO emissions limitations and the proposed alternative CO emissions

limitations for units with CEMS, EPA should consider additional alternative approaches to setting standards for CO and the accompanying ongoing compliance requirements. Discussed below are several additional alternative approaches. Each approach is well within EPA's authority to adopt, the approaches are not mutually exclusive, and each would result in emissions limitations that better reflect the limitations of the available data and better accommodate variability that even the best performers unavoidably exhibit.

Comment: The proposed emissions standards also fail to account for the inherent variability of emission control systems and trace metal concentrations in fuel supplies. Emissions tests are only a "snap shot" in time and do not reflect all potential operating scenarios. Emissions standards need to reflect worst case scenarios including the maximum trace metal concentrations in the fuel supply. Please revise the emissions standards accordingly.

Comment Excerpt Number: 4

Comment: CPI NC does not support the EPA's use of single tests to determine MACT floors. According to the Eastern Research Group (ERG) memo to EPA dated November 2011, 75% of the data included in the calculation of HCl MACT floor for solid fuel are based on a single test. Similarly, 50% of the data for PM for Stokers/Sloped Grate/Other Wet Biomass Units were obtained through single tests. *Id.* This use of single tests to determine MACT floors is statistically unsound due to the highly variability of fuel and operating conditions, particularly for multi-fuel blend facilities.

CPI NC recommends that EPA consider using multiple tests to establish the appropriate MACT floors. CPI NC believes that the use of single tests is unreasonable, and that the use of multiple tests would lead to a more accurate and representative MACT floor.

Comment Excerpt Number: 1

Comment: Under sections 112(d)(2) and 129(a)(2) of the CAA emission limits for existing sources must reflect the maximum degree of reduction in emissions that the EPA Administrator determines is feasible (Maximum Achievable Control Technology or “MACT”) **and** shall not be less stringent than the average emission limitation achieved by the best performing 12 percent of sources (for which the Administrator has emissions information) (the “MACT floor”). EPA concludes that recent court decisions require that (a) floors for existing sources must reflect the average emission limitation achieved by the best-performing 12 percent of existing sources; (b) a MACT floor cannot be “no control”; (c) EPA cannot ignore non-technology factors that reduce HAP emissions and (d) the levels of HAPs in fuels consumed by sources must be reflected in the MACT floor determination.¹

EPA has proposed to use an array of calculations, adjustments and defaults to determine the new and existing MACT floors and has provided most of the calculations underlying its proposed floors. Our review of the detailed calculation process leads us to conclude that EPA’s approach is flawed in several significant respects and in almost every instance overstates the variability in emissions performance that is shown in EPA’s data set and other readily available information. These inflated calculations have resulted in the establishment of excessively lenient MACT floors. Ironically, for a few subcategories, EPA inexplicably failed to provide any allowance for variability or arbitrarily assigned a variability that is far too low to account for expected operational differences in performance over time.

[Footnote]

(1) A source that is a low emitter because of low levels of HAP in its fuel can still be a “best performer” whose emission levels are part of the “average of the best performing 12 percent.”

Comment: Where EPA has data from testing at levels of precision sufficient to determine the actual variation in performance of a reasonably significant number of units, and where the agency’s approach to identifying the “best performing units” does not skew the results too significantly, the resulting calculations lead to proposed limits that would lead to significant emission reductions from some of the highly polluting subcategories. However, where these factors are not present, EPA’s procedures and assumptions lead to gross overestimates of the variability in performance of the best performing units and proposed emission limits that are higher than current emissions. Such limits simply create testing and paperwork burdens without providing any public health benefit. Moreover, these limits clearly do not meet the requirements of section 112 and are likely to lead to additional litigation that delays reduction in HAP emissions from the entire sector.

Comment: New and modified sources subject to section 165 of the CAA must install “the best available control technology” (BACT) for a number of criteria pollutants regulated under the CAA, including, as relevant here, CO, sulfur dioxide (“SO₂,”), nitrogen oxide (“NO_x”) and mercury. In the proposed rules EPA is setting limits for certain pollutants based on the application of “the maximum achievable control technology.” There is nothing in the plain text of the CAA or its legislative history that suggests that Congress intended MACT, which applies to emissions of highly toxic and carcinogenic pollutants, to be less stringent than BACT, which applies to criteria pollutants. Indeed, for new sources it is clear that Congress intended MACT³⁹ to be at least as stringent as the lowest achievable emission rate (LAER), which is generally recognized as being more stringent than BACT.

Regulatory authorities are to consider costs when establishing both BACT and MACT limitations that are more stringent than the MACT floor. There is nothing in the CAA that speaks to how EPA and permitting authorities must weigh costs against other considerations in establishing BACT. However, there has been a substantial body of precedent that speaks to this issue. In contrast, in establishing a requirement for a MACT floor, Congress effectively set a floor on what should be considered reasonable costs for MACT control technologies. Since MACT may be no less stringent than the performance level of the best-performing 12 percent, the costs to those sources of achieving that level of performance (including the worst-performing unit within a subcategory) must be within what was considered to be appropriate for MACT sources in that subcategory. This is of particular relevance to the set of rules under consideration, where the cost of control for similarly situated units is essentially the same but the calculated MACT floors are substantially different.

In its MACT determinations EPA needs to explain how an emission limit imposed for a unit subject to section 129 (and therefore presumably meeting the reasonable cost test for MACT) is not reasonable for an identical unit subject to section 112.

[Footnote]

(39) The MACT floor definition is essentially the same as the definition of LAER, which applies to new and modified sources in nonattainment areas.

Comment Excerpt Number: 6

Comment: One of AGA's chief concerns about previous versions of the major source Boiler MACT rule and preambles was that the agency appeared to be relying on an outmoded assumption about the availability of natural gas supply in the market. EPA's previous statements implied that there might be a shortage of supply that could lead to "curtailments." This is a thing of the past. With the advent of shale gas production, natural gas supplies are abundant and market prices are low and stable, as we explained in our comments on previous proposals in this docket and in our petition for reconsideration. We very much appreciate the proposed definition of "period of gas curtailment or supply interruption" stating that this is a "period of time during which the supply of gaseous fuel to an affected facility is halted for *reasons beyond the control of the facility*" and not because the facility owner the owner opts to enter into a contract with the utility to purchase natural gas at a lower price in exchange for a contractual agreement that the operator would accept switching off of natural gas during periods of high peak demand or the facility owner opts to switch fuels in order to obtain a lower price "due to normal market fluctuations not during periods of supplier delivery restriction." Proposed section 63.7575, 76 Fed. Reg. at 80653.

Commenter Name: Douglas Emerson et al.

Commenter Affiliation: American Crystal Sugar Company et al.

Document Control Number: EPA-HQ-OAR-2002-0058-3675-A2

Comment Excerpt Number: 3

Comment: It was found that the database did not include any information for the following affected sources:

- MIMISugarSebewaing Boiler #3
- NDMinnDakFarmers Boiler #6
- MNAmericanCrystalCrookston Boiler #2
- MNAmericanCrystalCrookston Boiler #3

- MNAmericanCrystalMoorhead Boiler #3
- MNAmericanCrystalEastGrandForks Boiler #1
- MNAmericanCrystalEastGrandForks Boiler #2

Considering that the emissions information for the boilers was submitted on information collection spreadsheets provided by the EPA and that a single spreadsheet contained information for multiple boilers at a given facility, the exclusion of certain boilers from the 2008 survey database is particularly troubling. Using data submitted by American Crystal Sugar Company as an example, information for nine boilers was submitted, but only four boilers were included in the 2008 survey database. This means only 44 percent of the submitted data was used in development of final emission limitations that are required to be based on a ranking procedure of all operating boilers for a given subcategory. If only 44 percent of the submitted data was included for American Crystal Sugar Company sources, an important question is raised to the inclusion of other source data.

Comment: As indicated in other comment letters, such as the U.S. Beet Sugar Association letter submitted under separate letterhead, lack of variability reflected in the proposed emission standards is of concern. As quoted in this letter, "The D.C. Circuit has held that variability, particularly in emission controls, must be accounted for when setting MACT standards. According to the D.C. Circuit, the CAA's statutory requirements for setting the MACT floor authorize EPA to set a standard which reflects what the best performing units can achieve under the 'worst reasonably foreseeable circumstances'".

The issue of variability in operations for industrial boilers is of great concern. Industrial boilers operate under a wide variety of conditions that may impact emissions at any given time, such as load swings and fuel quality changes to name a few. A final emission limitation based on a single test value for any boiler has a very low probability of repeatability. To highlight this fact, additional particulate matter test data for the American Crystal Sugar Company Crookston facility was obtained during further analysis and strategic planning for MACT compliance since the 2008 data submittal. It was found for each of the three existing boilers that results varied by as little as a factor of 2 and as much as a factor of 16 in two subsequent rounds of performance tests. This high degree of variability must be reflected in the proposed emission limits by establishing a final limit that accounts for the worst reasonably foreseeable circumstances with regard to repeatability. Therefore, when only one performance test is available, the highest individual test run result should be used, not the average, and certainly not the lowest test result. When multiple tests are available for a given unit, the highest result should be used. This will not account for all operational variability, but at least may provide for some level of compliance assurance.

Document Control Number: EPA-HQ-OAR-2002-0058-3685-A2

Comment Excerpt Number: 29

Comment: EPA Is Justified in Using Emissions Information from At Least Five Sources to Establish MACT Floors for Existing Sources

For many subcategories with more than 30 units, including the existing pulverized coal subcategory, EPA established the MACT floor using data from less than 5 units. That approach contradicts the primary structure of section 112(d). When drafting the 1990 Amendments to the Clean Air Act, Congress carefully established distinct approaches for establishing the MACT floors that would apply to existing and new sources. For existing sources, Congress established two alternate approaches in sections 112(d)(3)(A) and (B). Where there are "30 or more sources" in a subcategory, section 112(d)(3)(A) instructs EPA to select "the average emission limitation achieved by the best performing 12 percent of the existing sources." Similarly, where there are "fewer than 30 sources" in a subcategory, section 112(d)(3)(B) requires use of "the average emission limitation achieved by the best performing 5 sources" Both of these provisions were designed to ensure that a *group* of existing sources are used to establish the emissions limits for existing sources. In contrast, section 112(d)(3) specifies that the MACT floor "for new sources in a category or subcategory shall not be less stringent than the emission control that is achieved in practice by the *best controlled similar source* . . ." Thus, new source limits are to be set by a single source while existing source limits were to be set by reference to a group of representative peers. The Proposed Rule would cross that clean statutory line by treating existing sources functionally the same as new sources in some subcategories. Furthermore, the word "sources" in the first clause of §§ 112(d)(3)(A) and (B) clearly refers to the sources for which EPA has emissions information. Notably, the second use of the word "sources" in § 112(d)(3)(A) also clearly is a reference to sources for which EPA has emissions information. So, it is reasonable to conclude that Congress intended the word "sources" to have a consistent meaning for all purposes under these provisions. In other words, the reference "30 or more sources" at the end of § 112(d)(3)(A) and "fewer than 30 sources" at the end of § 112(d)(3)(B) reasonably should be construed as a reference to sources for which EPA has emissions information. This interpretation allows for EPA to naturally reconcile the application of §§ 112(d)(2)(A) and (B) such that the number of sources for which EPA has emissions information in a given category or subcategory dictates whether § 112(d)(2)(A) or (B) should apply. That alternate approach is far more consistent with section 112(d) and Congress' plain intent. It is also well within EPA's discretion to adopt this more consistent approach. The word "sources" as used in the last clause of sections 112(d)(3)(A) and (B) to describe the size of the subcategory at issue does not specify whether it refers to "sources" for which data exist or the total number of sources in the subcategory. However, the word "sources" in the earlier facets of those sections clearly refers to the sources for which EPA has emissions information. Thus, it is reasonable to conclude that Congress intended the word "sources" to have a consistent meaning within these subsections and that the reference "30 or more sources" at the end of section 112(d)(3)(A) and "fewer than 30 sources" at the end of section 112(d)(3)(B) reasonably means sources for which

EPA has emissions information. That interpretation allows EPA to read the statute such that Congress' chosen line between new and existing source-setting methodology is not blurred.³⁴

However, this dilemma does not exist if EPA properly uses all available emissions information to estimate emissions for all sources in the subcategory. This approach ensures that the top-performing 12 percent of a category with more than 30 sources will never fall below the five-source minimum that Congress established. Indeed, Congress likely did not anticipate a scenario in which EPA would develop a MACT floor with emissions information from less than 50 percent of the sources in a subcategory of 30 or more.

[Footnote 34: *See, e.g., United Savings Ass'n of Tex. v. Timbers of Inwood Forest Assoc., Ltd.*, 484 U.S. 365 (1988) (rejecting a "reasonable" meaning of a statutory term and stating that "[s]tatutory construction ... is a holistic endeavor. A provision that may seem ambiguous in isolation is often clarified by the remainder of the statutory scheme- because the same terminology is used elsewhere in a context that makes its meaning clear . . . or because only one of the permissible meanings produces a substantive effect that is compatible with the rest of the law" (citations omitted)); *S. Cal. Edison Co. v. FERC*, 195 F.3d 17 (D.C. Cir. 1999) (striking down FERC's statutory interpretation that rendered statutory text meaningless in favor of an alternate interpretation without this effect, noting that "statutory words are ... designed to carry out the statutory purposes").]

Document Control Number: EPA-HQ-OAR-2002-0058-3685-A2

Comment Excerpt Number: 30

Comment: The Sampling Data Used to Set the MACT Floors Does Not Reflect the True Operating Variability of the Sources at Issue. EPA is required to estimate the variability associated with all factors that impact a source's emissions, including process, operational, and non-technological variables, in setting MACT floors.³⁵ Any method used to estimate emissions rather than actually measure them "must allow a reasonable inference as to the performance of the top 12 percent of units," and EPA must show "why its methodology yields the required estimate."³⁶

EPA has acknowledged this responsibility and identified a number of factors that contribute to variability in emissions test data, including: (1) the emission test method, (2) the emission analytical method, (3) the design of the unit and the control device(s), (4) operating conditions of the facility and the control device(s), and (5) the composition and relative amounts of fuel constituents in the fuel or flue gases.³⁷ EPA is correct to incorporate variability into the MACT floor analysis in this rulemaking, but did not properly reflect the full range of variables potentially impacting emissions. Variability in boilers depends on a host of operating and load conditions. While EPA evaluated some of these variables, it did not evaluate a sufficient number to provide "an accurate picture of the relevant sources' actual performance."³⁸ For example, EPA does not have fuel quality data for all top performers.

Comment: EPA underestimates the true variability of the top performing sources. This results in a 99% upper prediction limit (UPL) that simply fails to account for all variables and fuel quality variability present in the top 12 percent best-performing units across all the subcategories and certainly across all regulated units. Municipal utilities would benefit from EPA revisiting its methodology and capturing more of the variability for coal-fired sources when it recalculates the MACT floors for the final rule.

103A. MACT Floor Methodology: Statistical Approach (“Best of the Best”) [DENIED PETITIONER ISSUE]

Commenter Name: Kevin G. Desharnais, Attorney, Mayer Brown LLP

Commenter Affiliation: United States Sugar Corporation

Document Control Number: EPA-HQ-OAR-2002-0058-3496-A1

Comment Excerpt Number: 15

Comment: Despite the time that has elapsed since publication of the Proposed Rule, EPA still has not gathered a meaningful amount of new data for numerous categories of sources, and many emissions limits continue to be supported by only a handful of sources.

U.S. Sugar explained in its prior comments, which it incorporates by reference here, that if EPA cannot gather data on more than 30 sources--either because fewer than 30 sources exist in a category or because gathering more data would be unreasonable--the statute *requires* that MACT floor be set based on the top five sources for which the EPA has data. 42 U.S.C. § 7412(d)(3). EPA's decision to set the MACT floor according to the top 12 percent of sources, even in situations where it possesses data on only a handful of sources, results in a single boiler setting the emission limits for entire categories. That is flatly contrary to the language and intent of the CAA.

U.S. Sugar requests that EPA reconsider its decision to rely upon the best performing 12 percent of sources where EPA does not possess data on at least 30 sources. U.S. Sugar also requests that EPA reconsider its data set and solicit new data as companies begin sampling their emissions to comply with the rule. As more data becomes available, EPA should reevaluate the feasibility of its emissions limits and adjust the standards accordingly.

Document Control Number: EPA-HQ-OAR-2002-0058-3503-A1

Comment Excerpt Number: 9

Comment: If we were sure that the available data were statistically representative of the entire subcategory (such that calculating the MACT floor with fewer sources would result in approximately the same value as the MACT floor using data from the entire subcategory), then the lack of data likely would not significantly skew the results. However, the proposed rule and supporting documentation provide no assurance that where limited available data are available that they are representative of the entire source category. As a result, we believe that the lack of available data will produce MACT floors that are not reflective of the subcategory as a whole. While it is true that the statute allows EPA to determine the MACT floor based on sources "for which the Administrator has emissions information," this provision does not excuse EPA from using its resources and legal authority to obtain as much information as it reasonably can prior to setting MACT standards. In this case, EPA has had 20 years to gather the needed information. The fact that, at this point, data on only a small subset of sources in each subcategory is available represents an abdication of EPA's responsibility and renders the resulting standards arbitrary and capricious.

Comment Excerpt Number: 11

Comment: The above table points out that EPA is using less than 5 sources to set the majority of the MACT floors for the light and heavy fuel subcategories. [See submittal for table] EPA has explained that it is using the top 12 percent of sources where there are more than 30 sources in a subcategory. EPA should use no fewer than 5 sources in setting the MACT floor for any source category – regardless of the number of sources in the category or subcategory. Congress clearly expected enough emissions information to be available for larger source categories to generally cause more than 5 sources to constitute the top 12%. It makes no sense for Congress to specify a minimum number of sources for source categories with few sources, but then to create a rule that would allow for standards to be set using data from fewer than 5 sources in larger source categories. Using no less than 5 sources would give effect to the clear intention of Congress.

Comment Excerpt Number: 12

Comment: We note that the word “sources” as used in the last clause of §§ 112(d)(3)(A) and (B) is ambiguous and, therefore, susceptible to reasonable interpretation by the Agency. As EPA explains in the preamble, the word “sources” might be construed to refer to all sources in the given category or subcategory. However, the word “sources” in the first clause of §§ 112(d)(3)(A) and (B) clearly refers to the sources for which EPA has emissions information. Notably, the second use of the word “sources” in § 112(d)(3)(A) also clearly is a reference to sources for which EPA has emissions information. So, it is reasonable to conclude that Congress intended the word “sources” to have a consistent meaning for all purposes under these provisions. In other words, the reference “30 or more sources” at the end of § 112(d)(3)(A) and “fewer than 30 sources” at the end of § 112(d)(3)(B) reasonably should be construed as a reference to sources for which EPA has emissions information. This interpretation allows for EPA to naturally reconcile the application of §§ 112(d)(2)(A) and (B) such that the number of sources for which EPA has emissions information in a given category or subcategory dictates whether § 112(d)(2)(A) or (B) should apply.

Comment: OTHER MACT FLOOR ISSUES

EPA is proposing a stringent set of emission limits that are not always based on the use of any technology. In many cases, boilers are achieving low emission rates not due to the use of any particular technology, but due to the mix of fuels being fired (which in many cases include fuels with pollutant contents below the limits of detection) or other unit specific characteristics that are not transferable to other sources. Facilities are limited in the fuels that their boilers can fire by design, cost, permits, and fuel availability. EPA should not set limits for hundreds of boilers based on data from a few boilers in which the specific mechanisms resulting in lower emissions are not fully understood and that are not available to all units in the subcategory.

Comment: *EPA is Using a Biased, Unrepresentative Data Set*

Clean Air Act § 112(d) requires EPA to set a MACT floor for existing sources that is not less stringent than "the average emission limitation achieved by the best-performing 12 percent of the existing sources (for which the Administrator has emissions information)." *See* 42 U.S.C. § 7412(d); *Nat. Res. Def. Council v. EPA*, 489 F.3d 1250, 1254 (D.C. Cir. 2007). The top 12% "best performing" sources are known as "MACT floor units" or "units comprising the MACT floor."

During Phase I of EPA's data gathering effort (August 2008), EPA requested and received emissions data from over 2,000 sources across all of the subcategories for PM, CO, NO_x, and many HAPs. After sifting the data into fuel-based categories, EPA issued a second §114 request in June 2009 requiring additional testing. During this second phase of data gathering, EPA targeted only those sources the Agency knew it needed data from to set the MACT floor (e.g., the top performers) instead of obtaining a sampling of emissions data across the entire population

of boilers in a subcategory to assess the variability in performance of boilers in a particular subcategory. In this way, EPA artificially limited the pool of data from which it drew its top 12% "best performing" sources and biased the collection of emissions data. The data are not evenly distributed, but are clustered well below the mean, and since EPA has chosen to select the top 12 percent of boilers for which it has stack test data instead of the top 12 percent of boilers for which it has any emissions information, this has resulted in the proposed MACT floors being based effectively on the top 12 percent of the top 12 percent of boilers.

Even more troubling is the fact that in many cases, a large population of boilers is being represented by only a handful of data points. The table below presents information on the number of boilers in each subcategory, the number of boilers for which EPA believes it has data, and the number of boilers on which the MACT floor is based. The only data being used to calculate MACT floors are the data obtained during the ICR and subsequent facility submittals to the docket, even though EPA has available data from other sources (e.g., NEI and TRI data).

If it could be ascertained that the available data were statistically representative of the entire subcategory (such that calculating the MACT floor with 12 percent of the number sources for which EPA received site-specific data would result in approximately the same value as the MACT floor using data from 12 percent of the entire subcategory), then the lack of data likely would not significantly skew the results. However, the Reconsideration Proposal and supporting documentation provide no assurance that the limited available data from a fraction of the sources in a category or subcategory are representative of the entire source category or subcategory. As a result, ACC believes that the lack of available data has produced MACT floors that are not being set by the best performing sources in a category or subcategory and are not reflective of the category or subcategory as a whole.

In some cases, EPA has augmented available stack test data with calculated emission factors in order to increase the number of sources on which the MACT floor is based (e.g., liquid fired boilers for which fuel data or stack test data from an identical boiler at the site are available). EPA should expand this approach by obtaining emissions data from all boilers in a subcategory, whether by obtaining additional fuel data, additional stack test data, or estimating emissions for these boilers based on available emission factors. In fact, EPA has estimated emissions for all of the boilers being regulated under the MACT in order to quantify the expected emissions reductions of the Final Boiler Rule. Therefore, EPA should be using data from the top 12 percent of the total number of boilers in each subcategory in order to set limits, not 12 percent of the sources for which it has received stack test or fuel analysis data. EPA is using this approach in the CISWI rule.

The following tables [see submittal for tables] demonstrate the disparity between the amount of data currently being used to set standards and the actual percentage of boilers in each subcategory that are being represented by each floor (assumes EPA has properly subcategorized units). *EPA has not used 12 percent of the number of existing sources to set floors in any subcategory that has more 30 or more sources.*

Comment: *EPA Should Adjust its Procedures for Setting New Source Limits*

Some of the new source and existing source limits are the same (for example, the solid fuel HCl limit) because the 99 UPL for the new unit data is higher than the 99 UPL for the existing unit data. If the emissions data for the top performing unit exhibits more variability than the emissions data for the existing units then EPA cannot ignore this fact. It is arbitrary to choose the calculated existing unit limit as the standard that both types of units must meet. EPA should instead set both the existing and new unit standards at the calculated new unit UPL in order to adequately reflect variability and apply a defensible fuel variability factor to appropriately determine an achievable existing source emission limit recognizing the limitations of the floor determination process as indicated above.

Comment: As pointed out in the 2010 Comments, EPA incorrectly assumed that sources’ emission levels would vary to the full extent of the 99th percent upper prediction limit (UPL). That assumption was wrong because, as the agency is well aware, many of the sources in the top 12% use control technology or other methods to control their emissions. Because such measures limit emissions, the emission levels at such sources do not vary randomly. Further, as EPA is also well aware, source operators’ training and care in operating their sources and control equipment also limit variability in emissions. Moreover, because sources test their emissions under operating conditions designed to reflect the worst possible emission levels, their unadjusted test results already reflect unrealistically high emissions and there is no basis to assume that these sources’ emissions will get even worse – far less significantly worse – during further tests. For each of these reasons, sources’ actual emission levels are in no way reflected by the 99th percent UPL merely because such a level might be statistically possible. By using the 99th percent UPL, EPA adopts an approach to estimating emissions that ignores factors that affect emissions. Significantly, EPA itself acknowledged in the 2011 final rule "that the variability of emissions is not solely statistical, but also represents some operational variability that may occur between different tests at the same units (intra-unit variability) as well as different tests at different units (inter-unit variability) in the floor." 76 Fed. Reg. 15,608, 15,630/1-2 (March 21, 2011). Nowhere, however, has EPA explained why it nonetheless pretends that sources’ emissions do vary to the full 99th percent UPL.

Comment: EPA invariably "rounded" the numbers generated by its UPL and fuel variability factors up. It rounded up values less than 100 to one significant figure, rounded up UPL values between 100 and 1,000 to two significant figures, and rounds up UPL values greater than or equal to 1,000 to three significant figures. 2010 Comments at 27. At proposal, EPA falsely claimed that its rounding approach had no significant effect on the floors. Confronted with record evidence of the falsity of that claim, the agency now argues that standards must be complied with at all times. That argument, however, does not alter the fact that EPA's rounded up numbers do not reflect the actual performance of any source and would not reflect sources' actual performance even if all the other floors in the agency's approach could be ignored. In any event, because the other aspects of EPA's approach grossly overstate sources' actual emission levels, rounding normally would not yield standards that were lower than sources' actual emissions; rather, it would merely yield standards that did not overstate their emissions so egregiously.

Comment: EPA's professed concerns about compliance tests are misplaced. EPA has a policy of allowing sources to be deemed in compliance with an emission standard if their emission test result can be rounded down to the level of the standard under normal rounding principles. For example, a test result of 3.49×10^{-6} would be deemed in compliance with the standard of 3.0×10^{-6} . EPA's decision to round up is unlawful in itself. The Clean Air Act requires floors to reflect the emission levels achieved by the best sources not those emission levels rounded up to the nearest whole number. EPA's departure from normal rounding practices by always rounding up in setting floors – i.e., rounding up whether the fraction is above or below one half – exacerbates that unlawfulness and is arbitrary. And the agency's inconsistent approach to rounding for standard setting and compliance determinations is inconsistent, irrational, unexplained, and therefore arbitrary.

Comment: EPA misrepresents the performance of the sources it has identified as the relevant best performers for the purposes of setting existing source floors. Specifically, EPA not only misrepresents each individual source's performance, but also adopts an existing source floor approach that does not yield an accurate estimate of the best performing twelve percent of sources in each subcategory for which the agency has emissions information and would not yield an accurate estimate even if the agency accurately represented the actual performance of the individual sources in these groups.

As explained in the 2010 Comments, EPA's floors do not reflect the "average" emission limitation achieved by the relevant best performing sources, but the 99% UPL for these sources. 2010 Comments at 24-26. Whatever else may be said of the EPA's 99th percentile UPL approach, the upper prediction limit of the emission level achieved by the best performing twelve percent of sources is not the "average" emission level achieved by those sources. Because Clean Air Act § 112(d)(3) unambiguously requires EPA to set floors reflecting the "average" emission level achieved by the best sources, setting floors that instead reflect a UPL for those sources is unlawful. By claiming that it can use the UPL for all sources in the top twelve percent, EPA misreads its authority to consider variability under the Clean Air Act and relevant caselaw. Although EPA may consider variability in estimating an individual source's actual performance over time, nothing in the Act or the caselaw even suggests that the agency may account for differences in performance between sources except as § 112(d)(3) provides, by averaging the emission levels achieved by the sources in the top twelve percent. Indeed, EPA errs by viewing the different emission levels achieved by different sources as "variability" at all. The different emission levels achieved by different sources are just differences in performance and provide no basis for applying statistical methods. Notably, EPA conceded at proposal that the objective of its statistical approach was to "estimate a MACT floor that is achievable by the average of the best performing sources if the best performing sources were able to replicate the compliance tests in our data base." 75 Fed. Reg. at 32019-32020 (emphasis added). The Clean Air Act requires EPA to set floors reflecting what the best sources actually achieved, not what the agency thinks is "achievable" – either for the best performing sources or any other group. Thus, EPA not only fails to propose floors reflecting the "average" emission level "achieved" by the relevant best sources, but admits that its goal was to set floors that would be "achievable" by those sources ninety-nine percent of the time. That stated goal is a result that the Clean Air Act does not permit. By attempting to rewrite the Clean Air Act to advance its own policy preferences – floors that reflect EPA's subjective notions about what is "achievable" ninety-nine percent of the time for all sources in the top twelve percent rather than the average emission level actually achieved by these sources, EPA acts unlawfully and frustrates Congress' intent in enacting § 112(d)(3).

Comment Excerpt Number: 24

Comment: EPA appears to have exacerbated the unlawfulness and arbitrariness of its floors by taking the 99% UPL for the group of alleged best performers even though it already applied the a

99% UPL to each individual source within the group. Specifically EPA used its UPL approach (and other means of inflating individual sources' performance described above and in the 2010 Comments) to assign to each individual source an emission level so high that even if the upward variability of that source's emission levels were not limited by control measures such as end-of-stack control measures, fuel selection, or operator care and control, that source would still achieve lower emission levels in 99% of all future tests. Because that approach clearly ensures that each individual source's performance cannot possibly be worse than the emission level EPA has assigned to it, the agency's decision to further inflate existing source floors by applying yet another 99% UPL to the entire group is egregiously unlawful and arbitrary. Such floors do not reflect the average performance of the best sources but, rather, the 99 % statistically worst possible performance within a group of sources each one of which is already unlawfully and arbitrarily assumed to perform at its 99% statistically worst possible level.

Document Control Number: EPA-HQ-OAR-2002-0058-3511-A1

Comment Excerpt Number: 25

Comment: EPA appears to have based some floors not on the top twelve percent of units for which it has emissions information but on the top five units. Revised MACT Floor Analysis (November 2011) at 5. The agency claims that it "identified the best performing 12 percent (or top 5 units) for each subcategory." *Id.* Although Clean Air Act § 112(d)(3) directs EPA to set floors based on the top five units for categories or subcategories with fewer than 30 sources, there are no "subcategories" within the industrial boilers category within the meaning of § 112. Specifically, although § 112(d) allows EPA to "distinguish among classes, types, and sizes of sources within a category or subcategory" in establishing emission standards, the agency does not create different "subcategories" merely by drawing such distinctions. Rather, EPA can create separate subcategories only by listing them under § 112(c). The groups of sources that EPA describes as "subcategories" are not actually "subcategories" at all, but merely groups of sources within the boilers category for which EPA believes it has authority to set different standards. Accordingly, EPA must base floors on the best performing twelve percent of sources for which it has emissions information for each such group regardless of whether they contain thirty or more sources.

Response: Section 112(d)(3) provides that EPA must establish MACT floors for existing sources based on the average of the best-performing twelve percent of sources "in the category or subcategory[.]" or the average of the best performing five sources "in the category or subcategory for categories or subcategories with fewer than 30 sources." The commenter does not allege that EPA has improperly based the MACT floors on the average of the best performing five sources for subcategories with 30 or more sources, but rather claims that EPA lacks authority to create subcategories for the boilers and process heater source category unless it expressly lists those subcategories under section 112(c). EPA disagrees with this interpretation of the Act. First, as noted above, section 112(d)(3)'s MACT floor provision specifically refers to the best twelve percent of sources (or best five sources) "in the category or subcategory[.]"

which recognizes EPA’s subcategorization authority and requires EPA to treat subcategories separately when establishing MACT floors for existing sources. Second, section 112(d)(1) states that EPA “may distinguish among classes, types, and sizes of sources within a category or subcategory in establishing [section 112(d)] standards[.]” (emphasis added) Thus, Congress envisioned that, when establishing MACT standards, EPA would evaluate the listed source category and determine whether establishing subcategories was appropriate, and then establish standards for each category or subcategory according to the provisions of section 112(d)(3). Nothing in these provisions suggests that Congress intended to require EPA to separately list each subcategory under section 112(c) before establishing MACT standards. Rather, the language of section 112(d)(1) referenced above indicates that Congress intended that EPA decide whether to exercise its subcategorization discretion at the time it established emissions standards for a listed source category.

Comment: In many instances, EPA’s floor approach yields floors that are mathematically impossible, absurd, or both. For the majority of its standards, the result of EPA’s new source floor analysis was a number higher – *i.e.*, worse – than its existing floors. It is mathematically impossible for the emission level achieved by the single best performing source in a group to be worse than the average emission level achieved by the best performing twelve percent of sources in that same group. Rather than recognizing this reality and adopting a different floor approach that does not yield such absurd results, the agency blithely asserts that it can simply paper over the problem by setting its new source floors at the same level as its existing source floors. That is neither a solution nor a rational response to the problem. First, floors that purport to reflect the emission level achieved by the best performing 12 percent of sources for which EPA has emissions information do not purport to reflect the emission level achieved by the single best performing source and, for this reasons as well as those identified in the 2010 Comments, EPA’s new source floors are unlawful and arbitrary. Second, when a floor approach generates mathematically impossible results, it makes no sense to simply paper over the problem by just making up a different floor as the agency has done here. Rather, the agency needs to reevaluate its floor approach and come up with a different one that meets the agency’s obligation to set floors that actually reflect the emission level achieved by the relevant sources.

Comment: Further, EPA’s statistical approach to variability yields numbers that are both impossibly low and impossibly high. First, if EPA were correct about the extent of the variability of many sources’ emissions, those sources would be capable of emission rates below zero. That is clearly impossible and yet, rather than recognizing that it has grossly overstated variability, EPA simply ignores the impossible downward variability and accepts the upward variability – which is no less impossible – as accurate. In other instances, EPA’s calculation of upward variability yields the impossible result of predicting that sources will emit more mercury than is contained in their fuel. Boilers cannot create mercury. Instead of recognizing this basic fact, however, EPA ignores it and continues to pretend that its floor approach is rational.

Overall, EPA’s floor approach leads to floors so high that few if any sources subject to any given standard will have to reduce their emissions. The agency’s games with statistics are, ultimately, just another attempt to avoid the Clean Air Act’s floor language and circumvent the D.C. Circuit decisions interpreting this language. Such evasion is not only unlawful but amounts to contempt for Congress and the courts.

Comment Excerpt Number: 35

Comment: EPA is proposing a stringent set of emission limits that are, in many cases, not based on the use of any technology. In many cases, boilers are achieving low emission rates not due to use of any particular technology, but due to the mix of fuels being fired (which sometimes includes fuels with pollutant contents below the limits of detection) or other unit specific characteristics that are not transferable to other sources. Facilities are limited in the fuels that their boilers can fire by design, cost, permits, and fuel availability. EPA should not set limits for hundreds of boilers based on data from a few boilers in which the specific mechanisms resulting in lower emissions are not fully understood and that are not available to all units in the subcategory.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 36

Comment: The suite of limits should be achievable by at least 6 percent of existing boilers in each subcategory and the remaining boilers should be able to comply through their range of normal operating scenarios by applying known control equipment solutions. This expectation is not met for a broad range of units. Based on our review of the available data, less than 6 percent of units in the dry biomass stoker, biomass suspension burner, coal stoker, pulverized coal, and

all liquid subcategories can comply with the entire suite of applicable limits. This indicates to us that EPA has not adequately addressed the variability of emissions from units in these subcategories in selecting numerical limits.

Comment Excerpt Number: 39

Comment: Some of the new source and existing source limits are the same (for example, the solid fuel HCl limit) because the 99 UPL for the new unit data is higher than the 99 UPL for the existing unit data. If the emissions data for the top performing unit exhibits more variability than the emissions data for the existing units, EPA cannot ignore this fact. It is arbitrary to choose the calculated existing unit limit as the standard that both types of units must meet. EPA should instead set both the existing and new unit standards at the new unit 99 UPL in order to adequately reflect variability and acknowledge the capabilities of the top performer to meet a standard.

Comment: In many cases, a large population of boilers is being represented by only a handful of data points. The table below presents information on the number of boilers in each subcategory, the number of boilers for which EPA believes it has data, and the number of boilers on which the MACT floor is based. The only data being used to calculate MACT floors are the data obtained during the ICR and subsequent facility submittals to the docket, even though EPA has available data from other sources (e.g., NEI and TRI data).

If the available data were statistically representative of the entire subcategory (such that calculating the MACT floor with fewer sources would result in approximately the same value as the MACT floor using data from the entire subcategory), then the lack of data likely would not significantly skew the results. However, the proposed rule and supporting documentation provide no assurance that where limited available data are available that they are representative of the entire source category. As a result, we believe that the lack of available data will produce MACT floors that are not reflective of the subcategory as a whole.

While it is true that the statute allows EPA to determine the MACT floor based on sources "for which the Administrator has emissions information," this provision does not excuse EPA from using its resources and legal authority to obtain as much information as it reasonably can prior to setting MACT standards. In this case, EPA has had 20 years to gather the needed information. The fact that, at this point, data on only a small subset of sources in each subcategory are available represents an abdication of EPA’s responsibility and renders the resulting standards arbitrary and capricious.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 56

Comment: EPA is using less than 5 sources to set MACT floors. EPA has explained that it is using the top 12 percent of sources where there are more than 30 sources in a subcategory. EPA should use no fewer than 5 sources in setting the MACT floor for any source category – regardless of the number of sources in the category or subcategory. Congress clearly expected enough emissions information to be available for larger source categories to generally cause more than 5 sources to constitute the top 12%. It is not plausible that Congress specified a minimum number of sources for source categories with few sources, but then created a rule that would allow for standards to be set using data from fewer than 5 sources in larger source categories. Using no less than 5 sources would give effect to the clear intention of Congress.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 57

Comment: We note that the word "sources" as used in the last clause of §§ 112(d)(3)(A) and (B) is ambiguous and, therefore, susceptible to reasonable interpretation by the Agency. As EPA explains in the preamble, the word "sources" might be construed to refer to all sources in the given category or subcategory. However, the word "sources" in the first clause of §§ 112(d)(3)(A) and (B) clearly refers to the sources for which EPA has emissions information. Notably, the second use of the word "sources" in § 112(d)(3)(A) also clearly is a reference to sources for which EPA has emissions information. So, it is reasonable to conclude that Congress

intended the word "sources" to have a consistent meaning for all purposes under these provisions. In other words, the reference "30 or more sources" at the end of § 112(d)(3)(A) and "fewer than 30 sources" at the end of § 112(d)(3)(B) reasonably should be construed as a reference to sources for which EPA has emissions information. This interpretation allows for EPA to naturally reconcile the application of §§ 112(d)(2)(A) and (B) such that the number of sources for which EPA has emissions information in a given category or subcategory dictates whether § 112(d)(2)(A) or (B) should apply.

Document Control Number: EPA-HQ-OAR-2002-0058-3525-A1

Comment Excerpt Number: 2

Comment: In light of the significant errors related to variability, NACAA strongly recommends that EPA revisit each of its MACT floor calculations, especially where the proposed floor is so lenient that a large majority of existing sources already meet the limit. We believe EPA has sufficient information available to EPA to correct the errors in its current proposal and issue a final rule on reconsideration in the next few months.

Comment: EPA's methodology results in a situation where, in a majority of EPA's proposed subcategories, the calculated new source MACT floor (based on the best performing unit) is higher (less stringent) than that for existing sources (based on the average of the top 12 percent of units in the subcategory). Common sense and basic arithmetic provide that the rate of emissions of the "best" unit (i.e., the lowest emitter in the group) must be less than the average of that unit and the emission rates of a group whose emissions are higher. At a minimum, the procedure adopted by EPA must achieve this result.

Comment: In calculating the average of the selected units, EPA assumes that the performance of a selected unit is defined by all test results⁶ available for that unit. [Footnote] (6) EPA includes all test results of “best performers” in its calculation of the MACT floor for each subcategory. This effectively over weights the contribution of sources that have been tested multiple times compared to those that may have been tested only once.

Comment: In the development of the 2004 rule for this sector, EPA determined the base performance level of the median unit in the top 12 percent and then applied a variability factor that was calculated on the average of the variance in performance for all units with similar pollution technologies. The U.S. Court of Appeals determined that EPA’s method for identifying the base performance level was inappropriate, but did not opine on the method for determining the variability factor.⁸ In developing the 2010 final rule, EPA attempted to calculate the anticipated variation in performance of each of the units in its “best performing” group on an individual unit or subcategory basis. Rather than simply determining the variance in performance, EPA chose to calculate the UPL of the best performing units, that is, the emission level that each unit in the top 12 percent could be expected to meet at a 99th percentile confidence level. EPA’s procedure also errs by attempting to determine the emission level that the bottom half of the top 12 percent will meet 99 percent of the time. However, EPA should not expect these units to meet the MACT floor limit since nominally half of the top 12 percent do not meet the average and therefore are not complying units.⁹ The development of a compliance margin should be limited to an evaluation of the variability of the top 6 percent performing units under the compliance conditions imposed by the regulation.

[Footnotes]

(8) It did agree that EPA could apply a variability factor to take into account expected variation in performance of such units.

(9) Those units in the top 12 percent, but with emission levels greater than the average of the top 12 percent (i.e., the 6th through 12th percent best performers), do not “comply.”

Comment: Pooled variance is a method for estimating variance given several different samples taken in different circumstances where the mean may vary between samples but the true variance (or precision) is assumed to remain the same. Under EPA’s revised UPL procedure, fuel analyses results are disaggregated from emission test results and further disaggregated by the number of unique sources. As a result, the method is highly sensitive to the number of tests and the number of units that are tested. However, in some subcategories the majority of the test and fuel analysis results were BDL and the detection limits for the emission test results are several times lower than those for the fuel analyses. EPA’s pooled variance process generates high levels of variability, based largely on differences in the degree of precision of the measuring process and EPA’s treatment of BDL data (where the results are known to be less than the BDL). This leads to unreasonable results where the sample size is relatively small. In addition to generating unrealistic results for a broad array of new source subcategories, EPA’s proposed new statistical approach also appears to lead to results for PM and CO that are not consistent with the in-use performance of units in a number of other subcategories with limited data.

Comment: EPA has recommended the use of the 99th percentile UPL of pre-regulation testing and argued that its use is justified because the agency adopted the same approach in the medical waste incinerator MACT rule. This rationale does not explain why EPA believes the 99th percentile UPL is appropriate and not the 50th,¹⁵ 90th or, for that matter the 99.99th percentile.¹⁶ The decision matters because with each increase in the “guaranteed” compliance margin, the standard increases, and there comes a point where the compliance margin is so great that sources can merely accept the risk of a failed compliance test rather than reduce emissions. If a source fails a compliance test it will ordinarily be afforded the opportunity for a retest and only if a source has a confirmed deficiency in its control equipment will a modification be ordered. We are unaware of any situation where a source that is willing to make such modifications as are necessary to meet an applicable limit has ever been ordered to permanently cease operation on the basis of a single failed stack test. In contrast, where an excessive compliance margin is provided emission standards can be ineffective.

[Footnotes]

(15) Civil enforcement of environmental standards is based on a “preponderance of the evidence,” which merely requires that a violation be more likely than not (51st percentile).

(16) Some in industry have argued that the levels should be set so that there is no significant probability that a facility would fail a compliance test at any point in its useful life.

Comment: The degree to which emission tests results can vary are not truly random, but are constrained by the laws of physics and chemistry and, in many instances, the performance of pollution control devices. EPA's statistical analyses of the data show that, if the data were randomly distributed, there would be a substantial number of instances where emission rates are less than zero. We know that this is not possible and so the data are "skewed" to the right. One method used by statisticians to adjust for this form of distribution is to assume what is known as a log-normal distribution. [See submittal for Figure 1.] With the assumption of a log-normal distribution, one then evaluates the distribution of the logarithm of the number rather than the number itself. EPA has employed this method in a number of instances. One feature of log-normal distributions is that they have "tails" that become very long as the variance increases. That is, the difference between the mean and the value that represents the 90th percentile probability is much greater where one assumes a log-normal distribution than otherwise. However, we know that the emission rate of specific pollutants, such as mercury, ("Hg"), can never be larger than the amount of Hg in the fuel and that emission rates are also influenced by the operational characteristics of installed pollution control devices. Yet, EPA's calculations routinely predict results that are inconsistent with these facts. They also lead to results, cited above, where the performance of the best performing unit is calculated to be worse than the average of the top 12 percent and where the calculated performance of the best units approximates the demonstrated performance of the worst units. These examples illustrate the point that in order to properly determine whether a particular statistical method is appropriate for a data set, one must determine whether the results of the method employed make sense. We submit that EPA's decision to use the 99th percentile leads to unrealistically large calculated variations in performance of the best performing units, especially where the distribution is assumed to be log-normal and especially where the sample size is small so that relatively large variances are computed.

Comment: There are additional facts to help guide EPA's determination of a standard compliance margin to be applied to all subcategories - the compliance obligations and testing conditions that are imposed by the standard. An equitable balance is struck when the same conditions used to establish the compliance margin are thereafter used to set the compliance obligation (and vice versa). If a source is required to be regularly tested under conditions that represent the 99th percentile "worst-case" conditions, then a 99th percentile compliance margin might well be appropriate. Additionally, a larger compliance margin is ordinarily appropriate for

standards with short averaging periods and continuous emission monitors ("CEMs") than for standards that have long averaging periods or where compliance is determined by scheduled stack tests conducted by the source.¹⁷

[Footnote]

(17) We do not intend to suggest that there is widespread cheating during compliance testing. Our point is that the source has substantial prior notice of such tests and is in control of the operating conditions during the test.

Comment: In the absence of sufficient data to make determinations of the variability of individual units and subcategories with limited data, EPA should develop a reasonable compliance margin to apply to the best-complying sources. The underlying issues are sufficiently complex that, in the absence of truly comprehensive data, no single analysis will likely prove to be dispositive. For this reason we recommend that EPA perform a series of analyses and examine the central tendency of the results of those analyses. From these results EPA can establish one or more default variability factors to apply where the limited number of test results affects the calculation of variability in a given subcategory. One such group of analyses, but by no means the only approach that could prove useful, is to start with the most comprehensive data set to determine a broad "default" variability factor and examine more specific data sets to determine whether a more limited variability factor can be assigned based on the data available.²⁷ Such an

approach could proceed as follows: Commence the process by identifying all units that may reasonably be found to be in the top 12 percent. This might include the top 25 – 33 percent of units based on their mean test result and all units whose mean test emissions are within an order of magnitude of the best performing unit.

Calculate the nominal “performance” of each unit; by summing the mean and one standard deviation²⁸ of the unit specific data. Average the performance of the top performing 12 percent, understanding that this is likely an overestimate, based on the low number of test runs for most units. Since this approach is likely to overestimate the variability to some degree, the results of the first assessment should be considered an upper bound of potential MACT floors, EPA should then look to see if the variability of the broad group is less than that calculated above. Using the pool of “best performers” identified above, normalize the emission test results for all sources for which EPA has data, including those not in the top 12 percent and determine the average variability in the performance for the broad group. EPA could accomplish this by dividing the variance for each unit by the mean of the data for that unit and average the results, not the UPL. It has been argued that sources in the top 12 percent have less variability than the population at large and so this variance should be considered to represent an upper bound of a permissible variance.

Repeat the above-described analyses for the three basic subgroups – solid, liquid and gas. This then would form a second set of possible default variability factors for the subgroups for which sufficient data are available. Since there are more tests available for the entire liquid-fired set of units, it may prove possible to develop a separate variability factor for liquid-fired units, which, while likely larger than that for the best performing units, is more accurate than that based on limited data for the best performing units. Repeat the above-described analyses using data for the top best-performing, 50 percent, 25 percent, 12 percent and 6 percent of the basic subgroups. Employ these results if the average variance is less than that for the larger group or if it can be established that the calculated increase in variance is due to differences in performance and not the consequence of the reduced sample size. Iteration in this fashion should identify a point where the reduction in sample size outweighs the improvements normally expected from better performing units. For purposes of determining the arithmetic average, results reported at a detection limit should be employed as recorded, however, for purposes of determining variance such results should be excluded as they artificially reduce the variance. For purposes of determining the arithmetic average of the best performing top 12 percent, all test results should be employed to identify the best performers, not the best single result. This will increase the arithmetic average, but is a more reasonable estimate of the performance of units with multiple tests than the lowest single result currently employed by EPA.

Once the variance of the data has been determined, it should be applied to the arithmetic average of the top 12 percent, not to any unit in the data set. Consistent with most of the enforcement expectations, we recommend that it be applied at the 90th percentile level. For those subcategories where the data are sufficiently robust, a variability factor specific to the subcategory may be applied; for all others the applicable MACT floor would be the arithmetic average of the data for the subcategory, as adjusted by the applicable default variability factor.

Where a source or group of sources wishes to maintain that a different variability factor should apply, those parties should be responsible for providing sufficient data to develop a factor that is not dominated by the paucity of data. Additionally, EPA could determine the “normalized”

variance for each unit where more than a certain number of tests (perhaps 10) are available and average those values. EPA should examine the performance of similar units in the electric generating unit sector and other sectors and review relevant BACT and LAER determinations. EPA should also examine the overall distribution of the data set at issue to determine a reasonable variability factor. Where there are a large number of units with similar emission levels, a large variability adjustment should not be applied. Where EPA determines that a source category's emissions are highly variable over a short period (e.g., CO), EPA should consider longer averaging periods, such as 30-day rolling averages, that reflect and accommodate this form of variability, while still preserving the environmental benefits the CAA contemplates. However, under no circumstances should 30-day CEM-based limits be higher than the corresponding reference method (three- hour) limit.

Comment: EPA's approach to "rounding" introduces an additional inappropriate bias to the calculation of MACT floors and should be revised to reflect technically correct rounding procedures and the requirements of the statute. In the calculation of the MACT floor, such as the application of calculated UPLs, EPA "rounded" the interim values and in each such instance rounded the values up. In most engineering calculations, rounding protocols provide for rounding down as well as up. Rounding ordinarily includes truncating the number of significant digits that are employed in a calculation and occurs at the end of the calculation process. EPA justifies its decision to only round up by asserting that to do otherwise would deprive sources of the "variability" cushion they were otherwise entitled to. Again, this argument ignores the public interest in reducing emissions of hazardous air pollutants, as well as normal engineering protocols. It would also seem to be contrary to written EPA policy concerning rounding for NSPS compliance purposes.³⁶ This policy, which has not been revised to our knowledge, adopts ASTM standard rounding protocols – carry at least five significant digits throughout all intermediate calculations and employ ASTM Procedure E 380 (round down if less than 5; round up if greater than 5) for the final calculation. Where a MACT floor would otherwise be calculated at 2.27, it would seem that "rounding" a final standard to 3.00 would be technically unjustifiable and would not comply with the requirement of section 112 that the MACT standard be not less stringent than the average of the top 12 percent.

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 20

Comment: The methodologies EPA has relied on to establish emission limits have resulted in some new sources and existing sources having the same standards. For example, the HCl limit is the same for solid fuel new sources and existing sources. This likely occurred because the 99 UPL for the new unit data is higher than the 99 UPL for the existing unit data and EPA choose the calculated existing unit limit as the standard that both types of units must meet. EPA’s approach is arbitrary. EPA should instead set both the existing and new unit standards at the new unit 99 UPL in order to adequately reflect variability.

Commenter Name: Robert D. Bessette

Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 21

Comment: EPA set many of the new source limits using one 3-run stack test. EPA should consider variability and use the UL instead of the UPL statistical calculation. This approach is appropriate and justified because sources will be required to meet the new source limits at all times. EPA should also consider fuel variability data for all units setting new source floors and that variability should be included in the calculated emission limits. As CIBO indicated in its earlier comments and Petition for Reconsideration of the Final Boiler MACT Rule, variability is important in setting achievable emission limits.

Document Control Number: EPA-HQ-OAR-2002-0058-3685-A2

Comment Excerpt Number: 28

Comment: EPA Impermissibly Ignored Non-Stack Emission Data and Used Inadequate and Biased Data to Set the MACT Floors Section 112(d) of the Clean Air Act requires EPA to set MACT floors for existing sources that are not less stringent than "the average emission limitation achieved by the best-performing 12 percent of the existing sources (for which the Administrator has emissions information)." 42 U.S.C. § 7412(d); *Nat. Res. Def. Council v. EPA*, 489 F.3d 1250, 1254 (D.C. Cir. 2007). The top 12 percent "best performing" sources become the MACT floor units. To identify these units, EPA must collect "emissions information" from units that are included in the source category. During Phase I of EPA's data gathering effort, it requested and received emissions data from over 2,000 sources across all of the subcategories for PM, CO, NOx, and many HAPs. After sifting the data into fuel-based categories, EPA issued a second section 114 request requiring additional testing. During this second phase, EPA impermissibly targeted only those sources the Agency had identified as the top performers based on Phase I, instead of obtaining a random sampling of emissions data across the entire population of boilers in a subcategory to assess the variability in performance of boilers in a particular subcategory. In this way, EPA artificially limited the pool of data from which it drew its top 12 percent and biased the data collection. The data is not evenly distributed, but is clustered well below the mean. EPA further limited the pool of data from which it established the MACT floors by considering only units with stack test data in identifying the top 12 percent. EPA ignored other "emissions information" that it is required to consider pursuant to section 112(d). This combination of missteps resulted in EPA proposing MACT floors that are based on the top 12 percent of the top 12 percent of units in each subcategory in violation of section 112(d).

This led to EPA considering data from only a portion of each subcategory in setting the MACT floors. For the existing solid fuel subcategory, for example, EPA considered HCl data from only 33 percent of the sources in the subcategory and Hg data from only 29 percent. This led to MACT Floors being set by 4 percent and 3.5 percent of the source category, respectively. The figures are even worse for CO. For existing coal-fired units, EPA considered emissions data from only 11 percent of stoker units and 19 percent of pulverized coal units, with the MACT floor limits being determined by only 1.5 and 1.1 percent of the respective categories. The number of sources used to establish PM limits for coal-fired units was higher, but still inadequate at 47 percent for stokers and 56 percent for pulverizers.

If it was certain that the available data were statistically representative of the entire subcategory (such that calculating the MACT floor with fewer sources would result in approximately the same value as the MACT floor using data from the entire subcategory), then the lack of data likely would not significantly skew the results. However, the Proposed Rule and supporting documentation provide no assurance that the limited available data are representative of the entire source category. As a result, there is no way to know if the available data are producing a

MACT floor that is not reflective of the subcategory as a whole. That lack of data raises serious doubts regarding the validity of the MACT floor determinations and resulting emissions limitations.

EPA's failure to use adequate data is inexcusable. EPA has been working on the Boiler MACT standards for more than 15 years, and had ample time to gather and evaluate sufficient emissions data. Furthermore, the Clean Air Act explicitly instructs EPA to base its MACT floors on all units for which EPA has "emissions information ." This is an unambiguous statutory directive, and EPA may not artificially limit its review to testing data. Emissions information extends beyond stack test data to include volume and types of fuels and the emissions controls used by the vast majority of industrial boilers and process heaters in use today. EPA has developed emissions factors for various types of units based on this information and published them in AP-42 and other compilations. Sources are encouraged to rely on these emission factors to estimate emissions in the absence of actual test data. EPA too, then, should have used these emissions factors to estimate emissions for those units without emission testing data. This is "emissions information" that is readily available to EPA and should be included in selecting the group of sources that represent the top 12 percent of performers.

EPA's failure to gather sufficient data and evaluate all emissions data available in each subcategory resulted in many units - including small municipal utilities without significant test data - being ignored in setting the MACT floors. EPA has (or could reasonably obtain) emissions information from virtually all coal-fired sources using AP-42 emissions factors, and is obligated to consider the data from all of these units in establishing the MACT floor.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 40

Comment: Many of the new source limits are set using one 3-run stack test. EPA could further consider variability by using the UL instead of the UPL statistical calculation and using a 99.9 percent confidence level instead of a 99 percent confidence level, since sources will be required to meet the new source limits at all times. In addition, fuel variability data should be collected for all units setting new source floors and factored into the calculated emission limits. Industrial boilers operate over a variety of conditions and fire a variety of fuels, so adequate consideration of variability is important in setting achievable emission limits. EPA continues to use a pollutant-by-pollutant approach instead of a source-based approach to setting new unit limits, so maximum consideration of variability is imperative.

Document Control Number: EPA-HQ-OAR-2002-0058-3503-A1

Comment Excerpt Number: 7

Comment: The suite of limits should be achievable by at least 6 percent of existing boilers in each subcategory and the remaining boilers should be able to comply through their range of normal operating scenarios by applying known control equipment solutions. This expectation is not met for a broad range of units. Based on our review of the available data, less than 6 percent of units in all liquid subcategories can comply with the entire suite of applicable limits. This indicates to us that EPA has not adequately addressed the variability of emissions from units in these subcategories.

Comment Excerpt Number: 8

Comment: Clean Air Act § 112(d) requires EPA to set a MACT floor for existing sources that are not less stringent than "the average emission limitation achieved by the best-performing 12 percent of the existing sources (for which the Administrator has emissions information)." *See* 42 U.S.C. § 7412(d); *Nat. Res. Def. Council v. EPA*, 489 F.3d 1250, 1254 (D.C. Cir. 2007). The top 12% "best performing" sources are known as "MACT floor units" or "units comprising the MACT floor."

During Phase I of EPA's data gathering effort, it requested and received emissions data from over 2,000 sources across all of the subcategories for PM, CO, NO_x, and many HAPs. After sifting the data into fuel-based categories, EPA issued a second section 114 request requiring additional testing. During this second phase, EPA impermissibly targeted only those sources the Agency knew it needed data from to set the MACT floor (e.g., the top performers) instead of obtaining a sampling of emissions data across the entire population of boilers in a subcategory to assess the variability in performance of boilers in a particular subcategory. In this way, EPA artificially limited the pool of data from which it drew its top 12% "best performing" sources and

biased the collection of emissions data. The data are not evenly distributed, but are clustered well below the mean, and since EPA has chosen to select the top 12 percent of boilers for which it has stack test data instead of the top 12 percent of boilers for which it has any emissions information, this has resulted in the proposed MACT floors being based effectively on the top 12 percent of the top 12 percent of boilers. This is patently at odds with section 112(d). In many cases, a large population of boilers is being represented by only a handful of data points. The table below presents information on the number of boilers in the liquid fuel subcategory, the number of boilers for which EPA believes it has data, and the number of boilers on which the MACT floor is based. The only data being used to calculate MACT floors are the data obtained during the ICR and subsequent facility submittals to the docket, even though EPA has available data from other sources (e.g., NEI and TRI data).

Comment Excerpt Number: 10

Comment: In some cases, EPA has augmented available stack test data with calculated emission factors in order to increase the number of sources on which the MACT floor is based (e.g., liquid fired boilers for which fuel data or stack test data from an identical boiler at the site are available). EPA should expand this approach by obtaining emissions data from all boilers in the liquid subcategories, whether by obtaining additional fuel data, additional stack test data, or estimating emissions for these boilers based on available emission factors. In fact, EPA has estimated emissions for all of the boilers being regulated under the MACT in order to quantify the expected emissions reductions. Therefore, EPA should be using the top 12 percent of the total number of boilers in each subcategory in order to set limits. EPA is using this approach in the CISWI rule. The following table demonstrates the amount of data currently being used to set standards and the actual percentage of boilers in light and heavy liquid fuel subcategories that are being represented by each floor (assumes EPA has properly subcategorized units). [See submittal for table] EPA has not used 12 percent of the number of existing sources to set floors in the light or heavy fuel subcategories.

Comment: EPA has studied its approved reference testing methods for years and has amassed significant information about the performance of those methods. Based on this body of knowledge, EPA reports that, where the result of a test is near the detection level applied, most of its test procedures are accurate to within +/- 50 percent; at other times EPA asserts that these

tests are accurate to within +/- 15 percent. Monitoring devices, such as CO monitors, must meet stringent requirements for drift and must be calibrated to within 2 percent of the full scale value of the expected emission level of the unit. The paired testing data and other data in the record of this case show that, especially at the better performing sources, the variability in Hg and other specific pollutants is quite low. Similarly, years of testing of pollution control devices found in this sector, such as PM controls (fabric filters and electrostatic precipitators (“ESP”)), show highly consistent performance. Thus far, EPA has not factored any of these facts into its determination of the performance of the best performing units.

In order to evaluate whether EPA’s procedure for calculating variability is appropriate, one first has to examine what “variability” EPA is calculating and whether it is relevant under sections 112 or 129. EPA’s procedure involved determining the 99th percentile UPL of the difference in performance between all test runs for all units in the top 12 percent. This calculation improperly combines two factors: (1) the inter-unit difference between the “best performers” and “the best of the best performers” and (2) the expected variability in performance for each of the best-performing units. EPA does not have the resources to evaluate each of these situations in detail to determine whether the difference represented inherent variability in performance of the unit or is a consequence of factors (such as fuel composition or specific hardware design) that are within the control of the source, and so it simply, and incorrectly, assumes that each of the units within the top 12 percent is identical and that all of the difference in performance is a “variability” in performance that is essentially random and therefore susceptible to statistical analysis. This can be addressed by normalizing the data so that one only examines the variability in performance. Replicate compliance method testing of the best performing units over a period of years and varying operating conditions would likely be the best method for determining which units are among the best performing units and for assessing the variability of the performance of such units. However, EPA does not have such information and development of this information is infeasible at this time. Moreover, EPA does not have sufficient data of any sort to make an accurate assessment of the variability of either individual units or subcategories with relatively limited data. As discussed earlier, the problem is readily apparent for new sources, where EPA’s attempts to determine the variability in the performance of the “best” unit based on a single reference test clearly produce an incorrect result. This problem also exists in a large number of existing source subcategories where EPA has insufficient test data to apply its method. EPA has acknowledged this problem and attempted to partially respond to it by using its “beyond the floor” MACT authority to raise the new source MACT limit to the level of the existing source MACT floor in 24 subcategories. While directionally correct, we believe it is unlikely that this will be found to be sufficient, since common sense and basic arithmetic demonstrate that the result is still wrong – the performance of the “best” individual unit cannot be the same as the average of the larger group. Moreover, EPA does not make a similar adjustment to existing source MACT floors that are also based on limited data. NACAA recommends that EPA examine a number of additional options for assigning a variability factor, including a return to the philosophy underlying its 2004 determination of variability of performance. We provide more detailed recommendations later in this section. EPA compounds the error associated with attempting to employ its statistical procedures to extremely limited data sets by applying a series of multipliers and alternate tests of variability. In most, but not all instances, EPA selects the test that leads to the least stringent MACT floor determination. Moreover, the basis for several key decisions respecting data management (discussed below) is not well supported. The lack of a consistent, reasoned basis for EPA’s choices creates a risk that the rule will be overturned and in

some instances, the resulting floor calculation will be substantially different if other, equally reasonable, factors are used in developing the final determination. We discuss a number of these issues in detail below, but the impact of EPA's new statistical approach in categories with relatively small numbers of tests is clearly illustrated by the Hg limit EPA calculated for liquid-fired boilers. While these factors affect all of EPA's MACT floor calculations, they are most apparent in the calculations for new sources, which, under EPA's methodology, always involve single units with limited testing. The following discussion sets out our best understanding of the relative impacts of several EPA choices on the overall effectiveness of the resulting MACT floor for other subcategories. We have included herein and attached as Appendix 1 a series of charts setting out EPA's test data as provided as appendices to its MACT floor memo for each unit, along with EPA's proposed limit for the applicable subcategory. These charts provide a basis for the assessment of the effectiveness of the proposed limit. EPA's appendices included only the "lowest test result" for a given unit rather than all test results. In most instances, the difference in effectiveness is minimal, as most sources were only tested once, so the "lowest test result" is also the highest test result. Where a significant number of units were subjected to more than one test, we have also produced a chart including all test results for the top 12 percent to assist in gauging the effectiveness of the proposed limit. We encourage EPA to produce similar charts, including all test results, for all units for the rules it ultimately adopts.

Comment: The Clean Air Act (CAA) MACT provisions clearly state that the MACT floor is to be calculated as "the average emission limitation achieved by the best performing 5 sources" for categories and subcategories with fewer than 30 sources (CAA Section 112(d)(3)). In the proposed MACT floor calculation, instead of following the plain language of the CAA, EPA limited the best performing sources for use in the floor calculation to the number that could comprise a minimum of 12% of the subcategory, or to one unit if there were 8 or fewer units in the subcategory. For a small subcategory with a widely varying range of emission rates such as the kiln-dried biomass subcategory, the floor calculation does not recognize the variability inherent among all boilers in the group and results in an emission limitation that is not achievable for nearly all boilers in the subcategory. We believe that establishing the floor based on one or two units would be arbitrary and capricious. AHFA urges EPA to implement an approach that considers the emissions variability inherent in this subcategory, and to 1) calculate the mathematical average of the top 5 performers with data, and 2) apply a 99.9% upper prediction limit (UPL) to account for variability within the subcategory. Without this type of common sense approach to the MACT floor calculation, we anticipate that our members will be faced with the prospect of switching from carbon-neutral biomass fuels to non-renewable fossil fuels, or shutting down facilities and shifting to overseas production.

Comment: NCASI is providing additional comments on the limitations associated with using the empirical rule on all variability ratios within a specific fuel subcategory, to identify and remove outliers. The following are worth mentioning:

- The assumption that the entire sample of variability ratios is normally distributed is false.
- Further, the outliers identified using this assumption can neither be discarded by graphical observation of the data including the suspected outlier(s) nor can they be discarded based on the requirement that the remaining data without the suspected outlier(s) be normally distributed.
- Additionally, the standard deviation criteria (eliminating outlier values that do not lie within three standard deviations of the mean of all of the computed ratios in the fuel subcategory) may not appropriately account for "intra-unit" variability in fuel pollutant concentrations. In such cases, the empirical rule may have to be applied on a unit-specific basis to reconfirm outliers. More details on this issue are submitted in separate comments by NCASI.

103C. MACT Floor Methodology: Ranking by Average [DENIED PETITIONER ISSUE]

Commenter Name: James Pew

Commenter Affiliation: Earthjustice, Clean Air Council, Partnership for Policy Integrity

Document Control Number: EPA-HQ-OAR-2002-0058-3511-A1

Comment Excerpt Number: 12

Comment: EPA ranked sources by their single lowest emission tests. For example, a source that with three tests reflecting emissions of 10 units, 100 units and 100 units respectively would be ranked better than a source with three tests reflecting emissions of 15 units, 15 units and 15 units respectively. For purposes of setting floors (as opposed to identifying the alleged best performers), however, EPA did not continue to measure individual sources' performance by their lowest emission test. Instead, EPA applied statistical factors allegedly to estimate each source's 99th percentile worst performance based on all their emission test results. Under this approach, EPA would conclude that the performance of the source with three tests of 10 units, 100 units and 100 units in the example above is substantially worse than the source with emission tests of 15 units, 15 units and 15 units respectively even though the agency would have identified the first source as better for the purpose of ranking sources and selecting the best performers. Not only does the first source have two tests that are much worse than any test results from the second source but the variation between the test results for the first source would lead EPA to claim that its adjusted performance is actually much worse even than its worst test. Because

EPA's floors do not reflect the performance of the relevant best sources as EPA itself measures performance, they contravene § 112(d)(3), which provides that new standards must, at a minimum, reflect the emission level achieved by the single best performing source and that existing source standards must, at a minimum, reflect the average emission level achieved by the average of the best performing twelve percent of the sources for which the agency has emissions information. Further, to the extent EPA claims these floors reflect the performance of the best sources, its claim is arbitrary and capricious both because the record shows that other sources are better performing and because EPA has not provided a rational explanation for choosing one method to rank sources' performance and another to measure it.

As a practical matter, EPA's inconsistent approach to identifying the best sources and measuring these sources' performance substantially decreases the protectiveness of its standards. By using different methods to identify sources as best performing on the one hand and to estimate these sources' performance on the other, EPA selects sources with relatively high variation as the "best" – even though these sources would not be labeled best if the agency ranked them under its own approach to measuring performance. Next, EPA uses that variability of performance in the sources it picked as best – sources that necessarily have higher variability in performance than do the sources that would be "best" under the agency's own approach to measuring performance – to inflate the floors. If EPA used a consistent approach to identifying the best sources and to estimating these sources' performance, the standards would be far more protective. If EPA selected as best the sources with the single lowest emission test and then – consistent with that approach – also measured sources' performance based on their single lowest emissions test, its standards would be far more protective. Likewise, if EPA identified the best sources based on its statistical analysis of all their emissions tests and – consistent with that approach – measured their performance the same way, its standards would be far more protective. Only by changing its measurement approach part way through the floor setting process does the agency arrive at floors that so greatly exceed the actual performance of the relevant best sources.

Comment Excerpt Number: 9

Comment: NACAA believes that EPA should use either the best test result for both purposes or use the best average of all test results for both purposes. This use of inconsistent definitions of performance has resulted in at least one MACT floor that is higher than it should be, as units with better average performance over all tests were excluded in favor of other units with a lower individual test result but higher overall emissions. We also believe that use of the average of all test results for an individual unit is an appropriate measure of the performance of that unit, provided that the subsequent analysis of variability does not then treat that average as a single test result. One way to address this issue may be to use the average of all test results to identify the best performing units in the calculation of the average of the top 12 percent, but then include all test results of the "best performers" in the determination of the potential variability of that average.⁷ The identification of the "best performers" should take place after all of the variability

adjustments have been made to the universe of “candidate best performers.” In this way the MACT floor would not be artificially increased by the use of data from sources that are ultimately not the best performers within a subcategory.

[Footnote]

(7) This is not the same as using the 99th percentile UPL of the individual runs as a factor to multiply the average.

103D. MACT Floor Methodology: Pollutant-by-Pollutant Approach [DENIED PETITIONER ISSUE]

Commenter Name: Kevin G. Desharnais, Attorney, Mayer Brown LLP

Commenter Affiliation: United States Sugar Corporation

Document Control Number: EPA-HQ-OAR-2002-0058-3496-A1

Comment Excerpt Number: 14

Comment: EPA continues to utilize a pollutant-by-pollutant approach in establishing its MACT floors in the Reconsideration Proposal, and does not address U.S. Sugar's objections to this methodology. U.S. Sugar reiterates the arguments it made in its comments to the Proposed Rule and incorporates them by reference herein. In the Final Rule, EPA also offered several additional justifications for its approach. U.S. Sugar requested reconsideration on this issue, but the Reconsideration Proposal fails to address the concerns we raised.

EPA has misinterpreted and misapplied section 112(d)(3) of the CAA. Under that subsection's plain terms, EPA must set the MACT floor at "the average emission limitation achieved by the best performing 12 percent of the existing sources" or the "best performing five sources," depending on the number of sources in the subcategory. 42 U.S.C. § 7412(d)(3)(A)-(B).¹ EPA has some flexibility in how it selects the "best performing" sources and determines their "average." See *Sierra Club v. EPA*, 167 F.3d 658, 661 (D.C. Cir. 1999) (the phrase "average emission limitation achieved by the best performing 12 percent of units" "on its own says nothing about how the performance of the best units is to be calculated"). Nevertheless, EPA's discretion is bounded. Most critically, EPA may *not* set the MACT floor at a level that an "average" of "the best performing 12 percent" does not "achieve[]." [*d.* This means that for any MACT floor, it must be possible to take 12 percent of a subcategory's boilers, average those boilers' emissions, and have that number meet the MACT floor. If this is not possible, then the MACT floor is necessarily unreasonable. And a MACT floor is patently unreasonable if *no* boiler in a subcategory achieves the floor's standard.

This reading, compelled by the statute's clear text, fully comports with Congress's purpose in enacting subsection (d)(3). Subsection (d)(3) merely sets *ajloor* at a level "achieved in practice," not a standard beyond every source's reach. 42 U.S.C. § 7412(d)(3); see *Sierra Club v. EPA*, 479 F.3d 875, 884 (D.C. Cir. 2007) (Williams, 1, concurring) (statute "embodies an assumption that standards based on achievability will be more stringent than ones based merely on past

achievement"). Section II2(d)(3) makes this purpose obvious by repeatedly stressing the word "achieved." 42 U.S.C. § 7412(d)(3)(A)-(B) (requiring EPA to determine "the average emission limitation *achieved* by the best performing 12 percent of the existing sources" or "the average emission limitation *achieved* by the best performing 5 sources") (emphases added). In accord with this clear intent, the D.C. Circuit has held that "EPA may not deviate from section 7412(d)(3)'s requirement that floors reflect what the best performers actually achieve." *Cement Kiln Recycling Coal. v. EPA*, 255 F.3d 855,861 (D.C. Cir. 2001) (per curiam); see also *id.* at 857 (remanding "[b]ecause the standards fail to reflect the emissions achieved in practice by the best-performing sources as required by the Clean Air Act"). For more onerous restriction, Congress enacted subsection (d)(2). See *Sierra Club v. EPA*, 353 F.3d 976,980 (D.C. Cir. 2004) (Roberts, 1) (EPA may impose restrictions beyond MACT floor only "if the Administrator determines them to be achievable after 'taking into consideration the cost ... and any non-air quality health and environmental impacts and energy requirements'" (quoting 42 U.S.C. § 7412(d)(2)). But for the purpose of determining the MACT floor, "past achievement" is key. *EPA*, 479 F.3d at 884.

EPA's proposed rule violates the statute's clear language and Congress's unambiguous intent because it sets MACT floors at levels far beyond what the average of the "best performing 12 percent of existing boilers" have achieved in practice. 42 U.S.C. § 7412(d)(3)(A). The flaws in the proposed rule stem directly from EPA's erroneous decision to make separate MACT rankings "[f]or *each* pollutant" within each subcategory. 75 Fed. Reg. 32,019 (emphasis added). Rather than selecting the "best performing" 12 percent of boilers *across* the source subcategory for all regulated pollutants, the proposed rule creates five distinct categories of best performers and sets *one* subcategory-wide MACT floor that incorporates the five independent standards. Under this approach, it makes no difference whether the proposed MACT floor is achieved by the average of the subcategory's "best performing 12 percent." 42 U.S.C. § 7412(d)(3)(A)-(B). Indeed, it is almost certain that the average of the best performing 12 percent of sources will lie outside of the MACT floor. That is manifestly contrary to Congress's intent.

EPA's interpretation of the statute will lead to absurdities. If EPA were establishing standards for one pollutant alone, there would be no problem; EPA's proposed MACT floor necessarily would be achieved by the average of best performing 12 percent of each subcategory's boilers. But problems emerge once a second pollutant is introduced. Unless the best 12 percent of boilers with respect to the first pollutant are exactly the same as the best 12 percent with respect to the second pollutant, then EPA's methodology necessarily results in a MACT floor that is not achieved by a subset of] 2 percent of the subcategory's boilers. Worse yet, the top 12 percent at controlling for the first pollutant might be entirely different from the top 12 percent at controlling for the second pollutant; in such a case, EPA will propose a MACT floor that *no* boiler in the subcategory has achieved.

Problems continue to pile on with the introduction of each new regulated pollutant, as each new pollutant essentially means that fewer boilers will achieve the new MACT floor. EPA's current decision to regulate only five chemicals-PM, mercury, HCl, CO, and D/F masks this problem to some extent. If EPA separately regulated each of the pollutants listed in 42 U.S.C. § 7412(b)(1), this would all but ensure that no boiler in any subcategory would achieve EPA's proposed MACT floor.

These problems are not merely theoretical. EPA's method does not control for the fact that boilers in each subcategory use different control technologies that emphasize certain pollutants at

the expense of others. No one technology succeeds in eliminating all pollutants from air emissions. The best performer under each regulated pollutant will be heavily influenced by the choice of control technologies. This variation again causes each MACT floor to be set at a level that is not achieved by an average of any 12 percent of boilers. Moreover, because EPA has not controlled for control technologies, its unreasonably stringent MACT floors may require sources to install every control technology. Such a result is both ludicrous and impossible.

Congress clearly did not intend for these absurdities when it required MACT floors to be set at a level "that is achieved in practice." 42 U.S.C. § 7412(d)(3). However EPA defines "average" or "best," there must be a way to take the "average" of the emissions from the "best" 12 percent of a subcategory's boilers and have that number meet the MACT floor.

The increased number of subcategories in the Reconsideration Proposal addresses part of the problem, since it ties the standards more closely to the unit regulated and avoids the application of standards established based on units with vastly different emissions characteristics. Nevertheless, increased use of sub categorization does not fully solve the problem. As long as the top 12 percent of boilers with respect to one regulated pollutant is not exactly the same as the top 12 percent of boilers for *every other* regulated pollutant, then EPA inevitably will propose MACT floors that are not achieved by an average of 12 percent of each subcategory's boilers. In order to address this flaw, EPA must completely revise its interpretation of section 112(d)(3) and its methodology for setting MACT floors. Only through such an approach will MACT floors accord with congressional intent and the statute's unambiguous language. Simply put, EPA should rescind its decision to use five separate and independent MACT floors within each subcategory of sources. EPA should instead adopt a method that results in MACT floors already achieved by an average of a 12-percent subset of each subcategories' existing boilers.

In the Final Rule, EPA defended its pollutant-by-pollutant approach by claiming Section 112(d)(3) is ambiguous and its methodology is a reasonable interpretation. EPA is mistaken in both assertions. There is no indication in the statutory language that Congress intended the MACT floor be set pollutant by pollutant. Rather, a plain reading of the text reveals Congress intended the MACT floor be set at a level actually achieved by the average of the best 12 percent of sources . As EPA noted in the Final Rule, Section 112(d)(3) emphasizes that the floor must be based on what "sources" "achieve[] in practice." A "source" means an actual boiler, not a hypothetical boiler that incorporates the optimal qualities of each boiler design and control technology. Indeed, evaluating what a hypothetical boiler achieves "in practice" is inherently contradictory. Because EPA's pollutant-by-pollutant approach would set the MACT floor at levels not actually achieved in practice, it is inconsistent with a straightforward reading of the statute. See *Chevron v. NRDC*, 467 U.S. 837 (1984).

EPA's critiques of U.S. Sugar's interpretation are not persuasive. EPA suggests that under U.S. Sugar's reading, there is a possibility the MACT floor could be satisfied by sources with "mediocre or no control." 76 Fed. Reg. at 15622. But Section 112(d)(3) requires the floor be based upon actual, in-practice achievement, not aspirational technologies. EPA has no legal basis for setting the MACT floor at a level not achieved in practice.

U.S. Sugar urges EPA to reconsider its pollutant-by-pollutant approach and to solicit comments on alternative means of identifying the best sources in each subcategory.

[Footnote]

(1) For the sake of simplicity, we will assume that section 112(d)(3)(A) applies. The analysis under section 112(d)(3)(B) is no different.

Commenter Affiliation: Florida Sugar Industry (FSI)

Document Control Number: EPA-HQ-OAR-2002-0058-3504-A1

Comment Excerpt Number: 29

Comment: The FSI still objects to EPA’s use of a pollutant-by-pollutant approach to setting emission limits. The FSI believes that this approach leads to emission limits that may not be achievable by any one boiler (i.e., would require a "super boiler"). FSI realizes that determining the top 12 percent of boilers for which EPA has emissions data is more difficult when based on overall emissions. However, EPA should ensure that all of the sources in the top 12 percent of a subcategory (i.e., all of the boilers used to establish the MACT floor) can comply with all of the emission limits in the final Boiler MACT Rule for that subcategory.

Commenter Name: James Johnson

Commenter Affiliation: United States Beet Sugar Association (USBSA)

Document Control Number: EPA-HQ-OAR-2002-0058-3508-A1

Comment Excerpt Number: 6

Comment: In the reconsideration of the major source Boiler Rule, EPA has reconsidered several of the MACT floor limits. However, EPA retained the HAP-by-HAP approach of regulating each HAP separately, without regard to the interplay between pollutants and pollution-control equipment that can lower efficiencies and make it more difficult to meet the prescribed standards. A HAP-by-HAP approach— using a pollutant-by-pollutant analysis that looks at the best performing sources for each HAP and sets the floor based on those sources— creates challenges for regulated entities looking at the overall pollutant levels of their facilities. Because a HAP-by-HAP approach looks at the pollutants piecemeal, it does not represent what an actual source can achieve over time. Setting the standard this way makes it exceedingly difficult for regulated entities working in good faith to improve efficiencies enough to meet the standards and doing so comes only at enormous cost. In addition, such an approach does not conform to section 112 of the CAA because this section of the Act speaks to regulating pollutants reflecting the performance of “sources,” not individual pollutants seen in the abstract. As the D.C. Circuit has found, “EPA may not deviate from section 7412(d)(3)’s requirement that floors reflect what the best performers actually achieve.” Therefore, when setting the MACT floor, EPA should use a rubric of the best controlled sources, not a HAP-by-HAP approach. The use of a HAP-by-HAP approach and the resulting stringent standards will cause significant hardship for sugarbeet processing facilities that are major sources because it is extremely

difficult to meet all the prescribed standards at the same boiler. The USBSA urges EPA to reconsider such an approach given its adverse economic impact on seasonal, agricultural industries such as sugarbeet processors.

Commenter Affiliation: American Chemistry Council (ACC)

Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1

Comment Excerpt Number: 74

Comment: The suite of limits should be achievable by at least 6 percent of existing boilers in each subcategory and the remaining boilers should be able to comply through their range of normal operating scenarios by applying known control equipment solutions. This expectation is not met for a broad range of units. Based on our review of the available data, less than 6 percent of units in the dry biomass stoker, biomass suspension burner, coal stoker, pulverized coal, and all liquid subcategories can comply with the entire suite of applicable limits. This indicates to us that EPA has not adequately addressed the variability of emissions from units in these subcategories.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: Alicia Meads

Commenter Affiliation: National Association of Manufacturers (NAM)

Document Control Number: EPA-HQ-OAR-2002-0058-3515-A1

Comment Excerpt Number: 16

Comment: The EPA ignored the record evidence of the performance of actual "sources" when establishing the suite of emissions limits. Instead, for each subcategory, the EPA set individual limits for each HAP that reflect the best performing source only for that individual HAP. The EPA then combined the HAP limits into a suite of emissions standards for each subcategory. This methodology results in a combined set of standards reflecting purely hypothetical boilers that have never actually been achieved by any single, real world source, and possibly never will. Creating hypothetical "best performing" units that demand compliance with emission standards

not achieved by any actual source in a subcategory (let alone the necessary 12% of sources for a true floor) is arbitrary and capricious and violates the EPA's statutory obligation to establish limits that are based on actual the performance of "sources."

The proposed MACT standards for industrial boilers and process heaters are based on pollutant-by-pollutant analyses that rely on a different set of best performing sources for each separate HAP standard. *See, e.g.*, 76 Fed. Reg. at 15,621-23. In other words, the EPA "cherry picked" the best data in setting each standard, without regard for the sources from which the data came. This approach violates the language of § 112, which is focused on the performance of "sources," and produces arbitrary and capricious standards.

The statute unambiguously directs the EPA to set standards based on the overall performance of "sources."⁸ Sections 112(d)(1), (2), and (3) specify that emissions standards must be established based on the performance of "sources" "in practice" for the category or subcategory and that the EPA's discretion in setting standards for such units is limited to distinguishing among classes, types, and sizes of sources. In particular, Section 112(d)(3) emphasizes that the EPA must focus on what emissions reductions are achievable "in practice" for a "source," using the word "source" no fewer than nine times.

These provisions make clear that standards must be based on actual sources, and cannot be the product of pollutant-by-pollutant parsing which results in a set of composite standards that do not necessarily reflect the overall performance of any actual source. Congress provided express limits on the EPA's authority to parse units and sources for purposes of setting standards under § 112 and that express authority *does not* allow the EPA to "distinguish" units and sources by individual pollutant as is proposed in this rule. *Sierra Club v. EPA*, 551 F.3d 1019, 1028 (D.C. Cir. 2008) (noting statutory limitations on EPA's authority to distinguish sources).

Further, the EPA has calculated its proposed MACT floors solely on the basis of emission data. The EPA utterly ignored the plain mandate of the Clean Air Act by entirely neglecting to determine whether there was emission control equipment in use in each subcategory that could actually achieve those inordinately strict emission limits, a critical and necessary analysis required by the Clean Air Act.

The EPA's focus on individual HAPs has resulted in a failure to recognize the critical interplay between emissions controls and emissions of other pollutants. For example, the NAM is concerned that the controls necessary to meet the stringent emissions limitations for CO will result in increased energy usage, with the concomitant increase in emissions of NO_x and other pollutants. Further, the EPA failed to account for this interrelationship in its economic analysis.

[Footnote 8: In the proposed CISWI rule, EPA similarly failed to follow the statutory mandate under Section 129 to examine the performance of "units." For the reasons discussed above, the CISWI standards must be based on actual sources ("units"), and cannot be the product of pollutant-by-pollutant parsing.]

Comment: We urge EPA to focus on emissions standards that can actually be achieved in practice by considering all relevant pollutant emissions together rather than adopting a pollutant-by-pollutant approach that ignores trade-offs between emission control technologies and produces standards that cannot currently be met by any biomass boilers. EPA establishes the MACT floor for each source category by calculating the numerical average of the emissions from the best performing (lowest emitting) 12 percent of sources. By adopting a pollutant-by-pollutant approach, EPA selects different sources as the best performing 12 percent for each pollutant and ignores the trade-offs that inevitably occur when some emissions are minimized at the expense of others. When all of the MACT standards are evaluated together, they do not reflect the actual emissions of the best performing sources.

Comment Excerpt Number: 4

Comment: The reconsidered emissions limits for each constituent (i.e., PM, HCl, mercury, CO and dioxin/furans) remain unreasonable and impractical⁵. EPA has proposed limits based on limited stack data for individual HAP's without considering combined HAP's associated with a specific emissions control technology for each subcategory. This approach is not practical and results in the most stringent Boiler MACT emissions standards. This approach potentially results in the most costly emissions control scenario and capital expenditures for boilers subject to these standards. As discussed above, this conservative approach is not justifiable since there is no documentation that industrial boiler HAPs result in any measurable air quality impacts. It is requested that the emissions standards be recalculated based upon combined HAPs emissions test results for each emission source category.

Commenter Name: Allison Watkins, Baker Botts
Commenter Affiliation: Class of '85 Regulatory Response Group
Document Control Number: EPA-HQ-OAR-2002-0058-3608-A1
Comment Excerpt Number: 14

Comment: EPA has established MACT standards in the Major Source Rule using a methodology that is inconsistent with the text of the CAA because it results in MACT standards that are not representative of the HAP emission limits being achieved by existing sources. The Class of '85 urges EPA to revise the standards so that they reflect the actual, overall performance of existing sources.³⁰

EPA developed the MACT floors based on the best performing sources for *each* pollutant, without regard to the overall performance of those units. EPA's attempts to justify its selection of this methodology are unpersuasive. EPA has argued that a "whole source" approach "'guts the standards' by including worse performers in the averaging process, whereas EPA's interpretation promotes the evident Congressional objective of having the floor reflect the average performance of best performing sources."³¹ EPA's reasoning ignores the plain language of the Act, which requires the Agency to set a MACT floor for existing sources that is based on "the average emission limitation achieved by the *best-performing* 12 percent of the *existing* sources."³² The use of the terms "best-performing" and "existing" clearly indicate that the sources used to set the MACT floor must be real, not theoretical or hypothetical, sources.³³ Indeed, § 112(d)(3) states that the MACT floor for new units shall not be less stringent than the emission control that is "*achieved in practice* by the best controlled similar source."³⁴ The phrase "achieved in practice" can only mean that Congress intended actual sources, performing under normal operating conditions, to be the benchmark for establishing the MACT floors.

The language of § 112(d) does not in any way suggest that MACT floors should be based on the best-performing sources for each individual HAP.³⁵ Instead, the focus is on the emission limits that the best performing existing sources can actually achieve for *all* pollutants collectively.³⁶ If Congress had intended for EPA to establish MACT floor levels by considering the achievable emission limits of individual HAPs, it could have worded § 112(d)(3) to refer to the best-performing sources "for each pollutant" or "for each group of pollutants."³⁷ It is clear from the plain text of the CAA that "EPA has a statutory duty to promulgate *achievable* standards."³⁸ Moreover, pollutant-by-pollutant MACT standards are inconsistent with the legislative history of § 112(d). As the Senate Report on the 1990 Amendments made clear, Congress required "the selection of emissions limitations which have been *achieved in practice* (rather than those which are merely theoretical) by sources of a similar type or character."³⁹ Congress' focus on overall performance in the 1990 CAA Amendments is consistent with its abandonment of individual pollutant standards and the adoption of the technology-based multipollutant approach for regulating toxics under the Clean Water Act.⁴⁰ Congress understood that if one source can achieve a high degree of control for one pollutant, but not for another, there is no justification for including it in the set of sources from which the floor is calculated.⁴¹ EPA's methodology for establishing the MACT standards is inconsistent with the text of the CAA. The Group urges EPA to revise its methodology to reflect the overall performance of existing units.

[Footnote 30: EPA's pollutant-by-pollutant methodology has been challenged in the D.C. Circuit but the court has not yet ruled on the issue of whether the methodology comports with the language of the CAA. *See, e.g., Medical Waste Institute and Energy Recovery Council v. Commenter Name: Randal G. Oswald

Commenter Affiliation: Integrys Energy Group

Document Control Number: EPA-HQ-OAR-2002-0058-3659-A2

Comment Excerpt Number: 13

Comment: EPA has established MACT standards in the Major Source Rule using a methodology that is inconsistent with the text of the CAA because it results in MACT standards that are not representative of the HAP emission limits being achieved by existing sources. Integrys urges EPA to revise the standards so that they reflect the actual, overall performance of existing sources.²⁶

EPA developed the MACT floors based on the best performing sources for *each* pollutant, without regard to the overall performance of those units. EPA's attempts to justify its selection of this methodology are unpersuasive. EPA has argued that a "whole source" approach "guts the standards" by including worse performers in the averaging process, whereas EPA's interpretation

promotes the evident Congressional objective of having the floor reflect the average performance of best performing sources."²⁷ EPA's reasoning ignores the plain language of the Act, which requires the Agency to set a MACT floor for existing sources that is based on "the average emission limitation achieved by the *best-performing* 12 percent of the *existing* sources."²⁸ The use of the terms "best-performing" and "existing" clearly indicate that the sources used to set the MACT floor must be real, not theoretical or hypothetical, sources.²⁹ Indeed, §112(d)(3) states that the MACT floor for new units shall not be less stringent than the emission control that is "*achieved in practice* by the best controlled similar source."³⁰ The phrase "achieved in practice" can only mean that Congress intended actual sources, performing under normal operating conditions, to be the benchmark for establishing the MACT floors.

The language of §112(d) does not in any way suggest that MACT floors should be based on the best-performing sources for each individual HAP.³¹ Instead, the focus is on the emission limits that the best performing existing sources can actually achieve for *all* pollutants collectively.³² If Congress had intended for EPA to establish MACT floor levels by considering the achievable emission limits of individual HAPs, it could have worded §112(d)(3) to refer to the best-performing sources "for each pollutant" or "for each group of pollutants."³³ It is clear from the plain text of the CAA that "EPA has a statutory duty to promulgate *achievable* standards."³⁴ Moreover, pollutant-by-pollutant MACT standards are inconsistent with the legislative history of §112(d). As the Senate Report on the 1990 Amendments made clear, Congress required "the selection of emissions limitations which have been *achieved in practice* (rather than those which are merely theoretical) by sources of a similar type or character."³⁵ Congress' focus on overall performance in the 1990 CAA Amendments is consistent with its abandonment of individual pollutant standards and the adoption of the technology-based multi-pollutant approach for regulating toxics under the Clean Water Act.³⁶ Congress understood that if one source can achieve a high degree of control for one pollutant, but not for another, there is no justification for including it in the set of sources from which the floor is calculated.³⁷

EPA's methodology for establishing the MACT standards is inconsistent with the text of the CAA. Integrys urges EPA to revise its methodology to reflect the overall performance of existing units.

Comment: MACT Floors Must Be Based on the Overall Performance of Actual Sources and Not on a Pollutant-by-Pollutant Basis

The proposed MACT standards rely on a pollutant-by-pollutant analysis that uses a different set of best-performing sources for each separate HAP standard. The result is a set of standards that reflect the hypothetical performance of a set of sources that simultaneously achieve the greatest emission reductions for each and every HAP without regard to whether such sources actually exist. This approach results in unachievable limits and is contrary to the language of section 112. The Clean Air Act unambiguously directs EPA to set standards based on the overall performance of *sources*. Sections 112(d)(1), (2), and (3) specify that emissions standards must be established based on the performance of "sources" in the category or subcategory and that EPA's discretion in setting standards for such units is limited to distinguishing among classes, types, and sizes of sources - it has no authority to distinguish sources by individual pollutant.³³ EPA's pollutant-by-pollutant approach results in a set of emission limits that do not reflect the performance of any existing "source." Although EPA has forecasted that some sources in the coal-fired subcategories can meet all of the emission limits, it is unlikely that these sources can meet all of the emission limits on a consistent basis. EPA's conclusion is based on the results of

reported stack test data that does not take into account the performance of the source over different operating loads, seasons, and fuel mixtures. In fact, vendors have confirmed that they will be unable to guarantee CO limits for coal -fired units at the levels in the Proposed Rule. EPA must revise its emission limits to reflect the performance of actual sources able to meet all emission limits simultaneously. Municipal utilities will benefit from the less stringent limits that reflect the true performance of actual sources as mandated by the Act.

Comment Excerpt Number: 6

Comment: EPA should revise its methodology in the calculation MACT floor for various pollutants and subcategories so that the limits can be consistently achieved by boilers that make up part of the floor. The proposed standards continue to be more stringent in some cases than needed to assure protection of health and the environment from industrial boiler HAP emissions and to fully meet EPA's obligations under the Clean Air Act.

103E. MACT Floor Methodology: 3x RDL [DENIED PETITIONER ISSUE]

Commenter Name: Mary Sullivan Douglas

Commenter Affiliation: National Association of Clean Air Agencies (NACAA)

Document Control Number: EPA-HQ-OAR-2002-0058-3525-A1

Comment Excerpt Number: 6

Comment: More than any other factor, EPA’s definition of “Best Performing Unit” leads to overestimates of performance of the best performing units. It creates a situation where units with high UPLs are designated as “best performing units” and displace better performing units in the “top 12 percent” category. EPA is obliged to base the existing source MACT floor on the performance of the “best performing units” and has offered no plausible explanation for its decision.

EPA has used two (or three) different methods for establishing the “performance” of the average of the best-performing 12 percent. In selecting the units to be included in the top 12 percent, EPA assumed that the performance of those units was demonstrated by the best test result.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

103H. MACT Floor Methodology: Exclusion of Co-Fired Data [DENIED PETITIONER ISSUE]

Commenter Name: Ahmed Idriss, Capital Power Corporation
Commenter Affiliation: CPI USA North Carolina (CPI NC)
Document Control Number: EPA-HQ-OAR-2002-0058-3524-A1
Comment Excerpt Number: 1

Comment: CPI NC does not support the EPA’s methodology for establishing emissions limits based limits for fuel on single fuel type facilities. In the Proposed Rule, EPA proposes to establish emissions at least 90% biomass in the case of PM and CO biomass categories, and 90% coal in the case of PM and CO coal categories. While this method may be appropriate for single fuel facilities, it does not reasonably consider maximum achievable control technologies for facilities utilizing multiple fuel types.

Capital Power recommends using fuel and fuel mixture variability for multi-fuel facilities in determining the top 12% of such facilities for the MACT floor. This approach is more reasonable because it captures each facility’s operational and fuel variability.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Commenter Name: Mary Sullivan Douglas
Commenter Affiliation: National Association of Clean Air Agencies (NACAA)
Document Control Number: EPA-HQ-OAR-2002-0058-3525-A1
Comment Excerpt Number: 34

Comment: In its most recent proposals EPA has employed a different approach to the determination of the emission limit to be applied. Whereas, in the 2011 rulemaking any test result where the source was combusting more than 10 percent coal was used in determining the MACT floor for the coal subcategories, in its most recent calculation of MACT floors EPA only used data from tests where the source was burning 90 percent or more coal during the test for existing sources and 100 percent coal for new sources. We believe that a 90-percent threshold is appropriate for the definition of this subcategory and appropriate for establishing a limit for “coal-fired” units, but see no reason to have a higher threshold for new units. Having done so, however, EPA needs to revise its definition of the subcategory to be consistent with its approach in setting standards. EPA may not exclude results from testing of clean sources within the subcategory. We recommend that fuel-based subcategory limits and subcategory definitions each be based on a minimum (e.g., 85-95 percent) usage of the fuel type and that EPA devise an approach for establishing emission limits for units that burn mixed fuels in lesser amounts.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Commenter Name: Steve Gossett

Document Control Number: EPA-HQ-OAR-2002-0058-3669-A2

Comment Excerpt Number: 16

Comment: Combination coal/biomass units should be defined as coal units so that they are subject to emission limits applicable to the combination of fuels they burn.

Discussion: If EPA responds to our comment request to separate coal boilers from biomass boilers to set PM, Hg, and HCl emission limits, a problem will surface concerning certain combination boilers specifically designed to burn varying percentages of coal, bark (biomass), and other solid fuel such as tire-derived fuel and old corrugated containers rejects. The current definition defines any such unit that burns greater than 10 percent biomass on an annual heat input basis as a "unit designed to burn biomass/bio-based solids". EPA did this so that these units would be subject to carbon monoxide limits derived from pure biomass units. Then, as EPA describes on page 15636 of the March 21, 2011 final rule preamble, they attempt to resolve the combination boiler dilemma by combining all solid fuel boilers into one subcategory for fuel based pollutants:

For combined fuel units that combust solid fuels, due to the many potential combinations and percentages of solid fuels that are or can be combusted, for the fuel-based pollutants, EPA selected the option of combining the subcategories for solid fuels into a single solid fuel subcategory. For the fuel-based pollutants, this alleviates the concerns regarding changes in fuel mixtures, promotion of combustion of dirtier fuels, and the implementation and compliance concerns.

We maintain that this change in subcategories, designed primarily to address combination units, is inappropriate for both combination units and pure coal-fired units. The reason is, as we have discussed above, that they are different types of boilers than biomass boilers and have very different emission profiles than biomass boilers due both to their design and the fuels they are designed to combust.

EPA should define any solid fuel boiler that burns at least 10 percent coal on an annual heat input basis as being in the "unit designed to burn coal/solid fuel subcategory". Because these combination boilers are specifically designed to burn a variety of materials (coal, bark, TDF, OCC rejects, etc.) that do have significant and varying chlorine and mercury contents, such classification is equitable for these units. This approach affords them the compliance options to either (1) shift to a cleaner relative mix of feeds (*e.g.* less coal and more bark or OCC rejects) or (2) install control technology to meet the emission standards. Just as with coal boilers, it would not be fair or appropriate to require these units to meet emission standards set by biomass boilers, some of the top performers of which have very low levels of mercury and chlorine in their feeds.

Alternative CO CEMS-Based Standards

4A. CO CEMS as Alternative Standard

Commenter Name: Paul Noe
Commenter Affiliation: American Forest & Paper Association (AF&PA) et al.
Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1
Comment Excerpt Number: 80

Comment: EPA originally developed a CO standard that boilers must meet at all times based on 3 run stack tests with no acknowledgment of the highly variable nature of CO emissions in solid fueled boilers. CO emissions from boilers can be highly variable, especially when fuel mix and load change. Facilities are typically required to conduct stack tests at least 90 percent of full load during normal operating conditions. A CO stack test is a small snapshot in time captured during the best operating conditions.

It stands to reason that the Boiler MACT standards should be "internally consistent," in that the test methods or measurement techniques used to gather the data used to set the standard should also be used to show compliance with the standard once it becomes applicable to affected facilities. If the test methods or measurement techniques are not consistent (or, at least, shown to be comparable), the compliance methods will not be a true or reasonable measure of compliance with the standard.

The CO standards included in the final Boiler MACT create this problem. The standards are based on short term stack tests that measured CO over a relatively short period of time during which operating conditions were stable, consistent, and optimal. However, many affected units already have CO CEMS for reasons unrelated to the Boiler MACT. These CEMS take data over long periods of time and, therefore, reflect variability in unit operations that was not measured in the stack tests on which the standards are based and was not factored into the test-based standards. Thus, these CO CEMS take data that are not compatible with the test-based standards and cannot reasonably be used to show compliance with these standards.

We appreciate that EPA has realized this problem and proposed to solve it by setting an alternative CO limit for units that choose to comply using CO CEMS. We note that EPA has broad authority in setting standards under § 112(d) to "distinguish among classes, types, and sizes of sources within a category or subcategory in establishing such standards." CAA § 112(d)(1). Industrial boilers with CO CEMS constitute a distinct and easily definable "class" or "type" of source, characterized by the existence of a CO CEMS and distinguished from other boilers by the abundance of CO data that they generate. Therefore, it is reasonable for EPA to set a separate standard for these sources that is compatible with the greater variability that these data reflect.⁴³

Response: The EPA thanks the commenter for their support of alternative CO CEMS-based limits.

Comment: EPA has made many changes throughout the rulemaking process to make the carbon monoxide (CO) emissions limits proposed more achievable for operators (see pages 80612 ff.). Nevertheless, there remains significant concern among industry that even these changes do not sufficiently allow for the extreme variability of carbon monoxide emissions and will need further modification. USW urges EPA to give full consideration to data submitted by industry sources that indicate need for the CO emissions limits to be further modified in order to allow them to be achievable by operators.

Response: EPA acknowledges the variability in CO emissions for the units subject to this rule. The proposed CEMS-based limits for each subcategory have been recalculated in the final rule based on the rolling average of longest duration allowed by the available data, up to a maximum of a 30-day rolling average. The proposed method of considering the maximum rolling average of the top 6 percent was also incorporated into the development of the CEMS-based limits in the final rule. EPA believes these steps properly account for the inherent variability in CO emissions and mitigate concerns over the achievability of CO standards.

EPA considered all data submitted prior to August 8, 2012 in its analyses for the final rule.

Comment Excerpt Number: 66, 67

Comment: *ACC Supports the Inclusion of Alternate CEMS Based Limits for CO*

EPA originally developed a CO standard that boilers must meet at all times based on 3 run stack tests with no acknowledgment of the highly variable nature of CO emissions in solid fueled boilers. CO emissions from boilers can be highly variable, especially with fuel mix and load

change. Facilities are typically required to conduct stack tests at least at 90 percent of full load during normal operating conditions. A CO stack test therefore is a small snapshot in time captured during the best operating conditions.

It stands to reason that the Boiler MACT standards should be "internally consistent," in that the test methods or measurement techniques used to gather the data used to set the standard should also be used to determine compliance with the standard. If the test methods or measurement techniques are not consistent (or, at least, shown to be comparable), the methods will not be a true or reasonable measure to determine compliance with the standard.

The CO standards included in the Final Boiler Rule present this problem. The standards are based on short-term stack tests that measured CO over a relatively short period of time during which operating conditions were stable, consistent, and optimal. However, many affected existing units already have CO CEMS for reasons unrelated to the rule. These CEMS collect data over long periods of time and, therefore, reflect variability in unit operations that was not measured in the stack tests on which the standards are based and was not factored into the test-based standards. Thus, these CO CEMS data are not compatible with the test-based standards and cannot reasonably be used to determine compliance with these standards.

ACC appreciates that EPA has acknowledged this problem and proposed to solve it by setting an alternative CO limit for units that choose to determine compliance using CO CEMS. ACC notes that EPA has broad authority in setting standards under § 112(d) to "distinguish among classes, types, and sizes of sources within a category or subcategory in establishing such standards." CAA § 112(d)(1). Industrial boilers with CO CEMS constitute a distinct and easily definable "class" or "type" of source, characterized by the existence of a CO CEMS and distinguished from other boilers by the abundance of CO data that they generate. Therefore, it is reasonable for EPA to set a separate standard based on CEMS data for these sources that is compatible with the greater variability that these data reflect.²⁵

Response: The EPA thanks the commenter for their support of alternative CO CEMS-based limits.

Commenter Name: Ahmed Idriss, Capital Power Corporation

Commenter Affiliation: CPI USA North Carolina (CPI NC)

Document Control Number: EPA-HQ-OAR-2002-0058-3524-A1

Comment Excerpt Number: 6

Comment: CPI NC supports the EPA's proposal to use CO CEMS, as further described in Table 2 of the Proposed Rule, as an alternative to CO stack testing and oxygen monitoring. Without such an alternative, CPI NC would be required to install costly monitoring equipment, which would not accurately monitor CO emissions. CPI NC notes that using O₂ CEMS to monitor and regulate emissions for stoker units is inappropriate, as the air flow distributions between under-grate and over-grate air can vary considerably based on unit load and impact the O₂ reading in flue gas. As mentioned by petitioners and EPA, in the Proposed Rule, an emission limit based on CO CEMS data from boilers would more accurately capture true variability in CO emissions over various operating conditions. This approach is a more rational approach for determining MACT floors for boilers and process heaters than a strict 99 UPL because it

contemplates whether top performers can actually meet the emissions limits based on their operating conditions.

Response: The EPA thanks the commenter for their support of alternative CO CEMS-based limits.

Commenter Name: Matthew Todd

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 56, 57

Comment: The CO CEMS best performers should be the basis for the CO emission limitations and compliance demonstrations should be allowed using either CO CEMS or stack testing.

Section 112 of the CAA requires that MACT emission limitations be based on the emissions reductions achieved by the best performing unit for new sources or the average emission limitation achieved by the best performing 12% of existing sources in a source category or subcategory. For CO, EPA proposes two different limits based on data from two separate sets of BPH. EPA reports it derived the CO limit for CEMS using data from sources that are not “best performers”¹⁶. EPA has flexibility in how it establishes the best performers and they can use information collected using different methodologies (e.g., stack tests and CEMS). With adequate CEMS data (reflecting operating variability) EPA could, and in this case should, conclude that such data is more representative of “achievable emissions” than is stack test data for CO for some subcategories and thus use the CEMS CO data to develop the numerical emission limit¹⁷. Using the CO CEMS basis for setting the emission limitation would allow EPA to account for the high CO levels that can occur during operating transitions, turndown operations, startups etc. in establishing CO limits that apply at all times. Compliance could then be demonstrated with a CEMS or by stack test.

Best performing units have historically been characterized based on stack tests, because those tests are done near or at design conditions and thus represent the operation at maximum potential emissions and are often the only data available. Averaging time and variability adjustments are then used to correct the stack test derived emission limitation for the vagaries of real operations, where combustion efficiencies are not as ideal as during stack test conditions. CEMS data, on the other hand, can reflect all the operating variability that can occur, but may not represent the emissions potential at maximum conditions as well as stack testing does. For CO, where operating conditions are a much more important variable than is firing rate, CEMS data is probably a much better indicator of variability and achievability than is stack test data and thus is likely to be a much better basis for selecting the best performers, where adequate data is available.

In this specific case, there appears to be no relationship between the CEMS data used to develop the proposed CO CEMS alternative and the stack test based emission limitations listed in Tables 1 and 2 of the proposal for CO, since they represent different units and different operations. This is clearly indicated by the fact that the relationship between the two emission limitations have no pattern (i.e., the CO CEMS limit is higher than the stack test limit in some cases, lower in others

and the ratios of the two limits vary widely), as shown in the following Table. [See submittal for Table 2 Comparison of CO limits]The randomness of the relationship between the two proposed CO limits makes clear that they do not represent related datasets.

On pages 80612-3 of the preamble, EPA explains “To evaluate whether our selection of the units identified as best performers for CO CEMS data correlates to the units identified as best performers for stack test data, we compared the CEMS data and the computed stack test CO MACT floor for each subcategory. Each unit identified as a best performing unit in the CO CEMS analysis had at least one 3-hour CEMS average at or below the corresponding stack test CO MACT floor for the subcategory, which suggests that the units identified as best performers based on the CEMS data are comparable to the units identified as best performers based on the stack test data.” We do not understand why one three-hour CEMS CO value below the stack test limit would be an indicator that these two sets of data are comparable. Compliance is required at all times not for one three-hour period. Thus, we would expect that a CO CEMS should always measure a value below the stack test based limit, if both limits are reflective of “best performers.” In fact, we would suggest that the lack of agreement for most 3-hour periods indicates that the stack test numerical emission limits do not reflect the “best performers” in the subcategory when variability is correctly reflected (i.e., achievability is considered as required by the CAA). Clearly, the stack test based CO limits do not accurately represent the performance of the best performers over time and are not achievable by the best performing sources as required by section 112(d) of the CAA.

In the dual standard approach of the proposal, we would expect some regulators to require that every occurrence of a higher CEM reading than the stack test limit (the primary CO limit in this proposal) be treated as credible evidence of a deviation, reportable under both the applicable MACT rule and Title V. Thus, we expect establishing two alternative CO limits, as is proposed, will cause untold confusion, regulatory burdens, erroneous deviations, and violation notices.

Under other MACT rules, the emission limits are derived from one set of emission sources (the best performers) almost always based on stack test information corrected for operating variability. A choice of methodologies is then provided for demonstrating compliance. Those compliance methodologies typically include use of a CEMS, where such monitors are available and proven. However, the CEMS is used to show compliance with the emission limit derived for the best performers just as other methodologies (e.g., periodic stack tests, parameter monitoring) do. We believe a similar approach should be used here, but with the CO emission limit established based on best performers being selected based on the CEMS data, where it is adequate, or adjusted for variability with consideration of the variability shown by the CEMS data, where the CEMS data is inadequate for establishing the best performers.

Response: In the March 2011 final rule, the EPA promulgated CO MACT emission limits, as a surrogate for non-D/F organic HAP emissions, based on CO stack test data and MACT floor analyses, as well as compliance provisions requiring annual performance testing, an oxygen content operating limit, and continuous oxygen monitoring. The EPA received petitions for reconsideration requesting, among other things, a rule revision to allow units with CO CEMS to use them to demonstrate compliance in lieu of performance testing and oxygen monitoring. Petitioners requested that EPA develop an alternative form of the CO emission limit, based on the use of CO CEMS and a longer averaging period such as a 30-day rolling average. As suggested by petitioners, the EPA proposed alternative CO emission limits based on CO CEMS

data, where sufficient data were available, based on 10-day or 30-day rolling averages, and solicited additional CO emissions data. The alternative CO CEMS-based limits were based on data that excluded periods of startup and shutdown. For more information on the alternative CO CEMS-based limits and periods of startup and shutdown, see the response to comment EPA-HQ-OAR-2002-0058-3521-A1, excerpt 84. This excerpt may be found in the CO CEMS “Averaging Time and Rolling Average Length” section of this comment response document.

The commenters concede that “EPA has flexibility in how it establishes the best performers” and “can use information collected using different methodologies (e.g., stack tests and CEMS)” but argue that EPA should finalize only one set of CO emission limits, based on CO CEMS data unless such data is lacking, and remove the stack test-based CO limits as an option in the rule. The EPA has considered the commenters’ arguments and reaffirms its position that the alternative CO CEMS-based limits are well-supported based on the information available to the EPA, and the commenters have not identified a persuasive reason to eliminate the ability of sources to comply with either the CO stack test-based limits or the alternative CO CEMS-based limits. In these comments, the commenters assert that a comparison between the CO CEMS data and stack test-based limits (or alternatively the CO CEMS-based limits and the stack test-based limits) show that there is no “pattern” or “relationship” between the two. The commenters fail to recognize that the EPA typically has a limited amount of information when developing MACT standards, and the EPA may rely on the information it has available to develop reasonable estimates of the emissions of best performing sources. As discussed in the preamble to the proposed rule (see memorandum titled “CO CEMS MACT Floor Analysis (November 2011) for the Industrial, Commercial, and Institutional Boilers and Process Heaters National Emission Standards for Hazardous Air Pollutants – Major Source” in the docket), the EPA has very limited CO CEMS data, often for only one or two units, in each of the subcategories for which we are setting alternative CO CEMS-based limits (and we are not setting alternative standards for several subcategories in which we do have sufficient CEMS data). Although we solicited additional CO CEMS data in the December 2011 notice of proposed rulemaking, we only received CO CEMS data for five subcategories. Accordingly, there is still very little overlap in the stack test and CEMS datasets, and it is unsurprising that the two different datasets, largely from different units, resulted in MACT floor analyses that are composed of different units within each subcategory and MACT emission limits that do not bear a direct correlation to each other, also considering that they were evaluated based on different averaging periods.

The commenters asked EPA to determine that the CEMS dataset is better suited for setting MACT standards than the stack test dataset such that the CEMS data, where available, should be the sole basis for CO standards. The EPA disagrees and believes that each dataset may be used to set technically sound and legally justified MACT standards. We note there are advantages and disadvantages to using either dataset. The stack test data are much more abundant, accounting for significantly more units and facilities in each subcategory. The CEMS data include more operating conditions than those during performance tests, as discussed in the memorandum titled, “CO CEMS MACT Floor Analysis (August 2012) for the Industrial, Commercial, and Institutional Boilers and Process Heaters National Emission Standards for Hazardous Air Pollutants – Major Source” in the docket. The CEMS-based limits differ from the stack test-based limits in that the CEMS-based limits have 10 or 30 day averaging periods. The EPA sees no inconsistency in applying its MACT methodology to the two datasets, where data are available, resulting in one set of standards based on stack test data and a second set of alternative

standards, with 10 or 30 day averaging periods, based on CEMS data. Each set of standards is based on relevant information available to EPA and complies with the statutory requirements for establishing MACT standards. Indeed, the commenters' contentions could lead to the opposite conclusion that the more abundant stack test data are better suited for setting MACT standards than the CEMS data, as suggested by comments from the Wisconsin DNR, addressed elsewhere in this document.

In addition, setting 10-day and 30-day CO emission limits based on CEMS data, without providing a short-term stack test-based limit as an option, would not make sense unless EPA were to mandate CO CEMS for every unit, which we expressly are not doing. Specifically, if a unit lacking a CO CEMS were required to comply with a 10-day or 30-day CO limit, there would be no basis to determine continuous compliance. Although the commenters say that compliance with a CEMS-based limit could be demonstrated by a CEMS "or by a stack test", they do not explain how the latter would be possible. For example, a stack test could not be run for the duration of a 10-day or 30-day averaging period, and if a source attempted to use a stack test in conjunction with continuous oxygen monitoring in lieu of a CO CEMS, the oxygen content operating limit would need to be based on the lowest oxygen content recorded while complying with the CO limit for a full averaging period, which again would necessitate a CO CEMS at least for purposes of setting the oxygen content operating limit. Accordingly, mandating compliance with the 10 and 30 day CO CEMS-based limits, instead of the stack test-based limits, without also mandating use of CO CEMS for every unit, would not be functional.

We also note that this final rule allows the commenters to comply in the manner they advocate, i.e., with a CO CEMS-based limit using a CO CEMS for compliance purposes.

The EPA disagrees that the presence of stack test-based and CEMS-based CO limits may cause confusion, regulatory burdens, deviations, and violation notices. EPA believes that the final rule clearly indicates the compliance approaches available to sources, and the flexibility in choosing the method of compliance allows sources significant flexibility and the ability to plan for such situations.

The EPA has requested and received information from the ICR process based on two different sets of data. We agree with the commenter that these data sets are not overlapping, but rather form two distinct and different sets of data from which to evaluate source emissions. As such, the final rule provides two different paths for source operators to achieve compliance; either using a certified CO CEMS or by conducting annual emissions testing and using an O₂ CEMS or O₂ trim system as a parametric monitor. The final rule also provides that sources with certified CO CEMS must comply with the ten or 30 day rolling average standard, depending on the particular subcategory, while sources without a certified CO CEMS must demonstrate compliance through an annual stack test and O₂ parametric monitoring. We do not intend that the stack test-based limits would apply to a unit using a certified CO CEMS, nor do we intend that the alternative CO CEMS-based limits would apply to a unit without a certified CO CEMS, relying instead on an annual stack test and O₂ monitoring.

Comment Excerpt Number: 5, 6, 18, 19, 20, 21

Comment: EPA can allow sources to use the CO/O₂ CMS trim system as a parametric monitoring alternative in place of meeting a continuous CO CEMS emission limitation. Under this approach the source periodically (biennial suggested) demonstrates compliance with the primary stack test based emission limit. A correlation is determined of stack test CO to the CO measured using the CO/O₂ CMS system over normal load ranges. The CMS CO concentration then becomes the value to be monitored on a continuous basis. EPA proposed this same type of approach using a PM CMS in place of a PM CEMs for continuous compliance. The parametric CO correlation can also show a source is in compliance with the stack test emission limit at full load but can also show that a source operating under good combustion at lower loads may emit at higher CO levels. We also propose that a source with a CO/O₂ CMS trim system be allowed to determine an alternative CO emission limitation at full load, if appropriate.

EPA is proposing to allow demonstrating compliance with carbon monoxide (CO) emission limitations by using a CO CEMs system. EPA is also proposing that a separate emission limit be established for the CEMs based compliance demonstration in place of the CO limit established based on stack test results.

The Department supports allowing the use of a CO CEMs system for demonstrating compliance. However, the Department believes that EPA should not establish a separate CO emission limitation for this compliance demonstration. A source using a CO CEMs should be allowed to demonstrate compliance with either the primary stack test based CO emission limitation or establish a correlation of CO emissions and good combustion for that source. Further, the source should be able to use a CO continuous monitoring system (CMS) in conjunction with stack testing every two years. Such a source would also establish a correlation between CO CMS data and good combustion or the CO CMS data and the stack emission limit.

First this discussion is premised on the fact that no sources included in the CO stack test or CEMs based floors have a catalyst system for controlling CO emissions; i.e. all CO emission limitations are based on good combustion. EPA has further defined through discussions of this and previous MACT notices that good combustion is the basis for reducing organic toxics including dioxins and furans. EPA has simply determined that CO is an appropriate surrogate for good combustion. Therefore, good combustion is the basis for all organic toxics requirements.

The Department feels establishing a carbon monoxide (CO) CEMs based emission limitation from limited data or data from sources different from the identified 12% best performing sources is problematic.

EPA should not establish a separate CO CEMs emission limitation for compliance on a continual basis. From a methodology point of view EPA does not have CEMs data for all sources identified as the best performers based on a stack test. Instead EPA is using CEMs data from available sources. As a result EPA is identifying two different groups of best performers based on stack test data and CEMs data. EPA simply should not follow an approach where there is not an identified single set of best performers. Two different pools of best performers means that EPA is not correctly identifying the pool of best performers or is incorrectly assuming that best performers can be identified. This latter point will be discussed in more detail. Further it is not

likely, without requiring further testing, that EPA will receive sufficient CEMs data from the pool of best performing sources identified by stack test data to develop a CEMs based emission limit for the same set of sources in a statistically sound manner.

EPA's analysis demonstrates that it is problematic to establish continuous CO emission limitations which apply to all sources even at the sub-category level. In looking at the proposed CO CEMs limits there are multiple categories where they are both more and less stringent than the stack test CO limit. One reason for this is because the CEMs data is based on normal operating levels versus the full operating level required under the stack test requirement. This shows that the stack test value does not represent good combustion at different operating levels for the source category. We believe that further evaluation of CEMs data available for sources currently identified as best performers will show that CO levels at good combustion will vary with load at the same source. This assertion is based on the Department's experience that sources with CO CEMs or CMS systems will use that data to operate as efficiently as possible. At a minimum, the difference between CO CEMs and stack test based limits shows that CO levels representing good combustion can vary significantly between sources. From this information and its past experience the Department concludes that a single CO value should not be set to represent good combustion at one source or between sources.

In lieu of setting a CO CEMs emission limitation the Department believes that a better approach is to retain the stack test emission limitation and allow continuous compliance with a CO CMS or parametric monitoring system. EPA recognized the value of CMS systems versus CEMs systems in proposing the PM CMS approach. EPA also recognized the value of a CMS system for continuous best operation of a source in proposing oxygen trim systems in place of only monitoring oxygen for continuous parametric monitoring requirements.

Under this CO CMS approach a source would establish a correlation during the initial stack testing between the CO emission limitation, CO CMS concentrations and good combustion of the unit at different normal load levels. This approach acknowledges that a source may operate at higher CO levels in achieving good combustion at lower loads. But that good combustion is being achieved at all times. This is corroborated for the source by meeting the CO emission limit at full load. Under this approach the operator should also be able to establish an alternative CO emission limitation at full load based on good combustion for specific fuel types. Such an alternative would have to be approved by the delegated authority. Finally, when using a CO CMS approach a source should not have to perform stack testing more frequently than every two years.

Response: For a response to concerns over variability in CO emissions, see response to comment EPA-HQ-OAR-2002-0058-3498-A1, excerpt 5.

For a response to comments regarding top performers differing between the stack test-based limits and CO CEMS-based limits, please see response to comment EPA-HQ-OAR-2002-0058-3677-A2, excerpts 56 and 57.

The EPA requested CO CEMS data from all sources during the initial ICR and made subsequent requests to source operators for data during reconsideration. All data that were received were factored into the analysis of the CO CEMS-based emission limits. However, only limited CO CEMS data were received.

Work practice standards have been established for the control of dioxin and furan emissions. The EPA disagrees with the commenter that CO is treated as a surrogate for good combustion; CO is selected as a surrogate for organic HAP. The commenter's suggestion to use continuous parameter monitoring to show "good combustion" even if exceeding applicable limits would be unjustified where, as here, viable emission measurement and monitoring approaches such as oxygen monitoring and, alternatively, CO CEMS are available.

The EPA agrees with the commenter that, where available, CO CEMS data can provide a better measure of emissions variability than a stack test value.

In the final rule, all units subject to a CO emission limitation must install, operate, and maintain either a CO CEMS or oxygen analyzer system. Oxygen trim systems are an acceptable oxygen analyzer system. Units which employ an oxygen trim system or other type of oxygen analyzer system are subject to operating limits and an annual performance test. Annual performance tests were selected instead of biennial performance tests because of the potential in this source category for operating conditions and the associated emissions to vary over time.

For units with a certified CO CEMS, the final rule requires the use of the CO CEMS to demonstrate compliance with the alternative CO CEMS-based limits. A certified CO CEMS is a CEMS that meets the Performance Specifications outlined in §63.7525 of the final rule. If a CO CEMS is not certified, the source cannot use the CO CEMS to demonstrate compliance and must instead perform annual performance testing and continuous oxygen monitoring to demonstrate compliance with the applicable stack test-based CO limit. A non-certified CEMS cannot be used to demonstrate compliance with a CEMS-based limit because it does not produce an accurate enough measurement. Sources may use the time until the compliance date specified in §63.7495 to establish certification of a pre-existing CO CEMS. CO CEMS may not be used to demonstrate compliance with a stack test-based limit due to the operational load requirements during performance testing.

Comment Excerpt Number: 12

Comment: The Proposed Boiler MACT Rule appears to allow the use of either an oxygen analyzer system (O₂ monitoring system) or a CO CEMS. See Section 63.7525(a); 76 F.R. 80636. During the reconsideration process, EPA should clarify that units that already have an installed CO CEMS may elect to use an O₂ monitoring and trim system, instead of the CO CEMS, as their compliance method. This option is appropriate because the location of the CO CEMS, the physical or operational limitations of the CO CEMS, and other factors affecting data quality assurance with the CO CEMS may not conform to the requirements in the Boiler MACT Rule. (See further discussion in paragraph 9, below, regarding "CEMS-Based CO Limits").

Response: See the response to comment EPA-HQ-OAR-2002-0058-3527-A1 and A2, excerpts 5, 6, 18, 19, 20, and 21.

Comment: OCC supports the proposed increased flexibility in the compliance monitoring requirements. In particular, where numerical limits must be measured, we support EPA's option to allow either continuous monitoring equipment or stack testing procedures. For example, this includes the proposed carbon monoxide (CO) limits that are based on either stack testing or continuous monitoring. This monitoring flexibility also includes the use of oxygen measuring systems in lieu of continuous CO monitoring systems. We support this as it will certainly lower the economic burden to the affected facilities. However, the option to use a CO CEMS instead of conducting stack sampling and using an oxygen monitor is also available.

Response: The EPA thanks the commenter for their support.

Comment: The EPA has received additional data from stakeholders and incorporated all of the data into the boiler MACT database. The new data included additional Hg test runs, PM test runs, dioxin/furan test runs, carbon monoxide (CO) test runs, HCI test runs, TSM test runs, and CO CEMS data. They also received several corrections to the project database and performed additional quality assurance activities on the best performers. The EPA's review of this data resulted in multiple changes to emission limits and the establishment of alternate CO CEMS based emission limits and monitoring for most subcategories.

The DEP commends the EPA on collecting and processing of additional data in order to establish more achievable emission limits and alternate CO CEMS emission limits.

Response: The EPA thanks the commenter for their support.

Comment: Increased Flexibility Needed for CO Compliance Monitoring

The VI supports EPA's revisions to the monitoring requirements for carbon monoxide (CO) for major source boilers. As an alternative to CO stack testing and oxygen monitoring, EPA proposed the use of a CO continuous emissions monitoring system (CEMS). EPA calculated a CO CEMS-based MACT floor for many subcategories based on data submitted by affected sources that currently use CO CEMS. This revision will lower the economic burden on affected facilities by providing flexibility in emissions monitoring and avoids duplicative requirements for those facilities currently using CO CEMS.

Response: The EPA thanks the commenter for their support.

Comment Excerpt Number: 1

Comment: EPA has proposed an alternative longer term averaging time emission limit for carbon monoxide when using CEMS. For biomass boilers this is a 10-day rolling average alternative to the manual 3-hour test. We support this alternative. We believe EPA should clarify that when a boiler is already equipped with a CO CEMS, the CO standard is complied with by meeting either the annual 3-hour manual test or the 10-day CEM standard. In other words, the facility is not required to meet both. Our request is based on our experience with State regulators who we suspect will reason that if a unit is already CO CEMS equipped, as many are per Title V permit requirements, then it should be required to meet the CEMS based CO limit. Conversely, a CO CEMS-equipped boiler may be required to conduct manual CO stack tests to meet permit requirements unrelated to MACT and that a boiler should not have to meet the short term limit if it chooses to meet the CEMS-based MACT standard. To prevent confusion and

misinterpretation, EPA should specify in the final rule that 1) if a unit is CEMS-equipped to comply with non-MACT requirements it can still choose to meet the short term CO limit using manual testing, and 2) if a source chooses to comply with the CO CEMS-based standard, it is not subject to the stack test-based CO standard-even if it conducts CO stack tests for other purposes.

Response: The EPA thanks the commenter for their support of CO CEMS-based alternative standards.

For a response to the comments regarding CO compliance options, see responses to comments EPA-HQ-OAR-2002-0058-3527-A1 and A2, excerpts 5, 6, 18, 19, 20, and 21 and EPA-HQ-OAR-2002-0058-3677-A2, excerpt 56.

Comment: ACA generally supports the following proposed changes in the Boiler MACT rule:

EPA's proposed alternative compliance option for facilities that wish to use CO CEMS instead of CO stack testing and oxygen monitoring, so long as EPA clarifies that a source is not subject to the stack test-based CO standard if it chooses to comply with alternative CEMS-based limits

Response: The EPA thanks the commenter for their support of CO CEMS-based alternative standards. For a response to the request for clarification that units are not subject to the stack test-based limits if they opt to demonstrate compliance with CEMS-based limits, please see responses to comments EPA-HQ-OAR-2002-0058-3527-A1 and A2, excerpts 5, 6, 18, 19, 20, and 21 and EPA-HQ-OAR-2002-0058-3677-A2, excerpts 56 and 57.

Comment: It is possible that a CO CEMS-equipped boiler may be required to conduct CO stack tests for reasons unrelated to this rule(e.g., the unit may have a PSD permit or state construction permit that requires such testing). To prevent confusion, EPA should clearly specify in the reconsidered final rule that, if an affected source chooses to comply with the CO CEMS-based standard, it is not subject to the stack test-based CO standard – even if it conducts CO stack tests for other regulatory purposes. Conversely, EPA should also clarify that even if a unit has CO CEMS installed, it may choose to comply with the stack test-based CO limit, and in this case, CO CEMS data are not to be used to demonstrate compliance.

Response: See the response to comments EPA-HQ-OAR-2002-0058-3527-A1 and A2, excerpts 5, 6, 18, 19, 20, and 21 and EPA-HQ-OAR-2002-0058-3677-A2, excerpts 56 and 57.

Comment Excerpt Number: 34, 35, 36

Comment: For coal-fired fluidized bed combustors (FBCs), pulverized coal (PC) and stoker units, EPA proposed 10-day rolling average (RA) limits of 59, 28 and 34 ppm @3% O₂, respectively. These limits were derived by calculating a 99.0% upper predictive limit (UPL) for daily averages corresponding to 1 coal FBC (IARoquetteAmerica), 1 coal PC (VAsmurfitStoneWestpt) and 1 coal stoker unit (WVDuPontWashingtonWorks). EPA also estimated an alternate limit which was based on the maximum 10-day rolling average for the duration of the available data. These limits were estimated at 78, 35 and 34 ppm @3% O₂ for the FBC, PC and stoker categories, respectively. Only the WVDuPontWashingtonWorks stoker unit was in the stack test-based MACT floor for its category. The VAsmurfitStoneWestpt PC unit was ranked No. 7 in the stack test-based MACT floor list with the top 5 making the floor. The IARoquetteAmerica FBC unit did not figure in the top 16 FBCs listed by EPA in relation to the stack test-based MACT floor. Only 52 daily averages were used to derive the limit for FBCs, 60 daily averages were used to derive the limit for PCs, and 31 daily averages were used to derive the limit for stokers. Clearly, these limits were derived based on very little data.

As discussed in more detail elsewhere in these comments, for units that already have CO CEMS for reasons unrelated to the IB MACT, compliance with the IB MACT stack-test-based CO emissions limitations would be difficult to maintain. Stack tests are required to be run under representative operating conditions, which typically is defined as operating at or near full load consistently for the duration of the stack test. In sharp contrast, CEMS take emissions data on a near-continuous basis, which means CEMS emissions measurements reflect significant variability in emissions (for example, due to load swings and low load conditions) that was not measured during the stack tests used to set the CO standard. This problem is not overcome by statistical manipulation of the CO standard, such as accounting for variability using the UPL method, because such statistical methods unrealistically extrapolate only from the variability measured during stack tests and the variability between stack tests. In other words, this is a classic "apples and oranges" situation where emissions data from CO CEMS are incompatible with emissions data from stack tests used to set the CO standard.

One way for EPA to resolve this incompatibility is to determine that emissions data from CO CEMS are not credible evidence for purposes of assessing compliance with the IB MACT stack-test-based CO emissions limitations. As the Agency explained in the "credible evidence rule," data and information derived from methods other than the specified reference test method (so-called "non-reference test data") are relevant to showing compliance only to the degree that "the appropriate reference test would have shown a violation." 62 Fed. Reg. 8314, 8323 (Feb. 24, 1997). Because the IB MACT CO standards are based on stack test data, and because the stack tests on which the standards are based were required to be conducted during representative operating conditions (*i.e.*, consistently operating at or near full load), then by definition CO CEMS data taken during periods of operation that do not reflect "representative operating conditions" are not data that are relevant to showing compliance with the standards.

In other words, the stack test data on which the standards are based reflect operation during a narrow, limited, and optimum set of conditions. Thus, CO CEMS data that are taken during periods of operation that do not reflect those conditions are not relevant to determining whether an affected source is in compliance with the standard.

Response: The final rule does not exempt certified CO CEMS data from the credible evidence rule. For clarification regarding CO compliance options, see responses to comments EPA-HQ-OAR-2002-0058-3527-A1 and A2, excerpts 5, 6, 18, 19, 20, and 21 and EPA-HQ-OAR-2002-0058-3677-A2, excerpts 56 and 57.

Comment Excerpt Number: 17, 18

Comment: EPA should revise certain continuous monitoring and reporting requirements that are infeasible and problematic.

EPA should determine that data from CO CEMS shall not be used to show compliance with stack test-based CO emissions limitations.

As discussed in the previous section, for units that already have CO CEMS for reasons unrelated to the Industrial Boiler MACT, compliance with the Industrial Boiler MACT stack-test-based CO emissions limitations would be difficult to maintain. Boise has two such units at its paper mills that will be required to demonstrate continuous compliance with the CO CEMS emission limit. Stack tests are required to be run under representative operating conditions, typically defined as operating at or near full load consistently for the duration of the stack test. In sharp contrast, CEMS take emissions data on a near-continuous basis, which means CEMS emissions measurements reflect significant variability in emissions (for example, due to load swings and low load conditions) that was not measured during the stack tests used to set the CO standard.

This problem is not overcome by statistical manipulation of the CO standard, such as accounting for variability using the UPL method, because such statistical methods unrealistically extrapolate only from the variability measured during stack tests and the variability between stack tests. In other words, this is a classic "apples and oranges" situation where emissions data from CO CEMS are incompatible with emissions data from stack tests used to set the CO standard.

One way for EPA to resolve this incompatibility is to determine that emissions data from CO CEMS are not credible evidence for purposes of assessing compliance with the Industrial Boiler MACT stack-test-based CO emissions limitations. As the Agency explained in the "credible evidence rule," data and information derived from methods other than the specified reference test method (so-called "non-reference test data") are relevant to showing compliance only to the degree that "the appropriate reference test would have shown a violation." 62 Fed. Reg. 8314, 8323 (Feb. 24, 1997). Because the Industrial Boiler MACT CO standards are based on stack test data, and because the stack tests on which the standards are based were required to be conducted during representative operating conditions {i.e., consistently operating at or near full load}, then by definition CO CEMS data taken during periods of operation that do not reflect "representative operating conditions" are not data that are relevant to showing compliance with the standards.

In other words, the stack test data on which the standards are based reflect operation during a narrow, limited, and optimum set of conditions. Thus, CO CEMS data that are taken during periods of operation that do not reflect those conditions are not relevant to determining whether an affected source is in compliance with the standard.

Comment: We strongly support: A longer averaging time for CO for boilers already equipped and required to operate CEMs, with adjusted emission levels to reflect the variability we see when operating CEMs compared to short term stack tests.

Response: The EPA thanks the commenter for their support.

4B. Statistical Analysis

Commenter Name: Chris M. Hobson

Commenter Affiliation: Southern Company

Document Control Number: EPA-HQ-OAR-2002-0058-3520-A1

Comment Excerpt Number: 14

Comment: EPA should not determine the final CO CEMS MACT floor based on each unit's minimum 10-day rolling average. This does not fully account for variability. In fact, EPA acknowledges that even the best 6% of units that established the CO CEMS MACT floor did not meet the calculated limit up to 25% of the time. EPA, however, did not propose a remedy.

Response: EPA has revised the methodology used to calculate the CO CEMS-based limits for the final rule. First, we calculated the 99% UPL on the rolling averages of the top 12 percent. Second, the maximum rolling average of the top 6 percent was compared to the calculated UPL. EPA believes the revised methodology fully accounts for the variability in the reported CEMS data sets. Further detail on the revised methodology can be found in the memo titled, "CO CEMS MACT Floor Analysis (August 2012) for the Industrial, Commercial, and Institutional Boilers and Process Heaters NESHAP" in the docket.

Commenter Name: Randall D. Quintrell

Commenter Affiliation: Georgia Paper & Forest Products Association

Document Control Number: EPA-HQ-OAR-2002-0058-3451-A1

Comment Excerpt Number: 9

Comment: The proposed CO limits for those units with continuous monitors (e.g., monitors which have been required for other reasons) do not adequately cover the normal range of boiler operations, and as such cannot be met continuously by even those floor units used to establish

these limits. As noted above, in the final rule, EPA should make changes so that the 99.9% UPL is used.

Response: For the reasons detailed in the preamble to the December 23, 2011 proposed reconsideration of the rule, EPA has chosen to retain a 99% UPL for the final rule. The EPA has revised the methodology for CO CEMS-based emission limits by adjusting the UPL equation to better represent the compliance condition, extending the averaging time to 30 days when data was available to make this extension, incorporating new data submissions provided by the commenters, and by incorporating the alternative CO emission limit methodology, which compares the 99% UPL with the maximum CO value from the top 6 percent of units. Please see the memo titled, "CO CEMS MACT Floor Analysis (August 2012) for the Industrial, Commercial, and Institutional Boilers and Process Heaters NESHAP" in the docket for details on these changes. The EPA has evaluated the revised emission limits and determined that these changes appropriately reflect the variability of emissions from best performers based on the data available to the EPA.

Document Control Number: EPA-HQ-OAR-2002-0058-3686-A2

Comment Excerpt Number: 16

Comment: Separate comments being submitted by AF&PA and NCASI discuss changes that are needed to the methodology being used to set the CO GEMS-based limits to ensure these limits are achievable. Boise fully endorses the approaches mentioned in the NCASI and AF&PA comments that develop the supporting rationale for use of the 99.9 UPL for establishing the final CO limits for the Boiler MACT rule. Because of the many various boiler designs and differences in solid fuel characteristics, EPA should recalculate the MACT floor and make appropriate adjustments to floor calculations in order to make CO emission limits achievable at all representative conditions.

Response: For a response to the request that a 99.9% UPL be used to establish CO CEMS-based limits, please see response to comment EPA-HQ-OAR-2002-0058-3451-A1, excerpt 9. For a response to the request that CO CEMS-based limits be recalculated with revised methodology, please see response to comment EPA-HQ-OAR-2002-0058-3520-A1, excerpt 14.

Comment Excerpt Number: 11

Comment: CraftMaster supports the concept discussed in the CO GEM's MACT memo that fuels fired by sources in the MACT Floor should not be process specific but representative of the entire source category. This concept should be applied to each MACT Floor determination especially where there are a limited number of units in the MACT Floor.

Response: The EPA thanks the commenter for their support of MACT floors not being calculated from the combustion of process-specific fuels. The EPA has applied this methodology to all MACT floor calculations for the rule.

4C. Averaging Time and Rolling Average Length

Commenter Name: Traylor Champion

Commenter Affiliation: Georgia-Pacific LLC (GP)

Document Control Number: EPA-HQ-OAR-2002-0058-3465-A1

Comment Excerpt Number: 32

Comment: EPA has determined that a 30-day rolling average is appropriate for parameter monitoring and demonstration of continuous compliance with O₂ operating limits established for demonstration of continuous CO emissions compliance. EPA notes in the preamble that *“We are aware from studies of emissions over long averaging periods that long term (e.g., 30-day) average emissions for operating in compliance will have a variability of about half of that represented by the results of short term testing. Given that short term tests are representative of distinct points along a continuum of that inherent operational variability, we believe it appropriate to propose 30-day averages in order to provide a means for the source operator to account for that variability by applying a long term average for establishing compliance.”*

For Boilers already equipped with CO CEMS or operators who elect to use the more restrictive CO CEMs to monitor combustion performance on their boilers, the operator should also be afforded at least a 30-day averaging period for monitoring CO emissions. The 10-day average currently proposed in the rule for CO compliance is, for the very reasons cited by EPA above, grossly insufficient to account for operating swings and variability that are inherent in industrial boilers.

Response: The EPA agrees that a 30-day rolling average better accounts for the inherent variability and operating swings in industrial boilers. We have revised the rolling average times for the CO CEMS-based limits in the final rule to be based on a 30-day rolling average, where data are available. For some subcategories, not enough data were reported to be able to calculate a 99 percent UPL based on a 30-day rolling average. For these subcategories, a 10-day rolling average was used.

Commenter Name: John S Williams
Commenter Affiliation: Maine Pulp & Paper Association (MPPA)
Document Control Number: EPA-HQ-OAR-2002-0058-3466-A1
Comment Excerpt Number: 12

Comment: EPA should retain a 30~day rolling average basis for compliance with CO limits. In the March 21,2011 Boiler MACT regulation, EPA included CO emissions limits based on 30-day rolling averages and operation of a continuous emission monitor system (CEMS) for boilers 100 MMBtu/hr and greater. The December 23, 2011 proposed amendments would shorten the averaging time for CO to a 10-day rolling average basis. Boiler MACT rule establishes CO limits with compliance based on stack tests, which does not provide time to average out inevitable swings in operation and resulting variable CO emissions. EPA also made changes to its methodology for establishing the final CO limits as compared to the methods used to establish the proposed limits. EPA should reconsider the CO limits because MPPA, its members and the Maine DEP could not reasonably discern at the time of proposal the way in which EPA would develop the limits and require compliance with the final standard and therefore did not have a meaningful opportunity to comment on these issues. MPPA members are aware that NCASI has extensively reviewed the methodology used by EPA in the development of the long term CO limit and finds that the data is auto correlated. When the data is assessed using a longer averaging period a higher CO limit is justified. We understand they will be providing recommendations and urge EPA to adopt this more scientifically based approach.

MPPA strongly urges that EPA either return to a 30-day rolling average for CO limits from biomass boilers equipped with CO continuous emissions monitors and establish more appropriate CO limits for wet biomass fuel boilers.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3465-A1, excerpt 32.

Commenter Name: Lorraine Gershman

Commenter Affiliation: American Chemistry Council (ACC)

Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1

Comment Excerpt Number: 71

Comment: Even with this approach, however, EPA should further consider that the available CO CEMS data in some cases were for short periods of time (e.g., 30 day tests required by EPA under CAA § 114 authority). Therefore, simply due to that limited time period, the boilers tested did not experience the full range of operational variations that would likely impact CO emissions and would occur over a longer time period, such as at least one year, where variables such as unit operating condition, seasonal steam demand, and fuel quality would pass through all seasons of the year. Thus, for those cases utilizing short term data, the floor setting methodology should provide further latitude to account for undocumented and undemonstrated inherent variability that would be seen by even the best performing units.

Response: The EPA is required by the Clean Air Act to establish MACT floor levels based on emissions information available to the Administrator. Additional data submissions were requested in the preamble to the proposed rule, but only limited additional data were received during the comment period. The methodology used to establish the alternative CO CEMS-based limits has been revised to more fully account for the operational variability within the averaging time length. For more information on the revised methodology, please see the memo entitled, "CO CEMS MACT Floor Analysis (August 2012) for the Industrial, Commercial, and Institutional Boilers and Process Heaters NESHAP" in the docket. See also response to comment EPA-HQ-OAR-2002-0058-3520-A1, excerpt 14. This excerpt may be found in the CO CEMS "Methodology: Statistical Analysis" section of this comment response document.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 83

Comment: EPA has proposed alternate CO CEMS-based limits for solid fuel boiler subcategories based on a limited amount of data, and is proposing a 10-day averaging period. We are aware of additional data that are being submitted by member companies and analyzed in NCASI's comments on the proposed rule. For many subcategories, there will be adequate data available for EPA to propose longer averaging times. As emissions of CO can be highly variable, as described in other sections of these comments, EPA should establish the longest averaging period that can be justified by the available data.

Response: We agree with the commenter. Any additional CEMS data provided during the comment period have been incorporated into the EPA ICR Databases, so long as the data were reported in a suitable format. The EPA has increased the averaging time for the alternative CO CEMS-based limits to a 30-day rolling average for the subcategories where the switch was justified by available data.

Commenter Name: Robert D. Bessette

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 84

Comment: EPA should specify how a 10-day rolling average for the CO CEMS limit is calculated, indicating that it includes the previous 240 hours of valid operating data. EPA should make clear that valid data excludes hours during startup and shutdown as well as unit down time. This clarification will be helpful in implementation, as some permitting authorities have interpreted how compliance is demonstrated with rolling averages in odd and sometimes unintended ways. For example, when a unit is down for an outage exceeding the rolling average period (10 days in this case) state regulators have sometimes sought to continue the 10-day calculation through the outage, ultimately basing the final rolling average on one sole CO reading – the final valid hourly reading before shutdown. As this value is likely to be higher than typical due to initiation of shutdown during that hour, this final 10-day average calculation would likely exceed the 10-day limit. We believe that such interpretation would be outside EPA's intention in setting the standard. Specification of the minimum number of readings ensures that the 10-day average concept is not undermined in cases of long outages.

Response: We agree that the rolling average period should include all valid hourly CO CEMS data points collected during the averaging period, and that these should exclude data points

pertaining to periods of startup and shutdown. Periods of startup and shutdown are not subject to the alternative CO CEMS-base emission limits, and are instead subject to a work practice standard. Where justified by available CEMS data, we have changed the averaging time to a 30-day rolling average for the alternative CO CEMS-based emission limits. The definitions of the rolling averaging times in the final rule have been revised to pertain to the arithmetic average of all hourly data, excluding periods of startup and shutdown, from the duration of the averaging time.

Commenter Name: Richard D. Garber

Commenter Affiliation: Boise Inc.

Document Control Number: EPA-HQ-OAR-2002-0058-3686-A2

Comment Excerpt Number: 3

Comment: We support inclusion of an alternative CO compliance standard, a 10-day averaging period, for biomass units equipped with CO CEMS for compliance demonstration. While Boise would urge EPA to re-evaluate the available CO CEMS data and move to adopt a longer averaging period and a higher emission limit (discussed further in our letter), we do want to acknowledge EPA's efforts to date for including this approach for units that have CEMs already installed, and for which the three-hour stack test compliance demonstration was unworkable.

Response: The EPA thanks the commenter for their support of an alternative CO CEMS standard. For response to allowing longer averaging times, please see response to comment EPA-HQ-OAR-2002-0058-3521-A1, excerpt 83.

Commenter Name: Kevin G. Desharnais, Attorney, Mayer Brown LLP

Commenter Affiliation: United States Sugar Corporation

Document Control Number: EPA-HQ-OAR-2002-0058-3496-A1

Comment Excerpt Number: 7

Comment: The CO CEMS-based compliance limit is intended to provide a reasonable compliance alternative for sources that have an existing CO CEMS unit. As EPA notes in the Reconsideration Proposal, various petitioners have pointed out that, "given the highly variable nature of CO emissions, an emission limit based on CO CEMS data from boilers over time would more adequately capture the true variability in CO emissions over various operating conditions." Reconsideration Proposal, 76 Fed. Reg. at 80611. EPA therefore calculated a CO CEMS-based MACT floor for each subcategory for which data were available. Unfortunately, the proposal then falls flat by establishing a 10-day rolling average compliance period. This averaging period is simply insufficient to account for the variability in CO emissions under a real-world range of operating conditions.

Response: The EPA has increased the averaging time to a 30-day rolling average for the subcategories where the switch was justified by available data. For a response to the request for a 12-month rolling average to account for high variability in bagasse-fired boilers, see response to comment EPA-HQ-OAR-2002-0058-3504-A1, excerpt 31. This excerpt may be found in the CO CEMS "Existing Results: Biomass Suspension/Grate" section of this comment response document.

Commenter Name: David A. Buff, Golder Associates Inc.

Commenter Name: Kevin G. Desharnais, Attorney, Mayer Brown LLP
Commenter Affiliation: United States Sugar Corporation
Document Control Number: EPA-HQ-OAR-2002-0058-3496-A1
Comment Excerpt Number: 6

Comment: As an alternative to CO stack testing and oxygen monitoring, the Reconsideration Proposal also includes CO CEMS-based limits. EPA has proposed a 1 O-day rolling average for determining compliance with these limits. This overly short averaging period undercuts the usefulness of this provision, rendering it unworkable, and US Sugar objects to the 10-day averaging period, particularly as applied to bagasse boilers.

Response: For a response to comments suggesting a 10-day rolling average is insufficient to capture natural variation in CO emissions from bagasse-fired boilers, see response to comment EPA-HQ-OAR-2002-0058-3496-A1, excerpt 7.

Commenter Name: Kevin G. Desharnais, Attorney, Mayer Brown LLP
Commenter Affiliation: United States Sugar Corporation
Document Control Number: EPA-HQ-OAR-2002-0058-3496-A1
Comment Excerpt Number: 8

Comment: Elsewhere in the proposal, EPA generally extends the time periods for parameter monitoring and demonstration of continuous compliance with operating limits from a 12-hour period to a 30-day rolling average. In support of this change, EPA states, "Concerns of variability outside the operators control such as fuel content, seasonal factors, load cycling and infrequent hours of needed operation prompted us to look at longer averaging periods on which to base operating compliance determination." 76 Fed. Reg. at 80610. These considerations are equally applicable to CO emissions. In the case of bagasse boilers, the potential variation is compounded by the natural variation in the fuel source, which can be affected by differences in

crop conditions, plant varieties, and weather conditions. The proposed ten-day rolling average is simply insufficient to capture the natural variation in CO emissions from bagasse boilers.

Response: For the reasons provided in the preamble to the December 2011 proposed rule, EPA has elected to extend averaging times for parametric monitoring to a 30-day rolling average. These averaging times may be different than the averaging period for some of the alternative CO CEMS-based emission limits. This is because the CEMS-based limits were calculated based on the longest averaging period allowed by available data, up to a 30-day rolling average.

For a response to comments suggesting a 10-day rolling average is insufficient to capture natural variation in CO emissions from bagasse-fired boilers, see response to comment EPA-HQ-OAR-2002-0058-3496-A1, excerpt 7.

Comment Excerpt Number: 2

Comment: BPA supports the alternative 10-day rolling average CO standard and the 30-day average monitoring provisions. However, there have been problems implementing rolling average standards which EPA should address. EPA should specify how the 10-day rolling average is calculated, indicating that each 10-day average includes the previous 240 hours of valid emission data. Similarly, each 30-day rolling average should be calculated using the previous 720 hours of valid data. Valid data excludes hours during startup and shutdown (when work practices apply) as well as unit down time. We believe this will be helpful in implementation, where States have looked at rolling averages in odd and sometimes unintended ways. For example, when a unit is down for an outage exceeding the rolling average period (10 days in the case of the CEMS-based CO standard) State regulators have sought to base the final rolling average solely on one CO reading - the final valid hourly reading before shutdown. Since this value is likely to be higher than typical due to initiation of shutdown during that hour, this final 10-day ave_age calculation would be more likely to exceed the 10-day limit. We believe that such interpretation would be outside EPA intention in setting the standard. The specified number of readings assures that the 10-day average concept is not undermined in cases of long outages.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3521-A1, excerpt 84.

Comment: Based on the information contained in the 2011 Reconsidered BMACT Rule, it is not clear how the 10-day rolling average for the CO CEMS limit is calculated. EPA needs to clarify that valid data excludes hours during startup and shutdown and unit down time. EPA

should specify the minimum number of readings, which will assure that the 10-day average concept is not undermined in cases of long outages.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3521-A1, excerpt 84.

Comment: Under 40CFR63.7575, EPA defines 30-day rolling average as “the arithmetic mean of all valid data from 30 successive operating days that is calculated for each operating day using the data from that operating day and the previous 29 operating days”. Please clarify if there is a minimum number of valid data points that need to be collected each operating day based on the number of hours the unit operated each day before the data is used to calculate the 30-operating day rolling average.

Response: For an explanation on how the definition of 30-day rolling average has been revised in the final rule, please see response to comment EPA-HQ-OAR-2002-0058-3521-A1, excerpt 84. Section 63.7525 of the final rule specifies the minimum data collection requirement when operating continuous emission or parameter monitoring systems. That is a minimum of 4 CO CEMS data values to have a valid hour of data.

Comment: Please clarify if units that operate intermittently should use the valid data points from their previous 29 operating days even if these operating days may be spaced throughout a three month or greater period.

Response: For an explanation on how the definition of 30-day rolling average has been revised in the final rule, please see response to comment EPA-HQ-OAR-2002-0058-3521-A1, excerpt 84. Units which operate intermittently should not include data points from periods of startup, shutdown, or when the unit is not operating. The averaging time corresponds to the previous 720 hours in which operations were not interrupted, even though valid emissions data may be limited for the time period for units which are operated intermittently. The 720 hour period may span a period greater than 30 calendar days if operations were intermittent.

Comment: It has also been our experience that a longer CO averaging period is more appropriate than a 10-day rolling average for a wet biomass stoker boiler in order to account for

the intricacies in burning this type of fuel. Biomass combustion is negatively impacted by a number of factors, including weather, harvest conditions and fuel variability. Weather impacts the fuel negatively through precipitation. Wetter fuel makes for more difficult combustion control. Harvest conditions play a role as well in that more green wood deliveries over an averaging period leads to higher CO emissions over that time frame. Finally, fuel variability issues also impact CO emissions. Fuel is supplied to our facility by multiple sources from multiple locations. Each of these fuels behaves differently due to its source and delivered condition. Since we have limited control of the delivered condition of each of these fuels, we need flexibility to meet the CO limits through a longer averaging period.

Response: The EPA recognizes the inherent variability of biomass fuels. EPA believes that the statistical procedures used to derive the alternative CO CEMS-based limits for Stoker/Sloped Grate/Other units designed to burn wet biomass, namely a 99% UPL and a 30-day averaging period, account for the inherent variability of the biomass fuel.

For response to request for longer averaging times for biomass-fired boilers, see response to comment EPA-HQ-OAR-2002-0058-3505-A1, excerpts 27, 28, 30, 31, 32, 33, and 37. These excerpts may be found in the CO CEMS “Alternative MACT Floor Using Highest Rolling Average” section of this comment response document.

4F. Alternative MACT Floor Using Highest Rolling Average

Commenter Name: Ashok K. Jain

Document Control Number: EPA-HQ-OAR-2002-0058-3505-A1

Comment Excerpt Number: 29

Comment: To address this dilemma where a significant fraction of the data in the best performing data sets exceed the estimated UPL-based limits, often well over and above what the confidence limits (99.0% or 99.9%) would have indicated, EPA proposed an “Alternate MACT Floor Calculation Methodology.” After the maximum 10-day rolling average was determined for each unit, the highest maximum 10-day rolling average from the top half of the best performers for each subcategory was selected as a MACT floor option. EPA reasoned that “In the CEMS-based compliance alternative, it is necessary for MACT floors to be achieved by the best performers at all times, even during large CO swings; the maximum rolling average value from the top half of the best performers is chosen to represent the performance of the average emission limitation achieved by the best performing 12 percent of existing sources (for which emission information is available).” Further, EPA noted that “since only one unit’s maximum rolling average is used for this option, the unit’s operation must be representative of the entire subcategory. Therefore, the unit selected must be firing a fuel which is reasonable to obtain for the entire subcategory and not process specific nor based on co-fired configurations.”

NCASI is in agreement with this alternate approach forwarded by EPA. This would essentially eliminate the possibility of a boiler in the best performing floor itself being in violation of the CEM-based limit. Based on this alternate methodology, a 919 ppm limit was determined for wet biomass stokers (rounded to 920 ppm), which corresponded to the maximum 10-day RA for the CASierraPacificLincoln biomass stoker unit. Similarly, a 478 ppm limit was determined for

biomass FBCs (rounded to 480 ppm), which corresponded to the maximum 10-day RA for the GATempleInland Rome biomass FBC unit.

Response: The EPA thanks the commenter for their support. For the alternative CO CEMS-based limits in the final rule, EPA considered the emissions of the top 6 percent for each subcategory. The maximum rolling average of the top 6 percent of the subcategory was selected as the basis of the CEMS-based limit if it was larger than the calculated 99% UPL for the same subcategory. For additional information, please see the memo titled, “CO CEMS MACT Floor Analysis (August 2012) for the Industrial, Commercial, and Institutional Boilers and Process Heaters National Emission Standards for Hazardous Air Pollutants – Major Source” in the docket.

Commenter Name: Ashok K. Jain

Document Control Number: EPA-HQ-OAR-2002-0058-3505-A1

Comment Excerpt Number: 27, 28, 30, 31, 32, 33, 37

Comment: There were 2224 daily averages considered for the 4 best performing boilers in the biomass stoker category (1468 for CASierraPacificLincoln, 500 for WABoisePaperWallula, 30 for MNDESPHansONyman, and 226 for MSGPNewAugusta). Only days when >90% biomass was fired were considered. Similarly, there were 866 daily averages considered for the 3 best performing boilers representing the biomass FBC category (30 for ORGeorgiaPacific Wauna Mill, 185 for ALIPCourtland and 651 for GATempleInlandRome).

The 99% UPL was estimated using the equation:

$$\text{UPL} = \bar{x} + t(0.99, n - 1) \times \text{sqrt}(s^2 \times (1/n + 1/m)) \text{ [Equation 1]}$$

The t-statistic was calculated using the following Excel equation:

$$\text{t-statistic} = \text{TINV}(2*(1-0.99),n-1) \text{ [Equation 2]}$$

where:

n = the number of daily averages in the best performing 12 percent

m = the number of daily averages in the compliance average; m = 10 for all subcategories based on 10-day rolling averages;

s = the standard deviation of the daily averages in the best performing 12 percent

\bar{x} = the sample mean of test runs from top performing units

For datasets that were determined to be lognormally distributed (generally the case for most data sets), the UPL (log normal) was equal to the exponential of the UPL estimated using eqn. 1 but with \bar{x} and s^2 referring to the data in the log normal space.

As mentioned above, a 99% UPL-based 10-day rolling average limit of 410 ppm @3% O₂ was estimated from analysis of the daily averages for the four biomass stokers (rounded up from 405 ppm). It should be noted that unlike assigning UPL-based limits to short duration tests conducted

on a boiler, assigning a UPL-based limit to boilers equipped with continuous monitors would always result in a conflict. For example, under Boiler MACT, by definition a 99% UPL-based limit implies that ~1% of the data in the “best performer” data set is expected to exceed this value. This would therefore imply that boilers with CO CEMs should be allowed a 1% exceedance or about 4 exceedances per year. In the current situation with biomass stokers, this problem is further exacerbated. As shown in Figure 1 [See submittal for Figure 1], which is a graphical display of all the 10-day rolling averages used to determine the 99% UPL value for biomass stokers, ~18% of the 10-day RAs would exceed the 99% UPL-based limit of 410 ppm. If a 99.9% UPL value were estimated (as was the case with the short term stack test data), the UPL value would have been ~466 ppm, and about 11.5% of the data in the best performer set would exceed this limit. As shown below, this is caused by severe autocorrelation that exists in these and likely all CEM-based hourly average and even 10-day rolling average data.

A similar trend can be seen with the treatment of data for the three biomass FBC units. A 99% UPL 10- day rolling average of 180 ppm @3% O₂ was estimated from the data for these units (rounded up from 177 ppm), which meant that 16.2% of the 10-d RAs would exceed this level. Once again, this is demonstrated by the graphical display of the data in Figure 2. [See submittal for Figure 2] If a 99.9% UPL were used, the 10-day rolling average value would have been ~208 ppm, and about 9.4% of the data in the best performer set would exceed this level.

The key reason why a 99.0% UPL or even a 99.9% UPL calculated as above results in a significant fraction of the data in the best performing floor itself to exceed the limit (well beyond the expected 1.0% or 0.1% of the time) can be traced to the fact that $m = 10$ was used in equation 1. In other words, EPA assumed that 10 consecutive daily averages in the current data set are independent data points with no auto-correlation. If this were the case, the standard deviation (SD) of the original “best performer” data set consisting of single daily averages when compared with the SD of the same data set but with 10-day (consecutive) block averages should be reduced by 68.4% ($1 - 1/\sqrt{10}$). Instead, for biomass stokers, the SD drops by only about 19.3%, and for biomass FBCs it drops by 31.3%, both of which suggest the data are highly auto-correlated and using $m = 10$ would lead to erroneous results.

Thus, if the UPL approach is to be used, the UPLs should be calculated using $m = 1$, with each data point constituting a 10-day (consecutive) block average. The 99.0% and 99.9% UPLs for the 4 best performing biomass stokers calculated using $m = 1$ and $n = 222$ (10-d block averages) are estimated at ~730 and 1010 ppm, respectively. For these UPL values, nearly 1.5% and 0.0% of the data in the best performer data set would exceed the corresponding limits, respectively. Similarly, the 99.0% and 99.9% UPLs for the 3 best performing biomass FBC units calculated using $m = 1$ and $n = 87$ (10-d block averages) are estimated at ~410 and 630 ppm, respectively, and for these UPL values, nearly 0.7% and 0% of the data in the best performer data set would exceed the corresponding limits, respectively.

From a biomass boiler operational point of view, CO limits based on a monthly rolling average would be more appropriate than limits based on daily, weekly or 10-day averages considering normal variations in fuel quality and fluctuating loads. Unfortunately, the majority of the biomass stokers (10 of 14) considered by EPA had only 30 to 60 days of CEM CO data. Thus, a monthly average would be difficult to estimate from these data. However, the same daily average CEM data for 14 biomass stokers and 3 biomass FBCs used to calculate the 10-day RA limits could be used to generate 15-day RA limits (a compromise). The following provides a look at

how the various limits described above would look like if a 15-day rolling average were used instead of a 10-day RA. It should be noted that additional data may become available to EPA both from the forest products industry's own testing and from other sources.

The same four boilers that represented the best performers for biomass stokers when using 10 day RAs are seen to be the best performers when using 15-day RAs. Using $m = 15$ (i.e. ignoring auto-correlation), a 99% UPL 15-day rolling average value of 374 ppm @3% O₂ is estimated from the daily average data for the four best performing biomass stokers, and ~23% of the 15-day RAs are seen to exceed this limit. Using $m = 15$, a 99.9% UPL monthly RA value of ~420 ppm is estimated, and nearly 16% of the data in the best performer set would exceed this limit.

The same three boilers that represented the best performers for biomass FBCs when using 10 day RAs are also determined to be the best performers when using 15-day RAs. Using $m = 15$, a 99% UPL 15-day rolling average value of 162 ppm @3% O₂ is estimated from the daily average data for the three biomass FBCs, with ~24% of the monthly RAs exceeding this limit. Using $m = 15$, a 99.9% UPL 15-day RA value of ~185 ppm is estimated, with about 15% of the data in the best performer set exceeding this limit. As with the 10-day averages, if the UPL approach is to be used, the UPLs should be calculated using $m = 1$, with each data point constituting a 15-day (consecutive) block average. The 99.0% and 99.9% UPLs for the 4 best performing biomass stokers calculated using $m = 1$ and $n = 147$ (15-d block averages) are estimated at ~720 and 980 ppm, respectively. For these UPL values, nearly 1.6% and 0.0% of the data in the best performer data set would exceed the corresponding limits, respectively. Similarly, the 99.0% and 99.9% UPLs for the 3 best performing biomass FBC units calculated using $m = 1$ and $n = 57$ (15-d block averages) are estimated at ~410 and 630 ppm, respectively, and for these UPL values, 0.0% of the data in the best performer data set would exceed the corresponding limits.

Once again, using $m = 15$ is shown to lead to the use of highly auto-correlated data in the case of both the biomass stokers and biomass FBCs, and thus erroneous results. While the SD of the original "best performer" data set when compared with the SD of the same data set but with 15-day (consecutive) block averages should be reduced by 74.2% ($1 - 1/\sqrt{15}$), for biomass stokers, it drops by only 20.5%, and for biomass FBCs, it drops by only 30.1%. Based on the alternate methodology proposed by EPA, where the maximum 15-day rolling average would be used as the limit, a 860 ppm limit (rounded up from 856 ppm) corresponding to the maximum 15-day RA for the CASierraPacificLincoln biomass stoker unit and a 400 ppm limit (rounded up from 398 ppm) corresponding to the maximum 15-day RA for the GATemple Inland Rome biomass FBC unit are determined to be the MACT floors for biomass stokers and biomass FBCs, respectively.

CEM CO emissions data for any industrial boiler are expected to be highly correlated even when compared on a daily average basis. The daily average CEM CO data in EPA's current database are no exception. Using $m = 10$ in the UPL equation used to calculate the 10-day rolling average limit assumes that 10 consecutive daily averages are independent data points. This assumption leads to limits that are exceeded by a significant fraction of the 10-day rolling averages recorded by the "best performing" units. This is unreasonable.

Based on the analysis presented above, we conclude that the alternate methodology offered by EPA, whereby the highest maximum rolling average from the top half of the best performers for each subcategory would be selected as the MACT floor, is the best option. This option would

also fulfill a necessary condition that significant fractions of the data used to set the floor cannot exceed the floor itself.

Using the alternate option, a 10-day rolling average limit of 920 ppm and 480 ppm at 3% O₂ is estimated for wet biomass stokers and biomass FBCs, respectively.

Despite the reservations expressed in this document, if EPA decides to pursue a 10-day average UPL-based approach, then it is recommended that 10 day block averages and $m = 1$ be used in the UPL equation instead of daily averages and $m = 10$. This approach is needed to address the autocorrelation issue in the datasets. For wet biomass stokers, this would result in 99.0% and 99.9% UPL values of 730 and 1010 ppm at 3% O₂, respectively. Similarly, using this approach, 99.0% and 99.9% UPL values of 410 and 630 ppm at 3% O₂, respectively, are estimated for biomass FBCs. If the 99.0% UPLs are chosen, then a 1% exceedance or 4 days/year should also be incorporated with the limit.

Since averages of longer time periods are desirable from a biomass boiler operational point of view, 15-day rolling averages should be considered in lieu of 10-day RAs.

Using the alternate option, a 15-day rolling average limit of 860 ppm and 400 ppm at 3% O₂ is estimated for wet biomass stokers and biomass FBCs, respectively.

If a UPL-based approach with $m = 1$ and 15-day block averages is used in the UPL equation, for wet biomass stokers, this would result in 99.0% and 99.9% UPL values of 720 and 980 ppm at 3% O₂, respectively. Similarly, using this approach, the 99.0% and 99.9% UPL values of 410 and 630 ppm at 3% O₂, respectively, estimated using 10-day averages for biomass FBCs remain unchanged. Again, if the 99.0% UPLs are chosen, then a 1% exceedance or 4 days/year should also be incorporated with the limit.

NCASI believes that EPA's alternate methodology that reasons "it is necessary for MACT floors to be achieved by the best performers at all times, even during large CO swings" is a sound one and should be used to set the floors for biomass stoker and FBC units equipped with CO CEMs.

The table below summarizes CO CEMS-based limits for solid fuel boilers if the UPL-based approach or the alternate approach suggested by EPA of using the maximum 10-day rolling average were to be adopted. As previously noted, EPA should consider using 15-day rolling averages to accommodate the inherent variability in biomass boiler CO emissions resulting from fluctuations in fuel quality and steam demand. [See submittal for Table]

Response: The EPA thanks the commenter for their support of the alternative CO CEMS MACT Floor calculation methodology. For response to the issue on data used in floor calculations not exceeding the floor itself, see response to comment EPA-HQ-OAR-2002-0058-3505-A1, excerpt 29.

We have revised the methodology used to calculate the CO CEMS UPL. Where justified by available CEMS data, we have switched to a 30-day rolling average. EPA evaluated the commenter's provided UPL calculations based on a 15-day rolling average. However, EPA made the decision to employ a 30-day rolling average where allowed by available data. A 15-day rolling average may experience the same issues with operational variability that would be experienced with a 10-day rolling average, but those concerns are greatly mitigated with a 30-

day averaging period. The UPL is also computed from all available CEMS data points from valid periods of operation (excluding periods of startup and shutdown) that comprise the 10-day or 30-day rolling average. For additional discussion on what constitutes valid operational periods for compliance with CO CEMS-based limits, see the response for comment EPA-HQ-OAR-2002-0058-3521-A1, excerpt 84. This excerpt may be found in the CO CEMS "Averaging Time and Rolling Average Length" section of this comment response document. For more information on the revised methodology, please see the memo titled, "CO CEMS MACT Floor Analysis (August 2012) for the Industrial, Commercial, and Institutional Boilers and Process Heaters NESHAP" in the docket. The EPA agrees that the UPL calculation should be revised to account for autocorrelation. In the calculation of the UPL, "m" has been assigned a value of 1 for the reasons specified by the commenter. However, a 99 percent confidence interval has been maintained with the UPL calculation in lieu of the 99.9 percent confidence interval suggested by the commenter. For the reasons identified in the preamble to the December 23, 2011 proposed rule, the EPA believes that the 99% UPL properly accounts for the variability in CO emissions.

We agree that the averaging times should be increased in order to more fully account for the inherent variability of CO emissions and operating load changes, particularly for units combusting biomass or bio-based solid fuels. Where justifiable from available CEMS data, we have increased the averaging time to a 30-day rolling average for the alternative CO CEMS-based emission limits. Statistical variability was calculated using a 99 percent UPL. The alternative CO CEMS-based limits were based on this calculated UPL or the maximum rolling average of the best emitting 6 percent of units in the subcategory, whichever value was greater. We believe this revised methodology and the switch to 30-day averaging periods for certain subcategories allows sources greater flexibility in operational load swings and the inherent variability of CO emissions.

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 82

Comment: EPA has proposed an "Alternate MACT Floor Calculation Methodology" where the highest maximum 10-day rolling average from the top half of the best performers for each subcategory was selected as a MACT floor option. Setting an alternative standard for data collected using CEMS is necessary because MACT floors must be "achieved by the best performers at all times, even during large CO swings." EPA's current approach would eliminate the possibility of a boiler in the best performing floor being in violation of the CEMS-based limit. Nothing in the CAA prohibits EPA from establishing alternative requirements for data gathered using CEMS. In fact, CAA § 112(d) provides EPA with broad authority to "distinguish among classes, types, and sizes of sources within a category or subcategory in establishing such standards." Boilers with CEMS are easily distinguishable from those that do not have CEMS.

Response: For a response on EPA's actions on considering a maximum rolling average for the top 6 percent in the final rule, please see response to EPA-HQ-OAR-2002-0058-3505-A1, excerpt 29.

Commenter Name: Lorraine Gershman
Commenter Affiliation: American Chemistry Council (ACC)
Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1
Comment Excerpt Number: 70

Comment: *EPA Should Use an Alternate CO CEMS MACT Floor Calculation Methodology*

The short term CO limits based on stack test data were developed from limited data sets and the stack test data were obtained at steady state, high load conditions. CO emissions will change as operational conditions within the boiler change, so complying with a stack test based CO limit using a CO CEMS would likely prove impossible. Therefore, EPA has proposed CO CEMS-based limits to more adequately capture the variability of CO emissions over various operating conditions. EPA has proposed 10-day average CO limits for units that have CEMS and has calculated the MACT floors for units with CO CEMS using much the same approach as the MACT floor calculation for units with stack test data.

In this Reconsideration Proposal, EPA considered an alternate method for determining CO CEMS floors that would adjust the CO CEMS-based emission limits to reflect the actual level that was demonstrated to be achieved at all times by those units. (76 Fed. Reg. 80613.) ACC agrees with EPA's alternate approach. This approach would essentially eliminate the possibility of a boiler in the best performing floor itself being in violation of the CEMS-based limit.

Response: The EPA thanks the commenter for their support.

Commenter Name: Paul Noe
Commenter Affiliation: American Forest & Paper Association (AF&PA) et al.
Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1
Comment Excerpt Number: 82

Comment: In order to avoid the situation described on preamble page 80613, where a significant fraction of the CEMS data in the best performing data sets are seen to exceed the estimated UPL-based limits, often well over and above what the confidence limits (99.0% or 99.9%) would have indicated, EPA proposed an "Alternate MACT Floor Calculation Methodology." After the maximum 10-day rolling average was determined for each unit, the highest maximum 10-day rolling average from the top half of the best performers for each subcategory was selected as a MACT floor option. EPA reasoned that "In the CEMS-based compliance alternative, it is necessary for MACT floors to be achieved by the best performers at all times, even during large CO swings; the maximum rolling average value from the top half of the best performers is chosen to represent the performance of the average emission limitation achieved by the best performing 12 percent of existing sources (for which emission information is available)."

We are in agreement with this alternate approach proposed by EPA. This approach would essentially eliminate the possibility of a boiler in the best performing floor itself being in violation of the CEMS-based limit.

Response: The EPA thanks the commenter for their support.

Comment: CO CEMS MACT Limits for Suspension Burner and Wet Stoker biomass subcategories. Per Table 11 in the CO GEMS MACT Floor Analysis²¹, the best 6% of units in the Suspension Burner and Wet Stoker biomass subcategories *complied with the 99% UPLbased CO GEMS MACT limit less than 75% of the time*. Then it is clear that the 99% UPL-based limit is not reasonable. We believe the CO GEMS MACT limits should be as outlined in Section 7 of the report, Alternative MACT Floor Calculation Methodology. That is, the CO CEMS MACT limits should be equal to the maximum 10-day rolling average of the top 6% of units.

Response: The EPA thanks the commenter for their support.

4H01 - MACT Floor Existing Results - Coal FB

Commenter Name: Dell Majure
Commenter Affiliation: Kimberly-Clark Corp.
Document Control Number: EPA-HQ-OAR-2002-0058-3692-A2
Comment Excerpt Number: 2

Comment: The CO emission limit for CEMs for coal-fired FB boiler is 59 ppmv @ 3 % O₂ (10-day rolling average) is derived from CO values from a single boiler "IARoquetteAmerica" firing bituminous coal. This boiler does not have a FBHE and the coal it fires contains approximately 9 % ash content.

There is a fundamental difference between the reference unit and K-C's FBHE boiler. The Chester FBHE boiler cannot operate firing coal with only 9 % ash content because there is not enough ash too facilitate the conductive heat exchange with the furnace tubes and FBHE. By comparison, the design for the K-C FB boiler with its integral FBHE design requires a minimum fuel ash content of 20 – 25 %. This demonstrates a fundamentally different design than a coal-fired FB without a FBHE.

Therefore, the boiler used to establish the CO CEM emission limit is not of the same design or CO emission rates as a coal-fired FB boiler with a FBHE. In addition, the same is true for the CO stack test emission limit assuming that those boilers do not have a FBHE.

Response: The EPA agrees with the fundamental difference in design between the sources. A new subcategory has been added to the final rule for fluidized bed units with an integrated heat exchanger. Separate CO CEMS-based emission limitations have been established for traditional fluidized bed units and for fluidized bed units with an integrated heat exchanger.

Comment: The K-C FB boiler with FBHE is designed to burn culm (high ash and moisture coal) mixed with other forms of coal (e.g. petroleum coke, bituminous, and anthracite). The mixture is 70 – 80 % culm and the balance is other forms of coal. K-C fires culm mixed with petroleum coke unless the local refineries shut down leaving no economically viable supply which has happened periodically. During these times other forms of coal are used in the culm mixture like bituminous.

K-C calculated the 99 % upper predictive limit for three different cases from the CO CEM values in the appendix [see submittal for appendix].

1. Culm and any fuel mixture fuel combination.
2. Culm mixture with petroleum coke.
3. Culm mixture without petroleum coke.

The results are show in the table [see submittal for table].

A concern that K-C has is that the emission limit for CO could be set at 84 ppmv for example reflecting the boiler perform on coal (i.e. all forms) and the refineries could shut down resulting in no economically viable supply of petroleum coke making it infeasible to achieve compliance.

Response: EPA has incorporated the provided CO CEMS data into the EPA ICR Databases, and the emissions data have been factored into the revised calculation of CO CEMS-based emission limits. For this rulemaking, emissions from the combustion of culm and petroleum coke are classified identically to emissions from coal combustion. As such, any mixture of coal and culm or petroleum coke was treated as 100% coal combustion in the development of the final rule. All CO CEMS data provided by the commenter were from the combined combustion of coal, culm, and/or petroleum coke, and thus all data were treated as 100% coal combustion and factored into the development of the alternative CO CEMS-based limits for the fluidized bed with integrated heat exchanger subcategory.

For a response to issues with FBHE boilers differing in design and having different emission and fuel profiles than the top performing emitter, please see response to comment EPA-HQ-OAR-2002-0058-3692-A2, excerpt 2.

Document Control Number: EPA-HQ-OAR-2002-0058-3688-A2

Comment Excerpt Number: 2

Comment: The proposed CO emission limit for pulverized coal (PC) boilers with CO CEMs is 28 ppmv at 3% oxygen (dry basis) or, as an alternative, 35 ppmv at 3% oxygen (dry basis) based on the alternate approach forwarded by EPA where the maximum 10-day rolling average value is

selected, both based on just 60 days of data from one PC boiler. As described in the Coalition and NCASI comments, these levels are not achievable for most PC boilers on a continuous basis. A case in point is the No. 8 Power Boiler at RockTenn's West Point, Virginia pulp and paper mill.

The data set that EPA used to calculate the 28 or 35 ppmv CEMS-based limits for PC boilers was CEMS data from the No. 8 Power Boiler at RockTenn's West Point mill (Unit ID PB08 at Facility ID VASmurfitStoneWestpt in EPA's database). Although the West Point mill's No. 8 Power Boiler is the floor-setting unit, it would not meet the proposed CEMS-based CO limit on a continuous basis.

Response: We have revised the CO CEMS-based emission limit alternative for Pulverized Coal units in the final rule. Additional CEMS data from Pulverized Coal units were submitted to EPA and included in the calculation of the CEMS-based limit. The resultant limit is significantly less stringent than the limit in the December, 2011 proposed reconsideration of the rule and should mitigate any achievability concerns. Additional information on the calculation of CO CEMS-based limits may be found in the memo titled, "CO CEMS MACT Floor Analysis (August 2012) for the Industrial, Commercial, and Institutional Boilers and Process Heaters National Emission Standards for Hazardous Air Pollutants – Major Source" in the docket.

Commenter Name: Ashok K. Jain

Commenter Affiliation: National Council for Air and Stream Improvement, Inc. (NCASI)

Document Control Number: EPA-HQ-OAR-2002-0058-3505-A1

Comment Excerpt Number: 35, 36

Comment: For PC-fired units, NCASI obtained 3 years duration of CO CEM data (2009, 2010 and 2011) from the VASmurfitStone Westpt unit that was used to calculate the 10-day rolling average floor of 28 ppm @3% O₂. Using the additional data, NCASI estimates the 99% UPL value would rise from 28 to 32 ppm @3% O₂, and the alternate limit rises from 35 to 67 ppm @3% O₂. As pointed out in the previous section 6a, the alternate limit based on determining the maximum 10-day rolling average in the data used to set the floor is much more defensible than a UPL-based limit.

There are several issues revolving around meeting a CEM-based limit of 67 ppm for pulverized coal units, the key issues being the inability to meet such a low limit during periods of low load operations and during transitions from high loads to low loads. For a boiler that is expected to fluctuate in its load capacity based on other factors that dictate the steam demand at a facility (such as in a paper mill where the steam demand will oscillate depending on the operational status of various steam-consuming unit processes), continuously meeting a 67 ppm limit is expected to be problematic. An option EPA should consider is to allow such boilers to meet the short-term based limit for PC boilers on an annual basis (same as for boilers with no CEMs), but not use the CO CEM data as a compliance assurance tool but rather as an indicator of such limits with appropriate surrogates (such as stack or boiler O₂) identified for corrective action.

Response: The EPA incorporated the additional CO CEMS data for the VASmurfitStoneWestpt boiler into the EPA ICR Databases and the data were considered in the revised calculation of the CO CEMS-based limit for the Pulverized Coal subcategory.

We disagree with the option to allow units to use CO CEMS data as only an indicator of limits with appropriate surrogates identified for corrective action. For discussion on compliance options for sources using a CO CEMS, please see the response to comment EPA-HQ-OAR-2002-0058-3257-A1, excerpt 6. We believe that the unit should demonstrate compliance with the limit at all times. We have revised the CO CEMS-based emission limit alternative for Pulverized Coal units in the final rule. The resultant limit is less stringent than the limit in the December, 2011 proposed reconsideration of the rule and should mitigate any achievability concerns.

Document Control Number: EPA-HQ-OAR-2002-0058-3755-A1

Comment Excerpt Number: 11

Comment: Alcoa-Warrick is not aware of any pulverized coal boilers that were required to measure CO emissions using a CEMS when the Section 114 tests of 2009 were performed. Alcoa-Warrick thus encourages EPA to evaluate more CO test results from using a CO CEMS and using EPA Method 10, and to evaluate CO emissions from low NOx burners before finalizing the CO emission limits.

Response: The EPA is required by the Clean Air Act to establish MACT floor levels based on emissions information available to the Administrator. Additional data submissions were requested in the preamble to the proposed rule, but only limited additional data were received during the comment period. The methodology used to establish the alternative CO CEMS-based limits has been revised to more fully account for the operational variability within the averaging time length. For more information on the revised methodology, please see the memo entitled, "CO CEMS MACT Floor Analysis (August 2012) for the Industrial, Commercial, and Institutional Boilers and Process Heaters NESHAP" in the docket. See also response to comment EPA-HQ-OAR-2002-0058-3520-A1, excerpt 14. This excerpt may be found in the CO CEMS "Statistical Analysis" section of this comment response document.

We have revised the CO CEMS-based emission limit alternative for Pulverized Coal units in the final rule. The resultant limit is less stringent than the limit in the December, 2011 proposed reconsideration of the rule and should mitigate any achievability concerns.

Comment Excerpt Number: 47

Comment: Many biomass boiler operators will be able to utilize the stack test-based CO limits and associated 30-day average oxygen monitoring to comply. However, some of our members with top performing biomass fluidized bed boilers and biomass stoker units equipped with sophisticated combustion controls like over-fired air, cannot say with certainty that they will meet the proposed CO CEMS-based limits 100% of the time. CO emissions vary significantly

with changes in load and fuel quality to the point that some of the units on which EPA is relying to set the MACT floors cannot comply all year round.

The burning of wood or wood-derived fuels, by themselves or in combination with other fossil fuels, involves very different combustion conditions than fossil fuel. The same stringent limitations on CO emissions that apply to fossil fuel-fired boilers with good combustion practices are not relevant. The high moisture content typical of most wood-derived fuels necessitates a larger than usual area of refractory surface to dry the fuel before combustion. Sufficient secondary air must be supplied over the fuel bed to burn the volatiles that account for most of the combustible material in the fuel. However, the air should not be so excessive as to cool the combustion flame.

Wood residue is typically comprised of about 50% moisture and has a heat value of about 4500 Btu/lb (as fired), compared with typical heat values of about 12,000 Btu/lb for coal, 18,750 Btu/lb for oil and 24,000 Btu/lb for gas (as methane). Thus, wood residue has significantly lower heat value on a per pound basis than most fossil fuels. The lower heat value generally translates to lower adiabatic flame temperatures, which leads to lower efficiencies of combustion of the carbon content of wood. EPA's AP-42 emission factor document gives, for example, a range of 0.7 to 21 lb CO/ton wood residue, with an average of 6.6 lb/ton (or about 100 to 2900 ppm CO, average 900 ppm CO @3% O₂).

In an NCASI study,³⁴ detailed analysis of CO monitoring data corresponding to three wood-fired boilers representative of recent design and operated in a "normal" manner showed that average CO emissions ranged between 0.18 and 0.50 lb/106 Btu for a 150 hour monitoring period (about 225 to 625 ppm CO at 3% O₂). While a correlation between CO emissions and flue gas oxygen content was observed, high CO emissions resulted when either too little or too much excess air was used. A well-operated biomass boiler will have much higher CO emissions than most fossil fuel-fired boilers, even when optimally operated using good combustion practices.

[Footnote: "Carbon Monoxide Emissions from Selected Combustion Sources Based on Short-Term Monitoring Records," NCASI Technical Bulletin No. 416, January 1984.]

Response: We agree that CO emissions vary with changes in load and fuel quality. For discussion on variability of CO emissions, please see the response to comment EPA-HQ-OAR-2002-0058-3498-A1, excerpt 5. This excerpt may be found in the "CO CEMS as Alternative Standard" section of this comment response document. See also responses to comments EPA-HQ-OAR-2002-0058-3505-A1, excerpts 27, 28, 30, 31, 32, 33, and 37. These excerpts may be found in the CO CEMS "Alternative MACT Floor Using Highest Rolling Average" section of this comment response document. However, the emission limitations do not apply during periods of startup or shutdown, the periods that exhibit the largest magnitude of changes in load. We have also revised the CO CEMS-based emission limitation for Fluidized Bed units combusting biomass or bio-based solid fuels in the final rule. The resultant limit is less stringent than the limit in the December, 2011 proposed reconsideration of the rule. We believe that the exclusion of periods of startup and shutdown and the less stringent limit mitigates any achievability concerns.

Document Control Number: EPA-HQ-OAR-2002-0058-3506-A1

Comment Excerpt Number: 13

Comment: There are some subcategories where proposed carbon monoxide (CO) emissions limits using a 3-hour average measurement are more stringent than the alternative CO CEMS measurements using a 10-day rolling average (notably for biomass suspension burners). This disconnect is indicative of a situation where the subcategories have been parsed too finely and too few data points are available on which to base the standards at this refined level.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3658-A2, excerpt 3.

4H07 - Existing Results: Biomass Suspension/Grate

Commenter Name: David A. Buff, Golder Associates Inc.

Commenter Affiliation: Florida Sugar Industry (FSI)

Document Control Number: EPA-HQ-OAR-2002-0058-3504-A1

Comment Excerpt Number: 31

Comment: The FSI believes that a 10-day rolling average for hybrid suspension grate boilers is not adequate to fully account for the variable nature of these boilers. Bagasse boilers are too highly variable, as discussed at length previously, because of fluctuations in steam load, crop conditions, cane varieties, weather conditions, mill fluctuations, etc., to comply with the proposed 10-day average limit for CO. Given the FSI's experience with the challenges of operating bagasse-fired boilers, the FSI believes the EPA's optional CEMS-based CO limits for hybrid suspension boilers should be based on an averaging time of at least 12 months. This request is supported by the CO data analysis presented below for hybrid suspension grate boilers.

Response: We agree that an averaging period longer than a 10-day rolling average would better account for the inherent variability of CO emissions and operational load swings in industrial boilers and process heaters. We have changed the averaging time for the alternative CO CEMS-based limits to be a 30-day rolling average where the switch was justified by available CEMS

data. We disagree that a 12-month rolling average is necessary for Hybrid Suspension Grate units. As mentioned in other rulemakings (e.g., MATS), we believe that a 30-day averaging period provides flexibility sufficient for sources to operate processes, in this case boilers and process heaters, and control devices to assure ongoing compliance and that the 30-day period provides for the level of environmental protection intended for this rule. The 30-day rolling average requires that the operator review and act on measurement data on at least a daily basis consistent with the enforcement and compliance provisions of the CAA (e.g., CAA section 113(d)). A rolling 12-month average would reduce that frequency to once per month. In addition, a 30-day rolling average is consistent with historical averaging times for this source category. For example, the new source performance standard, subpart Db for industrial, commercial, and institutional boilers in existence for over 25 years, uses 30 days for the rolling emissions averaging period.

Commenter Name: David A. Buff, Golder Associates Inc.

Commenter Affiliation: Florida Sugar Industry (FSI)

Document Control Number: EPA-HQ-OAR-2002-0058-3504-A1

Comment Excerpt Number: 32, 33, 34, 35, 36, 37

Comment: The FSI previously provided EPA with several years of continuous hourly CO data for U.S. Sugar Company's Boiler No. 8, spanning the period October 2007 through March 2010. Boiler No. 8 is a new hybrid suspension grate boiler that was designed to comply with the 2004 Boiler MACT Rule for new sources. The FSI now is submitting additional CO CEMS data for Boiler No. 8, covering the period from March 2010 through December 2011, so that the entire database spans 2007 through 2011. The additional data are attached to this letter. Therefore, with this submittal, EPA will have a database that includes almost four years of operations, which should be more than adequate for EPA to establish a CO CEMS limit that is based on an averaging time of greater than 30 days. It is noted that these data do not include periods of malfunction, which are discussed separately below.

The FSI has analyzed the CO CEMS data for Boiler No. 8 by using the same methodology that EPA used when EPA set its proposed CO CEMS emission limits in the Proposed Boiler MACT Rule, with certain exceptions. EPA's methodology was based on an Upper Prediction Limit (UPL) utilizing a 99 percent confidence level (99% UPL). Because the MACT floor limit is being set based on CO CEMS data from Boiler No. 8, which is the "best performing source" for which EPA has data, a greater allowance should be provided in order to set the MACT floor for new sources. Therefore, FSI has used a 99.9% UPL. Using EPA's same methodology, with 99.9% UPL and the expanded data set, excluding malfunctions, produces the following new source CO limits for various averaging times:

30-day rolling average: 515 ppmvd @ 3% O₂

60-day rolling average: 481 ppmvd @ 3% O₂

90-day rolling average: 466 ppmvd @ 3% O₂

182-day rolling average: 448 ppmvd @ 3% O₂

365-day rolling average: 437 ppmvd @ 3% O₂

Attached is a graph of the rolling average CO concentration for Boiler No. 8 versus time for the 10-day, 30-day and 365-day rolling averages, excluding malfunctions [See submittal for Figure C-1]. This plot compares the boiler's actual performance against the proposed EPA limit of 730 ppmvd @ 3% O₂. As shown, a CO limit based on a 365-day rolling average is much less variable than a 10-day or 30-day rolling average. The data for Boiler No. 8 (the best performing source in the subcategory based on its age and design) demonstrate that the EPA's proposed 10-day rolling average limit would have been exceeded on 79 days over this approximate 4-year period, and even if the limit were based on a 30-day rolling average, 34 exceedances of the limit would have occurred. However, no exceedances of the proposed limit would have occurred based on a 365-day rolling average.

Comparing the graph of 365-day rolling averages to the 99.9% UPL calculations above shows the actual highest 365-day rolling average experienced by Boiler No. 8 was about 510 ppmvd @ 3% O₂. Therefore, the CO limit for new sources should not be set any lower than this value, and preferably would include some safety margin.

The CO CEMS data submitted to EPA for U.S. Sugar Company's Boiler No. 8 are the same data that are reported to the Florida Department of Environmental Protection under the Title V operating permit for Boiler No. 8. It is important to recognize, however, that the data do not include periods of time when the boiler experiences an upset condition (i.e., a malfunction). The exclusion of such periods of time is consistent with current law, which recognizes that malfunctions may occur due to a process upset or other conditions that are beyond the reasonable control of the operator. Upset conditions can occur due to a variety of reasons, including mill stoppages, plugged bagasse feeders in the boiler, bagasse piling up on the boiler grate, etc.

Under EPA's "affirmative defense" provisions in the Proposed Boiler MACT, these upset conditions will have to be included in the CO CEMS averages, because these events occur too frequently to qualify for the proposed affirmative defense for each event. Accordingly, the CO CEMS data for Boiler No. 8 were analyzed with data for the previously excluded events. The results of the additional analyses are also attached to this letter in Appendix C. [See submittal for Appendix C] Analyzing these data in accordance with EPA's methodology, and using the 99.9% UPL, results in the following CO limits, including malfunctions, for the following averaging times:

30-day rolling average: 559 ppmvd @ 3% O₂

60-day rolling average: 518 ppmvd @ 3% O₂

90-day rolling average: 501 ppmvd @ 3% O₂

182-day rolling average: 480 ppmvd @ 3% O₂

365-day rolling average: 467 ppmvd @ 3% O₂

As indicated, these values are only slightly higher than those presented above, which exclude malfunction events.

Attached is a graph of the rolling average CO concentration for Boiler No. 8 versus time for the 10-day, 30-day and 365-day rolling averages, including malfunctions [See submittal for Figure

C-2]. This plot is similar to the preceding data/plot, except that the emissions are somewhat higher due to the malfunctions. The CO data based on a 365-day rolling average is much less variable than a 10-day or 30-day rolling average. The data for Boiler No. 8 demonstrate that the EPA's proposed 10-day rolling average limit would have been exceeded on 117 days over this approximate 4-year period, and if the limit were based on a 30-day rolling average, 82 exceedances of the limit would have occurred. However, no exceedances of the proposed limit would have occurred based on a 365-day rolling average, and the inclusion of malfunctions has very little effect on the 365-day rolling average. Review of the graphs show that malfunctions add about 50 ppmvd @ 3% O₂ to the 365-day rolling average.

To determine an appropriate CO CEMS-based limit for existing sources, some allowance must be made to account for the fact that data is available from only one source- U.S. Sugar Boiler No. 8. EPA's MACT Floor analysis showed that Boiler No. 8 was ranked second within the top 5 sources. Using the test averages from EPA's analysis, Boiler No. 8 averaged 567 ppmvd @ 3% O₂ over all tests, while the average of all boilers in the top 5 was 1,089 ppmvd @ 3% O₂. The ratio of these two results is 1.9. It therefore seems appropriate to adjust the new source MACT floor limit by this ratio, to account for the variability in CO data for all sources ranked in the top 5.

If EPA retains its proposed new source limit of 730 ppmvd, then the existing source CO CEMS limit would be 1,390 ppmvd @ 3% O₂. If some lower new source limit is determined based on the above data, the existing source limit should be derived accordingly.

Response: The corresponding CO CEMS data in the EPA ICR Databases have been given appropriate flags for periods of startup, shutdown, and malfunction (SSM) as denoted by the commenter. The commenter also provided additional CO CEMS data, which have been incorporated into the EPA ICR Databases and factored into the calculation of the alternative CO CEMS-based limit for the Hybrid Suspension Grate subcategory. EPA acknowledges the data analysis submitted by the commenter. For a discussion on the results of this data analysis, please see the response to comment EPA-HQ-OAR-2002-0058-3504-A1, excerpt 31.

For a response to the request for a 365-day rolling average to account for high variability in bagasse-fired boilers, see response to comment EPA-HQ-OAR-2002-0058-3504-A1, excerpt 31.

The CO CEMS variability was calculated using a 99 percent UPL and not a 99.9 percent UPL. The resultant emission limit alternative was based on either the 99 percent UPL or the maximum average of the top 6%, whichever was higher. Specifically for Hybrid Suspension Grate units, the CO CEMS-based alternative emission limit is less stringent for both existing and new sources than in the December, 2011 proposed reconsideration of the rule. We have also changed to a 30-day rolling average in lieu of a 10-day rolling average. EPA believes these changes provide enough flexibility to sources to account for the inherent variability of CO emissions without minimizing the environmental impact of the rule.

For the reasons specified in the preamble to the December 23, 2011 rule notice (76 FR 80598), EPA has retained a 99% UPL in its calculation of both the stack test-based and CEMS-based CO MACT floors. Where justified by available data, EPA elected to lengthen the averaging period to a 30-day rolling average in lieu of a 10-day rolling average. The Hybrid Suspension Grate subcategory was one such subcategory which has been switched to a 30-day rolling average.

EPA agrees with the commenter that the malfunction periods do not qualify for affirmative defense and should be factored into the MACT floor calculation since these flagged 'malfunctions' occur too often. We revised the analysis of the CO CEMS data to include the flagged malfunction periods. The final rule contains the revised emission limits. See also the response to comment EPA-HQ-OAR-2002-0058-3451-A1, excerpt 9. This excerpt may be found in the CO CEMS "Statistical Analysis" section of this comment response document.

The EPA disagrees with the commenter's suggestion to apply a ratio of average stack test data from best performers to the results of a CO CEMS analysis. The datasets for stack test data and CO CEMS data are separate and the EPA does not agree that a ratio of stack test data would be applicable to longer term CO CEMS data in this rulemaking since the stack tests are conducted at consistent loads, whereas the CO CEMS represents emissions over a wide variety of loads and fuel conditions. Further, the EPA has finalized an approach that analyzes the data from the top 12 percent of units that has been made available to the EPA at the time of this rulemaking. Several other units in other subcategories conducted voluntary CO CEMS testing to obtain additional CO CEMS data and the EPA has considered these other data in its analysis. The other units in the hybrid suspension grate subcategory had ample opportunities to submit additional data for the CO CEMS analysis, but no other data was received by the August 8, 2012 cutoff for consideration of additional data for this rulemaking. For more information on the August 8, 2012 deadline, please see the memo titled "Handling and Processing of Corrections and New Data in the EPA ICR Databases – Revised August 2012" in the docket.

Commenter Name: Kevin G. Desharnais, Attorney, Mayer Brown LLP

Commenter Affiliation: United States Sugar Corporation

Document Control Number: EPA-HQ-OAR-2002-0058-3496-A1

Comment Excerpt Number: 9, 10

Comment: A review of the CEMS data submitted by U.S. Sugar for its Boiler Number 8 clearly shows the need for a longer averaging period for demonstrating compliance with the CO CEMS-based limit for bagasse boilers. The monitoring data shows wide swings in 10-day and 30-day rolling averages for both CO and O₂ as a result of changes in operating conditions over time. In contrast, the 12-month rolling average data shows remarkable consistency within a reasonable range of values for both CO and O₂ and presents a more appropriate measure of compliance over time.

In order for the CO CEMS standard to be a viable compliance alternative, a longer averaging time must be allowed. In order to account for the natural variability in emissions over time, we believe that a 12-month rolling average would be more appropriate for bagasse boilers. In the Reconsideration Proposal, EPA notes that it expects to receive additional CEMS data, which "will likely change the CO CEMS floors, and may also result in different averaging times." 76 Fed. Reg. at 80611. U.S. Sugar requests that EPA reconsider the CO CEMS standard and establish a 12-month rolling averaging time applicable to bagasse boilers.

Response: We agree that a longer averaging time is warranted for Hybrid Suspension Grate units combusting biomass or bio-based solid fuels. However, we do not agree that a 12-month rolling average is appropriate. For additional information on the suggested 12-month rolling

average for this subcategory, please see the response to comment EPA-HQ-OAR-2002-0058-3504-A1, excerpt 31.

4H08. Existing Results: Wet Biomass Stoker/Sloped Grate/Other

Commenter Name: Stephen E. Woock

Commenter Affiliation: Weyerhaeuser Company

Document Control Number: EPA-HQ-OAR-2002-0058-3523-A1

Comment Excerpt Number: 5

Comment: We support EPA's decision to propose additional subcategories for CO for biomass units and to provide a longer averaging period limit as an alternative compliance option. The resulting proposed limits are more feasible for specific combustion unit designs by recognizing differences in the biomass fuel moisture characteristics.

However, for our boilers with existing CO CEMS that burn green biomass fuels and would be defined as "wet" biomass stoker units we are concerned with feasibility to demonstrate compliance with the proposed alternative 10-day limit.

Response: The EPA thanks the commenter for their support of additional subcategories for biomass units and a longer averaging period as an alternative compliance option. The CO CEMS-based limits have been revised in the final rule. Based on additional CO CEMS data submitted during the public comment, the CO CEMS-based limit for Stokers/Sloped Grate/Other units designed to combust wet biomass or bio-based solid fuels in the final rule has been revised and the averaging time for this subcategory was also revised to a 30-day (i.e., 720-operating hour) rolling average. The EPA believes the less stringent limit based on a longer averaging period mitigates any concerns on achievability.

Commenter Name: Paul Noe

Commenter Affiliation: American Forest & Paper Association (AF&PA) et al.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 48

Comment: Many biomass boiler operators will be able to utilize the stack test-based CO limits and associated 30-day average oxygen monitoring to comply. However, some of our members with top performing biomass fluidized bed boilers and biomass stoker units equipped with sophisticated combustion controls like over-fired air, cannot say with certainty that they will meet the proposed CO CEMS-based limits 100% of the time. CO emissions vary significantly with changes in load and fuel quality to the point that some of the units on which EPA is relying to set the MACT floors cannot comply all year round.

The burning of wood or wood-derived fuels, by themselves or in combination with other fossil fuels, involves very different combustion conditions than fossil fuel. The same stringent limitations on CO emissions that apply to fossil fuel-fired boilers with good combustion practices are not relevant. The high moisture content typical of most wood-derived fuels necessitates a larger than usual area of refractory surface to dry the fuel before combustion. Sufficient secondary air must be supplied over the fuel bed to burn the volatiles that account for

most of the combustible material in the fuel. However, the air should not be so excessive as to cool the combustion flame.

Wood residue is typically comprised of about 50% moisture and has a heat value of about 4500 Btu/lb (as fired), compared with typical heat values of about 12,000 Btu/lb for coal, 18,750 Btu/lb for oil and 24,000 Btu/lb for gas (as methane). Thus, wood residue has significantly lower heat value on a per pound basis than most fossil fuels. The lower heat value generally translates to lower adiabatic flame temperatures, which leads to lower efficiencies of combustion of the carbon content of wood. EPA's AP-42 emission factor document gives, for example, a range of 0.7 to 21 lb CO/ton wood residue, with an average of 6.6 lb/ton (or about 100 to 2900 ppm CO, average 900 ppm CO @3% O₂).

In an NCASI study,³⁴ detailed analysis of CO monitoring data corresponding to three wood-fired boilers representative of recent design and operated in a "normal" manner showed that average CO emissions ranged between 0.18 and 0.50 lb/106 Btu for a 150 hour monitoring period (about 225 to 625 ppm CO at 3% O₂). While a correlation between CO emissions and flue gas oxygen content was observed, high CO emissions resulted when either too little or too much excess air was used. A well-operated biomass boiler will have much higher CO emissions than most fossil fuel-fired boilers, even when optimally operated using good combustion practices.

Comment Excerpt Number: 1

Comment: Bay Front boilers #1 and #2 were originally designed to burn 100% coal. In the mid-1970s provisions were added to the boilers to allow waste wood to be blended with the coal. By 1979 either boiler was able to be fired entirely on wood, coal or blends of wood and coal. Shredded tires (tire derived fuel or "TDF") were added to the wood fuel mix in the mid-1980s to enhance combustion. Co-firing wood and coal ceased in the late 1990s due to ash fouling and slagging problems caused by file interactions of the fuels and the ash properties of the two fuels. The plant now operates primarily on woody biomass with less than a 2% TDF mixture by volume.

When wood waste was first introduced at the plant, there were no regulations in place requiring the plant to comply with a certain carbon monoxide ("CO") limit. With the passage of Wisconsin's air toxics rule in 1988, the plant was required to demonstrate "good combustion" technology when burning waste wood in order to comply with tile rule. The good combustion technology was determined to be the ability to meet a carbon monoxide limit of 500 parts per million ("ppm") corrected to 7% oxygen ("O₂").

Stack tests of these boilers conducted in May 1991 showed the CO emission level corrected to a dtT basis of 7% O₂ while burning 100% wood waste ranged from 1,533 ppm to 2,869 ppm. The company hired an engineering firm to perform a study to determine how the CO emissions could be reduced while burning 100% wood waste in these boilers. As a result of this study, in the years 1992 through 1994 the company installed side wall overfire air nozzles and modified the front and rear wall overfire air nozzles to improve combustion efficiency. The engineering firm believed a properly designed overfire air system would greatly improve wood combustion and result in CO levels below 500 ppm corrected to 7% O₂.

Stack tests conducted after the overfire air changes in 1994 showed CO emissions averaged 345 ppm @ 7% O₂. In 1995, CO continuous emissions monitors ("*CF~Ms*") were installed on both boilers, so the plant has been continuously monitoring its CO emissions for 17 years and has taken steps over those years to continue to optimize combustion and lower emissions. Today, excluding startup and shutdown, the plant may experience less than 5 hours per year when emissions from the boilers exceed 600 ppm CO @ 7% O₂. These higher levels are primarily due to poor fuel quality and/or switching from wood to coal or coal to wood. Over the past three years (2009 - 2011), CO emissions from these boilers have averaged less than 300 ppm @ 7% O₂.

Response: For a response to the differences between CO emissions from biomass and coal combustion, please see response to EPA-HQ-OAR-2002-0058-3521-A1, Excerpt No. 47. This excerpt may be found in the CO CEMS "Existing Results: Biomass FB" section of this comment response document.

EPA has revised the alternative CO CEMS-based emission limits for all subcategories in the final rule. The resultant limit for Stokers burning wet biomass is less stringent than the alternative CO CEMS-based limit in the December 23, 2011 proposed reconsideration of the rule.

Commenter Name: Richard D. Garber

Commenter Affiliation: Boise Inc.

Comment Excerpt Number: 14

Comment: EPA should address CO emission limit achievability for wet biomass stoker boilers and the compliance averaging time for those units equipped with CO CEMS for compliance demonstration.

Some biomass boiler operators will be able to utilize the stack test-based CO limits and associated 30-day average oxygen monitoring to comply. However, several of Boise's boilers are in the wet biomass stoker design subcategory and are required to monitor compliance with existing Title V air permit limits using CO GEMS due to prior permit actions. These units will be required to *continuously* meet the 10-day average 410 ppm CO limit at 3% O₂. We have two concerns with the standard: 1) the averaging period is likely too short to fully capture seasonal fuel variability and the variability in steam demand that are experienced by load-following boilers typically operated at paper mills; and 2) the 410 ppm limit is too low to be met continuously by all of the units in the MACT floor. Rapid changes in fuel feed rate necessary to

meet changing steam demands, especially during seasonal periods of wet fuel, can cause short-term spiking of CO emissions and generally higher averages than during periods of dry fuel availability. Boise is concerned of reports from several companies that have installed sophisticated combustion controls like over-fired air, but yet still cannot say with certainty that they will meet the proposed 410 ppm CO GEMS-based limits 100% of the time. CO emissions vary significantly with changes in load and fuel quality and seasonal moisture content to the point that some of the units on which EPA is relying to set the MACT floors cannot comply all year round.

Response: For a response to how CO emissions vary with changes in load and fuel quality and seasonal moisture content, as well as concerns over the achievability of the limit, please see response to EPA-HQ-OAR-2002-0058-3521-A1, Excerpt No. 47. This excerpt may be found in the CO CEMS "Existing Results: Biomass FB" section of this comment response document. For a response to overfire air and its benefit as a control for CO emissions, please see response to EPA-HQ-OAR-2002-0058-3682-A2, Excerpt No. 1.

Comment Excerpt Number: 15

Comment: The burning of wood or wood-derived fuels, by themselves or in combination with other fossil fuels, involves very different combustion conditions than fossil fuel. The same stringent limitations on CO emissions that apply to fossil fuel-fired boilers with good combustion practices are not relevant. The high moisture content typical of most wood-derived fuels necessitates a larger than usual area of refractory surface to dry the fuel before combustion. Sufficient secondary air must be supplied over the fuel bed to burn the volatiles that account for most of the combustible material in the fuel. However, the air should not be so excessive as to cool the combustion flame. Wood residue is typically comprised of about 50% moisture and has a heat value of about 4500 Btu/lb (as fired), compared with typical heat values of 12,000 Btu/lb for coal, 18,750 Btu/lb for oil, and about 24,000 Btu/lb for gas (as methane). Thus, wood residue has significantly lower heat value on a per pound basis than most fossil fuels. The lower heat value generally translates to lower adiabatic flame temperatures, which leads to lower efficiencies of combustion of the carbon content of wood. EPA's AP-42 emission factor document gives, for example, a range of 0.7 to 21 lb CO/ton wood residue, with an average of 6.61lb/ton (or about 100 to 2900 ppm CO, average 900 ppm co @3% O₂).

In an NCASI study,⁴ detailed analysis of CO monitoring data corresponding to three wood-fired boilers representative of recent design and operated in a "normal" manner showed that average CO emissions ranged between 0.18 and 0.50 lb/106 Btu for a 150 hour monitoring period (about 225 to 625 ppm CO at 3% O₂). While a correlation between CO emissions and flue gas oxygen content was observed, high CO emissions resulted when either too little or too much excess air was used. A well-operated biomass boiler will have much higher CO emissions than most fossil fuel-fired boilers, even when optimally operated using good combustion practices.

Comment Excerpt Number: 4

Comment: Xcel Energy has reviewed the spread sheet supplied by the United States Environmental Protection Agency ("USEPA") with the data used to calculate the 99% Upper Prediction Limit ("UPL") for CO from Wet Stoker Biomass Boilers and the subsequent limit for CO (Appendix B-8 to CO CEMS MACT Floor Analysis Memorandum)¹. The spread sheet shows approximately 30% of the data coming from the Boise Cascade Wallula plant, which is described in the spread sheet as a co-fired hogged fuel and natural gas boiler

Xcel Energy believes it is inappropriate to include CO data from a wet biomass stoker boiler co-firing natural gas when calculating the 99% UPL and subsequent CO limit for wet biomass stoker boilers not co-firing natural gas or perhaps only topping with natural gas. Controlling combustion air demands in a wet biomass boiler is the greatest challenge to minimizing CO emissions. Wood fuel quality varies more than coal quality. Proper tuning of the automatic combustion controls is more important when firing wood. Operators must pay close attention, and periodically adjust feeders to maintain even fuel distribution and adjust the ratio of overfire to underfire air. Wood combustion requires more excess air and more overfire air than coal combustion. Combustion in a wood fired boiler is not instantaneous. The combustion air cannot be distributed evenly to a solid fuel in the combustion zone. The moisture and heat (BTU) content of the biomass are variables that affect oxygen demand greatly as the fuel is metered into the boiler. This fuel variability causes savings in the combustion air input as boiler control chases the oxygen demand of the fuel. CO formation occurs as oxygen is consumed unevenly and incompletely in the combustion zone. Natural gas co-combustion allows for reducing the variability of the air demand and better distribution of heat in wet biomass combustion, and will reduce the CO formation. Xcel Energy believes that including Boise Cascade Wallula data is perhaps an oversight by the USEPA and requests that the data be removed from this data set.

[Footnote]

(1) ERG Memorandum dated November 2011 to Brian Schrage USEPA, Subject: CO CEMS MACT Floor Analysis for the Industrial, Commercial, and Institutional Boilers and Process Heaters National Emission Standards for Hazardous Air Pollutants - Major Source.

Response: For a response to comments regarding the variability of wet biomass fuel and the corresponding effects on excess air, overfire air, and CO formation, please see response to EPA-HQ-OAR-2002-0058-3521-A1, Excerpt No. 47. This excerpt may be found in the CO CEMS "Existing Results: Biomass FB" section of this comment response document.

EPA acknowledges that CO emissions may be reduced by co-firing natural gas, but disagrees that these data should be removed from consideration in the CO CEMS-based 99% UPL calculation. CEMS data are available for multiple Stokers burning wet biomass, some co-firing natural gas and some combusting 100% biomass fuel. EPA believes that the large amount of data for the subcategory minimizes any effect the lower emissions from co-firing natural gas could potentially have on the 99% UPL.

Commenter Name: Rick Rosvold

Commenter Affiliation: Xcel Energy Services, Inc.

Document Control Number: EPA-HQ-OAR-2002-0058-3682-A2

Comment Excerpt Number: 5

Comment: The Company also looked at individual data points used to establish the limit for this sub-category, and it appears that several were incorrectly included. It appears certain data points were collected when the unit was either offline or burning alternative fuels. CO concentrations below 50 ppm are probably not representative of operations on strictly biomass, but without having more background information on the Sierra Pacific Lincoln facility's operations, we have conservatively excluded only those data points below 10 ppm in the numbers presented below.

Response: EPA disagrees with assuming certain data points represent periods of startup, shutdown, malfunction, or minimal biomass combustion. The data in the EPA ICR Databases reflects the CO CEMS data as reported to EPA. Without actual documentation showing that these low CO emissions correlate to periods of startup, shutdown, malfunction, or minimal biomass combustion, EPA cannot reasonably disregard those data.

Commenter Name: Rick Rosvold

Commenter Affiliation: Xcel Energy Services, Inc.

Document Control Number: EPA-HQ-OAR-2002-0058-3682-A2

Comment Excerpt Number: 6

Comment: Xcel Energy has recalculated the 99% UPL after removing the inappropriate data included from the Wallula facility and 3 data points where the CO concentration was below 10 ppm from the Sierra Pacific Lincoln facility. (EPA used this data to determine the CO concentration limit from CEMS data as 410 ppm CO at 3% O₂). The recalculated 'normal' data calculations deliver a value of 468 ppm CO at 3% O₂ and the 'log normal' calculations present a value of 441 ppm CO at 3% O₂. Xcel Energy believes these are the appropriate values to calculate a CO limit for wet stoker biomass boilers based on the data available. Xcel Energy also suggests that the USEPA consider removing all data below 50 ppm or investigate more thoroughly the operations at the Sierra Pacific Lincoln facility to insure those data below 50 ppm are appropriately included. Xcel Energy encourages the USEPA to use these assumptions when setting the final limit.

Response: For a response to the request to remove all data below 50 ppm, please see response to EPA-HQ-OAR-2002-0058-3682-A2, Excerpt No. 5.

Energy Assessment

5A. Scope of Assessment

Commenter Name: Jessica Bridges

Commenter Affiliation: United States Clean Heat & Power Association (USCHPA)

Document Control Number: EPA-HQ-OAR-2002-0058-3501-A1

Comment Excerpt Number: 12

Comment: EPA proposes to restrict the energy assessment to sources and uses (our terms) on-site. USCHPA questions this. Removing the benefit obtained by reducing electricity purchases can undermine unnecessarily the benefits of CHP installations, especially one-off installations. Unfortunately when CHP is involved, this approach will undervalue the benefit of the CHP system, both in energy savings and in emissions reductions.

As indicated earlier, CHP has off-site benefits because the site doesn't have to buy so much electricity from "away." The energy savings and the CO₂ avoidance in the quotation from Oak Ridge National Laboratory⁵ cited above and referenced in 76 FR, 80606-80620 is based upon avoidance of energy consumption both at the site and away.

[Footnote]

(5) Oak Ridge National Laboratory, Combined Heat And Power, Effective Energy Solutions for a Sustainable Future, December 1, 2008, ORNL/TM-2008/224. P3. ORNL's data cites 1.9 quads of fuel savings and 248 MMTs of CO₂ savings based upon 85GW deployed. The lower numbers represent current estimates based upon 82GW deployed.

Response: We agree that there is a benefit in reducing electricity purchases but the applicability of the rule is limited to boilers and process heaters located at a major source facility.

Commenter Name: Robin Mills Ridgway

Commenter Affiliation: Purdue University

Document Control Number: EPA-HQ-OAR-2002-0058-3668-A2

Comment Excerpt Number: 20

Comment: Further clarification is required to limit the scope of effort relative to the percent of affected boiler(s) and process heater(s) energy output for different size facilities. Specifically, it is unclear how the percentages in the Energy assessment definition are to be applied. Purdue believes that EPA's intentions are to limit the scope of assessment based on energy use by discrete segments of a facility, and not by a total aggregation of all individual energy using elements of a facility, because the latter would be disjointed and unwieldy at best. The applicable discrete segments of a facility could vary significantly depending on the site and its complexity. However, Purdue believes the following addition to the Energy assessment definition in §63.7575 would help resolve current problems and allow for more streamlined assessments:

"...(4) The on-site energy use systems serving as the basis for the percent of affected boiler(s) and process heater(s) energy output in (1), (2), and (3) above may be segmented by production area or energy use area as most logical and applicable to the specific facility being assessed (e.g., product X manufacturing area; product Y drying area; Building Z)."

Response: We agree that the scope of the energy assessment and the on-site energy use system needs clarification. Our intent was to cover within the energy assessment the boiler system and discrete energy use systems. That is, if a boiler is supplying steam heat to several buildings, each building would be considered a discrete and separate energy use system. The definition of "Energy assessment" has been revised as suggested by the commenter to better clarify the meaning of or the extent of an on-site energy use system.

Commenter Name: Russell A. Wozniak

Commenter Affiliation: The Dow Chemical Company

Document Control Number: EPA-HQ-OAR-2002-0058-3449-A1

Comment Excerpt Number: 32

Comment: The definition of Energy Use System should be clarified.

In the preamble, V.H.1, Energy Assessment Scope (p. 80614 of FR), the EPA said the final definition for "Energy Use System" was intended only to list examples of potential systems that may use the energy generated by affected boilers and process heaters. Table 3, item 4(c) was changed to reflect the *inventory* of major energy consuming systems are those from affected boilers and process heaters; but the definition of "**Energy use systems**" does not clearly state the intended scope are only those systems using energy from the affected boilers and process heaters.

A large integrated site can contain many boilers and process heaters serving many energy users. Some of those boilers and process heaters could be excluded per 63.7491, excluded in definition of Boilers (such as Waste Heat Boiler burning natural gas, refinery gas, or other Gas 1), or excluded for some other reason. To clarify that the scope of the Energy Assessment is only limited to energy users associated with affected boilers and process heater, the definition of "Energy Use System" should be modified as recommended below.

Energy use system includes, but is not limited to, process heating; compressed air systems; machine drive (motors, pumps, fans); process cooling; facility heating, ventilation, and air conditioning systems; hot water systems; building envelop; and lighting. Energy use systems are only those systems using energy clearly produced by affected boilers and process heaters.

Response: We agree and the definition of "Energy use systems" is revised as suggested by the commenter.

Commenter Name: Russell A. Wozniak

Commenter Affiliation: The Dow Chemical Company

Document Control Number: EPA-HQ-OAR-2002-0058-3449-A1

Comment Excerpt Number: 33

Comment: EPA's proposal requires that the boiler system and energy use system that accounts for at least 20 percent of the energy output will be evaluated to identify energy savings opportunities if the heat input is greater than 1.0 trillion Btu per year. At larger petrochemical complexes, the energy output from a regulated boiler could be transferred to perhaps a number of individual operating plants that use the energy in the form of steam for distillation columns, reactors, etc. EPA should clarify how to define an Energy Use System for cases where there are multiple users of the utilities. For example, should the owner/operator apply the term Energy use System across a single chemical manufacturing process unit or apply it across a set of process units even if the processes are different? We suggest that the term process unit be considered analogous to the term Energy Use System for this regulation and that industry follow the regulations in individual 40 CFR 63 subparts in order to determine the boundaries of a process unit.

Response: We agree that the term "energy use system" needs clarification. See the response to comment EPA-HQ-OAR-2002-0058-3668-A2, excerpt 20 which indicates how the definition of "Energy assessment" is revised to clarify this issue.

Commenter Name: Paul Noe

Commenter Affiliation: American Forest & Paper Association (AF&PA) et al.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 120

Comment: EPA comment responses indicate that it was EPA's intention to only include within the scope of the energy assessment the equipment and facilities that are associated with energy output from the regulated combustion units. However, the energy use system definition included at 63.7575 still extends beyond that intended scope for facilities which purchase electricity for operation of compressed air systems, machine drive (motors, pumps, fans), process cooling, facility HVAC, building envelop(e), and lighting.

Although we continue to believe that EPA is not justified in its inclusion of this requirement in the Boiler MACT, if the energy assessment is retained as a beyond the floor requirement, the scope should be reduced to the boiler and its auxiliaries.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3449-A1, excerpt 32.

Commenter Name: Robert D. Bessette

Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 113

Comment: The Reconsidered Rule amendment to the scope of the assessment does not cure its illegality, and is arbitrary. In the Preamble, EPA asserts that it revised the requirement to address comments that the scope of the assessment was too broad. However, EPA pared back the scope of the assessment in one minor respect, which does not cure the problem. The assessment as re-proposed in the Reconsideration Rule remains illegally broad. The rule still defines "energy use system(s)" to include without limitation, process heating & cooling, in addition to boiler systems, machine drives, HVAC, and lighting. Further, the proposed amendment creates a division among

affected sources that arbitrarily imposes a greater burden on facilities with peripheral power demand supplied by energy made onsite than on facilities that rely more heavily on purchased power.

The rule continues to define energy assessment to include "energy use system(s)." 76 FR 80651. EPA now proposes to cover only "energy use systems that are under the control of the owner/operator." 76 Fed. Reg. 80664.

EPA proposes to amend this definition because, as EPA explains, it did not intend the scope of energy assessments to include "energy use systems using electricity purchased from an off-site source" nor "energy use systems located off-site." 76 Fed. Reg. 80664. EPA excludes them because EPA concludes they are inconsistent with its intent to cover systems that are directly related to the emissions of the regulated boiler. CIBO agrees they should not be covered by this rule, nor should any of the other energy using systems that continue to be covered by the rule.

Energy use systems located off-site and systems that run on purchased power should never have been covered by the rule, because the source category and emission source is the boiler. Although EPA appears to concur that scope is a concern, in fact EPA selectively addresses the comments, focusing only on the systems off-site and running on purchased power. EPA does not address the other more fundamental concern, relating to all other systems still covered by the rule.

While the scope of the covered energy use systems should certainly be narrowed, EPA's proposed exclusion of systems that run on purchased power creates an arbitrary distinction among efficiency measures at a facility based on the source of power. There is no logic to requiring a more reaching assessment of energy systems by sources that depend more heavily power produced onsite than by sources that purchase power. EPA's logic – the sole basis of this regulatory requirement – is that reduced energy demand = less fuel used = lower emissions from the combustion source. It matters little whether the power is produced by a utility or by an industrial boiler, if EPA rationally applies its reasoning to regulatory requirements. In addition, it is not always apparent what the source of the power is for any individual energy-consuming system at a facility. As EPA has made clear, the goal is "to reduce the facility energy demand which would result in reduced fuel use." 76 Fed. Reg. 15,573. While CIBO supports EPA's narrowing the scope of the energy assessment, the current definition remains over-broad and lacking in record support and legal authority.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3449-A1, excerpt 32 for a response on definition and clarification of "energy use system(s).

See the response to comment EPA-HQ-OAR-2002-0058-3501-A1, excerpt 12 for a response on clarification of energy use systems located off-site.

Commenter Affiliation: Occidental Chemical Corporation (OCC)

Document Control Number: EPA-HQ-OAR-2002-0058-3477-A1

Comment Excerpt Number: 10

Comment: OCC fully supports the clarification of the scope of the required energy assessments. This includes the final definition for “Energy use system,” which is intended to clearly limit the scope of the energy assessment to equipment that is located on-site and associated with the affected boilers and process heaters.

Response: The EPA thanks the commenter for their support.

Commenter Name: David A. Buff, Golder Associates Inc.

Commenter Affiliation: Florida Sugar Industry (FSI)

Document Control Number: EPA-HQ-OAR-2002-0058-3504-A1

Comment Excerpt Number: 45

Comment: EPA’s definition of an "energy use system" in Section 63.7575 is very broad and includes "machine drive (motors, pumps, fans), process cooling, facility heating, ventilation, and air-conditioning systems; hot water systems; building envelope; and lighting." 76 F.R. 80651. It is not appropriate to include energy assessment requirements in the Proposed Boiler MACT, but if the energy assessment is retained by EPA as a beyond-the-floor requirement, the scope of the energy assessment should be reduced to only include the boiler and its auxiliary components. Facilities and systems such as heating, ventilation, and air conditioning systems, hot water systems, the building envelope, and lighting, should be removed from the scope of any energy assessment.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3449-A1, excerpt 32.

Commenter Name: Felix Mestey, on behalf of Donald R. Schregardus

Commenter Affiliation: Clean Air Act Services Steering Committee, Department of Defense (DoD)

Document Control Number: EPA-HQ-OAR-2002-0058-3427

Comment Excerpt Number: 6

Comment: EPA should further clarify the equipment that must be included in the energy assessment. In some places, the rule refers to conducting the assessment on the boiler system (§63.7575), and in other places there are references to conducting the assessment on the entire facility (Table 3 to Subpart DDDDD), which implies that the assessment needs to include all energy consuming activities. EPA should clarify the parts of the boiler and energy use systems and facilities that are to be included in the energy assessment. This uncertainty could result in affected facilities expending unnecessary technical hours and incurring unnecessary costs due to ambiguity in the scope of the energy assessments. DoD believes that the scope should be limited to the boiler and process heater systems and only those energy use systems that are directly connected and served by the boiler and process heater systems.

Recommendation:

Revise §63.7500(c) and the "*if your unit is...*" column for requirement 4 in Table 3 to Subpart DDDDD to clarify that the energy assessment is not applicable to limited-use units or small units as follows:

§63.7500 (c) Limited-use boilers and process heaters must complete a biennial tune-up as specified in § 63.7540. They are not subject to the emission limits in Tables 1 and 2 to this subpart, the annual tune-up or the energy assessment requirements in Table 3 to this subpart, or the operating limits in Table 4 to this subpart. ~~Major sources that have limited-use boilers and process heaters must complete an energy assessment as specified in Table 3 to this subpart if the source has other existing boilers subject to this subpart that are not limited-use boilers.~~

(d) Boiler and process heaters systems with a rated capacity of less than 5 MMBtu/hr are not subject to the energy assessment requirement in Table 3 to this subpart.

Table 3 to Subpart DDDDD, "if your unit is..." column, requirement 4 as proposed: An existing boiler or process heater located at a major source facility, except for limited-use units and units with a rated capacity of less than 5 MMBtu/hr.

Revise the definition of "boiler system" in §63.7575 so that it only includes the boilers and those components directly connected and serving "energy use systems."

Boiler system means the boiler and associated components, such as, the feed water system, the combustion air system, the fuel system (including burners), blowdown system, and combustion control systems directly connected and serving the~~and~~-energy ~~consuming~~ use systems.

Revise the energy assessment requirement in the "You must meet the following..." column of Table 3 to Subpart DDDDD as follows. Most of the changes shown in ~~strikeout~~ are to make the requirements more consistent with the area source rule. The changes shown in ~~bold strikeout~~ will further clarify the intended scope of the energy assessments since the term "facility" could be interpreted much broader than the affected units.

Must have a one-time energy assessment performed ~~on the major source facility~~ by a qualified energy assessor. An energy assessment completed on or after January 1, 2008, that meets or is amended to meet the energy assessment requirements in this table, satisfies the energy assessment requirement. The energy assessment must include:

- a. A visual inspection of the boiler or process heater system.,
- b. An evaluation of operating characteristics of the ~~facility boiler or process heater systems~~, specifications of energy using systems, operating and maintenance procedures, and unusual operating constraints,
- c. An inventory of major energy ~~consuming~~ use systems consuming energy from affected boilers and process heaters and which are under the control of the boiler/process heater owner/operator.,
- d. A review of available architectural and engineering plans, facility operation and maintenance procedures and logs, and fuel usage,
- e. A review of the facility's energy management practices and ~~provide~~ recommendations for improvements consistent with the definition of energy management practice, if identified,
- f. A list of major energy conservation measures that are within the facility's control,

g. A list of the energy savings potential of the energy conservation measures identified, and h. A comprehensive report detailing the ways to improve efficiency, the cost of specific improvements, benefits, and the time frame for recouping those investments.

Response: Our intent was to limit the scope of the energy assessment to boilers and process heaters affected by the rule and only those energy use systems that are directly connected on-site and served by the affected boiler and process heater. We did not intend to include limited-use units within this scope. We have revised §63.7500(c) as suggested by the commenter. We disagree with the comments that units less than 5 MMBtu/hr should not be included in the energy assessment. The commenter provides no explanation for its recommendation that such units be excluded. We have revised Table 3 and the definition of "Boiler system" to better clarify the scope of the energy assessment.

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 110

Comment: EPA makes clear in the proposed Reconsidered Rule that the definition of "energy use system" is a non-exclusive list of examples of systems that a source may be required to include in its energy assessment. 76 Fed. Reg. 80,651. EPA emphasizes the open-endedness of this requirement in response to a comment, stating that the definition of "energy use system" is "intended only to list examples of potential systems that may use the energy generated by affected boilers and process heaters." 76 Fed. Reg. 80,615. Therefore, as broadly as "energy use system" is already defined, as applied to specific sites, the assessment requirement could be even broader.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3449-A1, excerpt 32.

Document Control Number: EPA-HQ-OAR-2002-0058-3659-A2

Comment Excerpt Number: 11

Comment: Under the final rule, the affected sources are "all existing industrial, commercial, and institutional boilers and process heaters" and "each new or reconstructed industrial, commercial, or institutional boiler or process heater."¹⁵ A process heater is defined as "an enclosed device using controlled flame, and the unit's primary purpose is to transfer heat indirectly to a process material (liquid, gas, or solid) or to a heat transfer material for use in a process unit, instead of generating steam."¹⁶ A boiler is defined as "an enclosed device using controlled flame combustion and having the primary purpose of recovering thermal energy in the form of steam or hot water."¹⁷

The affected source (*i.e.*, the process heater or boiler) clearly does not encompass the "boiler system" or "energy use systems" located at the major source. The fact that "including all of the energy using systems in the energy assessment can result in decreased fuel use"¹⁸ does not remedy this defect. For example, EPA's definition of "boiler system" includes "the boiler *and*

associated components, such as, the feedwater system, the combustion air system, the fuel system (including burners), blowdown system, combustion control system, and energy consuming systems."¹⁹ Similarly, the "energy use system" includes "process heating; compressed air systems; machine drive (motors, pumps, fans); process cooling; facility heating, ventilation, and air conditioning systems; hot heater systems; building envelop; and lighting."²⁰ Both the "boiler system" and "energy use system" by definition include components outside the boiler and process heater.

Accordingly, § 112 does not provide EPA with the authority to promulgate a requirement to conduct an energy assessment on energy use systems or parts of the "boiler system" that do not consist of the boiler or process heater, because such systems are not sources in the listed source category.

Comment: EPA has authority to regulate HAP emissions from major sources under section 112(d) of the Clean Air Act. This attempt to further regulate the way major sources consume energy under this rule is beyond EPA's authority. EPA should eliminate its definitions of "boiler system" and "energy use system". EPA should further limit the scope of energy assessments to "boiler(s)" and "process heater(s)" as currently defined.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3449-A1, excerpt 32.

Commenter Name: Allison Watkins, Baker Botts

Commenter Affiliation: Class of '85 Regulatory Response Group

Document Control Number: EPA-HQ-OAR-2002-0058-3608-A1

Comment Excerpt Number: 12

Comment: The Class of '85 requests that EPA eliminate the requirement that facilities complete a one-time energy assessment to identify cost-effective energy conservation measures for the boiler system and its energy use systems located at the source. EPA does not have the authority

under § 112 to go beyond the sources listed in a source category and impose requirements on other aspects of a facility.

EPA is a federal agency; it has no constitutional or common law existence or authority, but only the authority conferred upon it by Congress. “If there is no statute conferring authority, a federal agency has none.” Section 112 of the Act is designed to limit HAP emissions from specific emission units that are listed under § 112(c)(1). EPA is required to promulgate “emissions standards under subsection (d)” for each category and subcategory listed under § 112(c)(1). The methodology for establishing emissions standards for each source category is laid out in § 112(d); it authorizes the Agency to promulgate “[e]missions standards...*applicable to new or existing sources.*” Under the final rule, the affected sources are “all existing industrial, commercial, and institutional boilers and process heaters” and “each new or reconstructed industrial, commercial, or institutional boiler or process heater.” A process heater is defined as “an enclosed device using controlled flame, and the unit’s primary purpose is to transfer heat indirectly to a process material (liquid, gas, or solid) or to a heat transfer material for use in a process unit, instead of generating steam.” A boiler is defined as “an enclosed device using controlled flame combustion and having the primary purpose of recovering thermal energy in the form of steam or hot water.”

The affected source (*i.e.*, the process heater or boiler) clearly does not encompass the “boiler system” or “energy use systems” located at the major source. The fact that “including all of the energy using systems in the energy assessment can result in decreased fuel use” does not remedy this defect. For example, EPA’s definition of “boiler system” includes “the boiler *and associated components*, such as, the feedwater system, the combustion air system, the fuel system (including burners), blowdown system, combustion control system, and energy consuming systems.” Similarly, the “energy use system” includes “process heating; compressed air systems; machine drive (motors, pumps, fans); process cooling; facility heating, ventilation, and air conditioning systems; hot heater systems; building envelop; and lighting.” Both the “boiler system” and “energy use system” by definition include components outside the boiler and process heater. Accordingly, § 112 does not provide EPA with the authority to promulgate a requirement to conduct an energy assessment on energy use systems or parts of the “boiler system” that do not consist of the boiler or process heater, because such systems are not sources in the listed source category.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3449-A1, excerpt 32 for the definition of Energy Use Systems.

See the response to comment EPA-HQ-OAR-2002-0058-3427, excerpt 6 for energy assessment requirements for boilers and process heaters.

Document Control Number: EPA-HQ-OAR-2002-0058-3427

Comment Excerpt Number: 4

Comment: EPA should consider excluding limited-use units from the energy assessment requirement, as their energy usage seems insignificant when compared to the energy used by all the other non-limited-use units. For example, in the case of Arnold AFB, the large limited-use process heaters have been historically used less than 200 hours per year. The fact that these units are only used for a relatively low number of hours per year would make the preparation of an energy assessment expensive with little environmental benefit (i.e., an insignificant decrease in HAP emissions). Revise §63.7500(c) and the "if your unit is..." column for requirement 4 in Table 3 to Subpart

DDDDD to clarify that the energy assessment is not applicable to limited-use units or small units as follows:

§63.7500 (c) Limited-use boilers and process heaters must complete a biennial tune-up as specified in § 63.7540. They are not subject to the emission limits in Tables 1 and 2 to this subpart, the annual tune-up or the energy assessment requirements in Table 3 to this subpart, or the operating limits in Table 4 to this subpart. ~~Major sources that have limited-use boilers and process heaters must complete an energy assessment as specified in Table 3 to this subpart if the source has other existing boilers subject to this subpart that are not limited use boilers.~~

(d) Boiler and process heaters systems with a rated capacity of less than 5 MMBtu/hr are not subject to the energy assessment requirement in Table 3 to this subpart.

Table 3 to Subpart DDDDD, "if your unit is..." column, requirement 4 as proposed: *An existing boiler or process heater located at a major source facility, except for limited-use units and units with a rated capacity of less than 5 MMBtu/hr.*

Response: See the response to comment EPA-HQ-OAR-2002-0058-3427, excerpt 6.

Document Control Number: EPA-HQ-OAR-2002-0058-3427

Comment Excerpt Number: 5

Comment: Federal facilities, and in particular DoD installations, tend to be located on large tracts of land with numerous small buildings, which may be served by small boiler systems. For example, one AFB is located in three large counties, and has approximately 193 small units all with a capacity of less than 5 MMBtu/hr. Conducting an energy assessment for these boiler systems would be very time-consuming with little environmental benefit. These boilers at major sources are subject to tune-ups every 5 years regardless of fuel used. DoD recommends that smaller units be excluded from the energy assessment since each covered unit would likely require a site visit. The area source rule excludes units with a capacity of less than 10 MMBtu/hr from the energy assessment requirement. EPA should consider a similar exclusion in the major source rule, perhaps 5 MMBtu/hr, to improve the cost effectiveness of the energy assessment requirement.

Table 3 to Subpart DDDDD, "if your unit is..." column, requirement 4 as proposed: *An existing boiler or process heater located at a major source facility, except for limited-use units and units with a rated capacity of less than 5 MMBtu/hr.*

Document Control Number: EPA-HQ-OAR-2002-0058-3518-A1
Comment Excerpt Number: 5

Comment: We urge EPA to exempt "limited use" boilers from the energy assessment requirement. The energy assessment is projected by EPA to cost tens of thousands of dollars to complete. The ultimate impact on HAPs emissions, which EPA has already stated in most cases is either at or below the detection limit of the test method, will be miniscule.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3427, excerpt 6.

Commenter Name: Paul G. Page
Commenter Affiliation: AK Steel Corporation
Document Control Number: EPA-HQ-OAR-2002-0058-3457-A2
Comment Excerpt Number: 15

Comment: AK Steel remains uncertain as to what EPA's expectations are for the Energy Assessment. Specifically, AK Steel is unclear as to how these assessments are to be performed and what is supposed to be achieved. For example, one of our facilities is subject to this requirement based on a natural gas-fired process heater in a coating line operation being the only affected source. EPA needs to further clarify the Energy Assessment requirements for this facility, if these requirements remain in the final rule, because we see no valid reason to conduct an energy assessment for a coating line process heater nor do we see a valid reason to conduct a facility-wide energy assessment because the facility is subject to the rule as a result of a process heater.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3427, excerpt 6.

Commenter Name: Alicia Meads
Commenter Affiliation: National Association of Manufacturers (NAM)
Document Control Number: EPA-HQ-OAR-2002-0058-3515-A1
Comment Excerpt Number: 18

Comment: The NAM continues to believe that the EPA's proposed energy assessment requirements are unwarranted. Further, although the EPA has indicated that it is limiting the scope of its energy assessment requirements, the NAM believes that the measures still exceed the scope of the EPA's authority. Section 112(d) of the Clean Air Act is focused entirely on regulation of "sources." It requires the EPA to set emissions standards that are "applicable to new or existing sources" § 112(d)(2). Thus, it reaches no further than the specific "sources." The "affected source" regulated by this NESHAP is the specified emission unit – boilers – not any

other portions of the plant. Thus, if the EPA retains the energy assessment requirements, they should be clearly limited to addressing only the boiler and auxiliaries.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3427, excerpt 6.

Comment Excerpt Number: 80

Comment: The definition of energy assessment proposed in this reconsideration, while improved from the language in the Final Boiler Rule, continues to be too broad because it appears to establish obligations beyond the boiler or process heater source. The rule states that an energy assessment, or audit, is an in-depth energy study identifying all energy conservation measures appropriate for a facility given its operating parameters. It leads to the reduction of emissions of pollutants through process changes and other efficiency modifications. The purpose of an energy assessment is to identify energy conservation measures (such as process changes or other modifications to the facility) that can be implemented to reduce the facility energy demand which would result in reduced fuel use. EPA is requiring that the energy assessment be conducted by energy professionals and/or engineers that have expertise that covers all energy using systems, processes, and equipment. The broad definition of the scope of an energy assessment is unreasonable. The language attempts to include equipment and systems far beyond the intent of the "Industrial, Commercial and Institutional Boilers and Process Heaters" rule. In its definitions, EPA correctly defines a "Boiler" and a "Process heater" to refer to enclosed devices containing a controlled flame that are used to recover heat. However, EPA attempts to vastly expand the scope of this rule in its definition of a "Boiler system" by including the term "energy use systems." This expansion in scope is reinforced in EPA's choice of language describing the scope of energy assessments to include modifications to the facility. The expansion in scope is further reinforced by implication that those conducting the energy assessments should have expertise that covers all energy using systems.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3427, excerpt 6 and comment EPA-HQ-OAR-2002-0058-3449-A1, excerpt 32.

Document Control Number: EPA-HQ-OAR-2002-0058-3496-A1
Comment Excerpt Number: 4

Comment: While the energy assessment requirement should be eliminated in its entirety, to the extent the requirement is retained, the scope of the assessment as currently proposed remains significantly overbroad, potentially encompassing every energy-using piece of equipment at a regulated facility. The scope of the energy assessment as currently proposed extends far beyond the reasonable limits of what is properly considered the regulated source, *i.e.*, the regulated boiler or process heater. This attempt to expand the reach of the NESHAP regulations to such a wide array of equipment is well beyond EPA's authority to regulate hazardous air pollutants under the Section 112 rulemaking process. Any requirement to perform an energy assessment should be limited to the regulated source.

EPA should reconsider its mandatory energy assessment and eliminate the provision. To the extent the requirement to perform an energy assessment is retained, the scope of the energy assessment should be limited to the boiler or process heater constituting the regulated source.

Comment Excerpt Number: 23

Comment: While the proposed rule is clear that boilers and process heaters regulated under another MACT standard are not subject to Subpart DDDDD, including the energy assessment requirement, it is not clear that an energy use system that is regulated under another MACT standard is not subject to the energy assessment requirement. From a practical standpoint, there is nothing to gain by including such energy use systems in the energy assessment, because these energy use systems will be, in most cases, specifically engineered to comply with the other

MACT standard and cannot be improved or altered without affecting compliance. In the interest of clarity and consistency, the VI requests that EPA revise the energy assessment requirement to clearly exempt these energy use systems.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3427, excerpt 6.

Commenter Name: Lisa Barry

Commenter Affiliation: Chevron Corporation

Document Control Number: EPA-HQ-OAR-2002-0058-3687-A2

Comment Excerpt Number: 5

Comment: EPA is vastly expanding the scope of this rule in its definition of "boiler system" to include "energy use systems." Energy use in most manufacturing plants is related to the processes being used. The sweeping language exceeds EPA's authority by essentially requiring an evaluation and potential redesign of manufacturing systems, many of which are proprietary. Also, energy assessment and management system regulations are excessively costly and burdensome for the little air toxic benefit that will result, especially for gas-fired units. However, if EPA proceeds with this requirement, it must limit the scope of energy assessments to "boilers" and "process heaters" as currently defined.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3427, excerpt 6.

Comment: If EPA continues with this broad scope of coverage for the energy assessment, further clarification is required to limit the scope of effort relative to the percent of affected boiler(s) and process heater(s) energy output for different size facilities. Specifically, it is unclear how the percentages in the Energy assessment definition are to be applied. CIBO believes that EPA's intentions are to limit the scope of assessment based on energy use by discrete segments of a facility, and not by a total aggregation of all individual energy using elements of a facility, because the latter would be disjointed and unwieldy at best. The applicable discrete segments of a facility could vary significantly depending on the site and its complexity. However, CIBO believes the following addition to the Energy assessment definition in 63.7575 would help resolve current problems and allow for more streamlined assessments:

"(4) the on-site energy use systems serving as the basis for the percent of affected boiler(s) and process heater(s) energy output in (1), (2), and (3) above may be segmented by production area or energy use area as most logical and applicable to the specific facility being assessed (e.g., product X manufacturing area; product Y drying area; building Z)."

Commenter Name: Bruce A. Steiner

Commenter Affiliation: American Coke and Coal Chemical Institute (ACCCI)

Document Control Number: EPA-HQ-OAR-2002-0058-3547-A2

Comment Excerpt Number: 12

Comment: EPA cannot impose requirements that reach beyond the defined source category. Section 112(c) establishes the scope of regulation under §112 by requiring EPA to publish "a list of all categories and subcategories of major sources and area sources" for which "the Administrator shall establish emissions standards under subsection (d)." CAA §§112(c)(1) and (2), respectively. Pursuant to that requirement, EPA published a discrete list of major and area source categories. See 70 FR at 37824; see also 67 FR at 70428. Thus, that list of source categories sets both the maximum and minimum scope of EPA's regulatory authority to "establish emissions standards under subsection (d)."

The Reconsidered Rule explicitly states that the source categories affected by these rules are industrial, institutional, and commercial boilers and process heaters located at a major source. Section 112 does not authorize EPA to promulgate regulations affecting sources beyond those

specifically listed. Rather, as the legislative history confirms, “MACT standards shall be focused on a specific portion of a contiguous facility.... The entity covered by MACT would be defined at proposal of the standards.” (emphasis added). A Legislative History of the Clean Air Act Amendments of 1990, 1990 CAA Leg. Hist. 731, 866. Thus, this rulemaking under CAA §112(d) only extends to the “specific portion” of the facilities identified in EPA’s list under §112(c) and can go no further.

Response: We disagree that the energy assessment should be limited to only the boiler and associated equipment. The EPA has properly exercised the authority granted to it pursuant to CAA section 112(d)(2) which states that “Emission standards promulgated * * * and applicable to new or existing sources shall require the maximum degree of reduction in [HAP] emissions that the Administrator determines * * * is achievable * * * through application of measures, processes, methods, systems or techniques including, but not limited to measures which * * * reduce the volume of, or eliminate emissions of, such pollutants through process changes, substitution of materials or other modifications * * *.” The energy assessment requirement is squarely within the scope of this authority. The purpose of an energy assessment is to identify energy conservation measures (such as process changes or other modifications to the facility) that can be implemented to reduce the facility energy demand from the affected boiler, which would result in reduced fuel use. Reduced fuel use will result in a corresponding reduction in HAP, and non-HAP, emissions from the affected boiler.**Commenter Name:** Shannon S. Broome
Commenter Affiliation: Auto Industry Forum (AIF)
Document Control Number: EPA-HQ-OAR-2002-0058-3512-A1
Comment Excerpt Number: 48

Comment: As conveyed in the reconsideration proposal, the energy assessment requirement creates uncertainty in the regulated community, including AIF members, as to how to effectuate it, including with respect to the following issues:

- Are facilities supposed to conduct the assessment as to individual boilers or as to the facility as a whole? The reconsideration proposal appears to suggest that facilities should conduct the assessment on an individual boiler basis; however, Table 3 creates confusion as to the scope because it mixes references to boilers and process heaters in the singular and the collective, and it refers to the assessment being conducted "on" the facility as opposed to "at" the facility.³² *Id.* at 80,664.

[Footnote 32: Moreover, Table 3, in listing the requirements of the assessment, refers to an evaluation of the "specification of *energy using systems*," *id.*, 76 Fed. Reg. at 80,664 (emphasis added), which is an undefined term, although it is similar to the defined term, "energy use systems." EPA should clarify what it means by the phrase, "energy using systems" or revise the phrase to refer to the defined term "energy use systems."

Comment Excerpt Number: 20

Comment: EA Scope pertains to boiler, and not facility-wide.

NC DAQ concurs with this clarification. However, NC DAQ also recognizes the advantages that facilities may gain from facility-wide energy assessments by examining where and how energy efficiency measures may reduce overall energy requirements and overall emissions.

Response: The EPA thanks the commenter for their support.

Commenter Name: Michael Bradley

Commenter Affiliation: The Clean Energy Group

Document Control Number: EPA-HQ-OAR-2002-0058-3495-A1

Comment Excerpt Number: 2

Comment: The Clean Energy Group has long agreed that promoting efficiency is a key emissions-reduction strategy across a wide variety of pollutants, including HAPs. However, not clearly defining the scope of the assessment could inadvertently apply the requirement to the entire facility and unrelated systems, which would be complicated, time-consuming, and likely involve equipment outside EPA's NESHAP jurisdiction (such as at nuclear facilities). Therefore, in our comments on the proposed rules, we requested that EPA clarify that the process for and scope of the energy assessment is limited to the boiler unit and associated systems and controls, and does not include an in-depth assessment of the entire facility and unrelated systems. We support EPA's proposed revisions to clarify the scope of the assessment to ensure it is not overly broad.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3668-A2, excerpt 20.

Commenter Name: Holly R. Hart

Commenter Affiliation: United Steel Workers (USW)

Document Control Number: EPA-HQ-OAR-2002-0058-3498-A1

Comment Excerpt Number: 6

Comment: USW notes EPA now proposes as described at page 80602 that for each affected boiler the operator will have to comply with a beyond-the-floor requirement of a onetime energy assessment. Also noted is that EPA is proposing as described at page 80602 a systematic set of definitions of the requirements operators of eligible units will need to meet to be in compliance with the work practice standards proposed.

Response: The term "operator" as used in the rule, refers to the company that owns or operate the facility, and not to the individual actually operating the piece of equipment.

Commenter Name: Pat Dennis

Commenter Affiliation: Archer Daniels Midland Company

Document Control Number: EPA-HQ-OAR-2002-0058-3670-A2

Comment Excerpt Number: 12

Comment: While the scope of the covered energy use systems should certainly be narrowed, EPA's proposed exclusion of systems that run on purchased power creates an arbitrary distinction among efficiency measures at a facility based on the source of power. There is no logic to requiring a more reaching assessment of energy systems by sources that depend more heavily upon power produced onsite than by sources that purchase power. In addition, it is not always apparent what the source of the power is for any individual energy-consuming system at a facility. As EPA has made clear, the goal is to reduce the facility energy demand which would result in reduced fuel use. While ADM supports EPA's narrowing the scope of the energy assessment, the current definition remains over-broad and lacking in record support and legal authority.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3547-A2, excerpt 12.

Commenter Name: David A. Buff, Golder Associates Inc.

Commenter Affiliation: Florida Sugar Industry (FSI)

Document Control Number: EPA-HQ-OAR-2002-0058-3504-A1

Comment Excerpt Number: 46

Comment: The FSI also respectfully requests EPA to clarify what the operator is obligated to do after the energy assessment is completed. Specifically, EPA should confirm that a facility owner or operator is not obligated to implement any of the recommendations contained in the energy assessment report. At present, the Proposed Boiler MACT Rule requires the preparation of a report and recommendations, but the Proposed Boiler MACT Rule does not state whether any of the recommendations must be implemented. See Table 3 at 76 F.R. 80664.

Response: The rule does not state, or imply, that the findings of the energy assessment must be implemented. However, EPA expects that facilities will implement most or all of the measures identified in the energy assessment, based on the cost savings that will result from implementing

those measures. The rule does allow in 63.7533 a source to take credit for implementing any measures identified in an energy assessment if the source elects to comply with the alternative output-based emission limits.

Comment: If the energy assessment is finalized, energy assessor qualification requirements must be generalized. Proposed §63.7575 defines qualified energy assessor as follows.

Qualified Energy Assessor means:

(1) Someone who has demonstrated capabilities to evaluate energy savings opportunities for steam generation and major energy using systems, including, but not limited to:

(i) Boiler combustion management.

(ii) Boiler thermal energy recovery, including

(A) Conventional feed water economizer.

(B) Conventional combustion air preheater, and

(C) Condensing economizer.

(iii) Boiler blowdown thermal energy recovery.

(iv) Primary energy resource selection, including

(A) Fuel (primary energy source) switching, and

(B) Applied steam energy versus direct-fired energy versus electricity.

(v) Insulation issues.

(vi) Steam trap and steam leak management.

(vii) Condensate recovery.

(viii) Steam end-use management.

(2) Capabilities and knowledge includes, but is not limited to:

(i) Background, experience, and recognized abilities to perform the assessment activities, data analysis, and report preparation.

(ii) Familiarity with operating and maintenance practices for steam or process heating systems.

(iii) Additional potential steam system improvement opportunities including improving steam turbine operations and reducing steam demand.

(iv) Additional process heating system opportunities including effective utilization of waste heat and use of proper process heating methods.

(v) Boiler-steam turbine cogeneration systems.

(vi) Industry specific steam end-use systems.

There are at least two major problems with this definition. First, as written, this definition requires a single person to have all of the capabilities and experience listed. Such a person likely does not exist. For instance, people who specialize in boiler combustion management will likely have no experience with condensate recovery or industry specific steam end use systems. If instead of a single person, the definition is meant to apply to a team (as most energy assessments require) that is not reflected in the time, burden or cost estimates used for this rule. Secondly, the definition requires expertise and experience that will not be needed for most assessments. For instance, most facilities do not have boiler-steam turbine cogeneration systems, yet under this definition they cannot employ an assessor who lacks that experience. Similarly, the definition requires a boiler expert even if only process heaters (or mostly process heaters) are to be assessed and a process heater expert even if the facility only has boilers.

The wording of the proposed definition is also unclear that the qualified energy assessor(s) may be a company employee. Many companies employ specialists in combustion who have the appropriate expertise and we believe it is critical that the definition be clear that those employees may serve in this function.

Since every facility is different and every engineer's experience is different, it is impractical, arbitrary, and unreasonable to list specific experience and training requirements. We therefore, recommend the definition of qualified energy assessor be revised to the following.

Qualified Energy Assessor or Assessors means a person or persons who have demonstrated capabilities to evaluate energy savings opportunities for steam generation, process heat, and major steam and process heat using systems, as applicable to the facility. Qualified energy assessors may be company employees or outside specialists.

Response: We disagree that the definition of "Qualified energy assessor" is unclear and needs clarification. We realize that every facility is different and that it is impractical to require a single person to have all of the capabilities and experience listed to conduct an assessment of a simple heating boiler system. The term "Someone" is not intent to mean a single person. For more complicated boiler/energy use systems or facilities with multiple boilers, a group, such as a consulting firm or a company's engineering staff, with the needed expertise could perform the required engineering assessment. The definition is intended to indicate that the "someone" a facility employs to conduct the energy assessment should have the background, experience, and expertise to evaluate energy savings opportunities for the types of boiler/energy use systems located at the particular facility. The definition is not intended to imply that the any energy assessment, no matter how simple, can only be conducted by a person with expertise in all the issues listed in the definition. Basically, the definition is stating that a person is qualified to conduct an energy assessment if they have the needed experience and background in conducting

an energy assessment for a particular situation. For a particular boiler/energy system, a company employee may have the background, experience, and abilities to perform the assessment and prepare the report.

Comment Excerpt Number: 3

Comment: If the energy assessment requirement is finalized, the Table 3 Item 4 allowance for use of past energy assessments, must be amended to waive energy assessor approval and qualifications requirements.

Proposed Item 4 of Table 3 lists the elements that must be addressed in the energy assessment. In the introductory paragraph it states "An energy assessment completed on or after January 1, 2008, that meets or is amended to meet the energy assessment requirements in this table, satisfies the energy assessment requirement." However, to be acceptable an energy assessment must have been performed by an assessor approved by the Administrator and that assessor or team of assessors must have met all of the requirements in the proposed qualified energy assessor definition. As discussed in the previous comment, the energy assessor definition is unreasonably restrictive and it is virtually impossible that an existing assessment was done by a team that met all those specific requirements. Further, the assessor or assessors for a past assessment certainly were not approved by the Administrator. Thus, the allowance to use existing assessments, which we requested and fully support, is not usable in practice. A sentence needs to be added to Table 3 Item 4 that waives the energy assessor definition and approval where an existing assessment is being used to meet the energy assessment requirement.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3667-A2, excerpt 2.

Commenter Affiliation: National Tribal Air Association

Document Control Number: EPA-HQ-OAR-2002-0058-3667-A2

Comment Excerpt Number: 6

Comment: The definition of energy assessment is unclear whether the energy assessment applies to just boilers or to both boilers and process heaters. Since the size criterion (i.e., the facility boiler and process heater energy consumption) is based on both boilers and process heaters, we assume the assessment must deal with both steam and process heat. The energy assessment definition wording, as exemplified in Item 4 below, should be clarified on this point.

The definition of energy assessment has three categories based on facility heat input, but then requires that the assessment address "energy use systems." There is no basis for expanding the assessment beyond producers and users of steam or heat provided by boilers and process heaters subject to this rule (e.g., electricity users, imported steam users) and therefore the term "energy system" should be replaced with "steam and process heat consumers."

Each of the three paragraphs in the energy assessment definition call for evaluating “the boiler system and any energy use system” accounting for at least a specified percentage of the energy output. As in the previous item, the term “energy” is unclear and should be changed to “steam or process heat.” Additionally “output” is a meaningless term related to consumers and that word should be changed to “production or consumption.” Finally, it should be clarified the percent is the percent of the facility total steam and process heat production or consumption, as applicable.

For example, to address the above concerns, Paragraph 3 of the energy assessment definition should be revised to read as follows.

(3) In the Energy assessment for facilities with affected boilers and process heaters using greater than 1.0 trillion Btu per year, the boiler system, **process heater**, and any **energysteam or process heat** use system accounting for at least 20 percent of the **energysteam or process heat** ~~output~~**production or consumption, as applicable, at the facility** will be evaluated to identify **energysteam or process heat** savings opportunities.

Similar revisions to Paragraphs 1 and 2 of the energy assessment definition are also needed.

Response: We agree that definition of "energy assessment" needs clarification. Based on the various comments and suggested wordings, we have revised the definition to better clarify the intent and cope of the energy assessment. We have added, as suggested, "process heater" and "(e.g., steam, process heat, hot water, or electricity)" after energy, since there are several forms of energy that may be produced, to better define the "output."

Comment Excerpt Number: 111

Comment: The definition of energy assessment is too broad because it appears to establish obligations beyond the boiler or process heater source. The rule in relevant part states that an energy assessment, or audit, is an in-depth energy study identifying all energy conservation measures appropriate for a facility given its operating parameters. It leads to the reduction of emissions of pollutants through process changes and other efficiency modifications. The purpose of an energy assessment is to identify energy conservation measures (such as, process changes or other modifications to the facility) that can be implemented to reduce the facility energy demand which would result in reduced fuel use. EPA is requiring that the energy assessment be conducted by energy professionals and/or engineers that have expertise that covers all energy using systems, processes, and equipment.

The broad definition of the scope of an energy assessment is unreasonable. The language attempts to include equipment and systems far beyond the intent of the "Industrial, Commercial and Institutional Boilers and Process Heaters" rule. In its definitions, EPA correctly defines a "boiler" and a "process heater" to refer to enclosed devices containing a controlled flame that are used to recover heat. However, EPA attempts to vastly expand the scope of this rule in its definition of a "boiler system" by including the term "energy use systems". This expansion in scope is reinforced in EPA's choice of language describing the scope of energy assessments to include modifications to the facility. The expansion in scope is further reinforced by implication

that those conducting the energy assessments should have expertise that covers all energy using systems.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3667-A2, excerpt 6 and comment EPA-HQ-OAR-2002-0058-3449-A1, excerpt 32.

Comment Excerpt Number: 22

Comment: EPA Should Clarify the Scope of the Energy Assessment for Certain Equipment

The VI supports EPA's proposed revisions to the energy assessment requirement, which limit the energy assessment to the boiler system and the energy use system. EPA proposed thresholds for

including a given energy use system (e.g., process heating or cooling, lighting, compressed air) in the energy assessment. Specifically, the energy system must use at least 20 percent of the energy output—if the sum total energy consumption of the affected boilers and process heaters is greater than 1.0 trillion Btu per year; the threshold increases for affected boilers and process heaters that use less energy per year—to be a required part of the energy assessment.

EPA should clarify that the energy assessment requirement does not extend to equipment regulated under other MACT standards. The proposed rule states,

The types of boilers and process heaters listed in paragraphs (a) through (n) of this section are not subject to this subpart . . .

(h) Any boiler or process heater that is part of the affected source subject to another subpart of this part (i.e., another National Emission Standards for Hazardous Air Pollutants in 40 CFR part 63).

Response: We agree that boilers and process heaters that are not subject to the rule are not included in the energy assessment. We have made revisions to the various energy assessment requirements to make clear that only affected boilers and process heaters are to be included. See the response to comment EPA-HQ-OAR-2002-0058-3427, excerpt 6.

Commenter Affiliation: JELD-WEN, inc.

Document Control Number: EPA-HQ-OAR-2002-0058-3485-A1

Comment Excerpt Number: 3

Comment: In the Boiler MACT reconsideration, EPA has proposed to revise its "Energy assessment" requirement to change the maximum duration for performing the assessment. The final rule had established a maximum duration of three days for affected boilers and process heaters using 0.3 to 1 TBtu/year. JELD-WEN and other commenters explained that the assessment required by EPA could take longer than that time. In response, EPA has proposed to revise the energy assessment duration to a maximum of 24 technical hours to allow sources to perform longer assessments "at their discretion." JELD-WEN supports this revision. Since the Boiler MACT rule establishes an exhaustive list of items that need to be evaluated during the energy assessment, JELD-WEN agrees that sources should have discretion to perform longer assessments to properly address all of the items required by the rule. JELD-WEN also supports EPA's decision not to set a mandatory minimum amount of time for the assessment, agreeing with EPA's intent to "minimize the burden" for facilities that can perform the assessment in a shorter period of time.

Response: The EPA thanks the commenter for their support.

Commenter Name: Michael L. Krancer
Commenter Affiliation: Pennsylvania Department of Environmental Protection (DEP)
Document Control Number: EPA-HQ-OAR-2002-0058-3507-A1
Comment Excerpt Number: 17

Comment: The EPA has revised the definition of "Energy assessment" to change the maximum time from one day to eight technical hours and from three days to 24 technical hours and to allow sources to perform longer assessment at their discretion. EPA's intent for including "maximum time" in the final rule definition was to minimize the burden on the smaller fuel-use facilities, many of which are likely small entities, by limiting the extent of the energy assessment. EPA's concern was that if there was no time limit, then the small facilities would have no means to limit the time and effort of an outside energy assessor that is contracted to perform the energy assessment. The EPA has made other revisions to the definition of "Energy assessment" to better clarify its intent. The DEP agrees with the clarifying revisions to the definition of "Energy assessment."

Response: The EPA thanks the commenter for their support.

Commenter Name: Bill Wilson
Commenter Affiliation: Washington State University
Document Control Number: EPA-HQ-OAR-2002-0058-3786-A1
Comment Excerpt Number: 2

Comment: A maximum of 8 technical labor hours are prescribed for assessments in facilities with affected boilers and process heaters with annual energy consumption of less than 0.3 trillion Btu annually. A maximum of 24 technical labor hours are prescribed for boilers and process heaters with annual energy consumption from 0.3 to 1.0 trillion Btu annually. No maximum hours are prescribed for systems with annual energy consumption greater than 1.0 trillion Btu. For the two lower annual energy use brackets, a statement about optional additional time is provided.

I believe the prescribed hours for the two lower annual energy use brackets are inadequate for conducting the full energy assessment process in a manner which successfully fulfills the energy assessment criteria and outcomes listed in Table 3 – To Subpart DDDDD of Part 63 – Work Practice Standards, Items 4a – 4f. The 8 hour maximum for the lowest annual energy use bracket is woefully inadequate, and I believe will raise unrealistic expectations by those seeking energy assessment expertise. I would also like to point out energy assessment is only technical service described in the Final Rule Reconsideration in which hours to perform a task have been prescribed. Other technical services like burner tuning, stack testing, etc. do not have labor time limits prescribed.

Response: As indicated in the final, EPA's intent for including "maximum time" in the definition was to minimize the burden on the smaller fuel-use facilities, many of which are likely small entities, by limiting the extent of the energy assessment. EPA's concern was that if there was no time limit, then the small facilities would have no means to limit the time and effort of an outside energy assessor that is contracted to perform the energy assessment. However, the energy assessment can be longer at the owner discretion. The final rule definition has been revised to

clarify that the technical hours are "on-site" technical hours to conduct the evaluation of the boiler or process heater and its energy using systems, and does not include the off-site effort to prepare the report.

Commenter Name: Bill Wilson

Commenter Affiliation: Washington State University

Document Control Number: EPA-HQ-OAR-2002-0058-3786-A1

Comment Excerpt Number: 3

Comment: In my experience, the amount of pre-assessment time devoted making arrangements and obtaining information, on-site observation time and post-assessment analysis and report generation time expenditure is quite independent of unit maximum heat input ratings or system annual energy consumption. My experience has been no less than 24 hours of on-site time is typically required with very a very considerable amount of pre-assessment and post-assessment time involvement required. The stated time does not include time expenditures required by facility personnel. 24 hours (3 days) also the approximate on-site time allotted to assessors performing UDOE steam system and process heating SEN assessments. Significant additional time is allotted for preliminary tasks and reporting and follow-up activities.

I feel the prescriptive technical labor hour statements should be eliminated entirely. The Energy Assessment requirement was introduced presumably for identifying and quantifying opportunities which could, if implemented, reduce energy consumption and emissions. This outcome will not likely be realized, especially for smaller facilities, with the severe time restrictions prescribed.

Response: We disagree, see the response to comment EPA-HQ-OAR-2002-0058-3786-A1, excerpt 2.

Commenter Name: Jennifer Youngblood

Commenter Affiliation: National Tribal Air Association

Document Control Number: EPA-HQ-OAR-2002-0058-3667-A2

Comment Excerpt Number: 1

Comment: The revisions to the definition of "energy assessment" to allow EPA to incorrectly claim a reduced energy assessment cost do not accomplish that goal and the true cost should be reflected in the beyond-the-floor analysis and the Information Collection Request or EPA must change the energy assessment requirements to match the time allowed.

On page 80615 of the proposal preamble EPA states; "We have revised the definition of "energy assessment" to change the maximum time from 1 day to 8 technical hours and from three days to 24 technical hours. This would allow sources to perform longer assessments at their discretion." All this change does is revise the criterion for when the violation occurs (i.e., it is now a violation if you fail to meet all the energy assessment criteria in Table 3 because to do so would require more than 8 hours or 24 hours, rather than 1 day or 3 days.). Nothing in the proposed energy assessment definition relieves sources from the Table 3 requirements for energy assessment content if they cannot complete the assessment in the specified time. In fact, proposed §63.7530(e) requires that a facility certify in the NCS that "the energy

Since sources have no discretion whether or not to spend more time, it is false for EPA to assume the 8 and 24 hour limits have any meaning or to rely on those limits for the burden and cost analyses. Therefore, the cost estimates should be revised for the major and area source rules to reflect the full costs of this requirement (and the extra personnel costs needed to meet the definition of qualified energy assessor, as discussed in our next comment).

Response: We agree that the wording in Table 3 could be interpreted to require a complete energy assessment regardless of the maximum technical hours listed in the definition of "Energy assessment." That was not our intent. Item 4 of Table 3 has been revised to include: "The energy assessment must include the following with extent of the evaluation for items a. to e. appropriate for the on-site technical hours listed in §63.7575."

Commenter Name: Jennifer Youngblood

Commenter Affiliation: National Tribal Air Association

Document Control Number: EPA-HQ-OAR-2002-0058-3667-A2

Comment Excerpt Number: 4

Comment: Proposed §63.7545(e)(8)(ii) requires that the NCS certify that "This facility has had an energy assessment performed according to § 63.7530(e)." The referenced §63.7530(e) requires that a facility certify in the NCS that "the energy assessment was completed according to Table 3 to this subpart and is an accurate depiction of your facility." If the 8 hour and 24 hour limits on the energy assessment for facilities producing < 1 trillion BTU/year are made meaningful, most sources in those production ranges will not have completed energy assessments, since that amount of time is inadequate to even get started. Thus, those sources will be unable to sign the proposed certification wording. For those sources alternate wording must be provided in §63.7545(e)(8). **We suggest the following be provided as an alternate certification in the proposed §63.7545(e)(8)(ii) wording.**

[This facility has expended at least 8 or 24 technical hours, as applicable, towards evaluating steam and process heat production and consumption efficiencies.](#)

Response: We agree but believe that the revision to the wording in item 4 of Table 3 accomplishes the same purpose.

Commenter Name: Jessica Bridges

Commenter Name: Robert D. Bessette

Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 115

Comment: If EPA imposes an energy assessment, it should include the proposed change to the maximum time of the assessment. In the Reconsidered Boiler MACT Rule, EPA clarified that the time to conduct the energy assessment may be extended "at the discretion of the owner or operator of the affected source." 76 Fed. Reg. 80,651. CIBO supports this approach regarding the timing to conduct energy assessments.

In the Final Boiler MACT Rule, EPA included "stated 'maximum time'" language in the definition of energy assessment, 76 Fed. Reg. 80,615, which could have implied that a deviation or a potential violation would occur if the energy assessment effort exceeded the listed time limits. CIBO supports EPA's new approach because it recognizes that actual times for conducting the assessment can exceed stated maximum times depending on site-specific conditions. A clear statement is critical so that deviations or enforcement is not applicable to the elapsed times expended on energy assessments.

Response: The EPA thanks the commenter for their support.

Commenter Name: Shannon S. Broome

Commenter Affiliation: Auto Industry Forum (AIF)

Document Control Number: EPA-HQ-OAR-2002-0058-3512-A1

Comment Excerpt Number: 49

Comment: The threshold in the "energy assessment" definition appears based on *actual* heat input use as opposed to *potential* heat input use, however, again, the reconsideration proposal is not entirely clear on this point.³³ *See id.* at 80,651. If it is *actual*, what base year should facilities use and may facilities permissibly estimate actual use from centralized NG meters?[Footnote 33: As a corollary, the definition of "energy use assessment" refers to "facilities with affected boilers and process heaters *using*" certain amounts of heat output without clarifying whether "using" refers to actual use or rated capacity. *Id.* at 80,651.]

Response: The definition of "Energy assessment" in 63.7575 has been revised to clarify that the threshold is based on heat input capacity. Heat input capacity is used elsewhere in the rule to determine applicability. Using heat input capacity avoids the issue of identifying an appropriate base year or with estimating actual fuel use.

Commenter Name: Felix Mestey, on behalf of Donald R. Schregardus

Commenter Affiliation: Clean Air Act Services Steering Committee, Department of Defense (DoD)

Document Control Number: EPA-HQ-OAR-2002-0058-3427

Comment Excerpt Number: 3

Comment: The definition of energy assessment in §63.7575 states: "(3) *In the Energy assessment for facilities with affected boilers and process heaters using greater than 1.0 trillion Btu per year, the boiler system and any energy use system accounting for at least 20 percent of the energy output will be evaluated to identify energy savings opportunities.*" Unlike the facilities

with lesser heat usage, this category does not specify the appropriate duration of conducting energy assessments. Leaving the duration of the energy assessment open-ended for this category and the scope of the assessment unclear will likely result in long and expensive energy assessments.

Based on the other two categories used by the EPA, less than 0.3 and 0.3 to 1.0 TBtu/yr, it appears that EPA is using a ratio of one day or 8 technical hours per every 0.3 TBtu/yr. For larger facilities, this ratio is excessive and does not recognize the economy of scale (larger boilers servicing large buildings). DoD recommends a ratio of 8 technical hours per every additional 1.0 TBtu/yr beyond 1.0 TBtu/yr, not to exceed 160 technical hours, although facilities could perform longer duration energy assessments at their discretion. For example, excluding limited-use boilers, the largest USAF facility in terms of TBtu/yr is Tinker Air Force Base (AFB), with approximately 93 boilers having a total capacity of approximately 17.6 TBtu/yr. Using 24 hours for the first TBtu/yr and a ratio of 8 hours per additional 1.0 TBtu/yr, results in a technical hour limit for Tinker AFB's energy assessment of 157 technical hours or about 1.7 hours per boiler, which is sufficient for the purposes of the required energy assessment. However, this ratio could require an unreasonable number of technical hours in certain circumstances; therefore a cap on the number of technical hours should also be included. For example, Arnold AFB has a combined rated heat input capacity of 32.1 TBtu/yr when limited-use boilers are included, and a combined capacity of 14.5 if limited-use boilers are excluded. Using 24 hours for the first TBtu/yr and a ratio of 8 hours per additional 1.0 TBtu/yr results in a technical hour limit for Arnold AFB's energy assessment of 273 technical hours for 41 units including the limited-use units, or about 6.6 hours per boiler. The number of technical hours per boiler for the energy assessment in this case is excessive. This could be prevented by establishing a limit on the maximum number of technical hours for larger facilities.

Revise numbered paragraph (3) in the definition of "energy assessment" in §63.7575 for facilities with units using greater than 1TBtu/yr to specify time duration/size ratio and include a cap to the maximum number of hours that should be used in the energy assessment as follows:

(3) ~~In the e~~Energy assessment for facilities with affected boilers and process heaters using greater than 1.0 trillion Btu per TBtu/year, will be up to 24 technical labor hours in length for the first TBtu/yr plus 8 technical labor hours for every additional 1.0 TBtu/yr not to exceed 160 technical hours, but may be longer at the discretion of the owner or operator. ~~t~~The boiler system(s) and any on-site energy use system(s) accounting for at least 20 percent of the affected unit(s) energy output will be evaluated to identify energy savings opportunities.

Response: We agree with the commenter that leaving the duration of the energy assessment open-ended for this category and the scope of the assessment unclear will likely result in long and expensive energy assessments. The numbered paragraph (3) in the definition of "energy assessment" in §63.7575 has been revised as follows:

(3) Energy assessment for facilities with affected boilers and process heaters with a combined heat input capacity of greater than 1.0 trillion Btu/year will be up to 24 on-site technical labor hours in length for the first TBtu/yr plus 8 on-site technical labor hours for every additional 1.0 TBtu/yr not to exceed 160 on-site technical hours, but may be longer at the discretion of the owner or operator of the affected source. The boiler system(s), process heater(s), and any on-site energy use system(s) accounting for at least 20 percent of the affected unit(s) energy (e.g., steam,

process heat, hot water, or electricity) production or consumption, as applicable, will be evaluated to identify energy savings opportunities.

Comment: 40 CFR 63.7575, Revise the definition of “energy assessment” to clarify the length of days for each category of facilities. We are supportive of the shortening to 8 technical hours and 24 technical hours.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3427, excerpt 3.

Commenter Name: Felix Mestey, on behalf of Donald R. Schregardus

Commenter Affiliation: Clean Air Act Services Steering Committee, Department of Defense (DoD)

Document Control Number: EPA-HQ-OAR-2002-0058-3427

Comment Excerpt Number: 7

Comment: Revise numbered paragraph (3) in the definition of "energy assessment" in §63.7575 for facilities with units using greater than 1TBtu/yr to specify time duration/size ratio and include a cap to the maximum number of hours that should be used in the energy assessment as follows:

(3) ~~In the e~~Energy assessment for facilities with affected boilers and process heaters using greater than 1.0 ~~trillion Btu per TBtu~~/year, will be up to 24 technical labor hours in length for the first TBtu/yr plus 8 technical labor hours for every additional 1.0 TBtu/yr not to exceed 160 technical hours, but may be longer at the discretion of the owner or operator. ~~t~~The boiler system(s) and any on-site energy use system(s) accounting for at least 20 percent of the affected unit(s) energy output will be evaluated to identify energy savings opportunities.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3427, excerpt 3.

Commenter Affiliation: Washington State University

Document Control Number: EPA-HQ-OAR-2002-0058-3786-A1

Comment Excerpt Number: 1

Comment: My greatest concern about energy assessment language in the Final Rule Reconsideration is the approach specifying the duration of an energy assessment by prescribing a maximum time expenditure ("technical labor hours") based on affected boilers and process heaters annual energy consumption threshold brackets. As a definition of "technical labor hours" has not been provided, my assumption is this terms means the total time expenditure by an energy assessor to perform an energy assessment from pre-assessment contact and information gathering through the "on-site" systems observation period at the facility and subsequent post-assessment analyses and generation of a final report.

Response: The definition of "Energy assessment" has been revised to clarify that the technical hours are "on-site" technical hours to conduct the evaluations. The on-site technical hours do not cover the pre-assessment contact and information gathering and the subsequent post-assessment analysis and generation of a final report.

Comment Excerpt Number: 5

Comment: Proposed §63.7530(e) must also be revised to reflect the hour limits and to clarify that the facility is only certifying to the accuracy of the information used in the assessment as a snapshot. Since the assessment is a onetime requirement, the certification should indicate that it is only an accurate depiction of the facility at the time of the assessment, thereby removing any suggestion that a new assessment is needed if the facility changes. We recommend the following revisions to the proposed §63.7530(e).

You must include with the Notification of Compliance Status a signed certification that the energy assessment was completed according to Table 3 to this subpart or the hour limits specified in the energy assessment definition was reached and is an accurate depiction of your facility at the time of the assessment.

Response: We agree with the second edit and have revise §63.7530(e) to read "You must include with the Notification of Compliance Status a signed certification that the energy assessment was completed according to Table 3 to this subpart and is an accurate depiction of your facility at the time of the assessment. The first suggested edit has been addressed by the revision to Item 4 of Table 3.

Document Control Number: EPA-HQ-OAR-2002-0058-3424

Comment Excerpt Number: 8

Comment: EPA should allow facilities to conduct their own self assessments instead of hiring certified professionals. DGC has processes that would require third-party auditors to spend a great amount of time learning intricacies of the facility, possibly including information that is considered CBI, which could put DGC's competitive advantage at risk. DGC considers the energy assessment as a good business practice and is confident that the skills and knowledge of the in-house personnel would meet the qualified assessor and be sufficient to perform an energy assessment comprehensively and accurately.

Comment Excerpt Number: 9

Comment: The requirement of an energy assessment should provide net benefits to regulated entities as a whole, as well as substantial environmental and health benefits to the entire country. But in order to ensure that maximum net benefits are reaped, EPA should go further and require implementation of all "cost-effective energy conservation measures." Mandatory implementation is justified regardless of whether EPA continues to use its flawed definition of "cost-effective," or adopts the more economically rational definition discussed above.

First, it should be noted that the statutory touchstone for whether EPA should issue this requirement is whether it is "achievable" under Section 112(d). For a range of definitions of "cost-effective," EPA can determine that requiring implementation of "cost-effective energy conservation measures" is, in fact, both achievable and economically feasible.²⁵

As explained above, EPA has defined "cost-effective" to reflect only private costs and benefits. This makes the case for requiring implementation very simple. Given a suitable discount rate and time period for the analysis (discussed above), there will be zero net costs to regulated entities from implementing cost-effective measures. Since there will be zero net costs, the requirement should not pose any burden on regulated entities.

Of course, standard economic theory would suggest that regulated entities (as rational actors) would implement all energy conservation measures that have net private benefits on their own, without any requirement. But as discussed above, firms often fail to take advantage of all opportunities to decrease costs (or increase profits). If EPA issues this requirement, it can be assured that the regulated entities will not let this opportunity pass them by. EPA should take the step to ensure that regulated entities will not blindly comply with the bare minimum of the regulation by filing an energy assessment and then promptly forgetting about it.

[Footnote 25 Under CAA §112(h), EPA may exempt sources from requirements under Section 112(d) if the requirement is not feasible. However, given a proper definition of "cost-effective," this should not be an issue.]

Comment Excerpt Number: 3

Comment: The State of Wyoming would appreciate clarification in the rule regarding EPA's expectations for implementing the results of the energy assessment. By definition, an energy assessment is a review of the boiler system and energy use system accounting for specified percentages of the energy output to identify energy savings opportunities, within the time limit of performing energy assessment. It is anticipated that the results of the energy assessment will vary significantly in cost, and without guidance from EPA on implementing the results of the energy assessment, implementation will be fragmented.

Commenter Affiliation: AK Steel Corporation

Document Control Number: EPA-HQ-OAR-2002-0058-3457-A2

Comment Excerpt Number: 14

Comment: As EPA well knows, the iron and steel industry is highly energy intensive. In a global market, steel companies must reduce costs wherever possible to stay competitive and energy costs are a key component of those reductions. Accordingly, AK Steel is continually performing energy assessments to ascertain what programs, practices, or installations can be implemented in a cost-effective manner to reduce energy costs. We conduct these assessments by utilizing personnel and contractors with years of experience and expertise within our industry and at our facilities. As a result, we fail to see what additional benefit or to what purpose an additional energy assessment performed by a third-party assessor will achieve or how the costs can be justified.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Comment Excerpt Number: 11

Comment: If EPA keeps the energy assessment requirement in the rule, it should exclude electric utility auxiliary boilers from that requirement. As noted above, auxiliary boilers typically operate only during the startup of an EGU. In some cases, auxiliary boilers may be used to supply building heat but only when the main generating unit is offline. The annual capacity factor of auxiliary boilers is very low. Consequently, an energy assessment of an entire electric utility generating facility would not have any impact on the operation or fuel usage of an auxiliary boiler. Because the energy assessment requirement would serve no useful purpose for an electric generating facility, auxiliary boilers should be exempted from this requirement.

Document Control Number: EPA-HQ-OAR-2002-0058-3501-A1

Comment Excerpt Number: 14

Comment: The existing CHP fleet (82 GW) already avoids more than 1.8 Quadrillion British thermal units (Quads) of fuel consumption and 241 million metric tons of carbon dioxide (CO₂) emissions annually compared to traditional separate production of electricity and thermal energy. This CO₂ reduction is the equivalent of removing more than 45 million cars from the road. The potential additional CHP of 130-170 GW could double these benefits for the additional installations in terms of fuel consumption and CO₂ reduction.

Fortunately these benefits can be readily calculated for CHP projects at relatively low cost during the Energy Assessment Phase. We realize that cost of the Energy Assessments is an

important factor in EPA's analyses. However, a ready tool developed by EPA already exists. It is the CHP Emissions Evaluator available from EPA's CHP Partnership.⁷

For perspective in examining the EPA position here, we looked at TABLE 5—SUMMARY OF CAPITAL AND ANNUAL COSTS FOR NEW AND EXISTING SOURCES⁸ and took the cost estimate numbers for Energy Assessments Annualized Costs (considering fuel savings) that totaled \$28 million and divided it by the number of affected sites (1704). The result is an annualized \$16,432 per Energy Assessment. Using a tool such as the CHP Emission Evaluator, even if it requires some modification for the purpose, should not significantly raise the average energy assessment costs.

Commenter Name: Robert D. Bessette

Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 116

Comment: If EPA imposes an energy assessment, it should not be submitted to EPA and additional CBI protections are needed. In the Reconsidered Rule, EPA proposes to remove the requirement that sources submit their energy assessments upon a request from EPA. 76 Fed. Reg. 80,641; 40 C.F.R. § 63.7530(e). EPA notes that it recognizes the sensitivity of confidential business information (CBI) contained in energy assessments. EPA's Response to Public Comments on EPA's National Emission Standards for Hazardous Air Pollutants for Major Source Industrial Commercial Institutional Boilers and Process Heaters - Volume 1 of 2 (Response to Comment Excerpt Number 215). CIBO supports protecting CBI to the fullest extent allowed. As CIBO stated in its Petition for Reconsideration of the Final Area Source Rule, EPA should provide the same level of CBI protection for area sources as it does for major sources. Submission of energy assessments is not required under the Final Boiler MACT Rule. CBI is equally an issue for companies operating area source boilers as it is for major source boilers and process heaters. As such, a similar approach in both rules is justified.

Here, EPA is exercising its authority under §112. *See, e.g.*, 76 Fed. Reg. 80,625. As EPA acknowledges, §112 directs the agency "to develop NESHAP which require existing and new major sources to control emissions of HAP using MACT based standards." *Id.* An energy assessment is not an emission standard; therefore, if EPA would like to collect this information for policy purposes or to inform other rulemaking efforts, it must comply with the procedural requirements to issue a §114 request.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Commenter Name: Robert D. Bessette

Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 117

Comment: EPA must comply with the PRA, which requires that the agency receive approval from OMB before issuing similar §114 requests to ten (10) or more respondents collecting substantially similar information in any 12-month period. 5 C.F.R § 1340.3(c). The OMB's approval is in the form of an Information Collection Request ("ICR"), which must go through public notice and comment. Courts have determined that compliance with an information request is not required where "the demand for information or documents is arbitrary and capricious, an abuse of discretion, or otherwise not in accordance with law." *U.S. v. Pretty Prod., Inc.*, 780 F. Supp. 1488, 1506 n.23 (S.D. Ohio 1991).

The regulatory text of the Reconsidered Boiler MACT Rule indicates that sources must demonstrate compliance with the energy assessment requirement by including in their Compliance Status Report a certification that the facility has completed an energy assessment consistent with the regulatory requirements:

(e) You must include with the Notification of Compliance Status a signed certification that the energy assessment was completed according to Table 3 to this subpart and is an accurate depiction of your facility.

Section 63.7530(d), 76 Fed. Reg. 80,641.

However, the Preamble of the Reconsidered Boiler MACT Rule appears to indicate that in addition to the foregoing certification, sources must also submit documentation of cost effective energy conservation measures:

Further, all owners or operators of major source facilities having boilers and process heaters subject to this final rule are required to submit to the delegated authority or the EPA, as appropriate, documentation that an energy assessment was performed by a qualified energy assessor and documentation of the cost-effective energy conservation measures identified by the energy assessment.

76 Fed. Reg. 80,603.

As CIBO asserted in its comments on the Proposed Rule, much of the analysis of cost-effective efficiency measures will be CBI, and sources should not be required to submit that information to EPA. EPA's regulations provide that information must be protected from disclosure to protect trade secrets and a business' right to limit the use or disclosure of information "by others in order that the business may obtain or retain business advantages it derives from its rights in the information." 40 C.F.R. § 2.201(e). Commercial or financial information involuntarily submitted by a company to EPA is entitled to confidentiality if "disclosure of the information is likely to . . . cause substantial harm to the competitive position of the person from whom the information

was obtained." *Nat'l Parks & Conservation Ass'n v. Morton*, 498 F.2d 765, 770 (D.C. Cir. 1974); *Critical Mass Energy Project v. Nuclear Regulatory Comm'n*, 975 F.2d 871, 879 (D.C. Cir. 1992) (reaffirming the *National Parks* test for determining whether information submitted under compulsion is confidential); *see also* 40 C.F.R. § 2.208(e)(1). Parties claiming confidentiality need only show "competition and a likelihood of substantial competitive injury." *CNA Fin. Corp. v. Donovan*, 830 F.2d 1132, 1152 (D.C. Cir. 1987).

EPA's regulations provide that emissions data cannot be protected from disclosure as CBI. 40 C.F.R. § 2.301(e). "Emission data" is "any source of emission of any substance into the air" that is "necessary to determine the identity, amount, frequency. . . of any emission. . . emitted by the source." 40 C.F.R. § 2.301(a)(2)(i); *see also RSR Corp. v. EPA*, 588 F. Supp. 1251, 1255 (N.D. Tex. 1984).

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Commenter Name: Robert D. Bessette

Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 118

Comment: The information collected to comply with the energy assessment requirement is not "emissions data." 40 C.F.R. § 2.301(e). It is not "necessary" to determine emissions emitted by a source. *Id.* Rather, the energy assessment includes:

- An evaluation of operating characteristics of the facility, specifications of energy using systems, operating and maintenance procedures, and unusual operating constraints;
- An inventory of major energy consuming systems;
- A review of available architectural and engineering plans, facility operation and maintenance procedures and logs, and fuel usage;
- A review of the facility's energy management practices and recommendations for improvements;
- A list of major energy conservation measures and their energy savings potential;
- A comprehensive report detailing the ways to improve efficiency, the cost of specific improvements, benefits, and the time frame for recouping those investments.

The foregoing information is commercially valuable because its release would potentially provide competitors with a window into the reporter's current operations, operating costs, and expansion plans. For EPA to require the public disclosure of information of this nature (including engineering plans or the costs of energy savings projects), ignores the competitiveness implications of such disclosure. A company that develops a method to significantly reduce its energy costs – whether through improved maintenance practices or new projects - will not want its competitors to be aware of such proprietary information. Similarly, that company would not want to make its competitors aware of any operating constraints that might highlight weaknesses within a facility. If energy assessments are made publically available, competitors that took a

minimalist approach in conducting their own energy assessments could benefit from the disclosures of others without incurring the time and expense to independently develop those plans. *See Webb v. Dep't of Health & Human Serv.*, 696 F.2d 101, 103 (D.C. Cir. 1982). As a result, reporters that prepare more comprehensive and detailed energy assessments would suffer irreparable harm. EPA is not authorized under the CAA or its implementing regulations to cause companies such injuries by mandating the disclosure of proprietary information. 42 U.S.C. § 7414(c); 40 C.F.R. § 2.301(b)(i).

The lapse of time would not diminish the sensitivity of disclosing this information. There is no time after which this information could be released that would avoid these potential competitive harms. Given these concerns, it would not be appropriate to impose a time limit on the confidentiality of the energy assessment information.

CIBO objects to requiring sources to submit their energy assessments even if they are afforded CBI status because those protections are not necessarily complete or permanent. Such protections are insufficient because EPA CBI determinations are subject to reevaluation. 40 C.F.R. § 2.205(h). EPA has the discretion to modify prior CBI determinations and conclude that CBI is no longer entitled to confidential treatment because of a change in applicable law or newly discovered or changed facts. *Id.*

For the foregoing reasons, EPA should amend the Preamble to remove this statement about submitting such documentation so that the Preamble is consistent with the rule text, which only requires entities to submit a certification that the energy assessment was conducted.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Commenter Name: Bruce A. Steiner

Commenter Affiliation: American Coke and Coal Chemical Institute (ACCCI)

Document Control Number: EPA-HQ-OAR-2002-0058-3547-A2

Comment Excerpt Number: 15

Comment: But more fundamentally, this undertaking is a means to no particular end. Any potential emission reductions, energy reductions, or non-air quality health and environmental benefits are not estimable because the proposed energy assessment requirement is just a study. While the Reconsidered Rule speculates that facilities may elect to implement certain findings, it cannot quantify any emissions reductions that may occur with the requisite level of certainty. Thus, this requirement fails EPA's traditional cost-effectiveness evaluation, which focuses on the annual cost per ton of HAP emissions eliminated. *See, e.g., Artega Specialties S.A.R.L. v. EPA*, 323 F.3d 1088, 1089-90 (D.C. Cir. 2003). EPA apparently has not performed this calculation and it is impossible for any impacted entity to do so. While the Reconsidered Rule offers a rough emissions reduction estimate, that estimate apparently stems from presumed voluntary measures, with no solid indication that any HAP reduction will actually occur. Since there are no demonstrable emissions reductions from the proposed energy assessment requirement, the significant costs associated with that process are not warranted. As such, this proposed beyond-the-floor control fails the threshold test imposed by §112(d)(2).

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Commenter Name: Bruce A. Steiner

Commenter Affiliation: American Coke and Coal Chemical Institute (ACCCI)

Document Control Number: EPA-HQ-OAR-2002-0058-3547-A2

Comment Excerpt Number: 16

Comment: Even if viable, the proposed energy assessment requirement presents serious implementation difficulties. One threshold problem is that the proposed energy assessment must be performed by “qualified personnel.” These inspectors may well have a conflict of interest - particularly where their firms would stand to benefit from implementing any suggested modifications. As a result, regulated entities would have a difficult time delineating between truly appropriate modifications and those suggested by the evaluator in hopes of gaining additional business.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Commenter Name: Bruce A. Steiner

Commenter Affiliation: American Coke and Coal Chemical Institute (ACCCI)

Document Control Number: EPA-HQ-OAR-2002-0058-3547-A2

Comment Excerpt Number: 17

Comment: the number of personnel qualified to perform energy assessments is unknown. The Reconsidered Rule would require assessors to complete the Department of Energy’s Qualified Specialist Program or become a Certified Energy Manager by the Association of Energy Engineers. Given the huge number of facilities impacted by the Reconsidered Rule and related Area Source standards,²⁸ there may well be a shortage of qualified personnel. That raises serious concerns, including: (1) personnel with significant experience and true expertise will be unavailable, (2) compliance may become difficult or impossible in a timely manner, and (3) competition for the limited pool of highly qualified assessors will cause their rates to increase significantly. There would also be substantial inefficiency associated with getting a third-party inspector sufficiently “up to speed” to make informed conclusions regarding industries’ highly complex steelmaking operations. In contrast, existing operations personnel already have extensive manufacturing expertise and unique knowledge of the particular processes at each of our industries’ facilities. As such, they are better situated to make informed, realistic determinations of where energy reductions may be achievable than outside assessors - and at far lower cost. Indeed, they have already been doing so effectively for years at most of our industries’ major facilities.

[Footnote]

(28) For major sources, 1,608 facilities would be required to conduct energy audits. Methodology for Estimating Cost and Emissions Impacts for Industrial, Commercial, Institutional Boilers and Process Heaters National Emission Standards for Hazardous Air

Pollutants - Major Source, from S. McClutchey, A. Singleton & G. Gibson, to J. Eddinger, at §3.4 (Apr. 2010), Docket ID No. OAR-2002-0058-0812. Up to 94,339 area source facilities may also be required to conduct energy audits. Methodology for Estimating Impacts from Industrial, Commercial, Institutional Boilers at Area Sources of Hazardous Air Pollutant Emissions, from G. Gibson, S. McClutchey & A. Singleton, to J. Eddinger, at §3.2 (Apr. 2010), Docket ID No. OAR-2006-0790-0032.

Comment Excerpt Number: 18

Comment: We are concerned that the proposed requirement to conduct a facilitywide energy assessment will be duplicative and unnecessary. As recognized in the Reconsidered Rule, fuel and energy costs are major drivers at many facilities.²⁹ That is particularly true for companies such as coke production facilities that require large amounts of fuel and energy to operate. Given those existing business incentives, ACCCI members have already invested heavily to assess cost-effective energy efficiency opportunities. Further, we have made (and continue to make) significant voluntary investments implementing key efficiency projects - including under the EnergyStar program. For EPA to require facilities that have already completed these steps to repeat the effort offers little practical benefit.

[Footnote]

(29) Sector-Based Pollution Prevention: Toxic Reductions through Energy Efficiency and Conservation Among Industrial Boilers, The Delta Institute, at §3.2, Docket ID No. OAR-2002-0058-0842 (July 2002) (concluding that Fuel is traditionally the “most costly item associated with boiler operation”).

Comment: ADM objects to requiring sources to submit their energy assessments even if they are afforded CBI status because those protections are not necessarily complete or permanent. Such protections are insufficient because EPA CBI determinations are subject to reevaluation. EPA has the discretion to modify prior CBI determinations and conclude that CBI is no longer entitled to confidential treatment because of a change in applicable law or newly discovered or changed facts.

For the foregoing reasons, EPA should amend the Preamble to remove this statement about submitting such documentation so that the Preamble is consistent with the rule text, which only requires entities to submit a certification that the energy assessment was conducted.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Comment Excerpt Number: 1

Comment: We commend EPA for including provisions that support energy efficiency in the Rule. As EPA noted in the Response to Comments on the March Rule, "One of the opportunities for pollution prevention lies in simply using energy efficient technologies to minimize the generation of emissions."¹ Indeed, energy-efficient technologies can reduce fuel use and associated emissions not only of the hazardous air pollutants at the heart of the Boiler MACT, but of conventional pollutants as well.

Notably, the Boiler MACT includes a number of provisions that enable regulated entities to cost-effectively reduce emissions through energy efficiency. These include work-practice standards, energy which would also enhance electricity reliability in states that are concerned about that. We commend EPA for drafting a rule that encourages industrial boiler owners to consider CHP and WHR as part of a commonsense compliance option. The December Rule will lower emissions, save American manufacturers money on their energy bills, enhance their competitiveness, and increase electric reliability in industrial states.

[Footnote 2: Estimate assumes CHP installations for 478 major source, non-CHP, non-limited use boilers equal to or greater than 10 MMBTU/hr from EPA's "Emissions Database for Boilers and Process Heaters Containing Stack Test, CEM, & Fuel Analysis Data Reported Under ICR No. 2286.01 and ICR No. 2286.03 (Version 6).mdb", Feb, 2011. Estimate also includes an additional 61 non limited-use, coal-fired boilers with heat-input rates greater than or equal to 10

MMBTU/hr from EPA's updated "Appendix B-1 Emission Reduction Detail for Existing Units," December 2011. (both data sets available online at <http://www.epa.gov/ttn/atw/boiler/boilerpg.html>). Thus estimate based on capacity for 539 major source boilers.]

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Commenter Name: Tangelia Niemann

Commenter Affiliation: Texas Commission on Environmental Quality (TCEQ)

Document Control Number: EPA-HQ-OAR-2002-0058-3594-A3

Comment Excerpt Number: 6

Comment: The TCEQ opposes any revision to the rule that would require the implementation of the energy assessment recommendations. Only the companies operating the facilities are qualified to determine those energy efficiency improvement measures that are appropriate and cost-effective for implementation at the site. Attempting to enforce which recommendations a company should have implemented as being cost-effective energy efficiency measures would be difficult and entail the TCEQ performing a separate independent evaluation of the measures. Neither the TCEQ nor the EPA should arbitrarily accept an energy assessor's recommendations as an enforceable requirement under the rule. Additionally, a requirement to implement the results of the energy assessment might bias companies providing energy assessment services, particularly if the assessment companies also provide the services or products necessary for the energy improvements. The EPA has already expressed concern of outside energy assessors attempting to expand the scope and effort required for an energy assessment beyond what would be necessary for a facility. This concern was the EPA's rationale for establishing the maximum time limits for the energy assessment so that companies would have a means to limit the time and effort of an outside energy assessor contracted to perform the assessment (76 FR 80615). Attempting to mandate companies implement the recommendations of the energy assessors would only further encourage such actions.

The TCEQ strongly recommends that the EPA remove the energy assessment requirement from 40 CFR 63 Subpart DDDDD. While energy efficiency evaluations should be encouraged, such evaluations should remain voluntary through programs such as the EPA's Energy Star Program and not mandated through regulation.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

104A. Remove Energy Assessment [DENIED PETITIONER ISSUE]

Commenter Name: Paul G. Page

Commenter Affiliation: AK Steel Corporation

Document Control Number: EPA-HQ-OAR-2002-0058-3457-A2

Comment Excerpt Number: 12

Comment: AK Steel supports ACCCI's comments regarding the Energy Assessment requirement including questioning EPA's authority to require it as part of this NESHAP regulation, what it has to do with the establishment of HAP emissions associated with boiler operations, and how this information will lead to the promulgation of HAP emission standards.

Response: The EPA denies this petition for reconsideration issue and the comment is out-of-scope of the reconsideration proposal. The authority to require an energy assessment was subject to notice and comment. Rationale and responses to comments are provided at 75 FR 32041 and 76 FR 15633.

This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: Paul G. Page

Commenter Affiliation: AK Steel Corporation

Document Control Number: EPA-HQ-OAR-2002-0058-3457-A2

Comment Excerpt Number: 16

Comment: For multiple reasons, AK Steel encourages EPA to remove the requirement to perform the Energy Assessment. EPA has given no indication as to how this requirement is relevant to the NESHAP Standard, what they intend to do with the information, how the information will be relevant and comparative to other facility assessments based on a multitude of assessors performing them, and what EPA will expect companies to do as a result of these assessments. As a result, the Energy Assessment would appear to serve no beneficial purpose and, therefore, needs to be removed as a requirement from the final rule.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3457-A2, excerpt 12.

This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: Eric Guelker, Alliant Energy Corporate Services, Inc.

Commenter Affiliation: Interstate Power and Light Company (IPL) and Wisconsin Power and Light Company (WPL), Alliant Energy Corp.

Document Control Number: EPA-HQ-OAR-2002-0058-3492-A1

Comment Excerpt Number: 12

Comment: Alliant Energy does not believe EPA has substantiated that "beyond the floor" controls of an energy assessment are warranted. EPA can impose "beyond the floor" requirements that are more stringent than the MACT floor, but must take cost, energy, and other environmental impacts into consideration when doing so. EPA's rule impact analysis has not fully vetted the costs of conducting an energy assessment and Alliant Energy believes that further inquiry would find that these costs estimates are significantly understated. Moreover, EPA has not explained how adding this as a more stringent requirement results in any documentable reduction of environmental impacts and associated risks.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3457-A2, excerpt 12.

This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: Eric Guelker, Alliant Energy Corporate Services, Inc.

Document Control Number: EPA-HQ-OAR-2002-0058-3492-A1

Comment Excerpt Number: 13

Comment: Existing facilities already have sufficient incentive to run their combustion units as efficiently as possible by realizing reduced fuel consumption and lower operating costs. Therefore, the energy assessment achieves nothing more than being an unwarranted administrative cost burden to companies.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3457-A2, excerpt 12.

This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: Kevin G. Desharnais, Attorney, Mayer Brown LLP

Commenter Affiliation: United States Sugar Corporation

Document Control Number: EPA-HQ-OAR-2002-0058-3496-A1

Comment Excerpt Number: 3

Comment: In its Reconsideration Proposal, EPA retains the requirement that sources perform a mandatory energy assessment as a "beyond-the-floor" requirement. While the Reconsideration Proposal clarifies the scope of the energy assessment as limited to onsite energy use systems, it does not address the appropriateness of the energy assessment in the first instance, and fails to respond to the legitimate criticisms articulated in US Sugar's comments to the Proposed Rule.

EPA apparently continues to rely upon the arguments articulated in the Preamble to the Final Rule, supporting its mandatory energy assessment requirement with reference to CAA section 112(d)(2). See 76 Fed. Reg. at 15633. However, Section 112(d)(2) provides no authority for a work practice standard like an energy assessment, authorizing only an emissions standard, not a work practice standard. See 42 U.S.C. § 7412(d)(2) ("Emissions standards promulgated under this subsection ... "); The authority for a work practice standard comes from Section 112(h). But that section specifically states that a work practice standard may only be used when an emission standard is not feasible. See 42 U.S.C. § 7412(h)(1) ("For purposes of this section, if it is not feasible in the judgment of the Administrator to prescribe or enforce an emission standard for control of a hazardous air pollutant or pollutants, the Administrator may, in lieu thereof, promulgate a design, equipment, work practice, or operational standard, or combination thereof, which in the Administrator's judgment is consistent with the provisions of subsection (d) or (f) of this section").

As U.S. Sugar explained in its comments to the proposed rule, EPA has determined that an emission standard is feasible here, and has in fact proposed such a standard for all boilers above certain volume thresholds. Accordingly, not only is a work practice standard not needed, there is

no legal basis for EPA to require it. EPA may not require both a work practice standard and an emission limit, as the two provisions are mutually exclusive under the statute. See *Sierra Club v. EPA*, 479 F.3d 875, 884 (D.C. Cir. 2007) (striking down work practice standard because section 74 1 2 (h) "allows EPA to substitute work practice standards for emission floors only if measuring emission levels is technologically or economically impracticable").

Response: See the response to comment EPA-HQ-OAR-2002-0058-3457-A2, excerpt 12.

This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: Lee Zeugin and Lauren Freeman

Commenter Affiliation: Utility Air Regulatory Group (UARG)

Document Control Number: EPA-HQ-OAR-2002-0058-3500-A1

Comment Excerpt Number: 10

Comment: The scope of the energy assessment in the 2011 final rule goes beyond IB units to focus on the "major source facility" and the "major systems consuming energy" at the facility. EPA justifies the energy assessment requirement as a way "to identify energy conservation measures (such as process changes or other modifications to the facility) that can be implemented to reduce the facility energy demand for the affected boiler, which would reduce its fuel use."⁸ The problem with EPA's stated justification is that it fails to fully consider the ramifications of the energy assessment requirement on the entire universe of facilities subject to the rule. As a result, while EPA attempts to tie the energy assessment to the regulation of the IB unit at a given facility, the scope of the requirement is overly broad and can affect the operation of other parts of the facility and, as a result, exceeds EPA's legal authority.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3457-A2, excerpt 12.

This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: David A. Buff, Golder Associates Inc.

Commenter Affiliation: Florida Sugar Industry (FSI)

Document Control Number: EPA-HQ-OAR-2002-0058-3504-A1

Comment Excerpt Number: 44

Comment: FSI objects to the energy assessment as a "beyond-the-floor" requirement for all major sources of HAPs. The FSI already has provided EPA with extensive comments and objections concerning the proposed energy assessment,³ and the FSI adopts those same objections to the requirements in the Proposed Boiler MACT Rule. As indicated in the FSI's previous comments:

- At a minimum, EPA is over-reaching when it attempts to require energy assessments as part of EPA's efforts to set emission standards under Section 112 of the Clean Air Act ("CAA").

- At a minimum, EPA is over-reaching when it attempts to extend the proposed energy assessment to include equipment that is not located within the traditional boundaries of a "boiler system."
- At a minimum, EPA is overreaching when it attempts to extend its authority over boilers by expanding the definition of a "boiler system" to include unrelated "energy consuming systems".

The FSI continues to believe that EPA is not justified in extending the scope of the energy assessment beyond the affected source. The "affected source" regulated by this NESHAP consists of boilers and process heaters – not the other equipment and "energy consuming systems" that are co-located with the affected source. The energy assessment requirements in the Proposed Boiler MACT Rule will mandate investigations into equipment and systems that are not properly within the scope of this Section 112 rulemaking process.

[Footnote]

Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1

Comment Excerpt Number: 82

Comment: EPA has authority to regulate HAP emissions from major sources under section 112(d) of the Clean Air Act. This attempt to further regulate the way major sources consume energy under this rule is beyond EPAs authority. EPA should eliminate its definitions of "boiler system" and "energy use system." EPA should further limit the scope of energy assessments to "boiler(s)" and "process heater(s)" as currently defined.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3457-A2, excerpt 12.

This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: Shannon S. Broome

Commenter Affiliation: Auto Industry Forum (AIF)

Document Control Number: EPA-HQ-OAR-2002-0058-3512-A1

Comment Excerpt Number: 45

Comment: EPA does not propose to eliminate the energy assessment nor does it propose to limit the assessment to the boiler and/or process heater only. In fact, EPA proposes no changes to

the components of the assessment on which AIF commented. Instead, EPA merely clarifies that it did not intend in the final rule for the assessment to include energy use systems using electricity purchased from an offsite source or energy use systems located offsite, indicating by the energy assessment still includes energy use systems on-site, *i.e.*, the assessment still extends beyond the boiler and/or process heater itself. Specifically, EPA proposes to amend the prior language of the third component of the energy assessment enumerated in Table 3 from “[a]n inventory of the major energy consuming systems” to:

An inventory of major systems consuming energy from affected boilers and process heaters and which are under the control of the boiler/process heater owner/operator.

Commenter Name: Robert D. Bessette

Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 109

Comment: In the 2011 Final Boiler MACT Rule, EPA grounded its authority to require sources to conduct an energy assessment in CAA §112: "the energy assessment will generate emission reductions through the reduction in fuel use beyond those required by the floor" and that "the requirement to perform the energy audit is, of course, a requirement that can be enforced and thus a standard." 76 Fed. Reg. 15,632-33.

CIBO challenged that basis of authority in prior comments on these rules and reasserts those positions here. In short, an energy assessment does not purport to limit emissions, nor impose more stringent standards than the MACT floor and is, therefore, not a beyond-the-floor standard consistent with the text of the Clean Air Act. Furthermore, even if efficiency measures identified in the energy assessment were actually implemented, the reduced demand for the output of a regulated source is not an "emission control" technology to limit emissions from the regulated source. CAA §112(c)(2); 42 U.S.C. § 7412(d)(3). In addition, by defining the energy assessment

as a control, with the goal of reducing energy use, EPA illegally attempts to reduce demand for the product of the regulated source, in this case, the boiler. The scope of the energy assessment is illegally broad, and the proposed amendments to the scope in the Proposed Reconsidered rule do not cure the illegality. The energy assessment lacks a relationship to HAP reduction, and EPA provides no record basis demonstrating such a relationship. The rule irrationally assumes cost savings from projects that may (or may not) be identified or ever implemented by sources.

Section 114. Even as EPA proposes to not require sources to submit the energy assessment report to EPA under §112, EPA asserts in the proposed reconsidered Area Source rule, "the authority to obtain the energy assessment as authorized by section 114," 76 Fed. Reg. 80,540.

As CIBO has noted in earlier comments, the scope of the assessment is illegally broad. As proposed in the Reconsidered Rule, it remains as such, requiring sources to consider, inter alia, the "operating characteristics of the facility, energy system specifications, operating and maintenance procedures, and unusual operating constraints . . .;" "major energy consuming systems;" "available architectural and engineering plans, facility operation and maintenance procedures and logs, and fuel usage . . .;" and to identify "major energy conservation measures." 76 Fed. Reg. 32,014; *see also* 76 Fed. Reg. 80,664. EPA's authority under §112 is limited to setting emission limits for the affected combustion unit and does not extend to non-§ 112 sources, or generally to the entire "facility." What EPA requires goes far beyond its §112 authority.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3457-A2, excerpt 12.

This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: Bruce A. Steiner

Commenter Affiliation: American Coke and Coal Chemical Institute (ACCCI)

Document Control Number: EPA-HQ-OAR-2002-0058-3547-A2

Comment Excerpt Number: 11

Comment: The Reconsidered Rule Should Not Mandate Energy Assessments Energy conservation measures are laudable and a core part of everyday life in the cokemaking industry. In fact, many cokemaking facilities already perform many of the investigations associated with an energy assessment as they have implemented the EnergyStar guidelines for energy management. Nevertheless, as explained throughout this section, EPA lacks the statutory authority to mandate facility-wide energy assessments for at least three reasons: (1) the energy assessment is not an "emission standard," (2) EPA may not reach beyond the defined source category to impose legal obligations, and (3) EPA has not demonstrated that the proposed energy assessment requirement is a cost-effective beyond-the-floor standard. Further, even if such a requirement was legally viable, there are serious implementation issues that would impair the viability and functionality of energy assessments in many instances. Section 112 of the CAA does not authorize EPA to mandate that each facility housing a boiler or process heater perform an energy assessment. The

Reconsidered Rule characterizes this energy assessment requirement as a beyond-the-floor regulation issued pursuant to the agency's authority under §112(d)(2). That provision, however, only authorizes EPA to promulgate "emission standards," which are carefully defined in CAA §302(k) to mean: A requirement ... which limits the quantity, rate, or concentration of emissions of air pollutants on a continuous basis, including any requirement relating to the operation or maintenance of a source to assure continuous emission reduction, and any design, equipment, work practice or operation standard promulgated under this chapter." 42 U.S.C. §7602(k). The proposed energy assessment requirement falls beyond that definition.

The proposed energy assessment would require an "in-depth energy study identifying all energy conservation measures appropriate for a facility given its operating parameters." Thus, that measure just mandates an evaluation of the facility's processes to "identify energy conservation measures ... that can be implemented to reduce the facility energy demand..." (emphasis added). That one-time identification of possible emission reductions and process changes will not "limit the quantity, rate or concentration of emissions of air pollutants," much less "on a continuous basis." Nor is the proposed energy assessment a "design, equipment, work practice or operation standard." As such, it falls beyond the defined concept of an "emission standard." In fact, the U.S. Court of Appeals for the DC Circuit has held that a regulation imposing a general duty, without numerical emissions limits and without a mandatory plan for implementation, was not a free-standing emission limit and thus "not a section 112-compliant standard." *Sierra Club v. EPA*, 551 F.3d 1019, 1025-1028 (D.C. Cir. 2008). That same rationale applies here and confirms that the proposed energy assessment does not meet the threshold definition of an emission standard. As such, it is beyond EPA's authority under §112 to promulgate such a requirement.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3457-A2, excerpt 12.

This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: Bruce A. Steiner

Commenter Affiliation: American Coke and Coal Chemical Institute (ACCCI)

Document Control Number: EPA-HQ-OAR-2002-0058-3547-A2

Comment Excerpt Number: 13

Comment: The proposed energy assessment requirement exceeds that focused statutory charge to develop emissions standards by reaching far beyond the "specific portion" of the facilities identified in EPA's §112(c) list. Specifically, the proposed energy assessment would require the inspector to "establish operating characteristics of the facility, energy system specifications, operating and maintenance procedures, and unusual operating constraints," "review ... available architectural and engineering plans, facility operation and maintenance procedures and logs, and fuel usage," and facilities containing major sources must develop a "facility energy management program" in accordance with the EnergyStar energy management program. Additionally, the inspector is to "identify major energy consuming systems" and "list major energy conservation measures." *Id.* The inspector must then write up a comprehensive report summarizing his findings. *Id.* The only step properly limited to the regulated source category is the first one: "a visual inspection of the boiler system." *Id.* This step stands in stark contrast to the others, as it is

the only one explicitly limited to the regulated source category. Save the first requirement of visually inspecting the boiler, the entire energy assessment requirement attempts to regulate operations beyond the defined source category. EPA clearly lists the source categories subject to §112(d) and the Reconsidered Rule adheres to that same limitation by stating that it applies to industrial, commercial, and institutional boilers and process heaters. Nowhere is the source category defined as the facility that operates these units. Having defined the scope of this source category in its §112(c)(1) listing, EPA may not now reach beyond that category to impose obligations and limits. See *New Jersey v. EPA*, 517 F.3d 574, 583 (D.C. Cir. 2008) (“EPA may not construe [a] statute in a way that completely nullifies textually applicable provisions meant to limit its discretion.”) (quoting *Whitman v. Am. Trucking Ass’ns*, 531 U.S. 457, 485 (2001)). As such, EPA may not require the conduct of facility-wide energy assessments or the implementation of findings made during such an assessment. Instead, §112 limits EPA to regulating the source itself, in this case boilers and process heaters.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3457-A2, excerpt 12.

This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Commenter Name: Bruce A. Steiner

Commenter Affiliation: American Coke and Coal Chemical Institute (ACCCI)

Document Control Number: EPA-HQ-OAR-2002-0058-3547-A2

Comment Excerpt Number: 14

Comment: The proposed energy assessment requirement is not cost-effective, particularly for complex steelmaking facilities with cokemaking operations. For beyond17 the-floor controls, §112(d)(2) requires EPA to take “into consideration the cost of achieving ... emission reduction[s] and any non-air quality health and environmental impacts and energy requirements” which EPA “determines is achievable for new or existing sources in the category or subcategory to which such emission standard applies...” Thus, EPA must balance the cost of implementing pollution control measures with the magnitude of the reductions that will be achieved. As an initial matter, the cost estimates in the Reconsidered Rule significantly underestimate the magnitude of conducting an energy assessment at large, complex manufacturing facilities like integrated steel mills. Our industries’ extensive experience in voluntarily working to reduce energy consumption indicates that conducting the energy assessment described in the Reconsidered Rule at an integrated mill would be exceedingly costly - exclusive of the significant time and effort that plant personnel would need to dedicate to the task. Given our industries’ existing focus on securing voluntary energy reductions, that significant expenditure would be duplicative and wasteful in many cases.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3457-A2, excerpt 12.

This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Commenter Name: Tangelia Niemann

Commenter Affiliation: Texas Commission on Environmental Quality (TCEQ)

Document Control Number: EPA-HQ-OAR-2002-0058-3594-A3

Comment Excerpt Number: 4

Comment: The TCEQ is aware that the EPA is only proposing to amend certain definitions associated with the energy assessment requirements. However, the TCEQ does not consider it appropriate for the EPA to mandate energy efficiency assessments via a NESHAP rule. The energy assessment in 40 CFR 63 Subpart DDDDD is not a work practice or operational standard, and is not within the EPA's regulatory authority under FCAA, Section 112. Requiring companies to evaluate possible improvements in their operations does not constitute an actual work practice. Commenters challenged the EPA's authority on this requirement in the original proposal. The EPA's responses to these comments (76 FR 15631 – 15633) were that improvements in energy efficiency that reduce fuel use would reduce emissions, the requirement to perform an assessment was an enforceable requirement in the rule, and the EPA assumed that companies would implement those recommendations from the energy assessment auditor that they believed to be prudent. The EPA's responses to these comments fail to address the fundamental flaws in the EPA's beyond-the-floor argument for the energy assessment.

Foremost, the EPA is not correct in its claim that the energy assessment is a measure identified in FCAA, Section 112(d)(2) under the category of measures that "reduce the volume of, or eliminate emissions of, such pollutants through process changes, substitution of materials or other modifications..." (76 FR 15632). A reduction in fuel use would constitute such a measure; however, a requirement to conduct an evaluation of possible energy efficiency improvements that might reduce fuel use is not a measure included in FCAA, Section 112(d)(2). Furthermore, while the energy assessment is an enforceable requirement in the rule, the rule does not (and should not) require implementation of any aspect of the energy assessment. Therefore, the actual measure that could reduce emissions is not enforceable and the EPA cannot maintain that the requirement to perform an energy assessment results in emission reductions as provided in FCAA, Section 112(d)(2).

Response: See the response to comment EPA-HQ-OAR-2002-0058-3457-A2, excerpt 12.

Commenter Name: Tangela Niemann

Commenter Affiliation: Texas Commission on Environmental Quality (TCEQ)

Document Control Number: EPA-HQ-OAR-2002-0058-3594-A3

Comment Excerpt Number: 5

Comment: The EPA's claim that measures that conserve steam use from the boiler would reduce emissions through fuel savings might be correct in some cases but is not necessarily true in all cases. For example, a company may be able to expand operations as a result of the improved efficiency and not actually decrease the operating rates of the boiler. Any presumed benefit from the energy assessment is based on the assumption that companies will implement some of the measures as well as assumptions of the companies' future actions. The EPA's justification for the "beyond the floor" determination that the energy assessments will result in additional emission reductions is based solely on the EPA's assumptions. Furthermore, the

EPA's claim that the costs associated with the energy assessments are "minimal, in most cases," and implementation of any cost-effective conservation measures would be partially offset by fuel savings as part of its "beyond the floor" determination (75 FR 32026) is speculative and not valid. The technical support documents for the rule indicate the cost of an energy assessment ranges from \$2,000 - \$5,000 for a commercial or institutional facility and up to \$75,000 for an industrial facility. Total annualized costs for the facility energy assessments are estimated to be \$28 million nationwide for 40 CFR 63 Subpart DDDDD and while the energy assessment may lead to emission reductions, in and of itself, the assessment does not reduce emissions. Further, even if the assessment leads to emission reductions, the EPA cannot reliably quantify emission reductions associated with the energy assessment. Additionally, efficiency improvements are not always possible. A company could spend up to \$75,000 for an energy assessment only to learn that no additional improvements in efficiency at the facility are possible. As a result, companies that are already efficient in their operations are more likely to incur the costs of the required energy assessment with little or no benefit in terms of cost savings and little or no potential emissions reductions.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3457-A2, excerpt 12.

Commenter Name: Allison Watkins, Baker Botts

Commenter Affiliation: Class of '85 Regulatory Response Group

Document Control Number: EPA-HQ-OAR-2002-0058-3608-A1

Comment Excerpt Number: 13

Comment: Even if EPA had the authority to require an energy assessment of components beyond the boiler and process heater, which it does not, EPA has not substantiated that such "beyond the floor" control is warranted. In order to go "beyond the floor," EPA must consider the cost of achieving the emission reduction and the "beyond the floor" control must reduce the volume or eliminate emissions of HAPs. EPA has failed to satisfy these requirements.

Instead of considering the costs of achieving emissions reductions through the energy assessment requirement, EPA simply concludes without analysis or justification that "the costs of any energy conservation improvement will be offset by the cost savings in lower fuel costs." This assumes, first, that a facility will discover energy-saving strategies during the assessment, and, second, that the facility will be able to implement those strategies. Given that many companies already actively assess their energy usage, and that many business considerations must be evaluated before making process or equipment changes to address energy usage, both assumptions are arbitrary and irrational. EPA's consideration of the costs of achieving emissions reductions is therefore conclusory and not grounded in fact.

EPA also has failed to demonstrate that the performance of an energy assessment will result in any emissions reductions. EPA requires that facilities conduct an energy assessment, but not that they implement any of the assessment recommendations.²⁷ An assessment alone will not result in any emission reductions, disqualifying it as a "beyond the floor" control option. In its attempt to link the energy assessment requirement to emission reductions, EPA says only that "the

energy assessment will generate emission reductions through the reduction in fuel use beyond those reductions required by the floor.”EPA does not even attempt to explain (and indeed, cannot do so) how an *assessment* requirement, without an *implementation* requirement, will generate emission reductions. EPA further acknowledges that the implementation of assessment recommendations (and, therefore, the resulting emission reductions) is purely speculative: “the record indicates that energy assessments reduce fuel consumption and that parties will implement recommendations from an auditor *that they believe are prudent*.”EPA fails to link the assessment directly to a reduction in the emissions of HAPs.

For these reasons, EPA has not justified the energy assessment as a “beyond the floor” control and the requirement should be eliminated.

[Footnote 27: Requiring sources to implement the recommendations would be outside the scope of EPA’s § 112 authority because the boiler systems and energy use systems are not part of the affected source.]

Commenter Name: Randal G. Oswald
Commenter Affiliation: Integrys Energy Group
Document Control Number: EPA-HQ-OAR-2002-0058-3659-A2
Comment Excerpt Number: 10

Comment: Integrys requests that EPA eliminate the requirement that facilities complete a one-time energy assessment to identify cost-effective energy conservation measures for the boiler system and its energy use systems located at the source. EPA does not have the authority under §112 to go beyond the sources listed in a source category and impose requirements on other aspects of a facility.

EPA is a federal agency; it has no constitutional or common law existence or authority, but only the authority conferred upon it by Congress. "If there is no statute conferring authority, a federal agency has none."¹² Section 112 of the Act is designed to limit HAP emissions from specific emission units that are listed under §112(c)(1). EPA is required to promulgate "emissions standards under subsection (d)" for each category and subcategory listed under §112(c)(1).¹³ The methodology for establishing emissions standards for each source category is laid out in §112(d); it authorizes the Agency to promulgate "[e]missions standards...*applicable to new or existing sources.*"¹⁴

Comment: Comments on the energy assessment requirement.

A. The beyond-the-floor energy assessment requirement is not justified and should be deleted.

The proposal to impose a facility-wide energy assessment through this rulemaking is not practical, overstates benefits, understates costs, and is not authorized by the CAA. Since the energy assessment requirement impacts units other than BPH in a facility by including energy

consuming systems, this rulemaking expands this BPH rulemaking to many other source categories. The Agency's authority under section 112 of the CAA for that expansion is unclear at best.

There is no basis to claim any benefits for the energy assessment requirement since 1) major sources typically have already performed extensive energy assessments and installed those projects with high economic returns that make sense from a safety, reliability, operability and capital management perspective, and 2) the proposal separately requires BPH tune-ups, EPA's claimed main source of energy assessment benefits. In fact, EPA claims that the separate tune-up requirement saves 1% of the fuel fired from every BPH subject to that requirement, which is the majority of BPH (In Table 5 of the preamble EPA indicates 11,911 BPH in the gas 1 subcategory out of a total of 14,111 existing BPH). Thus, there are likely no net benefits from performing the energy assessment.

Our experience is that assessments such as specified in this proposal cost a minimum of \$100,000 for even a simple, small refinery and usually quite a lot more and require a large team of engineers intimately familiar with the site. While costs might be much lower for smaller facilities if they can avail themselves of the proposed 8 hour and 24 hour limit on assessment hours, there is no chance of any benefits in those cases, since 8 and 24 hours is inadequate to meet the assessment requirements as outlined in Table 3 or to certify compliance (See the following comment).

In refinery operations, many of energy "efficiencies" meeting the proposed definition of a "cost effective energy conservation measure" would not be manageable because of their operational or reliability impacts. Others would not be achievable because they would require capital that is required for mandated safety and environmental projects. Finally, many such measures would simply result in the transference of emissions to outside the refinery boundary and increase overall national emissions. One example is the shutdown of a steam turbine (presumably decreasing refinery emissions) and replacing it with an electric driver (transferring the emissions outside the boundary of the refinery) and increasing US emissions overall.

The current proposal appears to have considered a few minor points from our reconsideration request but certainly does not indicate any serious reconsideration of the energy assessment requirement. Nothing in the proposal or proposal preamble addresses 1) the legality of imposing this requirement on sources outside the regulated source category (i.e., energy consumers), 2) how this assessment is linked to HAP emissions, the legal basis for this rulemaking (which are miniscule from gas and light liquid fired equipment), 3) how equipment reliability, safety, and operability are to be protected, 4) the impact on national emissions of the transference of energy production to locations outside of our operations, or 5) the real costs of the proposal.

Comment Excerpt Number: 16

Comment: Proposed regulation 63.7500 and Table 3 requires that a one-time energy assessment must be performed. Alcoa- Warrick acknowledges that performance of an energy assessment would be a prudent business decision, but strongly objects to the inclusion of an energy assessment requirement in a regulation that regulates hazardous air pollutants. MACT floor determinations for this source category did not consider energy assessments. Thus, inclusion of the energy assessment requirement in this proposed regulation is contrary to the Clean Air Act. Accordingly, Alcoa-Warrick requests that item 4 of Table 3 and the definition of Energy Assessment listed in 63.7575 be removed from the proposed regulation.

Comment Excerpt Number: 81

Comment: Energy usage within most manufacturing facilities is directly and inextricably related to the processes being used and the qualities of the specific products being produced. The sweeping language EPA has proposed to modify manufacturing processes out of concern for HAP and non-HAP emissions would grant EPA the authority to redesign proprietary and confidential manufacturing systems at industrial sites across the country. This would require many, if not most, industrial facilities to grant third-party auditors and EPA access to a highly Confidential Business Information (CBI). Neither third-party auditors nor EPA fully understand the myriad technical and commercial analyses developed over years, or in some cases decades, by companies to optimize energy consumption, product performance and quality, and safety. This would paradoxically create a regulatory vehicle that would allow EPA the authority to mandate changes in energy-consuming manufacturing processes without first developing the in-house expertise to understand the full breadth of the processes, and with it the impact of potential changes to the safety of employees, competitive advantage of the product, or upstream and downstream processing activities at integrated sites.

Response: The energy assessment requirement of the Boiler MACT does not proposed to modify manufacturing processes or, in fact, grant the EPA the authority to redesign proprietary and confidential manufacturing systems. The revision made to the final rule allows company employees to conduct the actual energy assessment and the scope has been clarify to cover only the affected boilers and process heaters and the on-site systems using the energy from the affected boilers and process heaters. As for the authority to require an energy assessment, see the response to comment EPA-HQ-OAR-2002-0058-3457-A2, excerpt 12.

Commenter Name: Shannon S. Broome
Commenter Affiliation: Auto Industry Forum (AIF)
Document Control Number: EPA-HQ-OAR-2002-0058-3512-A1
Comment Excerpt Number: 47

Comment: EPA fails entirely to address the points previously raised by AIF. First, the energy assessment is impermissible under Section 112 of the CAA because the assessment is not an "emission standard" and it does not operate to reduce HAP emissions. EPA does not and cannot demonstrate that merely conducting an energy assessment will actually reduce HAP emissions or even that implementing the findings of such an assessment will lead to reduction in HAP emissions. EPA should eliminate the assessment on that ground alone. If EPA elects to retain the assessment, however, it exceeds EPA's authority under the CAA, even with the revision to certain language in Table 3. The energy assessment still operates to regulate sources beyond those strictly in the source category, *i.e.*, those not regulated by the Boiler MACT. The Boiler MACT does not regulate manufacturing facilities as a whole, therefore, EPA cannot properly include a variety of systems throughout facilities beyond the boilers and process heaters themselves. Therefore, to the extent it elects to retain the assessment, EPA should curtail the assessment to apply only to the boiler and/or process heater, not to the broader range of processes at a plant.

Commenter Name: Robert D. Bessette
Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)
Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1
Comment Excerpt Number: 112

Comment: Energy usage within most manufacturing facilities is directly and inextricably related to the processes being used and the qualities of the specific products being produced. The sweeping language EPA has proposed to modify manufacturing processes out of concern for HAP and non-HAP emissions would grant EPA the authority to redesign proprietary and confidential manufacturing systems at industrial sites across the country. This would require many, if not most, industrial facilities to grant third-party auditors and EPA access to a highly Confidential Business Information (CBI). Giving EPA the authority to mandate changes to manufacturing processes would put at risk competitive advantages that many manufacturers have secured for their products through careful technical and commercial analysis. Neither third-party auditors nor EPA fully understand the myriad technical and commercial analyses developed over years, or in some cases decades, by companies to optimize energy consumption, product performance and quality, and safety. This would paradoxically create a regulatory vehicle that would allow EPA the authority to mandate changes in energy-consuming manufacturing processes without first developing the in-house expertise to understand the full breadth of the

processes, and with it the impact of potential changes to the safety of employees, competitive advantage of the product, or upstream and downstream processing activities at integrated sites.

EPA has authority to regulate HAP emissions from major sources under section 112(d) of the Clean Air Act. This attempt to further regulate the way major sources consume energy under this rule is beyond EPA's authority. EPA should eliminate its definitions of "boiler system" and "energy use system". EPA should further limit the scope of energy assessments to "boiler(s)" and "process heater(s)" as currently defined.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3510-A1, excerpt 81.

Commenter Name: Stephen E. Woock

Commenter Affiliation: Weyerhaeuser Company

Document Control Number: EPA-HQ-OAR-2002-0058-3523-A1

Comment Excerpt Number: 14

Comment: EPA continues to propose an "above the floor" requirement to require facilities to conduct energy assessments. EPA's concept is in general, that by identifying cost-effective energy conservation measures, HAP emission would be reduced if some of the measures are implemented. Weyerhaeuser stridently opposes this proposed provision. While under the right circumstances there may be some merit to the general concept of conducting energy assessments to identify ways to reduce energy use and thereby reduce HAP emissions, EPA's proposal continues to miss the mark as an inefficient redundancy of a differently structured non-voluntary process that will potentially disrupt our continuing internal program and participation in voluntary efficiency programs. We refer EPA to our previous comments on this in docket ID EPA-HQ-OAR-2002-0058-2797 and the comments by our trade groups.

Response: Based on discussion with stakeholders, we are aware that some facilities may participate in a voluntary energy efficiency program or have recently conducted an energy assessment which a required additional energy assessment would be an unnecessary redundancy. The final rule has been revised to exempt owners and operators of affected boiler and process heaters that are in a energy efficiency program provided that the affected boilers and process heaters are included in the energy efficiency program. This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

104B. Five Year Time Frame [DENIED PETITIONER ISSUE]

Commenter Name: Michael Livermore, Jason Schwartz

Commenter Affiliation: Institute for Policy Integrity, NYU School of Law

Document Control Number: EPA-HQ-OAR-2002-0058-3432-A1

Comment Excerpt Number: 7

Comment: EPA's rule requires a one-time energy assessment for certain existing boilers. Mandatory energy assessments can be justifiable to correct market failures, and that justification can extend beyond a one-time energy audit for existing boilers only. Audits should be periodically repeated and should also apply, at appropriate times, to new boilers. More importantly, regulated entities should be required to implement any cost-effective energy conservation measures identified.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: Michael Livermore, Jason Schwartz

Commenter Affiliation: Institute for Policy Integrity, NYU School of Law

Document Control Number: EPA-HQ-OAR-2002-0058-3432-A1

Comment Excerpt Number: 10

Comment: The final regulation should also require an energy assessment for new sources several years after they come into existence. Even assuming a reason to exempt new sources when they first come online, the distinction between "new" sources and existing sources will diminish over time. After the passage of several years, conditions will change compared to when a new facility was originally designed. Markets and technologies evolve. If interest rates drop (and thus the related discount rates), more projects may become cost-effective. If expected fuel prices increase, the financial return from a given quantity of energy savings will be higher. Existing technologies may become cheaper. New technologies will increase the number of projects to consider. All of these changes mean that new sources may no longer be optimized after several years of operation.

The energy assessments of existing sources will become out of date on a similar timeframe. A new set of cost-effective energy conservation measures could be discovered every few years as a result. Thus, for both new and existing sources, audits should be periodic. This should be achievable at relatively low cost because much of the initial work would be done on the first assessment and would not need to be repeated.

Repeated energy assessments will also provide an easy mechanism for verification and enforcement of the required implementation of previously identified cost-effective conservation measures. If the regulated entity has not implemented their required energy conservation measures, this failure will turn up in subsequent energy assessments.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: Lee Zeugin and Lauren Freeman

Commenter Affiliation: Utility Air Regulatory Group (UARG)

Document Control Number: EPA-HQ-OAR-2002-0058-3500-A1

Comment Excerpt Number: 9

Comment: UARG argued in its comments on the 2010 proposed rule that the energy assessment requirement exceeded EPA's legal authority and that it should be removed from the

final rule. UARG remains convinced that CAA § 112(d) only authorizes EPA to regulate “sources” of HAP emissions.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

104C. Cost Analysis [DENIED PETITIONER ISSUE]

Commenter Name: Jessica Bridges

Commenter Affiliation: United States Clean Heat & Power Association (USCHPA)

Document Control Number: EPA-HQ-OAR-2002-0058-3501-A1

Comment Excerpt Number: 13

Comment: USCHPA questions the limitation to rely on a two-year or less payback criterion. Many capital investments, including combined heat and power systems, typically have longer payback periods, considering all benefit streams (both thermal and electricity). This should be reconsidered and broadened to permit greater aggregation of benefit streams. For example, Federal, State and even local tax credits should be applied to the benefit side of the calculation.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Commenter Name: David Gardiner

Commenter Affiliation: The Alliance for Industrial Efficiency

Document Control Number: EPA-HQ-OAR-2002-0058-3683-A2

Comment Excerpt Number: 6

Comment: EPA Should Refine Its Engineering Cost Analysis to Account for Savings Identified in the Energy Assessment.

While the Rule does not mandate implementation of cost-effective measures identified in the energy assessments, EPA properly notes that facilities are likely to implement many of the identified improvements. EPA acknowledged this likelihood in the March Rule, noting "while we do not know the precise reductions that will occur at individual sources, the record indicates that energy assessments reduce fuel consumption and that parties will implement recommendations from an auditor that they believe are prudent." It also implicitly recognizes the potential for regulated facilities to implement recommendations from the energy assessments in the December Rule, providing instructions for facilities that seek to "take credit for implementing energy conservation measures identified in an energy assessment." Despite this recognition, the Engineering Cost Analysis simply accounts for the cost of performing energy assessments, without accounting for potential savings that may result.²¹

The Engineering Cost Analysis should be modified to reflect conservative assumptions about potential fuel savings (and associated emissions reductions) that would result from implementing the results of the energy assessment.

[Footnote 21:US Environmental Protection Agency, OAQPS, Feb. 2011, “Regulatory Impact Analysis: National Emission Standards for Hazardous Air Pollutants for Industrial, Commercial, and Institutional Boilers and Process Heaters,” at 3-3 (Table 3-1) (http://www.epa.gov/ttn/ecas/regdata/RIAs/boilersriafinal110221_psg.pdf) (note that this estimate is unchanged in the Dec. 2011 Memorandum from Tom Walton to Brian Shrager, “Regulatory Impact Results for the Reconsideration Proposal for National Emission Standards for Hazardous Air Pollutants for Industrial, Commercial, and Institutional Boilers and Process Heaters at Major Sources” (<http://www.epa.gov/ttn/atw/boiler/boilersriaproposalrecon111201.pdf>)).]

104D. Definition of “Cost Effective” [DENIED PETITIONER ISSUE]

Commenter Name: Michael Livermore, Jason Schwartz

Commenter Affiliation: Institute for Policy Integrity, NYU School of Law

Document Control Number: EPA-HQ-OAR-2002-0058-3432-A1

Comment Excerpt Number: 3

Comment:

For some existing major and area sources, EPA has proposed requiring an "energy assessment" to identify "a list of energy conservation measures." While the regulations do not require implementation of any of the energy conservation measures identified, they do define "cost-effective energy conservation measures" as any measure with "a payback (return of investment) period of two years." EPA now seeks comments on the scope and definition of the required energy assessments.

The definition of "cost-effective measures" in the rule is fatally flawed statutorily and unjustified economically. If implementation of these measures is not required, there is arguably no need to define "cost-effective," and thus no definition should be issued. But since implementation of these measures is cost-benefit justified and should be required (see *infra*, section III of these comments), properly defining "cost-effective energy conservation measures" becomes important. The proper definition for that term should be: any energy conservation measure whose net present benefits are greater than zero.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Commenter Name: Michael Livermore, Jason Schwartz

Commenter Affiliation: Institute for Policy Integrity, NYU School of Law

Document Control Number: EPA-HQ-OAR-2002-0058-3432-A1

Comment Excerpt Number: 4

Comment: The definition of "cost-effective" chosen by EPA is improper for many reasons. There is no need for EPA to look to the Energy Policy and Conservation Act (EPCA) to define "cost-effective" under the Clean Air Act, and there are important differences between the statutes. The definition of "achievable" under Section 112(d) (and thus the subsidiary definition of "cost-effective" if the agency is to require implementation of "cost-effective energy conservation measures") should be based on the statutory text and purposes of the Clean Air Act and not on any part of the EPCA. In addition, the definition chosen by EPA is an improper interpretation of the clause from the EPCA that the agency looked to for guidance. The general context of the EPCA indicates that the clause sets a *floor* for "economically justified" and is not an independently valid definition of the term. Moreover, it is clear from the EPCA that Congress intended "economically justified" to mean cost-benefit justified.

The agency maintains that its definition—"a payback period of two years"—is based on section 325(o)(2)(B)(iii) of the Energy Policy and Conservation Act of 1975.¹⁰ The originally proposed rules' preamble explains that under this section "there is a presumption that an energy conservation standard is economically justified if the increased installed cost for a measure is less than three times the value of the first-year energy savings resulting from the measure."¹¹

First, it is not clear how the agency justifies reading the phrase "three times the value of the first year energy savings" under the EPCA to indicate a two-year payback period. These calculations are distinct in obvious ways.

Second, this interpretation omits crucial parts of the EPCA's statutory scheme. The full text of the cited clause from the EPCA is as follows:

If the Secretary [of Energy] finds that the additional cost to the consumer of purchasing a product complying with an energy conservation standard level will be less than three times the value of the energy, and as applicable, water, savings during the first year that the consumer will receive as a result of the standard, as calculated under the applicable test procedure, there shall be a rebuttable presumption that such standard level is economically justified. A determination by the Secretary that such criterion is not met shall not be taken into consideration in the Secretary's determination of whether a standard is economically justified.¹²

The final sentence of this clause indicates that a finding that a standard does not meet the criterion cannot even be taken into consideration for whether the standard is "economically justified." Thus, the definition chosen by EPA for "cost-effective" is inappropriate even within the context of the clause they cite to support it.

Third, the cited clause only makes sense in the context of EPCA's Section 325(o)(2)(A):

Any new or amended energy conservation standard prescribed by the Secretary under this section for any type (or class) of covered product shall be designed to achieve the maximum improvement in energy efficiency . . . which the Secretary determines is technologically feasible and economically justified.¹³

In this context, it is clear that the section cited by EPA as justification for the definition of "cost-effective" explicitly sets a floor for the Secretary of Energy's determination of "technologically feasible and economically justified," and is not a reasonable definition of "economically justified" or "cost-effective" by itself. More generally, Congress intended "economically justified" to mean cost-benefit justified, because the statute requires the Secretary of Energy to "determine whether the benefits of the standard exceed its burdens."¹⁴

Ultimately, the EPCA is not an appropriate place to look for a definition under the Clean Air Act at all. First, there are no statutory terms within the relevant sections of Clean Air Act that refer to the EPCA. Second, there is no duplication of statutory terms where proper interpretation would suggest that meanings should be harmonized across the statutes.¹⁵ For example, the EPCA uses "technologically feasible and economically justified" and then lays out criteria to guide the Secretary of Energy for making determinations based on that phrase.¹⁶ None of those criteria or terms is repeated in the Clean Air Act. For purposes of an energy assessment under Section 112(d) of the Clean Air Act, EPA should apply the statutory language of the Clean Air Act and standard economic principles, not the EPCA.

Comment Excerpt Number: 5

Comment: The proposed definition of "cost-effective energy conservation measure" is "a measure that is implemented to improve the energy efficiency of the boiler or facility that has a payback (return of investment) period of two years or less." By implicitly limiting the criteria to the private costs and benefits for regulated parties, this definition clearly falls short of the authority EPA has under the best interpretation of the statute. Because EPA has authority to consider a fuller range of social costs and benefits in determining which beyond-the-floor regulations are "achievable" under Section 112(d), the definition of "cost-effective" could include social costs and benefits.

However, as a practical matter, EPA will likely continue to exercise its statutory authority to stay focused on private costs and benefits in defining "cost-effective" for these purposes. An energy audit focused on private costs and benefits can still be a crucial element of a broader suite of regulatory policies designed to maximize net social welfare and minimize the negative impacts of hazardous air pollution. As such, these comments will explore how best to define "cost-effective" considering only private costs and benefits.

Given that it makes sense to define "cost-effective" in this context as reflecting private costs and benefits, it also makes sense to evaluate these costs and benefits in the way that an economically rational firm would value them. This means that all benefits and costs from a project should be considered, and a firm should undertake all investments where the net present value of all costs and benefits is higher than zero.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Comment Excerpt Number: 6

Comment: There are two important practical elements in determining the net present value of private investments: the timeframe of the analysis, and the discount rate for future costs and benefits.

The proper period of analysis for evaluating an investment is the period during which the investment affects relevant parties. The Economic Analysis Resource Document published by EPA's Office of Air Quality Planning and Standards states that:

It is common practice to calculate the costs of a regulatory option over the period of time corresponding to the expected useful lifetime of capital equipment purchased to comply with the rule. For example, if the capital equipment purchased as a result of the rule has an expected useful life of 15 years, an analyst might calculate the expected costs of the rule over a 15-year period. For consistency, benefits should be calculated over the same 15-year period.¹⁹

This rule of thumb should be used here as well. In the case of energy conservation measures, the "useful lifetime" of the project is the period when it provides benefits to the regulated party.

Because many (if not all) of the energy conservation measures being considered will have beneficial effects lasting longer than two years, EPA is unnecessarily limiting the consideration of benefits by defining the payback period as two years. Incorporating the full upfront costs of the measures but ignoring substantial future benefits would lead to under-adoption of energy conservation measures.²⁰ Given that the statutory explanation chosen by EPA for the two-year payback period is severely deficient, the agency should instead select the project's useful lifetime as the more economically rational period for analyzing energy conservation measures.

The discount rate is also important because it will determine how many measures will have a net present value above zero. In the context of an investment like an energy conservation measure, the costs of implementation will often be frontloaded and the benefits will be fairly constant from year to year (assuming fairly even amounts of energy savings and relatively stable prices). As a result, fewer energy conservation measures will look cost-effective with higher discount rates. For private investment decisions, the proper discount rate is the opportunity cost of capital, on the assumption that any dollar spent could earn the rate of return that the entity is achieving in its other projects. The correct rate will be the risk-adjusted rate of return that would be used to evaluate similar investment projects.²¹

[Footnote 19: OFFICE OF AIR QUALITY PLANNING AND STANDARDS, EPA, OAQPS ECONOMIC ANALYSIS RESOURCE DOCUMENT at 8-1(1999).]

[Footnote 20: Assuming that most capital costs are incurred in the early years of the project.]

[Footnote 21: The standard formulation would include the risk-free rate of return, plus an adjustment for the variance of the rate of return on the project. The risk of the particular energy conservation measure will be driven by volatility in energy prices or uncertainty in the actual quantity of energy savings.]

Comment Excerpt Number: 8

Comment: Ample evidence shows that businesses do not always take advantage of all cost-effective investments at their facilities. For example, a McKinsey & Company report from 2007 discovered many un-adopted greenhouse gas reduction measures that would have a negative marginal cost for private actors.²² Many of the measures identified in that report were available to the same the industrial and commercial sectors covered by EPA's Major Source and Area Source rules. EPA notes that the Department of Energy has done energy assessments and discovered that some facilities can reduce energy use by 10 to 15 percent.²³

The requirement of an energy assessment partially solves this problem. While somewhat controversial, Professor Michael Porter and others have argued that certain types of regulations can have negative costs, by forcing firms to rethink their production processes.²⁴ In this case, the

energy assessment requirement will provide each regulated entity with information it did not have before. New and better information can help overcome organizational inertia by giving evidence of cost-savings. A mandatory energy assessment, rather than a voluntary program, can be justified due to persistent barriers to the voluntary pursuit of energy efficiency—lack of information, lack of attention and salience, prioritization, and so forth.

The energy assessment requirement is a cost-benefit-justified regulation even if implementation of identified conservation measures is not mandatory. Armed with better information and focused attention thanks to an energy audit, regulated sources will be better able to take advantage of opportunities with significant private financial benefits, not to mention the environmental and health benefits from cutting energy use and associated pollution. While it is possible that some assessments may not lead to identifying of efficient energy efficient projects at some sources, there is sufficient evidence of general under-adoption of energy efficient technologies in the relevant sectors that substantial cost-savings can be achieved through the assessment requirement.

Comment Excerpt Number: 5

Comment: EPA Should Make the Energy Assessment Requirement More Robust By Expanding the Definition of Cost-Effective Energy Efficiency Improvements.

The Alliance is very supportive of the energy assessment requirement in the Rule. Such a requirement will enable regulated entities to lower compliance costs while reducing emissions of both hazardous and conventional pollutants. We are gratified by the broad scope of the energy assessment requirement and concur with EPA’s finding in the March 21, 2011 Rule that its inclusion of all major energy-consuming systems (and not merely the regulated boilers) will have substantial benefits. As we noted in our Reconsideration Petition, however, EPA should reconsider the definition of "cost effective" in the Rule in order to encourage regulated entities to identify more energy-saving opportunities.

In the March 21, 2011 rule, EPA defined "Cost-effective energy conservation measure" to mean "a measure that is implemented to improve the energy efficiency of the boiler or facility that has a payback (return of investment) period of 2 years or less." This definition remains unchanged in the December rule. Because such assessments are required of all existing major source facilities having affected boilers or process heaters, the scope of such an assessment is a fundamental element of the Rule. As written, we believe that the Assessment is too limited and the definition should therefore be changed to allow for a more comprehensive consideration of energy efficiency improvements at the regulated source. The current standard excludes some highly cost-effective measures that could generate substantial emissions reductions.

In particular, while delivering tremendous and cost-effective efficiency gains (and, therefore, emission reductions), CHP and WHR facilities require significant up-front expenditures.¹⁷ EPA in numerous other contexts has noted the enormous efficiency potential from CHP and WHR projects.¹⁸ The Alliance, therefore, reiterates its request for EPA to include language within its final rule that expressly encourages energy assessments that highlight the potential for CHP and WHR without imposing a two-year payback limitation.

104E. Energy Assessors Determine Time [DENIED PETITIONER ISSUE]

Commenter Name: Tangela Niemann

Commenter Affiliation: Texas Commission on Environmental Quality (TCEQ)

Document Control Number: EPA-HQ-OAR-2002-0058-3594-A3

Comment Excerpt Number: 14

Comment: The criteria that the EPA is proposing for a person to be considered a *qualified energy assessor* are overly specific and may force businesses to incur additional costs to conduct the energy assessment. The EPA is attempting to create a definition of *qualified energy assessor* that encompasses a broad range of industrial and commercial applications by establishing specific criteria for capabilities and knowledge. However, the effect is that owners and operators of sources will be required to contract a person meeting all the criteria in the EPA's definition to perform an energy assessment regardless of the application, rather than have the assessment performed by a person with the most specific knowledge for the application. Many of the facilities subject to 40 CFR 63 Subpart DDDDD are large industrial facilities, and some of these companies will have their own personnel that are much more knowledgeable about the operations at the facility. However, the EPA's definition of *qualified energy assessor* may force a company to contract an outside assessor because the company's own staff don't meet the specific criteria of the definition in §63.7575, even if the criteria are unrelated to operations at the facility. If the energy assessment is retained in the final rule, the definition of *qualified*

energy assessor should be made more general or revised such that the assessor is only required to have knowledge and capabilities specific to the processes at the site.

Response: The definition of "Qualified energy assessor" in the final rule has not been revised because it does prevent in-house experts from performing and preparing the energy assessment report.

This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Rationale for Regulated Pollutants

6A. Appropriateness of Work Practice for Dioxins/Furans

Commenter Name: James Pew

Commenter Affiliation: Earthjustice, Clean Air Council, Partnership for Policy Integrity

Document Control Number: EPA-HQ-OAR-2002-0058-3511-A1

Comment Excerpt Number: 44

Comment: The work practice standards EPA has proposed consist of an annual "tune-up," a "one-time energy assessment," and "good combustion practices." 76 Fed. Reg. at 80,664. Even if § 112(h) authorized EPA to set work practice standards in lieu of emission standards for boilers' emissions of dioxins and organic HAPs – which it does not – these work practice standards contravene § 112(h)(1), which provides that such standards must be "consistent with the provisions of subsection (d) or (f) of this section." 42 U.S.C. § 7412(h)(1). To be consistent with § 112(d), any work practice standards for boilers would have to reflect measures that yield the maximum achievable degree of reduction in these pollutants and that at a minimum reflect the measures adopted by the boilers with the lowest emission levels of dioxins and organic HAPs. EPA's proposal does not purport to satisfy this requirement and is untenable in light of record evidence that boilers can and do achieve reductions in dioxins through the use of activated carbon injection and reductions in other organic HAPs through the use of selective catalytic reduction systems. Further, as EPA is well aware, boiler operating parameters other than those mentioned in the proposed rule, 76 Fed. Reg. at 80,664, have a significant effect on dioxin emissions. In particular, EPA's previous MACT rules including its standards for medical waste incinerators show that the agency knows perfectly well that the composition of the fuel/waste being burned, temperature of the boiler combustion chamber, the residence time in the combustion chamber, the temperature of the gas exiting that chamber, the rapidity of the cooling of the gas, and the temperature of the air pollution control device all have significant effects on dioxin emissions. EPA, Chlorinated Dioxin and Furan Formation, Control and Monitoring (1997), Ex. 3 hereto. Assuming *arguendo* that EPA can set work practice standards at all for boilers' emissions of dioxins and other organic pollutants (and that the agency can set work practice standards for gas fired units and units with a relatively low capacity), these standards must be "consistent with the provisions of § 112(d)" by requiring the use of these control measures. Because EPA's proposed standards do not require the use of such measures they contravene § 112(h). Because EPA has not shown how its work practice standards comply with § 112(h) or even attempted to explain how they are consistent with § 112(d) given that many

boilers use control measures that reduce emissions of dioxins and other organic pollutants other than those contained in its proposed work practice standards, the agency's decision to promulgate such standards would be arbitrary and capricious.

Response: The EPA believes that the work practices being finalized for dioxins are appropriate and are consistent with the statute and with other NESHAP rulemaking efforts. Further, each source category is addressed individually and, although EPA strives for consistency in its approach, there are times where different approaches for different source categories are warranted. EPA took a different approach in the MWI rule, because section 129 requires that standards promulgated applicable to solid waste incineration specify numerical emission limitation and does not contain authority for work practice standards. Further, the emission limits for dioxins in the MWI rule are, in many cases, an order of magnitude higher than the dioxin levels measured (or the detection level for non-detects) from boilers and process heaters. EPA disagrees with the commenter's assertion that the work practice standard is not justified under section 112(h). That provision authorizes EPA to establish work practice standards for sources if the Agency determines that it is not feasible to prescribe or enforce an emissions standard. In this case, EPA has determined that it is not feasible to do so because the application of measurement methodology is impracticable due to technological and economic limitations. First, as explained in the preamble to the proposed reconsideration rule, the majority of emissions of dioxins for all subcategories of boilers and process heaters are below the detection levels of EPA test methods and, therefore, are technologically impracticable to measure. In addition, economic limitations make the application of measurement methodology impracticable because of the increased sampling time, manpower, and analyses in order to achieve measurement practicality. EPA also disagrees with the commenter's assertion that the work practice standard is inconsistent with section 112(d). The EPA understands that emissions of most organic HAP can be minimized by maintaining good combustion conditions. Furthermore, the EPA understands the other factors that affect dioxin emissions noted by the commenter, as cited in the record for EPA's 1997 emissions standards for medical waste incinerators, including the composition of the material being combusted and the conditions under which the material is combusted. However, we disagree that the 1997 analysis is relevant to today's action, because of differences between boilers and incinerators. Boilers are designed for high and nearly complete combustion whereas incinerators are designed primarily to reduce the volume of the organic waste material being feed, and the material combusted in a medical waste incinerator contains chlorinated plastics which is not part of the fuel burned in any boiler covered by the Boiler MACT. Thus, the factors that affect dioxin emissions, applicable to non-waste burning boilers, cited by the commenter can be controlled by and are part of the work practice standard that ensure boilers and process heaters are operated under good combustion conditions.

We continue to believe that the work practice standard that requires routine boiler/burner maintenance is the best measure for limiting emissions of dioxins from boilers and process heaters covered by the Boiler MACT, and it is justified consistent with CAA section 112(h). We disagree with the commenter suggestion that additional work practices are needed. Boilers are designed to routinely operate under the combustion conditions that will minimize dioxin emissions. This is confirmed by the fact that most of the dioxin emission test results obtained on boilers covered by the Boiler MACT are at or below the detection level.

Therefore, based on the combustion environment among boilers and process heaters, the requirement to conduct a periodic tune-up reflects the maximum degree of emissions reduction available, and is therefore consistent with section 112(d). The tune-up requirement will ensure that owners and operators of affected units verify combustion optimization and yet allow each unit to optimize combustion according to the best practice for the boiler type.

The work practice standard is a practical approach to ensuring that equipment is maintained and run so as to minimize emissions of dioxins, and we expect it to be more effective than establishing a numeric standard that cannot reliably be measured or monitored. The work practice requires maintaining and inspecting the burners and associated combustion controls (as applicable), tuning the specific burner type to optimize combustion, obtaining and recording CO, oxygen, and NOx (if applicable) values before and after the burner adjustments, keeping records of activity and measurements, and submitting a report for each tune-up conducted.

We disagree with the commenter that there is record evidence that boilers (non-waste burning) can and do achieve reduction in dioxin through the use of activated carbon injection (ACI) and selective catalytic reduction (SCR). ACI may have been demonstrated on medical waste incinerators (MWI) and municipal waste combustors (MWC) to reduce dioxins but they emit significantly higher dioxins due to incinerating chlorinated plastics. Further, we have no emission data showing the effect of ACI or SCR on controlling dioxin emissions from industrial (non-waste burning) boilers and the commenter did not submit this “record evidence” for units in this source category.

Commenter Name: Elizabeth McMeekin

Commenter Affiliation: PPG Industries, Inc

Document Control Number: EPA-HQ-OAR-2002-0058-3778-A1

Comment Excerpt Number: 8

Comment: PPG supports a work practice approach for dioxin/furan emissions from industrial boilers. Dioxin/Furan emissions cannot be reliably measured and there is no technically feasible means of ensuring continuous control of these emissions.

EPA has very little data on dioxin/furan emissions from industrial boilers and process heaters. In addition to the lack of actual data, the science is uncertain on how dioxin/furan emissions are formed and could be controlled from industrial boilers and process heaters. (Docket item EPA-HQ-OAR-2002-0058-02871 contains an extensive discussion on this subject.) While industry has experience controlling dioxin/furan emissions from sources such as municipal waste combustors where dioxin/furan emissions occur at much higher levels, there is no data showing that dioxin/furan emissions can be controlled using add-on control technology at the ultra low levels reported by boiler/process heater sources in the industrial boiler MACT ICR testing program.

Quantifying the actual, extremely low or non-existent dioxin emission levels for the Industrial Boiler MACT floor units is technologically impracticable and thus, it is not feasible to prescribe or enforce an emission standard for dioxin/furan emissions for these units. Therefore, EPA has ample authority and justification under Clean Air Act Section 112(h)(1) to establish a work practice standard for dioxin/furan in the Boiler MACT, as was done in the recently finalized

Mercury and Air Toxics Standard (MATS, or EGU MACT). The required tune-ups and other emissions reductions in the Industrial Boiler MACT will result in improved combustion and minimize dioxin/furan formation without establishing a numerical emission standard.

[Footnote]

Commenter Affiliation: Utility Air Regulatory Group (UARG)

Document Control Number: EPA-HQ-OAR-2002-0058-3500-A1

Comment Excerpt Number: 2

Comment: As EPA correctly notes, there are no proven emission controls for reducing dioxin and furan emissions below the already low levels indicated by IB testing. The work practice standards proposed by EPA will ensure efficient combustion practices and will avoid unnecessary and expensive compliance testing by IB operators.

Response: The EPA thanks the commenter for their support.

Commenter Name: David A. Buff, Golder Associates Inc.

Commenter Affiliation: Florida Sugar Industry (FSI)

Document Control Number: EPA-HQ-OAR-2002-0058-3504-A1

Comment Excerpt Number: 4

Comment: The FSI supports a work practice standard that requires an annual boiler tune-up. The annual tune-up will help ensure good combustion in the boiler, which will in turn help minimize dioxin/furan emissions. Conversely, the FSI is not aware of any commercially

available technology that will reduce dioxin/furan emissions from biomass-fired boilers to levels that are lower than the ones reported in the EPA database for the Proposed Boiler MACT Rule.

For all of these reasons, EPA's proposed work practice standard for dioxin/furan is more appropriate for the FSI's bagasse fired boilers than a numeric emission limit.

Response: The EPA thanks the commenter for their support.

Commenter Name: Lorraine Gershman

Commenter Affiliation: American Chemistry Council (ACC)

Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1

Comment Excerpt Number: 7

Comment: Based on the record supporting the Final Boiler Rule, EPA has very little data on dioxin/furan emissions from industrial boilers and process heaters since the majority of emission measurements are below the level that can be accurately measured using Method 23.

Furthermore, the science is still uncertain on how dioxin/furan emissions are formed and could be controlled from industrial boilers and process heaters. An extensive discussion on the subject can be found in the Docket.³ Industry has experience controlling dioxin/furan emissions from sources such as municipal waste combustors where dioxin/furan emissions occur at much higher levels than those reported by boiler/process heater sources in the industrial boiler MACT ICR testing program. [Footnote 3: Docket ID EPA-HQ-OAR-2002-0058-0287 Chlorinated Dioxin and Furan Formation, Control, and Monitoring, Presented at an ICCR Meeting, September 17, 1997.]

Commenter Name: Stephen E. Woock
Commenter Affiliation: Weyerhaeuser Company
Document Control Number: EPA-HQ-OAR-2002-0058-3523-A1
Comment Excerpt Number: 1

Comment: We support EPA's decision to establish a tune-up work practice to replace the dioxin and furan limits of the March 2011 final rules. This approach will eliminate concerns with technical infeasibility of controls to meet the limits proposed in 2010 and finalized in 2011. The EPA has responded reasonably and legally to the clear information that the limits were confounded by measurement uncertainties at the very low levels in the emissions database, as would be compliance measurements and strategies for control options.

Response: The EPA thanks the commenter for their support.

Commenter Name: Paul Noe
Commenter Affiliation: American Forest & Paper Association (AF&PA) et al.
Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1
Comment Excerpt Number: 1

Comment: EPA has Correctly Determined That a Work Practice Standard, Rather Than an Emission Limit, is Appropriate for Dioxin/Furan (D/F)

The majority of the data collected in order to set the D/F standards for industrial boilers are at levels below the capability of the analytical and stack test methods to detect emissions of these compounds (all but one of the test runs used to set the March 2011 Boiler MACT limits are marked as "detection level limited"). Much of the test data are labeled as being below the method detection limit and the remainder of the data is often flagged as being below the level the laboratory can report with confidence.

It is not appropriate to treat detection level limited data for purposes of establishing regulatory limits in the same manner as detected values because the uncertainty¹⁹ associated with measurements near or below the method detection limits is too high. The test methods were developed over 30 years ago to measure D/F at concentrations then found in some types of waste incinerator exhaust (levels orders of magnitude higher than those found in exhaust from today's industrial boilers).

All source emission measurements have random (precision) errors associated with sample collection, sample and equipment handling, sample preparation, and sample analysis. These errors define method detection and quantitation limits and uncertainty in a non-arbitrary, scientific manner (as discussed further below). When emission levels are much higher than the magnitude of these errors, there is a high degree of confidence in the measured value obtained from a single or a few test runs. However, as the measured value decreases, the contribution of these errors to the measured value increases, thus decreasing the confidence level in the accuracy of the measured value from a single or a few runs until the point where the measured value cannot be distinguished from the random error ("noise" level). This is the case with the boiler D/F data. When this occurs, the measurement value cannot be distinguished from zero with high confidence.

The magnitude of D/F measurement errors typically varies with every measurement and is affected by the characteristics of the sample, skills of the sampler and analyst, specific equipment used, techniques and procedures adopted by individual laboratories and other factors, even when following the same published test method (in this case, EPA Method 23). Although EPA Method 23 procedures minimize measurement errors at the stack emission levels and applications for which it was intended, measurement errors are not zero and become significant at the extremely low levels in industrial boilers.

Response: The EPA thanks the commenter for their support.

Commenter Name: Douglas A. McWilliams

Commenter Affiliation: American Municipal Power

Document Control Number: EPA-HQ-OAR-2002-0058-3685-A2

Comment Excerpt Number: 22

Comment: In both the final Utility MACT rule and the proposed Boiler MACT rule, EPA acknowledged that dioxin/furan exists in quantities too low to be accurately measured or detected by EPA Method 23, and that no known control technologies have a demonstrated ability to further reduce dioxin/furan below these already miniscule levels.²⁷ According to EPA's Boiler MACT analysis, more than half of the dioxin/furan measurements reviewed for purposes of setting the MACT floor were below the method detection level, and for several subcategories (including stoker coal units) all of EPA's data is below the level that can be accurately measured. These findings are consistent with EPA's findings in the Utility MACT rule, in which EPA acknowledged that the presence of sulfur in the exhaust gases prevents the formation of dioxins and furans in quantities greater than the detection limit, specifically when the sulfur-to-chlorine ratio in the gas is greater than 1.0. This ratio will exist for coal-fired boilers almost across the board.²⁹ The same analysis applicable to coal-fired Utility MACT boilers is applicable to the smaller coal-fired utility boilers subject to Boiler MACT operated by AMP members.

Commenter Name: Russell A. Wozniak

Commenter Affiliation: The Dow Chemical Company

Document Control Number: EPA-HQ-OAR-2002-0058-3449-A1

Comment Excerpt Number: 5

Comment: Dow supports EPA's decision to establish a work practice for dioxin/furan emissions.

Establishing a work practice standard for dioxin/furan emissions is supported by the emissions information collected by EPA. As detailed in our August, 2010 comments on the proposed rule, we shared similar concerns to those of EPA that the proposed numerical emission limits were below the method of detection and/or a level that can be accurately measured using EPA Method

23. Page 80606 of the December 23, 2011 preamble correctly points out the emission measurement problems and supports establishing work practice standards for these HAP. This proposed action is also consistent with EPA's recently promulgated MACT rule for electric utility boilers.

Response: The EPA thanks the commenter for their support.

Commenter Name: Melvin E. Keener

Commenter Affiliation: Coalition for Responsible Waste Incineration (CRWI)

Document Control Number: EPA-HQ-OAR-2002-0058-3454-A1

Comment Excerpt Number: 6

Comment: At 76 Fed. Reg. 80606, EPA explains that the majority of dioxin/furan data is below the detection limit. As such, the Agency made the decision to set work practice standards for dioxin/furans instead of numerical emission standards. CRWI supports that decision. Section 112(h) of the Clean Air Act allows the use of work practice standards when "the application of measurement technology...is not practicable due to technological and economic limitations." Not being able to reliably measure a pollutant certainly qualifies as a technology limitation. In addition, it is practically impossible to properly quantify the variability as a part of setting a floor standard when the majority of the data is below the detection limit.

Response: The EPA thanks the commenter for their support.

Commenter Name: Traylor Champion

Commenter Affiliation: Georgia-Pacific LLC (GP)

Document Control Number: EPA-HQ-OAR-2002-0058-3465-A1

Comment Excerpt Number: 3

Comment: GP supports EPA's decision to regulate dioxin / furan emissions from boilers and process heaters using a work practice standard established under Section 112(h) of the CAA as a result of the impracticality of establishing numerical limits: analytical quantification limitations for these pollutants make setting emissions limits impractical. As EPA states in the proposed rule, a very high percentage actual dioxin / furans measurements were below the level that can be accurately measured and therefore establishing a standard is not practicable due to technological and economic limitations. GP has conducted follow-up dioxin testing on a number of boilers to fully understand our emission profiles. In this follow-up testing, we have found that nearly all of the dioxin tests results were impacted by non-detectable levels of dioxin and furans. Our experience with dioxin testing is consistent with EPA's conclusion that it is impractical to measure dioxin / furans at the low levels found in industrial boilers emissions due to analytical limitations and imprecision in the sampling and testing procedures.

GP agrees with EPA's use of a work practice and we believe the work practice option is not only appropriate but the only available means of demonstrating compliance with dioxin / furan requirements.

Response: The EPA thanks the commenter for their support.

Commenter Name: Claudia M. O'Brien, Latham & Watkins LLP
Commenter Affiliation: JELD-WEN, inc.
Document Control Number: EPA-HQ-OAR-2002-0058-3485-A1
Comment Excerpt Number: 1

Comment: EPA has proposed work practice standards instead of numeric emission limits for dioxin/furans because its reassessment of the dioxin/furan data sets revealed that a majority of emission measurements were below the method detection level (MDL).² EPA explained that it adopted the work practice standards approach for dioxin/furans in its Utility MACT rule, and that rule and the Boiler MACT rule had similar data. In reassessing the Boiler MACT data, EPA found that approximately 55 percent of the measurements were below the MDL.³ Additionally, a much higher percentage of measurements for each subcategory were below the level that can be accurately quantified—more than half of the subcategories had 100 percent of measurements below the accurate measurement level, and the remaining subcategories had more than 80 percent of measurements below that level.⁴ Based upon this data analysis, EPA concluded that dioxin/furan emissions in industrial boilers and process heaters "cannot practically be measured."

[Footnote 4: The percentages of measurements below the level that can accurately be quantified are: 100 percent for Coal stoker; 89 percent for coal fluidized bed; 85 percent for pulverized coal; 100 percent for biomass stoker/other; 100 percent for biomass fluidized bed; 80 percent for biomass dutch oven/pile burner; 100 for biomass fuel cell; 96 percent for heavy liquid; 100 percent for light liquid; 100 percent for gas 2 (other process gases); and 100 percent for non-continental liquid (based on No. 6 oil data). EPA did not have data available for two of the biomass subcategories. 76 Fed. Reg. at 80,606.]

EPA's proposal to adopt work practice standards for dioxin/furan emissions is entirely consistent with EPA's practice in the context of other rules. In the Utility MACT proposal, EPA noted that "measurements made at or below the MDL have an accuracy on the order of plus or minus 50 percent, whereas other environmental measurements used by EPA in other rulemaking exhibit accuracies of plus or minus up to 15 percent."⁶ The Utility MACT data collection effort confirmed that the majority of testing showed data at or below the MDL, even where the testing time was doubled.⁷ EPA therefore concluded that it was questionable that any amount of expense and effort would make the tests viable.⁸ Thus, since the majority of emission measurements from electric generating units were below detection levels and the reliability of these dioxin/furan measurements presented both technological and economic obstacles to demonstrating compliance, EPA set work practice standards rather than emission standards for dioxin/furan in the Utility MACT proposal and finalized those standards in the Utility MACT rule. The Boiler MACT data similarly proves that industrial boilers face comparable technological and economic obstacles to demonstrating compliance, as dioxin/furan measurements are not reliable for these sources either.

[Footnote 7: 76 Fed. Reg. 24,976,25,040 (May 3, 2011) (Proposed Utility MACT Rule) (sampling time for

the 2010 Information Collection Request was extended to 8 hours)]

Comment: GRU supports the provision that would eliminate emission limits for dioxin and furans and would impose work practice standards to minimize dioxin/furan emissions, which consist of a periodic tune-up to ensure good combustion is achieved and maintained.¹

[Footnote]

(1) In the preamble of the reconsideration rule proposal EPA acknowledged that 55% of all data collected was below the detection limits for dioxin and furans

Response: The EPA thanks the commenter for their support.

Commenter Name: Michael Bradley

Commenter Affiliation: The Clean Energy Group

Document Control Number: EPA-HQ-OAR-2002-0058-3495-A1

Comment Excerpt Number: 1

Comment: Based on additional data and analysis, EPA acknowledged that direct measurement of dioxin/furan emissions is impractical, as was found for the Mercury and Air Toxics Standards (MATS). Thus, EPA proposes a work practice standard of an annual tune-up to ensure good combustion. The Clean Energy Group supports this change and agrees that the extensive measurement times and potential measurement inaccuracies warrant the use of a work practice standard. An annual tune-up to ensure good combustion is a reasonable measure to minimize emissions.

Response: The EPA thanks the commenter for their support.

Commenter Name: Lee Zeugin and Lauren Freeman

Commenter Affiliation: Utility Air Regulatory Group (UARG)

Document Control Number: EPA-HQ-OAR-2002-0058-3500-A1

Comment Excerpt Number: 1

Comment: UARG supports EPA's proposal to establish work practice standards in lieu of numeric emission limits for dioxin and furan emissions. Section 112(h) grants EPA discretion to set work practice standards in place of emission limits if the Administrator finds it is not feasible to prescribe or enforce emission limits. CAA § 112(h)(1). In the reconsideration notice, EPA

provides persuasive evidence about the very high percentage of non-detect measurements for dioxin and furan emissions from all categories of IBs. This is hardly surprising because IB operators have a strong economic incentive to operate their units as efficiently as possible.

The high percentage of measurements below the detection limit makes setting a meaningful MACT limit impossible for these HAPs because, by definition, a measurement below the detection limit has greater error associated with it than the value measured. In other words, one cannot say for sure that the substance is even present. Furthermore, setting an emission limit at the detection limit would be unenforceable because the error associated with a compliance measurement would make it impossible to certify the accuracy of a measurement. Setting an emission limit three times higher than the detection limit would only impose expensive dioxin testing with no practical value, since all future measurements are likely to be below that limit. Therefore, it is feasible neither to prescribe nor to enforce dioxin emission standards for IB units.

Response: The EPA thanks the commenter for their support.

Commenter Name: David A. Buff, Golder Associates Inc.

Commenter Affiliation: Florida Sugar Industry (FSI)

Document Control Number: EPA-HQ-OAR-2002-0058-3504-A1

Comment Excerpt Number: 3

Comment: FSI strongly supports EPA's decision to promulgate a work practice standard, in lieu of a numerical standard, for dioxin/furan emissions from biomass-fired boilers. There is little dioxin/furan data available to use for the establishment of a numerical emission limit for biomass-fired boilers, especially the hybrid suspension grate boilers and cell-type boilers used by the FSI. EPA concluded that "the large majority of the emissions measurements [for dioxin/furan] for all of the subcategories [of boilers] are below the level that can be accurately measured." 76 F.R. at 80606. EPA specifically noted that this conclusion is true with regard to several categories of biomass fired boilers. Consequently, it would be extremely difficult or impossible to establish a scientifically defensible limit for the dioxin/furan emissions from biomass fired boilers.

Response: The EPA thanks the commenter for their support.

Commenter Name: Michael L. Krancer

Commenter Affiliation: Pennsylvania Department of Environmental Protection (DEP)

Document Control Number: EPA-HQ-OAR-2002-0058-3507-A1

Comment Excerpt Number: 3

Comment: The EPA has proposed applying work practice standards for dioxins/furans in lieu of numeric emission limits for all boiler subcategories. The work practice standards require an annual tuneup, in accordance with § 63.7540, to ensure good combustion. The EPA reassessed the dioxin/furan data sets and determined that the large majority of the emission measurements for all subcategories are below the level that can be accurately measured by using the approved EPA test method. The EPA concluded that dioxin/furan emissions for all of the subcategories cannot be accurately measured using EPA Method 23.

The DEP agrees that dioxin/furan emissions cannot be accurately measured for certain subcategories. The DEP supports the inclusion of work practice standards, including an annual tune-up. This should provide adequate public protection by ensuring good combustion. The work practice standards approach would also alleviate the costly expenditures (a minimum of \$13,000 per test for EPA Method 23) that would be incurred for the performance of stack tests for dioxins/furans.

Response: The EPA thanks the commenter for their support.

Commenter Name: Chris M. Hobson

Commenter Affiliation: Southern Company

Document Control Number: EPA-HQ-OAR-2002-0058-3520-A1

Comment Excerpt Number: 7

Comment: As noted in Southern Company's comments⁴ on the proposed Industrial Boiler MACT, EPA does not have sufficient data above the detection limit to establish emission standards for dioxins and furans. Southern, therefore, supports EPA proposed decision to establish work practices standards in accordance with CAA § 112(h) as it is not practicable to apply the relevant measurement methodology to non-detect emissions.

Commenter Name: Paul Noe

Commenter Affiliation: American Forest & Paper Association (AF&PA) et al.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 2

Comment: As demonstrated by the measurement issues noted, quantifying the actual, extremely low or non-existent dioxin emission levels for the Boiler MACT floor units is technologically impracticable (as well as economically impracticable, given that the technological problems cannot be overcome by investing reasonable resources into the problem), and thus, it is not feasible to prescribe or enforce an emission standard for D/F emissions for these units. Therefore, EPA has ample authority and justification under Clean Air Act Section 112(h)(1) to establish a work practice standard for D/F in the Boiler MACT, as was done in the recently finalized MATS rule²⁴. The required tune-ups and other emissions reductions in the Industrial Boiler MACT will result in improved combustion and minimize conditions conducive to D/F formation without establishing a numerical emission standard. Again, we support EPA's conclusion in this proposal to establish work practice standards for D/F from industrial boilers.

[Footnote 24: 77 Fed. Reg. 9369 ("We are finalizing work practice standards [for organic HAP, including dioxins and furans] because the significant majority of data for measured organic HAP emissions from EGUs are below the detection levels of the EPA test methods....").]

Commenter Name: Richard Krock

Commenter Affiliation: The Vinyl Institute

Document Control Number: EPA-HQ-OAR-2002-0058-3526-A1

Comment Excerpt Number: 1

Comment: Work Practice Standards Are Appropriate For Controlling Dioxin Emissions

The VI supports EPA's decision to replace dioxin/furan emission limits with work practice standards for all boiler subcategories. During its reconsideration of the boiler MACT, EPA determined that a very high percentage of measurements in the data used to set the MACT floors were below the method quantitation level, *i.e.* the level at which dioxins can be accurately measured using the Agency's method for measuring dioxin emission from stationary sources—EPA Method 23. EPA concluded as a result that dioxin emissions from boilers cannot practicably be measured.

Response: The EPA thanks the commenter for their support.

Commenter Name: Richard Krock

Commenter Affiliation: The Vinyl Institute

Document Control Number: EPA-HQ-OAR-2002-0058-3526-A1

Comment Excerpt Number: 3

Comment: The detection limit of an analytical method is the lowest concentration that can be distinguished from replicate blanks.⁷ The quantitation limit of a method is the smallest concentration of the substance which can be measured with an acceptable level of uncertainty.⁸ Detection limits and quantitation limits are defined in a scientific, non-arbitrary manner in various published peer-reviewed consensus guidelines⁹ and EPA documents. Quantitation limits of test methods have great significance when measuring very low concentrations of pollutants. In practice, reported values below the method's quantitation limit should not be treated as real values. While speculation may serve a role in scientific research and exploration, such speculation is not a valid basis for imposing regulatory compliance requirements with significant legal penalties for noncompliance.

In the proposed rule, EPA has made the threshold determination that measurement of dioxin emissions from boilers is not practicable, because the data in the record shows that emission levels from boilers are in most cases below the level that can be reliably measured by the analytical methods. In the subcategories for which EPA had dioxin emission data, the percentage of measurements below the quantitation limit ranged from 80 to 100 percent. It is not surprising that the data fall below the method quantitation limit, given that the test methods were developed more than 30 years ago to measure dioxins in waste incinerator exhaust streams at concentrations that were orders of magnitude higher than those found in emissions from boilers. Given the infeasibility of measuring dioxin emissions, work practice standards are the appropriate approach.

Commenter Affiliation: Division of Air Quality, North Carolina Department of Environment and Natural Resources (NCDENR)

Document Control Number: EPA-HQ-OAR-2002-0058-3663-A2

Comment Excerpt Number: 18

Comment: Dioxin standard. EPA revised the procedure to calculate the final dioxin emission limits, given the proximity to the detection limits. EPA reassessed the lowest level accurately measured for dioxin emissions, compared those to the emission levels from all units tested, and found emissions were below the value accurately measured.

NC DAQ supports EPA's revised procedure for calculating a final dioxin emission limit. As mentioned above, we agree with EPA's conclusion to develop a work practice standard instead of emission limit standards, since most dioxin emissions were below the detection level.

Response: The EPA thanks the commenter for their support.

Commenter Name: Douglas A. McWilliams

Commenter Affiliation: American Municipal Power

Document Control Number: EPA-HQ-OAR-2002-0058-3685-A2

Comment Excerpt Number: 23

Comment: It is not appropriate to treat detection level limited data for purposes of establishing regulatory limits in the same manner as detected values because the uncertainty associated with measurements near or below the method detection limits is too high. All source emission measurements have random (precision) errors associated with the sample collection, sample and equipment handling, sample preparation, and sample analysis. These errors define method detection and quantitation limits and uncertainty in a non-arbitrary, scientific manner. When emission levels are much higher than the magnitude of these errors, there is a high degree of confidence in the measured value obtained from a single or a few test runs. However, as the measured value decreases, the contribution of these errors to the measured value increases, thus decreasing the confidence level in the accuracy of the measured value from a single or a few runs until the point where the measured value cannot be distinguished from the random error ("noise" level). This is the case with the boiler dioxin/furan data. When this occurs, the measurement cannot be distinguished from zero with high confidence.

Document Control Number: EPA-HQ-OAR-2002-0058-3815-A1

Comment Excerpt Number: 1

Comment: A work practice standard for dioxin/furans instead of a numerical emission limit. We were quite concerned about the expense and reliable quantification of our very low emissions with the available test methods. The proposed change resolves this concern.

Response: The EPA thanks the commenter for their support.

Commenter Name: Claudia M. O'Brien, Latham & Watkins LLP

Commenter Affiliation: JELD-WEN, inc.

Document Control Number: EPA-HQ-OAR-2002-0058-3485-A1

Comment Excerpt Number: 2

Comment: EPA's proposal to adopt work practice standards is also consistent with the agency's statutory authority. Clean Air Act (CAA) section 112(h) permits EPA to prescribe a work practice standard or other design, equipment, or operational standard consistent with CAA sections 112(d) or (f) "if it is *not feasible* in the judgment of the Administrator to prescribe or enforce an emission standard...."¹⁰ The statute further defines the phrase "not feasible to prescribe or enforce an emission standard" as including situations where the Administrator determines that "the application of measurement methodology to a particular class of sources is not practicable due to technological and economic limitations."¹¹

Here, EPA made the finding required by the statute to support adoption of work practice standards-that dioxin/furan emissions "cannot practicably" be measured for these sources. ¹² Setting a work practice standard here is well within the statutory framework-and stands in sharp contrast to *Sierra Club v. EPA*, 479 F.3d 875, 884 (D.C. Cir. 2007), where the D.C. Circuit struck down EPA's adoption of a work practice standard for ceramic kilns. In that case, EPA had not made *any* finding that measuring emissions from ceramic kilns was impracticable. Rather, EPA simply did not have data. That is clearly not the case here. EPA has the dioxin/furan data, but it has properly found that the data is not reliable and there are no methods of detection that would increase reliability at this time.

Thus, EPA's decision to adopt work practice standards here is consistent with past practice and its statutory mandate, and JELD-WEN supports it.

Commenter Name: Lorraine Gershman

Commenter Affiliation: American Chemistry Council (ACC)

Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1

Comment Excerpt Number: 9

Comment: Quantifying the actual, extremely low or non-existent dioxin emission levels for the industrial, commercial, and institutional (ICI) Boiler MACT floor units is technologically impracticable (as well as economically impracticable, given that the technological problems cannot be overcome by investing reasonable resources into the problem), and thus, it is not feasible to prescribe or enforce an emission standard for dioxin/furan emissions for these units. Furthermore, on February 17, 2012, EPA released its final non-cancer science assessment for dioxins and noted that —*As a result of efforts by EPA, state governments and industry, known and measurable air emissions of dioxins in the United States have been reduced by 90 percent from 1987 levels. The largest remaining source of dioxin emissions is backyard burning of household trash.*|| Additionally, the Agency also noted that "*generally, over a person's lifetime, current exposure to dioxins does not pose a significant health risk.*"

The EPA's findings further support the Agency's justification under Clean Air Act § 112(h)(1) to establish a work practice standard for dioxin/furan in the Boiler MATS.⁶ The required tune-ups

and other emissions reductions in the final Boiler MACT will result in improved combustion and minimize conditions conducive to dioxin/furan formation without establishing a numerical emission standard.[Footnote 6: 77 Fed. Reg. 9369, February 16, 2012 ("We are finalizing work practice standards [for organic HAP, including dioxins and furans] because the significant majority of data for measured organic HAP emissions from EGUs are below the detection levels of the EPA test methods....").]

Commenter Name: LESLIE SUE RITTS

Commenter Affiliation: National Environmental Development Association's Clean Air Project (NEDA/CAP)

Document Control Number: EPA-HQ-OAR-2002-0058-3529-A1

Comment Excerpt Number: 16

Comment: NEDA/CAP supports EPA's conclusion that it is not feasible to accurately measure dioxins and furans and thus a work practice standard is reasonable and appropriate. NEDA/CAP strongly supports the Agency's proposal to replace dioxin and furan emission limits with work practice standards. Section 112(d) of the Clean Air Act requires that MACT standards are limited to measures which are achievable and emission limits which are not capable of accurate measurement are not achievable. Further, Section 112(h) states that when it is not feasible for the Administrator to prescribe or *enforce an emission standard* for control of hazardous air pollutants, the Administrator may, in lieu thereof, promulgate a design, equipment, work practice or operational standard, which is consistent with Section 112(d). We concur with EPA's updated finding on page 80614 that for all categories of units, emissions were below the value that can be accurately measured. Method 23 is not capable of measuring these HAPs at the levels for various types of combustion units regulated under boiler MACT, and therefore the limits in the Final MACT rule were unenforceable. In addition, under Section 112(h)(2)(b) of the CAA, EPA has the authority to establish work practice standards when "the application of measurement methodology to a particular class of sources is not practicable due to technological and economic limitations." EPA originally found that dioxin/furan emissions can be precisely measured for at least some units in each subcategory except for Gas 1, therefore "Section 112(h)(2) did not apply because "measurement of emissions is impracticable due to technological and economic limitations." 76 Fed. Reg. 15,640. NEDA/CAP submits that EPA must directly address and correct its prior legal interpretation when the Agency finalizes the proposed rule.

Response: The EPA thanks the commenter for their support.

Commenter Name: James Pew

Commenter Affiliation: Earthjustice, Clean Air Council, Partnership for Policy Integrity

Document Control Number: EPA-HQ-OAR-2002-0058-3511-A1

Comment Excerpt Number: 29

Comment: EPA now proposes to set work practice standards instead of emission standards for dioxins. 76 Fed. Reg. at 80,614. The agency claims that "for all subcategories of units, emissions were below the value that can be accurately measured." *Id.* at 80,614, 80,606. EPA claims that about 55% of its test runs are below the MDLs and that a high percentage are below a level "that can be accurately measured" under EPA Method 23. *Id.* at 80,606. By "a level that can be accurately measured," EPA appears to mean a level three times higher than the RDL ("3 x RDL"). *See* EPA, Analysis of Dioxin/Furan Data and Minimum Detection Levels from Industrial, Commercial, and Institutional Boilers and Process Heaters National Emission Standards for Hazardous Air Pollutants – Major Source (November 2011) at 11. The agency concludes that it is, therefore, not "practicable" to measure dioxins from boilers. *Id.*

In claiming that it can set work practice standards in lieu of emission standards for boilers' dioxin emissions, EPA misreads § 112(h) as a license to set work practice standards whenever a number of emission tests falls below MDLs or 3 x RDL. That is not what § 112(h) says. Section 112(h) allows EPA to issue work practice standards in lieu of emission standards only where it is not feasible to prescribe or enforce an emission standard. 42 U.S.C. § 7412(h)(1). Further, it provides expressly that the term "not feasible to prescribe or enforce an emission standard" refers only to situations where: "(A) a hazardous air pollutant cannot be emitted through a conveyance designed and constructed to emit or capture such a pollutant, or that any requirement for, or use of, such a conveyance would be inconsistent with any Federal, State, or local law, or (B) the application of measurement methodology to a particular class of sources is not practicable due to technological and economic limitations." 42 U.S.C. § 7412(h)(2). EPA's claims that some boilers' dioxin emissions fall below the MDL these sources chose to employ does not speak to

this standard far less satisfy it. Neither does EPA's claim that a high percentage of boilers' dioxin emissions fall are below 3 x RDL. Those claims merely purport to show that some sources emissions are lower than the detection limits for some measurement methods, not that "measurement methodology" for boilers dioxin emissions is not practicable.

Response: The EPA disagrees with the commenter that it misreads §112(h). Section 112(h) clearly allows the Administrator to set a work practice standard instead of an emission limit if it is not feasible to prescribe or enforce an emission standard. As stated in the reconsideration proposal, the EPA assessed the dioxin/furan data sets and determined that the large majority of the emission measurements for all of the subcategories are below the level that can be accurately measured using EPA Method 23. As the commenter indicated, the percentages of measurements (test runs) below the method detection level (a level at which the pollutant is known to be present but is not accurately quantified) is about 55 percent. In addition to the high percentage of measurements below the method detection level, a very high percentage (85 to 100 percent) of measurements are below the level that can be accurately measured (i.e., 3 x RDL) for each subcategory. Based on the percentages of data below the method detection limit coupled with the percentage of data below the level that can be accurately quantified, the EPA concluded that emissions from industrial boilers and process heaters cannot practicably be measured, and, thus, it would be inappropriate (not feasible) to establish (prescribe) a numeric emission limits for dioxin/furan because it is unreasonable to required a source to demonstrate compliance with a questionably inaccurate emission limit based on questionable performance test results. The work practice standards require an annual tune-up to ensure good combustion. In addition, we are not aware of any emissions controls that are demonstrated to reduce dioxin emissions from the low levels indicated by the available data for boilers and process heaters.

Commenter Name: James Pew

Commenter Affiliation: Earthjustice, Clean Air Council, Partnership for Policy Integrity

Document Control Number: EPA-HQ-OAR-2002-0058-3511-A1

Comment Excerpt Number: 30

Comment: EPA offers no reason to believe that emission standards could not be set at a specific detection level. Certainly, EPA would not and could not dispute than it can set an emission standard at zero even though emissions below zero cannot be detected; the Clean Air Act expressly authorizes the agency to issue a "prohibition" on emissions where achievable. 42 U.S.C. § 7412d)(2). *A fortiori*, the agency can issue standards at a specific detection limit higher than zero even if emissions cannot be measured below that detection limit. That emissions below a certain level cannot be measured is always true, but this truism does not show that measurement of emissions is not practicable.

Further, EPA's claims that some test runs fall below sources' self-chosen detection limits does not establish that measurement is not practicable under § 112(h). As noted above, EPA refused to specify a test method for dioxin emissions and thereby effectively encouraged sources to use the cheapest and least accurate tests and to submit data that lacked precision and incorporated high MDLs. The agency cannot use its own choice to collect imprecise data as an excuse to avoid setting emission standards. That EPA chose not to collect better data does not show that measurement of dioxin emissions is not practicable. Rather, assuming *arguendo* that EPA lacks

data that are sufficiently precise to allow the agency to set emission standards, that fact would merely show that EPA chose not to collect adequate data.

Response: We disagree with the commenter that the EPA refused to specify a test method for dioxin emissions which encourage sources to conduct test that lack precision and incorporates high MDLs. In the tests conducted as part of the ICR for dioxin emissions, we required that EPA Method 23 be used and that the source collect a minimum volume of 2.5 cubic meters or have a minimum sample time of 4 hours per run that would result in low method detection levels (MDLs) in order to increase the possibility of collecting measurable amounts of dioxins and minimize the number of non-detects .

The EPA believes that the work practices being finalized for dioxins are appropriate and are consistent with the statute and other NESHAP rulemaking efforts. Further, each source category is addressed individually and, although EPA strives for consistency in its approach, there are times where different approaches for different source categories are warranted. The EPA does not believe that, at this time, it can specify a maximum MDL for dioxin emissions from boilers and process heaters covered by the Boiler MACT as that would require specifying laboratory analysis methods which, at this time, are not universally available in the U.S. (e.g., only one or two laboratories are equipped for high-resolution mass spectroscopy analyses.

Commenter Affiliation: Earthjustice, Clean Air Council, Partnership for Policy Integrity

Document Control Number: EPA-HQ-OAR-2002-0058-3511-A1

Comment Excerpt Number: 31

Comment: EPA still could set an emission limit at the detection level if it believes that the relevant best sources are emitting dioxins at or below that level. Assuming that it is lawful and non-arbitrary to adjust test results below the detection level upward – as EPA has done for other pollutants – the agency would be able to set an emission standard somewhat above the detection level if it believes that the relevant best sources are emitting dioxin emissions below the detection level. And even if the agency could not for some reason set standards based on the sources achieving emissions below the detection level, the agency admits that a substantial portion of the data it has (45%) are above detection levels. Thus, EPA could base standards on these emissions and specify a test method that would detect emissions at these levels.

Response: As indicated in the response to comment EPA-HQ-OAR-2002-0058-3511-A1, excerpt 14, we believe that using a measurement value of 3 times a method's detection limit established in a manner that assures 99% confidence of a measurement above zero will produce a representative method reporting limit (MDL) suitable for establishing regulatory floor values. In the case of dioxin emissions from boilers and process heaters, 98 percent of measurements are below the level (i.e., 3 x RDL) that can be accurately measured, even under the increased sampling times required in the ICR testing program. See the response to comment EPA-HQ-OAR-2002-0058-3511-A1, excerpt 30. We continue to conclude that dioxin emissions from industrial boilers and process heaters cannot practicably be measured and the EPA is finalizing work practice standards that require an annual tune-up to ensue good combustion.

Commenter Name: James Pew

Commenter Affiliation: Earthjustice, Clean Air Council, Partnership for Policy Integrity

Document Control Number: EPA-HQ-OAR-2002-0058-3511-A1

Comment Excerpt Number: 32

Comment: Nor is it relevant that many measurements fall below EPA's arbitrarily chosen "3x RDL." The 3x RDL is a product of two arbitrary decisions: (1) to look to the mean detection limit for all the best performers in any category, rather than determine a level below which dioxin truly cannot be detected; (2) to multiply that "RDL" by 3, without showing that three times that level reflects the an emission level below which dioxin cannot be detected. Obviously many of the tests were below 3x RDL; that is why the percentage of sources with levels below their self- chosen MDLs is 55% percent while the percentages of runs with emissions below the 3s RDL are higher. Because even many of the MDLs that sources self-selected can detect dioxin levels below 3x RDL, the mere fact that many test runs are below the detection level for EPA Method 23 scarcely shows that measuring boilers' dioxin emissions is impracticable.

Response: For each pollutant and associated test method, we established a pollutant concentration value that would be characteristic of the method detection limit achieved during collection of the data used in the floor calculations. The RMDL (Representative Method Detection Limit aka RDL) is not the lowest method detection limit reported but is a value typical of the method detection limits specific to the method used and the typical stack matrix. The RDL values used to support this rule are derived from the reported data used in setting the floor, from research studies of the test methods used in stack matrices similar to those encountered for a subject source category, or from calculations based on the method's required quality assurance and quality control requirements.

In the end, the RDL is a pollutant and method specific predictor of method detection limit capability in an application typical of that source category. The purpose of calculating a RMDL is to define a pollutant concentration value that accounts for at least some of the typical measurement variability at the method detection limit not otherwise addressed in the database used in the floor calculations. We believe that the outcome should minimize the effect of a test(s) with an inordinately high method detection level (*e.g.*, the sample volume was too small, the laboratory technique was insufficiently sensitive, or the procedure for determining the minimum value for reporting was other than the detection level). We then call the resulting mean of the method detection levels the representative detection level (RMDL) because it is characteristic of accepted source emissions measurement performance. To identify the RDL, the EPA first identifies the "method detection level" (MDL), which is the smallest quantity of a pollutant that can be measured. The MDL will vary among testing contractors for any number of reasons (*e.g.*, different testing equipment, sampling volumes, etc.). The EPA averages the MDLs from all tests from the best performing units in order to determine the level at which a competent testing contractor can measure emissions (the RDL). The RDL thus accounts for intra- and inter-laboratory variability since, by definition, it is the average of the capabilities of all contractors and their laboratories.

MDL (Method Detection Limit) is a value specific to each tester and laboratory combination. This number may be lower or higher than the calculated RMDL, but we expect it to be reasonably equivalent as these data were used in determining the RMDL. 3x RMDL is a value

used in MACT floor determination, in comparison to the 99% UPL calculated emission rate. It is not used as a detection limit decision point, as suggested by the commenter. 55% and greater of the sources reporting emissions had non detect values below the MDL which is much lower and, as stated above, we expect to be in the realm of the RMDL value. In this manner therefore, greater than 98% of sources will have emissions that were below the 3x RMDL value. Therefore, we continue to conclude that dioxin emissions from industrial boilers and process heaters cannot practicably be measured and the EPA is finalizing work practice standards that require an annual tune-up to ensue good combustion.

Commenter Name: James Pew

Document Control Number: EPA-HQ-OAR-2002-0058-3511-A1

Comment Excerpt Number: 33

Comment: EPA also chooses to ignore other dioxin measurement methods are available. Dioxin continuous emission monitors are available and EPA could use these to measure emissions. Further, it is well established that dioxins can be measured down to levels measured in femtograms per cubic meter. [See submittal p.22 for California Ambient Dioxin Air Monitoring Program (October, 2004).]

Response: The EPA recognizes the existence of other dioxin measurement methods and yet also recognizes the importance of consistency in measurements of these low magnitudes as well as the necessity of using the measurement technique for compliance determinations that was used to establish the emissions limit. At this time the EPA holds that method 23 is the appropriate tool for dioxin and furan emissions determinations. We disagree that dioxin continuous emission monitors are available. There is currently no performance specification (PS) for continuous chlorinated dibenzo(p)dioxin (dioxins) or chlorinated dibenzofuran (furans) monitoring. None of the approaches evaluated during the Environmental Technology Verification Program for Dioxin Emission Monitoring Systems met our nominal performance criteria requirement of 20 percent relative accuracy. While EPA believes there is potential to improve one or more of the continuous monitoring approaches for dioxins and furans to meet our performance requirements, we would need to further evaluate monitoring system performance and promulgate a performance specification before we would consider requiring continuous monitoring for dioxins/furans on a broad basis.

Commenter Name: James Pew

Commenter Affiliation: Earthjustice, Clean Air Council, Partnership for Policy Integrity

Document Control Number: EPA-HQ-OAR-2002-0058-3511-A1

Comment Excerpt Number: 34

Comment: EPA chooses to ignore that truth that dioxin can be measured – with the EPA Method 23 or with other methods – simply by extending the testing time. As EPA itself recognizes, the longer the testing time, the larger the dioxin sample. Thus dioxin emission levels that could not be measured in a one hour test can be measured in a two hour or five hour test. EPA, Analysis of Dioxin/Furan Data and Minimum Detection Levels from Industrial,

Commercial, and Institutional Boilers and Process Heaters National Emission Standards for Hazardous Air Pollutants – Major Source (November 2011) at 3-2 % Table 2-1.

Response: The EPA has proposed rules that include extended sampling times for EPA method 23 dioxin and furan measurements, and the guidance document we have recently issued to rule writers (“Data and procedure for handling below detection level data in analyzing various pollutant emissions databases for MACT and RTR emissions limits”), speaks to this directly.

As stated in the response to comment EPA-HQ-OAR-2002-0058-3511-A1, excerpt 30, in the tests conducted as part of the ICR for dioxin emissions, we required that EPA Method 23 be used and that the source collect a minimum volume of 2.5 cubic meters or have a minimum sample time of 4 hours per run in order to increase the possibility of collecting measurable amounts of dioxins and minimize the number of non-detects . Even at these extended sampling times, 98 percent of the measured dioxins were below the level that can be accurately measured (3 x RDL).

Comment Excerpt Number: 36

Comment: Ultimately, EPA’s claims simply ignore the reality that dioxin emissions can be measured and are being measured. Although EPA may be willing to pretend that dioxins cannot be measured in an effort to avoid setting a dioxin standard, the agency’s willingness to dissimulate in pursuit of that policy and political goal does not alter the reality that measuring

dioxin emissions is feasible. For all the reasons above, EPA's proposal to set work practice standards instead of emission standards for dioxins is unlawful and arbitrary.

Response: See the responses to comment EPA-HQ-OAR-2002-0058-3511-A1, excerpts 30, 33, and 35.

Commenter Name: Janice E. Nolen

Commenter Affiliation: American Lung Association

Document Control Number: EPA-HQ-OAR-2002-0058-3679-A2

Comment Excerpt Number: 11

Comment: The removal of emissions limits for dioxins and furans is especially troubling. Contrary to EPA's claim dioxin emissions can be measured and are being measured. But even if dioxins could not be accurately measured using the required test measurement, the EPA should set design or equipment requirements to accomplish the task, as is authorized in the same list as work practice standards in Section 112(h). The EPA should not simply default to "an annual tune up" (EPA, 2011d).

We support steps to improve work practices to ensure emissions do not increase. However, that is not enough. Work practice standards do not reflect measures that yield the maximum achievable degree of reduction in these pollutants nor, at a minimum, reflect the measures adopted by facilities with the lowest emission levels. If EPA were to set work practice standards, it would have to require the use of these technologies at a minimum. Moreover, the proposed rule provides no means to enforce compliance with even these limited requirements.

Response: See the responses to comment EPA-HQ-OAR-2002-0058-3511-A1, excerpts 29 through 36.

Comment Excerpt Number: 37

Comment: EPA listed boilers under Clean Air Act § 112(c)(6) because, under this provision, it must assure that sources accounting for ninety percent of the emissions of dioxins and POM are subject to emission standards under § 112(d)(2) or (d)(4). As the agency has acknowledged, it

cannot meet this ninety percent requirement without assuring that boilers are subject to such standards.

For boilers to be subject to standards under § 112(d)(2), EPA must set § 112(d)(2) standards for each hazardous air pollutant that boilers emit, including dioxins and POM. EPA may not regulate sources that it lists under § 112(c)(6) under § 112(h), nor may it issue § 112(h) standards for any pollutant that sources listed under § 112(c)(6) emit. For this reason alone, EPA's proposal to set § 112(h) work practice standards instead of § 112(d)(2) emission standards for boilers emissions of dioxins and POM is flatly unlawful.

EPA has argued that § 112(c)(6) does not require it to set § 112(d)(2) standards for all of the hazardous air pollutants emitted by the sources it lists under § 112(c)(6) but, rather, only the specific pollutants enumerated in § 112(c)(6). Even under the agency's interpretation of § 112(c)(6), therefore, it must set § 112(d)(2) standards for boilers' emissions of dioxins and POM, both of which are expressly enumerated in § 112(c)(6). Section 112(c)(6) does not say that EPA may set standards for such sources (or pollutants) under § 112(h), but rather specifies that the agency must set standards under § 112(d)(2) or (d)(4). EPA's proposal to set work practice standards for dioxins and POM contravenes that requirement.

Response: The commenter's argument is based on section 112(c)(6)'s provision that EPA establish standards pursuant to section 112(d)(2) or (d)(4). However, the commenter ignores the fact that section 112(h)'s authority to establish work practice standards applies "for purposes of this section," i.e., all of section 112. Therefore, EPA has authority to establish work practice standards in lieu of numeric emissions standards for any standard it establishes under any provision of section 112, not just standards for sources that are not needed to meet the Agency's section 112(c)(6) obligation. Had Congress intended that EPA must issue numeric emissions limits to meet that obligation, it could have specified so in section 112(c)(6), or could just as easily have limited EPA's work practice authority under section 112(h) to certain subsections of section 112. However, it chose not to do so.

Document Control Number: EPA-HQ-OAR-2002-0058-3511-A1

Comment Excerpt Number: 39

Comment: The Clean Air Act required EPA to complete its obligations under § 112(c)(6) no later than November 15, 2000, and the agency is subject to a court order requiring it to complete these long overdue standards by February, 2011. By failing to set emission standards under § 112(d)(2) or (d)(4) for boilers' emissions of dioxins and POM, EPA would not only violate the Clean Air Act but the court's order.

Response: EPA disagrees with the commenter's interpretation of the Clean Air Act, and of the Agency's obligation under the District Court order. First, the order required EPA to meet its obligations under section 112(c)(6) by February 21, 2011. EPA's issuance of the major source boilers rule was part of its actions to meet this obligation. Therefore, the court order required EPA to do only what the Agency is required to do under section 112(c)(6), and to have done so by a certain date.

Comment Excerpt Number: 9

Comment: Work practice standards. The American Lung Association is troubled by the EPA's continued reliance on work practice standards, particularly as they would be the sole means of reducing toxic emissions for 13 percent of boilers and heaters and for dioxins and furans. Although Section 112(h) of the Clean Air Act permits EPA to establish work practice standards as an option for reducing emissions, the Act intentionally limits their use, with explicit instructions that these are to be used only if it is infeasible to prescribe or enforce emission standards and further requires that any work practice standards be consistent with actual emission standards that EPA would set under § 112(d) if it were feasible to do so. Here, EPA has not shown and cannot show that it is infeasible to set emission standards for boilers, and the work practice standards it issued are not consistent with § 112(d). Rather, EPA has merely used work practice standards as an excuse to rationalize allowing industry to keep doing the same thing they currently do as being consistent with setting emissions standards on 195,000 boilers.

Response: See the response to comment EPA-HQ-OAR-2002-0058-A1, excerpt 37.

Commenter Name: Mary Sullivan Douglas

Commenter Affiliation: National Association of Clean Air Agencies (NACAA)

Document Control Number: EPA-HQ-OAR-2002-0058-3525-A1

Comment Excerpt Number: 30

Comment: EPA now proposes to adopt a similar "work practice" standard for dioxin and furan emissions, again asserting that enforcing a numerical limit is impracticable, notwithstanding the hundreds of D/F emission tests in the rulemaking record. EPA argues that this is demonstrated by the large number of results that are "non-detect" ("ND"), detection level limited ("DLL") or BDL. First, we note that this problem is of EPA's creation. EPA knew, before testing was to be conducted, that many results would be at or below detection limits if it only required sample periods of one hour per run. Indeed, industry sources specifically raised this issue and inquired whether they should extend sample periods to ensure more precise results. EPA's response was that sources need not do so and that EPA would "address" the issue in its rulemaking. Testing for

D/F and other pollutants often included detection and quantification limits that are quite high – one source reported a detection limit for mercury that equates to 6.57 lb of mercury emissions per year,³¹ while several sources reported D/F detection limits several orders of magnitude larger than the levels of regulatory interest. Further, if the standard is set at the most common detection limit, plus an appropriate variability factor, no harm is done, since a subsequent emission test that is BDL would not constitute a violation. Retaining such a limit would not require any change in performance for relatively clean units, but would at least require gross emitters to reduce emissions.

[Footnote]

(31) This is roughly equivalent to a quantification limit of more than 60 lb/yr. EPA refers to the quantification limit as the level at which emissions can be measured accurately.

Response: This comment speaks to justification for the work practice standards. See the response to comment EPA-HQ-OAR-2002-0058-3511-A1, excerpt 30

We disagree with the commenter assertion that EPA, knowing many results would be at or below detection limits if it only required sample periods of one hour per run, responded to industry that the sources need not extend sample periods to ensure more precise results. In fact, enclosure 1 to the ICR letter requesting testing stated the methods and sampling times or volumes. For example, for sampling for metals, it was stated EPA Method 29 be used and to collect a minimum volume of 4.0 cubic meters or have a minimum sample time of 4 hours per run. For dioxins/furans, enclosure 1 specified that EPA Method 23 be used and to collect a minimum volume of 2.5 cubic meters or have a minimum sample time of 4 hours per run.

Document Control Number: EPA-HQ-OAR-2002-0058-3525-A1

Comment Excerpt Number: 31

Comment: Developing a meaningful work-practice standard for controlling D/F emissions is far more difficult and resource intensive than merely reducing CO levels. According to the Industrial Combustion Coordinated Rulemaking (“ICCR”) study³², control of CO levels is not sufficient; one must also examine the interaction of several factors in a complex combustion environment. The ICCR study concludes that CO monitoring can help confirm that current operating conditions are the same as during a D/F emissions test, but are not a direct indicator of low D/F emissions; equivalent dioxin levels can be found at 1 ppm as are found at 4,000 ppm CO levels. Other factors were found to be more important and, based on the ICCR workgroup results, meaningful work-practice standards would have to include good combustion practices (including total hydrocarbon and CO concentrations, soot formation and particle entrainment), quench rate, air pollution control device temperature and fuel and waste parameters.³³ Large ICI boilers will have far higher flow rates than medical waste incinerators and so may actually emit a substantial amount of dioxin on an hourly (or certainly annual) basis. As discussed above, such a task would require significant resources. Indeed, such an effort would likely be more expensive than testing. There is no reason to suspect that manufacturers would voluntarily do so (even if it could be done) and no authority to require that they invest in such an effort.³⁴

Some manufacturers may, as a courtesy to their clients, publish “nominal” good combustion practices. However, there is no way for federal, state or local enforcement authorities to require that such practices have any practical impact. The end result would be additional paperwork demands on sources and permitting authorities and no environmental benefit.

(34) It is also likely that the manufacturers of a large number of boilers are no longer in business.

Response: The work practice standards require an annual tune-up to ensure good combustion. In addition, we are not aware of any emissions controls that are demonstrated to reduce dioxin emissions from the low levels indicated by the available data for boilers and process heaters.

The ICCR study was part of the original Boiler MACT rulemaking promulgated in 2004. In the September 13, 2004 preamble, we acknowledge that there are many factors that affect the formation of dioxin, and that dioxin can be formed in both the combustion unit and downstream in the associated PM control device. At that time, we indicated that minimizing organic HAP emissions can limit the formation of dioxin in the combustion unit. We reviewed all the good combustion practice (GCP) information available in the boiler population database and determined that no control existed, except for limiting CO emissions. One control technique, controlling inlet temperature to the PM control device, that has demonstrated controlling downstream formation of dioxins in other source categories (*e.g.*, municipal waste combustors) was analyzed for industrial boilers. In all cases, no increase in dioxins emissions were indicated across the PM control device even at high inlet temperatures.

Document Control Number: EPA-HQ-OAR-2002-0058-3525-A1

Comment Excerpt Number: 32

Comment: EPA’s real argument appears to be that setting D/F limits for these sources is “not worth it” because emission levels are “small.” If this is the case, EPA should make this argument clearly and support it with objective facts. It should, at least, compare daily/annual D/F emissions from medical waste incinerators (and other source categories) with D/F limits with anticipated D/F emissions from high emitters to see if those emissions are *de minimis*. Additionally, EPA should explore options to reduce testing burdens for the sector. Potential areas for reduced testing costs are pooled testing for units of similar designs and reduced testing frequencies for sources whose emissions are below a certain threshold. Additionally EPA could

attempt to review operating conditions for better performing units to determine whether there are readily discernible operating conditions (such as maximum boiler temperature, oxygen levels or chlorine content of fuel and designed residence time) where parametric monitoring can be employed in lieu of reference testing. EPA might also consider a threshold where, if sources demonstrate very low D/F emission rates, a one-time test, combined with parametric monitoring might suffice.

Response: As stated in the reconsideration proposal, the EPA assessed the dioxin/furan data sets and determined that the large majority of the emission measurements for all of the subcategories are below the level that can be accurately measured using EPA Method 23. As the commenter indicated, the percentages of measurements (test runs) below the method detection level (a level at which the pollutant is known to be present but is not accurately quantified) is about 55 percent. In addition to the high percentage of measurements below the method detection level, a very high percentage (85 to 100 percent) of measurements are below the level that can be accurately measured for each subcategory. Based on the percentages of data below the method detection limit coupled with the percentage of data below the level that can be accurately quantified, the EPA concluded that emissions from industrial boilers and process heaters cannot practicably be measured, and, thus, it would be inappropriate (not feasible) to establish (prescribe) a numeric emission limits for dioxin/furan because it is unreasonable to required a source to demonstrate compliance with a questionably inaccurate emission limit based on questionable performance test results. The work practice standards require an annual tune-up to ensure good combustion. In addition, we are not aware of any emissions controls that are demonstrated to reduce dioxin emissions from the low levels indicated by the available data for boilers and process heaters.

Commenter Affiliation: National Alliance of Forest Owners (NAFO)

Document Control Number: EPA-HQ-OAR-2002-0058-3519-A1

Comment Excerpt Number: 6

Comment: In its Major Source rule comments, NAFO urged EPA to adopt work practice standards for dioxin/furan,²⁶

For the same reasons, EPA should adopt work practice standards in lieu of emissions limits for mercury emissions from biomass boilers. As explained in our Major Source rule comments, EPA's proposed mercury emissions limits were also below detection limits and would require expensive control technology while providing little if any health benefit.²⁷

Thus, and we support EPA's decision to do so now. As EPA recognizes, baseline dioxin/furan emissions from biomass are already extremely low and, in many cases, are below detection limits. As a result, stringent emissions limits, such as those currently in effect, will require the installation of extremely expensive control technology while providing little if any health benefit. Further given the current detection limits, it will be impossible to distinguish between compliant and non-compliant facilities. For these reasons, we support EPA's proposal invoking its authority under section 112(h)(2)(B) of the Clean Air Act to issue work practice standards in lieu of emissions limits for dioxin/furan emissions. EPA should also adopt work practice standards in lieu of emissions limits for mercury emissions from biomass boilers. [Footnote 26: NAFO Major Source Rule Comments, at 7, 9.]

[Footnote 27: NAFO Major Source Rule Comments, at 7, 9.]

Response: The EPA thanks the commenter for their support of the dioxin/furan work practice standard.

The EPA disagrees with the commenter that work practice standards should be established for mercury emissions from biomass boilers. Over two-thirds of mercury emission test runs reported to EPA from the combustion of biomass fuels were reported above a detection limit. Thus, EPA does not agree that there is a significant measurement detection issue for mercury emissions from biomass boilers.

6B. Regulating PM as a Combustion-Based Pollutant

Commenter Name: David A. Buff, Golder Associates Inc.

Commenter Affiliation: Florida Sugar Industry (FSI)

Document Control Number: EPA-HQ-OAR-2002-0058-3504-A1

Comment Excerpt Number: 7

Comment: The FSI agrees with EPA that PM should be treated as a combustion-based pollutant, instead of a fuel-based pollutant. PM emissions are influenced by fuel characteristics (such as heating value, moisture and ash content) and the combustor design, both of which can vary greatly in biomass fired boilers. PM emissions also can be influenced greatly by the type of control devices that can be applied to the boiler. Consequently, it is appropriate for EPA to establish separate subcategories for biomass-fired boilers and to establish separate PM emission limits for each subcategory. As the FSI has noted in its prior comments to EPA, the PM emission limits for the FSI's hybrid suspension grate boilers and cell-type boilers should be based solely on the performance of the boilers in those subcategories.

Response: The EPA thanks the commenter for their support.

Commenter Name: Lorraine Gershman

Commenter Affiliation: American Chemistry Council (ACC)

Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1

Comment Excerpt Number: 15

Comment: There are not enough differences in levels of uncontrolled PM or TSM from these three types of coal-fired boilers to justify subcategorization. A review of EPA's database on controlled emissions does not reveal significant differences. This is evident from Appendices B and C of the ERG MACT floor memorandum found in the docket. Shown below are comparisons of the average of all test runs for top performers in the three coal subcategories compared to the two abovementioned biomass subcategories. [See submittal for table comparing PM emissions biomass categories.]

Here it can be observed that the two biomass subcategories differ substantially from the coal subcategories and would seem to merit their own subcategories as described in their petitions. However, there are relatively minor differences in the three coal subcategories. The emissions data for coal units do not indicate there is a substantial difference in PM emission rates between

stokers, pulverized coal, and fluidized bed coal boilers. Finally, either electrostatic precipitators (ESPs) or fabric filters can be deployed to effectively control PM/TSM emissions from any of these three boiler types. In conclusion, EPA should combine all coal boilers into one subcategory with one set of PM and alternative TSM emission limits.

Response: The EPA agrees with the commenter that there is not enough differences in levels of uncontrolled PM or TSM from the three types of coal boilers to justify subcategorization for PM or TSM. In the final rule, all coal units (regardless of combustor design) are subject to a single PM standard (or a single TSM alternative). Regulation of PM emissions on a combustor design basis has been retained in the final rule for the various biomass subcategories.

Commenter Name: Lorraine Gershman

Commenter Affiliation: American Chemistry Council (ACC)

Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1

Comment Excerpt Number: 12

Comment: *There is Not a Strong Technical Basis for Subcategorization of Coal Boilers for PM*

Coal-fired boilers should not be subcategorized by boiler design to set PM or TSM emission limits. EPA added a solid fuel subcategory to the Final Boiler Rule that replaced previously proposed separate subcategories for units designed to burn solid fossil-based fuels and units designed to burn solid bio-based fuels. The solid fuel subcategory applied to pollutants identified in the final rule as fuel-based pollutants (PM, HCl, and Hg). Standards for combustion-based pollutants (carbon monoxide (CO)), however, were based on specific subcategories for the various types and designs of combustion units, including the specific primary fuel types the units were designed to combust.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3510-A1, excerpt 15.

Commenter Name: Lorraine Gershman

Commenter Affiliation: American Chemistry Council (ACC)

Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1

Comment Excerpt Number: 13

Comment: In response to two petitioners' requests for separate subcategories for PM, EPA established a separate PM emission limit for the subcategory —hybrid suspension grate units designed to burn biomass/bio-based solid,|| which is defined by fuel with moisture content of at least 40 percent. However, in responding to these two petitioners, whose arguments appear to be strongly in support of separate subcategories for biomass units, EPA went a step further by setting separate PM standards for both biomass and coal design subcategories. EPA has no basis for applying the arguments presented to subcategorize *biomass* boilers to now subcategorize *coal* boilers.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3510-A1, excerpt 15.

Commenter Name: Lorraine Gershman

Commenter Affiliation: American Chemistry Council (ACC)

Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1

Comment Excerpt Number: 14

Comment: Of particular interest to ACC is the decision by EPA to subcategorize the coal-fired boilers into three groups by boiler type (stokers, pulverized coal, and fluidized bed). We agree that PM/TSM limits should be set separately for coal boilers apart from biomass boilers, but we disagree that coal units should be further subdivided. The results of EPA MACT floor determinations for PM by coal design type are counter-intuitive. The limit for coal fluidized bed boilers is highest and the limit for coal stoker boilers is lowest.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3510-A1, excerpt 15.

Commenter Name: Steve Gossett

Commenter Affiliation: Eastman Chemical Company

Document Control Number: EPA-HQ-OAR-2002-0058-3669-A2

Comment Excerpt Number: 11

Comment: Coal-fired boilers should not be subcategorized by boiler design to set particulate matter or total selected metals emission limits.

Two petitioners requested separate subcategories be established for particulate matter emission standards. One requested a subcategory for "nondrying suspension boilers" arguing that they are unique devices burning dry wood fuel that have a unique emissions profile with respect to PM due to combustion in suspension, high excess air, and a high peak combustion temperature. In response, EPA established a new subcategory called "stokers/sloped grate/others designed to burn kiln-dried biomass fuel". A second petitioner requested a subcategory for bagasse-fueled boilers due to the high moisture content and low density causing a less complete burn than occurs with drier, denser fuels, thereby elevating the levels of PM. Also, the petitioner argued that bagasse-fueled boilers emit a high amount of PM relative to their non-mercury metallic HAPs. In response, EPA established a separate PM emission limit for the subcategory "hybrid suspension grate units designed to burn biomass/bio-based solid", which is defined by fuel with moisture content of at least 40 percent. However, in responding to these two petitioners, EPA went a step further by setting separate PM standards for a total of 10 solid fuel subcategories, including these two. EPA has no basis for using this broad-brush approach to further subdivide the other solid fuel boilers.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3510-A1, excerpt 15.

Commenter Name: Steve Gossett

Commenter Affiliation: Eastman Chemical Company

Document Control Number: EPA-HQ-OAR-2002-0058-3669-A2

Comment Excerpt Number: 12

Comment: Of particular interest to Eastman is the decision by EPA to subcategorize the coal-fired boilers into three groups by boiler type (stokers, pulverized coal, and fluidized bed). As stated elsewhere in these comments, we agree that PM/TSM limits should be set separately for coal boilers apart from biomass boilers, but we disagree that coal units should be further

subdivided. The results of EPA MACT floor determination are counter-intuitive. First, the limit for fluidized bed is unreasonably high, and the limit for stokers is unexplainably low. Second, PM is supposed to be a surrogate for TSM, yet this analysis shows the two to be inversely related. There are not enough differences in levels of uncontrolled PM or TSM from these three types of coal-fired boilers to justify subcategorization. A review of EPA's database on controlled emissions does not reveal significant differences either. This premise is evident from Appendices B and C of the MACT floor memorandum found in the docket. Table 4 {of the submittal] below compares the average of all test runs for top performers in the three coal subcategories compared to the stoker and hybrid suspension biomass subcategories:

Here it can be observed that the two biomass subcategories differ substantially – by one or two *orders of magnitude* - from the coal subcategories and would seem to merit their own subcategories as described in their petitions. In contrast, there are relatively minor differences in the three coal subcategories.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3510-A1, excerpt 15.

Commenter Name: Steve Gossett

Commenter Affiliation: Eastman Chemical Company

Document Control Number: EPA-HQ-OAR-2002-0058-3669-A2

Comment Excerpt Number: 14

Comment: Eastman recognizes that EPA is limited to working with the data at its disposal for top performing units when calculating emission limits. However, this example illustrates the absurd results that come from EPA's decision to subcategorize within the family of coal boilers. As discussed earlier in these comments (see Section C.1, above), boiler design is fundamentally a function of fuel rank. To establish separate subcategories for high rank coal boilers versus low rank coal boilers, as EPA did in the Utility MACT, is logically and technically sound. To build upon that logical construct and establish subcategories for high rank coal boilers, low rank coal boilers, and even lower rank biomass boilers is also logically and technically sound. But to attempt to subcategorize within the family of high rank boilers, as EPA has effectively done by attempting to segregate industrial coal boilers based on their fuel feed systems, is illogical and produces absurd results. EPA should abandon this ill-conceived construct and instead treat all coal boilers as a single subcategory for PM emission limits.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3510-A1, excerpt 15.

Commenter Name: Steve Gossett

Commenter Affiliation: Eastman Chemical Company

Document Control Number: EPA-HQ-OAR-2002-0058-3669-A2

Comment Excerpt Number: 15

Comment: The data among EPA's top performers do not indicate there is a statistically significant difference in PM emission rates between stokers, PC, and FB coal boilers. Finally, either ESPs or fabric filters can be deployed equally to effectively control PM/TSM emissions from any of these three boiler types.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3510-A1, excerpt 15.

Commenter Name: Steve Gossett

Commenter Affiliation: Eastman Chemical Company

Document Control Number: EPA-HQ-OAR-2002-0058-3669-A2

Comment Excerpt Number: 13

Comment: Eastman also disagrees with EPA's premise that PM emissions are solely or primarily a function of the type of fuel feed system employed to fire the unit (i.e. PM emission differ for stoker coal units versus pulverized coal units versus fluidized bed units). Eastman owns and operates coal units with a variety of fuel handling & firing systems (deep bowl and shallow bowl pulverizers, attrition pulverizers; spreader stokers) and particulate collectors (precipitators and fabric filters). Eastman's extensive operating experience with a wide variety of units indicates that the size distribution of PM emission is highly dependent upon the firing system, as shown below in Table 5 [see submittal for Table 5]. However, Eastman's experience also teaches that the PM *emission rate* is also influenced by the size and design criteria of the *particulate collector* in addition to the firing system of the boiler. EPA's proposed PM limits presume, in contrast, that the firing system is the sole determinant of the PM emission rate. EPA concludes from its analysis of ICR test data that stoker coal units should comply with a lower PM emission standard (0.028 lb/MMBtu) than pulverized coal units (0.044 lb/MMBtu). But consider in Table 6 [see submittal for Table 6] the difference between Eastman's No. 19 Boiler (stoker coal boiler with an ESP) and No. 26 Boiler (pulverized coal boiler with an ESP).

If EPA's logical construct that PM Emission Rate was solely determined by the firing system were true, it would follow that the stoker coal unit (No. 19) would have a lower PM emission rate than the pulverized coal unit (No. 26). But instead the opposite is true: The PM emission rate from the stoker coal unit is an order of magnitude higher than the rate from the pulverized coal unit. The explanation can be seen in the design of the precipitator. The specific collection area (SCA) is an indication of how large the collecting surface of the precipitator is relative to the gas flow passing through it. Because No. 26 Boiler has a very large SCA (i.e. its ESP is very large, relative to the size of the boiler) compared to No. 19 (i.e. with a relatively small ESP, relative to the size of the boiler), No. 26 has a much lower PM emission rate compared to No. 19. It is clear that the emission rate of No. 26 has little if anything to do with the fact that it is a pulverized coal unit.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3510-A1, excerpt 15.

Commenter Name: Bart Sponsellar

Commenter Affiliation: Wisconsin Department of Natural Resources

Document Control Number: EPA-HQ-OAR-2002-0058-3527-A2

Comment Excerpt Number: 8

Comment: EPA is proposing that particulate emissions are a combustion based pollutant instead of a fuel-based pollutant. The Department agrees that the generation of particulate is primarily a function of combustion with good combustion practice being the first measure in reducing particulate emissions. However, particulate emission rates are being used as a surrogate for non-mercury metal emissions. As such, we must recognize that the reduction of the

particulate emissions, which are associated with metal emissions, is likely achieved through particulate control equipment such as fabric filters and electrostatic precipitators (ESP). For this reason EPA must rely primarily on controlled particulate emission rates relative to determining MACT for non-mercury metal emissions. However, as noted in the "solid fuel" discussion, the emission of all metals is first related to the concentration of metals in the fuel.

The Department asks EPA to clarify how designating particulate as a combustion-based pollutant relates to acting as a surrogate for non-mercury metal emissions. The Department believes such a designation is useful if good combustion is used in conjunction with operating particulate control equipment. This combined type of parametric monitoring approach could potentially be applied in combination with fuel testing to allow stack testing of metals every two years instead of the default annual test cycle.

Response: The TSM measurement, which directly quantifies the HAP metals rather than relying on a surrogate, is a more direct measurement of HAP than PM and is, therefore, appropriate as a pollutant group for regulation with numeric emission limits. Several petitioners to the March 2011 final rule provided information to support the position that PM should be considered a combustion-based pollutant rather than a fuel-based pollutant. After assessing the points raised by the petitioners, the EPA determined that PM emissions are influenced both by fuel type and unit design. Therefore, it is appropriate to treat PM as a combustion based pollutant. Differences in PM particle size, applicability of air pollution controls to units combusting various fuels, and the lack of demonstration of certain control technologies on certain designs of boilers suggested that PM is more appropriately classified as a combustion-based pollutant limits. For TSM in the March 2011 final rule, we chose to use PM as a surrogate. Most, if not all, TSM emitted from combustion sources will appear on the flue gas fly-ash. Therefore, the same control techniques that would be used to control the fly-ash PM will control TSM.

Document Control Number: EPA-HQ-OAR-2002-0058-3525-A1

Comment Excerpt Number: 16

Comment: Under EPA's current and proposed procedures, creating larger numbers of subcategories usually leads to higher MACT floors in two ways. First, if a small number of the best performers (e.g., fuel cells) can be culled from a larger group into its own subcategory, the MACT floor for the larger group (the wood-fired boilers) will rise. Second, because the small group will have a small number of tests, the statistical variability of the small group will also increase, leading to MACT floor increases for both the larger group and the smaller group. EPA's decision to create separate subcategories for PM emissions based on the design of the combustion chamber creates a situation where a unit with highly variable emissions is classified as a top performer, based on EPA's inappropriate definition of best performing unit. Since that unit has many more test results than others in the group, EPA's pooled UPL process causes that unit to dominate and results in a limit that is technically invalid. The resulting proposed limits are often substantially higher than the highest emitting unit. [See submittal for Chart 1 showing PM emissions for Coal FB units.]

Response: EPA disagrees with the commenter. For the reasons identified in the preamble to the December 23, 2011 proposed reconsideration of the rule, the final rule has retained the regulation of PM as a combustor-based pollutant for units designed to combust biomass or bio-based solid fuel. However, all units designed to combust coal or fossil-derived solid fuels (regardless of combustor design) are subject to a single coal-based PM standard in the final rule.

The methodology used to determine the MACT floors was consistent in all cases. The situation the commenter is referring to is unique in that for this particular subcategory there were numerous PM test results (158 test runs) for the 5 best performing units making up the MACT floor. One best performing unit reported test results covering 10 years with PM emissions varying by a factor of 5 over that time period.

Comment Excerpt Number: 3

Comment: In the Proposed Rule, EPA proposes treating PM as a combustion based pollutant by adding 7 subcategories for PM. This subcategorization approach would significantly limit the number of units used to establish a MACT floor. Therefore, CPI NC does not support this approach and recommends that PM remain treated as a fuel based pollutant.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3525-A1, excerpt 16. The EPA further notes that its subcategories are based on differences in class, type, or size among the affected units. The number of units in each resulting subcategory is not relevant to EPA's analysis of and conclusions regarding the appropriateness of defining subcategories within the boiler and process heater source category.

Commenter Affiliation: CPI USA North Carolina (CPI NC)

Document Control Number: EPA-HQ-OAR-2002-0058-3524-A1

Comment Excerpt Number: 2

Comment: CPI NC does not support the EPA's methodology for establishing emissions limits based on single fuel type facilities. In the Proposed Rule, EPA proposes to establish emissions limits for fuel subcategories by using data from the top 12% of units that use, for example, at least 90% biomass in the case of PM and CO biomass categories, and 90% coal in the case of PM and CO coal categories. While this method may be appropriate for single fuel facilities, it does not reasonably consider maximum achievable control technologies for facilities utilizing multiple fuel types. Capital Power recommends using fuel and fuel mixture variability for multi-fuel facilities in determining the top 12% of such facilities for the MACT floor. This approach is more reasonable because it captures each facility's operational and fuel variability.

Response: The EPA disagrees with establishing MACT floor emission limitations for multi-fuel facilities. The EPA also disagrees that the maximum achievable control technology identified for specific pollutants and fuels would not apply to a unit which combusts a mixture of fuels. Each boiler or process heater subject to the rule must demonstrate compliance with emission

limits for a subcategory based on the amount each fuel in the mixture is combusted. The EPA believes that, if facilities install controls in order to determine compliance with an emission limitation, that the performance of the control will be able to account for the operational and fuel variability that occur at the facility.

Comment: While EPA's proposed revisions to the PM emissions limits demonstrate an attempt at increasing flexibility and reducing regulatory burdens, it fails to produce this effect for many existing biomass boilers. EPA's decision to create PM subcategories for coal- and biomass- fired boilers, resulted in uneven results and in several cases we are concerned that the emissions limits included in the proposed rule remain too stringent. As explained in our prior comments, the current PM emissions limits will require biomass facilities to install costly new control technology and incur higher operating costs, creating a risk that facilities will avoid biomass fuels and turn instead to fossil fuel alternatives. But, rather than relieving this burden, the proposed PM emissions limits for existing "stokers/sloped grate/others designed to burn wet biomass fuel" – the most common type of biomass boiler currently in use – are actually more stringent than those under the current rule. Further reductions in PM emissions limits for the majority of existing biomass boilers will have a significant and detrimental effect on the viability of these boilers as alternatives to fossil fuel boilers. The wood products industry, which employs the majority of the wet stoker boilers, was significantly impacted by the recession and is still struggling to recover. EPA must reassess the emissions limits for existing wet biomass stoker boilers and adopt more reasonable standards that can be achieved in practice and will satisfy legal requirements, without prohibitive costs that will further threaten the health and viability of this important industry.

Response: For the reasons identified in the preamble to the December 23, 2011 proposed reconsideration of the rule, EPA disagrees with the commenter that the revisions to the PM emission limitations fail to increase flexibility between the different types of boilers in operation in the U.S. Comments pertaining to the economic impact of the rule are not relevant to the calculation of the MACT floor limits, and are outside the scope of this comment response document.

Comment Excerpt Number: 73

Comment: Major source emissions for PM (new sources) are as follows. The area source standard is 0.03 lb/mmbtu for boilers greater than 30 mmbtu/hr. It makes no sense for new major sources to be permitted to emit more PM than area sources. [See submittal for table of new source PM limits from area and major rules.]

Response: The PM emission limitations for new sources have been revised for all subcategories in the final amended rule. For all biomass subcategories, the revised new source PM emission limitation is at or below the area source limit of 0.03 lb/MMBtu in the final rule based either on recalculation, incorporating new data, or a beyond-the-floor determination. Refer to the preamble and the memorandum “Beyond the Floor Technology Analysis for Major Source Boilers and Process Heaters (Revised August 2012)” for a discussion of the rationale to select a beyond the floor level of control for new source PM emission values.

Comment Excerpt Number: 2

Comment: EPA’s expansion of the number of subcategories in its reconsideration proposal, appears to reflect the agency’s proposed conclusion that particulate matter (PM) is a "combustion-related" pollutant. 76 Fed. Reg. 80598, 80607 (December 23, 2011). The agency now claims that the differences in PM size from different boilers and the lack of demonstration of certain technologies on some boilers "(e.g. fabric filters are not used on any hybrid suspension grate boilers)" warrants proposing different limits for them. *Id.* Thus, EPA proposes to set separate PM standards for stoker, fluidized bed, and pulverized coal (PC) units that are "designed to burn" coal. *Id.* at 80601. EPA also proposes separate PM standards for "Biomass Wet Stoker/Sloped Grate/Other," "Biomass Kiln-Dried Stoker/Sloped Grate/Other," "Biomass Fluidized Bed," "Biomass Suspension Burner," "Biomass Dutch Ovens/Pile Burners," "Biomass Fuel Cells," and "Biomass Hybrid Suspension Grate." *Id.* at 80601. Regardless of whether PM can be viewed as a combustion related pollutant, EPA has not shown that the units in these purported subcategories are of a different class, type, or size. In particular, that some may not already have deployed a fabric filter is no excuse for subcategorizing them. EPA does not claim that any of these units are so designed that the use of fabric filters is infeasible. Thus, the agency’s decision to set separate (and significantly less protective) standards for them is a blatant attempt to subcategorize by emission levels or control measures. Any such subcategorization exceeds EPA’s authority and frustrates the purpose of the § 112’s floor language. If EPA wishes to set separate standards for units, the agency must show why any alleged design differences matter – i.e., would necessarily prevent a unit with a particular design from meeting standards set for a larger group of units including those with other designs – and support that explanation with record evidence. EPA has not done so here.

Response: The EPA disagrees with the commenter that the EPA has not shown that the subcategories based on PM as a combustion-related pollutant are of a different class, type, or size. The EPA has broad discretion to create subcategories which distinguish among “classes, types, and sizes of sources.” See CAA section 112 (d)(1). The EPA may exercise that discretion if sources are rationally distinguishable due to some difference in class, type, or size. Moreover, any basis for subcategorizing should be related to an effect on emissions, rather than to some difference among sources which does not affect emissions performance. The EPA may also exercise this discretion on a pollutant-specific basis, because the difference in class, type, or size may only have practical significance for certain HAP.

As noted at proposal, several petitioners provided information to support the position that PM should be considered a combustion-based pollutant rather than a fuel-based pollutant. After assessing the points raised by the petitioners, the EPA determined that PM emissions are influenced both by fuel type and unit design. Therefore, it was determined appropriate to treat PM as a combustion-based pollutant because the emissions from the different combustor types will differ in PM particle size, PM loading, and exhaust temperature which affects the technical feasibility and applicability of applying emission control technology. Therefore, the EPA proposed separate PM limits for each combustion-based subcategory.

The EPA disagrees that it is unreasonable to establish separate PM limits for each combustion-based subcategory. This subcategorization approach is appropriate because there are differences in the PM emission characteristics and the in the technical feasibility of applying control technology for the various combustion-based subcategories. We also disagree that the fact that the availability of similar control options negates the legitimacy of a subcategorization approach. In fact, the controls available to reduce PM are generally available for all types of sources, but that does not mean that all classes, types and sizes of sources are the same and must be included in the same subcategory. As noted above, section 112 provides EPA with broad discretion to subcategorize within a source category, and the terms “class, type, or size” are similarly broad terms that encompass a wide range of differences among sources, not just differences in available control technologies. Had Congress intended for EPA’s subcategorization authority to be limited in the manner commenters suggest, it could have done so, and it certainly would not have used such wide-ranging terms (class, type, and size) to describe the criteria for subcategorization.

In this action, EPA combined all coal boilers into a single subcategory with one set of PM limits. The EPA carefully reconsidered the possibility of retaining separate PM limits for the combustion-based subcategories and concluded that separate subcategories for PM are warranted for the units designed to burn biomass. We agreed with commenters, see response to EPA-HQ-OAR-2002-0058-3510-A1, excerpt 15, that there are not enough differences in PM from the three types of coal-fired boilers to justify subcategorization of such units but that biomass units merit their own separate subcategories for PM emissions. Therefore, in the final rule, the EPA combined all coal boilers into one subcategory with a single set of PM emission limits.

Commenter Name: James Pew

Commenter Affiliation: Earthjustice, Clean Air Council, Partnership for Policy Integrity

Document Control Number: EPA-HQ-OAR-2002-0058-3511-A1

Comment Excerpt Number: 3

Comment: EPA’s approach to subcategorization has resulted in significantly less protective emission limits for some of the worst emitters, not because these units are truly of a different class, type, or size but simply because the agency’s subcategories have isolated units that have not taken measures to reduce their emissions. For example, EPA’s proposed PM standard for existing Biomass Hybrid Suspension Grate boilers is .44, more than ten times higher than the .039 limit in EPA’s final rule. Allowing these units to emit ten times more PM pollution merely because they have not yet installed control technology rewards the worst polluters and punishes people who will be forced to live near sources that emit more than ten times the emissions of

hazardous metals and PM than cleaner boilers, as well as the responsible boiler owners who have installed controls who are placed at a competitive disadvantage.

Response: As stated in the response to comment EPA-HQ-OAR-2002-0058-3511-A1, excerpt 2, we continue to believe that it is appropriate to subcategorize based on boiler design for combustion-related pollutants which we have determined PM to be for boilers types designed to combust biomass. The PM limit proposed for existing Biomass Hybrid Suspension Grate boilers is the result of the MACT floor analysis which is based on the PM emissions from the best performing units in the subcategory, as mandated by section 112 of the Clean Air Act. A beyond-the-floor analysis was conducted but the analysis shown that going beyond the floor was not cost-effective. The cost-effective results was \$525,000 per ton of PM or \$260 million per ton of TSM. Contrary to the commenter's assertion, EPA is not subcategorizing units based on whether or not control technologies have been installed. Rather, we have subcategorized based on the different design types of units because different designs have different emission characteristics which influence the feasibility of effectiveness of applying emission control techniques. These design differences have an effect on organic HAP emissions, as well as on PM emissions. Hybrid suspension grate boilers are designed differently from other boiler types designed to burn biomass in order to combust the high moisture bagasse generated from the processing of sugar cane. The PM MACT floor limit for this subcategory is based on the best performing 5 units within the subcategory since there is less than 30 units within the subcategory. Of these 5 best performing hybrid suspension grate boilers, two are controlled with ESP and the others with wet scrubbers.

Document Control Number: EPA-HQ-OAR-2002-0058-3511-A1

Comment Excerpt Number: 72

Comment: In our review of biomass facility permits from around the country, we have never seen fuel moisture taken into consideration when setting emission limits at facilities.

EPA states that one reason for sub-categorization is its decision to treat PM as a "combustion-based pollutant". Page 80607 states:

Differences in PM particle size, applicability of air- pollution controls to units combusting various fuels, and the lack of demonstration of certain control technologies on certain designs of boilers (e.g., fabric filters are not used on any hybrid suspension grate boilers) suggest that PM is more appropriately classified as a combustion-based pollutant. Therefore, the EPA is now proposing separate PM limits for each "combustion-based" subcategory.

However, this does not correspond to real-world permitting. It should make no difference if a baghouse is demonstrated, an ESP can do about as well as a baghouse. EPA's proposed PM limit for suspension based boilers is 0.05 lb/mmBtu, much higher than is achievable with an ESP. The limit should be lower.

Response: We disagree with the assertion that fuel moisture does not affect emissions. Moisture content of the fuel will affect the combustion conditions which will affect the emissions of certain pollutants, mainly CO and NOx. One example of the effect of moisture is its effect on

the control technology of water/steam injection used to reduce NOx emissions from stationary gas turbine. NOx formation is increased under high temperature combustion conditions, whereas CO and organic HAP are reduced by high temperature combustion conditions, as demonstrated by the use of thermal oxidizers on offgases to control organic HAP emissions. The introduction of moisture into the combustion process has the effect of lowering combustion temperature which would decrease NOx formation (i.e., reduced NOx emissions) but have the opposite effect of decreasing CO and organic HAP reductions (i.e., increasing CO and organic HAP emissions). While the commenter asserts that they have never seen fuel moisture taken into consideration when setting emission limits at facilities, it provides no information, including the technical background information used in drafting the permits for biomass facilities, to support this assertion.

See response to comment EPA-HQ-OAR-2002-0058-3511-A1, excerpt 3 for a discussion of the PM emission limit for suspension based boilers.

Commenter Name: Mary Sullivan Douglas

Commenter Affiliation: National Association of Clean Air Agencies (NACAA)

Document Control Number: EPA-HQ-OAR-2002-0058-3525-A1

Comment Excerpt Number: 15

Comment: EPA proposes to establish seven subcategories of wood-fired boilers¹³ – wet stoker, dry stoker, fluidized bed, suspension, dutch oven, fuel cell and hybrid suspension – based on differences in the design of the combustion chamber of these units. However, most boilers and, in particular, the best-performing units, are equipped with PM control devices ranging in effectiveness from cyclones and multi-cyclones to electrostatic precipitators and fabric filters. The performance of the installed PM control device governs the level of PM and TSM emissions to a far greater extent than differences in design of the combustion unit itself. Indeed, in the stoker/sloped/other dry biomass subcategory we note that each of the units in the subcategory is only served by cyclone or multiclone particulate matter control devices, while in other subcategories most of the units are equipped with more effective fabric filter or electrostatic precipitator control devices. We do not believe that EPA is authorized to create a class of “poorly controlled units” and recommend that no separate subcategories be authorized for PM or TSM.¹⁴

[Footnotes]

(13) NACAA has raised a concern that differences in the combustion properties of “wet” wood and “dry” wood might

(14) These devices, along with sulfur dioxide and nitrogen oxide controls may also affect emission levels of hydrogen chloride and mercury.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3511-A1, excerpt 2.

Commenter Name: Robert E. Hunzinger

Commenter Affiliation: Gainesville Regional Utilities (GRU), Florida

Document Control Number: EPA-HQ-OAR-2002-0058-3488-A1

Comment Excerpt Number: 5

Comment: EPA has taken a different approach to establishing air toxics emission limits in the Reconsideration rule as compared to the final rule. EPA has created a distinction between "fuel-based" air toxics (mercury and HCL) and "combustion-based" air toxics (PM and CO) for establishing emission limits.³ EPA has proposed only one Hg limit and one HCl limit each for solid fuels and liquid fuels without regard to specific fuel types or boiler technologies. GRU is concerned that this approach does not recognize the wide range of mercury and chloride content of solid and liquid fuels. In addition, the valence state of mercury in the fuel has a direct impact of the removal efficiency of emission control systems.

However, since PM and CO are "combustion-based" pollutants, EPA has concluded that specific emission limits related to different combustion technologies are warranted. On this basis, EPA has proposed separate emission limits for fourteen different types of boilers to be covered by the rule, including three different types of coal units, two different types of liquid fuel units, and seven different types of biomass units, resulting in a greater number of subcategories than any prior industrial boiler MACT rule or proposal. GRU believes that the real issue is that both fuel composition and boiler combustion characteristics impact emissions as well as the effectiveness of control systems. We believe fuel type and composition should be considered in setting a NESHAPS emission limit.

[Footnote]

(3) Note PM is a surrogate standard for non mercury metals while CO is a surrogate for organic toxics.

Response: The EPA disagrees that the emission limitations for mercury and hydrogen chloride for solid and liquid fuels do not properly recognize the wide range of those pollutants which may be found in different types of solid and liquid fuels. The mercury and hydrogen chloride limits for solid fuels were based on a 99% UPL derived from emissions from both coal and biomass fuels. Similarly, the mercury and hydrogen chloride limits for liquid fuels were based on a 99% UPL derived from emissions from both distillate- and residual-type fuel oils. Two types of data variability were evaluated to determine the emission levels achieved by the best performing sources over the long term, the statistical variability and fuel analysis variability. The statistical variability (99% UPL) evaluates variability considering variability in control device performance, unit operations, and fuels fired during the test. Fuel variability considers the variability in the fuel constituents (mercury, metals, chlorine) outside of the test period. For this reason, the EPA believes that the mercury and hydrogen chloride limits properly account for the natural mercury and hydrogen chloride variation that may be found in different types of solid or liquid fuels.

For the reasons specified in the preamble to the December 23, 2011 proposed reconsideration of the rule (76 FR 80598), the EPA believes that the largest factor in emissions of PM (and CO) is the combustion style. For this reason, EPA has retained PM and CO as combustion-based pollutants in the final rule.

Commenter Name: Arthur N. Marin

Commenter Affiliation: Northeast States for Coordinated Air Use Management (NESCAUM)

Document Control Number: EPA-HQ-OAR-2002-0058-3506-A1

Comment Excerpt Number: 12

Comment: NESCAUM is concerned about the large variation in PM emission limits of the reconsidered major source rule for similar boilers in different subcategories (76 FR 80601, Table 1). Among existing biomass-fueled unit subcategories, the PM emission limits range from 0.029 lb/MMBtu for wet stoker units to 0.44 lb/MMBtu for hybrid suspension/grate units. In the “final” major source rule, all existing solid fueled units had been subject to an emission limit of 0.039 lb/MMBtu. The PM emissions limits for some biomass fuel subcategories therefore represent increases by approximately an order of magnitude from the PM emission limit in the “final” rule. Also disturbing is that several of the proposed MACT emission limits are less stringent than that required for biomass units under the New Source Performance Standard (NSPS), which established an emission limit for PM of 0.030 lb/MMBtu.

Based on these inconsistencies, it is clear that the analysis of the biomass units has been parsed to a degree that the analysis is no longer valid, and results in PM emissions limits that are not representative of the maximum achievable control technology as required by Section 112 of the CAA. Therefore, NESCAUM urges EPA to continue with the biomass PM emission limits promulgated in the March 21, 2011 final rule (76 FR 15608).

Response: For the reasons specified in the preamble to the December 23, 2011 proposed reconsideration of the rule (76 FR 80598), the EPA is treating PM as a combustor-based pollutant in the final rule. PM emissions have been shown to vary as a function of combustion style, most notably for the combustion of biomass or bio-based solid fuels. As such, the EPA feels it is necessary to regulate PM combustion on a combustor design basis. In setting emissions standards, the EPA must consider the emission variability of the lowest-emitting sources within the subcategory. The EPA has achieved this by establishing a 99% UPL based on the reported emissions data for the lowest-emitting sources in the subcategory. The wide range of PM emission limitations for the subcategories is evidence that PM emissions vary greatly with combustor design. For these reasons, the EPA believes it is appropriate to subcategorize biomass combustors for PM, based on our conclusion that PM is a combustion-based pollutant.

6C. TSM Alternative for non-Hg metals (solid and gas 2 fuels)

Commenter Name: David A. Buff, Golder Associates Inc.

Commenter Affiliation: Florida Sugar Industry (FSI)

Document Control Number: EPA-HQ-OAR-2002-0058-3504-A1

Comment Excerpt Number: 1

Comment: The FSI agrees with and supports EPA’s decision to establish a TSM standard as an alternative to the PM standard. The proposed TSM standard requires a direct measurement of eight metallic HAPs that are emitted from a boiler, rather than relying on PM as a surrogate for non-mercury metallic HAPs. The TSM standard will provide a more accurate measurement of the metallic HAPs emitted from the FSI’s boilers.

If the proposed TSM standard is not adopted, many of the FSI boilers may need new, expensive emissions controls based on the boilers’ PM emissions, even though the metallic HAPs

emissions from those boilers do not warrant the installation of the new PM controls. Stated differently, if the proposed TSM standard is not adopted, the FSI will be required to install new air pollution control equipment at great expense to control metallic HAPs, even though the new equipment will not provide meaningful reductions in the emissions of metallic HAPs.

Response: The EPA thanks the commenter for their support.

Commenter Name: Dirk J. Krouskop

Commenter Affiliation: MeadWestvaco Corporation (MWV)

Document Control Number: EPA-HQ-OAR-2002-0058-3493-A1

Comment Excerpt Number: 14

Comment: MWV supports the inclusion of Total Select Metals (TSM) as an alternative for particulate matter limits. EPA has proposed TSM limits as alternatives to PM limits for coal, biomass, and gas 2 units. This approach has the ability to provide cost benefits to certain units that have low metal HAP emissions, but might not be equipped with the very best in particulate controls. MWV is concerned that in its current construct these limits are too low to be of much practical value to individual boilers. MWV believes, however, that EPA should consider fuel and emissions variability in determining what these limits should be.

Response: The EPA thanks the commenter for their support. The EPA has considered fuel and emissions variability for TSM in the final rule. Fuel and emission variability were calculated using the same methods and assumptions as used in the analyses conducted for PM, HCl, and mercury. See the memorandum "Revised MACT Floor Analysis (August 2012) for the Industrial, Commercial, and Institutional Boilers and Process Heaters National Emission Standards for Hazardous Air Pollutants – Major Source" in the docket. **Commenter Name:** Lorraine Gershman

Commenter Affiliation: American Chemistry Council (ACC)

Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1

Comment Excerpt Number: 1

Comment: *ACC supports the inclusion of alternate TSM limits* ACC believes inclusion of a total selected metals (TSM) emission limitation as an alternative to the particulate matter (PM) emission limits in the Final Boiler Rule is appropriate, since the emissions of these non-mercury metals are the hazardous air pollutants (HAPs) the standard targets for regulation and reduction. We believe that a TSM option will provide greater flexibility for sources while still reducing the emissions of non-mercury HAP metals. This will offer the opportunity for sources to achieve low metal HAP emissions similar to those achieved with PM, but potentially at a lower cost.

Response: The EPA thanks the commenter for their support.

Commenter Name: Lorraine Gershman

Commenter Affiliation: American Chemistry Council (ACC)

Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1

Comment Excerpt Number: 2

Comment: As the implementation of the Final Boiler Rule will be extremely costly for industry, the use of the TSM alternative could help provide some cost savings by avoiding the installation and operation of PM continuous parameter monitoring system (CPMS) for units >250 MMBtu where the TSM limits are viable.

Response: The EPA thanks the commenter for their support.

Commenter Name: Paul Noe

Commenter Affiliation: American Forest & Paper Association (AF&PA) et al.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 86

Comment: EPA has proposed TSM limits as alternatives to PM limits for coal, biomass, and gas 2 units. EPA's recently signed Mercury and Air Toxics Standard also provides a choice between complying with a PM or a TSM standard for certain EGUs. There are some industrial boilers (e.g., most liquid and gas-fired units) that do not have any PM controls and there are some industrial boilers (e.g., some biomass units) that do not have sophisticated PM controls, but have low metals emissions.

However, to enhance flexibility and cost-effectiveness in the proposed rule, we support EPA's inclusion of a TSM emission limitation as an additional compliance option, allowing either fuel analysis or metals stack testing at the same frequency as the PM stack testing requirements for ongoing compliance. This approach will allow sources to comply using fuel analysis instead of costly annual or triennial stack testing and to design emissions reduction strategies around HAP metals instead of PM as their surrogate.

Response: The EPA thanks the commenter for their support.

Commenter Name: Stephen E. Woock

Commenter Affiliation: Weyerhaeuser Company

Document Control Number: EPA-HQ-OAR-2002-0058-3523-A1

Comment Excerpt Number: 13

Comment: We support EPA's proposal to include TSM limits as an alternative to the PM surrogate limit for Hazardous Air Pollutant (HAP) metals. In aggregate the eight metals EPA selected provide an adequate surrogate measure of all metal HAPs, and this approach may provide compliance flexibility where metal emissions are low and addition of PM controls is unnecessary or infeasible.

Response: The EPA thanks the commenter for their support.

Commenter Name: Robert D. Bessette

Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 42

Comment: CIBO supports EPA's decision to include a total selected metals (TSM) option for solid fuels into the Propose Reconsideration Rule. In its Petition for Reconsideration, CIBO stated that the "TSM option would offer the opportunity for sources to achieve low metal HAP emissions similar to those achieved with the use of PM as a surrogate for HAP metals, but potentially at a lower cost." Furthermore, CIBO noted that a TSM option provides for additional flexibility for Boiler MACT compliance.

EPA has proposed "TSM limits for each subcategory of units that combust solid fuels or Gas 2 fuels." 76 Fed. Reg. 80,606. Sources will also have the compliance option of meeting PM emission limits as well. EPA noted "the TSM measurement, which directly quantifies the HAP metals rather than relying on a surrogate, is a more direct measurement of HAP than PM and is, therefore, appropriate as a pollutant group for regulation with numeric emission limits." *Id.* Furthermore, EPA will include 8 (excluding cobalt and antimony), as opposed to 10, metals for measurement because more test data are available for the eight metals. *Id.*

The TSM option for solid fuels preserves flexibility and may lower compliance costs for sources. TSM does not provide any less environmental protection, but is simply another way for sources to measure compliance with non-mercury metals emission limits.

Response: The EPA thanks the commenter for their support.

Commenter Name: Vickie Woods

Commenter Affiliation: Division of Air Quality, North Carolina Department of Environment and Natural Resources (NCDENR)

Document Control Number: EPA-HQ-OAR-2002-0058-3663-A2

Comment Excerpt Number: 3

Comment: NC DAQ supports the concept of using the 8 total selected metals (TSM) as an alternative to PM emission limits and as a surrogate for non-mercury metal HAP. The TSM include arsenic, beryllium, cadmium, chromium, lead, manganese, nickel, and selenium. We also agree with use of 8 of the 10 HAP metals for which EPA has emission data, as the emission controls used to reduce the 8 metals would be equally effective in reducing the other 2 metals, antimony and cobalt.

Response: The EPA thanks the commenter for their support.

Commenter Name: Matthew Todd

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 60

Comment: EPA has proposed alternative TSM limits to PM limits for each subcategory of units that combust solid fuels or Gas 2 fuels. Establishing an alternate standard for TSM is appropriate and provides sources with flexibility to demonstrate compliance through either direct metal HAP measurement or through total PM measurement – either method achieving the required level of HAP pollution mitigation. Thus, we fully support establishing these alternative emission limits.

Response: The EPA thanks the commenter for their support.

Commenter Name: Michael D. Wendorf

Commenter Affiliation: FMC Corporation

Document Control Number: EPA-HQ-OAR-2002-0058-3453-A1

Comment Excerpt Number: 1

Comment: FMC Corp. supports EPA's decision to include an emission limit for TSM as an alternative *to* the PM limits specified in the final rule. It is logical and appropriate, whenever reasonable, to directly measure the pollutant(s) in question rather than to rely upon a surrogate.

Response: The EPA thanks the commenter for their support.

Commenter Name: Robert E. Hunzinger

Commenter Affiliation: Northeast States for Coordinated Air Use Management (NESCAUM)
Document Control Number: EPA-HQ-OAR-2002-0058-3506-A1
Comment Excerpt Number: 19

Comment: The EPA is proposing to add a more direct measurement of representative HAP metals emissions as an alternative to use of a surrogate PM emission limits (FR 75 80606). NESCAUM supports this alternative approach to meeting the emission standards because it more directly addresses the emissions of pollutants that the EPA intends to regulate through this rule.

Response: The EPA thanks the commenter for their support.

Commenter Name: Michael L. Krancer
Commenter Affiliation: Pennsylvania Department of Environmental Protection (DEP)
Document Control Number: EPA-HQ-OAR-2002-0058-3507-A1
Comment Excerpt Number: 1

Comment: The EPA has proposed emission limits for alternate total selected metals (TSM) as an alternative to the particulate matter (PM) limits. Alternative TSM limits were created for each subcategory of units that combust solid fuels or "Gas 2" fuels. These subcategories will have the option of complying with either the TSM limits or the alternative PM limits. For this rule, TSM includes eight metals: arsenic, beryllium, cadmium, chromium, lead, manganese, nickel and selenium. The DEP agrees with EPA's proposed alternative TSM limits for units that combust solid fuels or "Gas 2" fuels.

Response: The EPA thanks the commenter for their support.

Commenter Name: Bart Sponsellar
Commenter Affiliation: Wisconsin Department of Natural Resources
Document Control Number: EPA-HQ-OAR-2002-0058-3527-A2
Comment Excerpt Number: 1

Comment: EPA has proposed that sources can comply with total selected metals (TSM) limitations for solid and biomass fueled boiler source categories in lieu of complying with the particulate emission limitation. The Department supports this approach as it directly regulates the toxic pollutants of concern. The Department does encourage EPA to review any additional data it receives in setting the total metals emissions limits.

Response: The EPA thanks the commenter for their support.

Commenter Name: J. Michael Geers
Commenter Affiliation: Duke Energy
Document Control Number: EPA-HQ-OAR-2002-0058-3543-A1
Comment Excerpt Number: 4

Comment: In the December 23, 2011 proposal, EPA included an emission limit for TSM as an alternative to the PM limits in the final rule, particularly for biomass units. After assessing the available data, the EPA determined that inclusion of these limits was appropriate for some subcategories, and the EPA proposed TSM limits for each subcategory of units that combust solid fuels or Gas 2 fuels. Duke Energy supports this change and believes is it appropriate to give sources the flexibility to meet either the TSM limit or the alternative PM limit.

Response: The EPA thanks the commenter for their support.

Commenter Name: David A. Buff, Golder Associates Inc.
Commenter Affiliation: Florida Sugar Industry (FSI)
Document Control Number: EPA-HQ-OAR-2002-0058-3504-A1
Comment Excerpt Number: 2

Comment: FSI agrees with EPA's decision to establish the TSM standard by using the sum of 8-metals, rather than 10-metals (i.e., 8-metals plus antimony and cobalt). More data are available for the 8-metals than the 10-metals, and thus the establishment of a TSM standard based on eight metals is more likely to be appropriate and scientifically defensible. We agree with EPA's statement in the preamble that "The use of 8 of 10 metals should have little or no impact on a facility's selection of controls to meet the standards, and the controls that would be used to reduce emissions of the eight metals would be equally effective in reducing emissions of the other two metals. Therefore, TSM can serve as a surrogate for all metallic HAP except for Hg, which the final rule regulates separately." 76 F.R. 80606.

Based on available bagasse fuel analyses for which all 10-metals were analyzed, the sum of 8-metals (excluding antimony and cobalt) and the sum of 10-metals (including antimony and cobalt) for three FSI facilities averaged as follows:

[See submittal for table]

[See submittal for Appendix A- "Bagasse Metals Fuel Analysis Data."] As shown, antimony and cobalt do not contribute significantly to the total metals content of bagasse in Florida. Similar variations are observed with bagasse in Hawaii. Consequently, the use of 8-metals rather than 10-metals will not result in an underestimation of the risk associated with metallic HAPs emissions from the FSI's boilers.

Response: The EPA thanks the commenter for their support.

Commenter Name: Lorraine Gershman

Commenter Affiliation: American Chemistry Council (ACC)

Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1

Comment Excerpt Number: 3

Comment: For purposes of the final Boiler rule, TSM would be defined as the sum of 8 non-mercury HAP metals. It would not be practical or necessary for EPA to set emission limits for each of these individual metals due to the fact that so many of them are present below detectable levels. The use of a TSM alternative is therefore appropriate, and TSM emissions can be calculated using available metals emission data for each fuel type and subcategory.

Response: The EPA thanks the commenter for their support.

Commenter Name: Dean C. DeLorey

Commenter Affiliation: The Amalgamated Sugar Company LLC (TASCO)

Document Control Number: EPA-HQ-OAR-2002-0058-3522-A1

Comment Excerpt Number: 20

Comment: If the TSM limit is fuel-based, there should not be different standards for different boilers. There should be one TSM limit for each fuel.

Response: For the coal-fired subcategory, based on public comments the EPA determined that it is appropriate to subcategorize both PM and TSM8 as a fuel-based pollutant. As the commenters pointed out, all three combustor designs for coal-fired units can fire various coal types

(bituminous, sub-bituminous, lignite, or other). Further, there is not a significant difference in PM and metal emission from each of these three combustor designs. However, for the liquid and biomass subcategories EPA finalized its proposed approach of subcategorizing PM and TSM8 on a combustor-level basis. For biomass combustor designs, the design of the combustor is related to the make-up of the fuel. Certain combustor designs are relevant for higher moisture fuels or fuels with larger particle sizes, such as, Dutch ovens and stokers. These characteristics affect the design of the boiler and the emissions profile of PM and non-Hg metals. For liquid fuels, the EPA also identified several design differences for heavy and light liquids, see the discussion in the proposal at 76 FR 80608.

Commenter Name: Lorraine Gershman

Commenter Affiliation: American Chemistry Council (ACC)

Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1

Comment Excerpt Number: 6

Comment: *EPA should allow emissions averaging if sources comply with the TSM alternative*

Emissions averaging should be allowed for units complying with TSM emission limits, as it is allowed in the final MATS rule (§63.10009). Section 63.7522 of the Reconsideration Proposal does not include emissions averaging for TSM. However, the compliance provisions (either stack testing or fuel sampling and analysis) are virtually identical as those for hydrogen chloride (HCl) and mercury (Hg) for which emissions averaging is allowed. EPA provides no explanation in the preamble to the Reconsideration Proposal for not including emissions averaging for TSM, and since emissions averaging is allowed for PM, there is no reason not to include it for facilities choosing to comply with the TSM limits.

[Footnote 2: 77 Fed. Reg. 9304, February 16, 2012]

Response: TSM is an alternative standard to the PM emission limits. This rule incorporates several flexible compliance mechanisms one being an emissions averaging alternative for PM and another being the alternative emission standard for TSM8 in lieu of the PM emission limit. The emissions averaging provision in the final amended rule has been revised to allow averaging TSM.

Commenter Affiliation: American Forest & Paper Association (AF&PA) et al.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 88

Comment: As EPA explained in the preamble to the proposed Utility MACT rule, "the DC Circuit Court [in *National Lime II*, 233 F.3d 625] stated that EPA "may use a surrogate to regulate hazardous pollutants if it is "reasonable" to do so" and laid out criteria establishing a three-part analysis for determining whether the use" of a surrogate is reasonable. 76 Fed. Reg. at 25021. In that case, PM was found to be a reasonable surrogate for metal HAPs because: "(1) "HAP metals are invariably present in ... PM;" (2) "PM control technology indiscriminately captures HAP metals along with other particulates;" and (3) "PM control is the only means by

which facilities "achieve" reductions in HAP metal emissions." 233 F.3d at 639." 76 Fed. Reg. at 25021.

Under these criteria, TSM clearly would be a reasonable surrogate for metal HAPs (except for mercury) under the Boiler MACT. First, it is clear that covering 8 of the 10 relevant metals would assure that the individual HAPs will be "invariably present" in the 8 pollutant surrogate. Moreover, EPA explains in the proposal, "The use of 8 of 10 metals should have little or no impact on a facility's selection of controls to meet the standards, and the controls that would be used to reduce emissions of the eight metals would be equally effective in reducing emissions of the other two metals." Thus, EPA has correctly determined that control technologies will "indiscriminately" capture all 10 HAP metals and that the same control measures will be used for the 8 metal surrogate as would be used for the 10 metals individually. Thus, EPA has ample justification to set a standard for the 8-metal TSM surrogate. Notably, the TSM standard does not undermine the validity of or need for the PM standard for HAP metals. As explained above, the TSM standard will provide a more tailored compliance alternative for units where potential metal HAP emissions are expected to be low and, therefore, PM would be an overly conservative surrogate. However, EPA must gather fuel metals data from the TSM top performers and include a fuel variability factor when setting TSM limits for solid fuel units to ensure full consideration of variability.

Response: The EPA thanks the commenter for their support of using TSM8 as a surrogate for metallic HAP and for setting alternative TSM limits. The EPA has included fuel variability for TSM in the final rule.

Commenter Name: Dean C. DeLorey

Commenter Affiliation: The Amalgamated Sugar Company LLC (TASCO)

Document Control Number: EPA-HQ-OAR-2002-0058-3522-A1

Comment Excerpt Number: 19

Comment: Using TSM as a basis for emission standards is not sensitive to the fact that each of the metals specified in this definition has different hazard and toxicity characteristics. Please clarify how the agency rationalizes setting a standard based upon a "combination" of values. In any given sample if the concentration of one metal is significantly higher than the others, the one metal may skew the results. In fuel analysis data supplied by TASCO vendors, the concentration of manganese is more than one order of magnitude higher than any of the other metals on the TSM list. However, the health hazard of exposure to manganese is significantly less than the other metals (Le. NIOSH limits for Mn are higher than other metals).

Response: In this reconsideration, EPA proposed revisions to certain MACT standards for boilers and process heaters. As such, this action does not address health-based or risk-based standards. In this alternative metals standard, the EPA established an alternative MACT floor emission limit based on the reported sum of eight individual non-Hg metals. Each of these metals are regulated under Section 112 and are targeted pollutants under this source category. Therefore the EPA has determined it has the authority to regulate each of these metals and it is appropriate to establish an emission limit based on the total of these 8 metals as an alternative to the PM emission standards.

6E. TSM Alternative for non-Hg metals (liquid fuels)

Commenter Name: Matthew Todd

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 71

Comment: More importantly than this precedent, however, is that EPA's second concern should not preclude a TSM standard but should only influence what that standard is. Because of the variability identified, EPA should ensure that the alternative TSM standard is set at a level that takes this into consideration. As with all other standards in the proposed reconsideration, EPA has utilized a 99% UPL calculation to capture statistical variability, and compared this calculation to measurement detection level variability as well as a fuel variability determination. These variability determinations have already been calculated, although EPA has refused the results for the proposal, noting that they do not "appear to represent the actual performance of the best performing units." We encourage EPA to appropriately consider the application of variability in defining a TSM alternative for the non-continental liquid subcategory. EPA is afforded wide latitude in defining "achieved in practice", but it should be noted that the D.C. Circuit has enforced that the standard should represent what the best performing sources can "achieve under the worst foreseeable conditions,"³⁰ not what "appears to represent actual performance."

Response: The final rule includes an alternative TSM limit for the liquid fuel subcategories. In setting these alternative limits, the EPA has considered emission, detection level, and fuel variability, as is done for all other pollutants and subcategories. The fuel variability incorporates variability in fuel feedstocks that occur at best performing units during periods not covered by the stack tests. The fuel variability factor compares the fuel constituents (e.g., TSM) during the test with the fuel constituents during other periods of operation in order to evaluate the full range of fuels consumed by these best performing units. The EPA believes that its consideration of variability appropriately establishes standards for which best performing sources can achieve under the worst foreseeable conditions.

Commenter Name: Matthew Todd

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 61

Comment: While proposed for all solid fuel subcategories and the Gas 2 subcategory, alternative TSM limits were not proposed for any liquid subcategories.

We believe having alternative limits can be valuable and we encourage EPA to establish such an alternative for all subcategories. EPA currently has adequate data to establish a TSM alternative standard for the liquid subcategories. For example, EPA has TSM emissions tests and/or fuel analyses from 27 sources in the heavy liquid subcategory. The tests and analyses from these 27 sources was of sufficient quality for the Eastern Research Group, Inc. (ERG) to calculate and

suggest to EPA a 99% UPL for a TSM alternative for the heavy liquid subcategory representative of “the average emission limitation achieved by the best performing 12 percent of the existing sources.”²⁰ Furthermore, as noted in the November 2011 MACT Floor memorandum from ERG, even when TSM data was not available directly from sources in the non-continental liquid subcategory, EPA could appropriately calculate the floor “using the top performing tests firing #6 fuel oil since this is the type of liquid fuel reportedly fired at the non-continental refineries.”²¹ As a basis of comparison, EPA identified that a TSM alternative was appropriate for the Gas 2 subcategory based on a 99% UPL of only a single test from a single unit without a corresponding fuel analysis. It is clear that there is sufficient data currently available for EPA to appropriately establish TSM alternatives for the liquid subcategories as well.

Because a TSM alternative is a necessary option to provide sources with flexibility of compliance while still ensuring the maximum pollutant reduction of the HAPs driving the regulation, withholding a TSM alternative would unnecessarily penalize liquid-fired units without offering additional pollution reduction. EPA has recognized the value and appropriateness of the TSM alternative for all other subcategories, and even directly to liquid-fired units under the final Mercury and Air Toxics Standards.

[Footnote 20: Clean Air Act §112(d)(3)(A)..]

[Footnote 21:EPA-HQ-OAR-2002-0058-3387, Memo from ERG, Inc. to Brian Shrager, “Revised MACT Floor Analysis (November 2011) for the Industrial, Commercial, and Institutional Boilers and Process Heaters National Emission Standards for Hazardous Air Pollutants – Major Source”, November 2011.]

Response: The EPA agrees with the commenter's claim that there is enough data to establish alternative TSM standards for the liquid fuel subcategories. Alternative TSM standards for those subcategories are included in the final rule.

Commenter Name: Paul Noe

Commenter Affiliation: American Forest & Paper Association (AF&PA) et al.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 89

Comment: We support EPA’s efforts to collect additional data to establish TSM limits for liquid subcategory units. There is no compelling reason to establish TSM limits for solid and gas 2 boilers and not for liquid boilers. If the limited amount of data available makes the MACT floor based on the top 12 percent of units for which data are available unrepresentative of what the true top performing units should be achieving, then EPA could set TSM emission limits based on the top performing units in the PM subcategories. Having an option to comply with a TSM limit is a valuable alternative for liquid units.

Response: The EPA thanks the commenter for their support of alternative TSM emission limitations. In the final rule, the EPA has established a TSM alternative for all fuel subcategories, including liquid fuels. The EPA received sufficient metallic HAP emissions data from units designed to combust liquid fuels during the public comment period to set standards for all subcategories.

Commenter Name: Sarah E. Amick
Commenter Affiliation: Rubber Manufacturers Association (RMA)
Document Control Number: EPA-HQ-OAR-2002-0058-3503-A1
Comment Excerpt Number: 14

Comment: The proposed rule provided a TSM alternative for several subcategories. However, EPA did not set a TSM standard for liquid units as they were unable to draw a correlation between the PM and the TSM floor data. TSM floor data for liquid fired units primarily consists of fuel analysis data while the PM floor data was derived from source test results. RMA recommends that EPA set an alternative TSM limit utilizing the TSM results associated with the best performing units in the PM subcategories.

We support EPA's efforts to collect additional data to establish TSM limits for liquid subcategory units. There is no compelling reason to establish TSM limits for solid and gas 2 boilers and not for liquid boilers. If the limited amount of data available makes the MACT floor based on the top 12 percent of units for which data are available unrepresentative of what the true top performing units should be achieving, then EPA could set TSM emission limits based on the top performing units in the PM subcategories. Having an option to comply with a TSM limit is a valuable alternative for liquid units.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3521-A1, excerpt 89.

Commenter Name: Lorraine Gershman
Commenter Affiliation: American Chemistry Council (ACC)
Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1
Comment Excerpt Number: 5

Comment: *EPA should establish TSM limits for liquid units*

There is no compelling reason to establish TSM limits for solid and gas 2 boilers and not for liquid boilers. EPA's final Mercury and Air Toxics Standards (MATS)² provides a choice between complying with a PM or a TSM standard for liquid electric generating units (EGUs). If EPA is concerned that the limited amount of data available makes the Maximum Achievable Control Technology (MACT) floor based on the top 12 percent of units for which data are available might be unrepresentative of what the true top performing units should be achieving, then EPA could set TSM emission limits based on the top performing units in each of the PM subcategories.

Response: See the responses to comments EPA-HQ-OAR-2002-0058-3521-A1, excerpt 89 and EPA-HQ-OAR-2002-0058-3677-A2, excerpt 61.

Commenter Name: Matthew Todd
Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)
Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2
Comment Excerpt Number: 72

Comment: We urge EPA to define a TSM alternative for the non-continental liquid subcategory that represents what the best performing sources can meet under the worst foreseeable circumstances. For the TSM alternative specifically, which is comprised of a mix of both fuel analyses and emissions tests, it is suggested that EPA rank the top TSM performers based on the best performing sources for filterable PM, as all filterable PM data are directly comparable emissions test results. Based on this ranking for defining a TSM standard alternative for the non-continental liquid subcategory, we support the use of the 99% UPL calculation to define statistical variability of the top performing 12 percent of sources with No. 6 oil TSM data currently available to EPA, which includes No. 6 oil data from continental units (as was calculated by EPA but not incorporated into the proposed rule). As with the other standards, the 99% UPL should then be compared to the variability in the fuel, as well as the method detection level, with the maximum value chosen as the TSM alternative standard.

Response: See the responses to comments EPA-HQ-OAR-2002-0058-3521-A1, excerpt 89 and EPA-HQ-OAR-2002-0058-3677-A2, excerpt 71 for discussion. The TSM MACT floor limit for the non-continental liquid subcategory was based solely on TSM data received on 8 non-continental units.

Commenter Name: Matthew Todd

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 69

Comment: EPA should establish an alternative TSM limit for the continental and non-continental liquids subcategories.

EPA specifically requested sufficient information to support the TSM alternative standard for all liquid subcategories as noted in 76 FR 80606 and quoted in Comment II.4.C above, noting that the TSM alternative was not included in the proposal because of 1) the limited emissions test data, and 2) the large variability in TSM data. The sufficiency of the TSM data has been discussed previously.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3677-A2, excerpt 61.

Commenter Name: Lisa Barry

Commenter Affiliation: Chevron Corporation

Document Control Number: EPA-HQ-OAR-2002-0058-3687-A2

Comment Excerpt Number: 4

Comment: We understand that EPA is hesitant to provide an alternative TSM limit for liquid units since EPA's variability tool on the small metal data set for liquid units gives a TSM limit that seems high to EPA and not representative of the best performing 12% of units. Since EPA requested more metals data, API/AFPM did provide in their comments today additional liquid fuel metals data that may help EPA be more comfortable with the variability tool's results. However, we note that EPA already has metals data for 27 heavy liquid units nationwide, and EPA set a TSM limit for gas2 units using data from only a single unit. We believe that for

equitable treatment across fuel types EPA must establish an alternative TSM limit for liquid units. Also, the final NESHAP for island electric generating liquid units has an alternative TSM limit, and it would seem fair and logical for liquid units in other industrial sectors to also have a TSM alternative.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3677-A2, excerpt 61.

Commenter Name: Matthew Todd

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 70

Comment: As per EPA's second concern, similar variability can be observed for the fluidized bed coal boilers, which do have a TSM alternative. The ratio between the statistical variability calculated using the 99% UPL and the fuel variability for heavy liquid, non-continental liquid, and fluidized bed coal boilers is similar in each case. As well, the maximum ratio of TSM in the fuel samples for fluidized bed coal boilers is 1.14, which compares closely to the maximum ratio for heavy liquid and non-continental of 1.13. Because the TSM alternative was deemed appropriate for fluidized bed coal boilers with similar TSM variability to heavy liquid and non-continental units, it is only appropriate to establish TSM alternative standards for these subcategories as well.

Response: The EPA agrees with the commenter that the inherent variability in reported TSM emissions from fluidized bed coal combustors is similar to that of reported TSM data for liquid fuel combustors. The EPA has included an alternative TSM standard for the liquid fuel subcategories in the final rule.

Commenter Name: Michael L. Krancer

Commenter Affiliation: Pennsylvania Department of Environmental Protection (DEP)

Document Control Number: EPA-HQ-OAR-2002-0058-3507-A1

Comment Excerpt Number: 2

Comment: The EPA did not propose alternative TSM limits for the liquid fuel subcategories because of limited emission test data and the large variability in the TSM data in these subcategories. The EPA is soliciting comment on whether alternative TSM limits are appropriate for the subcategories of units designed to burn liquid fuels, and on whether an alternative approach to calculating the TSM MACT floors for these units is appropriate.

The DEP is in favor of providing alternative TSM limits for units that burn liquid fuels provide adequate data exists for the establishment of such limits.

Response: The EPA received additional TSM data from liquid units, and now has sufficient data exists to set alternative TSM standards for the liquid fuel subcategories. Alternative TSM standards for the liquid fuel subcategories have been added to the final rule.

Commenter Name: Robert D. Bessette
Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)
Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1
Comment Excerpt Number: 43

Comment: EPA did not provide a TSM option for liquid fuels. "For the light liquid, heavy liquid and non-continental liquid units subcategories, we are not proposing alternative TSM emission limits. Instead, we are proposing that these units meet the filterable PM emission limits in all instances." 76 Fed. Reg. 80,606. EPA determined that the emission data were too limited for TSM in this subcategory, but added that if it receives sufficient data indicating that TSM is appropriate, it would consider adopting a TSM option for liquid fuels as well. *Id.*

CIBO supports EPA's efforts to gather additional data to evaluate the possibility of a TSM option for liquid fuels. However, based on the analysis and conclusion EPA reached for solid fuel fired units, CIBO would expect that liquid fired units would lead to the same conclusions, based on logical conclusions with respect to these fuels and their typical emissions characteristics.

Response: For a response to the claim that the EPA should collect additional data and set alternative TSM standards for the liquid fuel subcategories, please see comment EPA-HQ-OAR-2002-0058-3507-A1, excerpt 2. The EPA acknowledges the commenter's opinion that sources burning liquid fuel would likely choose compliance with the PM standard, even if a TSM alternative is established.

Commenter Name: David L. Meeker
Commenter Affiliation: National Renderers Association (NRA)
Document Control Number: EPA-HQ-OAR-2002-0058-3476-A1
Comment Excerpt Number: 14

Comment: EPA issued the *National Emission Standards for Hazardous Air Pollutants from Coal- and Oil-Fired Electric Utility Steam Generating Units* (NESHAP Subpart UUUUU) and *Standards of Performance for Fossil-Fuel-Fired Electric Utility, Industrial-Commercial-Institutional Steam Generating Units* (modifications to NSPS Subparts D, Da, Db, and Dc) rules on December 16, 2011. NESHAP Subpart UUUUU is not applicable to boilers and process heaters at NRA member facilities since the units are not utilized to produce steam for electricity generating purposes above the thresholds defined in the rule. However, the proposed rule is relevant to this discussion concerning how EPA established emission standards for metal HAPs. In both the Boiler MACT and NESHAP Subpart UUUUU, EPA defined PM (filterable content) as an appropriate surrogate for metal HAP emissions.

The justification for using PM emissions as a surrogate pollutant for non-mercury metal HAP emissions in NESHAP Subpart UUUUU is the same DC Circuit Court determination used for the justification in NESHAP Subpart DDDDD. Electric generating units (EGUs) subject to NESHAP Subpart UUUUU will have the option to demonstrate compliance with the nonmercury metal HAP surrogate (PM) emissions limitation, the total selected metals (TSM) emissions limitation, or the individual non-mercury metal HAP emissions limitation(s). The reconsidered Boiler MACT, NESHAP Subpart DDDDD includes TSM or individual nonmercury metal HAP

emissions limitation(s) as an alternative to the metal HAP surrogate (PM) for the solid fuels (solid fossil fuels or biomass) only. The alternative compliance option is not provided for liquid fuel (light or heavy) fired units.

The NRA is not addressing in this comment letter whether PM is an appropriate surrogate option for non-mercury metal HAP from liquid fuel combustion. Instead, the NRA is bringing to EPA's attention that by not providing an option for direct measurement of TSM or individual nonmercury metal HAP content where it is feasible, EPA is detaching the rule from the underlying statutory requirements for control of HAP (of which PM is not). The NRA requests that EPA finds it is appropriate to include an option to demonstrate compliance directly with a TSM or individual non-mercury metal HAP emissions limitation(s) via fuel sampling for liquid fuels for NESHAP Subpart DDDDD. This comment is specifically for the NRA members and customers that will utilize a liquid fuel, not processed fats, as a back-up fuel source for boilers subject to NESHAP subpart DDDDD.

Response: The EPA is adopting a TSM alternative limit for the liquid fuel subcategories.

Commenter Name: Mary Sullivan Douglas

Commenter Affiliation: National Association of Clean Air Agencies (NACAA)

Document Control Number: EPA-HQ-OAR-2002-0058-3525-A1

Comment Excerpt Number: 60

Comment: EPA has not proposed a TSM alternative "because of the limited emission test data for TSM and the large variability in the TSM data for these subcategories. Using the EPA's maximum achievable control technology (MACT) floor methodology, the alternative TSM limits resulted in MACT floor values which do not appear to represent the actual performance of the best performing units." NACAA agrees with EPA's recommendation and the rationale for not proposing such limits. While EPA has sent follow-on inquiries to some sources for additional data, there is insufficient opportunity to meaningfully review and comment on any data that may be provided at this time.

Response: In the final rule, the EPA has established a TSM alternative for all fuel subcategories, including liquid fuels. The EPA received metallic HAP emissions data from units designed to combust liquid fuels during the public comment period. Enough data were available to set standards for all subcategories using the same MACT floor methodology as used for establishing TSM emission limits for the other subcategories. Moreover, EPA disagrees that the public did not have a meaningful opportunity to comment on alternative TSM limits. EPA clearly described its approach for establishing such limits in the proposed reconsideration and

solicited data to set such limits. Therefore, members of the public could comment on the appropriateness of alternative TSM limits as well as on the amount and type of data that should be used to set such limits. The fact that data was received during the comment period does not warrant further opportunity for public comment. To do so would potentially result in an endless loop of notice and comment that would delay final action.

Comment Excerpt Number: 9

Comment: As an alternative to the PM limits in the final rule, EPA proposes to allow compliance with an emission limit for total selected metals (TSM). Under this option, units combusting solid or Gas 2 fuels could opt to comply with a TSM limit, which would directly measure emissions of arsenic, beryllium, cadmium, chromium, lead, manganese, nickel, and selenium. This is a reasonable option, particularly for biomass units, for example, which may have PM emissions with lower HAP concentrations. EPA requests comment on whether the alternative should apply to liquid fuels. The Clean Energy Group sees no reason this compliance demonstration alternative should not apply to liquid-fueled units as well, although we expect that the majority of operators will choose the simpler PM tests.

Response: The EPA acknowledges this comment.

Comment: DGC supports EPA's determination of allowing for alternative TSM limit, except that EPA failed to include the alternative TSM for heavy liquid subcategory. EPA did include the heavy liquid subcategory in the PM GEMS monitoring requirements as a part of the affected categories. DGC agrees on the variability discussion on mixed fuels since DGC uses a variety of fuels (liquids and gases) recovering the heat value for combustion. As noted in the previous comment submitted by DGC, the GPSP operates boilers that have a Flue Gas Desulfurization Unit (FGD) to control SO₂ emissions. This control technology is considered BACT and works by

using ammonia to scrub the SO₂ from the flue gas forming ammonium sulfate, which is processed for use as a fertilizer. One of the natural functions of this FGD system is the slippage of small amounts of ammonia. This ammonia can combine with remaining low level sulfur in the flue gas to form ammonium sulfate in the atmosphere even after it passes through our Wet Electrostatic Precipitator (WESP). DGC operates FGD where a significant amount of ammonium sulfate particulate is produced and eventually emitted from the stack and by definition is not an HAP. For this reason, PM is not a representative surrogate for metal HAPs for DGC. The WESP works well enough to control emissions so that our most recent stack test shows only 27 lbs/hr of PM₁₀ and 22 lbs/hr filterable PM from the September 2011 test.

DGC should not be penalized for having particulate emissions that are not HAPs and should be allowed to demonstrate compliance with the alternative TSM limit, or to at least allow the use of the alternative TSM limit if it fails the PM emissions limit test. This standard does not seem practical or representative, and needs to be re evaluated. TSM is an option that would provide flexibility to affected sources as an alternative to the PM limit and represents directly the true area of concern. The standard as proposed for existing heavy liquid-fired boilers is not technically achievable for sustainable compliance for our facility configuration.

The use of particulate as a surrogate for metal HAPs at DGC's GPSP in effect results in a more stringent metal HAPs limit for the GPSP. It appears that DGC may not achieve the limit for PM even with the use of BACT such as a WESP on a sustainable basis. Therefore, DGC requests EPA either allow the compliance option (such as alternative TSM limit) in lieu of PM as a surrogate or create another

subcategory, such as wet ammonia scrubber, that will raise the particulate emission limit for units that use an ammonia absorber and WESP for SO₂ and PM control. As DGC mentioned earlier, this control technology is unique, and to DGC's knowledge there is only one other ammonia absorber in operation and that facility is in Canada.

Response: The EPA thanks the commenter for their support of the alternative TSM limits. The EPA has established an alternative TSM standard for all of the liquid fuel subcategories in the final rule. The EPA believes that the addition of the alternative standard for liquids provides the commenter flexibility that may be used to counter the inherent nature of PM emissions at the facility.

6Z. Out of Scope - Rationale for Regulated Pollutants

Comment Excerpt Number: 9

Comment: Although CO is being used as a surrogate for organic HAP emissions in this case, extremely low CO emission requirements are counterproductive for the overall environment when established without consideration of other requirements such as NO_x minimization or greenhouse gas generation. Conventional NO_x control technologies utilize staggered fuel or air systems that depress the maximum flame temperature thereby reducing thermal NO_x formation.

This same technique can generate CO values due to the staging process. Tuning these burners to reduce CO will increase flame temperatures thereby increasing NOx levels. Manufacturer and technical solutions for management of CO in conjunction with low NOx technology involves increasing the combustion product time at temperature (residence time) in order to completely convert the CO to CO2. Incorporating extended residence times is not possible without extensive modification to the basic structure of the chamber or footprint. For existing installations modifications of this nature are typically not financially feasible. For new installations incorporation of increased residence times involves increased capital investment.

Other means to reduce CO involve higher operating temperatures, involving higher fuel inputs coupled with increased potential operating load. One less than desirable aspect of increased energy rate is the impact on energy efficiency. Operating load is dependent upon the production plan developed for the facility that the boiler or process heater is supporting. If the demand is not there the boiler / process heater cannot increase energy rate without incorporating excess air to manage temperature. This practice will reduce the actual measured CO limit due to the influence of the oxygen correction. A second effect of the higher operating temperature is the increase in CO2 generation along with increased NOx formation.

Comment: EPA could allow for a petition to the permitting authority for determination of a unit-specific CO emission limit if it is determined that a boiler or process heater cannot attain the final rule CO emission limit without major unit redesign, oxidation catalyst addition with associated stack gas reheat and increased fuel usage, exceedance of an applicable NOx standard, or derating the unit. As EPA has monetized benefits for only PM2.5 and its precursors (NOx and SO2) it is apparent that requiring drastic reductions in CO emissions to the detriment of NOx emissions is not the desired outcome. Further, units close to Class I areas will be sensitive not only to increases in NOx emissions but also to implementation of NOx controls that might result in ammonia slip.

The process of determining a unit-specific CO limit could include:

- performing a tune-up according to a standard industry protocol (e.g., ASME PTC 4-2008, Fired Steam Generators, which provides rules and instructions for conducting performance tests of fuel fired steam generators)
- inspection and maintenance of the boiler/process heater and its fuel supply system to ensure they are in good operating condition,
- testing for CO emissions over the range of operating conditions to determine a site- specific CO limit and appropriate operating parameter limits, and
- establishment of a protocol for ongoing unit operation to ensure good combustion practices.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

102A. PM as a Surrogate for Non-Mercury Metallic HAP [DENIED PETITIONER ISSUE]

Commenter Name: James Pew

Commenter Affiliation: Earthjustice, Clean Air Council, Partnership for Policy Integrity

Document Control Number: EPA-HQ-OAR-2002-0058-3511-A1

Comment Excerpt Number: 7

Comment: EPA's use of surrogates continues to be unlawful and arbitrary for all the reasons given in the 2010 Comments, which are incorporated by reference as if fully stated herein and reiterated with respect to the agency's 2011 final rule and reconsideration proposal. 2010 Comments at 8-20. In addition, EPA has now finalized a definition of solid waste (and has proposed another on reconsideration) that excludes a wide variety of discarded materials including tires, sludges, spent solvent, scrap plastics, and the like. As a result of this definition, sources burning these materials would be regulated, if at all, under EPA's boilers rule. The emissions of metals from units burning secondary materials with relatively high metals emissions will be correlated less (if at all) with their emissions of PM. That is, emissions of metals (e.g. lead) could increase or decrease, without a corresponding increase or decrease in PM emissions, as a result of the materials such a source chooses to burn. For this reason as well as those given in the 2010 Comments, control of PM emissions is not the only means by which sources in the boilers category achieve lower emissions of metals such as lead, chromium and arsenic. Rather, some sources in the category achieve lower emission levels for these pollutants by choosing not to burn materials containing higher levels of these metals. For example, some sources choose not to burn whole tires or spent solvents or discarded oils that contain metals, and therefore have lower emissions of lead, chromium, arsenic and other metals. Because EPA has chosen to regulate waste burning sources as part of the boilers category rather than as incinerators, the variability of sources' metals emissions will increase or decrease for reasons unrelated to their PM control. Accordingly, for this category, PM fails the test as a surrogate for these metals.

Comment: In its final rule, EPA proffered a new rationale for its use of PM as a surrogate for non-mercury metals, that "[t]he partitioning of the metal HAPs is very complicated and can depend upon the fuel type, the form of metals in the fuel, other constituents in the fuel and the time- temperature profile of the post-combustion environment." Response to Comments Vol. 2 at 3187.1 cmt. That variations in "fuel type, the form of metals in the fuel, other constituents in the fuel and the time-temperature profile of the post-combustion environment" affect the partitioning of specific metal HAPs does not support the use of PM as a surrogate for these HAPs. To the contrary, it confirms the lack of a linear relationship between total particulate matter and hazardous air pollution – and further supports the insufficiency of total particulate matter as a surrogate.

Comment: EPA indicated – without further support – that "EPA's Office of Research and Development has conducted studies that showed that good control of the non-Hg metal HAP followed good control of bulk PM (filterable) across the primary PM control device." *Id.* Those studies are not, to our knowledge, in the record, and thus do not suffice to justify the Agency's decision (nor can the public meaningfully comment). Moreover, even if true, that general "following" of non-Hg metal control behind good particulate matter (filterable) control does not allow the Agency to substitute filterable particulate matter controls for direct controls on specific HAP; it does not, in particular, demonstrate the absence of other methods of limiting non-Hg HAP (in particular, fuel-switching) nor does it demonstrate the necessary fixed relationship between particulate matter control and control of non-Hg metallic pollutants.

Comment: We understand and do not challenge EPA's approach to using particulate matter as a surrogate for non-mercury metallic HAP since metals are a component of particulate matter from

boilers and testing for PM is simpler than testing for total metals. We do not wish to eliminate the use of PM as a compliance option.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

102B. CO as a Surrogate for Organic HAP [DENIED PETITIONER ISSUE]

Commenter Name: Claudia M. O'Brien, Latham & Watkins LLP

Commenter Affiliation: JELD-WEN, inc.

Document Control Number: EPA-HQ-OAR-2002-0058-3485-A1

Comment Excerpt Number: 9

Comment: EPA may only use surrogates to regulate HAPs "if it is *reasonable* to so do."²⁸ Among other factors for determining whether using a surrogate is reasonable, courts look to whether the agency has demonstrated a correlation between the HAP and the surrogate.²⁹ While it is still unsettled in law whether an agency is required to specifically quantify the correlation or assess its variability,³⁰ that does not matter here because EPA made only general statements regarding correlation, and any assumption that there is a valid correlation between CO and non dioxin/furan organic HAP in industrial boilers has been refuted by EPA's subsequent findings on correlation in its Utility MACT proposal.

In its Boiler MACT proposal, in which EPA first proposed the CO emissions standard as a means of regulating non-dioxin/furan organic HAP, EPA noted that CO "has *generally* been used as a surrogate for organic HAP because CO is a good indicator of incomplete combustion and organic HAP are products of incomplete combustion," and that its use as a surrogate "is a reasonable approach because minimizing CO emissions will result in minimizing non-dioxin organic HAP."³¹ Despite these and other general statements about why CO is an appropriate surrogate for non-dioxin/furan organic HAP, EPA did not reference any data supporting the correlation and EPA has not addressed this issue in the Boiler MACT reconsideration.

Comment Excerpt Number: 10

Comment: In contrast, EPA required testing to be conducted to examine potential surrogacy relationships for its Utility MACT proposal.³² EPA selected 170 units and required them to test for CO, volatile organic compounds (VOC), and total hydrocarbons (THC).³³ EPA acknowledged in its Utility MACT proposal that emissions of CO, VOC, and/or THC "have, in the past, been used as surrogates for the non-dioxin/furan organic HAP based on the theory that efficient combustion leads to lower organic emissions" (specifically citing the Boiler MACT proposal among others)³⁴ and stated that "[b]ecause CO and organics are both products of poor combustion, it is logical to expect that limiting the concentration of CO would also limit the production of organics."³⁵ However, despite this "logic," EPA found that "it is very difficult to develop direct correlations between the average concentration of CO and the amount of organics produced during the prescribed sampling period...."³⁶ Thus, after evaluating the data from the testing it required, EPA concluded that "it was difficult to correlate that concentration [of CO] to the quantity of organics produced...." and cited several reasons including the large number of potential organics that can be produced, the fact that they tended to be at or below the MDL in the same samples, and the fact that there were complications associated with the CO concentration values.³⁷ Because EPA considered it "impracticable to reliably measure emissions," EPA proposed a work practice standard for non-dioxin/furan organic HAP.³⁸

Comment: Sources' emissions of organic pollutants such as polychlorinated biphenyls (PCBs) and polycyclic organic matter (POM) will be correlated less (if at all) with their emissions of carbon monoxide, EPA's chosen surrogate for non-dioxins organic pollutants. Specifically, emissions of these pollutants could increase and decrease without a corresponding increase or decrease in CO emissions as a result of whether sources choose to burn tires, solvents, plastics, and the like. For this reason as well as those given in the 2010 Comments, control of CO emissions is not the only means by which sources in the boilers category achieve lower

emissions of organic pollutants including PCBs and POM. Accordingly, CO is not a valid surrogate for PCBs, POM and the other organic hazardous air pollutants that boilers emit.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

102C. Work Practice for Organic HAP [DENIED PETITIONER ISSUE]

Commenter Name: Paul Noe

Commenter Affiliation: American Forest & Paper Association (AF&PA) et al.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 50

Comment: In the recently-promulgated MATS rule, EPA established work practice standards for organic HAP emissions because "the majority of emissions of these pollutants are below the detection levels of EPA test methods and, therefore, are impractical to measure." 77 Fed. Reg. 9304, 9380 (Feb. 16, 2012). In testing of coal-fired boilers conducted in support of the Utility MACT, EPA found that "organic compounds tend[ed] to be at or below the MDL in coal combustion flue gas samples" even when CO was measured in the flue gas at levels of 23 to 137 ppm. 76 Fed. Reg. 24976, 25039 (May 3, 2011). In other words, even though valid CO measurements were available for coal-fired boilers, EPA determined that a work practice standard for volatile HAPs was appropriate and justified because at the levels of CO measured during testing, the corresponding amount of HAP emissions was below levels that reliably could be measured.

The same rationale supports a determination that work practice standards are appropriate and justified for coal-fired industrial boilers. While the amount of emissions testing for individual volatile HAPs is limited for coal-fired industrial boilers, EPA has good reason to conclude that the general relationship between CO emissions and volatile HAP emissions in the flue gas from industrial boilers should be the same as the relationship established in the testing conducted in support of the Utility MACT. For example, the same basic furnace designs are used in industrial boilers as are used in utility boilers. Moreover, it goes without saying that the same combustion chemistry and dynamics occur in industrial boilers as in utility boilers. In addition, operators of industrial coal-fired boilers purchase coal from the same markets as operators of utility boilers. In fact, the biggest overall differences between industrial boilers and utility boilers are size (with utility boilers generally being bigger than industrial boilers) and utilization (with industrial boilers typically having more variable loads and utilization). But, these differences should not be expected to cause the general relationship between CO emissions and volatile HAP emissions to be significantly different for fossil fuel-fired industrial boilers as compared to fossil fuel-fired utility boilers.

In short, at the relatively low CO levels measured in the flue gas from the best performing fossil fuel-fired industrial boilers, EPA can reasonably expect that the corresponding levels of volatile HAPs will be so low as to not be reliably measureable. This provides ample justification for setting work practice standards for volatile HAP emissions from fossil fuel-fired industrial boilers.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: Robert D. Bessette

Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 34

Comment: EPA hired a contractor to conduct an extensive pilot study to truly determine the expected emission profiles and relationship of non-dioxin organic HAP and CO for coal-fired units. This test program included a variety of types of coal and is titled "Surrogacy Testing in the Multi-Pollutant Research Control Facility", dated March 30, 2011. The excerpt from the preamble to the proposed MATS rule where EPA articulates its rationale for work practice standards in lieu of CO limits for coal-fired utility boilers is shown below.

"Tests were also conducted to examine potential surrogacy relationships for the non-dioxin/furan organic HAP. The amounts of Hg, non-Hg metals, HCl, HF, and Cl₂ in the flue gas are directly related to the amounts of Hg, non-Hg metals, chlorine, and fluorine in the coal. Control of these components generally requires downstream control technology. However, the presence of the organics in the flue gas is not related to the composition of the fuel but rather they are a result of incomplete or poor combustion. Control of the organics is often achieved by improving combustion conditions to minimize formation or to maximize destruction of the organics in the combustion environment.

During the pilot-scale tests, sampling was conducted for semi-volatile and volatile organic HAP and aldehydes. On-line monitors also collected data on THC, CO, O₂, and other processing conditions. Total hydrocarbons and CO have been used previously as surrogates for the presence of non-dioxin/furan organics. Carbon monoxide has often been used as an indicator of combustion conditions. Under conditions of ideal combustion, a carbon-based or hydrocarbon fuel will completely oxidize to produce only CO₂ and water. Under conditions of incomplete or non-ideal combustion, a greater amount of CO will be formed.

With complex carbon-based fuels, combustion is rarely ideal and some CO and concomitant organic compounds are expected to be formed. Because CO and organics are both products of poor combustion, it is logical to expect that limiting the concentration of CO would also limit the production of organics. However, it is very difficult to develop direct correlations between the average concentration of CO and the amount of organics produced during the prescribed sampling period in the MPCRF (which was 4 hours for the pilot-scale tests described here). This is especially true for low values of CO as one would expect corresponding low quantities of organics to be produced. Samples of coal combustion flue gas have mostly shown very low quantities of the organic compounds of interest. Some of the flue gas organics may also be destroyed in the high temperature post combustion zone (whereas the CO would remain stable). Semi-volatile organics may also condense on PM and be removed in the PM control device.

The average CO from the pilot-scale tests ranged from 23 to 137 ppm for the bituminous coals tests, from 43 to 48 ppm for the subbituminous coal tests and from 93 to 129 ppm for the Gulf Coast lignite tests. However, it was difficult to correlate that concentration to the quantity of

organics produced for several reasons. The most difficult problems are associated with the large number of potential organics that can be produced (both those on the HAP list and those that are not on the HAP list). This is further complicated by the organic compounds tending to be at or below the MDL in coal combustion flue gas samples. Further, there are complications associated with the CO concentration values. Some of the runs with very similar average concentrations of CO had very different maximum concentrations of CO (i.e., some of the runs had much more stable emissions of CO whereas others had some excursions, or "spikes," in CO concentration). For example, one of the bituminous runs had an average CO concentration of 69 ppm but a maximum concentration of 1,260 ppm (due to a single "spike" of CO during a short upset). Comparatively, another bituminous run had a higher average CO concentration at 137 ppm but a much lower maximum CO value at 360 ppm.

In the pilot tests, the THC measurement was inadequate as the detection limit of the instrument was much too high to detect changes in the very low concentrations of hydrocarbons in the flue gas.

EPA is proposing work practice standards for non-dioxin/furan organic and dioxin/furan organic HAP. The significant majority of measured emissions from EGUs of these HAP were below the detection levels of the EPA test methods, and, as such, EPA considers it impracticable to reliably measure emissions from these units. As the majority of measurements are so low, doubt is cast on the true levels of emissions that were measured during the tests.For the non-dioxin/furan organic HAP, for the individual HAP or constituent, between 57 and 89 percent of the run data were comprised of values below the detection level. Overall, the available test methods are technically challenged, to the point of providing results that are questionable for all of the organic HAP. For example, for the 2010 ICR testing, EPA extended the sampling time to 8 hours in an attempt to obtain data above the MDL. However, even with this extended sampling time, such data were not obtained making it questionable that any amount of effort, and, thus, expense, would make the tests viable. Based on the difficulties with accurate measurements at the levels of organic HAP encountered from EGUs and the economics associated with units trying to apply measurement methodology to test for compliance with numerical limits, we are proposing a work practice standard under CAA section 112(h)." 76 Fed. Reg. 25039

This study is as applicable to industrial boilers as it is to utility boilers. The EPA testing appears to support this conclusion since no correlations could be made at low CO emission levels associated with normal operation. This is further justification for not requiring ultra-low CO limits for coal-fired boilers in the industrial Boiler MACT, such as the 41 ppm limit proposed for existing pulverized coal boilers, the 56 ppm limit proposed for existing fluidized bed boilers, and the even lower CO limits proposed for new coal-fired units. These are prime examples of MACT limits the manufacturers have told our members they cannot guarantee. Real impacts on organic HAP emissions are not achieved by pressing ultra-low CO limits on fossil fuel combustion units compared to normal operating levels, but higher emissions of organic HAP might only occur with high levels of CO associated with malfunctions, equipment failures, or fuel interruptions. Therefore, while EPA can calculate a MACT Floor CO emission limit for the industrial boilers and process heaters as proposed, there is no defensible driver to impose such low emission limits, and modifying the floor setting procedure or allowing alternatives to accommodate higher allowable emission rates appears justified.

Mandating a work practice standard instead of an emission limit gets more to the core of the MACT rule: minimizing emissions while ensuring efficient operation. As such, CIBO requests EPA consider replacing the numerical CO emission limit in repropose Boiler MACT with a work practice standard similar to the approach used in the Utility MACT (77 FR 9369, February 16, 2012). In the preamble, EPA discusses their belief that "...the work practice standard will result in actions being taken that will reduce the emissions of these (organic) HAP."

However, if EPA continues to pursue imposition of CO limits on ICI boilers and process heaters, in addition to the proposed adjustments to the CO emissions limitations and the proposed alternative CO emissions limitations for units with CEMS, EPA should consider additional alternative approaches to setting standards for CO.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: Melvin E. Keener

Commenter Affiliation: Coalition for Responsible Waste Incineration (CRWI)

Document Control Number: EPA-HQ-OAR-2002-0058-3454-A1

Comment Excerpt Number: 4

Comment: EPA should set a work practice standard for organic HAPS for coal-fired boilers.

In the "Utility MACT" final rule (77 Fed. Reg. 9,304, February 16, 2012), EPA concluded that numerical emission standards for organic HAPs were not justified and, instead, set work practice standards. This decision was made because the majority of data for measuring organic HAP emissions were below the detection limit even when long duration tests were used. 77 Fed. Reg. at 9,369. As such, the Agency concluded this allowed the use of a work practice standard under section 112(h) of the Clean Air Act.

CRWI supports that decision and suggests that the same set of facts applies to the coal-fired boilers in this proposed rule. Coal-fired industrial boilers are similar in design, construction, and operation to coal-fired boilers used to generate electricity. Coal-fired boilers under both rule produce steam as their initial product. For the electric generation units, that steam is used to produce electricity. For industrial boilers, the steam is also used to produce electricity but can also be directly used in the production process, to heat buildings, to provide temperature control for the production processes, etc. Essentially, these two sets of coal-fired boilers are similar, just categorized differently based on their use of steam. If the Agency decided that it was inappropriate to set numerical limits for coal-fired boilers used to generate electricity, it also seems that it is inappropriate to set numerical emission standards for organic HAPs for coal-fired industrial boilers. CRWI urges EPA to set work practice standards for organic HAPs similar to what was promulgated in the "Utility MACT" final rule.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: Claudia M. O'Brien, Latham & Watkins LLP

Commenter Affiliation: JELD-WEN, inc.

Document Control Number: EPA-HQ-OAR-2002-0058-3485-A1

Comment Excerpt Number: 8

Comment: EPA has chosen to use CO as a surrogate for non-dioxin/furan organic HAP, and in EPA's Boiler MACT reconsideration, it proposes revised CO limits for sources in the non continental liquid unit subcategory²⁶ and to offer CO CEMS-based alternative emission limits and monitoring as an alternative to CO stack testing. However, these proposed modifications do not address the more fundamental problem with EPA's CO numeric emission limits-the problems associated with using CO as a surrogate, which EPA has recognized in its Utility MACT rule. Thus, JELD-WEN urges EPA to revise its reconsideration proposal to repeal the CO emission standard and, instead, establish work practice standards for non-dioxin/furan organic HAP.

Comment: It appears that EPA did not even attempt to collect data from industrial boilers to establish a correlation between organic HAP and CO levels to support the Boiler MACT rule. However, if it had done so, it almost certainly would have found the exact same problems in making the correlation as it did in the Utility MACT context. The Utility MACT data on CO and the organic HAPs expected to be present in utility flue gas is the most comparable data set to industrial boilers because industrial boilers are generally similar in design and operation to utility boilers, albeit much smaller and with more variable loads. Yet the utility data set did not show a strong enough correlation to support the surrogacy standard applied by the courts. The absence of a reasonable correlation between CO and non-dioxin/furan organic HAPs in the Utility MACT dataset- and the complete absence of any data showing a correlation in the Boiler MACT dataset- leaves EPA with no viable basis on which to use CO as a surrogate here. In the Utility MACT proposal, EPA has concluded, based upon data and calculations, that a work practice standard is appropriate due to the impracticability of reliably measuring non-dioxin/furan organic HAP through CO emissions. So too here, a work practice standard is supported under the legal standard discussed *supra* in section A.

Comment: Alliant Energy believes that this could be extended to other organic HAPs (similar to the final MATS) and thereby, completely eliminate all carbon monoxide (CO) emissions

limitations for all regulated emissions units. For MATs, the EPA concluded that work practices were appropriate, because the significant majority of measured data for organic HAPs were below detection levels of EPA test methods. Alliant Energy believes that this is also the case for smaller boilers and heaters, thus recommends EPA review the organic HAP data for these units to assure equitable treatment in this MACT evaluation. In particular, this is especially true for small house heating boilers with a nameplate capacity less than 100 mmBtu/hr.

Comment: EPA should extend the work practice standards it has proposed for dioxin and furan emissions to all organic HAPs emitted by IB units. To the extent organic HAP emissions from these units even exist, they result from incomplete combustion - just as in the case of any dioxin or furan emissions. As noted above, the economic incentives for efficient boiler operations will minimize the creation of incomplete combustion products. There is no reason for EPA to treat organic HAP emissions differently than dioxin emissions; work practice standards should be established for both pollutant groups.

Comment: EPA should eliminate the carbon monoxide (“CO”) emission limit established by the Major Source Rule⁹ and instead institute a work practice standard for organic HAPs. EPA adopted this approach in the final MATS, and the same rationale supports the adoption of work practice standards here. In the MATS, EPA determined that a work practice standard is appropriate for organic HAPs because a significant majority of data for measured organic HAP emissions from electric generating units (“EGUs”) are below the detection levels of EPA’s test methods.¹⁰ The Group believes that if organic HAP emissions from EGUs are below detection levels, then it is very likely that organic HAP emissions from boilers and process heaters at major sources also are below detection levels. In fact, at least one test run used to calculate the upper prediction limit for CO in the Major Source Rule was reported as non-detect data.¹¹ EPA should ensure that it is consistent in its treatment of detectable emissions levels across rulemakings. Accordingly, the Group urges EPA to consider whether organic HAP emissions can be practicably measured, and if not, EPA should instead institute a work practice standard.

Commenter Name: Robin Mills Ridgway

Commenter Affiliation: Purdue University

Document Control Number: EPA-HQ-OAR-2002-0058-3668-A2

Comment Excerpt Number: 9

Comment: Purdue agrees that CO is an appropriate surrogate for organic HAP. Carbon monoxide is the most common product of incomplete combustion (PIC), and because of its associated chemical kinetics, is one of the most difficult PICs to oxidize completely. As such, CO emissions have historically been used as an indicator of the quality of the combustion process. The concept is that low CO emissions equate to low emissions of other organic compounds.

While this is true in general, the mechanisms by which CO is formed and destroyed in the combustion process are different than for other organics. As such, in cases where other organic compounds have been completely oxidized, CO concentrations may still be elevated. While the tendency is to think that further reductions in CO emissions will improve the quality of the combustion, and in turn minimize emissions of other organic compounds, this is not necessarily true. Instead, forcing CO emissions lower and lower ends up over-constraining the combustion process, resulting in other air quality concerns and loss of unit efficiency, without achieving corresponding reductions in emissions of organics.

Mandating a work practice standard instead of a CO emission limit gets more to the core of the MACT rule: minimizing emissions while ensuring efficient operation. As such, Purdue requests EPA consider replacing the numerical CO emission limit in repropoed Boiler MACT with a work practice standard similar to the approach used in the Utility MACT (77 FR 9369, February 16, 2012). In the preamble, EPA discusses their belief that "...the work practice standard will result in actions being taken that will reduce the emissions of these (organic) HAP."

Comment Excerpt Number: 2

Comment: In the case of the Utility MACT, EPA went to the expense to hire a contractor to conduct an extensive pilot study to truly determine the expected emission profiles and relationship of non-dioxin organic HAP and CO. This test program included a variety of types of coal and is titled "Surrogacy Testing in the Multi-Pollutant Research Control Facility". The report of the results of this study is dated March 30, 2011. The excerpt from the preamble to the Utility MACT proposed rule where EPA articulates its rationale for work practice standards is shown below. It stands in stark contrast to the rationale shown above for industrial boilers.

Federal Register Page 25039, May 3, 2011

This study is equally applicable to industrial and institutional coal boilers as it is to utility boilers. Many industrial and institutional boilers, including one or more of Eastman's boilers, will make capital investments or de-tune their boilers to reduce CO at the expense of higher year-round NOx emissions to comply with the repropoed standards applicable to coal-fired boilers that utility boilers will not be required to make.

Therefore, as part of its reconsideration process, we request EPA change the rule to eliminate numerical emission standards for CO for coal-fired boiler subcategories and instead refer to the work practice standards. A requirement to conduct periodic tune-ups that optimize CO emissions, inspect and clean/replace burners, adjust flame patterns, and check the air/fuel ratio control system will be more than adequate to ensure proper operation of the boiler and minimize emissions of organic HAP.

Commenter Name: Robert Ellerhorst

Commenter Affiliation: Michigan State University

Document Control Number: EPA-HQ-OAR-2002-0058-3674-A2

Comment Excerpt Number: 1

Comment: U.S. EPA is proposing separate carbon monoxide (CO) limits for each boiler subcategory (pulverized coal units, coal-fired CFB, etc). CO is used as a surrogate for non-dioxin/furan organic hazardous air pollutants (HAPs), and therefore it is assumed that all non-dioxin/furan organic HAPs will be represented by CO emissions. These proposed limits must be met during various load conditions and exclude periods of startup and shutdown. CO is a byproduct of incomplete combustion; the average concentration can have very different maximum values (i.e. values can remain stable and can suddenly "spike") and can vary significantly over any given time period. Spikes can be caused by sudden external temperature changes and/or fluctuations in fuel composition. As such, MSU believes that the proposed CO limits for existing coal boilers are not achievable at various loads and suggests the work practice standards be used for compliance.

Document Control Number: EPA-HQ-OAR-2002-0058-3674-A2

Comment Excerpt Number: 7

Comment: MSU would like to note that U.S. EPA's opinions on the appropriate method to set MACT standards for organic hazardous air pollutants (HAPs) for coal-fired boilers has been inconsistent. In the final rule (March 21, 2011) and reconsidered final rule (December 23, 2011), it was concluded that numerical emission standards for CO were an appropriate method to control organic HAPs. However, in the final Mercury and Air Toxics (MATS) rule signed December 16, 2011(formally known as the Utility MACT), it was determined that numerical emissions standards were not justified and instead requires work practice standards (boiler turning) to minimize CO emissions. Utility and Industrial/Institutional boilers have similar operating deficiencies that cause variations in CO emissions. There are minimal differences between operation of a Utility boiler in comparison to one required to comply with the CO emissions for this regulation. As such, it does not seem appropriate to have deemed a CO emission limitation necessary for a boiler that does not generate electricity for an external customer base (i.e. a Utility boiler) as opposed to one used to provide electricity for a university, such as MSU. Therefore, MSU believes that U.S. EPA should remain consistent with the reasoning used to not require a CO emission limitation for the MATS in this reconsidered rule.

Document Control Number: EPA-HQ-OAR-2002-0058-3685-A2

Comment Excerpt Number: 24

Comment: It is not appropriate to treat detection level limited data for purposes of establishing regulatory limits in the same manner as detected values because the uncertainty associated with measurements near or below the method detection limits is too high. All source emission measurements have random (precision) errors associated with the sample collection, sample and equipment handling, sample preparation, and sample analysis. These errors define method detection and quantitation limits and uncertainty in a non-arbitrary, scientific manner. When emission levels are much higher than the magnitude of these errors, there is a high degree of confidence in the measured value obtained from a single or a few test runs. However, as the measured value decreases, the contribution of these errors to the measured value increases, thus decreasing the confidence level in the accuracy of the measured value from a single or a few runs until the point where the measured value cannot be distinguished from the random error ("noise" level). This is the case with the boiler dioxin/furan data. When this occurs, the measurement cannot be distinguished from zero with high confidence.

EPA discovered this during the development of emissions standards for the proposed Utility MACT rule/ 0 during which EPA conducted pilot tests on coal-fired boilers to determine if CO was in fact a proper surrogate for organic HAP. The results of the tests indicated that organic HAP exists in extremely low levels for these utility boilers, and below the point of detection or accurate measurement. These findings are reproduced below:

With complex carbon-based fuels, combustion is rarely ideal and some CO and concomitant organic compounds are expected to be formed. Because CO and organics are both products of poor combustion, it is logical to expect that limiting the concentration of CO would also limit the production of organics. However, it is very difficult to develop direct correlations between the average concentration of CO and the amount of organics produced during the prescribed sampling period in the MPCRf (which was 4 hours for the pilot-scale tests described here). This is especially true for low values of CO as one would expect corresponding low quantities of

organics to be produced. Samples of coal combustion flue gas have mostly shown very low quantities of the organic compounds of interest. Some of the flue gas organics may also be destroyed in the high temperature post combustion zone (whereas the CO would remain stable). Semi-volatile organics may also condense on PM and be removed in the PM control device. The average CO from the pilot-scale tests ranged from 23 to 137 ppm for the bituminous coals tests, from 43 to 48 ppm for the subbituminous coal tests and from 93 to 129 ppm for the Gulf Coast lignite tests. However, it was difficult to correlate that concentration to the quantity of organics produced for several reasons. The most difficult problems are associated with the large number of potential organics that can be produced (both those on the HAP list and those that are not on the HAP list). This is further complicated by the organic compounds tending to be at or below the MDL in coal combustion flue gas samples. Further, there are complications associated with the CO concentration values. Some of the runs with very similar average concentrations of CO had very different maximum concentrations of CO (i.e., some of the runs had much more stable emissions of CO whereas others had some excursions, or "spikes," in CO concentration). For example, one of the bituminous runs had an average CO concentration of 69 ppm but a maximum concentration of 1,260 ppm (due to a single "spike" of CO during a short upset). Comparatively, another bituminous run had a higher average CO concentration at 137 ppm but a much lower maximum CO value at 360 ppm.³¹

EPA's inability to accurately measure organic HAP emissions from these units made it impossible to establish a meaningful correlation between CO and inorganic HAP and made numeric emission limits infeasible. In light of this finding, EPA proposed and finalized a work practice standard for organic HAP for coal and oil-fired boilers in the Utility MACT rule. *See* 76 Fed. Reg. at 25028 ("We are proposing work practice standards because the data confirm that the significant majority of the measured organic HAP emissions from EGUs are below the detection levels of the EPA test methods, and, as such, EPA considers it impracticable to reliably measure emissions from these units.").

[Footnote 30: 76 Fed. Reg. 24976 (May 3, 2011).] [Footnote 31: 76 Fed. Reg. at 25039 (emphasis added). AMP incorporates by reference the full results of EPA's pilot-scale tests from the Utility MACT rule docket as if fully appended hereto and asks that EPA move the test results and all related documents into the Boiler MACT docket and administrative record.]

Commenter Name: Steve Gossett

Commenter Affiliation: Eastman Chemical Company

Document Control Number: EPA-HQ-OAR-2002-0058-3669-A2

Comment Excerpt Number: 1

Comment: Comment Summary: EPA has not justified that numerical emission standards are appropriate for carbon monoxide (CO) for coal-fired boilers and should replace these standards with work practice standards just as it has determined for coal-fired utility boilers.

Note: While EPA has not specifically solicited comment on this issue, we believe it is appropriate for EPA to consider these comments as they are based on data and information that

have become available after the close of the original proposed rule comment period and even after the deadline for filing of petitions for reconsideration. Also, these comments are appropriate as EPA has proposed to revise the emission standards for CO. Therefore, the issue of the appropriateness of the setting of numerical emissions limits is germane to this comment period.

EPA's opinions on the appropriate method to set MACT standards for non-dioxin organic hazardous air pollutants (HAPs) for coal-fired boilers has been inconsistent. On the one hand, in the industrial boiler MACT proposed rule (June 4, 2010) and final rule (March 21, 2011), EPA concluded that the appropriate method is to set numerical emission standards for CO as a surrogate for non-dioxin organic HAP. On the other hand, and subsequent to its decisions on the industrial boiler MACT, EPA concluded for similar coal-fired boilers in the "Utility MACT" proposed rule (May 3, 2011) and final rule (signed December 16, 2011) that numerical emission standards are not justified and instead set work practice standards for non-dioxin organic HAPs (using the same tune-up requirements used to address dioxin emissions).

EPA's discussion of its decision regarding Boiler MACT can be found on page 32018 of the June 4, 2010 preamble.

EPA concludes that controls such as oxidation catalyst designed to reduce CO will also reduce VOC. This is not necessarily true. Many coal-fired boilers emit CO in the range of 50 -100 ppm while emitting less than 1 ppm THC. This fact is supported by EPA's ICR database. Thus, a boiler required to reduce CO to meet the numerical standard could install an oxidation catalyst with no evidence that VOC will be reduced since there is little emitted to begin with. The chart [see submittal for Figure 1] plots all CO and THC paired stack test run data found in EPA's ICR database for industrial, commercial, and institutional boilers. As can be readily observed from this chart, there is no direct relationship between CO and THC for these coal-fired boilers. This draws into question the effectiveness of setting sub-400 ppm CO limits on coal-fired boilers as a means to minimize non-dioxin organic HAP emissions.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Document Control Number: EPA-HQ-OAR-2002-0058-3685-A2

Comment Excerpt Number: 25

Comment: EPA did not perform these extensive organic HAP and correlation tests when promulgating Boiler MACT limits. Instead, EPA relied upon the same presumed correlation between CO emissions and organic HAP emissions that it found impossible to substantiate when it measured similar units under the Utility MACT.³² The large utility boilers analyzed in the Utility MACT rule share the same fuels, design, and combustion characteristics as the smaller utility boilers subject to Boiler MACT. Therefore, low levels of organic HAP would be expected for these smaller units as well, only the levels would be even lower and harder to quantify because the Boiler MACT utilities use less fuel in smaller units. A review of the Boiler MACT emissions database indicates that many of the tests performed for organic HAP produced results that were either non-detect or were at or below the level of reliable measurement. It would be

arbitrary and capricious for EPA to disregard this relevant emissions information and continue to presume that the correlation it was not able to establish for large coal-fired utility boilers nonetheless exists for smaller coal-fired utility boilers. After extensive testing of organic HAPs, EPA determined that organic HAPs were at such low levels that a numeric emission limit for CO was improper. EPA should also impose a work practice standard on small coal-fired utilities under the Boiler MACT rule so there is parity between the regulations for large and small utility boilers. This relief would also reduce the burden on a subset of small entities for which EPA is required to consider mitigation measures.

[Footnote 32: *See, e.g.*, 75 Fed. Reg. 32006, 32018 (June 4, 2010); 76 Fed. Reg. at 15654; 76 Fed. Reg. at 80624.]

Commenter Name: Claudia M. O'Brien, Latham & Watkins LLP

Commenter Affiliation: JELD-WEN, inc.

Document Control Number: EPA-HQ-OAR-2002-0058-3485-A1

Comment Excerpt Number: 13

Comment: In establishing the CO emission standards, EPA also did not take into account the correlation between CO and NO_x emissions. There is an inverse relationship between CO emissions and NO_x emissions. Operating conditions necessary to achieve CO reductions will, therefore, result in NO_x increases. This will be particularly problematic for units that are operating under low NO_x limitations. Some units may be forced to install additional NO_x controls. Other units may simply be unable to comply with both the CO standards and NO_x limitations. Yet, EPA did not consider these consequences in establishing the CO emission standards. Since the operating conditions needed to achieve the CO emission standards will lead to an increase in NO_x emissions, this further undermines EPA's approach and counsels in favor of work practice standards for non-dioxin/furan organic HAP. Given the problems with establishing CO as a surrogate for non-dioxin/furan organic HAP, it is not even clear that the CO standards would result in any HAP reduction.

JELD-WEN respectfully submits that EPA should revise its Boiler MACT reconsideration proposal to repeal its CO emissions standard and replace it with a work practice standard for non-dioxin/furan organic HAP as it did in the Utility MACT proposal.

Commenter Name: Robert Ellerhorst

Commenter Affiliation: Michigan State University

Document Control Number: EPA-HQ-OAR-2002-0058-3674-A2

Comment Excerpt Number: 6

Comment: MSU requests that U.S. EPA revise the proposed CO limitations to work practice standards. MSU's experience in operating four coal-fired boilers shows that there are several

factors that have a fairly significant effect on CO emissions including, steam load, CFB bed temperature, and type of fuel fired. MSU operates our units with efficient combustion practices to minimize CO emissions to the maximum extent possible. Factors that facilitate efficient combustion include air-to-fuel ratio; CFB combustion temperatures, residence time, and turbulence (or mixing) of the combustion gases. Maximizing combustion efficiency must be balanced with the potential increase in NOx emissions that could occur when combustion efficiency is associated with high chamber temperatures. Maintaining reduced NOx levels is of particular concern to MSU in order to comply with current air use permit limits for NOx as well as Clean Air Interstate Rule (CAIR) ozone season requirements. MSU is in compliance with all other proposed emission limitations as set forth in that rule. It is uncomprehensible that MSU may have to incur significant costs in order to continue operation for one emission limit that was set with data that does not take into account variations in operation of boilers.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Commenter Name: Claudia M. O'Brien, Latham & Watkins LLP
Commenter Affiliation: JELD-WEN, inc.
Document Control Number: EPA-HQ-OAR-2002-0058-3485-A1
Comment Excerpt Number: 12

Comment: In addition to the fact that EPA has disproven the correlation between CO and organic HAP and that EPA has met the legal requirements for adopting a work practice standard both in Utility MACT and here, other factors suggest that EPA *should* abandon its CO emission limitation and adopt a work practice standard for non-dioxin/furan organic HAP. For instance, a potential unintended consequence of requiring the CO emission standard rather than a work practice standard is that some units may be forced to curtail biomass-fired operations in favor of more fossil fuel-fired operations. As an example, if a boiler with a 122 MM BTU/hr rating were limited to a 500 ppm CO limit (corrected to 7%), it would have to dramatically cut back wood combustion to meet this limit.³⁹ Additional fossil fuel would be combusted to replace the biomass fuel, and this action could result in emission of 5.5 tons of SO₂ for each ton of CO controlled (corresponding to a completely unknown if any- organic HAP reduction). It would be unfortunate if EPA's proposed CO emission standard forced facilities to curtail construction of new biomass burning units when the Agency and many states have been actively promoting biomass for sound environmental reasons. [Footnote 39: We note that several of the biomass CO limits are even more stringent than this illustration and would likely require further curtailment of biomass use.]

Document Control Number: EPA-HQ-OAR-2002-0058-3492-A1
Comment Excerpt Number: 3

Comment: Alliant Energy believes that the CO emission limits in the final rule are unnecessary in any case and are especially onerous for existing and new light oil-fired house heating boilers less than 100 mmBtu/hr that are burning the cleanest distillate fuel oil available (i.e., ultra-low sulfur content less than 15 ppm). These units may not be able to be retrofitted with further emission controls sufficient to achieve the stringent CO emission limitations in the final rule due to physical space constraints. Furthermore, in some cases, the units may also be constrained by a lack of available natural gas pipeline and unable to switch fuel.

Commenter Affiliation: PPG Industries, Inc

Document Control Number: EPA-HQ-OAR-2002-0058-3778-A1

Comment Excerpt Number: 2

Comment: PPG strongly supports the use of work practices as MACT for gas-fired boilers.

A correlation between a reduction in CO concentration and a corresponding reduction in organic HAP emissions below a CO concentration of approximately 100 ppmv for Gas 2 fueled sources has not been definitively established. Thus, setting a very low standard for CO does not ensure a proportional reduction in the organic HAP emissions, and may have the unintended consequence of increasing emissions of other pollutants such as nitrogen oxides due to the combustion of additional fuel and suboptimal operating conditions. Work practices are more appropriate.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

102E. Alternative CO Standards Corrected to a CO₂ Concentration [DENIED PETITIONER ISSUE]

Commenter Name: Traylor Champion

Commenter Affiliation: Georgia-Pacific LLC (GP)

Document Control Number: EPA-HQ-OAR-2002-0058-3465-A1

Comment Excerpt Number: 27

Comment: The proposed rule at Tables 1 and 2 to Subpart DDDDD specifies a CO concentration limit for a number of the boiler/process heater subcategories. For each subcategory, an O₂ correction factor is also specified for the CO limit. At Table 5, the proposed rule specifies EPA Methods 3A or 3B for the determination of O₂ and CO₂ concentrations and EPA Method 10 is specified for the measurement of CO concentrations. The purpose of this O₂ CEMS is to serve as the diluent analyzer needed to provide the data for the required O₂ correction data for the CO concentration. PS 2, however, allows the use of either a CO₂ or O₂ diluent analyzer to calculate the O₂ correction. CO₂ is commonly used by other CEMS (NO_x, SO₂, etc.) because CO₂ analyzers are generally considered to be more reliable and stable than O₂ monitors. Many existing boilers/process heaters with existing CEMS will already have a CO₂ CEMS in-place which could also be used for correction of the CO data. While the cited

Performance Standards and EPA Methods would permit its use, the text of the proposed rule appears to require the use of an O2 diluent gas analyzer only. While the use of CO2 data to calculate the O2 correction could be accomplished via a request to EPA for approval of alternative monitoring, amendment of the proposed rule to explicitly allow for its use would be a far more efficient resolution.

GP urges EPA to: Allow CO2 diluent analyzer data to be used to calculate the O2 correction in CO diluent calculations as an option to using O2 diluent analyzer data only.

Document Control Number: EPA-HQ-OAR-2002-0058-3466-A1

Comment Excerpt Number: 4

Comment: CO Standards should be based on Correction to 11 or 12% oxygen

Boiler MACT requires that the CO limit be standardized to 3% oxygen which is well below where most biomass boilers normally operate. This biases the stack CO higher when the adjustment from operating CO to the 3% standard is made.

Oxygen correction percents should be representative of normal stack conditions under normal operation. Three percent is not normal of most combustion units. This is not normal for the location where a certified CEMS needs to be installed to meet performance specification 1 requirements.

Comment Excerpt Number: 2

Comment: Xcel Energy's vast experience with wood firing in these boilers coupled with its vast amount of CO CEMs data leads the Company to question the use of a 3% oxygen correction for CO emissions from a solid fuel-fired boiler. A correction factor is normally used to standardize the concentrations of stack constituents (such as CO) to a standard oxygen concentration to remove the effect of dilution or "tramp" air leaking into the exhaust train after combustion. The correction factor should be based on the appropriate engineering guidelines for excess air required for the combustion of the fuel in use. Excess air is required since mixing of air and solid fuel is not perfect, and the combustion reaction must be shifted in order to achieve complete combustion. Engineering guidelines for wet biomass stoker grate boilers call for a minimum of 6% to a maximum of 12% oxygen in the post combustion air. These boilers typically require around 10% oxygen in the exhaust firm. The 3% correction is typically used for

liquid or gaseous fuels which need much less excess air to achieve complete combustion. Xcel Energy therefore requests the CO limit in the final rule be corrected to 7% oxygen as it is the normal and appropriate dilution correction standard for wet biomass stoker boilers.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: Heather Parent

Commenter Affiliation: Maine Department of Environmental Protection

Document Control Number: EPA-HQ-OAR-2002-0058-3691-A2

Comment Excerpt Number: 10

Comment: The proposed rule uses a 3% oxygen correction factor for CO emission standards. This correction factor is appropriate for liquid fuel and gaseous fired units, but biomass and multi-fuel fired boilers typically operate with flue gas oxygen levels at 6% to 8%. Maine DEP recommends applying an oxygen correction factor of 7% for the CO emission standards associated with all solid fuel units as EPA had established in the original Major Source Boiler MACT published on September 13, 2004 (69 Fed.Reg. 55228):

"The final rule provides revisions to the CO work practice emission levels. For new sources in the solid fuel subcategory, the work practice standard has been written to be corrected to 7 percent oxygen rather than 3 percent. Units in the gaseous and liquid fuel subcategories still have to correct to 3 percent oxygen."

Units burning only coal may be able to operate at 3% oxygen, but any biomass unit will not operate close to 3% oxygen even when firing auxiliary fossil fuel.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

102F. Alternative Standards for THC [DENIED PETITIONER ISSUE]

Commenter Name: Robert D. Bessette

Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 41

Comment: A total hydrocarbon alternative (THC) standard is needed for coal-fired boilers unable to meet the CO limit. Although EPA has not elected to reconsider (this issue was included in CIBO's petition for reconsideration) its decision to not include a THC option, we are aware that the Agency will be getting significant comment from the regulated community that the proposed CO limits for coal-fired boilers will prove to be problematic. THC is an alternate surrogate to EPA's proposed CO surrogate for non-dioxin organic HAPs. However, EPA, in its response to comments on the June 4, 2010 proposed rule, stated that its Office of Research and Development does not support the use of THC as a surrogate for organic HAP from industrial boilers. No other explanation is given and EPA has failed to respond adequately to a significant comment that goes to the issue of sources' ability to comply with the rule. Some coal boilers

have high (>100 ppm) CO levels but very low (<1 ppm) THC. To avoid forcing owners of these boilers to make large expenditures to the combustor to reduce CO and then add post-combustion control to reduce co-laterally increased NOx emissions, EPA should set an alternative THC limit. Sources, would then conduct stack tests to demonstrate compliance with the THC limit and operate O2 trim systems as an operating parameter.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Commenter Name: Steve Gossett

Commenter Affiliation: Eastman Chemical Company

Document Control Number: EPA-HQ-OAR-2002-0058-3669-A2

Comment Excerpt Number: 28

Comment: E.4 CO CEMS-Based Alternative

Comment Summary: An alternative limit using total hydrocarbons as a surrogate should be allowed if EPA determines that work practice standards are not appropriate to control emissions of non-dioxin organic HAPs from coal fired boilers.

Eastman requested that EPA set an alternative THC limit in its comments on the June 4, 2010 proposed rule. The company’s comment and response from EPA to this comment is shown below:

Commenter Name: Stephen R. Gossett

Commenter Affiliation: Eastman Chemical Company

Document Control Number: EPA-HQ-OAR-2002-0058-3137.1

Comment Excerpt Number: 16 This response from EPA is unsatisfactory. EPA cannot simply state that its Office of Research and Development does not support THC as a surrogate without explaining the basis for its disagreement. This EPA position unravels the Agency’s long history of recognizing that THC is good measure of organic emissions. Traditionally, CO monitoring has been preferred over THC monitoring due to technical and cost issues. Never has the EPA questioned that THC would be a better surrogate than CO, especially since THC is a direct measure of organic emissions. CO is more an indicator of combustion conditions. We note, for example, that the Portland Cement MACT sets standards for THC rather than CO as a surrogate for non-dioxin organic HAPs (40 CFR 63 Subpart LLL, Table 1). As we noted in our previous comments, without a THC alternative (which could likely be met with no controls or operational changes), the company will be spending significant funds to comply with the CO limit.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Commenter Name: Steve Gossett

Commenter Affiliation: Eastman Chemical Company

Document Control Number: EPA-HQ-OAR-2002-0058-3669-A2

Comment Excerpt Number: 29

Comment: Although EPA has not elected to reconsider (this issue was included in CIBO's petition for reconsideration) its decision to not include a THC option, we are aware that the Agency will be getting significant comment from the regulated community that the proposed CO limits for coal-fired boilers will prove to be problematic. In Eastman's case, it will cause us to make a large capital expenditure (~\$15 M) that we do not believe will have any impact on emissions of non-dioxin organic HAPs. Figure 2 [see submittal for Figure 2] summarizes recent CO and THC CEMS data we have collected on this boiler that demonstrate the CO emissions will not meet the proposed limit and that the THC emissions are very low.

We therefore renew our request that EPA either (1) establish an alternative THC limit under which a source would conduct a performance test to show compliance and set a minimum oxygen trim 30-day rolling average operating limit or (2) allow a source to petition its permitting authority for such an alternative limit.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: Steve Gossett

Commenter Affiliation: Eastman Chemical Company

Document Control Number: EPA-HQ-OAR-2002-0058-3669-A2

Comment Excerpt Number: 30

Comment: EPA has sufficient data from its 2009 ICR Phase II testing program to establish a THC limit. From our analysis of that data, it appears a THC limit of 2 ppm (3 hour stack test) would be appropriate.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: Pat Dennis

Commenter Affiliation: Archer Daniels Midland Company

Document Control Number: EPA-HQ-OAR-2002-0058-3670-A2

Comment Excerpt Number: 9

Comment: Strict CO levels will not result in greater reduction of emissions of other organic compounds. If EPA insists on setting CO limits below 100 ppm, the rule should allow for an alternative THC compliance limit. Insisting on compliance with strict CO limits will require sources to increase excess air levels which could adversely affect boiler efficiency and increase NO_x.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

102H. HCl as a Surrogate for Acid Gases [DENIED PETITIONER ISSUE]

Commenter Name: James Pew

Commenter Affiliation: Earthjustice, Clean Air Council, Partnership for Policy Integrity

Document Control Number: EPA-HQ-OAR-2002-0058-3511-A1

Comment Excerpt Number: 11

Comment: EPA proffered a new rationale for its use of hydrochloric acid as a surrogate for all acid gases: "it is highly likely that facilities will choose to control these acid gases by applying the same technology and the means for removal of each are similar." Resp. to Comments Vol. 2 (3187.1 Excerpt 12). EPA's new rationale is irrelevant under the well-established test for whether a surrogate is valid. It does not, for example, address HCN's variable relationship to HCl. *See* Comments at 13. Nor has the Agency demonstrated that add-on controls (rather than fuel-substitution or other methods) are the only means of removing all acid gases; as set forth in our comments, fuel choice can effectively reduce acid gas emissions.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Rationale for Subcategories

7A. Limited-Use Units

Commenter Name: Chris M. Hobson

Commenter Affiliation: Southern Company

Document Control Number: EPA-HQ-OAR-2002-0058-3520-A1

Comment Excerpt Number: 4

Comment: The use of a capacity factor is consistent with other regulations and requirements. Although some limited use boilers may choose to take a limit based on hours of operation for ease of monitoring, it makes more sense for many boilers to monitor their capacity factor on a heat input basis. In many cases, monitoring heat input (fuel use) is something the units are already required to do for other regulations, such as New

Source Performance Standard (NSPS) subparts Db and De. For example, Georgia Power's Plant McDonough combined-cycle facility, currently under construction, includes two auxiliary boilers that are permitted to operate up to a 10% capacity factor on a heat input basis. This capacity factor permit limit is directly used to determine the applicability of NSPS emission limits for PM, NO_x, and SO₂. Therefore, the capacity factor applicability for a limited use subcategory would be consistent with the applicability for NSPS at many facilities.

Response: The EPA agrees with the commenter, and the definition of the limited use subcategory has been revised in the final rule to be based on a 10 percent capacity factor. The annual operating hour threshold has been removed.

Commenter Name: Chris M. Hobson
Commenter Affiliation: Southern Company
Document Control Number: EPA-HQ-OAR-2002-0058-3520-A1
Comment Excerpt Number: 2

Comment: Southern's subsidiaries own and operate (or are building) 3 natural gas-fired and 6 distillate oil-fired auxiliary boilers. These auxiliary boilers are used to generate the steam necessary to bring a main electric generating unit (EGU), either a combined cycle, a coal-fired, or a nuclear unit, on line. Since the auxiliary boilers are primarily used during unit startup, annual operation is generally very limited (e.g., some are limited to a 10 percent capacity factor, and others generally operate less than 10 percent capacity factor but do not have a permit limit) and each event is usually short in duration (e.g., less than 24 hours). These boilers operate infrequently and only as needed, therefore, it would be difficult to schedule test crews and complete emission testing for all HAPs during the limited period of operation. Thus, it is likely that if EPA did not provide the limited use subcategory, each auxiliary boiler would have to be operated annually for the sole purpose of emission testing. This would create unnecessary boiler operation, fuel usage, and emissions and be contrary to the intent of the CAA.

Response: The EPA thanks the commenter for their support of the limited use subcategory. The definition of the limited use subcategory in the final rule has been revised to be based on a 10 percent capacity factor.

Commenter Name: Rick Rosvold
Commenter Affiliation: Xcel Energy Services, Inc.
Document Control Number: EPA-HQ-OAR-2002-0058-3682-A2
Comment Excerpt Number: 7

Comment: EPA has added a subcategory for limited use boilers. Xcel Energy is generally supportive of this sub-categorization as it eliminates operating these types of units for testing purposes when they otherwise would not be operated.

Xcel Energy does, however, take issue with how these units are defined. The definition includes a requirement that these units have a federally enforceable limit of no more than 876 hours per year of operation. This requirement would force applicability of this standard on units that rarely operate. For example, Xcel Energy owns an auxiliary boiler with a rated heat input of 125 mmBTU/hr at its Sherburne County Generating Plant, which operated a total of 60 hours for 2008, 2009 and 2010 combined. This boiler poses little threat to the environment when operated in this manner. However, this boiler would be subject to the new standard simply because it does not have a federally enforceable permit limit of no more than 876 hours per year of operation. It does not seem to be a reasonable expenditure of precious state permitting resources to force a regulated party to request that the state air permitting authority process a permit amendment to restrict operations of a unit that rarely operates simply to avoid regulation under this standard. We believe that EPA could revise this definition to minimize unnecessary permitting by specifically excluding these limited use units without a permit limit.

Response: The EPA has revised the definition of the limited use subcategory in the final rule to be based on a 10 percent capacity factor, and the annual operating hour threshold has been

removed, see the response to comment EPA-HQ-OAR-2002-0058-3500-A1, excerpt 7. The majority of permits place operating restrictions on a capacity factor basis instead of an operational hour basis, thus the EPA believes the capacity factor approach in the definition is more appropriate.

The EPA has maintained that the 10 percent capacity factor be a federally enforceable limit. It is also appropriate to maintain the requirement that the capacity factor be federally enforceable otherwise it would be difficult for a source or regulatory agency to determine year to year if the source would be in the limited use subcategory. Furthermore, it is a reasonable requirement, and consistent with other regulations (i.e., NSPS subpart Db for industrial boilers), if a source wants to avail itself of the limited requirements (in this case work practice standards) for units that operated on a limited basis compared to other units covered by the regulation.

Commenter Name: Michael Bradley

Commenter Affiliation: The Clean Energy Group

Document Control Number: EPA-HQ-OAR-2002-0058-3495-A1

Comment Excerpt Number: 8

Comment: The Clean Energy Group supports the creation of a limited use subcategory, currently defined as "any boiler or process heater that burns any amount of solid, liquid, or gaseous fuels, has a rated capacity of greater than 10 MMBtu per hour heat input, and has a federally enforceable limit of no more than 876 hours per year of operation" and subject to a work practice standard. In the utility industry, there are units that typically operate to provide back-up power or steam to power plants when the main generating units are off-line. EPA requested comment on the creation of a limited use subcategory in the final rule, as well as on whether the category should be defined based on capacity factor rather than an annual hours limit. The Clean Energy Group recommends that the subcategory be maintained and defined based on hours of operation at full load or as an annual capacity factor. Specifically, we recommend the same 8 percent annual capacity factor as finalized in the recent MATS. Thus, the limited use subcategory would be defined as "any boiler or process heater that burns any amount of solid, liquid, or gaseous fuels, has a rated capacity of greater than 10 MMBtu per hour heat input, and either (1) has a federally enforceable limit of no more than 876 hours per year of operation at full load or (2) has an annual capacity factor of less than 8 percent of its maximum or nameplate heat input, whichever is greater, based on a calendar year beginning on the initial date of compliance." (Bold denotes additions.) We also recommend that EPA clarify the requirements for limited use units that may increase operation.

Response: The EPA thanks the commenter for their support of the limited use subcategory. The EPA agrees with the capacity factor approach, but believes that a 10 percent capacity factor is more suitable. The 10 percent capacity is equivalent to the 876 hours at full load that was proposed. See the response to comment EPA-HQ-OAR-2002-0058-3500-A1, excerpt 7 for discussion on the 10% capacity factor. The 8 percent capacity factor finalized in MATS to define limited use was based on review of information and data from actual utility boilers operating on a limited basis. That type of detailed operating data was not available for industrial units. The 10 percent capacity factor is consistent with the definition of "limited use" that was in the original 2004 Boiler MACT and in the NSPS for industrial boilers.

Commenter Name: Traylor Champion
Commenter Affiliation: Georgia-Pacific LLC (GP)
Document Control Number: EPA-HQ-OAR-2002-0058-3465-A1
Comment Excerpt Number: 2

Comment: GP supports EPA’s retention of the provision in the final rule that subjects boilers and process heaters meeting the definition of the Limited Use Subcategory to only a work practice standard under Section 112(h) of the CAA. As EPA has stated in final rule (76 Federal Register 15634); *“The fact that the nature of these units is such that they operate for unpredictable periods of time, limited hours, and at less than full load in many cases has led EPA to determine that limited use units are a unique class of unit based on the unique way in which they are used and EPA is including a subcategory for these units in the final rule. The unpredictable operation of this class of units makes emission testing for the suite of pollutants being regulated impracticable.”*

EPA has defined a Limited Use boiler or process heater as a unit that operates for less than 876 hours per year. EPA should consider utilizing a 10% annual “capacity factor” rather than annual “operating hours”. The use of a capacity factor would be consistent with the “Limited Use” definition in the vacated Boiler MACT standard and in several other standards. Even with this change to the definition, the affected units would continue to be utilized sporadically, during unpredictable periods of time, and for a limited time. The use of a capacity factor versus annual operating hours will not diminish the justification EPA utilized in the development of this subcategory.

Response: The EPA thanks the commenter for their support of work practice standards for sources classified as limited use units. See the response to comment EPA-HQ-OAR-2002-0058-3500-A1, excerpt 7 regarding the definition of limited use with capacity factor instead of operating hours.

Commenter Name: Lee Zeugin and Lauren Freeman
Commenter Affiliation: Utility Air Regulatory Group (UARG)
Document Control Number: EPA-HQ-OAR-2002-0058-3500-A1
Comment Excerpt Number: 7

Comment: Electric utility auxiliary boilers often idle at very low loads to support the reliability of the generating units they serve. As a result, these boilers can be called on to operate more than 876 hours per year but still have annual capacity factors well under 10 percent. An example of a typical auxiliary boiler’s operation, supplied by a UARG member, involves a 314 MMBtu/hour auxiliary boiler having a maximum annual heat input of 2,750,640 MMBtu - its hourly heat rate times an assumed 8760 hours of operation per year. The actual usage of that unit over a five year period was as follows: [See submittal for data table provided by the commenter.]

This example shows that defining the limited use subcategory in terms of capacity factor instead of hours of operation would not result in higher HAP emissions.⁵ Defining the limited use subcategory in terms of capacity factor would provide more operational flexibility to IB units, especially those that must run at low idling rates to support facility operations. EPA should retain

the work practice standards for the limited use subcategory but define the category based on annual capacity factor rather than hours of operation.

[Footnote]

(5) Indeed, under the limited use definition in the 2011 final rule, a unit could operate at a capacity factor of up to 10 percent and still qualify for the subcategory - 876 hours of operation at 100 percent load.

Response: The EPA agrees that the definition of the limited use subcategory should be defined only using a capacity factor and not a set annual hours of operation. We agree that the potential to emit is the same for 876 hours of operation or 10% capacity factor. We agree with commenters that basing limited use on the annual capacity factor provide more operational flexibility because we are aware of situations where units are brought on line at low load to provide spinning reserves to meet electrical demand increases or steam requirement increases. See the response to comment EPA-HQ-OAR-2002-0058-3465-A1, excerpt 2 for discussion of the capacity factor applicability to work practice standards.

Commenter Name: Mark Thoma, Principal, Environmental Services Department

Commenter Affiliation: Otter Tail Power Company

Document Control Number: EPA-HQ-OAR-2002-0058-3436-A1

Comment Excerpt Number: 1

Comment: Otter Tail believes that a limited-use subcategory based on a 10% capacity factor will result in a reduction of air pollutants at least equivalent to a subcategory based on a 10% operating factor, and therefore qualifies as an alternative standard under Section 112(h)(3) of the Clean Air Act. This can be explained by the simple fact that the proposed rule allows any limited-use boiler to operate 876 hours at 100% capacity in a year, in which case the boiler would have both a 10% operating factor and a 10% capacity factor. Therefore, the potential-to-emit of any air pollutant would not increase by changing the limited-use subcategory to a 10% capacity factor basis since a boiler still would not be allowed to operate more than 876 hours at 100% capacity. Unfortunately, as currently proposed, the rule unduly creates “winners” and “losers” by favoring entities that operate their limited-use boilers at full capacity versus entities that operate their limited-use boilers at low capacity factors. Also, it should be noted that the final rule, “National Emission Standards for Hazardous Air Pollutants from Coal and Oil-fired Electric Utility Steam Generating Units”, creates a limited-use liquid oil-fired subcategory that is defined based on a capacity factor (*77 Fed. Reg.* at 9486). If EPA was able to justify a capacity factor definition for EGUs, Otter Tail is curious as to why it could not be justified for Industrial Boilers.

Response: See the response to DCN: EPA-HQ-OAR-2002-0058-3500-A1, excerpt 7 regarding inclusion of the capacity factor in the limited use definition, the response to DCN: EPA-HQ-OAR-2002-0058-3465-A1, excerpt 2 for discussion on capacity factor applicability to work practice standards, and the response to DCN: EPA-HQ-OAR-2002-0058-3495-A1, excerpt 8 for discussion on the Utility MACT and its use of capacity factor in relation to the boiler rule.

Commenter Name: Russell A. Wozniak
Commenter Affiliation: The Dow Chemical Company
Document Control Number: EPA-HQ-OAR-2002-0058-3449-A1
Comment Excerpt Number: 30

Comment: EPA's current definition of Limited-use boiler or process heater limits the source to no more than 876 hours per year of operation. EPA should also consider adding an option to the definition that includes sources that have an annual average capacity factor of no more than 10 percent.

Actual emissions from boilers and process heaters are typically a function of both hours per year of operation and operating rate. By adding an option to use an annual average capacity factor approach, the owner/operator would have the flexibility to operate for slightly more than 876 hours per year if the combustion source operates at less than 100% maximum heat input. Typically, operating in this mode should not result in more emissions than operating at 100% load for 876 hours per year. Given an additional option, the owner/operator could either record the number of operating hours or could calculate the annual capacity factor for a calendar year.

Thus, the definition of Limited-use boiler or process heater could be amended as follows:

"means any boiler or process heater that burns any amount of solid, liquid, or gaseous fuels, has a rated capacity of greater than 10 MMBtu per hour heat input, and has a federally enforceable limit of no more than 876 hours per year of operation or has an annual capacity factor of no more than 10.0 percent.

In addition, EPA could adopt the following definition of "annual capacity factor" from the 2004 version of the rule:

Means the ratio between the actual heat input to a boiler or process heater from the fuels burned during a calendar year, and the potential heat input to the boiler or process heater had it been operated for 8,760 hours during a year at the maximum steady state design heat input capacity.

Response: The EPA agrees that the capacity factor should be included in the definition of limited use in the rule, and the definition has been revised accordingly. See the response to comment EPA-HQ-OAR-2002-0058-3500-A1, excerpt 7 for discussion on basing the definition on capacity factor. See the response to comment EPA-HQ-OAR-2002-0058-3465-A1, excerpt 2 for discussion on capacity factor applicability to work practice standards.

Commenter Name: Lenny Dupuis
Commenter Affiliation: Dominion Resources Services, Inc.
Document Control Number: EPA-HQ-OAR-2002-0058-3486-A1
Comment Excerpt Number: 2

Comment: EPA should establish an alternative definition of the subcategory for auxiliary oil-fired boilers located at electric generating stations that would include units that operate at 10 percent or less of their annual capacity factor rather than 10 percent of the annual operating hours. EPA applied a percent of annual capacity factor-based approach in defining a limited use

subcategory for oil-fired units in the final Utility Mercury and Air Toxics Rule (MATS) on the basis that the operation of such units is infrequent and unpredictable, that numeric standards based on base load units would not likely be achievable during the very limited times these units operate and that required emission testing under the rule could require the operation of these units when they otherwise may not be needed for the sole purpose of testing, resulting in added costs (related to testing) and the release of hazardous air pollutants that otherwise would not have been emitted.¹

The same case can be made for auxiliary boilers used within the electric utility industry to generate the steam necessary to bring a main electric generating unit (EGU) on line (during startup). Since auxiliary boilers are primarily operated during unit startup, operation of these boilers is typically very limited and sporadic. The cost for sources with oil-fired auxiliary boilers to install and maintain the control equipment (and potentially monitoring equipment) necessary to meet emissions standards would be excessive, particularly for a unit that operates infrequently. In addition, since the demand for an auxiliary boiler to operate is very difficult to forecast, it is possible that each auxiliary boiler would have to be operated some time during each year for the sole purpose of emission testing.

Such an outcome would result in otherwise unnecessary emissions of air pollutants and use of a valuable and not unlimited resource (low sulfur diesel fuel). Furthermore, EPA applied a 10 percent capacity utilization factor as a means to define a limited use unit for several subcategories in the 2004 Industrial Boiler MACT rule.² Therefore, a subcategory for oil-fired auxiliary boilers defined with a 10 percent annual capacity factor should qualify for work practice standards in the reconsideration rule. In addition, the definition of a limited-use boiler (40 CFR 63.7575) should be revised to accommodate a capacity factor-based threshold.

[Footnote]

(2) 69 *Fed. Reg.* 55223.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3500-A1, excerpt 7 regarding inclusion of the capacity factor in the limited use definition, the response to comment EPA-HQ-OAR-2002-0058-3465-A1, excerpt 2 for discussion on capacity factor applicability to work practice standards and the 2004 vacated Boiler MACT and its use of capacity factors in relation to the boiler rule, and the response to comment EPA-HQ-OAR-2002-0058-3495-A1, excerpt 8 for discussion on the Utility MACT and its use of capacity factor in relation to the boiler rule.

Commenter Name: Kenneth Anderson

Commenter Affiliation: Ameren Corporation

Document Control Number: EPA-HQ-OAR-2002-0058-3487-A1

Comment Excerpt Number: 1

Comment: Ameren agrees with US EPA's inclusion of a limited use boiler and process heater subcategory in the final rule. However, Ameren believes improvements to the definition of limited use boilers and process heaters can easily be made without compromising air quality. Ameren requests that US EPA reconsider the use of a straight hourly threshold for defining the limited use subcategory.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3500-A1, excerpt 7 regarding inclusion of the capacity factor in the limited use definition.

Commenter Name: Kenneth Anderson

Commenter Affiliation: Ameren Corporation

Document Control Number: EPA-HQ-OAR-2002-0058-3487-A1

Comment Excerpt Number: 5

Comment: Because emissions of HAPs are directly proportional to capacity factor as opposed to time on line, capacity factor is a much better surrogate for defining the limited use subcategory. Emissions from the auxiliary boiler discussed above never approached those of a boiler operating at design heat input for 876 hours as allowed under the current limited use exemption. Just because the boiler was needed for more than 876 hours to meet facility needs should not elevate the boiler out of the limited use subcategory if the capacity factor remains less than 10 %.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3500-A1, excerpt 7 regarding inclusion of the capacity factor in the limited use definition and for discussion on changes in load and its impact on capacity factor versus operating hours, and the response to comment EPA-HQ-OAR-2002-0058-3465-A1, excerpt 2 for discussion on capacity factor applicability to work practice standards.

Commenter Name: Lorraine Gershman

Commenter Affiliation: American Chemistry Council (ACC)

Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1

Comment Excerpt Number: 35

Comment: In the Final Boiler Rule, EPA reiterates its support for a limited use subcategory, noting that limited use units are a unique class of units and that forcing them to start up solely to conduct emissions testing would be impractical and lead to increased emissions:⁷⁶ *Fed. Reg.* 15634.

However, ACC believes that units operating at less than 10 percent of their annual capacity factor or less than 10 percent of the annual operating hours should qualify as limited use units. A capacity utilization factor of 10 percent was chosen for the vacated 2004 boiler MACT final rule as the best means of defining a limited use unit.¹⁵ This definition is equally appropriate for the current rule. EPA has taken a capacity factor approach in the final MATS rule, establishing a subcategory for limited use liquid-fired units with an 8 percent capacity factor (limited-use liquid Docket EPA-HQ-OAR-2002 oil-fired subcategory means an oil-fired electric utility steam generating unit with an annual capacity factor of less than 8 percent of its maximum or nameplate heat input, whichever is greater, averaged over a 24-month block contiguous period).¹⁶ Therefore, ACC requests that EPA define the limited use subcategory to give sources the option of complying with an annual hourly limit or an annual capacity factor.

Comment: Discussion

Section V. B. 7. of the preamble requests comment on how a subcategory defined with a 10% capacity factor would qualify for work practice standards in lieu of emission limits and indicated that this was requested by several petitioners who failed to provide support that such a subcategory would qualify for work practice standards under section 112 of the Clean Air Act.

Boilers and process heaters may operate at varying capacities depending on the load requirements. In some cases, boilers and process heaters may be oversized and operate above the hourly limit suggested for limited use yet still be below a 10% operating capacity. In order to verify that the low use boilers and process heaters operate below the proposed 10% capacity,

EPA could provide the option to measure fuel use on a monthly basis and then average the operation of the boilers and process heaters over that monthly period. By using the total monthly fuel use and comparing it with the maximum potential available to the boilers and process heaters, an actual load capacity can be determined. This monthly monitoring period aligns with many current air pollution control district permit requirements allowing for an easy transition.

DoD also noted that some boilers and process heaters operate seasonally and that applying the capacity limit for limited use would be a more appropriate measure for determining the limited use category and would be consistent with 40 CFR part 60, which has different requirements for units with an annual capacity factor of 10% or less and defines annual capacity factor as follows: *"Annual capacity factor means the ratio between the actual heat input to a steam generating unit*

from the fuels listed in §60.42b(a), §60.43b(a), or §60.44b(a), as applicable, during a calendar year and the potential heat input to the steam generating unit had it been operated for 8,760 hours during a calendar year at the maximum steady state design heat input capacity. In the case of steam generating units that are rented or leased, the actual heat input shall be determined based on the combined heat input from all operations of the affected facility in a calendar year."

Recommendation.

DoD recommends that EPA retain the 10% of hours/year (876 hours) while adding a capacity-based approach for determining limited use. Revise the definition of "limited use boiler or process heater" based on language used in the definition of annual capacity factor in 40 CFR part 60 as follows:

Limited-use boiler or process heater means any boiler or process heater that burns any amount of solid, liquid, or gaseous fuels, has a rated capacity of greater than 10 MMBtu per hour heat input, and has a federally enforceable limit of no more than either 876 hours per year of operation or a fuel consumption equivalent to 10 percent of the maximum steady state design heat input capacity.

Response: The EPA disagrees with the suggestion for capacity factors to be applied on a monthly basis. This would be inconsistent with other provisions in the rule which are required on an annual basis, specifically performance testing. The EPA acknowledges that sources may exhibit load variability, but determining compliance with the capacity factor criteria would be inappropriate for units that operate only during a month or two during the year. In those cases, their annual capacity factors might be well below 10 percent whereas their capacity factor for those months would be well above 10 percent causing the unit to be in violation of the permit. See the response to comment EPA-HQ-OAR-2002-0058-3500-A1, excerpt 7 regarding inclusion of the capacity factor in the limited use definition, and the response to comment EPA-HQ-OAR-2002-0058-3495-A1, excerpt 8 for discussion on the Utility MACT and its use of capacity factor in relation to the boiler rule.

Commenter Affiliation: Class of '85 Regulatory Response Group

Document Control Number: EPA-HQ-OAR-2002-0058-3608-A1

Comment Excerpt Number: 6

Comment: The Group supports the existing definition of limited use units established by the Major Source Rule, but recommends that EPA adopt an additional, alternative definition of limited use unit based on an annual capacity factor. Defining limited use unit based on either the hours of operation *or* an annual capacity factor will provide important regulatory flexibility that will make compliance for many sources less burdensome.⁶ EPA currently defines a limited use unit as a unit that burns any amount of solid, liquid, or gaseous fuels, has a rated capacity of greater than 10 MMBtu per hour heat input, and has a federally enforceable limit of no more than 876 hours per year of operation. The Class of '85 recommends that EPA adopt an additional, alternative definition based on an 8 percent annual capacity factor as finalized in the recent Mercury and Air Toxics Standards for Utilities ("MATS").⁸ A limited use unit would therefore be defined as "any boiler or process heater that burns any amount of solid, liquid, or gaseous

fuels, has a rated capacity of greater than 10 MMBtu per hour heat input, and either (1) has a federally enforceable limit of no more than 876 hours per year of operation at full load *or* (2) has an annual capacity factor of less than 8 percent of its maximum or nameplate heat input, whichever is greater, averaged over a calendar year beginning on the initial date of compliance.” Adopting this alternative definition of limited use unit will simplify the regulatory requirements applicable to companies that own or operate boilers and electric generating units.

[Footnote 6: The Group also requests that EPA clarify the requirements for limited use units that subsequently increases operation.]

[Footnote 8: 77 Fed. Reg. 9304, 9371 (Feb. 16, 2012).]

Document Control Number: EPA-HQ-OAR-2002-0058-3659-A2

Comment Excerpt Number: 6

Comment: Integrys supports the limited use subcategory established by the Major Source Rule, but recommends that EPA adopt an alternative definition of limited use unit based on an annual capacity factor. Defining limited use unit based on hours of operation *or* an annual capacity factor will provide important regulatory flexibility that will make compliance for many sources less burdensome.³

EPA currently defines a limited use unit as a unit that burns any amount of solid, liquid, or gaseous fuels, has a rated capacity of greater than 10 MMBtu per hour heat input, and has a federally enforceable limit of no more than 876 hours per year of operation.⁴ We recommend that EPA adopt an alternative definition based on an 8 percent annual capacity factor as finalized in the recent Mercury and Air Toxics Standards for Utilities (“MATS”).⁵ A limited use unit would therefore be defined as “any boiler or process heater that burns any amount of solid, liquid, or gaseous fuels, has a rated capacity of greater than 10 MMBtu per hour heat input, and either (1) has a federally enforceable limit of no more than 876 hours per year of operation at full load *or* (2) has an annual capacity factor of less than 8 percent of its maximum or nameplate heat input, whichever is greater, averaged over a calendar year beginning on the initial date of compliance.” Adopting this alternative definition of limited use unit will simplify the regulatory requirements applicable to companies that own or operate boilers and electric generating units.

Comment Excerpt Number: 5

Comment: The use of capacity factor provides more operational flexibility and does not count periods of boiler startup equivalent to normal operation. Limited use boilers spend much of their operating time in startup and shutdown and typically cannot serve their intended purpose until reaching a certain load. Under an hourly operating restriction, however, the hours of low load and low heat input during startups and shutdowns would be treated equivalency to full load operation. At Plant McDonough, for example, the boiler may only operate for approximately eight hours at a time during normal conditions, but the startup will take about four hours, or half of the total operation. Thus, under EPA's proposed hourly limit, the period of time with low fuel consumption and heat input (i.e., startup) would be treated equivalency to full load operation. This would require auxiliary boilers, such as those at Plant McDonough, that already have a very stringent 10% capacity factor limit, to take even further operational restrictions to qualify as limited use boilers under the Industrial Boiler MACT.

Response: The EPA agrees with defining the limited use subcategory using an emission factor approach. See the response to comment EPA-HQ-OAR-2002-0058-3500-A1, excerpt 7 regarding the definition of limited use with capacity factor instead of operating hours.

Commenter Name: Kenneth Anderson

Document Control Number: EPA-HQ-OAR-2002-0058-3487-A1

Comment Excerpt Number: 2

Comment: US EPA should consider changing the definition of limited use to: "Limited-use boiler or process heater that burns any amount of liquid or gaseous fuels, has a rated capacity of greater than 10 MMBtu per hour, and has an annual capacity factor of no more than 10 %." The definition of annual capacity factor should then be added to the definitions in 40 CFR 63.7575 and it should be the same as the definition of annual capacity factor in both 40 CFR 60.41 b and 40 CFR 60.41 c.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3500-A1, excerpt 7 regarding the definition of limited use with capacity factor instead of operating hours and the response to comment EPA-HQ-OAR-2002-0058-3495-A1, excerpt 8 for discussion on the Utility MACT and its use of capacity factor in relation to the boiler rule.

Commenter Name: Robert D. Bessette

Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 5

Comment: EPA seeks comment on how a limited use subcategory defined with a 10% capacity factor would qualify for work practice standards in lieu of emission limits. CIBO in its Petition for Reconsideration, sought a change in the limited-use definition to be based on a 10% annual capacity factor, and a work practice standard for these units. EPA did not rely on a capacity factor in the Proposed Reconsidered Rule, but in the Utility MATS rule, EPA used an 8% factor, which CIBO supports. A capacity utilization factor of 10 percent was chosen for the 2004 Boiler MACT final rule as the best means of defining a limited use unit. This definition is equally appropriate for the current rule. A capacity factor versus hour of operation is a reasonable method for defining the limited use subcategory.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3500-A1, excerpt 7 regarding the definition of limited use with capacity factor instead of operating hours, and the response to comment EPA-HQ-OAR-2002-0058-3495-A1, excerpt 8 for discussion on the Utility MACT and its use of capacity factor in relation to the boiler rule, and the response to comment EPA-HQ-OAR-2002-0058-3465-A1, excerpt 2 for discussion of the 2004 vacated Boiler MACT and its use of capacity factor in relation to the boiler rule.

Commenter Name: J. Michael Geers

Commenter Affiliation: Duke Energy

Document Control Number: EPA-HQ-OAR-2002-0058-3543-A1

Comment Excerpt Number: 20

Comment: The EPA added a subcategory for limited-use units in the final rule, and subsequently petitioners requested the opportunity to comment on the creation of the subcategory and the definition of the subcategory. EPA indicated that multiple petitioners requested that rather than defining the subcategory to include units that operate less than 10 percent of the hours in a year, the EPA define the subcategory to include units that operate with a capacity factor of 10 percent or less. Duke Energy agrees that the limited use subcategory should be defined based on a 10% capacity factor. EPA goes on to state that:

The petitioners believe that such a change would provide more flexibility, but petitioners did not provide support that such a subcategory would qualify for work practice standards under section 112 the CAA. Therefore, the EPA is not proposing a change to the final approach but is requesting comment on how a subcategory defined with a 10 percent capacity factor would qualify for work practice standards in lieu of emission limits.

Duke Energy disagrees with EPA's statement in that the reasons for establishing a limited use subcategory based on capacity factor are essentially the same as those used to justify a subcategory based on hours of operation. The distinction is only a matter of minor difference in definition. Duke Energy believes that using capacity factor instead of a limit based on hours of operation is a reasonable approach for defining this boiler category.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3500-A1, excerpt 7 regarding the definition of limited use with capacity factor instead of operating hours, and the response to comment EPA-HQ-OAR-2002-0058-3465-A1, excerpt 2 for discussion on capacity factor applicability to work practice standards.

Commenter Name: J. Michael Geers

Commenter Affiliation: Duke Energy

Document Control Number: EPA-HQ-OAR-2002-0058-3543-A1

Comment Excerpt Number: 21

Comment: Duke Energy believes that using capacity factor instead of a limit based on hours of operation is a reasonable approach for defining this boiler category. Limited use units are likely to be operated infrequently. Many will be in cold-standby until their operation is needed. Compared to combustion turbines and IC engines, boilers require more time for startup. This can be 2 to 4 hours for a smaller unit, and several hours to a day for larger units. During portions of the start-up, the boiler is not producing steam for use by its load customers. As currently defined, start-up would constitute an "operating hour", decreasing the available hours for a limited use boiler to operate.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3500-A1, excerpt 7 regarding the definition of limited use with capacity factor instead of operating hours, and for discussion of changes in load and its impact on capacity factor versus operating hours.

Commenter Name: J. Michael Geers

Commenter Affiliation: Duke Energy

Document Control Number: EPA-HQ-OAR-2002-0058-3543-A1

Comment Excerpt Number: 23

Comment: Duke Energy believes that using capacity factor instead of a limit based on hours of operation is a reasonable approach for defining this boiler category. The use of a 10% capacity has precedent in other EPA rulemakings. For example 40 CFR 75, Appendix E, provides relief from the burdensome NO_x continuous emissions monitoring requirements of the Acid Rain Program for affected units that limit the capacity factor to less than 10% on a 3-year average. In addition in 40 CFR Part 60, for subpart DB units, EPA established a 10% capacity factor for limited use units. The CAA gives EPA discretion to define subcategories based on size, type and class. Clearly EPA has the authority to define the limited use subcategory based on a 10% capacity factor.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3500-A1, excerpt 7 regarding the definition of limited use with capacity factor instead of operating hours, and the

response to comment EPA-HQ-OAR-2002-0058-3534-A1, excerpt 6 regarding the relationship to the Acid Rain program limited use subcategory.

Commenter Name: Robert R. Perry

Commenter Affiliation: FirstEnergy Generation Corp (FGCO)

Document Control Number: EPA-HQ-OAR-2002-0058-3518-A1

Comment Excerpt Number: 1

Comment: FGCO supports EPA's inclusion of the "limited use" exemption for boilers operated less than 876 hours annually but encourages EPA to broaden the exemption. FGCO has a number of liquid fired (No. 2 fuel oil) ICI boilers with rated heat inputs greater than 10 mmBtu/hr which would be subject to the proposed ICI Boiler MACT limits. These industrial-sized boilers are used very infrequently to provide a source of steam to power steam driven auxiliaries for much larger electric generating units (EGU) during the start-up process and potentially for station heating.

We encourage EPA to broaden the "limited use" exemption by:

- 1) excluding startup and shutdown operating time from the 876 hours which EPA has excluded for other subcategories,
- 2) excluding tune-up activity hours from the 876 hours,
- 3) dropping the requirement that the limited use exemption be "federally enforceable" which unnecessarily complicates the exemption (maintaining records as required in the regulations should be sufficient to demonstrate compliance),
- 4) allowing dual fuel boilers that are capable of burning both natural gas and liquid fuel to exclude the operating time on natural gas from the 876 hours,
- 5) allowing the compliance period to be on a calendar year basis running January to December, and
- 6) allowing a multiple year averaging time such as five years under the limited use exemption.

Response: The EPA thanks the commenter for their support of the limited use subcategory. The EPA has revised the definition of the limited use subcategory in the final rule to be based on an average annual 10 percent capacity factor, and has removed the annual operational hour threshold. See the response to comment EPA-HQ-OAR-2002-0058-3500-A1, excerpt 7.

The EPA disagrees that the "federally enforceable" clause causes unnecessary complications with the definition of the subcategory, See the response to comment EPA-HQ-OAR-2002-0058-3682-A2, excerpt 7.

The EPA also disagrees with the commenter's request that natural gas combustion should be excluded from operating time consideration; a limited use unit is one that operates infrequently regardless of the fuels being combusted in it. The commenter is suggesting an approach to circumvent the Gas 1 subcategory limitation on combusting oil outside of periods of gas curtailment which is inappropriate.

The EPA also disagrees with a multiple year averaging time since the definition has been changed to annual capacity factor from hours per year. Averaging over multiple years is not appropriate because in any one year the unit could operate well beyond the limited use criteria resulting in emissions much higher than a simpler operated unit that in the limited use subcategory and subject to emission limits instead of work practices.

Commenter Affiliation: American Chemistry Council (ACC)

Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1

Comment Excerpt Number: 34

Comment: *WORK PRACTICES FOR LIMITED-USE UNITS*

EPA has appropriately established a subcategory for —limited use units. Limited use sources operate intermittently and for shorter periods of time (*e.g.*, small package boilers that are only used during plant outages, a backup boiler that runs when other units are being fixed, a peaking unit used to supplement electric generation during particularly hot summer days, a process heater that operates for a few hours at a time to warm up a heat transfer fluid for use in a chemical process, or a process heater that only operates intermittently in order to maintain the temperature of a process fluid in the desired range). Compared to most boilers and process heaters, these units spend a relatively greater percentage of their time starting up and shutting down. As a result, their emissions profiles differ from sources which operate for long periods of time in efficient steady-state manners. For example, the limited-use units are likely to experience higher CO levels as the boiler or process heater heats up during startup due to incomplete combustion. Similarly, many pollution control technologies are either difficult to use or ineffective during startup and shutdown periods and would be cost prohibitive to install and use for only short periods of time during a year. These are just the sort of "class" and "type" distinctions that merit consideration for subcategorization under §112(d)(2).

Because limited use boilers and process heaters do not operate on a regular schedule and typically operate for only short periods of time, emissions profiles for these boilers and process heaters can vary significantly from those of a similar boiler or process heater operating in a steady state. "Combustion units operate most efficiently when operated at or near their design capacity. The combustion efficiency tends to decrease as the unit's load (steam production) decreases."¹² Given their short run times, there are also technological limitations on how effectively emissions from these units can be controlled, particularly for organic HAP emissions.

EPA indicated the following in the responses to comments on the final 2004 Boiler MACT rule: "[W]e could not identify any control technologies that would reduce organic HAP emissions [for limited use boilers]. Therefore, while larger units may emit more than smaller units, ACC has not identified any appropriate technology or method that could be used to reduce organic HAP emissions."¹³ Finally, since "limited use boilers, when called upon to operate, must respond without failure and without lengthy periods of startup,"¹⁴ a significantly larger percentage of their annual operation will be devoted to maintenance and readiness testing than other commercial, industrial, or institutional boilers. These differences noted in the 2004 boiler rule remain valid today and justify the creation of a subcategory for limited use boilers and process heaters.

Comment Excerpt Number: 9

Comment: The EPA's establishment of a limited use subcategory subject to work practices is warranted for a variety of reasons previously highlighted by the NAM, including the fact that these units spend a far greater percentage of their time starting up and shutting down than other units, leading to different emission profiles and control options.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3465-A1, excerpt 2.

Commenter Name: Chris M. Hobson

Commenter Affiliation: Southern Company

Document Control Number: EPA-HQ-OAR-2002-0058-3520-A1

Comment Excerpt Number: 6

Comment: EPA's rationale for establishing work practice standards for limited use boilers applies whether the subcategory is defined based on hours or capacity factor. In the final Industrial Boiler MACT, EPA states that a limited use subcategory is appropriate because these boilers "operate for unpredictable periods of time, limited hours, and at less than fullload."² EPA goes on to say, "[t]he unpredictable operation of this class of units makes emission testing for the suite of pollutants being regulated impracticable" and "[i]n order to test the units, they would need to be operated specifically to conduct the emissions testing because the nature and duration of their use does not allow for the required emissions testing."³ Southern asserts that establishing a limited use subcategory based on capacity factor rather than hours per year has no impact on this rationale. Under normal conditions, the auxiliary boilers would only be needed when start-up steam is not otherwise available from other electric generating units on-site. It is impossible to predict the frequency and duration of these events in order to schedule emission testing. A limited use subcategory based on capacity factor versus hours per year would serve the purpose of providing operating flexibility during unpredictable startups or number of events, but would in no way change EPA's rationale for a limited use subcategory.

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 35

Comment: Inclusion of a subcategory for limited-use BPH is appropriate.

The March 21, 2011 final rule included a limited-use subcategory that includes units that operate less than 10% of the hours in a year. The rationale for establishing that subcategory was provided at 76 Fed. Reg. 15633-4 (March 21, 2011). Limited-use BPH are significantly different from steady-state units and it is therefore appropriate for them to have their own subcategory. Limited-use units spend a large percentage of their operating time in reduced-efficiency operating conditions. Operating more frequently in these conditions makes emission profiles of limited-use units very different from sources which operate in more efficient steady-state modes. Thus, emission limitations based on continuous operations are not appropriate for limited-use units. EPA was correct to conclude that limited-use BPH are a unique class of unit based on the unique way in which they are used. Furthermore, the unpredictable and varying operation of this class of BPH and their limited operating time makes emission testing for the suite of pollutants being regulated technically infeasible. Thus, application of a design or work practice for emission control to this subcategory is justified and aligns with the requirements of section 112(h) of the CAA.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3465-A1, excerpt 2 for discussion on capacity factor applicability to work practice standards, and the response to comment EPA-HQ-OAR-2002-0058-3520-A1, excerpt 2 for discussion on the additional costs which would arise without a limited use category.

Commenter Name: Douglas A. McWilliams

Commenter Affiliation: American Municipal Power

Document Control Number: EPA-HQ-OAR-2002-0058-3685-A2

Comment Excerpt Number: 34

Comment: EPA also requested comment on defining limited use boilers to include those units using no more than 10 percent of their annual capacity, rather than defining them as units operating no more than 876 hours per year. Specifically, EPA asked commenters to explain how such units could qualify for work practice standards pursuant to CAA § 112(h). The justification for applying work practice standards to units using no more than 10 percent of their annual capacity is the same as the justification for applying work practice standards to units operating no more than 10 percent of the year. Industrial boilers cannot maintain steady state operation at very low capacity utilization levels. Limited use boilers will operate between 60 and 95% of rated capacity to ensure stable and efficient operation. Thus, a limited use unit defined on an annual capacity basis will still be operating in response to special circumstances; it cannot operate continuously at or near 10% load.

A capacity-based limit ensures 90% reduction from the maximum allowable annual emissions. The annual hour-based limit has no direct correlation to emissions, making its benefit more difficult to quantify and calculate. Also, capacity utilization is easily measurable because sources track the amount of fuel used and its heat rate. By contrast, the number of "operating" hours is more problematic. Do we count startup and shutdown hours? Does "operating" begin when the primary fuel is introduced? Are partial hours counted or should we use every 60-minutes? Operating hour limits may also incentivize inefficient behavior as operators would be motivated to startup quicker or shutdown faster than conditions may warrant to conserve limited use hours. These complications are unnecessary if EPA adopts 10% of annual capacity as the limited use definition.

Under CAA § 112(h), it is appropriate to establish a work practice standard in lieu of numeric emission limits when these limits are infeasible or technically impracticable. AMP urges EPA to alter the definition of "limited use boiler" to use ten percent of the source's rated annual capacity, rather than ten percent of the annual hours, to increase flexibility and accountability for facilities operating limited use units. EPA is fully justified in creating this subcategory and establishing work practices for limited use units, and should retain this subcategory in the final rule.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3465-A1, excerpt 2 for discussion of capacity factor applicability to work practice standards, and the response to comment EPA-HQ-OAR-2002-0058-3520-A1, excerpt 4 regarding the ease of monitoring heat input.

Commenter Name: Kenneth Anderson

Commenter Affiliation: Ameren Corporation

Document Control Number: EPA-HQ-OAR-2002-0058-3487-A1

Comment Excerpt Number: 6

Comment: For limited use boilers, the economics of installation of ESPs or fabric filters and activated carbon injection for Hg control, wet scrubbers for control of acid gases and potentially catalytic oxidizers for the control of organic HAPs is not cost effective. Assuming a no.2 fuel oil fired 250 MMBtu/hr auxiliary boiler with a 10 % capacity factor and using AP-42 particulate emission factors, average PM_{2.5} and Hg factors from the US EPA emission test database for the Boiler MACT rulemaking, the particulate emissions (PM) from that boiler is on the order of 1.5 tpy, PM_{2.5} on the order of .3 tpy and Hg on the order of 0.33 lb/yr. Using the US EPA summary of Capital and Annual Costs for control in Table 5 of the Preamble of the proposed rule for the Light Liquid Units, the average annualized cost of control for existing liquid fuel fired boilers after considering fuel savings is \$476,764 per boiler. In terms of cost effectiveness, assuming 100 % reduction of all three pollutants, the annualized cost of reduction is \$317,843 per ton of PM reduction, \$1,589,214 per ton of PM_{2.5} reduced and \$1,444,740 per pound of Hg reduced. We include PM and PM_{2.5} for this analysis because US EPA's benefits analysis for this proposed rule is based on PM_{2.5} reductions. At these costs, it does not make sense to require controls on limited use boilers even as large as 250 MMBtu/hr that are limited to a 10% capacity factor.

Response: The definition of the limited use subcategory has been revised in the final rule to be based on a 10 percent capacity factor, and the annual operating hour threshold has been removed. See response to comment EPA-HQ-OAR-2002-0058-3500-A1, excerpt 7.

Comment Excerpt Number: 44

Comment: Clearly, the rationale for applying design or work practices to gas-fired BPH is even more applicable to limited use BPH, since those units have even lower emissions, emissions vary much more than in continuous use BPH, and add-on control costs would be even more economically infeasible than for a continuously operating BPH.

Response: The EPA acknowledges this comment.

Commenter Name: Kenneth Anderson

Commenter Affiliation: Ameren Corporation

Document Control Number: EPA-HQ-OAR-2002-0058-3487-A1

Comment Excerpt Number: 4

Comment: Ameren has several auxiliary boilers located at Ameren facilities for use when all facility electric generating units are offline at the same time or when supplemental steam is required. These units are operated erratically and could easily exceed the current limited use criteria of 876 hours. For example, Ameren has recently encountered this issue during installation of flue gas desulfurization systems at one of our facilities. Because the outages for the tying in of two FGD systems at two units at one facility occurred over the course of several months, the auxiliary boiler at that facility was required to operate more than 876 hours over a 12 month period. Conversely, this auxiliary boiler never approached a capacity factor of 10 % despite operating for up to 1,950 hours during a 12 month period. With the promulgation of both the EGU MACT rule and the Cross State Air Pollution Rule we expect this situation to occur more frequently as changes to Ameren's generating fleet are made to comply with these new rules. Without a change to the definition of limited use boilers, Ameren's auxiliary boilers may have to forgo limited use status in order to accommodate steam needs at their facilities while other units at their facility upgrade pollution control devices to meet the new EGU MACT or other newly promulgated federal standards. This will result in significant costs with little air quality benefit.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3500-A1, excerpt 7 for discussion on changes in load and its impact on capacity factor versus operating hours, and the response to comment EPA-HQ-OAR-2002-0058-3520-A1, excerpt 2 for discussion on the additional costs which would arise without a limited use category.

Alliance (CBEA)

Document Control Number: EPA-HQ-OAR-2002-0058-3489-A1

Comment Excerpt Number: 3

Comment: EPA appropriately established a separate subcategory for limited use boilers, and work practices as the mechanism for compliance. However, we think that the limited use boiler definition should be tied to 10 percent of annual capacity utilization (MMBTU/year) rather than 10 percent of the annual operating hours. Boilers running at low loads are limiting their use but according to EPA definition would be consuming capacity as though they were running at full load.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3500-A1, excerpt 7 for discussion on changes in load and its impact on capacity factor versus operating hours.

Commenter Name: Kenneth Anderson

Commenter Affiliation: Ameren Corporation

Document Control Number: EPA-HQ-OAR-2002-0058-3487-A1

Comment Excerpt Number: 3

Comment: By changing from an annual hourly limitation to a capacity limitation EPA would then be consistent with the recently signed Utility MACT rule (MATS) (77 Fed Reg. p. 9304 (February 16, 2012)). EPA used the following rational for the use of capacity factor for limited use oil EGU boilers in the MATS rule: "

... Because the operation of these units is infrequent and unpredictable, performing testing to demonstrate that emission limits are being met requires the sources to be scheduled to be operated merely for the purpose of performing testing. We realize that similar situations occurred in the gathering of emissions data through the 2010 /CR. However, unlike the case of one-time testing on a limited number of these units, such testing would be mandatory on a yearly basis for all of the EGUs upon the effective date of the final rule. Because requiring testing under this rule would in many cases require operators of these EGUs to schedule operation of these EGUs at times they would not otherwise run, it would result in both extra cost related to the testing as well as extra emissions; therefore, the Agency believes that it is technically and economically impracticable to monitor emissions for these EGUs, and that they should be subject to work practice standards that would not require emissions monitoring. "

The same is true for industrial boilers. EPA uses this same rational for industrial boilers:

" ... EPA agrees that a subcategory for limited use units is appropriate for many of the reasons stated by the commenters. The fact that the nature of these units is such that they operate for unpredictable periods of time, limited hours, and at less than full load in many cases has lead EPA to determine that limited use units are a unique class of unit based on the unique way in which they are used and EPA is including a subcategory for these units in the final rule. The unpredictable operation of this class of units makes emission testing for the suite of pollutants being regulated impracticable. In order to test the units, they would need to be operated specifically to conduct the emissions testing because the nature and duration of their use does not allow for the required emissions testing. As commenters noted, such testing and operation of

*the unit when it is not needed is also economically impracticable, and would lead to increased emissions and combustion of fuel that would not otherwise be combusted. "*²

In the final EGU MACT (MATS) rule EPA justifies an 8% capacity factor for limited use units and work practice standards under CAA 112(h). It makes no sense that Industrial oil/gas fired boilers that are generally less than 250 mmbtu/hr and orders of magnitude smaller than EGU boilers be held to a higher standard than utility oil fired EGU boilers. Since EPA has justified work practice standards based on unit capacity factor for EGUs under CAA section 112(h) as part of the MATS rule it seems reasonable that the same can and should be done for industrial oil fired boilers as demonstrated by EPA's comments above.

Commenter Name: Lee Zeugin and Lauren Freeman

Commenter Affiliation: Utility Air Regulatory Group (UARG)

Document Control Number: EPA-HQ-OAR-2002-0058-3500-A1

Comment Excerpt Number: 5

Comment: UARG supports EPA's inclusion of a limited use subcategory in the final rule as well as its decision to establish work practice standards for that subcategory. As UARG noted in its comments on the 2010 proposed rule, electric utilities operate auxiliary boilers that are subject to Subpart DDDDD because those boilers do not generate steam used to produce electricity. Auxiliary boilers operate infrequently, normally during plant startups. They combust either natural gas or distillate fuel. As a result, HAP emissions from those units are exceedingly low and do not pose any risk to public health.

Response: The EPA thanks the commenter for their support. See the response to comment EPA-HQ-OAR-2002-0058-3495-A1, excerpt 8 for discussion on the Utility MACT and its use of capacity factor in relation to the boiler rule.

Commenter Name: William C. Herz

Commenter Affiliation: The Fertilizer Institute (TFI)

Document Control Number: EPA-HQ-OAR-2002-0058-3448-A1

Comment Excerpt Number: 10

Comment: EPA requests comment on the limited-use subcategory. Most ammonia plants have a <50 MMBtu/hr fired start-up heater which is only used during the initial cold start-up of an ammonia converter. The start-up heater is required to be fired every turnaround, which could be once in five years. It is not uncommon for the start-up heater to remain idle for three years or more.

As defined in the Proposed Rule, several TFI members have start-up heaters that would meet the definition of a "limited-use process heater" since the heaters are less than 10 MMBtu/hr and limited in hours of operation below the threshold of 876 hours of operation. However, some TFI members have permitted heaters that, based on emissions limits, are permitted to operate 8,760 hours per year.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3682-A2, excerpt 7 regarding removal of language requiring a federally enforceable limit of 876 operating hours.

Commenter Name: William C. Herz

Commenter Affiliation: The Fertilizer Institute (TFI)

Document Control Number: EPA-HQ-OAR-2002-0058-3448-A1

Comment Excerpt Number: 13

Comment: For those units permitted to operate for greater than 876 hrs/yr based on a federally enforceable emissions limit, TFI requests that EPA allow such units to be deemed in the limited-use subcategory when they document the actual hours of operation per year and use that as the basis for determining the feasibility/need for a periodic tune-up.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3682-A2, excerpt 7 regarding removal of language requiring a federally enforceable limit of 876 operating hours.

Commenter Name: William C. Herz

Commenter Affiliation: The Fertilizer Institute (TFI)

Document Control Number: EPA-HQ-OAR-2002-0058-3448-A1

Comment Excerpt Number: 11

Comment: TFI requests that EPA provide a categorical exemption from the regulation for any boiler or process heater that operates less than 100 hrs/yr and has a federally enforceable limit for hours of operation. This could be done either within the definition of "limited-use boiler or process heater" (proposed 40 C.F.R. § 63.7575) or could be added to the list of boilers and process heaters not subject to the rulemaking (proposed 40 C.F.R. § 63.7491). There is precedent for this approach.

Response: The EPA disagrees that sources that operate less than 100 hours per year should be categorically exempt from the rule. While these units emit much lower amounts of the regulated pollutants on a per-source basis, the aggregate emissions from all sources that comprise this subset can have a significant impact on the environment. Moreover, these sources are part of the listed source category regulated in today's action, and the commenter has not explained how the Clean Air Act authorizes the EPA to exempt such sources.

Commenter Name: Mark Thoma, Principal, Environmental Services Department

Commenter Affiliation: Otter Tail Power Company

Document Control Number: EPA-HQ-OAR-2002-0058-3436-A1

Comment Excerpt Number: 3

Comment: At a minimum, if EPA is unwilling to change the limited-use subcategory to a 10% capacity factor basis, Otter Tail requests that the proposed definition of a limited-use boiler be changed to be based on a longer-term average of operating hours, such as three years¹. This would help account for unique circumstances that Otter Tail is faced with at one electric generating facility where we will install selective catalytic reduction equipment, flue-gas desulfurization equipment, and a baghouse to comply with a Regional Haze State Implementation Plan. This will require a 3-4 month outage whereby the auxiliary boiler will potentially need to be operated throughout the outage period to prevent equipment freeze up. Since the auxiliary boiler operation may exceed 876 hours during that outage, in absence of changing the proposed rule definition, Otter Tail would be faced with having to meet significantly more stringent standards for an extremely rare event. This unique circumstance will likely be faced by electric generating facilities in northern climates that will need to take extended outages to install pollution control equipment for compliance with upcoming EPA rulemakings (such as the electric utility MATS, Cross-State Air Pollution Rule, and the Regional Haze Rule).

[Footnote]

(1) The revised definition in §63.7575 would then read: "*Limited-use boiler or process heater* means any boiler or process heater that burns any amount of solid, liquid, or gaseous fuels, has a rated capacity of greater than 10 MMBtu per hour heat input, and has a federally enforceable limit of no more than 876 hours per three-year average of operation."

Response: The definition of the limited use subcategory has been revised in the final rule to be based on a 10 percent capacity factor approach, and the annual operational hour threshold has been removed.

Commenter Name: Eric Guelker, Alliant Energy Corporate Services, Inc.
Commenter Affiliation: Interstate Power and Light Company (IPL) and Wisconsin Power and Light Company (WPL), Alliant Energy Corp.
Document Control Number: EPA-HQ-OAR-2002-0058-3492-A1
Comment Excerpt Number: 10

Comment: Alliant Energy supports EPA's determination to include a "limited-use" subcategory for boilers and process heaters. Power plants maintain auxiliary boilers and process heaters that are used infrequently and run only in limited circumstances, but must be available to ensure reliability of electricity production. These units result in minimal emissions making the application of air pollution controls or other measures to reduce emissions cost-prohibitive. Therefore, it is critical that the EPA retain the limited use subcategory in the final reconsidered rule. Most importantly, the allowed 876 hours per year of operation should not be decreased in the final reconsidered rule.

Response: The EPA thanks the commenter for their support of the limited use subcategory. The definition of the limited use subcategory has been revised in the final rule to be based on a 10 percent capacity factor, and the annual operating hour restriction has been removed. The EPA believes this provides sources with additional flexibility in demonstrating limited use subcategorization.

Commenter Name: J. Michael Geers
Commenter Affiliation: Duke Energy
Document Control Number: EPA-HQ-OAR-2002-0058-3543-A1
Comment Excerpt Number: 22

Comment: Duke Energy believes that using capacity factor instead of a limit based on hours of operation is a reasonable approach for defining this boiler category. From a compliance perspective, monitoring hours of operation in a boiler is more of an administrative challenge than it is for IC engines. While IC engines can utilize a non-resettable hour meter requirement, this concept is not easily adapted to a boiler because of the different firing systems. For boilers, particularly those utilizing gas and/or oil, it is significantly easier to record total fuel consumed and compare that value with the unit's maximum potential operation based on 8760 hours of operation at maximum capacity.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3520-A1, excerpt 4 regarding the ease of monitoring heat input.

Commenter Name: James M Parker
Commenter Affiliation: PPL Montana, LLC
Document Control Number: EPA-HQ-OAR-2002-0058-3528-A1
Comment Excerpt Number: 1

Comment: EPA Should Define an "Idled Boiler" Subcategory for Boilers that Are Currently Idled, But May Be Needed at a Future Date.

EPA should define an additional subcategory for boilers that are currently idled and consequently do not operate routinely. EPA should exempt these boilers from all requirements of the Proposal until these boilers are re-started, at which time they would be required to comply with the appropriate regulations.

At one of our facilities, PPL Montana has boilers that are designed for startup and heating in emergency situations, when the facility is in a "black start" condition, but these boilers are not and have not operated routinely for many years since the contingent "black start" condition has not occurred in that time period. Yet, we (and possibly other facilities in the same situation) would have need for these boilers should the "black start" condition occur at some future date. If that need were to occur, PPL Montana would re-start the boilers under current regulatory requirements.

Since the boilers do not operate routinely, the required tune-ups in the Proposal would actually result in more emissions than are currently being experienced from these boilers. Thus, EPA should recognize a subcategory for idled boilers that will only require the facility to operate the boiler in compliance with applicable requirements at the time of future re-start.

Response: We disagree that a separate subcategory needs to be created for idled boilers. However, we have revised section 63.7510 of the final rule to add subparagraph (j) that addresses the commenter's concerns. Subparagraph (j) applies to units that have not operated (idled) indicating that the tune-up requirement need not be conducted until the unit is re-started.

Commenter Name: Stuart A. Clark

Commenter Affiliation: State of Washington Department of Ecology

Document Control Number: EPA-HQ-OAR-2002-0058-3665-A2

Comment Excerpt Number: 4

Comment: We are disappointed that EPA did not harmonize the CISWI and Major Source Boiler MACT requirements as they apply to units that may operate periodically as part of its final rule. Washington State appreciates the complexity involved in establishing NESHAP standards over the varied range of source types and sizes addressed by these proposed rules. EPA's efforts to gather additional data, carefully consider that data and public comments is apparent. These efforts have resulted in a set of rules that reduce the burden on industry, clarify and streamline the rules to facilitate smoother implementation and still maintain public health protection.

Response: Comments pertaining to the harmonization of the CISWI and Major Source Boiler and Process Heater NESHAPs are outside the scope of this comment response document.

Commenter Name: Robert D. Bessette

Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 6

Comment: We offer the following additional points in support of a capacity factor approach:

- Limited use units are likely to be operated infrequently. Many will be in cold-standby until their operation is warranted. This requires, typically, a 2 to 4 hour startup, depending on the size of the boiler, etc. During the start-up period, the boiler is not producing steam for use in a turbine or by heating/process load customers. In general, fuel will be burned for a short period of time (5 to 10 minutes) a couple of times an hour, then the boiler “buttoned up” in between to keep the heat in to allow the metal to slowly warm in order to prevent metal stress. *As currently defined, each hour of start-up would constitute an “operating hour”, decreasing the available hours for a limited use boiler to operate.*
- From a practical compliance perspective, monitoring hours of operation is an administrative challenge. It is more effective in a permit for a source to accept a fuel consumption limit, and also easier to monitor electronically. While IC engines are equipped with a non-resettable hour meter, the same is not true for boilers. In addition, monitoring fuel usage is already required in the Boiler MACT and other permit requirements, so this requirement would not create the additional burden that monitoring hours of operation would.
- 40 CFR 75, Appendix E, provides relief from the burdensome NOx continuous emissions monitoring requirements of the Acid Rain Program for affected units that limit the capacity factor to less than 10% on a 3-year average. This is an example of where EPA implemented a work practice standard based on a capacity factor instead of the standard requirement.
- In the RICE NESHAP, EPA implemented a work practice standard for emergency and limited use units.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3500-A1, excerpt 7 regarding inclusion of the capacity factor in the limited use definition, the response to comment EPA-HQ-OAR-2002-0058-3465-A1, excerpt 2 for discussion on capacity factor applicability to work practice standards, and the response to comment EPA-HQ-OAR-2002-0058-3520-A1, excerpt 4 regarding the ease of monitoring heat input. Comments related to capacity factors or work standards in other rules or subparts (e.g., 40 CFR Part 75 Appendix E, or 40 CFR Part 63 Subpart ZZZZ) are outside the scope of this comment response document.

Commenter Name: John C. Hendricks

Document Control Number: EPA-HQ-OAR-2002-0058-3685-A2

Comment Excerpt Number: 33

Comment: A Limited Use Subcategory is Appropriate and Should Be Maintained

EPA requested comment on final adoption of the limited use subcategory. AMP supports a limited use subcategory for all of the reasons stated in the 2010 AMP Comments. EPA was justified in creating this subcategory because these units have a distinct operating mode and come online only during special circumstances (e.g., emergencies, primary boiler outage). This distinct operating mode results in unplanned and infrequent operation that is not amenable to scheduled testing and monitoring, making emission limits infeasible for these units.

Response: The EPA thanks the commenter for their support.

7B. Solid Fuel for Hg and HCl

Commenter Name: Lorraine Gershman

Commenter Affiliation: American Chemistry Council (ACC)

Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1

Comment Excerpt Number: 18

Comment: Coal-fired boilers are fundamentally different than biomass units. For example, a boiler designed to burn coal as its primary fuel cannot burn biomass without experiencing

unacceptable performance degradation, including fouling and loss of fan capacity. This is due to the differing chemical constituents of the ash, which influence fouling characteristics (increased fouling potential with biomass), and the significantly higher moisture in biomass versus coal, which increases volumetric flow rate and thereby limits fan capacity with biomass. A pulverized coal boiler with no grate will not be able to accommodate other solid fuels. Additionally, the boiler backpass (convection section) configuration is designed specifically for the fuel type. This is another reason a coal boiler cannot burn significant amounts of biomass, and vice-versa. CIBO produced a 2003 document entitled —Energy Efficiency and Industrial Boiler Efficiency: An Industry Perspective. The following excerpts from that document provide further evidence that coal and biomass boilers truly are different types of boilers: *Wood and biomass are solid fuels with both high hydrogen to carbon and high moisture content (greater than 40%). Because of energy loss due to moisture from the combustion of hydrogen and conversion of moisture to vapor (1000 Btu per pound), it is very difficult to obtain efficiencies, either MCR or annual average, equal to or approaching those of natural gas, never mind, oil or coal. A very good annual average efficiency for a wood or biomass unit may be in the 60% range. While fuel property variations may be better than coal, these variations usually occur in the moisture content with a direct and major impact on boiler efficiency. (page 3)*

Fuel characteristics determine the design of a particular unit. Fuel changes, especially in hydrogen and moisture content outside the range of 1 or 2% for natural gas, 3 to 5% for oil and 10% for coal and other solid fuels, will have an impact on efficiency, both MCR and annual average. When fuels are switched, the interaction of the new fuel and the boiler often produces negative impacts on either the load or the boiler efficiency. These effects often are amplified because of limitations encountered in specific areas of the boiler where these adverse interactions occur. (page 3)

Fuel type and availability has a major effect. Fuels with high heating values, high carbon to hydrogen ratios, and low moisture content can yield efficiencies up to 25% higher than fuels that have low heating values, low carbon to hydrogen ratios, and high moisture contents. A rule of thumb for the efficiency hierarchy in descending order is coal, heavy fuel oil, light fuel oil, natural gas, and biomass. From these rankings, it is obvious that fuel availability plays a major role. (page 11)

Response: The EPA acknowledges that not all solid fuel units are designed to combust biomass. As stated in the preamble to the 2010 proposed rule (75 FR 32017), the design of the boiler or process heater, which is dependent in part on the type of fuel being burned, impacts the degree of combustion. However, the formation of fuel-dependent HAP (metals, mercury, and acid gases) is dependent upon the composition of the fuel. These fuel-dependent HAP emissions generally can be controlled by either changing the fuel property before combustion or by removing the HAP from the flue gas after combustion. Based on information contained in the survey database in the docket, similar technologies for controlling these fuel-related HAP are used on both coal units and biomass units. The existing MACT floor emission limitations for Hg and HCl for solid fuel boilers were calculated from the emissions from both dedicated coal and dedicated biomass combustion, and the variability between the two fuels is factored into the calculation of the 99% UPL. For this reason, the EPA believes that the floor has been established at a level that is representative of low emitting coal and biomass sources in the top 12 percent of units.

On the other hand, organic HAP are formed from incomplete combustion and are influenced by the design, which is influenced by the type of fuel, and operation of the unit. Organic HAP (which we use CO as a surrogate) are combustion-related and, therefore, a boiler type (e.g., stoker) designed for biomass will have a different emission characteristics which influence the feasibility or effectiveness of controls than a similar boiler type designed for coal.

Comment: *EPA Should Establish Separate Subcategories for Hg and HCl for Coal and Biomass*

In the preamble to this Reconsideration Proposal, EPA solicited comments on its decision in the Final Boiler Rule to combine biomass and coal-fired units into one subcategory for the fuel-based HAPs (PM (as a surrogate for non-Hg metals), HCl, and Hg). 76 Fed. Reg. 80607. Previously, in the 2010 Proposed Boiler Rule, EPA had proposed separate standards for biomass and coal-fired units. To establish CO standards, EPA further subdivided coal into stoker, pulverized coal, and fluidized bed, and subdivided biomass into stokers, fluidized beds, suspension burners/Dutch ovens, and fuel cells. The 2010 Proposed Boiler Rule placed certain combination-type units designed to burn both biomass and coal in the coal subcategory if they burned at least 10 percent coal on a heat input basis as an annual average. In justifying these subcategories, EPA recognized the differences between biomass and coal-fired units. *See* 75 Fed. Reg. 32017 (June 4, 2010).

Response: See the response to comment EPA-HQ-OAR-2002-0058-3510-A1, excerpt 18.

Comment Excerpt Number: 17

Comment: In the Final Boiler Rule, EPA grouped coal-fired boilers with biomass-fired boilers for fuel-based pollutants (Hg, HCl and PM) into a single solid fuel subcategory. *See* 76 Fed. Reg. 15612, Table 1. In neither the Final Boiler Rule MACT Floor memo nor the Final Boiler Rule preamble explaining its rationale for selecting the recommended approach (one solid fuel subcategory) over the alternative approach (to subcategorize coal and biomass) for fuel based pollutants has EPA discussed its approach. Finally, no mention is made of this alternative in the Reconsideration Proposal. The solid fuel grouping is ripe for reconsideration because it appeared for the first time in the Final Boiler Rule, and hence the public did not have an opportunity to comment on it. EPA has offered no further explanation of its decision in the record to the reconsideration proposal.

Response: We agree that the solid fuel grouping appeared for the first time in the Final 2011 Boiler Rule, but disagree that the public did not have an opportunity to comment on it. In response to the variety of comments received on the 2010 proposed rule regarding combination

fuel boilers, the EPA revised the subcategories (see 76 FR 15636) in order to simplify implementation, improve the flexibility of units in establishing and changing fuel mixtures, promote combustion of cleaner fuels, and provide MACT standards that are enforceable and consistent with the requirements of section 112. For combined fuel units that combust solid fuels, due to the many potential combinations and percentages of solid fuels that are or can be combusted, for the fuel-based pollutants, the EPA selected the option of combining the subcategories for solid fuels into a single solid fuel subcategory. For the fuel-based pollutants, this alleviated the concerns regarding changes in fuel mixtures, promotion of combustion of dirtier fuels, and the implementation and compliance concerns. See the response to comment EPA-HQ-OAR-2002-0058-3510-A1, excerpt 18.

Comment Excerpt Number: 20

Comment: ACC understands that there are certain "combination" units that are designed to be able to burn both biomass and coal. If EPA does separate coal boilers from biomass boilers to set PM, Hg, and HCl emission limits, as ACC strongly urges the Agency to do, a problem will surface concerning certain combination boilers specifically designed to burn varying percentages of coal, biomass, and other solid fuels such as tire-derived fuel and biomass residuals. The current biomass subcategory definition includes any such unit that burns greater than 10 percent biomass on an annual heat input basis as a "unit designed to burn biomass/bio-based solids." EPA did this so that the combination units would be subject to CO limits derived from pure biomass units, since combustion of biomass produces a CO emissions profile that is different from combustion of coal. As EPA describes in the Final Boiler Rule preamble, it attempts to resolve the combination boiler dilemma by combining all solid fuel boilers into one subcategory for fuel based pollutants:

"For combined fuel units that combust solid fuels, due to the many potential combinations and percentages of solid fuels that are or can be combusted, for the fuel-based pollutants, EPA selected the option of combining the subcategories for solid fuels into a single solid fuel subcategory. For the fuel-based pollutants, this alleviates the concerns regarding changes in fuel mixtures, promotion of combustion of dirtier fuels, and the implementation and compliance concerns."(76 Fed. Reg. 15636)

ACC maintains that this change in subcategories, designed primarily to address combination units, is inappropriate for coal only-fired units because, as discussed above, coal-fired boilers are different types of boilers than biomass boilers and have very different emission profiles due both to their design and the fuels they are designed to combust.

Comment Excerpt Number: 12

Comment: Coal-fired boilers are fundamentally different than biomass units. For example, a boiler designed to burn coal as its primary fuel cannot burn biomass without experiencing

unacceptable performance degradation, including fouling and loss of fan capacity. This is due to the differing chemical constituents of the ash, which influence fouling characteristics (increased fouling potential with biomass), and the significantly higher moisture in biomass versus coal, which increases volumetric flow rate and thereby limits fan capacity with biomass. A pulverized coal boiler with no grate will not be able to accommodate other solid fuels. Additionally, the boiler backpass (convection section) configuration is designed specifically for the fuel type. This is another reason a coal boiler cannot burn significant amounts of biomass, and vice-versa. The Council of Industrial Boilers (CIBO), an organization that represents both designers/manufacturers of boilers as well as boiler owners/operators, produced a document in 2003 entitled "Energy Efficiency and Industrial Boiler Efficiency: An Industry Perspective". The following excerpts from that document provide further evidence that coal and biomass boilers truly are different types of boilers:

Wood and biomass are solid fuels with both high hydrogen to carbon and high moisture content (greater than 40%). Because of energy loss due to moisture from the combustion of hydrogen and conversion of moisture to vapor (1000 Btu per pound), it is very difficult to obtain efficiencies, either MCR or annual average, equal to or approaching those of natural gas, never mind, oil or coal. A very good annual average efficiency for a wood or biomass unit may be in the 60% range. While fuel property variations may be better than coal, these variations usually occur in the moisture content with a direct and major impact on boiler efficiency. (page 3)

Fuel characteristics determine the design of a particular unit. Fuel changes, especially in hydrogen and moisture content outside the range of 1 or 2% for natural gas, 3 to 5% for oil and 10% for coal and other solid fuels, will have an impact on efficiency, both MCR and annual average. When fuels are switched, the interaction of the new fuel and the boiler often produces negative impacts on either the load or the boiler efficiency. These effects often are amplified because of limitations encountered in specific areas of the boiler where these adverse interactions occur. (page 3)

Fuel type and availability has a major effect. Fuels with high heating values, high carbon to hydrogen ratios, and low moisture content can yield efficiencies up to 25% higher than fuels that have low heating values, low carbon to hydrogen ratios, and high moisture contents. A rule of thumb for the efficiency hierarchy in descending order is coal, heavy fuel oil, light fuel oil, natural gas, and biomass. From these rankings, it is obvious that fuel availability plays a major role. (page 11)

Comment Excerpt Number: 4

Comment: Separate subcategories for biomass and coal-fired boilers are appropriate when setting particulate matter, hydrogen chloride, and mercury emission standards.

In the proposed rule (June 4, 2010), EPA set separate standards for biomass and coal-fired units. To establish CO and D/F standards, EPA further subdivided coal into stoker, pulverized coal,

and fluidized bed, and the Agency subdivided biomass into stokers, fluidized beds, suspension burners/Dutch ovens, and fuel cells. The proposed rule placed certain combination-type units designed to burn both biomass and coal in the coal subcategory if they burn at least 10 percent coal on a heat input basis as an annual average. In justifying these subcategories, EPA properly recognized the differences between biomass, coal, liquid, and gas-fired units. *Id.* at 32017.

In the Final Rule, and without any notice to the regulated community that it was going to do so, EPA grouped coal fired boilers with biomass fired boilers for fuel based pollutants (Hg, HCl and PM) into a single solid fuel subcategory. *See*, Final Rule, 76 Fed. Reg. at 15612, Table 1. We note that EPA has no discussion either in the Final Rule MACT Floor memo or the Final Rule preamble explaining its rationale for selecting the recommended approach over the alternative approach, which was to subcategorize coal and biomass. EPA does not even mention the alternative in its narrative. Finally, no mention is made of this alternative in the Reconsideration Proposal. This grouping is ripe for reconsideration because it appeared for the first time in the Final Rule, and hence the public did not have an opportunity to comment upon it. We recognize that EPA is reconsidering this issue but has offered no further explanation of its decision in the record to the reconsideration proposal.

Response: See the responses to comments EPA-HQ-OAR-2002-0058-3510-A1, excerpt 18 and EPA-HQ-OAR-2002-0058-3510-A1, excerpt 17 .

Comment Excerpt Number: 5

Comment: Coal fired boilers are fundamentally different than biomass boilers. Eastman has conducted extensive engineering analysis of its fleet of coal boilers in an effort to quantify how much, if any, biomass fuel could be burned in order to prepare for future greenhouse gas regulations and/or renewable fuel portfolio standards. One dimension of this analysis engaged the boiler OEM to understand what fundamentally distinguishes a coal unit from a biomass unit. Eastman learned that from the boiler design engineer's perspective, coal and biomass units are fundamentally and irreconcilably different, in much the same sense that diesel fuel is incompatible with a gasoline engine, and vice versa. Superficially, coal and biomass units share similar features (e.g. stoker units for both coal and biomass firing can utilize spreader stokers and traveling grates; waterwalls and refractory in the furnace; pendant and platen superheaters; economizers and air preheaters; etc.). But from the boiler designers perspective, the sizing of the furnace, spacing of the heat transfer elements, fan requirements, and fuel handling equipment are fundamentally different. Most fundamental is the size (plan area) and volume of the furnace, which is primarily a function of the rank of the fuel. Consider Alstom Power's Figure 3-2 (Effect of coal rank on sizing of a pulverized-fuel furnace) from their 2009 edition of Clean Combustion Technologies. That figure shows how both the plan area and the overall furnace height changes with the rank of fuel. As rank changes from low (lignites) to high (bituminous) fuels, the plan area and total furnace volume decrease dramatically, as shown below in Table 1 {see submittal for Table 1}.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3510-A1, excerpt 18.

Commenter Name: Steve Gossett
Commenter Affiliation: Eastman Chemical Company
Document Control Number: EPA-HQ-OAR-2002-0058-3669-A2
Comment Excerpt Number: 6

Comment: Table 1 [of the submittal] clearly shows that from a design perspective, the rank of the fuel is fundamental to the boiler's basic structure. And as EPA is well aware, once the plan area and height of a boiler are fixed at the design stage, changes to these fundamental criteria cannot be made once construction has started any more than a gasoline engine could be modified to burn diesel fuel.

And if the boiler's fundamental design is predicated on rank, a full understanding of rank is warranted. Rank can be quantified by various physical and chemical properties (e.g. fixed carbon, volatile matter, moisture, hardness, etc.), but fundamentally the term refers to the energy density of a given fuel. The term is most frequently used in the context of distinguishing between types of coals, such as lignites, sub-bituminous, bituminous and anthracite coals. But rank can be used more generally to compare any number of solid fuels based on their energy density. Refer to Figure 9 (The coalification process) on page 9-4 of Babcock and Wilcox's Steam (41st edition, 2005). That diagram not only shows the cycle that organic fuels proceed through, but also lists fuels of varying rank from wood to peat to coal. As listed in that figure, solids can be viewed through the lens of rank as shown below in Table 2 {see submittal for Table 2}.

As reported by Babcock and Wilcox, and summarized above in Table 2 {see submittal for Table 2}, it can be seen that wood is the lowest of fuel ranks of all the major types of solid fuels used in the US. Taken together, Tables 1 and 2 {of the submittal} illustrate that the most fundamental and unchangeable aspect of a boiler's design (i.e. the plan area and volume) is predicated by the rank of the fuel, and that biomass (wood) is the lowest rank of solid fuel found in the US and is completely distinguished from coals. It can only be concluded that from a boiler designer's and boiler engineer's point of view, biomass boilers are fundamentally and irrevocably different from coal boilers.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3510-A1, excerpt 18.

Commenter Name: Steve Gossett
Commenter Affiliation: Eastman Chemical Company
Document Control Number: EPA-HQ-OAR-2002-0058-3669-A2
Comment Excerpt Number: 7

Comment: Another dimension of the biomass firing analysis commissioned by Eastman was to understand the limitations of co-firing biomass in a coal boiler. Recognizing that some amount of biomass co-firing was both technically feasible and commercially demonstrated, the scope of the analysis was to understand how much biomass could be introduced into pulverized coal and stoker coal boilers in Eastman's fleet before significant performance, reliability and/or safety degradation occurred. Eastman learned that even if the significant and capital intensive fuel handling challenges were addressed, the design of the heat transfer surfaces would limit the total amount of biomass that could be fired in the units to less than 20% of the total heat input of the unit. This limit was due to a variety of design issues, including the spacing between the

superheater tubes; the number, location, and allowable wear due to soot blowers; the fouling characteristics of the ash found in biomass fuels; and the impact of the much higher nominal moisture levels in biomass fuels on existing fan capacity. This analysis made clear the fact that coal and biomass boilers are so fundamentally different that it is not possible to freely substitute one fuel for the other unless extensive capital modifications were undertaken, and even then the amount of substitution was very limited. The superficial similarities between some coal and biomass units (e.g. the use of spreader stokers is common in both industrial coal and biomass boilers) are no more fundamental to the design of the boilers than the choice of carburetor versus fuel injection is to an engine. The choice of fuel (e.g. biomass versus coal) is more akin to choosing a diesel engine versus a gasoline engine in a pickup truck: it is a choice that forever and irreconcilably differentiates one from another. Eastman's specific analysis demonstrates that coal units and biomass units are not interchangeable, and EPA should not lump them together as if they were.

Comment Excerpt Number: 8

Comment: The amount of biomass that could potentially be fired in any given coal-fired boiler will vary depending on the specific configuration of the unit, but Eastman's conclusions are typical for most coal units. Consider the Council of Industrial Boilers (CIBO), an organization that represents both designers/manufacturers of boilers as well as boiler owners/operators, produced a document in 2003 entitled "Energy Efficiency and Industrial Boiler Efficiency: An Industry Perspective". The following excerpts from that document provide further evidence that coal and biomass boilers truly are different types of boilers:

Wood and biomass are solid fuels with both high hydrogen to carbon and high moisture content (greater than 40%). Because of energy loss due to moisture from the combustion of hydrogen and conversion of moisture to vapor (1000 Btu per pound), it is very difficult to obtain efficiencies, either MCR or annual average, equal to or approaching those of natural gas, never mind, oil or coal. A very good annual average efficiency for a wood or biomass unit may be in the 60% range. While fuel property variations may be better than coal, these variations usually occur in the moisture content with a direct and major impact on boiler efficiency. (page 3)

Fuel characteristics determine the design of a particular unit. Fuel changes, especially in hydrogen and moisture content outside the range of 1 or 2% for natural gas, 3 to 5% for oil and 10% for coal and other solid fuels, will have an impact on efficiency, both MCR and annual average. When fuels are switched, the interaction of the new fuel and the boiler often produces negative impacts on either the load or the boiler efficiency. These effects often are amplified because of limitations encountered in specific areas of the boiler where these adverse interactions occur. (page 3)

Fuel type and availability has a major effect. Fuels with high heating values, high carbon to hydrogen ratios, and low moisture content can yield efficiencies up to 25% higher than fuels that

have low heating values, low carbon to hydrogen ratios, and high moisture contents. A rule of thumb for the efficiency hierarchy in descending order is coal, heavy fuel oil, light fuel oil, natural gas, and biomass. From these rankings, it is obvious that fuel availability plays a major role. (page 11)

Commenter Name: Lorraine Gershman
Commenter Affiliation: American Chemistry Council (ACC)
Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1
Comment Excerpt Number: 19

Comment: ACC notes that EPA acknowledged boiler design considerations driven by fuel type in a similar source category MACT standard – the final MATS Rule. In the MATS, EPA observed significant differences in mercury emissions between boilers burning high-rank and low-rank coals and concluded that the different mercury emission standards were appropriate for these two different fuel types. In the final rule preamble, EPA states:

"...we believed at proposal that the boiler size was the cause of the different Hg emissions characteristics that led us to propose subcategorization, but many commenters indicated that it was not the boiler size but the fact that the EGUs burned a nonagglomerating virgin coal having a calorific value (moist, mineral matter-free basis) of less than 19,305 kJ/kg (8,300 Btu/lb) (low rank virgin coal) that causes the disparity in Hg emissions." (77 Fed. Reg. 9378, February 16, 2012)

EPA goes on to explain that it has the latitude under the Clean Air Act (CAA) to base subcategorization on fuel type:

*"We recognize that some commenters have taken the position that it is unlawful to subcategorize based on factors such as fuel type but nothing in the statute prohibits such an approach and the case law supports this approach to the extent courts have considered subcategorization based on such factors. See *Sierra Club v. Costle*, 657 F. 2d 298, 318-19 (D.C. Cir. 1981) (differing pollutant content of input material can justify a different standard based on subcategorization authority to "distinguish among classes, types and sizes within categories of new sources"). Furthermore, we believe had Congress intended to prohibit the EPA from subcategorizing based on an EGU being designed to use and using a certain material input (e.g., fuel) it would have clearly stated such intent in the CAA. However, we believe the Agency could decline to exercise its discretion to subcategorize even if the potential result would be the prohibition of the use of some materials if the circumstances warranted." *Id.* Similar logic applies in the boiler rulemaking, and should be followed to create separate subcategories for biomass and coal. A boiler designed to burn coal cannot fire biomass and meet its operational requirements, and the resulting HCl, Hg, and PM emissions are dictated by boiler design.*

Response: See response to comment EPA-HQ-OAR-2002-0058-3510-A1, excerpt 18.

Comment: We note also that EPA acknowledged boiler design considerations driven by fuel type in a similar source category MACT standard – the Utility MACT Final Rule (February 16, 2012). In the May 3, 2011 Utility MACT proposed rule (see page 25037), EPA observed significant differences in mercury emissions between boilers burning high-rank and low-rank coals and concluded that the different mercury emission standards were appropriate for these two different fuel types. In the final rule preamble (page 9378), EPA states:

...we believed at proposal that the boiler size was the cause of the different Hg emissions characteristics that led us to propose subcategorization, but many commenters indicated that it was not the boiler size but the fact that the EGUs burned a nonagglomerating virgin coal having a calorific value (moist, mineral matter-free basis) of less than 19,305 kJ/kg (8,300 Btu/lb) (low rank virgin coal) that causes the disparity in Hg emissions.

EPA goes on to explain that it has the latitude under the Clean Air Act to base subcategorization on fuel type: *We recognize that some commenters have taken the position that it is unlawful to subcategorize based on factors such as fuel type but nothing in the statute prohibits such an approach and the case law supports this approach to the extent courts have considered subcategorization based on such factors. See Sierra Club v. Costle, 657 F. 2d 298, 318-19 (D.C. Cir. 1981) (differing pollutant content of input material can justify a different standard based on subcategorization authority to "distinguish among classes, types and sizes within categories of new sources"). Furthermore, we believe had Congress intended to prohibit the EPA from subcategorizing based on an EGU being designed to use and using a certain material input (e.g., fuel) it would have clearly stated such intent in the CAA. However, we believe the Agency could decline to exercise its discretion to subcategorize even if the potential result would be the prohibition of the use of some materials if the circumstances warranted. (page 9379 of the February 16,2012 Federal Register).*

Similar logic applies in the Boiler MACT and should be followed to create separate subcategories for biomass and coal. A coal boiler cannot fire biomass and meet its design requirements, and the HCl, mercury, and PM emissions are then dictated by this fuel type design choice.

Just as in the Utility MACT where EPA recognized that there would be significant differences in mercury emissions between units designed to burn low-rank and high-rank coals, there are significant differences in HCl, mercury, and PM emissions from coal (high rank fuels) and biomass (very low rank fuels) boilers that would also justify this subcategorization.

Response: While the commenter is correct that in the MATS rule, "Coal-fired unit low rank virgin coal" is listed as a subcategory in the tables listing the emissions limits, the subcategory is actually established based on the design of the boiler combusting low rank coal. The definition of the subcategory in MATS is: *Unit designed for low rank virgin coal subcategory means any coal-fired EGU that is designed to burn and that is burning nonagglomerating virgin coal having a calorific value (moist, mineral matter-free basis) of less than 19,305 kJ/kg (8,300 Btu/lb) that is constructed and operates at or near the mine that produces such coal.*" This is consistent with the establishment of subcategories in Boiler MACT. That is, the subcategory is based on the design of the boiler which is based on the type of fuel burned in the boiler. See the response to comment EPA-HQ-OAR-2002-0058-3510-A1, excerpt 18.

Comment: For regulation of PM, HCl, and Hg, EPA should place any solid fuel boiler that burns at least 10 percent coal on an annual heat input basis in the —unit designed to burn coal/solid fuel|| subcategory. Since combination boilers are specifically designed to burn a variety of materials (coal, bark, TDF, biomass residuals, etc.) that do have significant and varying chlorine and mercury contents, such classification may be appropriate for these units. This affords them compliance options to either: (1) shift to a cleaner relative mix of feeds (e.g., less coal and more biomass); or (2) install control technology to meet the emission standards. Just as with coal boilers, it would not be fair or appropriate to require these combination units to meet emission standards set by boilers burning at least 90 percent biomass, the top performers of which have very low levels of mercury and chlorine in their feeds and therefore do not have add-on controls for these pollutants. EPA should allow combination units to remain subject to the CO standards for the applicable biomass design subcategory as long as they burn at least 10 percent biomass. CO emissions from combination units are influenced more by the biomass burned than the coal.

Response: For a response to the claim that a solid fuel subcategory is unjust for Hg and HCl, please see comment EPA-HQ-OAR-2002-0058-3510-A1, excerpt 18.

Comment Excerpt Number: 13

Comment: Defining the emissions limits for Hg and HCl based on a combined coal/biomass subcategory results in artificially low Hg and HCl emissions standards for coal-fired boilers. The consistent achievability of these low emissions limits for most coal-fired boilers is very uncertain. Weighing the high cost of installing controls on these coal-fired boilers and the uncertainty of achieving consistent compliance even with the controls, many facilities, such as PPG's, may be forced to shut down their coal-fired boilers.

Response: The EPA disagrees that the emission limits are biased low. Based on reported emissions data, 87 existing coal-fired boilers are already demonstrating compliance with the mercury emission limit in the final rule and 40 existing coal-fired boilers are already demonstrating compliance with the HCl emission limit in the final rule. The EPA therefore believes that all coal-fired sources have the ability to demonstrate compliance with the limits. Comments pertaining to the economic impact of the rule on individual facilities are outside the scope of this comment response document.

Comment Excerpt Number: 65

Comment: We support retaining the solid fuel subcategory for HCl and Hg. EPA correctly points out that HCl and Hg are fuel-based pollutants and that the top performers in the solid fuel subcategory combust a variety of solid fuel types (biomass, coal, petcoke, and TDF). There are several designs of boilers (e.g., stokers, hybrid suspension grate, suspension/ pulverized coal, and fluidized bed units) that are capable of burning multiple types of solid fuel. EPA has quite a bit of emissions data from these "combination" units. To accommodate the fuel diversity among solid fuel units, it is appropriate to use the data from boilers burning multiple types of solid fuel, and not just data from those burning 90 percent of one kind of solid fuel to develop limits for HCl and Hg for a solid fuel subcategory. The MACT standards must be achievable, and this approach of analyzing data from units burning many types of solid fuels makes the MACT floors for HCl and Hg from a combined solid fuel subcategory achievable for many types of boilers.

Response: The EPA thanks the commenter for their support.

Comment: We support EPA's decision to keep the solid fuel subcategory finalized in March 2011 for HCl and Hg. As EPA points out, HCl and Hg are fuel-based pollutants and the top performers in the solid fuel subcategory combust a variety of solid fuel types. In addition, the top performers represent a variety of boiler types and controls.

Response: The EPA thanks the commenter for their support.

Commenter Name: Bart Sponsellar

Commenter Affiliation: Wisconsin Department of Natural Resources

Document Control Number: EPA-HQ-OAR-2002-0058-3527-A2

Comment Excerpt Number: 3

Comment: The MACT rule originally distinguished between coal and biomass fuels in establishing emission limitations for fuel based pollutants such as mercury and chlorine. Under the MACT Reconsideration, EPA is proposing to establish one "solid fuel" category with one limit that encompasses coal and biomass fuels. The only distinction in emission limitations is between new and existing solid fuel sources.

The Department supports a single solid fuel category in setting MACT mercury and Hydrogen Chloride emission limitations for source categories which can burn either coal or biomass. This approach acknowledges that biomass is a cleaner fuel – in many cases cleaner without controls than coal fueled sources with controls. Because biomass with controls is much more stringent than coal meeting MACT, a source may very well switch back to coal and emit more total emissions even though the source is controlled to the MACT emission limitation. Fuel switching to cleaner fuels has long been considered a control option by EPA and the MACT standards should not work against this approach. Establishing the single category also acknowledges that sources may have switched to biomass fuels in response to other pollutant regulations or renewable energy mandates. These sources should not be asked to control pollutants to levels required for coal fired sources. Further, some sources would be punished for voluntarily reducing greenhouse gas emissions or utilizing clean biomass residues instead of fossil fuels.

Response: The EPA thanks the commenter for their support.

Commenter Name: Bart Sponsellar
Commenter Affiliation: Wisconsin Department of Natural Resources
Document Control Number: EPA-HQ-OAR-2002-0058-3527-A2
Comment Excerpt Number: 4

Comment: Although we support a single solid fuel category, it appears that this category should only apply for subcategories of boilers capable of burning both coal and biomass. The Department sees a distinction where boilers or processes designed to burn only biomass should remain in a biomass category. Clearly, several subcategories such as pile burners, dutch ovens, suspension burners, fuel cells, and kiln-dried wood boilers are designed or are dedicated to burn only biomass. Most sources in other boiler types that typically burn coal or even a mixture of coal and biomass are not even capable of burning 100% biomass. Therefore, the fuel based emission profiles of these dedicated biomass source subcategories are not applicable to other boiler subcategories. The Department believes that certain source categories, which are dedicated or designed as a whole for primarily burning biomass, should remain as a separate biomass fuel category. This suggested biomass category appears to include pile burners, dutch ovens, suspension burners, and fuel cells.

Response: The MACT floor emission limitations for Hg and HCl for solid fuel boilers were calculated from the emissions from both coal and biomass combustion. In addition, the threshold criterion for considering performance tests from co-fired units was 90 percent of a fuel type. For this reason, the EPA believes that all sources will be able to demonstrate compliance with the emission limitations regardless of the fuel they are combusting. The EPA believes this mitigates any concerns over units not being designed to combust one type of solid fuel versus another.

Commenter Name: Bart Sponsellar
Commenter Affiliation: Wisconsin Department of Natural Resources
Document Control Number: EPA-HQ-OAR-2002-0058-3527-A2
Comment Excerpt Number: 5

Comment: Biomass fuel is not equally available to all sources or even in the same form or quality. Many sources burning biomass have a dedicated or specific source of biomass material such as bagasse or a by-product from a facility process such as dry kiln wood or waste bark. Even where boilers are burning logging residues the fueling is inherent to the surrounding resources. It is well known that placing sizable units which are 100% biomass fired requires a fuel aggregation system over a very large area. For these reasons, EPA cannot reasonably assume that the emission characteristics found for individual boilers firing biomass can be applied to other units in the same source sub-category. Rather, the fueling of biomass in these categories should be viewed as a site specific alternative and is simply a cleaner burning fuel used in controlling emissions compared to coal. In contrast sources firing coal have the ability to alter and obtain fuels on the open market with consistent and desired characteristics. The Department believes that certain source categories, which are dedicated or designed as a whole for primarily burning biomass, should remain as a separate biomass fuel category. This suggested biomass category appears to include pile burners, dutch ovens, suspension burners, and fuel cells.

Response: The EPA acknowledges that not all solid fuel units are designed to combust biomass, and that not all biomass fuels are widely available to all sources. The MACT floor emission limitations for Hg and HCl for solid fuel boilers were calculated from the emissions from both coal and biomass combustion. The units combusting biomass were located in several different parts of the U.S., and the variability of these fuels was factored into the 99% UPL. For this reason, the EPA believes that all sources will be able to demonstrate compliance with the Hg and HCl emission limitations regardless of the fuel they are combusting. The EPA believes this mitigates any concerns over the availability of biomass fuels.

Commenter Name: Bart Sponsellar

Commenter Affiliation: Wisconsin Department of Natural Resources

Document Control Number: EPA-HQ-OAR-2002-0058-3527-A2

Comment Excerpt Number: 6

Comment: The Department believes it is appropriate to include pulverized coal, stoker, and fluidized bed boilers in an overall solid fuel fired category in establishing mercury and hydrogen chloride emission limitations. However, the setting of these emission limitations should be based on sources firing 90% or more of coal at the time of testing. At a minimum the emission limitations should not be based on sources firing biomass in sizable quantities. Biomass is a fuel which is not readily available to all sources. This approach to a solid fuel category will alter a significant number of sources currently counting toward the solid fuel MACT floor. The Department reviewed the sources included in the MACT floor and cross-referenced those sources identified as burning biomass fuels by EPA. This analysis, shown in Appendix A, [See submittal, page 9, for Appendix A] shows that for mercury, 13 of 19 sources in the floor (33%) are dedicated or primarily biomass fired. The biomass sources are highlighted in the table. In the hydrogen chloride floor, 16 of 45 sources (36%) appear to be dedicated or primarily biomass fired. The emission limitations for solid fuel, should at a minimum, eliminate sources burning primarily biomass in determining the MACT floor. The Department also suggests EPA evaluate this same suggested solid fuel and biomass hybrid approach for nonmercury metals which are also fuel-based.

Response: The EPA intends for source to demonstrate compliance with emission limitations at all times (excluding periods of startup, shutdown, or when the unit is not operating), regardless of the fuel mixture. Given that the best-performing Hg and HCl emitters comprise a mixture of tests combusting biomass and coal, the EPA believes that any mixtures of the two fuels should yield similar emissions profiles. For this reason, the EPA has elected to retain the criterion for the Hg and HCl MACT floor calculations that tests must be burning at least 90% solid fuel, and not just 90% coal or 90% biomass. In addition, as the commenter points out, a high percentage of the best performers used to established the Hg and HCl emission limits are dedicated biomass units,

For the reasons specified in the preamble to the December 23, 2011 proposed rule notice (76 FR 80598), the alternative emission limitations for total metals remain on a combustor design basis.

Commenter Name: Bart Sponsellar

Commenter Affiliation: Wisconsin Department of Natural Resources

Document Control Number: EPA-HQ-OAR-2002-0058-3527-A2

Comment Excerpt Number: 7

Comment: An alternative needs to be considered for the suggested biomass dedicated source category. Since these sources burn fuels which are not widely available to all sources and which in many cases are site specific. Therefore EPA should not apply the emissions profile across this source category. This is particularly true for many sources where the chloride and mercury content is a result of environmental conditions or deposition of the contaminant. The Department suggests EPA consider whether an emission limitation can be accurately established in this case or if these pollutants should be subject to a work practice requirement.

Response: The EPA acknowledges that not all solid fuel units are designed to combust biomass, and that not all biomass fuels are widely available to all sources. The MACT floor emission limitations for Hg and HCl for solid fuel boilers were calculated from the emissions from both dedicated coal and biomass combustion. For this reason, the EPA believes that all sources will be able to demonstrate compliance with the emission limitations regardless of the fuel they are combusting. The EPA believes this mitigates any concerns over the availability of biomass fuels.

Document Control Number: EPA-HQ-OAR-2002-0058-3692-A2

Comment Excerpt Number: 1

Comment: FB boilers are designed to combust fuel with relatively low heating value and high ash compared to other combustor designs. There are two subcategories for FB boilers, one is for coal and the other is for biomass that have emission limits of 56 ppmv @ 3 % O₂ and 370 ppmv @3 % O₂, respectively. The large difference in the emission limits reflects the differences in the fuel properties of coal and biomass.

The fuel properties of coal have a wide range of heating values and ash content. The design of coal-fired FB boilers depends on the fuel properties. The design has to be altered to sustain combustion as the heating value decreases and to ensure the heat in the ash is utilized in order to be economically viable to operate the boiler as the ash content increases.

FB boilers are designed to have large tube surface areas to transfer heat from the fuel through the process of conduction and convection. Conductive heat transfer takes place with ash to tube surface contact in the furnace section through the cyclone flue gas circuit. Convective heat transfer with flue gas occurs after the cyclone outlet in the back pass of the boiler.

As the heating value decreases and ash content increases the amount of tube surface area in the furnace required for conductive heat transfer is exceeded. A separate tube surface area is required outside of the furnace section to achieve the desired steaming rate and required conductive heat transfer.

In order to achieve this design requirement, certain FB boilers adopt a FBHE design to achieve rapid heat transfer. This ability can be simply explained by the FBHE design where the entire tube surface is exposed to the flue gas stream containing ash, as compared to approximately a

third to half of the furnace tube surface area in a conventional FB design. The FBHE is located at the exit of the cyclone section of the unit and facilitates a means of providing heat to the evaporative water and superheated steam circuits of the boiler.

In addition, the FBHE is designed with the injection of fresh air into the flue gas to improve mixing and combustion of the remaining fuel in the flue gas that is recirculated to the furnace section. This allows the boiler to combust coal with a lower heating value than a coal-fired FB without a FBHE.

Figure 1 and 2 shows a diagram of a FB boiler without a FBHE and one with a FBHE [see submittal for Figures 1 and 2].

Response: We agree with the commenter that Fluidized Bed units with an integrated heat exchanger warrant further subcategorization. Under CAA section 112(d)(1), the Administrator has the discretion to distinguish among classes, types, and sizes of sources within a category or subcategory in establishing standards. The EPA maintains that, normally, any basis for subcategorization (*i.e.*, class, type, or size) must be related to an effect on HAP emissions that is due to the difference in class, type, or size of the units. Because this design allows the boiler to combust coal with a lower heating value than a coal-fired fluidized bed boiler without a fluidized bed heat exchanger, this boiler design does have different combustion-related HAP emission characteristics. Thus, a new subcategory of coal fluidized bed with integrated heat exchanger was added to the final rule. This is similar and consistent to the subcategory added in MATS for boilers designed to burn low rank coal.

The final rule includes emission limitations for this subcategory.

Commenter Name: C. Richard Neff

Commenter Affiliation: Cogentrix Energy, LLC

Document Control Number: EPA-HQ-OAR-2002-0058-3627-A2

Comment Excerpt Number: 1

Comment: Cogentrix operates two facilities, one with coal-fired cogeneration units and the other with coal-fired electric generation units, each of which has generator capacity of more than 25 megawatt electrical (MWe) and combustion units of less than 250 MMBtu/hr. Both Cogentrix sites are designed with two "three-on-one" boiler-to-generator configurations, in which three boilers provide steam to one 55-MWe electric generator. All boilers have opted-in to the Acid Rain Program (ARP) and are equipped with dry scrubbers and bag houses.

The three-on-one boiler-to-generator configuration results in an unusual, and perhaps unique, issue regarding applicability of NESHAPs, the ARP, and the Cross-State Air Pollution Rule (CSAPR). Specifically, despite having already opted-in to the ARP and installed scrubbers and baghouses, the boilers at both Cogentrix sites now face being whipsawed between the proposed NESHAP for Industrial, Commercial, and Institutional Boilers and Process Heaters ("Boiler MACT") and the CSAPR, which is intended to be applicable only to electric generating units (EGUs).

I. Regulatory Inequality and Disparate Impact Demand a Further Boiler MACT Subcategory.

Cogentrix has noted in its previous comments to EPA on the proposed Utility MACT, and CSAPR rules that these two facilities have historically been treated as EGUs by the permitting authorities. Indeed, EPA originally included these two facilities in the Utility MACT ICR, not in the Boiler MACT ICR. Although the proposed "Boiler MACT" in 40 CFR 63.7491(a) appeared to exclude electric utility steam generating units from applicability of this rule, the proposed Utility MACT was ambiguous. It appeared to exclude units such as Cogentrix's, thus leaving them orphaned and subject to the Boiler MACT. Cogentrix commented to seek clarification that its units would be covered by the Utility MACT. To its surprise, in the December 2011 Responses to Comments on Utility MACT, EPA determined, "[T]he combustion units at the two [Cogentrix] facilities are subject to the Industrial Boiler NESHAP rather than the EGU NESHAP because they do not meet the size requirement of the CAA section 112(a)(8) definition of an EGU."

The crux of the comments in this letter address the regulatory inequality and competitive distortion that EPA has created by, on the one hand, treating the two facilities as EGUs by subjecting them to CSAPR, while on the other hand, not treating the two plants as EGUs (i.e., imposing Boiler MACT rather than Utility MACT).

The applicability of NESHAP rules, CSAPR, and ARP are focused on different industry source groups. That the two Cogentrix facilities are being whipsawed between rules that were created for different industry source groups creates both competitive distortions against these plants and difficult compliance challenges for Cogentrix. The proposed Boiler MACT establishes emissions limitations for both hydrochloric acid (HCl) and carbon monoxide (CO), while the analogous NESHAP for EGUs, the "Utility MACT," does not require reductions (or monitoring) of either CO or HCl. The CSAPR requires TR NO_x Annual Units either to emit less than their annual and ozone-season allocations of NO_x for both operating periods or to purchase additional allocations. Since emissions of CO and NO_x are inversely related, Cogentrix faces greater challenges to control emissions than do its electric utility competitors for power sales: both Cogentrix and its competitors must reduce NO_x emissions under CSAPR, but only Cogentrix must do so while simultaneously reducing CO and HCl. There is no public policy rationale to support this disparate treatment.

The most suitable way for EPA to avoid such unwarranted disparate impact of its NESHAP rules is to craft appropriate subcategories of sources and to tailor the requirements for each. Section 112(c)(1) directs EPA to make the industrial categories and subcategories for NESHAP's rules "consistent with the list of source categories established pursuant to" section 111 (New Source Performance Standards), "to the extent practicable." Section 112(b)(2) in turn authorizes the Administrator to "distinguish among classes, types and sizes within categories of new sources." For purposes of the NESHAPs, section 112(c)(1) preserves "the Administrator's authority to establish subcategories under this section, as appropriate." The need for a subcategory here is more than "appropriate," it is compelling.

Cogentrix urges EPA to cure this unequal impact of its NESHAP rules by creating a subcategory in Boiler MACT for facilities that are subject to CSAPR and have opted-in to the ARP and installed scrubbers and baghouses. Under this sub-category, a Boiler MACT facility could comply with NESHAP requirements for acid gases and dioxin/furans using compliance methods defined under Utility MACT. A facility that looks and operates like an EGU while being subject to this sub-category under Boiler MACT would have the capability to comply with its applicable

NESHAP, CSAPR, and ARP without the competitive disadvantage it will experience absent such a sub-category.

With respect to HCl, for example, EPA recognized in the Utility MACT the effectiveness of scrubbers. HCl is a strong acid with a large acid dissociation constant. As such, HCl readily separates in acid-base reactions with caustic sorbents. EPA cites both HCl and hydrofluoric acid (HF) as being effectively removed using flue gas desulfurization (FGD) control technologies (e.g., dry sorbent injection) upstream from a PM control device.³ While both acid gases and SO₂ are absorbed when using this control technology, EPA states that acid gases are removed even more rapidly and readily than SO₂. Having opted-in to the ARP, Cogentrix operates FGD technology and an SO₂ CEMS to comply with the provisions of the ARP. Cogentrix's ARP subcategory proposal is thus consistent with the Utility MACT while achieving the HCl reduction goals of Boiler MACT. EPA already considers SO₂ a commonly measured pollutant and allows SO₂ to be monitored as a surrogate for acid gases. Allowing this compliance method for a narrow sub-category of FGD-equipped units under Boiler MACT would achieve EPA's HAP reduction goal, while treating similar sources equally and avoiding competitive distortions.

With respect to the use of CO as a surrogate for non-dioxin/furan HAPs, EPA's Utility MACT ICR showed that non-dioxin/furan organic HAP emissions from EGUs are low and often below EPA test method detection levels. EPA determined that inaccuracy in measurements along with the extended sampling times from the ICRs fulfills the criteria in CAA Section 112(h) for implementation of work practice standards for organic HAP, rather than using CO, VOC, or THC as surrogates.⁴ The Cogentrix boilers operate with organic HAP emission rates comparable to other utility boilers that are treated as EGUs under section 112. In fact, the Cogentrix boilers were included in the Utility MACT ICR. There is no reason to believe that the composition of non-dioxin/furan organic HAP would be dissimilar from those other EGUs tested in the Utility MACT ICR.

Likewise, EPA concluded in the proposed Boiler MACT that work practice standards are appropriate for dioxin/furan emissions based on boiler data similar to that collected from EGUs. Therefore, Cogentrix requests that work practice standards (per Utility MACT), rather than a surrogate CO emission standard, be established for non-dioxin/furan organic HAP emissions from units within the Boiler MACT subcategory that are subject to the CSAPR and have opted-in to the ARP and installed FGD controls. This compliance option would eliminate the serious competitive disadvantage for units that would otherwise be subject simultaneously to CO limitations under Boiler MACT and to NO_x caps under CSAPR.

[Footnote 2: Please see: http://www.epa.gov/ttn/atw/utility/mats_rtc_chapters_foreword-1-2-3-4-121611.pdf; regarding Commenter 17845 (page 294).][Footnote 3: Federal Register *I* Vol. 76, No. 85 *I* May 3, 2011 Proposed Rules.]

[Footnote 4: Federal Register *I* Vol. 76, No. 85 *I* May 3, 2011 Proposed Rules.]

Response: The EPA disagrees with establishing subcategories based on the end use (i.e., electricity production) of a boiler or process heater. The EPA maintains that, normally, any basis for subcategorization (i.e., class, type, or size) must be related to an effect on HAP emissions that is due to the difference in class, type, or size of the units. The EPA has instead established subcategories based on the boiler design which is based on the fuel type combusted. The EPA does not believe the

Cogentrix units exhibit vastly differing emissions profiles than other similarly-designed boilers or process heaters in the industrial, commercial, and institutional source category solely because they produce electricity. There are many other boilers included within the source category that are producing electricity.

7C01. New Biomass Subcategories (General Comments)

Commenter Name: James Pew

Commenter Affiliation: Earthjustice, Clean Air Council, Partnership for Policy Integrity

Document Control Number: EPA-HQ-OAR-2002-0058-3511-A1

Comment Excerpt Number: 70

Comment: EPA has decided to designate any major source that burns at least 10% biomass as a biomass burner (pages 80601 and 80655 of the major source rule). This means that a facility burning 90% coal and 10% biomass would be held to the less rigorous PM emission standard for biomass than for coal. This is arbitrary. At a minimum, the rule should make basic sense. This does not pass that test. [See Submittal for table comparing coal and biomass limits.]

Response: Several comments were received on initial June 4, 2010 proposal with respect to how combination fuel units should be classified. The EPA presented its rationale in its response to comments on the appropriate fuel use threshold of combination boilers (see 76 FR 15635). EPA did not propose to revise this rationale in this reconsideration action and maintained a consistent cutoff of 10% biomass to determine the appropriate subcategory assignment in this final amendments. The EPA was not petitioned for reconsideration on this topic and it did not re-open the fuel threshold level for subcategory determination in this final notice therefore this comment is outside the scope of this reconsideration action.

Commenter Name: Michael Livermore, Jason Schwartz

Commenter Affiliation: Institute for Policy Integrity, NYU School of Law

Document Control Number: EPA-HQ-OAR-2002-0058-3432-A1

Comment Excerpt Number: 2

Comment: EPA should explore the justifications for subcategorization for new sources separately. Compared to existing sources, new sources do not face the same limitations on their design options. EPA must explain why for new, still-unconstructed sources, it would not be more efficient to set a single standard and let all new sources choose any fuel type and design option capable of meeting that standard.

Response: The EPA disagrees that a single standard for all new sources is justified. Emissions of CO, PM, and metallic HAP vary greatly with the design of the combustion unit; the same lot of fuel could exhibit a vastly different emission profile between different combustor designs. Additionally, sources may be limited in their subcategorization choices due to the geographic availability of some fuels and their energy requirements. These conditions may limit or dictate what design type of coal or biomass boilers can be installed. The design types currently being used were installed for specific reasons which may be just as applicable for future installations. For these reasons, the EPA believes that separate emission limitations are justified for all of the combustor-based subcategories.

Commenter Name: James Pew

Commenter Affiliation: Earthjustice, Clean Air Council, Partnership for Policy Integrity

Document Control Number: EPA-HQ-OAR-2002-0058-3511-A1

Comment Excerpt Number: 4

Comment: EPA's subcategories for new units are, if possible, even more unlawful and irrational. Nowhere does the agency explain why it wishes to encourage the construction of obsolete boilers that, according to the agency at least, emit far more pollution than other boilers. It is entirely possible for a company that wishes to build a new boiler to build one that is clean. Assuming *arguendo* that the boiler designs on which EPA has seized as an excuse for setting different standards for existing boilers truly do affect emissions in a meaningful way, then they are also necessarily a means by which pollution can be controlled. Accordingly, EPA should set new source standards based on sources that have the lowest emissions as a result of their cleaner design as well as of the other factors that affect their emission levels.

Response: The commenter disagrees with the EPA's subcategories for new sources, but does not provide any explanation or analysis to support its assertion that the subcategories are "unlawful and irrational." As noted elsewhere in the record for today's action, section 112 provides EPA with broad discretion to subcategorize among sources in a source category. Under the commenter's approach, EPA would likely never be able to exercise this authority, since some types of sources will generally always be lower-emitting than others. Given that Congress used such broad language when authorizing EPA to create subcategories, it is unlikely that such a result is what it intended. Moreover, as explained elsewhere in the record for today's action, the EPA has established emissions standards for new sources based on the best-performing similar source, as required by section 112(d). Therefore, the EPA's standards are in fact based on sources with the lowest emissions levels, consistent with the requirements of the Act.

As indicated in the response to comment EPA-HQ-OAR-2002-0058-3432-A1, excerpt 2, the type of boilers selected for installation in the future is based on several factors including fuel availability and the facilities' energy demands. For example, a facility planning on a new coal boiler may select a pulverized coal unit because it requires a high steam production which a stoker would not provide, or it may select a fluidized bed coal unit if the fuel is of low quality. The same is true for biomass, certain types of biomass can only be combusted in a certain type of boiler designed to combust that type of biomass. In either case, the final rule has a single emission limitation for mercury and HCl for all solid fuel subcategories, and a single PM emission limitation for the 3 coal subcategories. In addition, any new boiler (above 30 MMBtu/hr) will be subject to an NSPS (subpart Db for units greater than 100 MMBtu/hr, subpart Dc for boiler 30 to 100 MMBtu/hr.) which regulate PM, SO₂ and NO_x emissions which will also factor into what boiler type a facility will elect to install for future energy needs.

Comment Excerpt Number: 71

Comment: Sub-classifications do not correspond to the population of burners now being permitted EPA has designated still more sub-classifications of biomass boiler type than it had before. Our permit database indicates that new boilers now being permitted around the country do not fall under the categories of biomass boiler that EPA designates. Almost all are either stokers or fluidized bed boilers. We have never seen a permit for a new "dutch oven" or "biomass fuel cell". EPA's ever-growing number of categories corresponds to a shrinking population of burners in each category, rendering the MACT floors meaningless. The floors set in subclassifications do not reflect generally achievable rates, as illustrated above.

Response: The EPA acknowledges that the majority of new units designed to combust biomass fuels are projected to be stokers or fluidized bed units. The EPA disagrees that subcategorization outside of stokers and fluidized bed units is unjustified. Regardless of new unit construction, there are many Dutch Ovens (22) and fuel cells (29) combusting biomass fuels that are currently in operation in the United States with the latest one (FC) being installed in 2006. In any energy application, the boiler is designed to make the best use of temperature, turbulence, and time (the three "T" of combustion). All three of these aspects relate directly to the properties of the fuel to be used (moisture content, particle size, ash content, and heat value). For example, Dutch ovens find application where the anticipated wood fuel has a high (up to 60 percent) moisture content. Further, the EPA continues to believe that the subcategories for new and existing units should be identical because of the fact that a reconstructed existing unit will be subject to the same emission limitations as a newly constructed boiler. If the Dutch Oven and Fuel Cell subcategories are eliminated for new sources, they would also be removed for existing sources; this would potentially place units currently in operation into subcategories for which their combustion characteristics and emissions profiles are vastly different.

Comment Excerpt Number: 9

Comment: The EPA should consider further separation of Suspension Combustion sub-categories:

Biomass Suspension Combustion:

1. With unsupported flames.
2. Load following thermal applications with more than 40% of run time at less than 75% capacity
3. With powdered fuel that is site milled. This would separate "dust burning" technology from technology designed to run with high efficiency, standard boilers without significant bottom ash. This is a significant issue, as hammer-mill technology cannot economically produce powder that is fine enough to reduce CO levels at or near the proposed 58 PPM.

New data should be collected within these categories. The 3-hour test should be modified to more correctly measure the operation of the boiler at 50% or 60% fire rates. A properly tuned suspension combustion system can combust more than +99.5% of the fuel and boiler efficiency

can exceed 84%. Load following applications reduce fuel consumption and overall plant emissions but can result in higher, short term CO levels.

Response: The EPA disagrees that further subcategorization is necessary for Suspension Burners. The EPA acknowledges that units which combust biomass fuel in suspension have different combustion characteristics and emissions profiles than other combustor designs (e.g., Stokers). The EPA does have data to determine if the differences in combustion styles result in different emission profiles between the three specified subcategories of suspension burners to warrant further subcategorization. The commenter also did not provide data to support the comment.

Comment Excerpt Number: 3

Comment: Biomass Subcategory assignment method. We have learned from previous comments and responses (see Document Control Number EPA-OAR-0058-1907.1, Comment Excerpt #3) that USEPA had assigned the biomass-fired boiler and process heater units to their respective combustor design subcategories using the procedure outlined in USEPA's memo "Revised Development of Baseline Emissions Factors for Boilers and Process Heaters at Commercial, Industrial, and Institutional Facilities", January, 2011. *For units employing more than one biomass combustor design*, the procedure established a hierarchy to assign the unit to a single subcategory. The hierarchy was, 1) Fluidized Bed, 2) Stokers, 3) Dutch Oven/ Suspension Burners, 4) Suspension/ Grate, and 5) Fuel Cells. Then, under the hierarchy approach, if a biomass boiler could have been fired using a combination of "Air-Swept Stokers" and "Suspension Burners", the boiler was assigned to the "Stoker" subcategory.

If the hierarchy is still in use (albeit modified to accommodate the changes to the biomass subcategories found in the current proposed rules), we must confirm CraftMaster's earlier objection because we believe the hierarchy approach is arbitrary and an inappropriate method of assigning units to a subcategory. This concern applies to units that make up the MACT Floors and for classification of units for ongoing compliance purposes. The assignment should be based on a meaningful parameter, the heat input from each combustor design. For the MACT Floor units, the subcategory assignment should be based on the fuel *and combustor design* that provided 90% or more of boiler heat input during the stack test. For compliance purposes, the applicable subcategory (and limits) should be determined based on the combustor design that provided the majority of the heat input over the last twelve consecutive month period.

Response: The EPA is maintaining the approach as described in the memorandum "Revised Development of Baseline Emissions Factors for Boilers and Process Heaters at Commercial, Industrial, and Institutional Facilities", November 2011. The Clean Air Act does not require that the EPA establish subcategories within a source category, but rather provides discretion to do so based on class, type, or size. The EPA believes the approach described in the memorandum referenced above represents a reasonable subcategory assignment given the data available to the EPA at the time of this rulemaking. The ICR survey data did not contain information on heat input provided to each specific type of combustor, and thus there was no way to distribute the

database according to the methods described by the commenter. The EPA has worked to correct the subcategory assignments of several units in the inventory based on public comments and when specific examples of multiple combustor units were provided to the EPA to indicate that the majority heat input was provided by a certain type of combustor, the unit's classification was changed to reflect the combustor design most representative of the unit.

Comment Excerpt Number: 4

Comment: We acknowledge that in the current proposed rules USEPA has considered for those units in the CO and PM MACT Floors that they must be $\geq 90\%$ biomass-fired during the stack testing to be considered in the Floor. However this should be taken one step further to $\geq 90\%$ biomass-fired *and fired by the combustor design for the applicable subcategory*. To do otherwise could introduce data that is not representative of the subcategory due to a co-firing situation similar to that noted in the PM MACT Floor study for biomass suspension-fired units where units co-fired with natural gas were removed from the MACT Floor.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3814-A1, excerpt 3.

Document Control Number: EPA-HQ-OAR-2002-0058-3814-A1

Comment Excerpt Number: 5

Comment: With respect to guidance in classifying a unit employing more than one biomass combustor design for compliance purposes, the proposed regulations are silent.

It is not known how many sources are not properly classified in the MACT Floors as a result of the hierarchy, however, many boilers do utilize multiple combustor designs. For compliance purposes it is essential that each biomass unit be assigned to its proper combustor-design subcategory and not arbitrarily assigned to the "Stoker/ sloped grate/ other firing wet biomass" subcategory.

Response: For compliance purposes, it is the source that submit the Initial Notification of Applicability in which the source would identify the affected units and their subcategory. The regulatory agency would only assigned the subcategory if the source requested an Applicability Determination. The regulatory agency would make the determination based on data and information supplied by the source.

Response: The EPA thanks the commenter for their support.

Commenter Name: Bart Sponsellar

Commenter Affiliation: Wisconsin Department of Natural Resources

Document Control Number: EPA-HQ-OAR-2002-0058-3527-A2

Comment Excerpt Number: 9

Comment: The EPA is proposing carbon monoxide (CO) and particulate (PM) emission limitations for kiln-dried wood boilers (biomass dry stokers) and hybrid suspension grate boilers. This approach by default adjusts the emission limitations for biomass subcategories which previously included these boilers. The Department supports EPA's proposal to more specifically apply emission limitations for CO and PM to each biomass boiler type. However, the Department does have a preferred approach as discussed below. The Department supports EPA's approach because the emission levels of these pollutants are specific to the subcategory sources: CO based on combustion configuration for each boiler type and metals (PM surrogate) based on metal content of the site specific biomass along with the particulate control device. In this latter case, the metals content of kiln-dried biomass is likely very low compared to biomass exposed to the environment. In considering this further, metals content between biomass types will also vary with the length of time it is exposed to the environment. For example, metals accumulating through deposition will be found in increased amounts on tree bark versus on crops harvested annually such as sugar cane. Similar, trends are likely seen for metals taken up from soils – the older biomass may have increased concentrations.

Response: The EPA thanks the commenter for their support.

Comment Excerpt Number: 1

Comment: We are pleased that EPA segregated biomass boilers by design type under the Major Source Boiler MACT Rule. This segregation better reflects the capabilities of the various boiler designs. The clear separation of biomass from coal units has provided particulate emission limits that better reflect the capabilities of units burning coal and biomass.

Response: The EPA thanks the commenter for their support.

Commenter Name: Bill Lane

Commenter Affiliation: American Home Furnishings Alliance (AHFA)

Document Control Number: EPA-HQ-OAR-2002-0058-3676-A2

Comment Excerpt Number: 1

Comment: AHFA strongly supports EPA's proposal to establish a new subcategory for units designed to burn kiln-dried biomass. For nearly a century, the wood furniture manufacturing industry has used kiln-dried wood containing less than 20% moisture to generate heat and steam. By combusting kiln-dried biomass in steam-generating boilers, the wood furniture industry avoids the need to rely upon fossil fuels (coal, oil, or gas) for process and domestic heating purposes. By minimizing fossil fuel consumption, our industry has been avoiding a potentially significant source of greenhouse gas emissions for over a century. Our use of this biomass energy resource is consistent with sustainable business practices and EPA goals for reducing emissions of greenhouse gases. Combustion of clean "off-fall" from the furniture manufacturing process for energy recovery purposes also avoids the disposal of this valuable material in landfills.

Due to the unique characteristics of kiln-dried wood, our industry boilers have been sized differently and designed differently to maximize efficiency for the combustion of dry biomass. In addition, our fuel feed systems are uniquely developed for dry storage and handling of wood off-fall. It is clearly appropriate for EPA to designate a new subcategory for this discrete group of boilers.

Response: The EPA thanks the commenter for their support.

Commenter Name: Michael Cassidy

Commenter Affiliation: Kohler Co.

Document Control Number: EPA-HQ-OAR-2002-0058-3803-A1

Comment Excerpt Number: 2

Comment: Kohler Co. agrees with and supports EPA's proposed expansion of boiler/process heater subcategories, especially the inclusion of the kiln dried biomass subcategory.

Response: The EPA thanks the commenter for their support.

Commenter Name: Arthur N. Marin

Commenter Affiliation: Northeast States for Coordinated Air Use Management (NESCAUM)

Document Control Number: EPA-HQ-OAR-2002-0058-3506-A1

Comment Excerpt Number: 14

Comment: Another example of inappropriate parsing of emissions data is the creation of wet and dry biomass fuel subcategories. In principle, NESCAUM does support having separate categories for wet and dry biomass fuel, because different moisture content in biomass fuel changes the CO emission profile of the fuel considerably. With proper emission control technologies installed, both wet and dry stokers units should be able to achieve large PM emission reductions. By creating subcategories for industries in which sources use kiln dried biomass fuel and have not installed adequate controls, the EPA is missing an opportunity to better control these sources.

Response: The EPA disagrees with the commenter's assertion that subcategorization into wet and dry biomass is unnecessary. Under CAA section 112(d)(1), the Administrator has the discretion to distinguish among classes, types, and sizes of sources within a category or subcategory in establishing standards. The EPA maintains that, normally, any basis for subcategorization (*i.e.*, class, type, or size) must be related to an effect on HAP emissions that is due to the difference in class, type, or size of the units. The commenter itself states that there are differences between wet and dry biomass. Facilities which combust kiln-dried biomass (*i.e.*, lumber) fuel are carefully integrated to utilize their available resources, and the combustion units are sized to efficiently combust biomass that has undergone a drying process. This drying process enhances the combustion quality of the fuel. The facilities monitor and maintain specific moisture levels in the fuel, typically to less than 2 percent. The differences between virgin biomass (timber/Green wood) and kiln-dried biomass warrant differing combustion styles and parameters for each fuel type, for which EPA believes subcategorization is justified.

Commenter Name: Paul Noe

Commenter Affiliation: American Forest & Paper Association (AF&PA) et al.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 62

Comment: Biomass Dry Stoker/Sloped Grate/Other. Stoker/sloped grate/other unit designed to burn dry biomass means the unit is in the units designed to burn biomass/bio-based solid subcategory that is either a stoker, sloped grate, or other combustor design and is not in the stoker/sloped grate/other units designed to burn wet biomass subcategory. The dry biomass stoker/sloped grate/other unit subcategory should not be limited to kiln-dried biomass, as there are other types of dry biomass, such as wood dried at plywood and other composite wood products manufacturing facilities in dryers.

Response: The subcategory is not limited to only kiln-dried biomass even though the subcategory is titled as such. As defined in the rule, combustion units designed to burn biomass or bio-based solid fuels may qualify for the Stoker/Sloped Grate/Other unit designed to burn kiln-dried biomass if the unit is either a stoker, sloped grate, or other combustor design and the moisture content of the biomass combusted is less than 20 percent on an annual heat input basis.

7C03. Biomass: Hybrid Suspension/Grate

Commenter Name: David A. Buff, Golder Associates Inc.

Commenter Affiliation: Florida Sugar Industry (FSI)

Document Control Number: EPA-HQ-OAR-2002-0058-3504-A1

Comment Excerpt Number: 8

Comment: The FSI agrees that it is appropriate and necessary for EPA to (a) establish a separate subcategory for hybrid suspension grate boilers designed to combust bagasse and (b) establish corresponding emission limits for PM, TSM, and carbon monoxide ("CO") that are based solely on the performance of the hybrid suspension grate boilers in this subcategory. The FSI's rationale for requesting this subcategory is summarized in the FSI's petition for reconsideration, which was filed with EPA on May 12, 2011. The FSI's petition for reconsideration demonstrates that a hybrid suspension grate boiler fired with bagasse faces

unique challenges that directly affect the boiler's emissions. The unique features of these boilers and their emission profiles warrant a separate subcategory and separate emission limits for PM, TSM, and CO.

Response: The EPA thanks the commenter for their support.

Commenter Name: David A. Buff, Golder Associates Inc.

Commenter Affiliation: Florida Sugar Industry (FSI)

Document Control Number: EPA-HQ-OAR-2002-0058-3504-A1

Comment Excerpt Number: 6

Comment: The FSI agrees with and strongly supports EPA's decision to create additional subcategories for solid fuels, including a subcategory for hybrid suspension grate boilers.

Response: The EPA thanks the commenter for their support.

Commenter Name: Paul Noe

Commenter Affiliation: American Forest & Paper Association (AF&PA) et al.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 64

Comment: Biomass Hybrid Suspension Grate. Hybrid suspension grate boiler means a boiler designed with air distributors to spread the fuel material over the entire width and depth of the boiler combustion zone. The biomass fuel combusted in these units exceeds a moisture content of 40 percent (annual average) on an as-fired basis. The drying and much of the combustion of the fuel takes place in suspension, and the combustion is completed on the grate or floor of the boiler. Fluidized bed, dutch oven, and pile burner designs are not part of the hybrid suspension grate boiler design category. We also request that the 40 percent fuel moisture content cutoff in the hybrid suspension grate subcategory specify that it is for biomass and that it is on an annual average basis in order to acknowledge the variability in biomass moisture content.

Response: The EPA thanks the commenter for their recommended revisions to the definition of the Hybrid Suspension/Grate subcategory. We agree that it is appropriate to define the moisture specification on an annual heat input basis rather than on an as-fired basis due to the inherent variability (i.e., annual basis) of the moisture content and to be consistent with the criteria listed for determining applicability of other subcategories. The specified revisions have been made to the definition in the rule.

Commenter Name: Robert D. Bessette

Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 7

Comment: In its Petition for Reconsideration, CIBO requested that the definition of a 'suspension/grate' boiler specifically include the words 'spreader stoker' as a type of combustion system in a suspension/grate boiler in addition to those with independent suspension burners.

The Proposed Reconsideration Rule states that “Stoker means a unit consisting of a mechanically operated fuel feeding mechanism, a stationary or moving grate to support the burning of fuel and admit under-grate air to the fuel, an overfire air system to complete combustion, and an ash discharge system. This definition of stoker includes air swept stokers. There are two general types of stokers: underfeed and overfeed. Overfeed stokers include mass feed and spreader stokers. Fluidized bed, dutch oven, pile burner, hybrid suspension grate, suspension burners, and fuel cells are not considered to be a stoker design.” 76 Fed. Reg. 80,655.

The Proposed Reconsideration Rule also indicates that EPA agrees that “dutch ovens and pile burners should be included in the same subcategory and suspension burners should be a separate subcategory. Therefore, the EPA is proposing separate emission limits for the combustion-based pollutants for these subcategories.” 76 Fed. Reg. 80609.

The Proposed Reconsideration Rule revised the definition of “hybrid suspension grate boiler” to include the italicized sentence:

a boiler designed with air distributors to spread the fuel material over the entire width and depth of the boiler combustion zone. *The fuel combusted in these units exceed a moisture content of 40 percent on an as-fired basis.* The drying and much of the combustion of the fuel takes place in suspension, and the combustion is completed on the grate or floor of the boiler. Fluidized bed, dutch oven, and pile burner designs are not part of the hybrid suspension grate boiler design category.

76 Fed. Reg. 80,652. This revision assists in better defining the source. CIBO recommends that the definition further specify that the moisture content be 40 percent on average, as the precise moisture content will fluctuate somewhat over time. CIBO suggests the addition in red below to the text:

The fuel combusted in these units exceed an average annual moisture content of 40 percent on an as-fired basis.

Response: For a response to the request for the moisture content in the definition of Hybrid Suspension Grate Boiler to be on an annual average basis, please see comment EPA-HQ-OAR-2002-0058-3251-A1, excerpt 64.

7C04. Biomass: Suspension burner

Commenter Name: Mark Weiss

Commenter Affiliation: Reciprocal Energy Company

Document Control Number: EPA-HQ-OAR-2002-0058-3658-A2

Comment Excerpt Number: 1

Comment: While we appreciate the changes reflected in the March 21st Rule Publication, we do not believe that the EPA has considered all of the relevant information pertaining to suspension combustion technology. We agree that suspension combustion should be treated within distinct biomass categories. The new, single, category is however too broad to accommodate significant variations within the suspension combustion field.

Response: The EPA disagrees that the single Suspension Burner subcategory is too broad. The commenter provided no information or data to support this assertion. The EPA does not believe that any significant variations within the Suspension Burner subcategory result in vastly different emission profiles.

Commenter Name: Mark Weiss

Commenter Affiliation: Reciprocal Energy Company

Document Control Number: EPA-HQ-OAR-2002-0058-3658-A2

Comment Excerpt Number: 4

Comment: The biomass fuel used in suspension combustion varies greatly by species and combustion particle size. No allowance is made for these variations yet they are primarily determinate of CO levels.

Response: For response to the claim that the single Suspension Burner subcategory is too broad, please see comment EPA-HQ-OAR-2002-0058-3658-A2, excerpt 1.

Commenter Name: M.L. Steele

Commenter Affiliation: CraftMaster Manufacturing, Inc.

Document Control Number: EPA-HQ-OAR-2002-0058-3814-A1

Comment Excerpt Number: 1

Comment: The "Suspension Burners" subcategory should include those units firing fine, dry, biomass particles in suspension that are conveyed in an airstream to the furnace like pulverized coal. This firing method. is described as "True Suspension" on page 15634 of the preamble to the March 21, 2011 final rules. The definition of "Suspension burner" instead describes "fuel distributors" and "injecting air at the point where the fuel is introduced ... in order to spread the fuel material over the boiler width." Also, the biomass fuel is described as "the wet fuel". These terms describe the "Air-swept Stoker". Then the current definition does not clearly include the True Suspension-fired units in the "Suspension Burner" subcategory and should be revised. The requested clarification would make the definition consistent with all the units evaluated by USEPA in the CO and PM MACT Floors. All "Suspension Burner" units are noted in the database as firing dry biomass.

Response: We agree with the commenter that the units evaluated in the MACT floor analysis for this final rule include "True Suspension" boilers as noted by the commenter and that these units are firing dry biomass materials. The references to the wet fuels and air-swept stoker fuel injection mechanisms were inadvertently left in the definition from the June 4, 2010 proposal. At that time, the suspension burner group included both these "True Suspension" units as well as hybrid suspension grate units. Since that proposal the hybrid suspension grate units now belong to a separate subcategory due to fundamental differences in their design. The EPA has revised the definition of suspension burner in the final rule to be consistent with the types of units it included in the data analysis for this subcategory.

7C05. Biomass: Dutch Oven/Pile Burner

Commenter Name: Paul Noe

Commenter Affiliation: American Forest & Paper Association (AF&PA) et al.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 61

Comment: Within the biomass subcategory, EPA is proposing different CO and PM limits for several boiler types – wet stoker, dry stoker, fluidized bed, fuel cell, and Dutch oven, suspension burner, and hybrid suspension grate units – due to design differences among these types of units. We agree with EPA’s decision to split Dutch ovens and suspension burners for regulation of CO emissions in the proposed rule. Dutch ovens and suspension burners are fundamentally different in design and fuel firing capabilities. Dutch ovens have two chambers. Solid fuel is dropped down into a refractory-lined chamber where drying and gasification take place in the fuel pile. Gases pass over a wall into the second chamber where combustion is completed. Dutch ovens are capable of burning high moisture fuels such as bark, but have low thermal efficiency and are unable to respond rapidly to changes in steam demand. Suspension burners combust fine, dry fuels such as sawdust and sanderdust in suspension. Rapid changes in combustion rate are possible with this firing method. They can be of watertube or firetube design, and may be package units or field-erected. It is not appropriate to combine these two types of boilers for CO standards given their very different characteristics.

Response: The EPA thanks the commenter for their support.

Commenter Name: M.L. Steele

Commenter Affiliation: CraftMaster Manufacturing, Inc.

Document Control Number: EPA-HQ-OAR-2002-0058-3814-A1

Comment Excerpt Number: 2

Comment: We question the need for separate subcategories for the Dutch Oven and Fuel Cell combustors. Wellons units are described as Fuel Cells in the literature but are found in the CO MACT Floor evaluations under Dutch Ovens as well as Fuel Cells. Konus units, another pile burner design, are listed in the Fuel Cell subcategory also. Interestingly Konus units also appear in the Stoker/ sloped grate/ other subcategory. These should be evaluated for a possible change in subcategorization.

Response: We disagree with the suggestion that there should be a single subcategory for Dutch Ovens and Fuel Cell combustors. Under CAA section 112(d)(1), the Administrator has the discretion to distinguish among classes, types, and sizes of sources within a category or subcategory in establishing standards. The EPA maintains that, normally, any basis for subcategorization (*i.e.*, class, type, or size) must be related to an effect on HAP emissions that is due to the difference in class, type, or size of the units. Based on the HAP emission data we have on these units, it is appropriate to have separate subcategories for these units. As part of the reconsideration process, we have redone the MACT floor analysis based on new data, corrected data, and changes in inventory. Several facilities which operate combustion units in one of these subcategories submitted comments specifying that their combustion units should be reclassified into another combustor design subcategory. The EPA accepted the comments from these facilities and processed the combustor design changes in the EPA ICR Databases.

7C06. Biomass: Wet Biomass Stoker/Sloped Grate/Other

Commenter Name: Paul Noe

Commenter Affiliation: American Forest & Paper Association (AF&PA) et al.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 63

Comment: Biomass Wet Stoker/Sloped Grate/Other. Stoker/sloped grate/other unit designed to burn wet biomass means the unit is in the units designed to burn biomass/biobased solid subcategory that is either a stoker, sloped grate, or other combustor design and more than 10 percent of the annual amount of biomass/bio-based solid fuel combusted in the unit exceeds 20 percent moisture (annual average, as-fired), on a heat input basis. The wet biomass stoker/sloped grate/other unit subcategory should be based on units burning at least 10 percent wet biomass on an annual basis (for consistency with other subcategories that have a 10 percent cutoff); the 20 percent moisture content specification should be based on an annual average basis, since the moisture content of dry biomass can vary (for example, lumber mills avoid over-drying the wood, a work practice that minimizes energy use and limits emissions).

Response: The EPA thanks the commenter for their recommended revisions to the definition of the Stoker/sloped grate/other unit designed to burn wet biomass subcategory. We agree that it is appropriate to define the moisture specification on an annual heat input basis due to the inherent variability (i.e., annual basis) of the moisture content and to be consistent with the criteria listed for determining applicability of other subcategories. In the final rule, the definition specifies that the biomass fuel must exceed 20 percent moisture on an annual heat input basis.

7D01. Liquid

Commenter Name: Sarah E. Amick

Commenter Affiliation: Rubber Manufacturers Association (RMA)

Document Control Number: EPA-HQ-OAR-2002-0058-3503-A1

Comment Excerpt Number: 15

Comment: Although EPA set separate emission limits for PM and CO for the light and heavy fuel subcategories, EPA did not set separate limits for Hg and HCl. Hg and HCl are fuel based pollutants. Light liquid fuels include distillate oil, biodiesel and vegetable oil. Heavy liquids include all other liquid fuels that are combusted in boilers, including byproduct liquid fuels generated at industrial facilities and residual oil. Because emissions of Hg and HCl are based on the type of fuel that is combusted, RMA recommends that EPA set separate emission limits for Hg and HCl for the light and heavy fuel subcategories.

Response: The Hg and HCl MACT floor emission limits for liquid boilers in the final rule are calculated from emissions data from both heavy and light liquid fuels. The EPA therefore disagrees with the commenter, as available emissions data show that the two types of fuels can exhibit similar emissions profiles for Hg and HCl. See the memorandum entitle "Revised MACT Floor Analysis (May 2012) for the Industrial, Commercial, and Institutional Boilers and Process Heaters National Emission Standards for Hazardous Air Pollutants – Major Source" in the docket.

Commenter Name: Robert D. Bessette
Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)
Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1
Comment Excerpt Number: 24

Comment: EPA seeks comment on whether Hg and HCl should have limits for heavy and light liquid fuels, not just all liquid. 76 Fed. Reg. 80608. CIBO has supported EPA subcategorizing for light versus heavy liquid fuels in both its comments on the proposed rule and in its Petition for Reconsideration. There are many technical arguments for this sub categorization to separate the liquid fuel units given that HAP content can vary greatly. Furthermore, as CIBO states in its Petition, units can purchase the highest costing liquid fuel available, that provides the lowest PM and CO emission, but cannot meet both the HCl and HG emission limits that EPA is imposing. If units are already using cleaner fuel, EPA should create a standard that holds that as sufficient to meeting limits.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3503-A1, excerpt 15.

Commenter Name: David L. Meeker
Commenter Affiliation: National Renderers Association (NRA)
Document Control Number: EPA-HQ-OAR-2002-0058-3476-A1
Comment Excerpt Number: 7

Comment: EPA should establish a unit designed to burn processed fats subcategory, wholly separate from units designed to burn liquid subcategory due to these units not being similar sources. There are two key definitions in determining the MACT Floor (Boiler MACT).

1. Similar source
2. Achieved in practice

As identified in *Sierra Club v. EPA*, the differentiation of broad source categories into subcategories is provided in the CAA itself, subject to reasonableness in the choice of subcategorization.⁷

Section 112(d)(1) authorizes the Administrator to "distinguish among classes, types and sizes of sources within a category or subcategory," and the language of subsections 112(d)(2) and (3) pervasively refers to standards for sources in each "category or subcategory." The authority to generate subcategories is obviously not unqualified; at the least it must be limited by the usual ideas of reasonableness. [Sierra Club v. EPA]

Following the direction in the CAA, EPA developed a definition for *similar source*.

Similar source means a stationary source or process that has comparable emissions and is structurally similar in design and capacity to a constructed or reconstructed major source such that the source could be controlled using the same control technology. [§63.41]

A separate subcategory is warranted because HAP emissions from petroleum-based liquid fuels include different constituents and are higher than the HAP emissions from processed fats, which

are insignificant, specifically for the metal HAP (including mercury), acid gas HAP (specifically HCl), and organic HAP emissions controlled under the Boiler MACT. The inclusion of processed fats in the broad "unit designed to burn light liquid" subcategory is not warranted due to the insignificant HAP emissions anticipated from the processed fats compared to petroleum-based liquid fuels.

[Footnote 7: *Sierra Club v. EPA* (intervenor Brick Industry Association) (03-1202).]

Response: The EPA disagrees that further subcategorization is necessary for units burning processed fats. Under CAA section 112(d)(1), the Administrator has the discretion to distinguish among classes, types, and sizes of sources within a category or subcategory in establishing standards. The EPA maintains that, normally, any basis for subcategorization (*i.e.*, class, type, or size) must be related to an effect on HAP emissions that is due to the difference in class, type, or size of the units. The EPA believes it is not reasonable to exercise our discretion without such a difference because if sources can achieve the same level of emissions reductions notwithstanding a difference in class, type, or size, the purposes of CAA section 112 are better served by requiring a similar level of control for all such units in the category or subcategory. Even if we determine that emissions characteristics are different for units that differ in class, type, or size, the Agency may still decline to subcategorize if there are compelling policy justifications that suggest subcategorization is not appropriate. Reported fuel analysis data in the EPA ICR Databases show that pollutant constituents in processed fats are similar when compared to other liquid fuels. For these reasons, the EPA does not believe a separate subcategory for units combusting processed fats is warranted.

Commenter Name: David L. Meeker

Commenter Affiliation: National Renderers Association (NRA)

Document Control Number: EPA-HQ-OAR-2002-0058-3476-A1

Comment Excerpt Number: 1

Comment: The Clean Air Act (CAA) Section 112(c)(1) requires emission units located at major source and area source applicable categories to be regulated. Section 112 of the CAA requires that, when setting HAP emission limitations for categories with more than 30 sources, EPA must determine "the average emission limitation achieved by the best performing 12% of the existing sources."

Where fewer than 30 sources exist in a category, EPA should rely upon "the average emission limitation achieved by the best performing five sources." However, before EPA can use the best performing five sources in setting its standard, it is required to analyze all sources "for

which the Administrator has or could reasonably obtain emissions information." The purpose of Section 112(d)(3) of the CAA is to establish the MACT Floor based on the top performers in the industry. Only by first adequately examining the entire industry can EPA evaluate which sources are among the best in their class.

EPA has gathered data for the liquid fuel-fired boiler subcategories (light and heavy) currently defined in NESHAP Subpart DDDDD. This data can then be used to craft an additional subcategory MACT Floor that complies with the requirements of the statute. Since EPA is not limited in establishing a specific total of subcategories for regulation under NESHAP Subpart DDDDD, the NRA is requesting a separate subcategory for units burning processed fats.

Response: For a response to the request for an additional subcategory for units burning processed fats, please see comment EPA-HQ-OAR-2002-0058-3476-A1, excerpt 7.

Commenter Name: David L. Meeker

Commenter Affiliation: National Renderers Association (NRA)

Document Control Number: EPA-HQ-OAR-2002-0058-3476-A1

Comment Excerpt Number: 2

Comment: NRA is submitting the request for a new "units designed to burn processed fats" subcategory under NESHAP Subpart DDDDD based on EPA's determination of the aforementioned proposed rule comment from an NRA member (Darling International Inc.).⁵ The proposed rule comment requested that processed fats not be considered as a solid waste, but instead a biomass solid fuel potentially subject to NESHAP Subpart DDDDD when burned in a boiler or process heater located at a major HAP source or area source, respectively. EPA noted that they agreed with the comment and subsequently added "liquid biofuels" to the definition of "liquid fuel" in the March 21, 2011 final rule at §63.11237 for NESHAP Subpart JJJJJ only. The NRA agrees with the EPA determination that processed fats are not solid waste, and are not considered a solid fuel (biomass) category under NESHAP Subpart DDDDD as identified in the response.

[Footnote 5: Boiler MACT proposed rule comment (Document Control Number EPA-HQ-OAR-2006-0790-1911.1) submitted by Barr Engineering Company and Darling International Inc.]

Response: For a response to the request for an additional subcategory for units burning processed fats, please see comment EPA-HQ-OAR-2002-0058-3476-A1, excerpt 7.

Commenter Name: David L. Meeker

Commenter Affiliation: National Renderers Association (NRA)

Document Control Number: EPA-HQ-OAR-2002-0058-3476-A1

Comment Excerpt Number: 5

Comment: A liquid fuel includes petroleum products, such as distillate oil, residual oil, any form of liquid fuel derived from petroleum products, on-spec used oil, biodiesel, and vegetable oil. These fuel types, other than vegetable oil, are different than processed fats in both origin and content and result in different HAP emissions when combusted in boilers and process heaters.

Processed fats are obtained from the recycling of animal (livestock) and plant (crop) related byproducts from the food processing industry. Processed fats fuel are utilized in the same liquid fuel-fired boilers that burn petroleum-based liquid fuels. No special designed burners are required for the burning of processed fats in liquid fuel-fired boilers. As identified in this letter, the HAPs content of processed fats are insignificant and similar to the HAPs content of Gas 1 fuels and not petroleum-based liquid fuels.

The NRA requests that the following two definitions be added to §63.7575 for NESHAP Subpart DDDDD.

Processed fats fuel means, but is not limited to, yellow grease, poultry grease, brown grease, tallow oil, and any form of liquid fuel derived from animal and vegetable fats, with less than 0.2% by volume petroleum-based fuel content added for alternative fuel blending requirements.

Unit designed to burn processed fats subcategory includes any boiler or process heater that burns any processed fats fuel, but less than 10 percent coal/solid fossil fuel, less than 10 percent biomass/bio-based solid fuel, and less than 10 percent liquid fuel on an annual heat input basis, either alone or in combination with gaseous fuels.

Response: For a response to the request for an additional subcategory for units burning processed fats, please see comment EPA-HQ-OAR-2002-0058-3476-A1, excerpt 7.

Commenter Name: David L. Meeker

Commenter Affiliation: National Renderers Association (NRA)

Document Control Number: EPA-HQ-OAR-2002-0058-3476-A1

Comment Excerpt Number: 6

Comment: The NRA wants to clarify the incorrect reference in the aforementioned proposed rule comment response and confirm EPA's non-classification of processed fats as a biomass (solid) fuel under the major source rule. Specifically, the comment submitted to EPA by Darling International Inc. (NRA member) focused on processed fats not being defined as solid waste (and subject to CISWI rule) and identified the material as worthy of inclusion within a "biomass" fuel subcategory and definition under the Boiler MACT, NESHAP Subpart DDDDD and Boiler GACT, NESHAP Subpart JJJJJ based on the proposed version of each of those rules, which is admittedly different than the reconsidered version being commented on in this letter. EPA did not define the material as a solid biomass, and the NRA agrees with this determination as the fuel is not a solid fuel with HAP content or combustion characteristics similar to biomass solid fuels.

The NRA confirms processed fats are renewable energy materials derived from vegetable (plants) and animal (livestock) sources that have a short-term carbon cycle. The processed fats periodic availability to displace a fraction of fossil fuel demand makes the fuels a renewable fuel, but does not require processed fats to be defined as a biomass solid fuel. The regulation of processed fats as a biomass fuel under NESHAP Subpart DDDDD will result in NRA member facilities not using this renewable fuel due to more stringent control requirements for biomass fuels compared to other fossil fuels (i.e., petroleum-based liquid fuels).

Response: The EPA thanks the commenter for their support of not classifying processed fats as a solid bio-based fuel. For a response to the request for an additional subcategory for units burning processed fats, please see comment EPA-HQ-OAR-2002-0058-3476-A1, excerpt 7.

Commenter Name: David L. Meeker

Commenter Affiliation: National Renderers Association (NRA)

Document Control Number: EPA-HQ-OAR-2002-0058-3476-A1

Comment Excerpt Number: 8

Comment: Included [see submittal for Table 1] is a summary of six processed fat samples analyzed for the metal HAP content. Specific processed fats analyses available for this comment

letter include yellow grease (three samples), poultry grease (one sample), and tallow (two samples).

The metal HAP content in the processed fats were "non-detect" or below detection levels for each pollutant, except lead and manganese. The NRA assumes the different ASTM analysis methodologies are the reason for the anomalies concerning the lead and manganese content measured in samples. Specifically, the lead and manganese content in the yellow grease No. 2 and tallow No. 2 samples were measured using ASTM D 3683. However, the lead and manganese content in three processed fats samples were measured using ASTM E 1613, and one other sample content was measured using ICAP method. The sample set indicates confidence that the metal content of the processed fats samples is insignificant and is comparable to the metal HAPs emitted from units designed to burn Gas 1 fuels (Gas 1 units) as identified [see submittal for Table 2]. With a similar minimal metal HAP content to Gas 1 units, the processed fats-fired boilers do not result in significant metal HAP emissions required to be subject to emissions limitations under NESHAP Subpart DDDDD.

Response: The fuel analysis samples were not incorporated into the EPA ICR Databases because they could not be attributed to a specific facility. For a response to the request for an additional subcategory for units burning processed fats, please see comment EPA-HQ-OAR-2002-0058-3476-A1, excerpt 7.

Commenter Name: David L. Meeker

Commenter Affiliation: National Renderers Association (NRA)

Document Control Number: EPA-HQ-OAR-2002-0058-3476-A1

Comment Excerpt Number: 10

Comment:

Since the processed fats samples metal HAP emissions are drastically different in type and quantities than the petroleum-based liquid fuels, the boilers burning these two types of fuels are not similar sources. Due to the fuels not being identified as similar sources, the NRA requests that the processed fats be categorized as a separate liquid fuel subcategory.

Response: The fuel analysis samples were not incorporated into the EPA ICR Databases because they could not be attributed to a facility. For a response to the request for an additional subcategory for units burning processed fats, please see comment EPA-HQ-OAR-2002-0058-3476-A1, excerpt 7.

Commenter Name: Lorraine Gershman

Commenter Affiliation: American Chemistry Council (ACC)

Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1

Comment Excerpt Number: 156

Comment: *EPA SHOULD CLARIFY THE DEFINITION OF LIQUID FUEL*

The definition of "liquid fuel" at § 63.7575 currently includes the words "on-spec used oil," but "on-spec used oil" is not defined in the Final Boiler Rule. Congress recognized that in

establishing air standards to meet requirements in the CAA and RCRA, there may be regulatory overlaps between the two statutes. Congress therefore intended for EPA to minimize, if not eliminate regulatory overlap to the maximum extent practicable and to harmonize requirements so that they are consistent. See, for example, § 112(n)(7) of the CAA and § 1006(b) of RCRA. Based on these Congressional directives, ACC believes that EPA should delete the term “on-spec used oil,” as the Boiler MACT rule fails to define “on-spec,” and instead use the term “used oil” which is a defined term in RCRA at 40 CFR 279.11.

Response: We agree with the commenter that the definition of used oil under RCRA at 40 CFR 279.11 is appropriate and we have removed the phrase on-spec from the definition of liquid fuel in the final rule. This change does not impact the makeup of the subcategories or the MACT floor analysis and does not suggest that used oil is or is not solid waste.

Commenter Name: Matthew Todd

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 30

Comment: The 10% liquids allowance in the Gas 2 subcategory should be reflected in the liquid subcategory definitions.

The definitions of “unit designed to burn gas 2 (other) subcategory” and “unit designed to burn liquid subcategory” are provided in Table 1, above. [See submittal for Table 1. Comparison of BPH NESHAP Gas and Liquid Subcategory Definitions]

Under these definitions a boiler or process heater that burns Gas 2 and up to 10% liquid would be in both subcategories, an obviously untenable position. The “unit designed to burn liquid subcategory” definition must be modified to exclude boilers and process heaters meeting the Gas 2 subcategory definition if the 10% allowance is not provided for both gas subcategories as discussed in the previous comment.

Response: The EPA agrees with the commenter's concerns. The definitions of Unit Designed to Burn Gas 2 (Other) Subcategory and Unit Designed to Burn Liquid Subcategory have been revised in the final rule. The EPA believes the revised definitions removes the ability for units to demonstrate simultaneous classification within the gaseous and liquid subcategories.

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 25

Comment: Dividing the liquids subcategory reflects real differences between equipment firing light and heavy liquids.

EPA is proposing to subdivide the current liquid fuels subcategory into separate subcategories for heavy liquid-fired and light liquid-fired BPH for PM and CO, pollutants whose emissions are dependent on combustor design and BPH operation. A single liquid fuels subcategory will remain in place for Hg and HCl, pollutants whose emissions are dependent on fuel composition. Separating subcategories for light and heavy liquid fuels reflects real differences in how light and heavy liquids are handled and differences in fuel system and burner designs associated with the differences in the overall physical properties of the fuel and thus we support this proposed change.

Response: The EPA thanks the commenter for their support.

Commenter Name: David L. Meeker

Commenter Affiliation: National Renderers Association (NRA)

Document Control Number: EPA-HQ-OAR-2002-0058-3476-A1

Comment Excerpt Number: 4

Comment: And thus, by considering liquid biofuels as a light liquid for the Boiler MACT, any boiler or process heater combusting processed fats at a major HAP source is grouped in the "light liquid subcategory" and the "unit designed to burn light liquid subcategory" defined in §63.7575.

The NRA requests that EPA evaluate the impact of this "grouping" and consider the pertinent information presented in this letter that demonstrates that it is both reasonable and technically necessary for EPA to consider processed fats as a separate subcategory that is wholly distinct from petroleum-based oils and other liquid biofuels.

Response: For a response to the request for an additional subcategory for units burning processed fats, please see comment EPA-HQ-OAR-2002-0058-3476-A1, excerpt 7 under the chapter for Liquid.

7D03. Heavy Liquid

Commenter Affiliation: Rubber Manufacturers Association (RMA)

Document Control Number: EPA-HQ-OAR-2002-0058-3503-A1

Comment Excerpt Number: 4

Comment: Residual fuel oils also have significantly different firing properties than do distillate fuel oils. The combustion characteristics of light and heavy liquids are different, because these fuels have very different flow/viscosity and atomization characteristics and different energy contents. As a result of these property differences, at a minimum, heavy fuel oil firing requires different burner tips than are needed when firing lighter fuel oils. The heating value and flame height differences between these fuels may also impose unit design and operating constraints.

Response: The EPA acknowledges this comment.

Commenter Name: Sarah E. Amick

Commenter Affiliation: Rubber Manufacturers Association (RMA)

Document Control Number: EPA-HQ-OAR-2002-0058-3503-A1

Comment Excerpt Number: 5

Comment: Residual fuel-fired boilers must operate a soot blowing cycle on a periodic basis to maintain their heat transfer efficiency, during which opacity and PM levels increase. While the database does not appear to include any data characterizing soot blowing emissions from liquid-fired units, the proposed emission limits would apply during that time and thus these emissions must be considered. It is, therefore, clear that metal HAP and PM emissions at least, distinguish residual fuel-fired units from distillate-fired units. Indeed, EPA recognized this fact by creating an implicit subcategory for residual-fuel fired units in the rule by requiring in § 63.7525 that residual oil-fired process heaters and boilers (but not distillate units) install a PM CPMS.

Thus, from an equipment design and operations standpoint as well as an emissions standpoint, there is a clear distinction between boilers and process heaters firing light liquids versus those that fire heavy liquids.

Response: The EPA thanks the commenter for their support.

Comment Excerpt Number: 28

Comment: In addition, residual fuel-fired boilers must operate a soot blowing cycle on a periodic basis to maintain their heat transfer efficiency, during which opacity and PM levels increase. While the liquids database does not appear to include any data characterizing soot blowing emissions, the proposed emission limits would apply during that time and thus these emissions must be considered. It is, therefore, clear that metal HAP and PM emissions distinguish residual fuel-fired units from distillate-fired units. Indeed, EPA has recognized this fact by creating an implicit subcategory for residual-fuel fired units in the rule by requiring in §63.7525 that residual oil-fired process heaters and boilers (but not distillate units) >250 MMBtu/hr install a PM CPMS.

Thus, from an equipment design and operations standpoint as well as an emissions standpoint, there is a clear distinction between boilers and process heaters firing light liquids versus those that fire heavy liquids. EPA has appropriately subcategorized these units.

Response: The EPA thanks the commenter for their support.

Comment: Residual fuel oils typically contain higher levels of ash and somewhat higher levels of metals³⁸ than do distillate fuel oils. The combination of these characteristics means that residual fuel oil-fired boilers and process heaters have higher emissions of metal HAPs and PM than boilers and process heaters burning distillate fuel oils (light liquid fuels).[Footnote 38: See AP-42 factors for oil firing, Section 1.3.1. However, HAP metals content in residual fuel oil is strongly influenced by crude oil processed at a given refinery, because these metals volatilize only at very high temperatures and thus typically stay in the bottoms in crude units or in Vacuum units. Thus, the level of metals in a crude oil will be directly related to the metals in residual fuel oil. AP-42, Volume I, Fifth Edition, Section 1.3.1, <http://www.epa.gov/ttn/chief/ap42/>]

Comment: Residual fuel oils also have significantly different firing properties than do distillate fuel oils. The combustion characteristics of light and heavy liquids are different, because these

fuels have very different flow/viscosity and atomization characteristics and different energy contents. As a result of these property differences, at a minimum, heavy fuel oil firing requires different burner tips than are needed when firing lighter fuel oils. The heating value and flame height differences between these fuels may also impose unit design and operating constraints.

Response: The EPA acknowledges this comment.

Comment Excerpt Number: 3

Comment: EPA should consider allowing an additional subcategory of heavy liquid fuels that combust residual fuels or byproducts to meet the non-continental liquid units CO limit of 18 ppm limit or a 91 ppm limit with an averaging time of 10 days or increase the CO limit for units that combust residual fuels or byproducts to something more applicable to the type of fuels combusted.

Response: The EPA disagrees that separate subcategorization is needed for units combusting process-specific residual-type liquid fuels. The EPA ICR Databases contain emissions data from these units, and the EPA must set emissions limitations based on emissions information available to the Administrator. Based on the data, CO emissions limits were calculated for CO for the heavy liquid subcategory. The EPA established the non-continental liquid subcategory because the non-continental liquid units face several unique challenges that prohibit them from operating similarly to continental liquid units.

Comment Excerpt Number: 23

Comment: In direct response to EPA's specific request for "comment on whether additional subcategories are appropriate", as alternatives NNS proposes the following:

(1) NNS requests that EPA amend §63.7499 of the Boiler MACT by adding a new subcategory for test steam boilers and that EPA simultaneously establish limited, corresponding requirements for the new test steam boiler subcategory by amending §63.7500, as follows: §63.7499 (t) Test steam boilers used to provide steam for testing the propulsion systems on military vessels. §63.7500 ([paragraph number as appropriate]) Test steam boilers must complete a tuneup as specified in §63.7540 prior to each period of vessel steaming. They are not subject to the emission limits in Tables 1 and 2 to this subpart, the annual tune-up requirement in Table 3 to this subpart, or the operating limits in Table 4 to this subpart.

(2) Or, in the alternative, NNS requests that EPA affirm that NNS' FTFSF test steam boilers are exempt from the Boiler MACT pursuant to the provision at 40 CFR §63.7491(c), in that the FTFSF is test equipment used for research and development.

(3) Or, in the alternative, NNS requests an Applicability Determination by EPA that affirms that NNS' FTFSF test steam boilers are not within the class of industrial, commercial, or institutional boilers that EPA studied in its development of MACT Subpart DDDDD regulations and that EPA intended to regulate under Subpart DDDDD, and accordingly that NNS' FTFSF test steam boilers are not to be included among the sources affected by Subpart DDDDD.

Response: In the final rule, the exemption for boilers or process heaters used specifically for research and development has been revised to clarify that test steam boilers used to provide steam for testing the propulsion systems on military vessels are included in the definition. Please see §63.7491 for the exemption.

Comment: The NNS Floating Test Steam Facility (FTFSF) boilers are marine boilers utilized in a unique manner and are not designed, constructed or operated like industrial, commercial or

institutional boilers. The NNS FTFSF marine boiler facility is the only one of its kind, a unique tool designed to test the steam systems of nuclear powered aircraft carriers after new construction or refueling and overhaul. This facility is unique to NNS, because NNS is the nation's sole manufacturer and refueler of nuclear-powered aircraft carriers. The FTFSF boilers are marine boilers, not conventional industrial boilers. They were manufactured by Combustion Engineering in 1977 and were originally designed and built for shipboard use to propel a bulk oil cargo ship. The FTFSF marine boilers are floating, barge-mounted units. The FTFSF barge includes integral storage of over 500,000 gallons of No. 6 fuel oil below deck. While the FTFSF marine boilers are operating, the FTFSF barge can be resupplied with No. 6 fuel oil from a fuel delivery barge at fuel flow rates exceeding 3,000 gallons per minute. Marine boilers in general have characteristics of design, construction and operation which differ considerably from those of conventional industrial, commercial or institutional boilers.

Response: The EPA acknowledges this comment. For a response to the request for an exemption for the NNS Floating Test Steam Facility boilers and corresponding changes to rule language, please see comment EPA-HQ-OAR-2002-0058-3548-A2, excerpt 23.

Comment: The NNS Floating Test Steam Facility (FTFSF) boilers are marine boilers utilized in a unique manner and are not designed, constructed or operated like industrial, commercial or institutional boilers.

The FTFSF marine boilers are designed to achieve exceptionally high "ramping rates". "Ramping rate" refers to a boiler's ability to respond within seconds to minutes to drastic load transients (changes in steam demand), as would be experienced when a ship is maneuvering (e.g., when a carrier is conducting flight operations). The FTFSF marine boilers meet the following Navy performance requirements (among others which cannot be identified here for national security reasons):

- a. Meet transient loads of a baseload of 20,000 Lb/hr increasing to 100,000 Lb/hr in 2 minutes.
- b. Meet transient loads of a baseload of 20,000 Lb/hr increasing to 200,000 Lb/hr in 4 minutes.
- c. Increase load in 100,000 Lb/hr increments in 45 seconds.
- d. Decrease load from 100% to 0% in 35 seconds.
- e. Transient load change shall be accomplished without a boiler shutdown or delivered steam pressure dropping below 580 psig (pounds per square inch gauge).

Comment: The NNS Floating Test Steam Facility (FTSF) boilers are marine boilers utilized in a unique manner and are not designed, constructed or operated like industrial, commercial or institutional boilers.

The steam pressure and temperature must be maintained in line to the aircraft carrier during “24/7” testing, as well as when there is no user demand for up to 2 weeks. Industrial boilers would be shut down in such cases. The FTSF marine boilers cannot be shut down and must be maintained in a “ready” state at all times.

Response: The EPA acknowledges this comment. For a response to the request for an exemption for the NNS Floating Test Steam Facility boilers and corresponding changes to rule language, please see comment EPA-HQ-OAR-2002-0058-3548-A2, excerpt 23.

Comment: The NNS Floating Test Steam Facility (FTSF) boilers are marine boilers utilized in a unique manner and are not designed, constructed or operated like industrial, commercial or institutional boilers.

Many of the specifications governing the steam delivered by the FTSF marine boilers to an aircraft carrier are prohibited from release by NNS. The protections afforded under EPA

regulations at 40 CFR Part 2 Subpart B - Confidentiality of Business Information do not provide the protections required by the U.S. Department of Defense (DoD) and the Naval Nuclear Propulsion Program. The existence of such specifications further underscores the uniqueness of the FTSF marine boilers and sets them apart from boilers providing steam to industrial manufacturing processes.

Response: The EPA acknowledges this comment. For a response to the request for an exemption for the NNS Floating Test Steam Facility boilers and corresponding changes to rule language, please see comment EPA-HQ-OAR-2002-0058-3548-A2, excerpt 23.

Comment: The NNS Floating Test Steam Facility (FTSF) boilers are marine boilers utilized in a unique manner and are not designed, constructed or operated like industrial, commercial or institutional boilers.

The FTSF marine boilers are designed to achieve a higher “turndown” ratio than is typical or necessary of industrial boilers. “Turndown” is defined as the ratio of a burner’s maximum firing capability (in BTU/hr) to the burner’s minimum firing capability (in BTU/hr). High turndown ratios are intended for boilers that must operate over a wide range of capacities or demands, in contrast to industrial boilers that are intended to operate at steadier loads to achieve optimum efficiency. Conventional industrial watertube boilers firing No. 6 fuel oil would be expected to achieve a turndown ratio of no more than about 4:1 (meaning that the boiler cannot be operated below about 25% of full load without combustion becoming unstable and causing the boiler to shut down). The FTSF marine boilers must achieve a much higher turndown ratio to help ensure that the FTSF boilers do not shut off, or “trip”, when operated over a wide range of rapidly varying steam loads.

Comment: The NNS Floating Test Steam Facility (FTSF) boilers are marine boilers utilized in a unique manner and are not designed, constructed or operated like industrial, commercial or institutional boilers.

In conventional use marine boilers are located onboard a vessel and generate steam used by the vessel's propulsion system for moving the ship through the water, by turbine generators for creating electrical power, by water heating systems for personnel and by other steam-driven systems. It is well established that marine boilers used in such a manner are not considered to be stationary sources and are not regulated by EPA as stationary sources. The FTSF operates in an analogous manner and generates steam for the same general purposes, the difference being that the steam generated onboard the FTSF vessel is not delivered to systems onboard the FTSF as described above, but rather is delivered by flexible piping to the same types of systems onboard an adjacent vessel, an aircraft carrier.

Response: The EPA acknowledges this comment. For a response to the request for an exemption for the NNS Floating Test Steam Facility boilers and corresponding changes to rule language, please see comment EPA-HQ-OAR-2002-0058-3548-A2, excerpt 23.

Comment Excerpt Number: 10

Comment: The steam condensate systems of the NNS Floating Test Steam Facility (FTSF) boilers differ materially from those of most industrial boilers. Steam condensate generated on an aircraft carrier during normal operation at sea is recycled to the onboard steam generating system. However, during RCOH the steam condensate will contain small amounts of dissolved and particulate matter as new system components and piping are brought online for the first time and flushed with steam. Many aircraft carrier steam plant components have very low tolerance specifications for any foreign materials, preventing the condensate from being recycled in such cases and requiring that the condensate be dumped for extended time periods. Therefore, the FTSF marine boilers are designed to handle and are operated at the full range of condensate return, from zero (dumping all condensate) to 100 percent (full recycle of all condensate), requiring that the boiler feedwater treatment and supply system be over-engineered to handle once-through feedwater at maximum system flow and requiring that special boiler feedwater

treatment chemistry be utilized. This aspect of operation differs significantly from most industrial, commercial or institutional boiler systems, where the amount of condensate return is designed to be within a certain range and where the boiler's associated feedwater and treatment systems are sized for that given amount of condensate return. Industrial, commercial or institutional boiler systems that achieve a substantial amount of condensate return, for example, are not intentionally over-designed to handle once-through feedwater at zero condensate return, as are the FTFSF boilers. Additionally, the return of less than 100 percent of the steam condensate to the FTFSF boilers significantly reduces the energy efficiency of the boilers, demonstrating the limited value of an energy assessment or boiler tune-ups for the FTFSF boilers. The information provided above demonstrates that the FTFSF marine boilers are not within the class of boilers contemplated by EPA to be regulated in the development of MACT regulations for industrial, commercial, and institutional boilers.

Response: The EPA acknowledges this comment. For a response to the request for an exemption for the NNS Floating Test Steam Facility boilers and corresponding changes to rule language, please see comment EPA-HQ-OAR-2002-0058-3548-A2, excerpt 23.

Comment Excerpt Number: 11

Comment: The energy efficiency of the NNS Floating Test Steam Facility (FTFSF) boilers is not a factor in their design or operation, and operation at highest efficiency is detrimental to their required performance. Industrial, commercial or institutional boilers and the steam systems they supply are designed to operate at or near peak thermal efficiency and with minimal variation in load when possible. Many such steam plants utilize more than one boiler so that most of the boilers can be "base loaded" to achieve the desired efficiency and steady-state operation goals, while utilizing only one or a few boilers to "float" with the variable portion of the facility's steam load. In stark contrast, the FTFSF steam load is intentionally varied over an extremely wide range to simulate aircraft carrier mission requirements. The sole purpose of the FTFSF marine boilers is to provide steam in direct response to an aircraft carrier's demand for steam during testing of its propulsion systems, which simulates steam demand conditions that would be encountered by the carrier in carrying out its military mission. Therefore, the FTFSF marine boilers are designed and operated to reliably respond to extreme variability in steam loads. Prior to each carrier steaming event, the FTFSF boilers are tuned in a specific manner to ensure that they will meet the steam demand requirements over their full range of operation. They are not intentionally operated or maintained at or near their point of highest efficiency or lowest fuel usage and cost, and to do so would preclude their ability to deliver steam in the manner necessary to successfully conduct propulsion plant testing. Combustion efficiency is not a factor that is, or can reasonably be, considered as an operating parameter while operating the FTFSF marine boilers in accordance with aircraft carrier testing requirements. Although it is feasible to conduct the one-time energy assessment and annual boiler tune-ups required by the Boiler MACT, these studies would yield little information useful to minimizing emissions from the FTFSF marine boilers or for adjusting the operation of the boilers to improve efficiency.

Response: The EPA acknowledges this comment. For a response to the request for an exemption for the NNS Floating Test Steam Facility boilers and corresponding changes to rule language, please see comment EPA-HQ-OAR-2002-0058-3548-A2, excerpt 23.

Comment Excerpt Number: 12

Comment: The NNS Floating Test Steam Facility (FTSF) marine boilers are used in research and development and should not be subject to the Boiler MACT. The FTSF marine boiler barge is essentially considered to be “a piece of test equipment” for the Navy’s fleet of aircraft carriers. As explained above, the sole purpose of the FTSF marine boilers is to provide “test steam” to an aircraft carrier for a temporary period to test its steam-driven equipment and systems. In fact, during original permitting in 1985 the name of this barge-mounted system was intentionally chosen to be “Floating Test Steam Facility”, reflecting its design and use as test equipment. The use of these boilers qualifies as research and development (R&D), because each RCOH includes the design, installation, testing, evaluation and potential redesign of various propulsion system technologies that have been developed over the 25-year period since the carrier was first commissioned and placed into service. The aircraft carrier cannot be returned to the Navy as a fully operating ship until all newly installed technologies have been successfully operated and certified. The Boiler MACT regulations at §63.7491(c) specifically exempt boilers that are used for research and development. Notwithstanding the fact that the FTSF marine boilers are located at a major source and may appear to fit the definitions of “boiler” and “industrial boiler” contained within the Boiler MACT, NNS believes that its FTSF marine boilers are used for research and development and should be exempt from the Boiler MACT pursuant to the provision at 40 CFR §63.7491(c).

Response: The EPA acknowledges this comment. For a response to the request for an exemption for the NNS Floating Test Steam Facility boilers and corresponding changes to rule language, please see comment EPA-HQ-OAR-2002-0058-3548-A2, excerpt 23.

Comment Excerpt Number: 13

Comment: The NNS Floating Test Steam Facility (FTSF) marine boilers are portable units and are not stationary sources subject to the Boiler MACT. The Boiler MACT emission limitations are established pursuant to §112 of the Clean Air Act, whose scope of authority is limited to stationary sources. As explained earlier, NNS constructed the FTSF as a portable steam generating facility by mounting two residual oil-fired marine boilers on a specially designed barge. When testing of an aircraft carrier's steam-driven systems is ready to begin, the FTSF barge is moved by tugboat over open water from its storage location and is positioned adjacent to the aircraft carrier at its designated waterfront locations. The steam and condensate piping that connects the FTSF to the aircraft carrier is flexible, and the FTSF floats with the tide and is

subject to wave action while operating. As previously described the FTSF is a vessel. It permanently resides in the James River along the NNS shipyard waterfront, except during periods of dry-docking for hull inspection, hull recoating and repairs, and is used in a portable manner to supply steam to another vessel, also located in the James River. Although NNS obtained an air permit to construct and operate the FTSF boilers in 1985 from the Virginia Department of Environmental Quality (DEQ), it is arguable that the FTSF boilers are not stationary sources and should not have received a permit under the stationary source regulations. NNS believes that the fact that the DEQ issued a minor New Source Review permit for the FTSF boilers does not render this argument moot with respect to Boiler MACT applicability, and that the EPA can properly determine that, for the particular purpose of determining Boiler MACT applicability, the FTSF is not a stationary source subject to the Boiler MACT. Notwithstanding the question of applicability of stationary source regulations to the FTSF boilers in general, it remains that the FTSF boilers reside on a portable barge located in the James River and are utilized in a manner unlike any of the industrial, commercial or institutional boilers examined by EPA during its development of the Boiler MACT regulations or contemplated by EPA for regulation under the Boiler MACT. Furthermore, the FTSF marine boilers are utilized only for a limited period on an intermittent schedule repeating every few years, depending on the Navy's schedule for overhauling its fleet of nuclear aircraft carriers, and the FTSF marine boilers are shut down, relocated and made non-operational in the period between carrier overhauls. The periodic operation of the portable FTSF with intervening shutdown periods of several years is normal for these test steam boilers, which is unlike industrial boilers which usually are operated year-round or annually on a seasonal basis.

Response: The EPA acknowledges this comment. For a response to the request for an exemption for the NNS Floating Test Steam Facility boilers and corresponding changes to rule language, please see comment EPA-HQ-OAR-2002-0058-3548-A2, excerpt 23.

Comment Excerpt Number: 15

Comment: Retrofitting the NNS Floating Test Steam Facility (FTSF) marine boilers to combust natural gas as a compliance option has not been determined to be safe or feasible. If the FTSF marine boilers combusted natural gas or propane, no numeric emission limits would apply pursuant to the Boiler MACT, and compliance with the Boiler MACT would only require an energy assessment and annual tune-ups. Therefore, NNS is currently evaluating the feasibility of converting its FTSF marine boilers from No. 6 fuel oil to natural gas or propane. The original boiler manufacturer, Combustion Engineering, no longer exists, and its successor owner no longer designs, services or supports marine boilers. Therefore, NNS sought and has retained the services of other firms experienced in steam power generation to assist NNS in its evaluation. After ten months of extensive research, NNS is not able to state at this time that such a fuel conversion can be technically and safely accomplished within allowable timeframes. Significant additional study, including collection of boiler internal temperatures and metallurgical data, will be required before a conversion to a gaseous fuel can be determined to be feasible. Due to the Navy's long term planning and contracts, the FTSF marine boilers are already scheduled for specific aircraft carrier steaming events for at least the next ten years (into the year 2021).

During that 10-year timeframe, the FTSF marine boilers are only shutdown and available for maintenance for three separate limited periods. The Navy's schedule allows very little time to remove the boilers from service, make the fuel conversions, test the modified equipment, and return the boilers to successful operation prior to the next scheduled steaming event. For example, combustion of a fuel of a vastly different nature than that for which the FTSF marine boilers were originally designed is not simply a matter of replacing the oil burners with gas burners, but rather requires detailed engineering studies and boiler modifications that will require a significant amount of time to complete. Examples of matters that must be evaluated and resolved include, among others:

- fuel combustion aspects (e.g., differences in gas flame size and shape compared to oil; potential impingement of the gas flame causing damage to the waterwall tubes due to the short firebox design of these boilers; and differences in radiative and convective heat transfer characteristics of the gas flame which presents a possibility of out-of-range operating temperatures in the main combustion zone, the superheater tubes and the main steam generating tubes);
- the need for a thorough inspection of the boilers' internals to determine the boilers' ability to withstand changes in combustion characteristics and internal operating temperatures;
- practical limits on achievable volumetric heat release rate within the existing furnace firebox;
- the potential need for an economizer to allow for any required reduction in burner size driven by the aforementioned heat release rate limitation issues;
- achievable turndown ratio;
- the availability of natural gas in the quantities needed and without supplier interruption during seasonal high-demand periods concurrent with carrier steaming operations;
- the ability of the FTSF marine boilers to meet NSPS Subpart Dc industrial boiler emission limits for NO_x;
- the feasibility of adding post-combustion NO_x controls (such as selective catalytic reduction, or "SCR") if the NSPS Subpart Dc NO_x emission limit cannot be directly achieved by the FTSF marine boilers through burner design and combustion control;
- whether combustion control driven by NO_x emission concerns will affect the ability of the boilers to meet Navy transient steam load specifications;
- the safety of using natural gas in boilers not designed for gaseous fuel; and
- the safety of using natural gas below deck in a barge with numerous confined spaces and ignition sources.

NNS has not yet been able to determine the feasibility of conducting the above work and successfully converting the FTSF marine boilers to gas-1 subcategory units without delaying the Navy's RCOH schedule. Also, NNS cannot yet fully determine the cost of converting the FTSF marine boilers to gas-1 subcategory units, because most of the concerns described above have not yet been resolved. Regardless of the ultimate estimated cost, if add-on SCR emission control equipment were ultimately required to meet NSPS Subpart Dc NO_x emission limits, the cost of

conversion of the FTSF marine boilers to the gas-1 subcategory would be increased by another \$1.5 million to \$2.0 million.

Response: The EPA acknowledges this comment. For a response to the request for an exemption for the NNS Floating Test Steam Facility boilers and corresponding changes to rule language, please see comment EPA-HQ-OAR-2002-0058-3548-A2, excerpt 23.

Comment Excerpt Number: 16

Comment: Conversion of the NNS Floating Test Steam Facility (FTSF) marine boilers to natural gas or propane would also introduce a fuel availability risk that currently does not exist. Because the existing FTSF contains onboard storage of approximately 500,000 gallons of No. 6 fuel oil, fuel is delivered by the supplier on a periodic basis even though it is being combusted continuously. Fuel delivery delays due to adverse weather conditions or other reasons can be reasonably accommodated without risking interruption of boiler operations and carrier steaming. However, natural gas or propane cannot be stored onsite or onboard the FTSF and must be delivered by pipeline directly to the boiler burners on a continuous, “as-burned” basis. Even a momentary interruption of the gas supply at any point along approximately two miles of pipeline would cause the boilers to immediately shut down and disrupt carrier steaming. Steaming tests of particular equipment and systems run continuously for periods of several days up to a few weeks; interruption of one of these tests would likely require that the test be restarted and entirely repeated. If NNS were to attempt to mitigate this risk by constructing an onsite, compressed gas storage system, the storage system itself would introduce additional safety risks and building code requirements that could prevent or prohibit its construction. Thus, conversion of the FTSF marine boilers to gas-1 subcategory units would force NNS and the Navy to operate at a higher risk of interruption of carrier steaming than is currently experienced. A leak of fuel oil at a flange, valve or vent onboard the FTSF is immediately visible, is limited in extent by the viscosity of the liquid fuel, is not flammable, is relatively safe and simple to clean up with absorbent obtained from the onboard spill kit, and results in no downtime or interruption of boiler operations. In contrast a leak of natural gas is not visible, cannot be seen or heard, is extremely flammable, and presents an explosion potential because the FTSF contains numerous confined spaces, as shown by many of the photographs in Exhibit 4. [See submittal for Exhibit 4]. Furthermore, the lower levels of the FTSF boilers are located below deck and provide numerous potential ignition sources. Even if a leak were to occur with no ignition, immediate shutdown and evacuation of personnel from the FTSF would be required, and confined space regulations would require an exhaustive evaluation of gas levels within all compartments in the FTSF before reoccupancy would be allowed. The FTSF boilers would also need to be purged and restarted, and extensive downtime would result. The use of a gaseous fuel in the FTSF boilers, therefore, presents significant safety concerns that NNS would have to resolve, necessitating thorough study and renovation of the barge as well as the boilers.

Response: The EPA acknowledges this comment. For a response to the request for an exemption for the NNS Floating Test Steam Facility boilers and corresponding changes to rule language, please see comment EPA-HQ-OAR-2002-0058-3548-A2, excerpt 23.

Comment Excerpt Number: 17

Comment: NNS must ultimately obtain agreement from the Navy that the steam delivered to its aircraft carriers from a significantly altered boiler system would continue to be acceptable to the Navy in all respects. This certification process would require six months to complete, which has a significant potential to delay the steaming of the next aircraft carrier, which is already scheduled and under contract with the Navy. To complicate matters further, the FTSF boiler manufacturer, Combustion Engineering, no longer exists, having been purchased in 1990 and its divisions subsequently acquired by several other companies in later years. As a result of the above circumstances, NNS has not yet been able to confirm definitively that the conversion of its FTSF marine boilers to natural gas or propane is feasible and, therefore, NNS cannot yet commit to conversion to natural gas or propane as its means of achieving compliance of the FTSF marine boilers with the Boiler MACT. NNS continues to diligently and in good faith evaluate the feasibility of this Boiler MACT compliance option.

Response: The EPA acknowledges this comment. For a response to the request for an exemption for the NNS Floating Test Steam Facility boilers and corresponding changes to rule language, please see comment EPA-HQ-OAR-2002-0058-3548-A2, excerpt 23.

Document Control Number: EPA-HQ-OAR-2002-0058-3548-A2
Comment Excerpt Number: 19

Comment: NNS believes that EPA was unaware of the significant distinction between the NNS Floating Test Steam Facility (FTSF) boilers and the class of industrial, commercial and institutional boilers targeted by the Boiler MACT and that EPA did not specifically intend to regulate the FTSF boilers as industrial boilers. On June 19, 2009, NNS received a “§114 letter” from EPA pursuant to an information collection request (ICR), OMB Control No. 2060-0616, requiring emissions and fuel testing on one of the FTSF test steam boilers at NNS, specifically Unit ID FTSF-E1. On July 24, 2009, NNS contacted EPA’s Office of Air Quality Planning and Standards (OAQPS) by telephone and requested approval to substitute an NNS industrial steam boiler for Unit FTSF-E1. In that telephone conversation NNS explained to EPA that Unit FTSF-E1 is a No. 6 fuel oil-fired “test steam boiler” which is used intermittently to supply temporary steam to nuclear-powered aircraft carriers in order to test onboard steam-driven machinery before the nuclear propulsion system is made operational. NNS further explained that Unit FTSF-E1 is bargemounted to facilitate placement in proximity to aircraft carriers at several locations throughout the shipyard, and would not be appropriate to test pursuant to the ICR. NNS thus proposed to substitute one of its NNS No. 6 fuel oil-fired facility Powerhouse steam boilers for this testing. At the conclusion of that conversation EPA approved NNS’ proposal to substitute one of the facility steam boilers for Unit FTSE1. This telephone conversation was memorialized in a follow-up email to OAQPS on July 27, 2009 (copy provided in Exhibit 5 below). [See submittal for Exhibit 5] During EPA’s subsequent review of the voluminous

amount of data it most certainly obtained from the ICR and its development of the Boiler MACT regulations ultimately proposed on March 21, 2011, NNS believes EPA overlooked its early determination that the FTSF test steam boilers were not conventional industrial steam boilers and should not have been included among the class of industrial, commercial or institutional boilers considered for regulation pursuant to the Boiler MACT.

Response: The EPA acknowledges this comment. For a response to the request for an exemption for the NNS Floating Test Steam Facility boilers and corresponding changes to rule language, please see comment EPA-HQ-OAR-2002-0058-3548-A2, excerpt 23.

Comment Excerpt Number: 21

Comment: The NNS Floating Test Steam Facility (FTSF) boilers are required for only six additional carrier refueling events, after which they are no longer planned to be necessary. Only six aircraft carriers remain in the Nimitz class which will require refueling during a mid-life RCOH: the USS Abraham Lincoln (CVN-72), the USS George Washington (CVN-73), the USS John C. Stennis (CVN-74), the USS Harry S. Truman (CVN-75), the USS Ronald Reagan (CVN-76), and the USS George H.W. Bush (CVN-77). The new Ford class of carriers, beginning with the Gerald R. Ford (CVN- 78), which is currently under construction, incorporates new technologies and will not require mid-life refueling. In addition nuclear-powered submarines, which in the past have occasionally been steamed by the FTSF, are currently being designed to not require mid-life refueling. Therefore, NNS does not expect that Navy propulsion plant testing procedures will require the FTSF or other source of shore steam after the George H.W. Bush (CVN-77) mid-life RCOH.

Response: The EPA acknowledges this comment. For a response to the request for an exemption for the NNS Floating Test Steam Facility boilers and corresponding changes to rule language, please see comment EPA-HQ-OAR-2002-0058-3548-A2, excerpt 23.

Comment: For the reasons set forth herein, NNS requests that EPA amend the Boiler MACT by adding the following provision to the exemptions in §63.7491: ([paragraph number as appropriate]) Any boiler used to provide steam for testing the propulsion systems on military vessels.

Response: The EPA acknowledges this comment. For a response to the request for an exemption for the NNS Floating Test Steam Facility boilers and corresponding changes to rule language, please see comment EPA-HQ-OAR-2002-0058-3548-A2, excerpt 23.

7D04. Non-Continental Liquid

Commenter Name: James Pew

Commenter Affiliation: Earthjustice, Clean Air Council, Partnership for Policy Integrity

Document Control Number: EPA-HQ-OAR-2002-0058-3511-A1

Comment Excerpt Number: 5

Comment: EPA's new non-continental subcategory in particular is unlawful and arbitrary. The subcategory includes units designed to burn liquid fuel located in the State of Hawai'i, the Virgin Islands, Guam, American Samoa, the Commonwealth of Puerto Rico, or the Northern Mariana Islands. EPA advances two arguments for the change. First, it claims some such units "cannot physically access natural gas pipelines," and lack port facilities for delivery of crude oil. 76 Fed. Reg. at 15,635. Second, it claims some units lack access to fresh water and thus rely on "fin fan" cooling systems. *Id.* Although a lack of access to ports, natural gas, and water, might hypothetically justify some subcategory for units that truly lack access, the subcategory EPA has created is far broader. The Agency does not claim that its new subcategory contains only units that lack access to ports, natural gas and water or even that it contains only units that face some of these purported challenges. EPA does not claim, for example, that no units in these areas maintain cooling systems or have access to substantial port facilities. Thus, sources (existing or new) that are not even arguably a different class, type, or size and that are fully capable of meeting more protective limits may be included in the new subcontinental subcategory and excused from achieving limits that should apply to them. By defining the sub-category broadly by geography, rather than the alleged technical differences cited as justification for creating it, EPA acts arbitrarily and unlawfully. Finally, EPA admits that it does not have any emissions data for the newly minted "non-continental subcategory" and simply made up emission standards for these sources based on data from sources in other categories. Because EPA's standards for the sources in the non-continental categories do not reflect the actual performance of the best units in this group, or even purport to reflect such performance, they are unlawful and arbitrary.

Response: The EPA disagrees with the commenters assertion that the non-continental subcategory is arbitrary and unlawful. For the reasons outlined in the preamble to the March 21, 2011 final rule notice (76 FR 15608), the EPA continues to believe subcategorization for the non-continental units is justified. While the commenter asserts that some units in this subcategory will not face such obstacles, it provides no information or analysis, including identifying specific such units, to support this assertion.

The EPA believes that the unique considerations faced by noncontinental units warrant a separate subcategory for these units and the data show that the difference in location causes a difference in emissions apparently due to the fuel that is available for such units; thus, the Agency has maintained such a subcategory in the final amended rule. The EPA agrees with other commenters that the unique considerations faced by non-continental refineries, including a limited ability to obtain alternative fuels that lead to different emissions characteristics, continue to warrant a separate subcategory for these units. The EPA believes that units in this subcategory will comply through the use of cleaner oils or, for PM, through the installation of an ESP.

Via additional data submitted by non-continental units, all emission limitations for the subcategory in the final rule have been calculated from available data from actual units in the subcategory. The limits no longer default to the emissions data from another subcategory.

Commenter Affiliation: National Association of Clean Air Agencies (NACAA)
Document Control Number: EPA-HQ-OAR-2002-0058-3525-A1
Comment Excerpt Number: 50

Comment: NACAA notes that EPA's rationale for the establishment of a non-continental liquid subcategory (without emission data for each pollutant) is undercut by the use of continental liquid data for missing pollutant data.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3511-A1, excerpt 5.

Commenter Name: Matthew Todd
Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)
Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2
Comment Excerpt Number: 26

Comment: We support the establishment of a non-continental liquids subcategory, but believe the definition should be revised to 1) allow for variability due to the forced use of liquid fuels not pertinent to most continental units, and 2) make it consistent with the "unit designed to burn liquid subcategory" definition.

1. EPA explained the basis for establishing a non-continental liquids subcategory in the preamble to the March 21, 2011 final rule at 76 Fed. Reg. 15635. In part that discussion states:

... it is clear that the unique design of this type of unit warrants a separate subcategory because design constraints would not enable the sources to meet the same standards, particularly for CO, as stateside units.

We concur with this conclusion. Limitations on fuels available and the design impacts of needing to fire either liquids or gases in non-continental BPH as internal fuel gas supplies vary, makes this group of units a distinct subcategory from the continental liquid fuels subcategories for PM and CO.

2. Unlike the other gas and liquid subcategory definitions, the "unit designed to burn liquid fuel that is a non-continental unit" text refers to the unit design rather than to what it actually burns as the basis for subcategory assignment. [See submittal for Table 1. Comparison of BPH NESHAP Gas and Liquid Subcategory Definitions.] Thus, a non-continental unit that exclusively burns gas 1, but was originally designed to burn liquids, would appear to be in the non-continental liquids subcategory rather than in the gas 1 subcategory, while an identical continental unit would be in the gas 1 subcategory. This inconsistency must be addressed. 3. During times of refinery gas shortages (e.g., during a gas producing unit maintenance outage), some non-continental BPH must burn liquid fuels. Such use of liquids is minimized because of the high relative cost of liquid fuels. None-the-less, an allowance is needed to allow for such liquids firing without causing the BPH to be reclassified to the non-continental liquid subcategory for these short time occurrences.

We recommend the “unit designed to burn liquid fuel that is a non-continental unit” definition be revised to the following.

Unit designed to burn liquid fuel that is a non-continental unit means an industrial, commercial, or institutional boiler or process heater ~~designed to burn liquid fuel meeting the definition of the unit designed to burn liquid subcategory~~ located in the State of Hawaii, the Virgin Islands, Guam, American Samoa, the Commonwealth of Puerto Rico, or the Northern Mariana Islands.

Response: The EPA thanks the commenter for their support of the non-continental liquid subcategory. The EPA also agrees with the commenter's suggestions for revisions that would make the definition consistent with the "unit designed to burn liquid subcategory" definition in order for non-continental Gas 1 units to be treated consistently in regards to periods of gas curtailment as continental Gas 1 units.

Commenter Name: Matthew Todd

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 34

Comment: The definition of “unit designed to burn liquid fuel subcategory” in the proposal specifically notes that “Gaseous fuel boilers that burn liquid fuel during periods of gas curtailment or gas supply emergencies of any duration are also not included in this definition.” The driver for this exclusion appears to be based solely on continental units preferentially burning natural gas delivered via a pipeline, except when unavailable, and allowing such units to remain under the “unit designed to burn gas 1 subcategory” despite the occasional need to burn liquids due to supply disruptions. It is entirely reasonable that subcategory assignment reflect the primary and optimized fuel situation for each BPH.

Although non-continental facilities do not have access to natural gas pipelines, many non-continental units are subject to a comparable situation – they may normally burn and be optimized for gaseous fuel, but must rely on residual fuel oil produced on site when refinery gas supply is disrupted. For example, a boiler or process heater at a non-continental refinery may primarily fire refinery gas, but also fires fuel oil when the refinery gas supply is insufficient, such as during production unit turnarounds at the refinery. This is analogous to continental gaseous fuel units firing oil during periods of natural gas curtailment. However, the proposed “unit designed to burn liquid fuel that is a non-continental unit” definition does not provide a comparable exclusion for liquid firing under this situation. An exemption for liquid firing for non-continental gaseous fuel BPH gas curtailments should be added to the period of gas curtailment or supply interruption definition.

Response: For discussion on suggested revisions to the non-continental liquid unit definition to provide exemptions for gaseous fuel boilers which combust residual oil in periods of gas curtailment, please see comment EPA-HQ-OAR-2002-0058-3677-A2, excerpt 26.

7E. Boilers Used in Place of Flares

Commenter Name: Mary Sullivan Douglas

Commenter Affiliation: National Association of Clean Air Agencies (NACAA)

Document Control Number: EPA-HQ-OAR-2002-0058-3525-A1

Comment Excerpt Number: 54

Comment: EPA has requested comment on a stakeholder proposal that EPA consider creating a subcategory for units that are installed and used in place of flares that are currently used to combust process gases. The stakeholders also suggested that it would be appropriate to assume that the emissions from process gases diverted from flares to boilers have "zero emissions" for the purposes of classifying the boiler in which they are combusted. Since the process gases must be combusted in either event, they requested that the EPA develop an approach where it uses a concept similar to the emissions averaging provisions, for example, to simply assume that combustion of such process gases in a boiler rather than a flare should not be counted as emissions from the boiler because there is no net increase in emissions. NACAA supports the use of well-controlled closed combustion devices in lieu of open. However, it appears that such devices would be governed by Gas 2 limits. EPA provides an exemption for combustion devices used as pollution control devices where 50 percent of the heat value of the device is provided by the exhaust stream that is being controlled. The stakeholder proposal would effectively remove the 50-percent limit. NACAA believes this is excessive and would substantially eliminate HAP emission reductions in the Gas 2 category.

Response: The EPA agrees with the commenter. No provisions or exemptions have been added to the final rule for boilers which are used in place of flares to combust process gases.

Commenter Name: Arthur N. Marin

Commenter Affiliation: Northeast States for Coordinated Air Use Management (NESCAUM)

Document Control Number: EPA-HQ-OAR-2002-0058-3506-A1

Comment Excerpt Number: 28

Comment: The EPA has also requested comment (76 FR 80617, Section V.M.2) on a proposal to assume that units installed to divert process gases from flares to boilers have “zero emissions” for the purpose of classifying the boiler. The EPA reports that stakeholders support this proposal with the reasoning that process gases will be combusted in either case, and thus there is no net increase in emissions. No net increase in emissions does not equate to “zero emissions.” MACT serves to minimize HAP emissions, not just to result in a net decrease in emissions. The NESCAUM states believe that this would run counter to application requirements under the EPA’s federal regulations and would require changes to those regulations and many state implementation plans. Furthermore, this proposed “zero emissions” assignment implicitly assumes that the flare and boiler would be under the same management, which may not always be the case. NESCAUM does not support this proposal.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3525-A1, excerpt 54.

7Z. Out of Scope: Rationale for Subcategories

Commenter Name: Michael Livermore, Jason Schwartz

Commenter Affiliation: Institute for Policy Integrity, NYU School of Law

Document Control Number: EPA-HQ-OAR-2002-0058-3432-A1

Comment Excerpt Number: 1

Comment: The agency does have discretion to divide sources into subcategories based on differences in class, type, or size.⁵ In a recent concurring opinion, however, Judge Williams cautioned that while section 112 of the Clean Air Act “pervasively refers to standards for sources in each ‘category or subcategory,’ . . . the authority to generate subcategories is obviously not unqualified; at the least it must be limited by the usual ideas of reasonableness.”⁶

The proposed source subcategorizations may not represent the groupings that would lead to the most efficient regulatory program. Subcategorizations should be made to the extent that they increase the rule’s net benefits. Setting separate standards for multiple different subcategories incurs administrative costs: collecting separate information, setting the different standards, and monitoring and enforcing different standards. Such costs are only warranted if different sources face sufficiently different costs or could generate sufficiently different benefits such that setting a unique standard would increase overall net benefits.

EPA should justify any subcategorizations it makes along these ground. Its current explanation for the subcategories begins to address the differing costs and benefits of regulating different existing sources. Retrofitting existing plants with control devices or process changes can be costly, and plants designed for different fuel types may face different retrofit costs and may be able to achieve different levels of emissions reductions. But EPA should be more explicit about the costs and benefits it is weighing in making these determinations, should try to quantify the costs and benefits to the extent possible, and should only propose subcategories for existing sources to the extent that different standards will enhance net benefits.

[Footnote 5: *Sierra Club v. EPA*, 551 F.3d 1019 (D.C. Cir. 2008) ("Congress specifically permitted the Administrator to 'distinguish among classes, types, and sizes of sources within a category or subcategory in establishing such standards.'"), cert. denied by *Am. Chemistry Council v. Sierra Club*, 2010 U.S. LEXIS 2265 (2010) (citing 42 U.S.C. § 7412(d)(1); *NRDC v. EPA*, 489 F.3d 1364, 1375 (D.C. Cir. 2007) ("Because Congress has vested EPA with subcategorization authority under Section 112(c)(1), and its exercise of that authority involves an expert determination, [petitioner] carries a heavy burden to overcome deference to the agency's articulated rational connection between the facts found and the choices made.").]

[Footnote 6: *Sierra Club v. EPA*, 479 F.3d 875, 885 (D.C. Cir. 2007) (Williams, J., concurring) ("Section 112(d)(1) authorizes the Administrator to 'distinguish among classes, types and sizes of sources within a category or subcategory,' and the language of subsections 112(d)(2) and (3) pervasively refers to standards for sources in each '*category or subcategory*.' The authority to generate subcategories is obviously not unqualified; at the least it must be limited by the usual ideas of reasonableness Nonetheless, one legitimate basis for creating additional subcategories must be the interest in keeping the relation between 'achieved' [in the MACT floor analysis] and 'achievable' [in the beyond-the-floor analysis] in accord with common sense and the reasonable meaning of the statute.".)]

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Commenter Name: Arthur N. Marin

Commenter Affiliation: Northeast States for Coordinated Air Use Management (NESCAUM)

Document Control Number: EPA-HQ-OAR-2002-0058-3506-A1

Comment Excerpt Number: 15

Comment: As we stated in our August 23, 2010 comments on the proposed rule for area and major source boilers (document control number EPA-HQ-OAR-2002-0058-2893.1, excerpt 1), NESCAUM is concerned by the widely varying emission limits proposed for similar units regulated under section 112 of the CAA. In that comment, NESCAUM urged that the MACT and GACT levels be harmonized across all applicable rules, thus resulting in consistent emission limits for similar units. The EPA's response indicated that calculated emissions limits are a function of data availability based on the best performing sources in each subcategory. NESCAUM agrees that this should be the case, but urges the EPA to only create subcategories and associated emissions limits where sufficient data exist to determine an applicable emissions limitation. Where data are insufficient to properly characterize what sources in a sector could do to improve emissions control (i.e., maximum achievable control technology), NESCAUM urges the EPA to set standards for less refined subcategories that have more emissions and control data available.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Commenter Name: Alicia Meads

Commenter Affiliation: National Association of Manufacturers (NAM)

Document Control Number: EPA-HQ-OAR-2002-0058-3515-A1

Comment Excerpt Number: 7

Comment: The CAA unequivocally authorizes the EPA to establish appropriate subcategories of sources. CAA §112(c)(1) instructs EPA to establish "categories and subcategories" of sources for regulation under Section 112. CAA §112(d)(1) then further provides that the EPA "may distinguish among classes, types and sizes of sources within a category or subcategory" when establishing MACT standards. These provisions vest the EPA with the clear authority to group like units for purposes of establishing emissions limitations. Further, the EPA's ability to subcategorize is a key tool in ensuring that MACT floors are achievable. *See Sierra Club v. EPA*, 479 F.3d 875, 884-85 (D.C. Cir. 2007) (Judge Williams' concurrence noting the need to use subcategorization to avoid imposing unreasonable or unachievable MACT floors).

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Commenter Name: Paul Noe

Commenter Affiliation: American Forest & Paper Association (AF&PA) et al.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 60

Comment: EPA has developed subcategories of boilers under the proposed rule by fuel type, and in some cases, boiler type. We believe that it is appropriate to develop subcategories based on these criteria, as it recognizes the differences in boiler design, operation, and emissions. For example, a solid fuel-fired unit having the combustion occur on a grate has different challenges for optimizing the fuel-air ratio than that of a unit in which the combustion occurs in suspension. Combustion on a grate is subject to piling and smoldering that cannot simply be controlled by increasing the amount of excess air, yet can cause CO emissions to spike unexpectedly. The use of subcategorization in the proposed rule is amply supported by the language of the statute, the legislative history, applicable case law, and the Agency's own past practices.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Commenter Name: Mary Sullivan Douglas

Commenter Affiliation: National Association of Clean Air Agencies (NACAA)

Document Control Number: EPA-HQ-OAR-2002-0058-3525-A1

Comment Excerpt Number: 13

Comment: NACAA supports the development of subcategories in MACT rule development, where such subcategories are based on meaningful differences in anticipated fuels and unit designs. EPA has received a significant number of comments from sources making general assertions and theoretical arguments in support of additional subcategories; accordingly, the agency has proposed to greatly expand the number of subcategories for several pollutants. NACAA agrees that EPA's proposal to establish four broad categories based on fuel type – coal, biomass, liquid and gas – is reasonable.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Commenter Name: Mary Sullivan Douglas

Commenter Affiliation: National Association of Clean Air Agencies (NACAA)

Document Control Number: EPA-HQ-OAR-2002-0058-3525-A1

Comment Excerpt Number: 17

Comment: EPA has the means to objectively evaluate requests for subcategories and should do so for all subcategories incorporated in its rule. It should determine through the use of statistical techniques, such as a T-test of significance, that the emissions performance of each proposed subcategory is in fact significantly different from the broader category or subcategory of which it is a member. If a significant difference is shown, EPA should determine whether the difference is a function of the design of the combustion unit itself or is related to the prevalence of post-combustion controls that can be employed throughout the category. Where EPA determines that the emissions performance of the proposed subcategory is, in fact, significantly different from the broader category and is associated with the design of the combustion chamber itself, rather than post-combustion controls, EPA should compute the arithmetic average of the best performing unit(s). However, unless the proposed subcategory has sufficient data (nominally 50 data points) upon which to determine the variability of performance, EPA should apply the variability factor from the broader category to the arithmetic average of the best source(s) in the new subcategory. Where EPA did not collect emissions data from a representative sample of all units within a proposed subcategory, EPA has no basis to assume that any particular unit is in the top 12 percent of that subcategory. It is therefore insufficient to establish a subcategory on the basis that a particular unit's emissions are greater than the top 12 percent of the broader category.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Commenter Name: Shawn Good

Commenter Affiliation: Pennsylvania Chamber of Business and Industry

Document Control Number: EPA-HQ-OAR-2002-0058-3671-A2

Comment Excerpt Number: 3

Comment: The Pennsylvania Chamber supports proposed revisions to the rules that add flexibility and avoid unintentional overreaching, and encourages further clarification to accommodate site- or sector-specific concerns. The proposed revised rules reflect EPA's efforts to add greater flexibility and to recognize site-or sector-specific differences among regulated sources. Notably, the Pennsylvania Chamber supports the proposal of several key subcategories, including distinct subcategories for units combusting light liquid fuels and heavy liquid fuels, and a new subcategory for seasonally-operated boilers. However, several points warrant clarification and/or modification to insure that the intended flexibility is achieved and unintentional overreaching is avoided.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

107A01. Limited Use of Liquids in Gas 1 Units [DENIED PETITIONER ISSUE]

Commenter Name: William C. Herz

Commenter Affiliation: The Fertilizer Institute (TFI)

Document Control Number: EPA-HQ-OAR-2002-0058-3448-A1

Comment Excerpt Number: 2

Comment: The change in the definition of a "Unit designed to burn gas 1 subcategory" unfairly prejudices TFI's members because instead of relying on the "at least 90 percent natural gas and/or refinery gas" threshold to remain in the "Unit designed to burn gas 1 subcategory," owners and operators must now prepare and submit to EPA a site-specific fuel analysis plan and demonstrate that the mercury concentration meets the "other gas 1 fuel" limits. Further, based on conversations with laboratories, TFI members are having difficulties locating laboratories to run the designated mercury analysis specified in Table 6.

Because this change will substantively affect TFI members from both a cost and feasibility standpoint; and was made without discussion in the final *Industrial Boiler Major Source NESHAP*, or providing the public with the ability to comment on it.

TFI formally requests that EPA revert to its proposed definition of this subcategory, namely:

Unit designed to burn gas 1 (NG/RG) subcategory includes any boiler or process heater that burns at least 90 percent natural gas and/or refinery gas on a heat input basis on an annual average.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: Russell A. Wozniak

Commenter Affiliation: The Dow Chemical Company

Document Control Number: EPA-HQ-OAR-2002-0058-3449-A1

Comment Excerpt Number: 39

Comment: EPA should republish the definition of Liquid Fuel subcategory from the March 21, 2011 final rule.

EPA's March 21, 2011 Federal Register final rule contains the following definition of Liquid Fuel Subcategory:

Includes any boiler or process heater of any design that burns more than 10 percent liquid fuel and less than 10 percent solid fuel, based on the total annual heat input to the unit.

EPA's December 23, 2011 Federal Register reconsideration proposed rule no longer contains this definition. EPA should include this definition into the final rule to address minor periods of time when a predominantly gas fired boiler needs to burn a very small amount of liquid fuel, such as a natural gas condensate stream. Combusting such a small amount of liquid on an

infrequent basis should not require the boiler to be considered as a "Unit designed to burn liquid fuel".

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Comment: Boilers at RMA member facilities combust either natural gas or a combination of natural gas and liquid fuel oils. Although boilers at RMA member facilities mainly burn natural gas, these boilers may also burn more than 10% liquid fuel in a given year and therefore would be classified as either light or heavy fuel boilers. We believe the emission limits for light and heavy fuel boilers remain unachievable. It is evident that major capital investments in add-on control technology will be required for continued use of liquid fuel in RMA member boilers. RMA members may choose fuel switching to natural gas as a compliance option. Because fuel costs are one of the top three costs of doing business, RMA members would like to maintain the option to burn more than 10% liquid fuel per year. The stringent emission limits EPA has proposed for light and heavy liquid fuel boilers would create a competitive disadvantage for tire manufacturing facilities located in the United States.

The U.S. tire manufacturing industry faces a withering economic slump and fierce competition from overseas manufacturers. In the face of such existing economic pressure, the proposed rules would make matters far worse by imposing large costs on U.S. tire manufacturers. We believe that EPA still has a lot of work to do in tailoring the rule so that it protects health and the environment without imposing unnecessary control requirements and corresponding costs.

Comment: ***THE DEFINITION OF UNIT DESIGNED TO BURN GAS 1 SUBCATEGORY SHOULD BE REVISED***

In the Reconsideration Proposal at § 63.7575, EPA defines units designed to burn Gas 1 as:

"any boiler or process heater that burns only natural gas, refinery gas, and/or other gas 1 fuels; with the exception of liquid fuels burned for periodic testing not to exceed a combined total of 48 hours during any calendar year, or during periods of gas curtailment and gas supply emergencies."

EPA then defines oil (liquid) unit as:

"any boiler or process heater that burns any liquid fuel, but less than 10 percent coal/solid fossil fuel and less than 10 percent biomass/bio-based solid fuel on an annual heat input basis, either alone or in combination with gaseous fuels. Gaseous fuel boilers and process heaters that burn liquid fuel for periodic testing of liquid fuel, maintenance, or operator training, not to exceed a combined total of 48 hours during any calendar year or during periods of maintenance, operator training, or testing of liquid fuel, not to exceed a combined total of 48 hours during any calendar year are not included in this definition. Gaseous fuel boilers and process heaters that burn liquid fuel during periods of gas curtailment or gas supply emergencies of any duration are also not included in this definition." In the proposed reconsidered area source rule at 40 CFR 63.11237, EPA defines a gas-fired boiler as —any boiler that burns gaseous fuels not combined with any solid fuels, burns liquid fuel only during periods of gas curtailment, gas supply interruption, startups, or periodic testing on liquid fuel. Periodic testing of liquid fuel shall not exceed a combined total of 48 hours during any calendar year.|| (emphasis added) (76 Fed. Reg. 80547, December 23, 2011)

EPA has consistently used 10% as a threshold for movement from one subcategory to another. For example the most stringent – coal – includes units that burn at least 10% coal. The next – biomass – includes units that burn at least 10% biomass and less than 10% coal. The first sentence of the oil (liquid) subcategory includes any liquid fuel, but less than 10 % solid fuel. Therefore, it logically follows that a plain reading of the Gas 1 subcategory would be that EPA intended to include any unit that burns at least 90% gas and less than 10% of any other fuel. EPA should include an allowance for oil firing in the Gas 1 subcategory definition of 10 percent (as allowed in other subcategory definitions). At a minimum, EPA should make the Gas 1 subcategory definition consistent with the area source definition, which places no restriction on oil firing during startup. A new gas-fired boiler that is designed to burn liquid fuel as backup must be allowed to burn oil for more than 48 hours per year in order to ensure that the oil burners are properly tuned during initial startup.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Commenter Affiliation: American Chemistry Council (ACC)

Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1

Comment Excerpt Number: 155

Comment: ACC proposes the following definition for the Gas 1 subcategory:

"Unit designed to burn gas 1 subcategory includes any boiler or process heater that burns at least 90 percent natural gas, refinery gas, and/or other gas 1 fuels on a heat input basis on an annual average and less than 10 percent of any solid or liquid fuel."

This definition change would simplify the process of determining if a unit qualifies for the gas 1 subcategory and would eliminate the need to determine whether periods during which liquid fuel is fired constitute natural gas curtailment, gas supply emergency, or periodic testing. It would also accommodate the need to be able to burn oil during initial startup in order to test and tune the oil burners on a new unit or an existing unit where new burners have been installed. EPA

already acknowledges in §63.7510(a)(2)(i) that units burning a supplemental fuel for startup, shutdown, and transient flame stability purposes are single fuel units, and the supplemental fuel is not subject to fuel analysis requirements.

This change would also be consistent with how EPA has defined the Gas 2 subcategory (the definition includes an allowance for burning 10 percent liquid fuel):

"Unit designed to burn gas 2 (other) subcategory includes any boiler or process heater that is not in the unit designed to burn gas 1 subcategory and burns any gaseous fuels either alone or in combination with less than 10 percent coal/solid fossil fuel, less than 10 percent biomass/bio-based solid fuel, and less than 10 percent liquid fuels on an annual heat input basis."

Commenter Affiliation: Auto Industry Forum (AIF)

Document Control Number: EPA-HQ-OAR-2002-0058-3512-A1

Comment Excerpt Number: 51

Comment: EPA Should Amend the Definition to Permit Such Units to Burn Up to 10% Other Fuels.

In the June 4, 2010, proposal for the Boiler MACT, the definition of "unit designed to burn gas 1 subcategory" was formulated as follows:

Unit designed to burn gas 1 (NG/RG) subcategory includes any boiler or process heater that burns at least 90 percent natural gas and/or refinery gas on a heat input basis on an annual average.

*National Emission Standards for Hazardous Air Pollutants for Major Sources: Industrial, Commercial, and Institutional Boilers and Process Heaters, 75 Fed. Reg. 32,006, 32,065 (June 4, 2010) (the "Proposed Boiler MACT") (underline added). The Boiler MACT Reconsideration Proposal contains the following revised formulation to the definition:*³⁴

Unit designed to burn gas 1 subcategory includes any boiler or process heater that burns only natural gas, refinery gas, and/or other gas 1 fuels; with the exception of liquid fuels burned for periodic testing not to exceed a combined total of 48 hours during any calendar year, or during periods of gas curtailment and gas supply emergencies.

Boiler MACT Reconsideration Proposal, 76 Fed. Reg. at 80,655 (underline added to indicate revisions). AIF supports the proposed exclusion in this definition for periods of time that a NGfired unit combusts fuel oil for testing purposes and when needed as an "emergency back-up" fuel. However, AIF is concerned about the 48-hour restriction associated with "periodic testing" and that gas curtailment and/or gas supply emergencies may not address all of the foreseeable emergency situations. Accordingly, AIF urges EPA to amend this definition to allow units in the Gas 1 category to burn up to 10% other fuels annually, thereby returning to the prior formulation

of the definition from the Boiler MACT Proposal. *See Proposed Boiler MACT*, 75 Fed. Reg. at 32,065.

With respect to the 48-hour restriction for “periodic testing,” consider, for example, the request by a state agency to conduct emission testing using fuel oil to demonstrate compliance with emission limits that would be imposed when combusting fuel oil pursuant to state regulations. In AIF members’ experience, boilers in such a circumstance may have to operate on fuel oil for approximately one week to ensure that they have achieved representative operation to allow for an acceptable emission test using the federal reference test methods. It would be inappropriate to then consider the boiler no longer covered by the NG category because of such emission testing. Thus, while 48 hours may be adequate to confirm that a boiler could operate using fuel oil as designed, it is insufficient to provide adequate operation to perform emission testing when required by a state regulatory agency.

With regard to the exclusion of NG curtailment and/or supply emergencies, AIF members recall events during the 1980’s when there was extensive uncertainty regarding the availability of a continuous supply of NG and fear about potential NG shortages and interruptions. To be clear that fuel oil can be used during periods of inadequate NG supply or interruption, AIF believes that the exception provided in the definition needs to be expanded to allow for periods of potential supply interruption.

Therefore, AIF urges EPA to amend the definition to allow for units in the Gas 1 category to burn up to 10% other fuels annually. If EPA does not revise the definition as AIF urges, it will result in taking units that would otherwise fall within the ambit of this definition – and that are designed to burn Gas 1 – outside of it. There is no rational basis for such a result.

[Footnote 34: The formulation for this definition in the Boiler MACT Reconsideration Proposal is consistent with the formulation in the final rule. *See Boiler MACT*, 76 Fed. Reg. at 15,686.]

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Commenter Name: Paul Noe

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 127

Comment: In the proposed rule at 40 CFR 63.7575, EPA defines units designed to burn Gas 1 as: "any boiler or process heater that burns only natural gas, refinery gas, and/or other gas 1 fuels; with the exception of liquid fuels burned for periodic testing not to exceed a combined total of 48 hours during any calendar year, or during periods of gas curtailment and gas supply emergencies." EPA then defines oil (liquid) unit as: "any boiler or process heater that burns any liquid fuel, but less than 10 percent coal/solid fossil fuel and less than 10 percent biomass/bio-based solid fuel on an annual heat input basis, either alone or in combination with gaseous fuels. Gaseous fuel boilers and process heaters that burn liquid fuel for periodic testing of liquid fuel, maintenance, or operator training, not to exceed a combined total of 48 hours during any calendar year or during periods of maintenance, operator training, or testing of liquid fuel, not to exceed a combined total of 48 hours during any calendar year are not included in this definition.

Gaseous fuel boilers and process heaters that burn liquid fuel during periods of gas curtailment or gas supply emergencies of any duration are also not included in this definition."

In the area source rule at 40 CFR 63.11237, EPA defines a gas-fired boiler as "any boiler that burns gaseous fuels not combined with any solid fuels, burns liquid fuel only during periods of gas curtailment, gas supply interruption, startups, or periodic testing on liquid fuel. Periodic testing of liquid fuel shall not exceed a combined total of 48 hours during any calendar year." (emphasis added)

EPA has been very consistent throughout the proposal to use 10% as a threshold for movement from one subcategory to another. For example the most stringent threshold – coal – includes units that burn at least 10% coal and less than 10% biomass. The next –biomass – includes units that burn at least 10% biomass. The first sentence of the oil (liquid) subcategory includes any liquid fuel, but less than 10% solid fuel.⁵⁶ Therefore, it logically follows that a plain reading of the Gas 1 subcategory would be that EPA intended to include any unit that burns at least 90% gas and less than 10% of any other fuel. EPA should include an allowance for oil firing in the Gas 1 subcategory definition of 10 percent (as allowed in other subcategory definitions).

[Footnote 56: As discussed immediately below, that definition should also be revised to avoid conflict with the current definition of the Gas 2 subcategory (and the definition of the Gas 1 subcategory as we propose it be revised).]

Commenter Name: Douglas Price

Commenter Affiliation: Tesoro Companies, Inc

Document Control Number: EPA-HQ-OAR-2002-0058-3630-A2

Comment Excerpt Number: 3

Comment: *Include a 10 Percent Liquid Fuel Burning Allowance for the Gas 1 Subcategory*

As discussed in more detail in the API/AFPM comment letter dated February 21, 2012. Tesoro is very concerned about the re-proposed rule's definition of "unit designed to burn gas 1 subcategory."

Previous versions of 40 C.F.R. Subpart DDDDD demonstrate that the EPA has intended to allow gas-fired boilers or process heaters to burn up to 10 percent of liquid fuels on an annual average heat input basis and still remain within a gas-fired subcategory. For example, in the preamble of the March 21, 2011 final 40 C.F.R. Subpart DDDDD rule, it states the following:

"If your facility is located in the continental United States and your new or existing boiler or process heater burns at least 10 percent liquid fuel (such as distillate oil, residual oil) and less than 10 percent coal and less than 10 percent biomass, on an annual average heat input basis, your unit is in the liquid subcategory. "

Also, the current re-proposed 40 C.F.R. Subpart DDDDD rule allows for a 10 percent liquid fuel burning allowance in the definition of "Unit designed to burn gas 2 (other)" which is as follows:

Unit designed to burn gas 2 (other) subcategory includes any boiler or process heater that is not in the unit designed to burn gas 1 subcategory and burns any gaseous fuels either alone or in combination with less than 10 percent coal/solid fossil fuel, less than 10 percent biomass/bio-based solid fuel, and less than 10 percent liquid fuels on an annual heat input basis.

These two references clearly demonstrate EPA's intent to allow for the use of a 10 percent annual heat input allowance for liquid fuel burning. Therefore, this allowance should be included in the "unit designed to burn gas 1 subcategory" definition of the currently re-proposed 40 C.F.R. Subpart DDDDD.

Tesoro owns and operates two refineries located in the continental United States that have the permitted flexibility to burn liquid fuels on a very limited basis. For example, Tesoro's Mandan Refinery's boilers and process heaters primarily burn refinery fuel gas or natural gas. However, one boiler has the capability and is allowed to burn liquid fuel during periods of documented natural gas curtailment *and* as necessary to ensure that the refinery can use fuel oil during periods of natural gas curtailment. With the current design of the fuel oil system, a certain small amount of fuel oil is burned frequently in order to ensure the system is ready and can come online quickly during a curtailment period. Without this small amount of on-going burning, the fuel oil circulation system would be susceptible to plugging and the refinery may not be able to respond quickly in the event of a gas supply emergency. While this fuel oil use amounts to a limited amount of liquid fuel burning on an annual basis, the current definition of "unit designed to burn gas 1 subcategory" would require this practice to stop quickly after 48 hours of a limited amount of liquid fuel being fired. In addition, Tesoro's Anacortes Refinery relies on a limited amount of permitted fuel oil firing in certain units to maintain the safe and reliable operation of the refinery during certain maintenance activities, in addition to natural gas curtailment periods and routine testing.

The inclusion of a 10 percent annual heat input liquid fuel allowance is the more appropriate approach for allowing some level of required liquid fuel burning, but still ensuring the use is limited enough to remain in the gas 1 subcategory.

Recommendation: For the reasons described above, Tesoro requests that the 10 percent annual heat input allowance for liquid fuel burning be included in the "unit designed to burn gas 1 subcategory" definition.

Comment Excerpt Number: 3

Comment: While the Reproposed BPH MACT appears to make some effort to make the supply disruption definition applicable to those maintenance or other activities that may cause a temporary increase in oil usage at a non-continental facility, the language is far from clear and is muddled by the "beyond the control" language. HOVENSA suggests that this definition be made applicable by language creating a clear safe harbor, similar to the following:

"For non-continental boilers and process heaters, supply interruption also includes periods where on site supplies of gas fuels are reduced because operations of gas producing process units have been halted or reduced due to turnarounds, maintenance, unanticipated shutdown or gas transmission bottlenecks or disruptions."

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: Christopher Coleman

Commenter Affiliation: HOVENSA LLC. , Hess Corporation

Document Control Number: EPA-HQ-OAR-2002-0058-3673-A2

Comment Excerpt Number: 4

Comment: HOVENSA supports API/NFPM comments on the application of the 10% allowance. We believe this is necessary and appropriate because units burning small amounts of liquid along with Gas 1 have approximately the same emissions profile and should be treated the same for regulatory purposes. This can be accomplished either by (i) including it in the Gas1 definition or (ii) the "Units designed to burn liquids subcategory" definition and coordinating noncontinental, heavy and light liquid subcategories so that units that are NOT liquid units as defined cannot be in those subcategories. HOVENSA notes that even the relatively simple use of the subcategory descriptions in Table 1 and 2 for solid fuel "Units in all subcategories designed to burn solid fuel" would help make it clearer that the "Units designed to burn liquids subcategory" is the subcategory superset and the light, heavy and non-continental units are subsets of that category.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: Christopher Coleman

Commenter Affiliation: HOVENSA LLC. , Hess Corporation

Document Control Number: EPA-HQ-OAR-2002-0058-3673-A2

Comment Excerpt Number: 5

Comment: It is essential that both the 10% allowance and the supply curtailment provisions work together to treat non-continental units in a manner similar to mainland units. HOVENSA typically burned far more than 90% refinery fuel gas and propane and far less than 10% liquids in its BPH on an annualized basis. The emissions profile of HOVENSA BPH would be very similar to and have the same emissions measurement issues as do units in the Gas 1 category. The only time this situation changes is a fuel gas supply disruption, primarily if the Coker or FCCU are taken off line for scheduled or unscheduled maintenance. In this case, one or more BPH could switch categories from Gas 1 to Non-continental, and then switch back in a year, creating significant confusion as to what emissions limits and controls might apply and at what time. As our comments and those of API and AFPM have stated, this is essentially the same situation a continental refinery faces when supply of natural gas is curtailed. HOVENSA recommends that fuel oil burned during periods of curtailment not be included in the 10% allowance.

As an alternative, HOVENSA has suggested using a three year averaging period instead of a one year period for determining the 10% threshold. This approach is consistent with the exemption from the EGU category for natural gas fired units, which can average 10% over a three year period.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Commenter Name: Matthew Todd

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 28

Comment: The 10% minimum liquid fuel criterion for the “units designed to burn liquid subcategory” was removed in finalizing the March 21, 2011 BPH NESHAP with no explanation or justification and no opportunity for public comment. In fact, that rule preamble indicated the 10% criterion remains. That change is carried through into this proposal. EPA must return that 10% allowance or provide justification for the revision for notice and comment. It also must revise the unit designed to burn gas 1 subcategory definition to reflect the 10% allowance.

Table 1 [See submittal for Table 1. Comparison of BPH NESHAP Gas and Liquid Subcategory Definitions] compares the gas and liquid subcategory definitions from the June 4, 2010 BPH NESHAP proposal, the March 21, 2011 final rule, and the current proposal.

The 10% liquid allowance is contained in the definition of “liquid fuel subcategory” in both the June 4, 2010 original proposal and the March 21, 2011 final rule. It was also contained in the “unit designed to burn oil subcategory” in the original proposal. However, neither of these terms is used in the March 21, 2011 final rule or in the current proposal when imposing requirements (e.g. Tables 1 and 2). Rather the term “unit designed to burn liquid subcategory” is the term used in the final rule and the current proposal and that definition does not contain the 10% allowance.

Similarly, the gas 1 subcategory definition was changed to drop the 10 percent allowance between proposal and final, while the allowance was added to the gas 2 subcategory definition. The final rule gas subcategory definitions were carried forward into this proposal.

On page 15637 of the March 21, 2011 final rule preamble, EPA describes the liquid and gas subcategories as follows.

The subcategories for the combustion based pollutants are now determined in the following manner. ... If your facility is located in the continental United States and your new or existing boiler or process heater burns at least 10 percent liquid fuel (such as distillate oil, residual oil) and less than 10 percent coal and less than 10 percent biomass, on an annual average heat input basis, your unit is in the liquid subcategory. If your non-continental new or existing boiler or process heater burns at least 10 percent liquid fuel (such as distillate oil, residual oil) and less than 10 percent coal and less than 10 percent biomass, on an annual average heat input basis, your unit is in the non-continental liquid subcategory. Finally, for the combustion-based

pollutants, if your unit combusts gaseous fuel that does not qualify as a “Gas 1” fuel, your unit is in the Gas 2 subcategory.

Clearly, the promulgated gas 1 and liquids subcategory definitions did not reflect the preamble descriptions or the proposal relative to the 10% liquids criterion. Since removing the 10% criterion from the gas 1 and continental liquids subcategory and not including it in the non-continental subcategory was not discussed in the record and is not a logical outcome of the proposal, the definitions in the March 21, 2011 BPH NESHAP were not been properly promulgated and the definitions in the current proposal should correct that error or EPA should explain the basis for the change in a new notice and request comment.

The 10% allowance is needed because the testing and gas curtailment exclusions in this proposal and in the March 21, 2011 final rule are inadequate because they do not provide for liquid fuel firing by primarily gas-fired BPH in all the situations where it is necessary or desirable.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Commenter Name: Matthew Todd

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 29

Comment: Liquid firing is needed on some typically gas fired BPH in the following situations.

- When refinery gas is curtailed, when the curtailment is due to a situation that might be deemed to be under the control of the facility, such as shutdown or cutback (either planned or unplanned) of a refinery gas producing unit or the gas treating and transport system or where maintenance is needed on the gas system. In most cases, natural gas is used to replace refinery gas when a site refinery gas producer is not available (e.g., undergoing maintenance) or at reduced rates (e.g., because of product demand). However, for non-continental refineries and some continental ones, adequate natural gas supply is not available⁹ and liquids must be used to make-up for a refinery gas shortfall. Under the existing and proposed §63.7575 definition of “period of gas curtailment or supply interruption,” outages of on-site gas production due to process maintenance or product demand mismatch would not be considered curtailments and thus any liquid firing during that period would make the impacted BPH liquid subcategory units rather than gas subcategory units.
- Where liquid fuel is the backup for gas 1 fuel emergency outages, facilities often need to introduce small amounts of liquid continuously into the burner to assure the liquid fuel will be instantaneously available should an emergency or malfunction cause an unexpected loss of fuel gas¹⁰. The 48 hour allowance in the proposal is inadequate for this situation, particularly since most of the 48 hours could be needed for testing and training. Maintaining boiler operation in such emergencies can be critical to avoiding emergency shutdowns of processes and to providing steam to prevent flare smoking.
- In some cases, small amounts of non-hazardous secondary materials are used as supplemental fuel in BPH. Where such fuels meet the criteria in Part 241, such an operation

would be subject to this regulation. Recovery of energy from such streams is environmentally desirable and should be encouraged. Allowing for up to 10% liquids before a BPH is reclassified to the liquid subcategory fosters this energy recovery.

[Footnote 9: For continental refineries, natural gas supply can be limited by delivery piping constraints.]

[Footnote 10 One refinery reports the following configuration. Under normal operating conditions, oil is circulated through a piping loop in which a 1 gpm slipstream is continuously sent to the burners of the boiler to be burned while the remaining oil returns to the storage tank. Oil circulation through the loop with a minimum oil burn rate has allowed this system to remain in standby service should either a natural gas curtailment or fuel gas supply emergency require its use to maintain boiler operation. In the case in which continuous burning is no longer permitted, the oil circulation system would be susceptible to plugging, especially in the stagnant, un-insulated lines and valves. Pluggage of any of these lines or valves would result in a non-operational oil fuel system should it be needed. A reliable and operational oil system could very well save refinery operations in the event of a fuel supply emergency.]

107A02. Automatically Include Other Gases in Gas 1 Definition [DENIED PETITIONER ISSUE]

Commenter Name: William C. Herz

Commenter Affiliation: The Fertilizer Institute (TFI)

Document Control Number: EPA-HQ-OAR-2002-0058-3448-A1

Comment Excerpt Number: 8

Comment: TFI requests that EPA revise the *Industrial Boiler Major Source NESHAP* to explicitly recognize purge gas from an ammonia plant as an "other gas 1 fuel" in EPA's regulations without the need for (1) preparation and submission to EPA of a site-specific fuel analysis plan, and (2) sampling and analysis of the purge gas stream to demonstrate that the mercury concentration meets the "other gas 1 fuel" limits. There is no benefit to developing and implementing a sampling plan for this purge gas stream when it is just unreacted desulfurized natural gas in the first instance.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: William C. Herz

Commenter Affiliation: The Fertilizer Institute (TFI)

Document Control Number: EPA-HQ-OAR-2002-0058-3448-A1

Comment Excerpt Number: 9

Comment: As further support for TFI's request, EPA states in the preamble to the Proposed Rule that "The emissions data for natural gas-fired units show the overwhelming majority of

emissions to be below the level that can be accurately quantified by the available test methods." In addition, ammonia plant operators are provided with periodic analyses of the constitution of the natural gas feed; and these indicate that contaminants are typically *de minimus*.

As ammonia plants utilize this purge gas stream which is simply unreacted desulfurized natural gas, TFI requests that an exemption be granted for purge gas utilization in this context.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: Peter Pagano

Commenter Affiliation: American Iron and Steel Institute (AISI)

Document Control Number: EPA-HQ-OAR-2002-0058-3490-A1

Comment Excerpt Number: 17

Comment: The definition of "other gas 1 fuels" should be amended so that process gases covered by parts 60, 61, or 63 are covered without demonstrating they contain less than 40 ug/m³ mercury. Members of the iron and steel industry send process gases, including coke oven gas and blast furnace gas, to boilers and process heaters, that are equivalent to, if not superior to traditional environmental controls. They beneficially reuse these gases for their heat content, conserve energy, reduce the use of other fuels in the operation of boilers and process heaters, and reduce overall emissions. Process gases should be accorded the same treatment as natural gas and refinery gas in this provision and the definition of "other gas 1 fuels" in section 63.7575 should be amended to reflect this.

Comment: While AIF Supports EPA's Proposal to Eliminate the H₂S Specification, Given Landfill Gas' Relative Equivalence to Natural Gas and Refinery Gas in Relevant Emission Measures, EPA Should Automatically Classify Landfill Gas as a Gas 1 Fuel.

In the reconsideration proposal, EPA does not propose to change the Gas 1 category to automatically include LFG; it still proposes to classify use of LFG in the Gas 2 category. *See Boiler MACT Reconsideration*, 76 Fed. Reg. at 80,641, 80,652, 80,655. Yet, as EPA offers no sound science or policy rationale supporting its proposed listing of LFG as a Gas 2 fuel, AIF urges EPA to automatically identify LFG in the Gas 1 fuel category in the final reconsideration rule.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Comment: As noted above, [See DCN EPA-HQ-OAR-2002-0058-3512-A1.] July 15, 2011, comments concluded that LFG is comparable to the Gas 1 fuels NG and RG in the relevant emission measures. In the [See DCN EPA-HQ-OAR-2002-0058-3512-A1.], dated December 2011, CH2M Hill provides further support as to its relative equivalence. *See* [See DCN EPA-HQ-OAR-2002-0058-3512-A1.] (December 2011), (attached to these comments). CH2M Hill conducted a comparison of the emission properties of boilers firing LFG as fuel to those of boilers firing Gas 1 fuels NG and RG, and examined the readily available public information to compare those fuels. As reflected in the report, CH2MHill concludes that sufficient data were readily available for EPA to establish that LFG is comparable to NG and RG with regard to HAP emissions, and that both emissions and raw gas analysis data support classification of LFG as a Gas 1 fuel. Accordingly, EPA cannot reasonably treat LFG differently from the Gas 1 fuels NG and RG. It should identify LFG as a Gas 1 fuel in the final reconsideration rule.

Comment Excerpt Number: 17

Comment: *As Extensive Data Reflect Hg Concentrations in Landfill Gas as Consistently and Considerably Below the 40 µg/m³ Limit in the “Other Gas 1 Fuel” Specification, EPA Should Automatically Classify Landfill Gas as a Gas 1 Fuel.* As discussed in greater detail below, EPA proposes to eliminate the H₂S fuel specification and use a fuel specification for “other Gas 1 fuel” based only on the Hg level in the gaseous fuel (using the same level as EPA included in the final rule). *See Boiler MACT Reconsideration Proposal*, 76 Fed. Reg. at 80,653. EPA proposes a new definition of “other Gas 1 fuel” in 40 C.F.R. § 63.7575 as: a gaseous fuel that is not natural gas or refinery gas and does not exceed the maximum concentration of 40 micrograms/cubic meters of mercury.

Id. Under this proposal, LFG – as well as other gaseous fuels besides NG and RG – still would still initially fall under a Gas 2 fuel classification but could now gain classification in the “other Gas 1 fuel” category with a demonstration of not exceeding the previously published Hg limit of 40 µg/m³.

The large quantity of available data, including data developed by EPA in 2008, demonstrates that LFG consistently tests for concentrations of Hg well below the 40 µg/m³ threshold.⁸ The Hg concentrations reported in the numerous studies listed in Attachment D (attached to these comments) provide sufficient evidence, in accordance with § 63.7521(i), and without the need to conduct further studies, to identify LFG as a Gas 1 fuel along with NG and RG. As is articulated in Attachment D, based on the individual data measurements reported in the numerous published

studies, the mean concentration of Hg in LFG is 2 µg/m³ and the 95% upper confidence limit is 2.7 µg/m³—*i.e.*, well below the 40 µg/m³ threshold.⁹

The abundant published data on Hg levels in LFG, including the many studies sponsored by EPA, support an automatic Gas 1 categorization for LFG as a Gas 1 fuel. The data demonstrate that Hg concentrations in LFG are consistently below the 40 µg/m³ fuel specification level. There are far more data on the record demonstrating LFG as containing concentrations of Hg well below the 40 µg/m³ threshold than data demonstrating, for example, concentrations of RG as falling below that threshold. EPA’s determination to automatically classify RG as a Gas 1 fuel based on that dataset indicates that LFG should be treated similarly given the dataset on its emissions levels.¹⁰ There is no rational basis to subject units that utilize LFG to the certification and monthly testing provisions of the demonstration mechanism (discussed in more detail in the succeeding sections).

[Footnote 8: This data is outlined in greater detail in the attached document entitled “Studies of Mercury Concentrations in Landfill Gas,” Attachment D (attached to these comments).]

[Footnote 9: The overall mean concentration of Hg in LFG and the highest 95% upper confidence limit, calculated from one study that presents only summary statistics as opposed to individual test results, is 4 µg/m³ and 12 µg/m³, respectively.]

[Footnote 10: The AIF agrees that RG should be treated as Gas 1. EPA should treat similar fuels similarly and cannot justify imposing a higher testing or “proof” standard to LFG.]

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Comment Excerpt Number: 18

Comment: *Compelling Policy Reasons Support EPA Automatically Classifying Landfill Gas as a Gas 1 Fuel.*

LFG functions as a viable replacement for fossil fuel and AIF’s members have chosen to purchase LFG and utilize it as an alternate fuel to NG, in part *in response to EPA programs* encouraging its use in this manner. For some members, this can function as a key element in their corporate sustainability goals. The imposition of new and unreasonable regulatory burdens on LFG combustion would undercut LFG’s viability as a renewable alternative fuel and the investment made in its use by many companies, including AIF’s members. EPA’s failure to identify LFG as a Gas 1 fuel would subject units utilizing LFG to stringent emission limits, which many facilities, including those owned and/or operated by AIF members, would struggle to meet, thereby creating strong disincentives to the use of LFG in boilers.¹¹ Such an outcome would conflict with EPA’s stated policy of encouraging the beneficial use of LFG. *See LMOP, supra.* Under the Boiler MACT, units designed to burn Gas 2 fuels are subject to strict numeric emission limits for certain HAPs. By EPA’s own analysis, the estimated control costs for Gas 2 units are higher than the combined compliance capital costs for boilers and process heaters in all

other categories. *See* LMOP, *supra*. Many of the facilities owned and/or operated by AIF members would be forced to consider using only NG or some other fossil fuels if LFG-firing in boilers is subjected to Gas 2 emission limits.

Discouraging the use of LFG as an alternate to NG could lead to detrimental environmental impacts. As of September 20, 2011, EPA's LMOP contained data on 60 boiler projects and 17 boiler-steam turbine projects that utilize LFG. EPA estimates reflect the 60 boiler projects as utilizing approximately 1900 Million British Thermal Units per hour ("MMBtu/hr") of LFG and the 17 boiler-steam turbine projects as utilizing approximately 2400 MMBtu/hr of LFG.¹² If those project owners and/or operators were to stop combusting LFG and instead combust NG, the landfills could not simply cease producing the LFG those projects use; rather, the landfills would have to combust the neglected LFG, increasing emissions of greenhouse gases and criteria pollutants. Based on EPA's own calculations, the resulting net increase in overall fossil fuel-based CO₂ emissions from those boiler and boiler-turbine projects would be 2,025,698 tons. Further, the nation would experience additional emissions of 12,841 tons of CO, 291 tons of PM and 684 tons of NO_x, as well as slight increases in SO₂ and Hg emissions.

Unless EPA amends the reconsideration proposal, the regulated community, including AIF's members, would likewise incur significant financial costs combusting NG rather than LFG to comply with the Boiler MACT. For boiler and boiler-turbine projects now using LFG, the order-of-magnitude estimate of the total direct costs of switching to NG is \$ 1.064 billion. *See* CH2M Hill, *Boiler MACT Economic Impact Evaluation* (Nov. 9, 2011), Attachment B (attached to these comments). Moreover, project owners would lose the value of the LFG processing and transport equipment that they would have to abandon in ceasing to use LFG. *See id.* The total estimated capital assets lost for existing projects would be \$87 million. *See id.*

These compelling policy reasons indicate that EPA should automatically identify LFG as a Gas 1 fuel in the final reconsideration rule.

[Footnote 11: AIF members with units presently utilizing LFG anticipate they would not be able to meet the Gas 2 category's stringent emission limits (*e.g.*, for CO), particularly in the case of units designed and permitted to minimize emissions of NO_x (for ozone attainment).]

Comment: EPA's revisions, however, do not go far enough. The fuel gas specification should be amended to remove mercury when the gas in question is hydrogen. Hydrogen is a very clean fuel and as a consequence few labs are experienced in analyzing and testing hydrogen gas, nor are they equipped to do so because of its explosible nature. To the VI's knowledge, there is only

one mercury cell chlorine plant left in the U.S. that generates hydrogen gas that might be used in boilers or process heaters. Many other plants produce hydrogen byproducts that could be burned in boilers or process heaters, but have no contact with mercury in their processes. EPA should amend the fuel specification to allow hydrogen gas to qualify as a Gas 1 fuel without mercury testing where the facility's processes could not contaminate the hydrogen gas with mercury.

Comment: Under proposed Section 63.730(g), other gaseous fuels must meet the Hg standard during an initial test and if the fuel varies above the initial test additional Hg testing must be performed monthly. This section also requires that the other gas fuel not exceed the standard and requires a "Notification of Compliance Status." Based on the data in Table 2, these requirements should not apply to LFG. [see submittal Table 2] Furthermore, applying monthly testing of LFG is onerous, costly, and not supported by the data.

Again, NSWMA recommends that LFG be classified as a Gas 1 fuel. However, before EPA imposes these requirements on LFG, EPA needs to justify such action. We also recommend that EPA revise the language in the section such that a designated representative can actually sign the notification without undo legal or fiduciary risk.

Comment Excerpt Number: 1

Comment: LFG should be classified as a "gas I" in the final rule publication. As presently written, only natural gas (NG) and refinery gas (RG) qualify as 'gas I' fuels. As such, boilers using NG or RG and subject to work practice standards rather than emission standards. RG is defined in the Boiler MACT as follows:

Refinery gas means any gas that is generated at a petroleum refinery and is combusted. Refinery gas includes natural gas when the natural gas is combined and combusted in any proportion with

a gas generated at a refinery. Refinery gas includes gases generated from other facilities when that gas is combined and combusted in any proportion with gas generated at a refinery.

In "Refinery Gas Category Analysis and Hazard Characterization" the American Petroleum Institute (API) discusses the production and variability of RG. Stating that RG:

are primarily produced in petroleum refineries as the light end fractions of numerous distillation and cracking processes, or in gas plants that separate natural gas and natural gas liquids. These gases exist as substances in closed systems in the refinery, with none being sold as finished products because one or more constituents of refinery gases make them unsuitable for commercial sale (pg4).

RG is typically used to generate power in the refinery. When this is not possible the gases are flared to control emissions.

Similarly, LFG must be flared when it cannot be beneficially used. It is essential to consider that if onerous regulations preclude the beneficial use of LFG, no emission reductions will be gained because the LFG will be controlled by flaring. In fact, the use of fossil fuels in place of LFG (while flaring LFG) will increase emissions, therefore LFG use is preferable.

Although LFG is capable of qualifying as an "other gas 1" by either certifying the quality or subjecting to monthly testing, categorizing LFG as either "gas 2" or "other gas 1" puts an undue burden on landfills and the industries that utilize LFG. Imposing these additional requirements has the potential to severely hinder the beneficial use of LFG because many LFGTE projects are only marginally economically viable. The reconsideration should not limit the utilization of LFG or otherwise discourage its beneficial use. The most direct way of ensuring this is to extend the definition of "gas 1" to include LFG.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Document Control Number: EPA-HQ-OAR-2002-0058-3681-A2

Comment Excerpt Number: 1

Comment: From an environmental and economic perspective, the combustion of LFG in boilers is a positive alternative to control of LFG in flares. Failure to categorize LFG as a "Gas 1" fuel will subject LFG boilers to stringent emission limits, thereby creating strong disincentives to the use of LFG in boilers and hampering many private, local government and federal government facilities' sustainability efforts and significantly disrupting domestic renewable energy production. The U.S LFG to energy sector is a significant portion of the domestic renewable energy sector, producing more than 7 times the energy output of the entire domestic solar energy sector².

Comment Excerpt Number: 2

Comment: Under the proposed Boiler MACT Reconsideration Rule, units designed to burn Gas 1 fuel (including natural gas and refinery gas) are not subject to emission limits, while units designed to burn “Gas 2” fuels are subject to strict numeric emission limits for PM, HCL, Mercury and CO. By EPA’s own analysis, the control costs for Gas 2 boilers are estimated to be higher than the combined compliance capital costs for boilers and process heaters in all other categories. WM’s LFG customers have indicated that they may not be able to meet the proposed Gas 2 emission limits (e.g., for CO) particularly for units designed and permitted to minimize NOx emissions (for ozone attainment). Therefore, the boiler owners may be forced to switch to natural gas if LFGfired boilers are subject to “Gas 2” emission limits. EPA’s creation of such disincentive for use of LFG is contrary to the Agency’s own stated policy of encouraging the beneficial use of LFG³. The environmental consequences of creating barriers to using LFG are very detrimental. As of September 20, 2011, EPA’s LMOP has data on 60 U.S. boiler projects and 17 projects that utilize LFG in boiler-steam turbines. EPA estimates that the 60 boiler projects utilize approximately 1900 Million British Thermal Units (MMBtu) per hour of LFG, and that the 17 boiler-steam turbine projects utilize approximately 2400 MMBtu per hour of LFG. If the project owners switch from LFG to natural gas, LFG will still be generated by the landfills and therefore must be combusted, increasing emissions of greenhouse gases and criteria pollutants. EPA calculated the net increase in overall fossil fuel based CO2 emissions from boiler and boiler – turbine projects would be 2,025,698 tons. The nation would also realize an additional 12,841 tons of CO, 291 tons of PM and 684 tons of NOx. SO2 and mercury emissions would also increase slightly by 10.2 and 0.0052 tons, respectively. [See submittal for Attachment A –EPA LMOP Environmental Analysis provided to WM]

Commenter Name: Kerry Kelly

Commenter Affiliation: Waste Management (WM)

Document Control Number: EPA-HQ-OAR-2002-0058-3681-A2

Comment Excerpt Number: 4

Comment: EPA has already evaluated, and regulated, hazardous air pollutant (HAP) emissions that may result from the two circumstances under which LFG may be used in a boiler under the Landfill NSPS and the Landfill MACT. First, LFG fired directly to a boiler operating as a control device is subject to the non-methane organic compounds (NMOC) emission standard that was established pursuant to the Landfill NSPS and determined under the Landfill MACT to adequately address HAP emissions. Imposition of additional emission limits from such control devices would constitute an impermissible duplication of emission limits under Section 112 of the CAA. Second, the Landfill NSPS and the Landfill MACT require that LFG used as a fuel must be treated and processed in a manner that ensures proper combustion in accordance with specifications required by the receiving combustion unit. Imposition of emission limits under the Boiler MACT Reconsideration Rule, as proposed for this use of LFG, where natural gas and refinery gas are not subject to such limits, would create an extreme disincentive to the use of LFG for energy recovery. For these reasons, the Gas 2 emission limits in the Boiler Rule should not apply to LFG-fired boilers. The emission limits established for Gas 2 units are technically infeasible and cost prohibitive to promoting renewable sources of energy. As previously stated, WM’s LFG customers have indicated that they may not be able to meet the Gas 2 emission limits particularly units designed and permitted to minimize NO_x emissions (for ozone attainment). Therefore, they may be forced to switch to natural gas if LFG-fired boilers are subject to “Gas 2” emission limits.

Document Control Number: EPA-HQ-OAR-2002-0058-3681-A2

Comment Excerpt Number: 5

Comment: In our Petition for Reconsideration of the Boiler MACT Rule, WM requested that the Agency reconsider its categorization of LFG as “Gas 2” and amend the rule to clarify that LFG constitutes a “Gas 1” fuel for which the imposition of emission limits is infeasible and impracticable. EPA’s proposed Boiler MACT Reconsideration Rule fails to do so. Furthermore,

the proposed Boiler MACT Reconsideration Rule offers no sound science or policy rationale for continuing to list LFG as a Gas 2 fuel.

WM contracted with CH2M Hill to conduct a comparison of the emissions properties of boilers firing LFG as fuel to those of boilers firing Gas 1 fuels, and to examine the publicly available information to compare LFG to Gas 1 fuels, specifically natural gas and refinery gas. [See submittal for Attachment C – Boiler MACT Fuel Classification Review for Landfill Gas] CH2MHill concluded that sufficient data were readily available for EPA to establish that LFG is comparable to natural gas and refinery gas with regard to HAP emissions, and that both emissions and raw gas analysis data support the conclusion that LFG should be classified as a Gas 1 fuel. A brief summary of the report conclusions follows. Table 3 from the CH2M Hill report provides a comparison of the readily available data for total mercury in LFG to comparable data for natural gas and refinery gas. [See for Table 3 of Attachment C]

Comment Excerpt Number: 6

Comment: EPA’s 2008 effort to establish an appropriate default parameter for Hg in LFG found no instances of LFG exceeding the fuel specification value of 40 micrograms per cubic meter ($\mu\text{g}/\text{m}^3$) among the numerous tests conducted that EPA reviewed. Data developed by EPA in its 2008 BID support the conclusion that the mercury levels in LFG are consistently much lower than the Gas 1 fuel specification level of 40 $\mu\text{g}/\text{m}^3$, which should serve as a basis for listing LFG in the same Gas 1 category as natural gas and refinery gas. The data for mercury in LFG supports its characterization as a Gas 1 fuel. Mercury levels in raw LFG from 15 landfills reported in EPA’s BID (2008) indicated a range of total mercury levels comparable to levels found in the available data for mercury in natural gas. Because of the dearth of available data for HAP and surrogate parameters in the Gas 1 fuels, one cannot effectively compare the constituents of raw LFG to the recognized Gas 1 fuels for those parameters. However, a comparison of the readily available emissions data for boilers fueled by only LFG indicates that the ranges of reported results for mercury, PM, CO, and dioxin/furans are within or below the ranges of those parameters for one or both of the recognized Gas 1 fuels, natural gas and refinery gas. No HCl data were available for refinery gas for comparison to LFG. However, the few HCl emissions data available from LFG-fueled boilers (0.00321 to 0.00398 pounds per million British thermal units [lb/MMBTU]) are lower than the Boiler MACT emission limits for both new and existing solid fuel-fired units (0.022 lb/MMBTU).

Comment Excerpt Number: 7

Comment: Numerous Published Studies Have Measured Mercury Concentrations in LFG. A large dataset of mercury concentrations in LFG is available from numerous published studies and reports. In the proposed rule, however, it appears the Agency considered only three LFG samples and these were evaluated on a lb/MMBtu basis (Excel Spreadsheet. MACT Floor Memo Appendixes C, D, and E. Boiler Maximum Achievable Control Technology docket site, EPA Docket No. EPA-HQOAR- 2002-0058-1388.1).⁴ Although emission limits are evaluated on a lb/MMBtu basis, the fuel specification limit is based on the mercury concentration in LFG reported in units of micrograms per cubic meter ($\mu\text{g}/\text{m}^3$). The published studies that have included sampling of mercury in LFG are shown in the table below. [See pg 5 of the submittal for the table of studies] Samples have been collected from more than 30 landfills located throughout the United States and the United Kingdom. All of these studies are readily available through the internet and, in fact, several were conducted for EPA. This wealth of information should be considered by the Agency as part of this proposed rule.

[Footnote]

(4) The three mercury measurements, collected from a single landfill gas unit at a BMW facility, were incorrect. EPA indicated in its response to comments that this error has been corrected (See comment and response on May 18, 2011 reconsideration notice in 76 FR 28662 at EPA Docket Control No. EPA-HQ-OAR-2002-0058-2775.1).

Commenter Affiliation: Waste Management (WM)

Document Control Number: EPA-HQ-OAR-2002-0058-3681-A2

Comment Excerpt Number: 8

Comment: Mercury Concentrations in LFG Are Consistently Below the 40 $\mu\text{g}/\text{m}^3$ Fuel Specification Limit. As noted above, a large dataset of mercury concentrations in LFG is available from numerous published studies and reports, including many studies conducted for EPA (USEPA 2005, 2007, 2008, 2009, 2012; Frontier 2003; Lindberg et al. 2005; Netcen 2003; UKEA 2004). These data have been collected from 30 landfills located throughout the United States and 12 landfills in the United Kingdom. Overall, these studies provide a robust database of more than 150 measurements that reliably characterizes the levels of mercury in LFG. To demonstrate that a gaseous fuel other than natural gas or refinery gas qualifies as a Gas 1 fuel (76 FR 80633), the rule requires that a fuel specification analysis be conducted. The analysis must characterize mercury concentrations in the fuel, demonstrate that mercury concentrations do not exceed 40 $\mu\text{g}/\text{m}^3$, and address a variety of associated requirements related to sampling and analysis (e.g., descriptions of sample locations, procedures for collecting and analyzing samples). The existing database of mercury LFG measurements complies with the objectives of the proposed Boiler MACT Reconsideration Rule regarding a fuel specification analysis. In fact, this database presents a more comprehensive characterization of mercury in LFG than would be

developed for any individual fuel source. The sample size of the existing dataset is substantially greater than the number of samples that would be collected under the proposed rule. Indeed, the proposed rule appears to indicate that collection of three samples from each fuel type would be adequate for a fuel specification analysis and Section §63.7521(h) implies that even one sample may be adequate. In addition, each of the published LFG studies provides descriptions of sample locations, sample collection and analysis methods, and assessments of data quality. These elements address the fuel specification requirements laid out in §63.7521(g)(2). The mercury concentrations reported in the existing database provide sufficient evidence, in accordance with §63.7521(i) and without the need to conduct further studies, to qualify LFG as a Gas 1 fuel. These data consistently demonstrate that concentrations are below the 40 µg/m³ fuel specification limit. All of the measurements reported in the published literature are below 40 µg/m³. Additionally, the mean concentration of mercury in LFG is 2 µg/m³ and the 95% upper confidence limit is 2.7 µg/m³, based on the individual data measurements reported in the many published studies noted above. The overall mean concentration of mercury in LFG and the highest 95% upper confidence limit, calculated from one study which presents only summary statistics and not individual test results, is 4 µg/m³ and 12 µg/m³, respectively. In sum, the Agency should consider the abundant published data on mercury levels in LFG in this rulemaking, including the many studies that it has sponsored. These data demonstrate that mercury concentrations in LFG have been proven to be consistently below the 40 µg/m³ fuel specification limit and support the characterization of LFG as a Gas 1 fuel. Based on the above analysis, WM strongly recommends that LFG be categorized as Gas 1 under the Boiler MACT Reconsideration Rule. The data for mercury and hydrogen sulfide (H₂S) in LFG support its characterization as a Gas 1 fuel.

Comment Excerpt Number: 2

Comment: Although ConocoPhillips believes the fuel used for boilers and process heaters (BPH) at many oil and natural gas facilities will fall into the definition of natural gas, we are concerned that some natural gas plants use a gas stream containing higher concentrations of ethane, propane, and butane, and may not meet the definition of natural gas because the gas contains less than 70% methane or does not fit into the heating value range of 910 to 1,150 Btu/SCF. We request for EPA to classify fuel gas at natural gas plants not meeting the definition of a natural gas, to be classified as "other gas 1" and not be required to verify mercury content. This change would make the process gas at natural gas plants more consistent with refinery fuel gas which is defined separately.

Document Control Number: EPA-HQ-OAR-2002-0058-3778-A1
Comment Excerpt Number: 5

Comment: PPG, like many integrated chemical plants, uses process gases from processing areas as fuels in boilers and process heaters. PPG's process gas is a clean-burning hydrogen. The use of this hydrogen is critical to maintaining energy efficiency and cost efficiencies at our sites. Based on the extremely low numeric standards proposed for Gas 2 units and the uncertainty surrounding the efficacy of expensive add-on controls, PPG would likely be forced to burn these process gases in a non-optimal manner, such as routing this fuel to flares or other combustion sources at the site, and replacing the lost fuel value by burning more natural gas. Forcing this switch is contrary to the nation's goal of reducing fossil fuel use and encouraging use of alternate energy sources.

107A03. Re-Evaluate Gas 2 Subcategory [DENIED PETITIONER ISSUE]

Commenter Name: Peter Pagano
Commenter Affiliation: American Iron and Steel Institute (AISI)
Document Control Number: EPA-HQ-OAR-2002-0058-3490-A1
Comment Excerpt Number: 30

Comment: The MACT floor for Gas 2 units is based on insufficient data.

EPA's reconsidered rule magnifies an error that AISI identified in its comments on the previous Boiler MACT proposed rule submitted on August 23, 2010. EPA improperly relies on a single source to set the Gas 2 MACT Floor emission rates. In the reconsidered rule, EPA now relies on a single source for *all* of the Gas 2 emission limits. We understand and support EPA's decision to reduce the size of the Gas 2 subcategory in the reconsidered proposed rule. However, Congress directed EPA to use a group of sources to set existing source MACT standards as distinct from the best single source, which Congress reserved for the new source MACT standard. Cf. §§ 112(d)(3)(A) and (B). EPA must recalculate the Gas 2 MACT Floors to reflect more than one source for a subcategory that now contains 129 sources by EPA's count.

In fact, Congress preferred that EPA use a minimum of five sources when setting the MACT Floor emission limits for a source category. The word "sources" as used in the last clause of §§112(d)(3)(A) and (B) to describe the size of the subcategory at issue does not specify whether it refers to "sources" for which data exist or the total number of sources in the subcategory. However, the word "sources" in the earlier facets of those sections clearly refers to the sources for which EPA has emissions information. Thus, it is reasonable to conclude that Congress intended the word "sources" to have a consistent meaning within these subsections and that the reference "30 or more sources" at the end of § 112(d)(3)(A) and "fewer than 30 sources" at the end of § 112(d)(3)(B) reasonably means sources for which EPA has emissions information. That interpretation allows EPA to read the statute such that Congress' chosen line between new and

existing source-setting methodology is not blurred. Alternately, EPA's use of at least 5 sources could also be justified under the "absurd results" doctrine. Congress clearly expected enough emissions information to be available for larger source categories to generally cause more than 5 sources to constitute the top 12%. It makes no sense for Congress to specify a minimum number of sources for source categories with few sources, but then to create a rule that would allow for standards to be set using data from fewer than 5 sources in larger source categories. Using no less than 5 sources would give effect to the clear intention of Congress.

Comment: A single source used to establish the MACT Floor raises a number of additional concerns. First, the single source cannot adequately represent the variability across sources within a subcategory based on design, age, load, or location. Second, a single source MACT Floor offers no check on irregularities or anomalies in the stack test sampling or laboratory analysis for the data that EPA is using to set the standard. If multiple sources are used to set the MACT Floor, clear outliers or data errors can be better assessed and are mitigated by the averaging across different sources using different stack testing companies and laboratories. Finally, the single source may prove to be in an entirely different subcategory. The single source used for Gas 2 MACT Floors is a coke plant in Follansbee West Virginia that burns coke oven gas or a mixture³⁹ containing coke oven gas in its affected boiler. In its November 2011 MACT Floor Memo, at page 4, EPA states, "We did not assume that coke oven gas would be able to meet the fuel specification that is in the proposed rule, although some coke oven gas may meet the specification." If the Follansbee boiler burns coke oven gas that meets the Gas 1 specification, the entire Gas 2 MACT Floor analysis is without basis. EPA should revisit the quality and quantity of data that it relied on in setting the MACT Floor for the Gas 2 subcategory.

[Footnote]

(39) EPA's gas 2 subcategory includes affected gas-fired units (not otherwise exempt) that burn any amount of a Gas 2 fuel. *See* 76 FR 80655 (Dec 23, 2011) (defining "*unit designed to burn gas 2 (other) subcategory*"). It follows that the MACT Floor for the Gas 2 subcategory could be based on test data from units burning primarily natural gas or other gas 1 fuel. EPA should identify the mixed gas ratio for the unit establishing the gas 2 MACT Floor so we can assess its relevance to the gas 2 subcategory.

Comment Excerpt Number: 8

Comment: If EPA Decides That Gas 2 Numerical Emission Limits Apply to Coke Oven Gas-Fired Units, a Separate Subcategory for Coke Oven Gas-Fired Units Should Be Considered EPA has proposed the Gas 2 subcategory to encompass all gaseous fuels that are not natural gas or refinery gas. This catch-all subcategory includes landfill gas, coke oven gas, coal-derived gas, biogas, and other process gases. EPA offers no justification for combining these disparate gases into a single subcategory but it may have been driven by a lack of data. With just five sources in the Gas 2 subcategory with dioxin-furan data and just eight sources with data for Hg and HCl, EPA had tied its own hands by not collecting sufficient data to properly distinguish between fuels with significantly different chemical compositions, heating values, and combustion characteristics. EPA's decision to lump these Gas-2 sources together based on what they are not (e.g., because they are not burning natural or refinery gas) is arbitrary and unlawful. Gas 2 fuels are not interchangeable. These gaseous fuels are combusted at or near their point of generation and used to reduce reliance on fossil fuels. Therefore, a Gas 2 source cannot decide to burn landfill gas to help meet the Hg emission standards if they are not in the vicinity of a landfill. Similarly, coke oven gas is only available in the vicinity of coke batteries. Thus, most of the 199 Gas 2 sources cannot use coke oven gas to help other Gas 2 emission limits. Nor does it make environmental or economic sense to displace process gases with natural gas, because flammable process gases must be combusted to meet health and safety requirements. Flaring process gases and burning natural gas to reduce emissions at the boiler increases facility-wide emissions, decreases energy independence, and wastes opportunities for energy efficiency. Process gas-fired sources are not candidates for fuel switching. EPA must, as a result, evaluate and understand the emission characteristics of each process gas fuel to determine if its Gas 2 subcategory is properly defined as a reasonable aggregation of similar sources. EPA has proposed an arbitrary aggregation of dissimilar fuels in the Gas 2 subcategory, which would result in emission limits that are not achievable when burning some process gases even when implementing all available control measures. This should be a strong signal that further subcategorization is warranted prior to the promulgation of the final Boiler MACT rule. If EPA will be setting numeric emission limits for coke oven gas-fired boilers, then these units need a separate subcategory because they have no pathway to attain emission limits established by dissimilar landfill gas and biogas-fired units.

Comment Excerpt Number: 10

Comment: To gain a better understanding of the potential risk faced by coke oven gas-fired units under the broad Gas 2 subcategory proposed by EPA, an ACCCI member company conducted stack tests on four coke oven gas-fired boilers in July 2010. These test results were reported in our August 23, 2010 comments on the originally proposed rule and will not be repeated in detail here. Suffice it to state that the test results confirm that the proposed Gas 2

emission limits for HCl, Hg, and CO are not achievable for these coke oven gas-fired boilers using commercially available emission control technologies. The levels of HCl, Hg, and CO exceed the proposed Gas 2 limits by such a large margin that available emission control measures would be insufficient to achieve the proposed Gas 2 limits. Even if optimistic assumptions for control efficiency are applied to the uncontrolled levels measured in these tests, it is clear that the Gas 2 emission limits cannot be reliably achieved. Based on this analysis, it is technically infeasible for coke oven gas-fired boilers to achieve the proposed Gas 2 emission limits. Therefore, in the event that numerical emission limits are imposed on coke oven gas-fired units over our prior noted objections, we recommend that EPA consider developing a separate subcategory for coke oven gas-fired units to accommodate their unique chemical composition and emission profile.

107A04. Metal Process Furnace Definition [DENIED PETITIONER ISSUE]

Commenter Name: William C. Herz

Commenter Affiliation: The Fertilizer Institute (TFI)

Document Control Number: EPA-HQ-OAR-2002-0058-3448-A1

Comment Excerpt Number: 1

Comment: When EPA proposed the *Industrial Boiler Major Source NESHAP* (75 Fed. Reg. 32006 (June 4, 2010)), the Agency recognized that the designation of subcategories for boilers and process heaters should be based on the "primary fuel" that the boiler or process heater is designed to burn.² To that end, the Agency recognized when defining a number of the subcategories that a boiler or process heater may burn fuels other than the primary fuel, so long as the other-than-primary fuels are burned at no more than 10 percent of the heat input to the unit. Several examples are cited below: *Blast furnace gas fuel-fired boiler or process heater* means an industrial/commercial/institutional boiler or process heater that receives 90 percent or more of its total heat input (based on an annual average) from blast furnace gas.

Liquid fuel subcategory includes any boiler or process heater of any design that burns more than 10 percent liquid fuel and less than 10 percent solid fuel, on an annual heat input basis.

- and relevant to TFI members -

Units designed to burn gas 1 (NG/RG) subcategory includes any boiler or process heater that burns at least 90 percent natural gas and/or refinery gas on a heat input basis on an annual average.³

In the final *Industrial Boiler Major Source NESHAP* and the Proposed Rule, EPA retains the flexibility for units to remain within a subcategory while also burning other fuels, so long as the other-than-primary fuels are burned at no more than 10 percent of the heat input to the unit.

As examples:

Blast furnace gas fuel-fired boiler or process heater means an industrial/commercial/institutional boiler or process heater that receives 90 percent or more of its total annual gas volume from blast furnace gas.

Liquid fuel subcategory includes any boiler or process heater of any design that burns more than 10 percent liquid fuel and less than 10 percent solid fuel, based on an total annual heat input to the unit.

However, relevant to TFI members, in the final *Industrial Boiler Major Source NESHAP* and the Proposed Rule, EPA deletes the no more than 10 percent other-than-primary fuels flexibility for units to remain within the "Unit designed to burn gas 1 subcategory":

Unit designed to burn gas 1 subcategory includes any boiler or process heater that burns only natural gas, refinery gas, and/or other gas 1 fuels; with the exception of liquid fuels burned for periodic testing not to exceed a combined total of 48 hours during any calendar year, or during periods of gas curtailment and gas supply emergencies.

Notably, in neither the preamble to the final *Industrial Boiler Major Source NESHAP* nor the preamble to the Proposed Rule discussing changes to the definitions section of the rule does EPA discuss why it removed the flexibility for gas 1 subcategory units to burn no more than 10 percent of fuels other than natural gas or refinery gas and still remain in this subcategory. [Footnote 2: 75 Fed. Reg. at 32017.]

[Footnote 3: 75 Fed. Reg. at 32063 – 32065 (proposed for codification at 40 C.F.R. § 63.7575) (emphasis added).]

Commenter Affiliation: American Iron and Steel Institute (AISI)

Document Control Number: EPA-HQ-OAR-2002-0058-3490-A1

Comment Excerpt Number: 11

Comment: The definition of metal process furnaces and EPA's metal process furnace subcategory needs to be more inclusive to apply to the iron and steel industry and other process gas industries.

AISI previously provided comments to EPA regarding the impractical scope of its Metal Process Furnace Subcategory as proposed in the June 4, 2010, proposed rule. AISI does not believe the scope of the subcategory adequately addresses EPA's intent. To more accurately capture EPA's intention of developing the Metal Process Furnace Subcategory as it would apply to the iron and steel industry, EPA should include furnaces that combust process gases that would otherwise be flared. The steel industry employs numerous metal process furnaces, including reheat furnaces, annealing furnaces, and heat treating operations. Some of these are direct-fired and are not covered by the rule, but others are indirect-fired units, which would cause them to be classified as process heaters. AISI supports the separate classification of "metal process furnaces," which EPA found to be a "class of natural gas-fired process heaters that are designed and operated

differently compared to typical process heaters."²¹ As explained in the EPA's prior proposed rule from June 4, 2010:

A review of information gathered on process heaters used in the metal processing industries shows that these process heaters typically are designed with multiple burners that fire into individual combustion chambers. These individual burners are operated to cycle on and off to maintain the proper temperatures throughout the various zones of the process heater. Thus, due to their design, these process heaters rarely operate in a steady-state condition due to burners constantly starting up and shutting down. This results in emissions characteristics different from the process heaters used in other industries.²²

That passage correctly identifies the technological and operational issues that justify creation of a metal process heaters subcategory. However, the current proposed rule circumscribes that rationale by defining the subcategory to include only units that combust natural gas. While many metal process furnaces do use natural gas, others beneficially combust process gas, such as coke oven gas, to reduce the amount of additional natural gas needed to operate these units. Combusting process gases in metal process furnaces lowers emissions and increases energy efficiency by supplementing natural gas with a gas that would otherwise be flared.

Commenter Name: Peter Pagano

Commenter Affiliation: American Iron and Steel Institute (AISI)

Document Control Number: EPA-HQ-OAR-2002-0058-3490-A1

Comment Excerpt Number: 12

Comment: The type of gas combusted in a given metal process heater has nothing to do with the technical and operational distinctions that render them unique, including the distinctions that they are designed with multiple burners in a single unit and rarely operate in a steady-state condition. Rather, those same findings apply equally to all metal process heaters combusting any gaseous fuel. As such, there is no legitimate basis for limiting this subcategory to natural gas-fired units and EPA should redefine this subcategory to include furnaces combusting any gaseous fuel. Such a redefinition would also be in agreement with EPA's goals of reducing emissions and increasing energy efficiency.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: Peter Pagano

Commenter Affiliation: American Iron and Steel Institute (AISI)

Document Control Number: EPA-HQ-OAR-2002-0058-3490-A1

Comment Excerpt Number: 14

Comment: In addition, AISI requests that EPA revise the definition of metal process furnace to include the phrase "includes, but is not limited to" to acknowledge the fact that there may be other furnaces that should be excluded for the same reasons that the specifically mentioned examples are exempt. Specifically, in addition to annealing, preheat, reheat, aging, heat treat, and homogenizing furnaces, the following furnaces should be exempt:

Stress relief furnaces, which are similar to aging and heat treat furnaces in that they are used to heat and cool metal to eliminate stresses from forging and similar activities.

Galvanizing/galvanneal furnaces, which are similar to annealing furnaces in purpose and operation, but operate on a continuous (strip) rather than batch (coil) basis. Like annealing furnaces, these units fire sporadically as necessary to achieve an annealed consistency in the metal.

Alternatively, we request that EPA specifically add both of these units to the list of "metal process furnace" examples included in proposed §63.7575 and amend the definition as follows:

Metal Process furnaces include natural gas-fired annealing furnaces, preheat furnaces, reheat furnaces, aging furnaces, heat treat furnaces, and homogenizing furnaces, stress relief furnaces, and galvanizing/galvanneal furnaces.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

107B. Designed to Burn Subcategorization [DENIED PETITIONER ISSUE]

Commenter Name: James Pew

Commenter Affiliation: Earthjustice, Clean Air Council, Partnership for Policy Integrity

Document Control Number: EPA-HQ-OAR-2002-0058-3511-A1

Comment Excerpt Number: 1

Comment: In its new proposal, EPA expands the number of subcategories to thirty-eight, nineteen subcategories for both new and existing sources. All of EPA's subcategories are unlawful and arbitrary for the reasons given in the comments of Clean Air Task Force, Earthjustice, Natural Resources Defense Council and Sierra Club ("2010 Comments"), which are attached hereto and incorporated by reference as if fully stated herein and reiterated with respect to the agency's 2011 final rule and the most recently created subcategories in its reconsideration proposal as well as the subcategories EPA initially proposed in 2010. *See* 2010 Comments at 6-8. In particular, units are not of a different "class, type, or size" merely because they are allegedly "designed to burn" a type of fuel when: (1) they are otherwise the same as or closely similar to units that are allegedly "designed to burn" another type of fuel; (2) these units do in fact burn more than one type of fuel; and (3) these units may actually burn a majority of fuel that is not the type they are allegedly "designed to burn." For example, it is unlawful and arbitrary to set different standards for units allegedly "designed to burn" biomass but capable of burning (or actually burning) just 11% biomass and 89% coal on the one hand and for similarly designed

units allegedly “designed to burn” coal and but capable of burning (or actually burning) 9% biomass and 91% coal on the other. Indeed, EPA freely admits that sources can “switch categories” based on the fuel they choose to burn at any given time. Revised MACT Floor Analysis (2011) at 6. Because such units are not of a different “class, type, or size,” EPA lacks authority to set separate emission standards for them and any claim that they are of a different class, type or size is arbitrary.

The unlawfulness and arbitrariness of EPA’s subcategories is exacerbated by the agency’s approach to establishing the statutory minimum stringencies (“floors”) for its standards. To generate its existing-source floors, the Agency restricted its analysis to units burning 90% of the specified fuel. *Id.* New source floors are based on units burning 100% of the specified fuel. *Id.* As a result, the standards which apply to one set of sources (e.g., units burning no more than 10% biomass and more than 10% coal) are generated from the actual emissions of an entirely different group of sources (those burning 90% or 100% coal). That divergence violates the Act, which requires MACT standards to be at least as stringent as the best performing source or sources for the specified category. 42 U.S.C. § 7412(d). Assuming *arguendo* that EPA’s subcategories are valid and can be maintained, the agency’s standards for each one must reflect the emission level achieved by the relevant best performing sources in that specific subcategory. Because EPA has chosen to base floors not on the best performers in its chosen subcategories but instead on a group within the category that is using a certain type of fuel or mix of fuels, EPA’s standards contravene that requirement.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial. In particular, EPA disagrees that EPA’s rationale for subcategorizing boilers based on unit design is inconsistent with the Clean Air Act. The commenter first claims that units designed to burn different fuels are in fact “the same as or closely similar to” each other. As explained in the preamble to today’s action, that is not the case. Different provisions for fuel handling and preparation, fuel combustion, heat recovery, among other things, are needed when burning different fuels. In addition, boiler systems can encounter operational problems if operated on a different fuel than specified for that boiler design. The commenter provides no specific characteristics that to support its assertion that boilers burning different fuels are in fact the same. Further, section 112(d) provides EPA with broad discretion to subcategorize based on class, size, or type. For example, differences between given types of units can lead to corresponding differences in the nature of emissions and the technical feasibility of applying emission control techniques. . It is certainly possible that boilers can have some similar characteristics, but still be of sufficiently different classes, sizes, or types to warrant placing them in different subcategories.

The commenter also states that boilers may burn more than one type of fuel or a mixture of fuels. The commenter claims that it is “unlawful and arbitrary” to create different subcategories for units that are capable of burning more than one fuel or a mixture of fuels because such units are not of different classes, sizes, or types. EPA disagrees with the commenter. Given the broad statutory discretion to create subcategories, and the fact that some boilers do burn different fuels or a mixture of fuels at certain times, it is reasonable for EPA to establish criteria to distinguish among the different types of boilers, including boilers that combust different or a mixture of fuels at certain times. The definition of “Unit designed to burn ...” in the final rule is based on the actual annual heat input of the specific fuel type. Thus, we disagree with the comment that

“EPA freely admits that sources can switch categories ... at any given time. In the final rule, a source compliance demonstration depends on the subcategory it was in based on the fuels it burned the previous 12 months. We also disagree with the commenter assertion that it is arbitrary to set different standards for units designed to burn biomass but capable of burning just 11% biomass and 89% coal. First, as stated previously in the preamble, boiler systems are designed for specific fuel types and will frequently encounter combustion, slagging, fouling, or ash handling problems if a fuel with characteristics other than those originally specified is fired. Based on the technical literature, our engineering judgement is that a boiler will be burning a fuel type at more than 10% on an annual heat input basis only if it was designed for that specific fuel type. The National Energy Technology Laboratory of the Department of Energy has recommended when co-firing with coal, biomass or other co-firing materials should be limited to 10 percent to reduce or eliminate operation problems. (National Energy Technology Laboratory, 2009). In addition, test burn data from a coal-fired boiler co-firing biomass showed that the CO emission increased by 200 percent (from 98 ppm at 100% coal to 286 ppm at 90% coal/10% biomass) when co-firing 10 percent biomass. One of the criteria for subcategorization is differences in the nature of emissions. The subcategories were defined in such a manner so that all combination fuel-fired boilers would be covered by one of the subcategories. We believe it is unlikely that a boiler designed to burn coal would operate at 11% biomass and 89% coal just to be covered by one of the biomass subcategories. First, the unit may experience operational problems or need to be derated because biomass tends to have a high moisture content which reduces heating value and requires a larger volume boiler with larger auxiliary equipment (e.g., fans). In addition, the unit would be subject to the same mercury and HCl emission limits regardless of its fuel mix. The main difference would be the CO emission limit it is subject to which is appropriate because it is the combustion related pollutants that was the basis for the subcategorization.

As previously stated in the June 2010 proposal preamble (75 FR 32016-32017) and the March 2011 final rule preamble (76 FR 15635), the CAA allows EPA to divide source categories into subcategories based on differences in class, type, or size. For example, differences between given types of units can lead to corresponding differences in the nature of emissions and the technical feasibility of applying emission control techniques. The design, operating, and emissions information that EPA has reviewed indicates differences in unit design that distinguish different types of boilers. Data indicate that there are significant design and operational differences between units that burn coal, biomass, liquid, and gaseous fuels. [\[1\]](#)

Industrial boilers use heat to convert water into steam for a variety of applications. Steam flow rates and operating conditions (e.g., temperature and pressure) are the principal design considerations. The primary fuel has perhaps the most significant impact on the boiler configuration and design. When fossil or biomass fuels are burned, widely differing provisions are made to account for differences in fuel handling and preparation, fuel combustion, heat recovery, fouling of heat transfer surfaces, corrosion of materials, and emission controls. For example, in a natural gas-fired boiler, only a small furnace (i.e., combustion chamber) is needed for combustion and closely spaced heat transfer surfaces may be used because of a lack of ash deposits (fouling). For units firing a solid fuel such as coal (which can contain a significant amount of noncombustible ash), the systems must include a much larger furnace, more widely spaced heat transfer surfaces, and an ash removal system. The fuel and the combustion system define the design geometry of the furnace. The furnace volume is set to allow complete fuel

combustion. Adequate clearances are specified to prevent flame impingement on the furnace surfaces, which could overheat the tubes and cause tube failures.[2]

A variety of boiler systems are used to handle the variety of fuel characteristics and boiler sizes. Boiler systems that are designed for burning coal include pulverized coal (PC) units, stokers, and fluidized-bed combustion (FBC) units. Boiler systems that are designed for burning biomass fuels include stokers, Dutch ovens (pile burners), suspension burners, grate burners, and fluidized bed burners. All of these boiler designs have their strengths and weaknesses depending on the particular application.

Boiler systems are designed for specific fuel types and will frequently encounter combustion, slagging, fouling, or ash handling problems if a fuel with characteristics other than those originally specified is fired.[3] For example, the fuel feed rate for wood for a given heat input is about twice that of coal on a weight basis, and more than four times that of coal on a volume basis. Also, a combination of wood and coal firing often produces worse slagging and fouling conditions than coal firing alone. Wood combustion requires more excess air and more overfire air than coal combustion.[4] The National Energy Technology Laboratory of the Department of Energy has recommended when co-firing with coal, biomass or other co-firing materials should be limited to 10 percent on a weight basis to reduce or eliminate operation problems. (National Energy Technology Laboratory, 2009) The fuel has a major impact on boiler design due to fouling and erosion characteristics of the flyash and heat transfer properties of the fuel gas (including moisture content). Biomass requires significantly different combustion systems than coal, oil, or gas and can also result in different boiler corrosion characteristics. Changes to the fuel type would generally require extensive changes to the fuel handling and feeding system (*e.g.*, a stoker using wood as fuel would need to be redesigned to handle fuel oil or gaseous fuel). Additionally, the burners, combustion chamber, and combustion air system (*i.e.*, fans) would need to be redesigned and modified to handle different fuel types and account for increases or decreases in the fuel volume. In some cases, the changes may reduce the capacity and efficiency of the boiler or process heater. An additional effect of these changes would be extensive retrofitting needed to operate using a different fuel.

The design of the boiler or process heater, which is dependent in part on the type of fuel being burned, impacts the degree of combustion. Boilers and process heaters emit a number of different types of HAP emissions. Organic HAP are formed from incomplete combustion and are influenced by the design and operation of the unit. The degree of combustion may be greatly influenced by three general factors: time, turbulence, and temperature. In any energy application the combustion unit is designed to make the best use of time, turbulence, and temperature. All three of these aspects relate directly to the properties of the fuel to be used (moisture content, particle size, ash content, and heat value). On the other hand, the formation of fuel-dependent HAP (metals, mercury, and acid gases) is dependent upon the composition of the fuel. These fuel-dependent HAP emissions generally can be controlled by either changing the fuel property before combustion or by removing the HAP from the flue gas after combustion.

We first examined the HAP emissions results to determine if subcategorization by unit design type was warranted. We concluded that the data were sufficient for determining that a distinguishable difference in performance exists based on unit design type. Therefore, because different types of units have different emission characteristics which may influence the feasibility of effectiveness of emission control, they should be regulated separately (*i.e.*,

subcategorized). Accordingly, we subcategorized boilers and process heaters based on unit design in order to account for these differences in emissions and applicable controls.

For the fuel-dependent HAP (metals, mercury, acid gases), we identified five basic unit types as subcategories. These are the following: (1) units designed to burn coal, (2) units designed to burn biomass, (3) units designed to burn liquid fuel, (4) units designed to burn natural gas/refinery gas, and (5) units designed to burn other process gases. Within the basic unit types there are different designs and combustion systems that, while having a minor effect on fuel-related HAP emissions, have a much larger effect on organic HAP emissions due to the geometry of the combustion chamber and how combustion air is introduced into the boiler. Organic HAP are unburned fuel or the products of incomplete combustion. Therefore, we decided to further subcategorize based on these different unit designs in establishing standards for organic HAP emissions. We have identified the following 11 subcategories for organic HAP:

- Pulverized coal units,
- Stokers designed to burn coal,
- Fluidized bed units designed to burn coal,
- Stokers designed to burn biomass,
- Fluidized bed units designed to burn biomass,
- Suspension burners/Dutch Ovens designed to burn biomass,
- Fuel Cells designed to burn biomass,
- Units designed to burn liquid fuel,
- Units designed to burn natural gas/refinery gas,
- Units designed to burn other gases, and
- Metal process furnaces.

These subcategories are the different boiler system (designs) types used primarily in the source category and are based on the primary fuel that the boiler or process heater is designed to burn. Therefore, the subcategories are defined to account for the fact that boilers designed for a specific fuel type will encounter operational problems if another fuel type, that was not considered in its design, is fired at more than 10 percent of the heat input to the boiler. Units designed as “combination boilers”

Generally, boilers are designed based on a specific fuel type. However, certain industrial sectors employ “combination boilers” that are designed for fuel flexibility to burn both coal and biomass. These combination boilers require a compromise in its design, adopting design features of "coal units" and "biomass units". These design features often result in performance (e.g., combustion/boiler efficiency) compromises but are adopted for fuel flexibility in order to maintain steam production if the primary fuel supply is curtailed. These combination boilers are generally of the stoker design. One compromise is in the design of the stoker. The design of the stoker width and depth is related to the specific fuel. A high heating value, low moisture fuel (i.e., coal) would require a wider, less deep stoker because coal will tend to burn more rapidly. A low heating value, high moisture fuel (i.e., wood/biomass) would require a narrow, deeper

stoker because more residence time on the stoker is usually needed. Another compromise needed is in the fuel feeding system. When biomass is burned with coal in a stoker, the biomass is introduced to the furnace through a separate conveying system. Also, the amount of ash from coal is greater than the amount from biomass. Therefore, the design parameters for the coal (slagging and fouling) will govern the design. Another compromise is in the design of the combustion system. The split between undergrate air and overfire air flows in a stoker type boiler depends largely upon fuel size, volatility and moisture content. For biomass firing, a higher portion of the combustion air requirement is supplied as overfire air than when firing coal. The design of these combination boilers effects the organic HAP emissions.

Because combination boilers are designed to burn both biomass and coal, either alone or as a mixture, it would not be appropriate to classify combination boilers as being in one of the “coal” subcategories because the boiler design is such that when burning greater than 10% biomass, even at a mixture of 11% biomass/89% coal, the combination boiler has an organic HAP/CO emission profile that is similar to units designed to burn 100% (or nearly 100%) biomass. Whereas, a boiler designed to burn coal as it primary fuel could not combust more than 10% biomass or a boiler designed to burn biomass could not combust more than 10% coal without significant retrofitting or design changes. Therefore, to account for these combination boilers in the appropriate subcategories, we continue to define boilers and process heaters that burn at least 10 percent biomass (on an annual heat input basis) as being in one of the biomass subcategories. We also continue to define boilers and process heaters that burn at least 10 percent coal but less than 10 percent biomass (on an annual heat input basis) as being in one of the coal subcategories. We define boilers and process heaters that burn at least 10 percent liquid fuel, and less than 10 percent solid fuel and less than 10 percent biomass (on an annual heat input basis) as being in the liquid subcategory. We continue to define boilers and process heaters that burn only natural gas and/or refinery gas (on an annual heat input basis) as being in the Gas 1 subcategory. This would ensure that each boiler and process heater is subject to emissions standards calculated on the basis of the best performing units with similar design and operation. The remaining boilers and process heaters would be in the Gas 2 subcategory.

[1] EPA did not, as some commenters suggest, subcategorize boilers and process heaters based on fuel type. However, EPA disagrees that subcategorizing based on material inputs would be inconsistent with the CAA. Nothing in the statute prohibits EPA from subcategorizing based on material inputs. *See Sierra Club v. Costle*, 657 F.2d 298, 318-19 (D.C. Cir. 1981) (differing pollutant content of input material can justify a different standard based on subcategorization authority to “distinguish among classes, types and sizes within categories of new sources”). Had Congress intended to prohibit subcategorization based on material inputs, it would have clearly stated that prohibition in the statute. Instead, it used the broad terms “class, type, or size” to authorize EPA to subcategorize sources. Given that the authority to subcategorize is discretionary, as evidenced by the use of the word “may” in section 112(d), the Agency does believe that it could decline to exercise that authority even if the potential result would be the prohibition of use of certain materials, if the circumstances warranted.

Comment Excerpt Number: 6

Comment: The "designed to burn" concept underlying all of EPA's fuel-based subcategories is further undermined by the agency's definition of this same term to mean "can burn" or "does burn" in its proposed revisions to the non-hazardous secondary material (NHSM) definition. 76 Fed. Reg. 80,452, 80,480-80,481 (December 23, 2011). There, the agency claims that a unit is "designed to burn" a given fuel so long as it "can burn" that fuel or "does burn" that fuel, regardless of whether its air permit lists that fuel. *Id.* That claim belies the agency's previous claim that sources that can and do burn different materials as fuel are a different class type or size of source because they are allegedly "designed to burn" a specific fuel. As EPA itself recognizes in the NHSM rule, the "designed to burn" concept is essentially meaningless and gives way to what sources actually can and do burn when it suits the agency's policy interests. The conflicting meanings that EPA gives the term "designed to burn" in its boilers and NHSM rules and EPA's failure to reconcile the conflict renders both rules arbitrary and capricious.

Response: The NHSM rule was issued pursuant to the Resource Conservation and Recovery Act (RCRA), and does not relate to EPA's discretion to establish subcategories under section 112 of the CAA. Under section 112, EPA may distinguish between sources based on class, type, or size, and as explained elsewhere in the record for today's action, EPA's has done so in establishing subcategories within the boiler and process heater source category. These subcategories are based on EPA's evaluation of information relating to the different types of boilers and process heaters, as well as emissions test data identifying differences in emissions due to differences in types of boilers. The NHSM rule, in contrast, establishes EPA's interpretation of the RCRA-defined term "solid waste" for non-hazardous secondary materials. Thus, the purpose of the NHSM rule -- to identify non-hazardous secondary materials that are solid waste -- is different than that of this action. The contaminant comparison criterion in that rule is part of the overall approach developed to distinguish between materials that are solid waste when combusted and those that are not, and is unrelated to distinguishing between classes, types, and sizes of boilers and process heaters as well as to establishing emissions limits for these sources.

However, we disagree that the concept underlying the subcategorization that boilers are designed for specific fuel types is undermined by the EPA's definition of designed to burn in the NHSM definition. As stated in the June 2010 proposal preamble (75 FR 32017) and in various technical document (see "Steam/its generation and use" by The Babcock & Wilcox Company), boiler systems are designed for specific fuel types and will encounter problems if a fuel with characteristics other than those originally specified is fired. The design of the boiler, including the size and shape of the furnace, the spacing of the boiler tubes, and the size and location of the combustion air system, is a function of the combustion characteristics, fouling and slagging characteristics, ash analysis, etc. of the fuel type selected. Burning another fuel type would be

physically impossible with modification to the boiler and fuel handling system. For example, in firing biomass in a boiler designed for coal, wood (i.e., biomass) fuel feed rate for a given heat input is about twice that of coal on a weight basis, and more than four times that of coal on a volume basis. In addition, wood combustion requires more excess air and more overfire air than coal combustion and a combination of wood and coal firing often produces worse slagging and fouling conditions than coal firing alone.

The definition of “Unit designed to burn ...” in the final rule is based on the actual annual heat input of the specific fuel type. Based on the technical literature, our engineering judgement is that a boiler will be burning a fuel type at more than 10% on an annual heat input basis only if it was designed for that specific fuel type. The NHSM definition of “designed to burn” is for determining if the secondary material is comparable in contaminants to a tradition fuel. NHSM definition of contaminants is:

Contaminants means any constituent in non-hazardous secondary materials that will result in emissions of the air pollutants identified in Clean Air Act section 112(b) or the nine pollutants listed under Clean Air Act section 129(a)(4)) when such non-hazardous secondary materials are burned as a fuel or used as an ingredient, including those constituents that could generate products of incomplete combustion.

Thus, if the secondary material is determined to be comparable, the secondary material when combusted would have similar emissions to the traditional fuels and under the Boiler MACT would be considered, that is, meets the definition of, either a “Solid fossil fuel,” “Biomass or bio-based solid fuel,” or “Liquid fuel.”

Comment Excerpt Number: 14

Comment: EPA proposes, however, to subdivide these broad categories into 38 subcategories for existing and new units. In support of the explosion in the number of subcategories, EPA explains the differences in design between, for example, a coal-fired stoker boiler and a coalfired pulverized coal (“PC”) boiler. However, large boilers do not come off an assembly line¹² and can last for up to 50 years. Almost every large boiler will have differences in design from every other large boiler. Even smaller boilers will have differences in design from small boilers produced by other manufacturers. As a result, it is insufficient to simply identify design differences. Where EPA seeks to establish additional subcategories it must explain why those differences matter and point to information in the record that supports its conclusion. For example, within the Boiler MACT “coal-fired” category, EPA proposes separate subcategories for stoker, fluidized bed and pulverized coal designs. However, we know of no reason why well-controlled units of these designs should differ significantly in levels of HAP emissions.

[Footnote]

(12) Even mass-produced automobiles will exhibit design differences within and between models and manufacturers.

Comment: When a source combusts only one type of fuel at all times, determining which emission limit to apply is straightforward. However, many sources combust different types of fuels at different times and a substantial number of sources combust different mixtures of these fuels at different times. In developing its Model Permit Guidance,³⁵ NACAA attempted to address this issue by examining test results where only one type of fuel is employed to set the recommended range of suggested limits. It was anticipated that state and local permitting authorities would then determine the appropriate procedure for establishing permit limits on a case-by-case basis, either by applying the limit that was the most stringent at all times, by determining the weighted average of relevant limits or by requiring a compliance demonstration based on full utilization of one fuel. EPA has taken a different approach. It has adopted a “designed to combust” test and a hierarchical scheme for determining the fuel category of a source.

1. If a source generates more than 10 percent of its heat from biomass, it is in the biomass category.
2. If it uses less than 10 percent biomass and more than 10 percent coal it is in the coal category.
3. If it burns oil, but less than 10 percent coal and less than 10 percent biomass it is in the liquid-fired category.
4. If it burns any amount of gas other than natural gas (Gas 1) it is in the Gas 2 category.

EPA has not explained the rationale for this approach, which places many sources in fuelcategories other than those that dominate emissions. This approach also appears to invite “category shopping” and does not seem to address all possible combinations. For example, if a fluidized bed boiler burns 91 percent coal and 9 percent biomass, the proposed CO limits are 56 ppm. If that same boiler combusts 90 percent coal and 10 percent biomass, the proposed CO limits are 370 ppm. This change is far larger than what one would expect based on such a small difference in the fuel combusted.

8A. Tune-Up Requirements

Commenter Name: William C. Herz

Commenter Affiliation: The Fertilizer Institute (TFI)

Document Control Number: EPA-HQ-OAR-2002-0058-3448-A1

Comment Excerpt Number: 4

Comment: The Proposed Rule also includes a contradiction regarding the timing for a tune-up. As set forth in the Proposed Rule's regulatory language: "As applicable, inspect the burner, and clean or replace any components of the burner as necessary (you may delay the burner inspection until the next scheduled or unscheduled unit shown)."¹² On the other hand, the preamble to the Proposed Rule appears to limit the tune-up only to scheduled shutdowns: "Instead, we are proposing that burner inspections that cannot be completed during a tune-up can be delayed until the next scheduled shutdown."

Response: Section 63.7540(a)(10)(i) of the final rule as been revised to be consistent with EPA's intent, as explained in the preamble to the proposed rule. That is, the burner inspection can be delayed until the next scheduled unit shutdown.

Commenter Name: William C. Herz

Commenter Affiliation: The Fertilizer Institute (TFI)

Document Control Number: EPA-HQ-OAR-2002-0058-3448-A1

Comment Excerpt Number: 5

Comment: Unscheduled shutdowns may only last a very short duration and this duration would not allow adequate time for the burner inspection to be completed. EPA includes a definition of shutdown in the Proposed Rule as follows, "Shutdown means the period that begins when a unit last operates at 25 percent load and ending with a state of no fuel combustion in the unit."¹⁴ As an example, for steam methane reformers, which are found in both refineries and ammonia plants, an "unscheduled" shutdown may only last a few minutes, but the burner inspections could take more than 10 days. Thus, using the definition of "shutdown" provided in the Proposed Rule and applying it to the discussion of "unplanned shutdowns" may require the unit to be taken out of service for an extended period of time. This does not appear to be EPA's intent.

TFI supports EPA's preamble language discussion limiting the tune-up to the next scheduled shutdown and requests that EPA revise the regulatory language to that end.

Response: We agree; see the response to comment EPA-HQ-OAR-2002-0058-3448-A1, excerpt 4.

Commenter Name: Russell A. Wozniak

Commenter Affiliation: The Dow Chemical Company

Document Control Number: EPA-HQ-OAR-2002-0058-3449-A1

Comment Excerpt Number: 6

Comment: EPA's proposed rule in 40 CFR 63.7540(a)(10)(i) regarding annual or biennial burner inspection requirements states that the owner/operator may delay the burner inspection until the next scheduled or unscheduled unit shutdown. Dow generally supports these provisions, but is concerned with the new requirement to address the burner inspection, cleaning, or replacement components of the burner during an unscheduled shutdown. When an unscheduled shutdown occurs, typically our sites will need to return the boiler or process heater back to operation as soon as possible to minimize the impact of steam loss or the loss of a process heater. EPA's rule amendments should include the 36 month concept that was contained in the March 21, 2011 final rule to allow some flexibility when dealing with unplanned shutdown. The owner/operator should not be required to conduct a burner inspection during an unscheduled shutdown if a burner inspection has occurred in the previous 36 months. Suggested rule text is provided below:

(1) As applicable, inspect the burner, and clean or replace any components of the burner as necessary (you may delay the burner inspection until the next scheduled or unscheduled unit shutdown). A burner inspection is not required during an unscheduled unit shutdown if the most recent burner inspection has occurred within the last 36 months).

Response: See the response to comment EPA-HQ-OAR-2002-0058-3448-A1, excerpt 4.

Commenter Name: Jessica Bridges

Commenter Affiliation: United States Clean Heat & Power Association (USCHPA)

Document Control Number: EPA-HQ-OAR-2002-0058-3501-A1

Comment Excerpt Number: 8

Comment: We appreciate EPA removing the every 36-month inspection provision if it would require the unit to shut down when it would not have otherwise been required to power down. It is appropriate to propose that burner inspections that cannot be completed during tune-up should be delayed until the next scheduled shutdown.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3448-A1, excerpt 4.

Commenter Name: Matthew Todd

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 47

Comment: Burner inspections should not be required for unplanned BPH outages, unless the inspections can be performed without extending the outage or causing other problems.

§63.7540(a)(10)(i) specifies that burner inspections for BPH that cannot be performed with the BPH in-service must be performed at the next planned or unplanned outage. Requiring these inspections in the event of any unplanned boiler or process heater outage has potentially serious economic and unit integrity ramifications and the tune-up inspections should only be required for unplanned outages where the BPH will be totally cooled and only if the unplanned outage is of long enough duration to allow the inspections without extending the outage and if it is consistent

with good engineering judgment (e.g., will not cause safety, equipment damage or other problems).

Response: See the response to comment EPA-HQ-OAR-2002-0058-3448-A1, excerpt 4.

Commenter Name: Matthew Todd

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 48

Comment: We strongly support EPA's sensible decision not to require BPH shutdowns in order to perform burner inspections (part of the tune-up). As EPA describes on page 80614 of the proposal preamble, it is reasonable that "burner inspections that cannot be completed during a tune-up can be delayed until the next scheduled shutdown." For clarity, we request EPA make clear in the regulatory language that this delay is allowed until the next scheduled shutdown of the BPH and is not required if other portions of the associated process are shutdown. Unnecessary shutdowns of BPH are to be avoided because of the potential damage to the boiler or process heater (particularly to the refractory) when it undergoes a cool down and heat up cycle. Thus, it should be clear that the delayed burner inspections are only required if the boiler or process heater is shutdown and cooled off for other reasons.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3448-A1, excerpt 4.

Commenter Name: William C. Herz

Commenter Affiliation: The Fertilizer Institute (TFI)

Document Control Number: EPA-HQ-OAR-2002-0058-3448-A1

Comment Excerpt Number: 3

Comment: Both the final *Industrial Boiler Major Source NESHAP* and the Proposed Rule contain an annual inspection program for units in the Gas 1 subcategory.⁷ The final *Industrial Boiler Major Source NESHAP* allows the annual burner inspection to be delayed until the next scheduled shutdown of the unit, provided the inspection occurs at least once every 36 months.⁸ In the Proposed Rule, the "at least once every 36 months" requirement is proposed for removal.⁹ TFI supports this part of the Proposed Rule.

In its comments on the proposed *Industrial Boiler Major Source NESHAP*, TFI urged EPA to recognize limitations associated with inspecting the burners in a reformer on an annual basis.¹⁰ As noted by TFI, burner adjustments or pulling burners while units or associated process equipment are operating may present worker and/or safety hazards. Further, not all boilers and process heaters can be readily shutdown, which is required for reformers, and the reformer cannot be spared or shutdown without shutting down the entire ammonia manufacturing process.

In its response to TFI's comments on this issue, EPA stated "[a]s long as owners/operators complete the parts of the tune-up that can be completed, they can postpone impractical requirements until the next scheduled outage."¹¹ This suggests that the time period between outages is determined by the owner/operator of the unit, or based on industry-recognized

standards such as ASME Section 1. However, as previously discussed, the regulatory language in the final *Industrial Boiler Major Source NESHAP* (at 40 C.F.R. § 63.7540(a)(10)(i)) provides contrary language – that the inspection must occur at least every 36 months.

Response: The EPA thanks the commenter for their support. Section 63.7540(a)(10)(i) in the final amended rule is consistent with what was proposed. That is, 63.7540(a)(10)(i) in the final amended rule reads as follows:

(i) As applicable, inspect the burner, and clean or replace any components of the burner as necessary (you may delay the burner inspection until the next scheduled unit shutdown). Units that produce electricity for sale may delay the burner inspection until the first outage, not to exceed 36 months from the previous inspection. At units where entry into a piece of process equipment or into a storage vessel is required to complete the tune-up inspections, inspections are required only during planned entries into the storage vessel or process equipment;

Commenter Name: John C. Hendricks

Commenter Affiliation: American Electric Power (AEP)

Commenter Affiliation: Maine Department of Environmental Protection

Document Control Number: EPA-HQ-OAR-2002-0058-3691-A2

Comment Excerpt Number: 15

Comment: Maine DEP supports EPA's proposed 30 day allowance for completing any required CO adjustments to a unit following completion of a tune-up in order to allow sufficient time for multiple adjustments and optimization of CO emissions to occur.

Response: The EPA thanks the commenter for their support.

Commenter Name: Jessica Bridges

Commenter Affiliation: United States Clean Heat & Power Association (USCHPA)

Document Control Number: EPA-HQ-OAR-2002-0058-3501-A1

Comment Excerpt Number: 9

Comment: EPA is correct in setting a period of 30 days after the tune-up for making CO adjustments and optimization.

Response: Section 63.7540(a)(13) of the final rule has been revised to be consistent with the proposal preamble language for allowing 30 days after startup to conduct the tune-up.

Commenter Name: Matthew Todd

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 50

Comment: Allowing 30 days for CO adjustments to be completed after the tune-up inspections and adjustments is a very important change, since many tune-ups will be done with the BPH out-of-service, making CO adjustments impossible until the unit is back in service and because the tune-up inspections may result in burner changes that impact emissions. We strongly support this reasonable change.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3501-A1, excerpt 9.

Commenter Name: Arthur N. Marin

Commenter Affiliation: Northeast States for Coordinated Air Use Management (NESCAUM)

Document Control Number: EPA-HQ-OAR-2002-0058-3506-A1

Comment Excerpt Number: 23

Comment: NESCAUM urges the EPA to require tune-ups for wood-fired boilers. As currently proposed by the EPA, the tune-up requirements for other boiler types are not appropriate for wood-fired boilers. As an alternative, NESCAUM is currently working with EPA Region 1 to develop regional guidance for what would constitute appropriate requirements for tuning a biomass boiler. NESCAUM recommends that the EPA adopt this regional guidance as national guidance for biomass boiler tune-ups.

Response: EPA is not adopting a tune-up requirement that is specific for wood-fired boilers which generally are stokers. The tune-up requirement in 63.7540 is general with certain requirement only required (e.g., inspect the burner) if applicable. The EPA appreciates NESCAUM's effort to develop a regional guidance for biomass boiler tuneup and we will post it on the EPA webpage when it has been developed.

Commenter Name: Lorraine Gershman

Commenter Affiliation: American Chemistry Council (ACC)

Comment Excerpt Number: 79

Comment: *ACC SUPPORTS MODIFICATIONS TO TUNE-UP FREQUENCY AND PROCEDURES FOR VERY LIMITED USE UNITS*

EPA should also reconsider and modify the tune-up provisions for process heaters that operate on a very limited basis. The Reconsideration Proposal includes a requirement that a limited use process heater must conduct a tune-up biennially as specified in § 63.7540. Implementation of all of the tune-up requirements for process heaters that are operated on a very limited basis is

problematic due to the few hours per year that some of these devices operate. In some cases, small start-up heaters run for about one hour at a time and they typically only run a handful of times a year at random times on an as needed and often unplanned basis. They are only and can only be used during a very limited time, i.e., startup of the process to pre-heat a process material prior to the reactor coming on line. Because of the shortness of this time period, it is not possible to optimize the system to reduce CO emissions and conduct CO emission screening before and after the adjustments. The Dow Chemical Company, an ACC member company, advocated in its comments that these limited use process heaters should only be subject to a recordkeeping requirement.²⁶ At a minimum, the tune-up requirements in §63.7540(a)(10) need to be modified to reflect the fact that the only element of the work practice that can be executed for these very limited use process heaters is § 63.7540(a)(10)(i) regarding burner inspections and replacements.

[Footnote 26: See Docket ID No. EPA-HQ-OAR-2002-0058-2632]

Response: We agree and §63.7540(a)(12) of the final rule has been revised to require tune-ups for limited-use units every 5 years instead of biennial. The proposed rule would have been more burdensome on units with short seasonal, or limited, operations than on units operating year round. The seasonal/limited use nature means that each unit must undergo tune-ups every two to three months of operation. This is far more frequent than envisioned by the proposed rule of conducting a tune-up every 12 months of operation. We have revised the final rule to address the issue by requiring limited-use units to complete subsequent tune-up every five years.

We understand that there may be certain process heaters for which scheduling a tune-up may be difficult. However, giving a blanket exception is not appropriate nor necessary to address the scheduling concerns. Requiring tune-ups every 5 years for limited-use units should provide sufficient time in which to schedule and conduct a tune-up.

Document Control Number: EPA-HQ-OAR-2002-0058-3537-A2

Comment Excerpt Number: 5

Comment: Section 63.7540 a(12) of the draft rule requires limited use boilers to perform biennial tune-ups.

63.7540 a(12) references the requirements in 63.7540 a(10) which specify that the biennial tuneup include measurements of CO, records of CO measurements before and after the adjustments made during the tune-up, and inspections of flame patterns. It is too costly to require a very large limited use boiler to start up and run just to meet the requirement to perform biennial tune-ups, as explicitly outlined in the rule. Some limited use boilers will not run at any point during a two year period. (Paragraph 13 of this section does provide some relief in that if a boiler is not operating on the date required for a tune-up, then the tune-up needs to be conducted within one week of startup.)

Limited use boilers often do not run continuously for long enough periods to conduct a live tuneup where CO data can be collected. There is a large energy penalty associated with running a very large boiler solely for tune-up purposes when it is not needed for steam demand. The rule needs to be modified to not explicitly specify how maintenance activities or tune-ups will occur.

The rule does not realistically consider boilers which are maintained in a moth-balled or ready state for emergency use or in order to support maintenance activities on other boilers. Discretion in maintenance activities needs to be left to the facilities.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3510-A1, excerpt 79.

Commenter Name: Chris M. Hobson

Commenter Affiliation: Southern Company

Document Control Number: EPA-HQ-OAR-2002-0058-3520-A1

Comment Excerpt Number: 8

Comment: Southern urges EPA to modify the frequency of the boiler tune-up work practice standard to better coincide with outage schedules. Large biomass boilers that serve electricity for sale may not require annual outages and would therefore need to be taken off-line for the sole purpose of an annual tune-up. Southern suggests that EPA modify the requirements such that the tune-up is required at each outage, but no later than once every 36 months. This frequency would be consistent with the requirements of the final Utility MACT standard that EPA finalized on February 16, 2012.⁵

[Footnote]

(5) 77 Fed. Reg. at 9493

Response: We understand the issue with electricity only units and we agree. We have revised Table 3 to be consistent with the requirement in the MATS rule. Our intent was that this work practice standard could be performed in conjunction with routine maintenance operations at a facility and be a logical extension of routine best practices for boiler inspection and optimization. Based on the comments received on this rulemaking and on the MATS rulemaking, for units that produce electricity, the final rule [63.7540(a)(10)(i)] has been revised to allow for the inspection to be delayed until the first outage but not to exceed 3 years from the previous inspection.

Commenter Affiliation: National Association of Clean Air Agencies (NACAA)

Document Control Number: EPA-HQ-OAR-2002-0058-3525-A1

Comment Excerpt Number: 49

Comment: NACAA agrees with the suggestion that, where burner inspection is impossible without destroying the unit, it should not occur. In such instances, however, the source should conduct CO monitoring to determine whether the burner has deteriorated to the point that it should be replaced. We do not believe that burner inspections should be waived where they are merely “difficult” as this term is unenforceable. We suggest that such sources be allowed to determine CO baseline emissions after a tune up and thereafter substitute CO testing in lieu of inspection if they prefer.

Response: The EPA thanks the commenter for their support. Under the tune-up provision, if the burner inspection is not possible, the tune-up requirement [63.7540(a)(10)(iv)] of measuring and

optimizing CO emissions must still be conducted. 63.7540(a)(10)(i) only allows for the burner inspection to be delayed, not other parts of the tune-up requirements.

Document Control Number: EPA-HQ-OAR-2002-0058-3661-A2

Comment Excerpt Number: 11

Comment: EPA has not changed the proposed work practice requirement for natural gas-fired boilers and process heaters in §63.7540(a)(10)(vi)(C) that would require a source to include in the on-site annual report the "type and amount of fuel used over the 12 months to the annual adjustment". Masco continues to view this requirement as unnecessarily burdensome as most facilities do not presently have such meters installed.

Response: We disagree that this is unnecessarily burdensome. §63.7540(a)(10)(vi)(C) allows for estimating fuel use if such meters are not installed.

Commenter Name: John M. Cullen

Commenter Affiliation: Masco Corporation

Document Control Number: EPA-HQ-OAR-2002-0058-3661-A2

Comment Excerpt Number: 12

Comment: Masco continues to assert that a boiler or process heater that has not operated in the previous year should be allowed to forego the annual tuneup requirements.

Response: The final rule already addresses this situation. §63.7540(a) (13) allows for units to delay the tune-up until it is operated.

Commenter Name: Robin Mills Ridgway

Commenter Affiliation: Purdue University

Document Control Number: EPA-HQ-OAR-2002-0058-3668-A2

Comment Excerpt Number: 7

Comment: It is Purdue's understanding that in the proposed rule, tune up records for the work practice standard are only to remain available on site, not to be turned into the agency. Please confirm this is the correct interpretation.

Response: The commenter is correct. 63.7540(a)(10)(vi) only requires that the tune-up records be maintained on site and submitted only upon request by the Administrator.

Commenter Name: Matthew Todd

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 49

Comment: We believe the allowance for delay needs to be expanded to include other aspects of the tune-up that also cannot always be done with the unit in service. For instance, proposed 63.740(a)(10)(iii) states: "Inspect the system controlling the air-to-fuel ratio, as applicable, and ensure that it is correctly calibrated and functioning properly." Depending upon the equipment design, this requirement may only be able to be safely and effectively completed while the boiler or process heater is shut down. For instance, to determine if a draft controller is operating properly or calibrated properly may require it be moved to a position that would cause an upset to the units operation. Forcing unnecessary boiler or process heater shutdowns in order to complete any of the tune-up requirements is equally unreasonable as forcing shutdowns for burner inspections and thus should also be allowed to be delayed when necessary.

Response: We agree with the commenter that other aspects of the tune-up requirement in addition to the boiler inspection cannot be performed when the unit is operating. For example, inspection of the system controlling the air-to-fuel ratio. In the final amended rule, 63.740(a)(10)(iii) has been revised in the final rule to be similar to 63.740(a)(10)(i).

Commenter Name: Matthew Todd

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 51

Comment: Some process heaters cannot be accessed on even a five year cycle and further delay of repair should be allowed for them. For instance, some process heaters are installed in tanks and entry into the tank to access the heater may not occur within a five year period. Where entry into a piece of process equipment or into a storage vessel is required to complete the tune-up inspections, inspections should only be required when the process equipment interior is accessed for other reasons (i.e., only during planned entries into the storage vessel or process equipment).

Response: We understand the concerns raised by the commenter about shutting down process equipment in order to enter them to conduct the inspection of the process heater contained within. We have revised 63.7540(a)(10)(i) in the final rule to address the issue to include the statement "At units where entry into a piece of process equipment or into a storage vessel is required to complete the tune-up inspections, inspections are required only during planned

entries into the storage vessel or process equipment." However, the main aspects of the tune-up, measuring and optimizing CO emissions to manufacturer's specifications, must still be conducted on the frequency as required by the final amended rule.

Document Control Number: EPA-HQ-OAR-2002-0058-3755-A1

Comment Excerpt Number: 13

Comment: Tune-up of Solid Fuel Boilers with a Heat Input Capacity greater than 250 mm Btu/hr.

Table 3 is applicable for any new or existing boiler or process heater with heat input capacity of 10 mm Btu/hr., or greater, and requires that the tune-up requirements proposed in 63.7540, which are designed for the natural gas and metal process furnace subcategories, also be applied for large solid fuel boilers.

The large solid fuel boilers need different tune-up criteria, due to their requirements to *also* comply with low NOx emission limits, and the nature of outages they take.

Alcoa~ Warrick thus proposes that Table 3 be amended to specify the following tune-up requirements for solid fuel boilers with a heat input capacity in excess of 250 mm Btu/hr., as follows:

[See page 7 of the submittal for Table of language suggested by the commenter]

Response: We are aware that some units, not just large solid fuel boilers, will be subject to either Federal or State NOx requirements. The tune-up requirements in 63.7540(a)(10) do not prevent a unit from complying with NOx emission limits. However, in the final rule, 63.7540(a)(10)(iv) has been revised to clarify that "This optimization should be consistent with manufacturer's specification, if available, and with any NOx requirement to which the unit is subject."

Commenter Affiliation: Kohler Co.

Document Control Number: EPA-HQ-OAR-2002-0058-3803-A1

Comment Excerpt Number: 1

Comment: In the proposed Boiler MACT rule, "tune up" means "adjustments made to a boiler in accordance with procedures supplied by the manufacturer to optimize the combustion efficiency." Many boilers employ "full-metered, cross-limited" combustion control systems. Full-metered control means that both fuel and airflow are continuously measured and controlled separately. Metered control recognizes that variations in fuel feed pressure affect fuel flow and variations in draft pressure affect combustion airflow. Full-metered control permits the independent adjustment of combustion air and fuel flows in order to maintain optimum air/fuel ratio. The benefit of this control system is improved boiler efficiency on a continuous basis.

Cross-limited control is “safety logic” superimposed on a full-metered control system. In the event of a mechanical failure (e.g. jammed fuel valve, blocked air damper), it is possible to create a fuel rich combustion mixture. Cross-limited control prevents combustion airflow from falling below fuel flow and fuel flow from exceeding airflow. Full-metered, cross-limited control systems improve boiler efficiency by continuously compensating for variations in fuel and combustion airflows, and they improve boiler safety with active constraints over the air/fuel combustion mixture. This type of control system employs oxygen trim and fuel/air sensors to continuously monitor fuel flow, air flow, and exhaust gas recirculation flow to continuously ensure the highest possible combustion efficiency. Full-metered, cross-limited control systems are recommended by boiler manufacturers to continuously monitor combustion efficiency, so boiler operators can react to changes that reduce combustion efficiency immediately, for economic and safety reasons.

Kohler Co. believes that boilers utilizing a full-metered, cross-limited combustion control system maintain peak combustion efficiency on a real-time and continuous basis. As these control systems trigger boiler adjustments on an as needed and continual basis, they represent a superior approach to maintaining peak combustion efficiency and minimizing combustion emissions versus the requirement in the proposed MACT rule for a once-per-year boiler tune-up. The annual tune-up requirement in the proposed rule will require many sources with this control technology to expend significant funds with no improvement in efficiency or environmental benefit (reduced emissions). As such, Kohler Co. requests that full-metered, cross-limited control systems be included as a compliance alternative to the annual tune-up requirement in the proposed rule. Specifically, for boilers with full-metered, cross-limited combustion controls, 40 CFR §63.7540(10), items (i) through (vi) can be replaced with requirements to: (i) calibrate weekly the oxygen trim sensors, (ii) calibrate annually the air/fuel control system components, and (iii) maintain on-site records of calibrations and maintenance activity, as well as data storage of the oxygen trim and air/fuel control systems operation and performance.

Response: We agree that units with oxygen trim systems or "full-metered, cross-limited" combustion control systems that maintain optimum air/fuel ratio may not benefit from annual tune-ups because these systems trigger boiler adjustments on an as needed basis. 63.7540 of the final rule has been revised to required units with these types of combustion control systems to conduct a tune-up on a less frequent basis (i.e., once every 5 years) which is deemed sufficient to verify calibration of the trim or combustion control system.

Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1

Comment Excerpt Number: 78

Comment: *ACC SUPPORTS THE TUNE-UP FREQUENCY CHANGE FOR SMALL UNITS*

EPA has proposed to change the frequency for tune-ups (following the initial tune-up) for gas and light liquid boilers and process heaters that are equal to or less than 5 MMBtu/hr to a tune-up once every 5 years. (76 Fed. Reg. 80614.) For new units, EPA has proposed to remove the requirement for the initial tune-up, considering that new units will likely be tuned during the initial startup process as part of commissioning. For facilities with a large number of small units, completion of tune-ups on a biennial basis can quickly become a logistics issue, due to the need to schedule periods where the boilers can be tuned without undue disruption to the operation of the facility. ACC believes that a tune-up every 5 years is appropriate for gas and light liquid units 5 MMBtu/hr or less in size, as emissions from these boilers are small, and allowing a reduced tuning frequency will reduce the cost of the rule. Therefore, ACC supports these changes, as they minimize the compliance burden for small units with minimal emissions impact.

Response: The EPA thanks the commenter for their support.

Commenter Name: Shannon S. Broome

Commenter Affiliation: Auto Industry Forum (AIF)

Document Control Number: EPA-HQ-OAR-2002-0058-3512-A1

Comment Excerpt Number: 40

Comment: *In the Alternative, AIF Supports a Less-Frequent Tune-Up Requirement for Certain Units with Heat Input Capacities of 5 MMBtu/hr or Less.*

To the extent that, in lieu of promulgating a *de minimis* exemption, EPA elects to retain work practice standards for most units with heat input capacities of 10 MMBtu/hr or less, AIF supports EPA's proposed change of the biennial tune-up requirement for certain units²⁷ with heat input capacities equal to or less than 5 MMBtu/hr. As explained above, this proposed change fails to account for AIF's analysis that, due to the insignificance of emissions from those units and the considerable administrative burdens associated with regulating them,²⁸ EPA should exempt from the final reconsideration rule NG-fired hot water and process heaters with heat input capacities up to 10 MMBTU/hr. To the extent that EPA finalizes the work practice standards, however, there is a rational basis for decreasing the frequency of the tune-ups for NG-fired, RG, other clean gas such as LFG (that meets the "other Gas 1 fuel" specification) and light liquid-fired units with heat-input capacities of 5 MMBtu/hr or less. In the alternative, then, EPA should finalize the proposed, less-frequent tune-up requirement for those units.²⁹

[Footnote 27: NG-fired, RG, other clean gas such as LFG (that meets the fuel specification) and light liquid-fired units.]

[Footnote 28: Expounding on the cost analysis outlined above, a typical, well-tuned 1 MMBtu/hr burner emitting HAPs at the rate published in EPA's AP-42 NG emissions factor tables, *see Compilation of Air Pollutant Emission Factors, supra*, would emit around 16 pounds of HAP per year. Although highly unlikely, a poorly-tuned unit of this size could emit HAPs at about twice the rate of a well-tuned unit. Then, a facility with twenty poorly-tuned 1 MMBtu/hr burners could collectively emit HAP at a rate of about 1/8 ton per year in excess of well-tuned units. Therefore, using the typical costs noted above, the cost of inspections on a five-year schedule for such units would effectively cost at least \$64,000 per ton abated (or \$160,000 to \$320,000 per ton abated if one assumes a more-typical tuning profile). A hypothetical facility operating two 100 MMBtu/hr boilers and three 12 MMBtu/hr boilers, in addition to the twenty 1 MMBtu/hr burners in the example above, would be spending around 50% of its tune-up budget on the small units to minimize 8% of its HAP emissions due to tune-up requirements. AIF believes that units are generally not "poorly tuned," so the cost per ton, in fact, will be dramatically higher than even estimated here.]

[Footnote 29: Moreover, to the extent that EPA finalizes its proposed work practice standards in lieu of emission limits for certain units, EPA clearly possesses the authority under Section 112(h) of the CAA to issue such standards. The plain text of Section 112(h) provides that EPA may adopt work practice standards instead of emission standards "if it is not feasible in the judgment of the Administrator to prescribe or enforce an emission standard for control of a [HAP]." CAA § 112(h)(1); 42 U.S.C. § 7412(h)(1). The section further explains that it is "not feasible" to set an

emission standard when the “application of measurement methodology to a particular class of sources is not practicable due to technological and economic limitations.” CAA § 112(h)(2)(B); 42 U.S.C. § 7412(h)(2)(B). AIF supports the explanation put forth by EPA that it is not feasible with the meaning of the CAA to prescribe or enforce an emission standard for the control of HAP as to the source categories and subcategories for which EPA has prescribed work practice standards in lieu of emission standards.]

Comment: The VI agrees that tune-ups do not need to be performed annually for small natural gas, refinery gas, other clean gas (that meets the fuel specification) and light liquid-fired units. For these small units (equal to or less than 5 MMBtu/hr), tune-up requirements are appropriately

proposed as once every 5 years, with the initial tune-up required by the compliance date and subsequent tune-ups required at intervals no greater than 5 years from the previous tune-up.

Response: The EPA thanks the commenter for their support.

Commenter Name: Bart Sponsellar

Commenter Affiliation: Wisconsin Department of Natural Resources (DNR)

Document Control Number: EPA-HQ-OAR-2002-0058-3527-A1

Comment Excerpt Number: 7

Comment: EPA in several cases reconsidered the schedule of requirements for smaller oil boilers and limited use boilers. The Department agrees that the frequency of tune-ups for these sub-categories should be reduced because these sources are relatively low emitters. In this context we believe that EPA also needs to apply some bottom threshold at which boilers are subject to the rule requirements. Currently, boiler categories are defined by thresholds such as less than 10 mmBtu/hr or less than 5 mmBtu/hr. This means that even the smallest boiler at an area or major source is subject to the requirement. EPA does not supply a justification for regulating the very smallest emission sources in such an open-ended manner and needs to establish thresholds at which boilers are too small to be subject to the requirements. Clearly, at some level these sources do not contribute to the sources emissions in a significant manner. Further, we find it hard to resolve this issue when all Gas 1 and 2 boilers are subject to requirements under the major source rule while they are not regulated under the area source rule. These sources are exempt under the area source rule because their emissions are deemed to be minor if not insignificant.

Response: The EPA thanks the commenter for their support for the proposed tune-up frequency requirements. However, EPA disagrees that smaller boilers should be exempt from the requirements of the final rule. While emissions from such units may be lower than from larger units, smaller boilers do emit HAP. As explained in the record for the March 2011 final rule, EPA established work practice standards for smaller units in lieu of numeric emissions limits.

Commenter Name: Robert D. Bessette

Commenter Affiliation: Council of Industrial Boiler Owners (CIBO)

Document Control Number: EPA-HQ-OAR-2002-0058-3534-A1

Comment Excerpt Number: 14

Comment: EPA rejected a request to exempt very small (between 2 and 10 MM Btu/hr) oil-fired units. However, EPA has proposed to change the frequency for tune-ups (following the initial tune-up) for boilers or process heaters that are less than 5 MMBtu/hr to a tune-up once every 5 years (76 FR 80644, Dec. 23, 2011). For new units, EPA has proposed to remove the requirement for the initial tune-up, considering that new units will likely be tuned during the initial startup process as part of commissioning. For facilities with a large number of small units, completion of tune-ups on a biennial basis can quickly become a logistics issue, due to the need to schedule periods where the boilers and process heaters can be shutdown and tuned without undue disruption to the operation of the facility. For such small boilers and process heaters, we believe that a reduction in the tune-up frequency from every two years to every 5 years is appropriate, as emissions from these boilers and process heaters are small, and allowing a

reduced tuning frequency will reduce the cost of the rule. Therefore, we support these changes, as they minimize burden on small sources with minimal emissions impact.

Response: The EPA thanks the commenter for their support.

Commenter Name: Vickie Woods

Comment Excerpt Number: 8

Comment: EPA has proposed to change the frequency for tune-ups (following the initial tune-up) for gas and light liquid boilers and process heaters that are equal to or less than 5 MMBTU/hr from every two years to a tune-up once every 5 years following the initial tuneup (76 FR 80614; §63.7500(d) and Table 3(1)). For new units, EPA has proposed to remove the requirement for the initial tune-up, considering that new units will likely be tuned during the initial startup process as part of commissioning. For facilities with a large number of small units, such as the 95 small units at Purdue University's West Lafayette campus, completion of tune-ups on a biennial basis can quickly become a logistics issue, due to the need to schedule periods where the boilers can be tuned without undue disruption to the operation of the facility. Purdue believes that a tune-up every 5 years is appropriate for natural gas boilers and heaters 5 MMBTU/hr or less in size, as emissions from these boilers are small, and allowing a reduced tuning frequency will reduce the implementation cost of the rule. Therefore, Purdue support these changes, as they minimize the compliance burden for small units with minimal emissions impact.

Response: The EPA thanks the commenter for their support.

Commenter Affiliation: American Gas Association (AGA)

Document Control Number: EPA-HQ-OAR-2002-0058-3672-A2

Comment Excerpt Number: 2

Comment: We agree with your proposal to vary the frequency of these tune-ups with the size of the unit. Large boilers and process heaters with a heat input capacity of 10 million Btu per hour (MMBtu/hr) or greater that are fired with natural gas would be subject to annual tune-ups, whereas those between 5 and 10 MMBtu would be tuned up every two years. We appreciate your proposal to extend the tune-up frequency for very small units with heat input capacity of 5 MMBtu/hr or less from biennial to every 5 years. The agency accepted comments demonstrating that it is logistically burdensome to conduct biennial tune-ups because a single institution may have several hundred of these smaller units. To reduce this burden, EPA proposes to require these smaller units to have a tune-up by the rule's compliance date and then at intervals up to 5 years thereafter. See 76 Fed. Reg. at 80614. AGA supports this common sense proposal.

Response: The EPA thanks the commenter for their support.

Document Control Number: EPA-HQ-OAR-2002-0058-3685-A2

Comment Excerpt Number: 46

Comment: AMP Supports a 5-year Tune-up Frequency for Gas- and Light Liquid-fired Units Less Than or Equal to 5 mmBtu/hr

EPA proposed changing the frequency for tune-ups (following the initial tune-up) for gas and light liquid boilers that are equal to or less than 5 MMBtu/hr to a tune-up once every five years. This tune-up frequency is appropriate for these units. Municipal utilities that operate these small units do so to provide supplemental power and heating when the main boilers are not operating. Operation of these units may be infrequent, and a biennial testing requirement may force these units to operate more often than necessary simply to comply with the tune-up requirement. This would cause an increase in emissions that would not occur but for the Boiler MACT tuning requirement. Furthermore, emissions from these boilers are small, and allowing a reduced tuning frequency will minimize the compliance burden for small units with minimal emissions impact. AMP supports the five-year tune-up frequency for these units.

Response: The EPA thanks the commenter for their support.

Commenter Name: William C. Herz
Commenter Affiliation: The Fertilizer Institute (TFI)
Document Control Number: EPA-HQ-OAR-2002-0058-3448-A1
Comment Excerpt Number: 12

Comment: If EPA is not willing to provide a categorical exemption, TFI would like to make the following comment. In the Proposed Rule, EPA added a requirement for natural gas and certain other units that are less than or equal to 5 MMBtu/hr to conduct a required tune-up at least once every five years.¹⁸ TFI requests that EPA add units that have a federally enforceable operating limit of less than or equal to 100 hrs/yr to this five-year tune-up requirement. EPA has previously used the 100 hrs/yr threshold for defining a limited-use unit in its Reciprocating Internal Combustion Engine rule at 40 C.F.R. § 63.6675.

Response: Units that have a federally enforceable operating limit of less than or equal to 100 hrs/yr would meet the definition of "Limited-use boiler or process heater" in the final amended rule and final amended rule has been revised to require a tune-up for limited-use units once every 5 years.

Commenter Name: Lenny Dupuis
Commenter Affiliation: Dominion Resources Services, Inc.
Document Control Number: EPA-HQ-OAR-2002-0058-3486-A1
Comment Excerpt Number: 7

Comment: EPA should also apply more flexible work practice standards to limited use units, including oil-fired auxiliary boilers (regardless of size). The requirement for these units to perform annual tune-ups (if greater than or equal to 10 mmBtu/hr) is excessive since these units operate so infrequently. EPA should decrease the required frequency of tune-ups from annual to every 5 years. In the alternative, or at a minimum, EPA should apply the same triennial cycle (tune-ups every 3 years) that is established for limited use oil units in the final Utility MATS rule for oil-fired auxiliary boilers.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3448-A1, excerpt 12.

Document Control Number: EPA-HQ-OAR-2002-0058-3492-A1
Comment Excerpt Number: 11

Comment: Alliant Energy recommends that the biennial tune-up requirement should be revised to every five years. This frequency is more appropriate given the very low utilization of limited use units and also eliminates costly testing, especially given that there may be periods with one or more years of no operation.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3448-A1, excerpt 12.

Commenter Name: Russell A. Wozniak
Commenter Affiliation: The Dow Chemical Company
Document Control Number: EPA-HQ-OAR-2002-0058-3449-A1
Comment Excerpt Number: 7

Comment: EPA should consider modifications to the tune-up provisions for process heaters that operate on a very limited basis. The proposed rule has a new provision that allows a very small process heater (< 5 MMBTU/Hr) to conduct a tune-up every five years. However, implementation of all of the tune-up requirements for process heaters that are operated on a very limited basis remains problematic due to the few hours per year that some of these devices operate. In some cases, small start-up heaters run for about one hour at a time and they typically only run 5 or 6 times a year and at random times on an as needed and often unplanned basis. They are only and can only be used during start up of the process to pre-heat a process material prior to the reactor coming on line and this has a very limited maximum time and cannot be false loaded or extended. Thus, the act of optimizing the system to reduce CO emissions and conducting CO emission screening before and after the adjustments is not possible during the short timeframe when the process heater is operating.

At a minimum, the tune-up requirements in 63.7540(a)(10) need to be modified for this isolated case of a very limited use process heater. The only elements of the work practice that can be executed for these very limited use process heaters are 63.7540(a)(10)(i) and (ii) regarding burner inspections and flame pattern inspections. There simply isn't sufficient operating time to measure CO concentration before and after burner adjustments since the device only runs for ~ 1 hour at a time.

Response: We understand the concern with units that are only used for starting up a large utility boiler or a industrial process and operated for only a few hours at a time. We believe that all units should be properly operated and maintained. A tune-up helps to ensure that a unit is properly operated and maintained. We proposed a five year schedule for tuning a limited-use unit because they operate infrequently. We continue to believe this is appropriate for limited-use units. In addition, measurements of CO and oxygen as part of the tune-up requirement are not required to be taken as required for a performance stack test, but may be taken using a portable hand-held CO/oxygen analyzer.

Commenter Name: Shannon S. Broome
Commenter Affiliation: Auto Industry Forum (AIF)
Document Control Number: EPA-HQ-OAR-2002-0058-3512-A1
Comment Excerpt Number: 41

Comment: A final, related, technical issue for comment is that EPA states in the preamble that it is changing the tune-up frequency for units that are *equal to or less than* 5 MMBtu/hr, the proposed regulatory language applies only to units *less than* 5 MMBtu/hr. EPA should revise the final regulatory language to reflect the change to the tune-up frequency for those units as stated in the preamble.

Response: Table 3 of the final rule has been revised to be consistent with EPA's intent, as explained in the preamble to the proposed rule.

Commenter Name: Lenny Dupuis
Commenter Affiliation: Dominion Resources Services, Inc.
Document Control Number: EPA-HQ-OAR-2002-0058-3486-A1
Comment Excerpt Number: 6

Comment: We support the more flexible work practice provisions in the revised proposal that would change the cycle of required unit tune-ups from every 2 years to every 5 years for small boilers and process heaters. However, EPA proposes to apply this more flexible provision only for units under 5 mmBtu/hr. Since a 110 mmBtu/hr threshold has been used throughout this rule to distinguish between small and large sources and define certain subcategories, EPA should extend these provisions to all units below 10 mmBtu/hr so that all units within a defined subcategory at a given facility are subject to the same work practice standards and subject to the same frequency/cycle of scheduled tune-up requirements.

Response: The EPA thanks the commenter for their support but we disagree that the threshold should be raised to 10 million Btu per hour for conducting a tune-up every 5 years. The commenter provides no explanation or information to support its recommendation that the threshold should be changed.

Commenter Name: Mary Sullivan Douglas
Commenter Affiliation: National Association of Clean Air Agencies (NACAA)
Document Control Number: EPA-HQ-OAR-2002-0058-3525-A1
Comment Excerpt Number: 47

Comment: NACAA recommends that the frequency of mandated tune ups be based on objective data concerning decay of performance after a tune up.

Response: The requirement to conduct an annual tune-up, or at other frequencies, to demonstrate compliance with the work practice is based on information available to the agency showing the increase in fuel use each year that the boiler is not serviced (tuned). The frequencies established are based on duty cycle (year round operation vs. limited use operation) and to provide ease of scheduling the required tune-up for facilities that have numerous small boilers and process heaters. In addition, the rationale for establishing the work practice of the tune-up instead of emission limits was that measuring emissions was impractical due to technical and economic limitations. The commenter did not provide an explanation or information to support its recommendation.

Commenter Name: Bart Sponsellar
Commenter Affiliation: Wisconsin Department of Natural Resources
Document Control Number: EPA-HQ-OAR-2002-0058-3527-A2
Comment Excerpt Number: 22

Comment: EPA is proposing that small gas and oil fired sources smaller than 5 mmbtu/hr be required to perform tune-ups once every 5 years. Petitioners originally requested EPA to consider reducing the tune-up frequency for boilers smaller than 10 mmbtu/hr or which are limited use.

The Department supports reducing the tune-up frequency for boilers smaller than 5 mmbtu/hr. We believe the majority of these units operate at a single setting or over a small load range which reduces the likelihood for combustion conditions to vary over time. On this basis, Department believes EPA should consider reducing the tune-up frequency for larger units which also operate at a single or preset level. Such units may include metal treating furnaces or annealing processes and small biomass boilers. The operators of these sources can self identify under a final rule and therefore no additional analysis of source categories is required by EPA. Another option is to allow sources smaller than 10 mmbtu/hr to extend tune-ups to every 4 years if combustion settings did not vary between the biennial tune-ups. Lastly, EPA can allow any source with a continuous O₂ and CO trim system to perform tune-ups every four years. Sources with this type of system are essentially performing tuning on a continuous basis. A four year schedule coincides with required inspection of the mechanical system and burners.

Response: We agree that units with oxygen trim systems that maintain optimum air/fuel ratio may not benefit from annual tune-ups because these systems trigger boiler adjustments on an as needed basis. 63.7540(a)(12) of the final rule has been revised to required units with these types of combustion control systems to conduct a tune-up on a less frequent basis (i.e., once every 5 years).

Commenter Name: Bart Sponsellar

Commenter Affiliation: Wisconsin Department of Natural Resources

Document Control Number: EPA-HQ-OAR-2002-0058-3527-A2

Comment Excerpt Number: 28

Comment: This proposed schedule for CO, PM, and tune-ups is premised on the CO/O₂ trim system and a two year stack test schedule. A three or four year tune-up and stack test schedule could be considered for sources which implement a neural network system in operating the boiler system. This approach is adopted under in the finalized EGU MACT rule. The default requirement is for EGU boilers to undergo tune-ups every 36 months or 3 years. However the rule allows EGU sources with a neural network system in place to perform tune-ups on a four year cycle. To put a neural network system in place a source is typically tested intensively with computer fluidized modeling performed to determine optimum conditions for operating the boiler. The Department feels that a source which is optimized and operated to this level can be placed on a three or four year stack test schedule at a minimum for PM and CO emissions and for tune-ups.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3527-A2, excerpt 22.

Commenter Name: Bart Sponsellar

Commenter Affiliation: Wisconsin Department of Natural Resources

Document Control Number: EPA-HQ-OAR-2002-0058-3527-A2

Comment Excerpt Number: 23

Comment: In addressing limited-use units, the Department suggest that these units perform tune-ups based on operating hours which coincides to the primary tune-up schedule for that type of source: annual, biennial, five years. In fact, any source should be allowed the option to track operating hours and perform tune-ups accordingly. This approach could also be used by EPA to

streamline or eliminate the need for distinguishing limited use or seasonal sources or the need to have a separate requirement and time constraints in place for the start-up and shutdown work practices.

Response: We thank the commenter for their suggestion. However, units that chose to exercise such an option would need to record and report hours of operation to determine tune-up frequency, which would likely complicate the compliance and enforcement because different units at a particular facility could be on different tune-up schedules.

Commenter Name: Matthew Todd

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 46

Comment: We support the proposed reduced frequency of tune-up requirements for small boilers and process heaters but believe there is no justification for requiring tune-ups at all for BPH firing gas 1 or for BPH with a design heat input capacity of 10 MMBTU/hr firing other fuels and a simple design requirement or an Operations and Maintenance Plan work practice is more reasonable.

EPA is proposing to change the existing BPH NESHAP to allow BPH firing gas or light liquid fuels with a design heat input of <5 MMBTU/hr to tune-up once every 5 years, rather than annually or biennially, with an initial tune up required by the compliance date. The potential emission reductions from tune-ups on such small emission sources (and even large gas 1 BPH) is so insignificant that tune-ups are not justified at all. In the aggregate tune-ups for such units are extremely costly and it is arbitrary and capricious to impose these costs and the associated burdens for no benefit. On page 80614 of the preamble EPA cites the fact that one institution has 700 sources of less than 5 MMBTU/hr. While we believe EPA has underestimated the costs for these tune-ups, using EPA's estimate of \$5000 per unit initially and \$1000 for each later tune-up, means this one institution will incur at least \$3.5 million in initial tune-up costs and \$700,000 in additional costs every five years. The required permitting, recordkeeping and reporting associated with these tune-ups will add cost and burdens to the out-of-pocket costs. EPA fails to quantify organic HAP or metal HAP emissions in the rulemaking record from any of the sources subject to tune-up requirements. Rather it estimates VOC and PM emissions, of which these HAP categories are a small portion. Even then, in Table 4 of the preamble, EPA only estimates 118 Tons of PM and 85 Tons of VOC will be reduced from the 11,911 gas 1 units subject to the tune-up requirements. That is less than 20 pounds per year PM and less than 15 lb per year VOC per gas 1 BPH. EPA does not indicate the average firing for gas 1 BPH, but units below 5 MMBTU/hr are likely well below average, so the potential emission reductions from them are even smaller. Thus, EPA's own estimates indicate that for \$2,875 per year this requirement reduces, at the most, a few pounds of HAP per BPH and even smaller quantities from BPH firing less than 5 MMBTU/hr. Even assuming 5 lb per year of HAP emissions per BPH, just this tune-up requirement represents over \$1 million per ton of HAP reduction. Since there are negligible emission reductions associated with these tune-ups and thus negligible, if any, health benefits to claim, a unsubstantiated 1% fuel savings is arbitrarily assumed to justify the tune-up costs. However, even if true, the CAA is an air emission law and section 112 is devoted to reducing

HAPs and thus the Agency is not authorized to impose requirements for the purpose of reducing energy usage. Since the potential emissions reductions from small BPH are essentially insignificant, all of this cost and burden is wasted and thus should not be imposed.

Instead of the proposed five year tune-up for gas 2 units under 5 MMBTU/hr and the tune-up requirements for any gas 1-fired BPH, EPA should only impose a design requirement that documents that the unit is designed for firing gas 1 fuel. For less than 10 MMBTU/hr BPH firing other fuels, an Operations and Maintenance Plan work practice, such as incorporated into the Engine NESHAP should be required. Item 9 of Table 6 of part 63 subpart ZZZZ addresses the parallel situation for small and limited use engines. It requires that the owner/operator follow a work practice and demonstrate continuous compliance by “(i) Operating and maintaining the stationary RICE according to the manufacturer's emission-related operation and maintenance instructions; or (ii) Develop and follow your own maintenance plan which must provide to the extent practicable for the maintenance and operation of the engine in a manner consistent with good air pollution control practice for minimizing emissions.”

Response: We disagree with the comment that EPA should only impose a design requirement, instead of the work practice of a tune-up, for units burning Gas 1 fuel. First, EPA disagrees with the commenters characterization of the Agency’s authority under the Clean Air Act. When establishing work practice standards, EPA must ensure that the standard represents the maximum achievable control technology, and cannot take cost into account when determining that level of emission reduction. Further, the commenter is incorrect that EPA’s work practice requirement for Gas 1 units is based on reducing energy usage. Rather, the tune-up requirement is intended to reduce HAP emissions from units subject to the requirement, as explained in the preamble to the March 2011 final rule.

The commenter suggests that, for boilers and process heaters firing other than Gas 1 fuels, the design requirement should be similar to item 9 of table 6 of subpart ZZZZ. The requirements in item 9 of table 6 of ZZZZ are to operate and maintain the engine according to the manufacturer's emission-related operation and maintenance instructions, which is analogous to tuning/optimizing the boiler emissions to manufacturer's specifications. Also, ZZZZ requires inspection of certain engine equipment which is similar to what is required under the boiler tune-up with requirements on a more frequent basis that every 5 years. Therefore, for boilers and process heaters firing other than Gas 1 fuels, there is no practical difference between the requirements in each rule.

8C. New Source Tune-up Compliance Date

Commenter Name: Bruce W. Ramme

Commenter Affiliation: Wisconsin Electric Power Company (WE Energies)

Document Control Number: EPA-HQ-OAR-2002-0058-3452-A1

Comment Excerpt Number: 5

Comment: We Energies supports EPA’s proposal to require the initial tune-up for a new unit to be performed within one year of startup. This should provide a sufficient amount of time for the boiler operator to learn how to most efficiently operate a new boiler prior to performing the boiler tune-up.

Response: The EPA thanks the commenter for their support.

Commenter Name: Jessica Bridges

Commenter Affiliation: United States Clean Heat & Power Association (USCHPA)

Document Control Number: EPA-HQ-OAR-2002-0058-3501-A1

Comment Excerpt Number: 11

Comment: It is appropriate that EPA recognize that initial tune-ups at new sources generally occur as part of installation and that the initial tune-up after installation can take advantage of the learning curve in efficiently operating new units. Therefore having the initial tune-up within one year after start up provides appropriate opportunity to improve efficiency based upon experience.

Response: The EPA thanks the commenter for their support.

Commenter Name: Michael L. Krancer

Commenter Affiliation: Pennsylvania Department of Environmental Protection (DEP)

Document Control Number: EPA-HQ-OAR-2002-0058-3507-A1

Comment Excerpt Number: 16

Comment: The EPA has proposed that the initial tune-up after startup of a new unit must be completed within one year of startup.

The DEP agrees with this approach for new sources because the units are well tuned as part of the installation.

Response: The EPA thanks the commenter for their support.

Commenter Name: Shannon S. Broome

Commenter Affiliation: Auto Industry Forum (AIF)

Document Control Number: EPA-HQ-OAR-2002-0058-3512-A1

Comment Excerpt Number: 53

Comment: EPA Should Amend Its Proposal to Base the Time Period for Completion of the First Tune-Up After Installation on the Tune-Up Cycle Germane to the Specific Unit.

Based on the request of petitioners that EPA clarify the timing of tune-ups with respect to the compliance dates for new sources, EPA proposes to require completion of the initial tune-up after startup within one year of startup. *See id.* at 80,614. EPA makes this proposal based on its recognition that, generally, units are tuned as part of installation. *See id.*

In the experience of AIF's members, EPA is correct in recognizing that, generally, units are tuned as part of the installation process. Accordingly, AIF supports EPA's proposal in principle, however, EPA should amend it to make the deadline for the first tune-up after installation consistent with the tune-up cycle germane to the specific unit. For example, under the proposed reconsideration rule, units such those fired by NG, RG, other clean gas like LFG (that meets the "other Gas 1 fuel" specification) and light liquid operate on a five-year tune-up cycle. *See id.* Consistent with that requirement, EPA should amend the proposal to require units fitting within

that classification that are located at new sources to complete their initial tune-up after installation within five years of startup—as opposed to within one year after startup under the reconsideration proposal. As EPA correctly acknowledges that, generally, units are tuned as part of installation, it would be arbitrary and capricious for EPA to require a unit to conduct its initial tune-up after installation on a different timetable than the cycle otherwise germane to that specific type of unit. Therefore, while AIF supports the principle underlying EPA’s proposal, it recommends that EPA finalize the proposal with the suggested amendment that would key the initial tune-up requirement to the tune-up cycle that is germane to the specific unit.

Response: We agree with the commenter that for new units their first tune-up should be on the same cycle from startup as required after the initial tune-up. 63.7510(g) in the final rule has been revised to key the initial tune-up to the tune-up cycle that is germane to the specific unit. The reason being is that new units on initial start-up are tune-up/adjusted to manufacturer's specifications.

Commenter Name: Matthew Todd

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 14

Comment: We support EPA’s proposal to allow 365 days from startup for new/reconstructed sources subject to a tune-up requirement to complete the initial tune-up.

1. It takes time for a new BPH to shakedown and for an owner/operator to learn how to most efficiently operate a new or reconstructed unit. Allowing a year for the initial tune-up, will accommodate this learning curve, allow the BPH to reach a normal operating mode and to make any needed equipment modifications, and, thereby, foster good air pollution control.

2. The one year compliance time for the initial tune-up for a new or reconstructed BPH is contained in the second sentence of proposed §63.7510(g). However, the language imposes a retroactive requirement on a new or reconstructed BPH that started up before the effective date of the final rule (i.e., that it was tuned up within a year after startup). Thus, we recommend §63.7510(g) be revised to eliminate the retroactivity as follows:

For new or reconstructed affected sources, you must demonstrate initial compliance with the applicable work practice standards in Table 3 to this subpart no later than the compliance date that is specified in § 63.74595 and according to the applicable provisions in § 63.7(a)(2). You must conduct the initial tune-up within 365 days after the initial compliance date specified in §63.7495(a) of this subpart startup of the source. Thereafter, you are required to complete the applicable annual, biennial, or 5-year tune-up as specified in § 63.7540(a).

Response: See the response to comment EPA-HQ-OAR-2002-0058-3512-A1, excerpt 53. 63.7510(g) has also been revised to clarify the initial compliance date for new units that started up prior to the promulgation of the final rule.

Comment Excerpt Number: 17

Comment: DoD also supports EPA's decision to retain the tune-up delay provision in §63.7540(a)(13) that if a unit is not operating on the required date for a tune-up, the tune-up must be conducted within one week of startup.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Commenter Name: Lenny Dupuis

Commenter Affiliation: Dominion Resources Services, Inc.

Document Control Number: EPA-HQ-OAR-2002-0058-3486-A1

Comment Excerpt Number: 14

Comment: While reasonable limits for PM are appropriate, EPA should establish alternative good combustion practice and tune-up requirements for other HAPs for biomass units, just as it has proposed for units that combust natural gas. In justifying its decision to apply work practice standards in place of emission limits for gas boilers and process heaters, EPA cites a potential cost of over \$14 billion for installing controls to meet such limits. EPA further notes that control requirements would provide a disincentive for fuel switching to gas as a control option for other fuel subcategories, and could even encourage some facilities to switch from gas to a cheaper fuel such as coal.³ This rationale could also apply to biomass boilers and therefore provides ample support for adopting work practice standards in lieu of emission limits for boilers that burn biomass. This approach would also provide the opportunity for more time to re-evaluate both the need and the feasibility of emission limits for biomass units during the next MACT review cycle from what should be a more robust data base as this fuel option continues to be added to the fleet of existing electric generation systems.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

Commenter Name: Paul Noe

Commenter Affiliation: American Forest & Paper Association (AF&PA) et al.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 6

Comment: We recommend that once EPA has determined the quantitation limits of different reference methods, it should compare its boiler emission data to determine whether or not there were any sources with emissions above the reference method quantitation limits. If the majority of source emissions are below the reference method quantitation limits, a work practice standard in lieu of a numeric emission standard is appropriate as MACT, since sources will not be able to accurately measure emissions against any numerical standard.

Response: This comment pertains to an issue that is outside the scope of this reconsideration action. The EPA has not prepared a response to this comment.

101A. Emissions Standards for Gas 1 Units [DENIED PETITIONER ISSUE]

Commenter Name: James Pew

Commenter Affiliation: Earthjustice, Clean Air Council, Partnership for Policy Integrity

Document Control Number: EPA-HQ-OAR-2002-0058-3511-A1

Comment Excerpt Number: 40

Comment: In its 2011 final rule EPA proposed a new rationale for its use of work practice standards for the "Gas 1" subcategory. It notes that "the measured emissions from these units are routinely below the detection limits of EPA test methods," and concludes therefrom that it is "impracticable to reliably measure emissions from these units." 76 Fed. Reg. at 15,638. This decision is unlawful and arbitrary for the reasons given in the 2010 Comments, which are incorporated by reference as if set forth fully herein, and above with respect to EPA's work practice standards for dioxins.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: James Pew

Commenter Affiliation: Earthjustice, Clean Air Council, Partnership for Policy Integrity

Document Control Number: EPA-HQ-OAR-2002-0058-3511-A1

Comment Excerpt Number: 45

Comment: EPA's work practice standards for Gas 1 units, Gas 2 units, smaller units, and periods of startup and shutdown are unlawful and arbitrary. EPA has not shown that any of these standards are consistent with § 112(d) in the sense of reflecting measures that reflect either the maximum achievable degree of reduction in emissions (as required by § 112(d)(2)) or the

performance of the relevant best performing units (§ 112(d)(3)). In particular, EPA's work practice standards for Gas 1, Gas 2, and smaller units are merely tune up requirements and do not purport to reflect with the maximum degree of reduction that is achievable for these units or the best units' performance.

Comment: Work Practice Standards Are Appropriate Emission Controls for Gas 1 Units

The principles that warrant the use of work practice standards for dioxin emissions also apply to emissions from natural gas and refinery gas (“Gas 1”) fired units, which utilize clean burning fuels. As noted above, an emission standard is “not feasible” when “the application of

measurement technology to a particular class of sources is not practicable due to technological and economic limitations.”¹¹ VI members, as well as other industries, face exactly this problem in measuring hazardous air pollutant (HAP) emissions from Gas 1 fuels.

Natural gas and refinery gas are among the cleanest burning fossil fuels and HAP emissions associated with the combustion of these gases are minute and therefore extremely difficult to measure because the levels at which they are present are far below the levels that can be accurately measured using existing analytical methods. Further, at an EPA-estimated cost of \$14 billion, emission controls for Gas 1 units would be catastrophically expensive to the point of being economic impracticable.¹² Further, such controls would provide a disincentive for facilities to switch from “dirtier,” cheaper fuels to cleaner natural gas, and would result in a net HAP emissions increase in the long term. Creating this disincentive would, in EPA’s words, “be inconsistent with the emissions reductions goals of the CAA, and of section 112 in particular.”¹³ Therefore, work practice standards are appropriate under the Act for these units.

Comment: EPA could ease the cost burden of the major source proposal, by simply adopting a design standard for gas fired equipment: equipment designed to fire gas is subject to only recordkeeping requirements that they meet the design standard. EPA chose such a path in the recent review and final rule for Marine Loading Operations by referencing a Coast Guard design standard. If EPA chooses not to utilize a design standard approach it should provide a transparent analysis on why that was not the most cost-effective option available.

Comment: In the prior final rule issued March 21, 2011, and in this proposed rule, the EPA argues against measuring emissions in these boilers from the stacks and justifies the use of work practice standards as the only remaining option. Even if the EPA could demonstrate that the Agency could not set emission standards for boilers, the Agency misses the opportunity to take one of the other options available under Section 112(h): that is, to “promulgate a design, equipment,” or “operational standard” that might ensure that these toxic emissions are reduced. Requiring the adoption of equipment that is in use in the lowest emitting facilities would be much more likely to reduce exposure than just ordering a periodic “tune up.” Instead, the EPA argues that “tuned up” boilers will suffice to address toxic emissions from 195,000 boilers (EPA, 2011d). We support fully encouraging plants to follow the manufacturer’s instructions for preventing emissions from getting worse, but that is not the same as reducing already harmful emissions. Unfortunately, the proposed rule does not seek to improve work practice standards or to assess whether they effectively reduce toxic air emissions from those facilities. It is hard to imagine that emissions standards cannot be successfully incorporated that would actually reduce emissions from one in eight boilers.

Comment Excerpt Number: 13

Comment: EPA has the statutory authority as identified in Section 112(h) of the CAA to prescribe the type of compliance demonstration required to be met to control HAP emissions under the Boiler MACT and other NESHAP regulations.

(h) WORK PRACTICE STANDARDS AND OTHER REQUIREMENTS.—(1) IN GENERAL.—For purposes of this section, if it is not feasible in the judgment of the Administrator to prescribe or enforce an emission standard for control of a hazardous air pollutant or pollutants, the Administrator may, in lieu thereof, promulgate a design, equipment, work practice, or operational standard, or combination thereof, which in the Administrator’s judgment is consistent with the provisions of subsection (d) or (f). In the event the Administrator promulgates a design or equipment standard under this subsection, the Administrator shall include as part of such standard such requirements as will assure the proper operation and maintenance of any such element of design or equipment.

(2) DEFINITION.—For the purpose of this subsection, the phrase “not feasible to prescribe or enforce an emission standard” means any situation in which the Administrator determines that—

(A) a hazardous air pollutant or pollutants cannot be emitted through a conveyance designed and constructed to emit or capture such pollutant, or that any requirement for, or use of, such a conveyance would be inconsistent with any Federal, State or local law, or

(B) the application of measurement methodology to a particular class of sources is not practicable due to technological and economic limitations.

A work practice standard can be used for compliance demonstration when it is "not feasible to prescribe or enforce an emission standard" due to technological and economic limitations for a specific subcategory of emission sources. For NESHAP Subpart DDDDD, EPA determined that work practice standards are appropriate for ensuring HAP emissions are effectively controlled from Gas 1 units.

The information provided in this comment letter for processed fats HAP content is analogous to the data used by EPA to determine Gas 1 units are not required to meet a MACT Floor, and instead demonstrate control of HAP emissions for Gas 1 units by enforcing work practice standards. The NRA feels that the non-detect analysis data identified for the metal HAP content in processed fats samples indicates the infeasibility for establishing a MACT Floor for the requested separate subcategory (unit designed to burn processed fats subcategory). Processed fats are essentially an "equivalent fuel" to Gas 1 regarding metal HAP, acid gas HAP, and organic HAP content, based on the defined thresholds established by EPA. Furthermore, the processed fats-fired boilers can meet the current explanations identified by EPA for requiring work practice standards for Gas 1 units to demonstrate compliance with the Boiler MACT.

"If your unit combusts only natural gas, refinery gas, or equivalent fuel (other gas that qualifies as Gas 1 fuel), with limited exceptions for gas curtailment and emergencies, your unit is subject to a work practice standard that requires an annual tune-up in lieu of emission limits." [76 FR 15612]

The NRA feels the control of HAP emissions from processed fats-fired boilers will be accomplished most cost effectively by work practice standards developed for the requested separate subcategory. Due to the similar HAP emissions as identified in this comments letter for processed fats-fired boilers and Gas 1 units, the NRA requests similar work practice standards compliance requirements for the requested separate processed fats subcategory. Specifically, the NRA requests that processed fats-fired boilers are subject to the following work practice standards included in Table 3 to NESHAP Subpart DDDDD.

- A facility with a new or existing boiler with heat input capacity greater than 10 MMBtu/hr must conduct a tune-up of the boiler annually in accordance with §63.7540.
- A facility with an existing boiler must complete a one-time energy assessment performed by a qualified energy assessor.

Comment Excerpt Number: 28

Comment: In 2004, EPA candidly admitted that it could not develop CO work practice standards for ICI Boilers:

Consequently, any uniform requirements or set of work practices that would meaningfully reflect the use of good combustion practices or that could be meaningfully implemented across any subcategory of boilers and process heaters could not be identified.²⁹

EPA has nonetheless asserted that measuring CO levels is impracticable³⁰ and has set out what it describes as a work-practice standard. What EPA has adopted and continues to propose is not a set of good combustion practices that could be meaningfully implemented across a subcategory, but a requirement to follow the manufacturer's recommendation for good combustion practices. This assumes that manufacturers can do what EPA could not – identify a set of good combustion practices applicable to boilers designed and built over the past 50 years. It also assumes that the manufacturers of these units are still in business and will invest the resources needed to do so voluntarily. These assumptions are patently incorrect. There is no obligation on the part of manufacturers to develop any meaningful set of broadly applicable good combustion practices or to determine the set of work practices employed by the best performers in the sector or to determine whether any particular set of work practices approximates the emission performance of the best performers in a subcategory. Conceivably, an organization like The National Board of Boiler & Pressure Vessel Inspectors might be able to provide a certification/best practices review of any legacy boiler, even if the original manufacturer is no longer in business and individual sources can retain consulting firms to study the operation of individual boilers and recommend a set of best practices for that boiler. We submit that such a program, that imposes obligations on relatively clean boilers as well as high emitters, if conducted in a technically sound manner, may prove to be more costly overall and provide far less environmental benefit than a defined numerical limit that requires significant emission reductions from gross emitters. CO CEMs are available, relatively inexpensive and used by industry for process control. These devices should be required for all combustion units covered by the major source and CISWI rules.

Comment Excerpt Number: 96

Comment: EPA acknowledges that the cost of testing small boilers and process heaters is prohibitive. While the cost of emissions testing larger units is less prohibitive, EPA must consider these costs when establishing the frequency of testing.

The benefits of testing more frequently than every 5 years do not justify the costs. HAP emissions change only when operating parameters change (e.g., firing rate, maximum contaminant input limits for chloride and mercury, type of fuel, combustion efficiency, oxygen content, etc.) or when design changes occur. Absent these changes to an affected source, operating parameters established by implementation of Boiler MACT are more than sufficient to ensure that emissions will not significantly change over time. Furthermore, the Boiler MACT provisions require owners and operators to measure and monitor prescriptive operating limits, as well as monitor, measure, and keep records of each type of fuel on a continuous basis to verify compliance with limits established during the compliance test. The Boiler MACT regulations also stipulate that sources must perform testing under a representative operating load and require sources to maintain within 110% of the average operating load observed during testing. Based on these stringent monitoring requirements, the operating parameters established during testing are sufficient for a source to demonstrate compliance for a 5-year period. Modifications will be tested under the provisions for new and modified sources, and do not need to be considered in ongoing test requirements.

Comment Excerpt Number: 6

Comment: Gas 2 Units Combusting Coke Oven Gas or Other Process Gases Should be Subject to the Same Work Practices as Natural Gas-Fired Units The work practices applicable to Gas 1 units are equally applicable to units that combust coke oven gas and other process gases. To the extent that the best performing units combusting those alternate fuels conduct tune ups (or other similar work practices) to achieve emissions reductions, EPA can promulgate those measures as work practice based emissions standards to ensure continuous reductions in the quantity and/or rate of emissions of air pollutants under §112(d) and §302(k). As such, there is no need to delve into the prerequisites that exist under §112(h) for these units.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Commenter Name: Bruce A. Steiner

Commenter Affiliation: American Coke and Coal Chemical Institute (ACCCI)

Document Control Number: EPA-HQ-OAR-2002-0058-3547-A2

Comment Excerpt Number: 7

Comment: Should the agency feel compelled to press forward with its §112(h) analysis, we believe that EPA's findings regarding the infeasibility of controlling and monitoring emissions from natural gas-fired boilers and process heaters are both appropriate and equally applicable to units fired with coke oven gas or other process gases. As found by EPA in its originally proposed Boiler MACT, work practices should supplant numeric emission limits on Gas 1-fired units because “[f]irst, the capital costs estimated for installing controls on these boilers and process

heaters to comply with MACT limits for the five HAP groups is over \$14 billion,” a cost “higher than the estimated combined capital cost for boilers and process heaters in all of the other subcategories.” Second, EPA found that proposing emission standards for gas-fired boilers and process heaters “would have the negative benefit of providing a disincentive for switching to gas as a control technique (and a pollution prevention technique)” and “may have the negative benefit of providing an incentive for a facility to switch from gas (considered a ‘clean’ fuel) to a ‘dirtier’ but cheaper fuel (i.e., coal).” As EPA correctly concluded, “[i]t would be inconsistent with the emissions reductions goals of the CAA, and of §112 in particular, to adopt requirements that would result in an overall increase in HAP emissions.”

These same arguments apply with even greater force to coke oven gas-fired and process gas-fired units. First, the costs of controlling coke oven gas-fired units are similar to the per-unit costs faced by Gas 1 units. Just like Gas 1 units, coke oven gas units, if subjected to Gas 2 requirements, would face the need to install fabric filters for the control of particulate matter (PM) and mercury (Hg), as well as wet scrubbers to control hydrochloric acid (HCl) and an oxidizing catalyst to control carbon monoxide (CO) - all at a cost well beyond that already calculated by EPA. Second, imposing emission standards on these units would clearly incentivize operators to cease burning coke oven gas in preference for the fossil fuels that cost less to burn, resulting in an increase in emissions “inconsistent with the emissions reductions goals of the CAA, and of section 112 in particular.”

But unlike natural gas, which is generally stored as a commodity when not consumed, coke oven gas must be flared as a waste gas to ensure a safe environment if not immediately usable at a facility. As a result, creating incentives which cause operators of coke oven gas-fired units to fuel-switch (even to natural gas) would result in significant net emissions increases. That is because the facility would necessarily combust both the coke oven gas (at a flare) and the additional fossil fuel necessary to generate sufficient heat for its operations. Simply put, any standard that creates a disincentive to recover energy from process gases is bad for the environment and thus contrary to the goals of the CAA. Extending work practice tune-up standards to coke oven gas or process gas-fired boilers will ensure that there is no environmentally detrimental incentive to displace coke oven gas or process gas with natural gas or other fuels in the boiler and flare those recoverable energy sources.

Comment Excerpt Number: 2

Comment: Dow supports EPA’s direction and this proposal to require work practice standards for natural gas, refinery gas, and other gas 1 fuels.

As previously detailed in our August 19, 2010 comments on the proposed rule, Dow supports Other Gas 1 fuels being regulated by work practice standards in the same manner as natural gas and refinery gas for the following reasons:

- The use of petrochemical and chemical plant off-gas streams as fuel is essential to being energy efficient at larger chemical production facilities. These fuels are typically clean fuels with a composition similar to natural gas or refinery gas.
- Imposing strict emission limits, especially for CO, would likely have the undesirable environmental impact of source owner/operators having to operate in a less efficient manner by combusting more fuel which in turn would likely increase emissions of criteria air pollutants and GHG pollution.
- Imposing strict emission limits, especially for CO, would likely complicate NOx emission reduction efforts that may be required for some sources in the future to meet the future 75 ppbv 8-hour ozone NAAQS.

Commenter Affiliation: Georgia-Pacific LLC (GP)

Document Control Number: EPA-HQ-OAR-2002-0058-3465-A1

Comment Excerpt Number: 1

Comment: GP strongly supports EPA’s retention of the provision in the final rule that subjects boilers and process heaters utilizing clean burning gas fuels (Gas 1) to only a work practice standard under Section 112(h) of the CAA. As EPA has stated in final rule (76 Federal Register 15638); “*EPA has determined that it is not feasible to prescribe numerical emissions standards for Gas 1 units because the application of measurement methodology is not practicable due to technological and economic limitations.*” “*The commenters correctly point out that the measured emissions from these units are routinely below the detection limits of EPA test methods, and, as such, EPA considers it impracticable to reliably measure emissions from these units.*”

For a number of our boilers and process heaters subject to the Boiler MACT requirements, GP is evaluating the option of fuel switching to natural gas as a compliance option if the conversion can be economically justified. If EPA were to require unnecessary controls on Gas 1 sources, the cost of these additional controls would be a disincentive to switching to these cleaner fuels. GP agrees with EPA’s use of a work practice and we believe this option is not only appropriate but the only available means of demonstrating compliance for Gas 1 units due to the impracticality of establishing a numerical limit.

Commenter Name: Barry Christensen

Commenter Affiliation: Occidental Chemical Corporation (OCC)

Document Control Number: EPA-HQ-OAR-2002-0058-3477-A1

Comment Excerpt Number: 1

Comment: OCC continues to strongly support the exemption from numerical emission limits for existing gas fired units and the use of the periodic tune-ups as an alternative work practice. Natural gas is the cleanest fossil fuel and HAP emissions associated with the combustion of natural gas are minimal. The environmental and cost reduction benefits of requiring work practices, such as employing good combustion practices, far outweigh any benefits potentially obtainable through emission limitations. For example, periodic tune-ups performed according to established criteria will ensure that combustion systems remain optimized according to manufacturer's recommendations. Furthermore, implementing emission limits instead of work practices for natural gas firing would be catastrophically expensive.

Commenter Name: Peter Pagano

Commenter Affiliation: American Iron and Steel Institute (AISI)

Document Control Number: EPA-HQ-OAR-2002-0058-3490-A1

Comment Excerpt Number: 13

Comment: All metal process furnaces (regardless of fuel burned) should be subject to work practices in lieu of numeric criteria. The proposed rule provides work practice standards for the metal process furnaces subcategory. (Table 3 of Subpart DDDDD.) Section 112(h)(1) of the CAA authorizes the promulgation of work practices in lieu of emission limits "if it is not feasible in the judgment of the Administrator to prescribe or enforce an emission standard for control of a hazardous air pollutant or pollutants." EPA properly concluded that emission standards are not feasible for metal process heaters for two reasons. First, imposing emission limitations on these units would be economically impracticable-particularly in contrast to the very limited emissions reductions that could be achieved.²³ Second, EPA noted that proposing emission standards for

metal process heaters would run contrary to § 112's goals because they "would result in an overall increase in HAP emissions" by "providing a disincentive for switching to gas as a control technique (and a pollution prevention technique)"²⁴ These concepts are equally applicable to all gaseous fuels. Indeed, any standards that threaten to penalize the preferred practice of combusting process gases would pose a grave environmental threat. Process gasses are, by definition, the product of another process. If these gases are not reclaimed for their heat content (in place of natural gas or another fossil fuel), they are typically flared. Given the exorbitant costs EPA identified for controlling emissions from metal process furnaces, metal process furnaces currently burning process gas in lieu of natural gas might switch to natural gas exclusively and flare the process gas, resulting in "an overall increase in HAP emissions." Further, greenhouse gases and criteria pollutant emissions also would increase due to flaring the process gases while nearby boilers also combust virgin fossil fuels. To avoid that untoward result, work practices should apply equally to all metal process furnaces.

Commenter Affiliation: American Chemistry Council (ACC)

Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1

Comment Excerpt Number: 31

Comment: *GASEOUS FUEL SPECIFICATION*

ACC and its members strongly support the use of work practices as MACT for gas-fired boilers and process heaters. The following points summarize the arguments presented by ACC and others in previous comments and petitions for reconsideration.

HAP emissions from gas-fired boilers and process heaters are extremely low and cannot be reliably measured at these low levels due to deficiencies in both laboratory analysis methods and stack sampling methods. Detection limits reported in the test reports received by EPA during the boiler MACT data collection efforts varied greatly, pointing to the lack of repeatability of measurements at these very low levels.

As the majority of source emissions are below the reference method quantitation limits, the standard is appropriately set as a work practice standard and not an emission standard, since sources would not be able to accurately measure emissions against any numerical standard

ACC is not aware of any data that shows a correlation between a reduction in CO concentration and a corresponding reduction in organic HAP emissions below a CO concentration of approximately 100 ppmv for gas fueled (other Gas 1 fueled or Gas 2 fueled) sources. Thus, setting a very low standard for CO does not ensure a proportional reduction in the organic HAP emissions, and may have the unintended consequence of increasing emissions of other pollutants such as nitrogen oxides due to the combustion of additional fuel and suboptimal operating conditions.

Good combustion practices and periodic tune-ups as work practices will ensure proper operation of gas-fired units and continuous minimization of emissions. In fact, for gas-fired sources, these types of practices serve as MACT currently for minimizing organic HAP emissions.

Many gas-fired boilers and process heaters do not have vents or stacks to which EPA measurement methods can be applied, and to significantly modify the stacks would be technically infeasible in some applications and would be economically infeasible in many others.

Measurement infeasibility and control cost issues serve to justify the technical and economic feasibility criteria under §112(h) of the CAA for establishing work practices in lieu of numeric emission standards.

Commenter Name: Alicia Meads

Commenter Affiliation: National Association of Manufacturers (NAM)

Document Control Number: EPA-HQ-OAR-2002-0058-3515-A1

Comment Excerpt Number: 4

Comment: The EPA has ample legal authority to set the standard in terms of a work practice. First, section 112(d)(1) authorizes – if not requires – the EPA to set "emission standards" for each category or subcategory, and section 302(k) defines "emission standard" to include work practice standards. Thus, if the EPA determines that the best performing sources achieved their emissions performance through work practices rather than control equipment, those work practices should be identified as the "floor." Second, section 112(h)(2)(b) independently authorizes the EPA to use a work practice standard where, as here, the application of a system for measuring the effect of the control measure for enforcement purposes is not practicable.

The EPA has independent authority to promulgate work practices as emission standards under CAA §302(k) as long as the work practices provide a continuous limit on emissions or are part of a set of regulations that provide a continuous limit on emissions. As required by CAA § 112(d), the EPA must promulgate "emission standards" for the control of hazardous air pollutants at major sources. Originally, these "emission standards" were found to be limited to only numeric emission limits. *See, e.g., Adamo Wrecking Co. v. U.S.*, 434 U.S. 275 (1978). However, in the 1990 Amendments, Congress expanded the definition of "emission standards" in §302(k) to expressly include work practices. As a result, the plain language of the Clean Air Act now authorizes the promulgation of work practices: (1) as direct emission standards under §302(k), and (2) in lieu of emission standards under CAA §112(h).

That statutory authority greatly simplifies the development of work practice standards for boiler units. Instead of turning to the alternate stop-gap provisions in §112(h) that apply when continuous emissions standards are not feasible, the EPA can focus on the direct establishment of work practices that existing sources use to ensure continuous compliance under §§112(d) and 302(k). For example, if the top 12% of existing natural gas-fired boilers are using tune-ups to achieve their "best performing" status, then the EPA has the authority to establish that protocol as a work practice-based emission standard. Tune-ups are an appropriate emission standard for these units because, if conducted with adequate frequency, they provide continuous reduction of the quantity and rate of HAP emissions from boilers by ensuring that they operate properly.

The NAM agrees with the EPA's conclusions regarding the basis for relying on work practices for units that combust only natural gas, refinery gas, or equivalent fuels. As the EPA recognizes, the capital cost of emissions controls for the numerous existing gas-fired boilers would be extraordinarily high. *See* 75 Fed. Reg. at 32,025, 32,029. Further, the EPA correctly concluded that imposing emission limitations on gas-fired boilers would create a disincentive for switching

to gas from oil, coal or biomass as a control technique. *Id.* In fact, it could create an incentive for facilities to switch away from gas to other fuels. Both outcomes should be avoided. Finally, the EPA recognized that "[t]he inability to accurately measure emission from Gas 1 units and the related economic impracticability associated with measuring levels that are so low that even carefully conducted tests do not accurately measure emissions warrant setting a work practice standard under CAA section 112(h)." 76 Fed. Reg. at 15,638.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 3

Comment: Instead of prescribing numeric HAP emissions limitations on boilers burning clean gas fuels (the "Gas 1" subcategory), EPA adopted work practices requiring a tune up of the boiler. EPA explained in the preamble to the June 4, 2010 proposal that:

[T]he need to employ the same emission control system as needed for the other fuel types would have the negative benefit of providing a disincentive for switching to gas as a control technique (and a pollution prevention technique) for boilers and process heaters in the other fuel subcategories. In addition, emission limits on gas-fired boilers and process heaters may have the negative benefit of providing an incentive for a facility to switch from gas (considered a "clean" fuel) to a "dirtier" but cheaper fuel (i.e., coal). It would be inconsistent with the emissions reductions goals of the CAA, and of section 112 in particular, to adopt requirements that would result in an overall increase in HAP emissions.²⁵ In short, EPA proposed that work practice standards are appropriate and justified for units in the Gas 1 subcategory out of concern for the cost of complying with numeric emissions limitations and based on the adverse policy incentives that would be created.

In the final rule, EPA provided further reasons for establishing work practices for Gas 1 boilers. EPA explained that "the measured emissions from these units are routinely below the detection limits of EPA test methods, and, as such, EPA considers it impracticable to reliably measure emissions from these units." 76 Fed. Reg. at 15638. EPA further explained that CO emissions test results were "below the level EPA considers to be a reliable measurement for more than 80 percent of the test runs that were conducted on Gas 1 units" and that the "case for other pollutants is even more compelling as the majority of measurements are so low as to cast doubt on the true levels of emissions that were measured during the tests." *Id.* Based on these data, EPA concluded that, "The inability to accurately measure emission from Gas 1 units and the related economic impracticability associated with measuring levels that are so low that even carefully conducted tests do not accurately measure emissions warrant setting a work practice standard under CAA section 112(h)." *Id.*

We concur with EPA's conclusions. For the gas-fired boiler and process heater source categories, it is not possible to discern in light of the reported data any economically or

technically practicable means of measuring compliance with a numeric emissions limitation. As a result, EPA has ample authority to set the standard for Gas 1 units in terms of a work practice.

Commenter Name: Pamela Lacey
Commenter Affiliation: American Gas Association (AGA)
Document Control Number: EPA-HQ-OAR-2002-0058-3672-A2
Comment Excerpt Number: 1

Comment: AGA strongly supports EPA's proposal to apply a work practice standard to natural gas-fired industrial and commercial boilers at major sources, rather than an emissions limit. As noted in the preamble, EPA's "data for natural gas-fired units show the overwhelming majority of emissions to be below the level that can be accurately quantified by the available test methods." See 76 Fed. Reg. at 80609. We agree that it is inappropriate to impose emission limits given that natural gas boilers emit negligible or non-detectable amounts of hazardous air pollutants (HAPs). 76 Fed. Reg. 15608, 15638. Only poor combustion in these units could lead to HAP emissions, and the best way to ensure that natural gas-fired boilers and process heaters are operating properly and combusting efficiently is to conduct regular tune-ups.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Comment Excerpt Number: 39

Comment: We strongly support EPA's conclusion that the CAA 112(h) criteria are met and therefore design, equipment, work practice, or operational requirements are the appropriate and legal means of meeting the requirements of CAA section 112(d)(2) for D/F emissions, for the Gas 1 and Limited-Use subcategories and for smaller boilers and process heaters (i.e., <10 MMBTU/hr).

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: Matthew Todd

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 43

Comment: Design or good combustion work practices are the appropriate standard for all gas 1-fired units since the combustion and emission characteristics of all gas 1-fired units are similar and emissions are so low that their measurement is technically and/or economically infeasible. Thus, EPA is legally correct in proposing work practice requirements for BPH firing gases other than natural gas and refinery gas, particularly to units firing chemical fuel gas, by establishing reasonable criteria for "other gas 1 fuels". See our comment on these criteria in Comment II.2.A, above. Chemical and refinery fuel-gas systems are often integrated at major sites and some chemical processes are present in some refineries as well as in chemical plants. Thus, establishment of a broad other gas 1 fuel category also reflects real operations and the gaseous fuels in use when the emissions data that serves as the basis for this rulemaking were collected.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: Elizabeth McMeekin
Commenter Affiliation: PPG Industries, Inc
Document Control Number: EPA-HQ-OAR-2002-0058-3778-A1
Comment Excerpt Number: 1

Comment: PPG strongly supports the use of work practices as MACT for gas-fired boilers.

HAP emissions from gas-fired boilers and process heaters are extremely low and cannot be reliably measured at these low levels due to deficiencies in both laboratory analysis methods and stack sampling methods.

Detection limits reported in the test reports received by EPA during the boiler MACT data collection efforts varied greatly, pointing to the lack of repeatability of measurements at these very low levels.

As the majority of source emissions are below the reference method quantitation limits, the standard is appropriately set as a work practice standard and not an emission standard, since sources would not be able to accurately measure emissions against any numerical standard.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Commenter Name: Elizabeth McMeekin
Commenter Affiliation: PPG Industries, Inc
Document Control Number: EPA-HQ-OAR-2002-0058-3778-A1
Comment Excerpt Number: 3

Comment: PPG strongly supports the use of work practices as MACT for gas-fired boilers.

Good combustion practices and periodic tune-ups as work practices will ensure proper operation of gas-fired units and continuous minimization of emissions. In fact, for gas-fired sources, these types of practices serve as MACT currently for minimizing organic HAP emissions.

Many gas-fired boilers and process heaters do not have vents or stacks to which EPA measurement methods can be applied, and to significantly modify the stacks would be technically infeasible in some applications and would be economically infeasible in many others.

Measurement infeasibility and control cost issues serve to justify the technical and economic feasibility criteria under §112(h) for requiring work practices in lieu of numeric emission standards.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section ‘Other Actions We Are Taking’ for the reasons for the denial.

Commenter Name: Elizabeth McMeekin

Comment Excerpt Number: 5

Comment: We support EPA's decision to retain work practices rather than emission limits for smaller coal- and oil-fired units (under 10 mmBtu/hr) that were established in the March 2011 final rule.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: Kenneth Anderson

Commenter Affiliation: Ameren Corporation

Document Control Number: EPA-HQ-OAR-2002-0058-3487-A1

Comment Excerpt Number: 7

Comment: Ameren requests US EPA reconsider whether a threshold higher than 10 million Btu per hour meets the technical and economic limitations as specified in CAA section 112(h).

Ameren raised this issue during comments on the proposed Boiler MACT rule but could not find that US EPA responded to this issue in the preamble or in the response to comments documents. Ameren believes that US EPA should consider setting only work practice standards for all liquid fuel fired boilers and process heaters below 100 MMBtu/hr as it does for units of all sizes in the gas 1 subcategory. Assuming a no.2 fuel oil fired 100 MMBtu/hr auxiliary boiler and using AP-42 particulate emission factors, average PM_{2.5} and Hg factors from the US EPA emission test database for the Boiler MACT rulemaking, the particulate emissions from that boiler is on the order of 6 tpy, PM_{2.5} on the order of 1.8 tpy and Hg on the order of 1.2 lb/yr. Using the US EPA summary of Capital and Annual Costs for control in Table 5 of the Preamble of the proposed rule, the average annualized cost of control for existing liquid fuel fired boilers after considering fuel savings is \$476,764 per boiler. In terms of cost effectiveness, assuming 100% reduction of all three pollutants, the annualized cost of reduction is \$79,460 per ton of PM reduction,

\$264,869 per ton of PM_{2.5} reduced and \$397,303 per pound of Hg reduced. We include PM and PM_{2.5} for this analysis because US EPA's benefits analysis for this proposed rule is based on PM_{2.5} reductions. At these costs, it does not make sense to require controls on small liquid fuel fired boilers as small as 100 MMBtu/hr. EPA should define work practice standards under CAA section 112(h) for these boilers similar to the limited use category.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Commenter Name: James Pew

Commenter Affiliation: Earthjustice, Clean Air Council, Partnership for Policy Integrity

Document Control Number: EPA-HQ-OAR-2002-0058-3511-A1

Comment Excerpt Number: 43

Comment: Addressing its work practice standards for smaller units, EPA also asserted for the first time in the final rule that it has not established a separate sub-category for smaller units (and acknowledged the lack of any justification for such a subcategory) even though it has provided a separate work practice standard for units burning any fuel at a rate less than 10 MMBtu per hour. Resp. Comments. Vol. 2 at 2818.1 Ex. 18. EPA nonetheless asserted authority to exempt sources from Section 112(d), based on the argument that it is too impracticable (or, in this case, expensive) for those units to employ the prescribed measurement methods. 76 Fed. Reg. at 15,641. Clean Air Act Section 112(h) only allows the Agency to set work practice standards instead of numeric standards only if there is no feasible method of measuring HAP emissions, 42 U.S.C. § 7412(h)(1). The Agency only asserts here that "the suite of test methods required by *this* final rule" are precluded by the design of these smaller units. 76 Fed. Reg. at 15,641 (emphasis added). That falls short of the statutory standard for the reasons provided in the Comments. Comments at 42-43, 45-48. Moreover, Section 112(h) does not provide the authority to create work practice standards that apply only to specified units within a category (or subcategory). It allows work practice standards in lieu of "emission standards." 42 U.S.C. § 7412(h)(1). "Emission standards," in turn, are those "achievable for new or existing sources in [a] category or subcategory." 42 U.S.C. § 7412(d)(2) (emphasis added). The Agency's refusal to establish numeric standards for small boilers, accordingly, is unlawful and lacks an adequate rationale.

Response: EPA disagrees with the commenter's interpretation of the Clean Air Act. Nothing in section 112(h) limits EPA's authority to establish work practice standards to an entire category or subcategory. Rather, if EPA finds that it is not feasible to prescribe or enforce an emission standard, the Agency may establish a work practice standard in lieu thereof. The fact that section 112(d)(2) requires that EPA establish "emissions standards" reflecting MACT for sources "in a category or subcategory" neither expressly nor implicitly prohibits EPA from exercising its discretion to establish work practice standards for a portion of a source category or subcategory, where the Agency concludes that it is infeasible to prescribe or enforce a numeric emissions limit only for some sources in the category or subcategory. Had Congress intended to so limit EPA's authority in section 112(h), it could have done so.

This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

Document Control Number: EPA-HQ-OAR-2002-0058-3518-A1
Comment Excerpt Number: 2

Comment: EPA should exempt small units (e.g. units less than 10 mmBtu/hr firing natural gas and/or liquid fuel) from tune-up work practice requirements under 40 CFR Part 63 Subpart DDDDD specifically Table 3 since the emissions from these units are insignificant. The impact of these units on the environment is negligible while further regulation places additional burdens on the regulated community as well as governmental agencies that will need to administer permits for these insignificant sources.

Response: This comment relates to a petition that was denied by the EPA. Refer to the preamble section 'Other Actions We Are Taking' for the reasons for the denial.

New Data or Corrections to Existing Data

9A. New Data Submissions

Commenter Name: Nina Butler
Commenter Affiliation: Rock-Tenn Company
Document Control Number: EPA-HQ-OAR-2002-0058-3688-A2
Comment Excerpt Number: 3

Comment: NCASI analyzed the West Point mill's No. 8 Power Boiler CO CEMS data for the years 2009 to 2011 and determined that the No. 8 Power Boiler would have exceeded the proposed 28 or 35 ppm 10-day rolling average limits 23.6% or 9.7% of the time, respectively. The hourly average CO CEMS data for the West Point mill's No.8 Power Boiler for 2009 through 2011 are attached [see Attachment 1].

NCASI estimates that using this additional data to set the CEMS-based CO limit for the PC boiler subcategory would increase the 99% UPL values to 30 ppm and the alternate limit of the maximum 10-day rolling average would increase from 35 to 69 ppm. NCASI has included the results of this analysis for the No.8 Power Boiler CO CEMS data for years 2009 to 2011 in their comments on the Proposed BMACT Reconsideration Rule.

Response: The additional CO emissions data for the specified combustion unit have been incorporated into the EPA ICR Databases.

Commenter Name: Temple-Inland
Commenter Affiliation: Carole J. Stapper
Document Control Number: EPA-HQ-OAR-2002-0058-3423
Comment Excerpt Number: 2

Comment: Temple-Inland conducted another compliance stack test on BW-B001 on December 7, 2010, which is being submitted to EPA at this time. We believe it is imperative that EPA also

incorporate these data into the floor analysis so that the final short-term CO limit adequately reflects boiler variability. Please note that this stack test was conducted while firing a mixture of sander dust and natural gas, but since the sander dust firing rate was 94.6% of the total heat input, these data are representative of " biomass" firing. [See DCN: EPA-HQ-OAR-2002-0058-3423.2 for test report.]

Response: The results of the December, 2010 emissions testing of the specified combustion unit have been incorporated into the EPA ICR Databases and will be factored into future MACT floor analyses.

Commenter Name: David A. Buff, Golder Associates Inc.

Commenter Affiliation: Florida Sugar Industry (FSI)

Document Control Number: EPA-HQ-OAR-2002-0058-3504-A1

Comment Excerpt Number: 28

Comment: The FSI appreciates EPA's willingness to consider the FSI's data concerning hybrid suspension grate boilers, and it appears that EPA has appropriately considered the data that were previously submitted by the FSI. The FSI requests EPA to consider the additional data attached hereto and set an appropriate CO CEMS-based emission limit, as discussed in paragraph (9) below.

Response: The provided fuel sampling and emissions data have been incorporated into the EPA ICR Databases.

Commenter Name: David A. Buff, Golder Associates Inc.

Commenter Affiliation: Florida Sugar Industry (FSI)

Document Control Number: EPA-HQ-OAR-2002-0058-3504-A1

Comment Excerpt Number: 32

Comment: The FSI previously provided EPA with several years of continuous hourly CO data for U.S. Sugar Company's Boiler No. 8, spanning the period October 2007 through March 2010. Boiler No. 8 is a new hybrid suspension grate boiler that was designed to comply with the 2004 Boiler MACT Rule for new sources. The FSI now is submitting additional CO CEMS data for Boiler No. 8, covering the period from March 2010 through December 2011, so that the entire database spans 2007 through 2011. The additional data are attached to this letter. Therefore, with this submittal, EPA will have a database that includes almost four years of operations, which should be more than adequate for EPA to establish a CO CEMS limit that is based on an averaging time of greater than 30 days. It is noted that these data do not include periods of malfunction, which are discussed separately below.

The CO CEMS data submitted to EPA for U.S. Sugar Company's Boiler No. 8 are the same data that are reported to the Florida Department of Environmental Protection under the Title V operating permit for Boiler No. 8. It is important to recognize, however, that the data do not include periods of time when the boiler experiences an upset condition (i.e., a malfunction). The exclusion of such periods of time is consistent with current law, which recognizes that malfunctions may occur due to a process upset or other conditions that are beyond the reasonable control of the operator. Upset conditions can occur due to a variety of reasons, including mill stoppages, plugged bagasse feeders in the boiler, bagasse piling up on the boiler grate, etc.

Response: The additional hourly CO emissions data for the specified combustion unit have been incorporated into the EPA ICR Databases.

Commenter Name: Ashok K. Jain

Commenter Affiliation: National Council for Air and Stream Improvement, Inc. (NCASI)

Document Control Number: EPA-HQ-OAR-2002-0058-3505-A1

Comment Excerpt Number: 23

Comment: In this subcategory, the MACT floor pool for CO has 10 units. One of these is ARWestFraser Huttig SN- 24, which has 3 tests (3/1/05, 8/6/09, and 3/18/10). As part of AF&PA's effort to obtain additional CO CEMS data for best performing units in this subcategory, this boiler was selected for installation of a temporary CEMS. Unfortunately, a major boiler failure occurred shortly after the installation and certification of the temporary CEMS which prevented further data collection. However, Method 10 tests were successfully carried out as part of CEMS certification, and these results are being submitted to EPA by West Fraser. The additional Method 10 runs should be incorporated in EPA's UPL calculations for the subcategory. Using EPA's UPL calculation methodology results in a 99% UPL of 1,000 ppm at 3% O₂ and a 99.9% UPL of 1,150 ppm at 3% O₂.

Response: The additional CO emissions data for the specified combustion unit have been incorporated into the EPA ICR Databases.

Commenter Name: Ashok K. Jain

Commenter Affiliation: National Council for Air and Stream Improvement, Inc. (NCASI)

Document Control Number: EPA-HQ-OAR-2002-0058-3505-A1

Comment Excerpt Number: 24

Comment: One of the five floor units for this subcategory is OKGPMuskogeeMill B-4. Georgia-Pacific is submitting an additional Method 10 test conducted in 2010. These additional three runs should be included in the floor calculations for the UPL. Our calculations using EPA's methodology indicate the existing source limit would be 51 ppm at 3% O₂ if based on the 99% UPL or 57 ppm based on the 99.9% UPL.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3465-A1, excerpt 26.

Commenter Name: Ashok K. Jain

Commenter Affiliation: National Council for Air and Stream Improvement, Inc. (NCASI)

Document Control Number: EPA-HQ-OAR-2002-0058-3505-A1

Comment Excerpt Number: 26

Comment: Due to concerns about the adequacy and representativeness of the limited CO CEMS data for these two subcategories, AF&PA and NCASI undertook an effort to obtain additional CO data by installing temporary CEMS on boilers already deemed to be best performers in the stack test-based MACT floors. Only two such boilers were ultimately identified for additional testing, one a wet biomass stoker unit (MSGPNew Augusta) and one a biomass fluidized bed unit (TNBewaterNewsprint). To date, NCASI has obtained 105 days of hourly average CEM data on the MSGPNew Augusta biomass stoker (10/20/11 to 2/1/12) and 49 days of hourly average CO CEM data for the TNBewaterNewsprint FBC unit (11/20/11 to 12/28/11), both these units being among the best performer list in their respective categories. The data for the TNBewaterNewsprint FBC unit are incomplete and could not be analyzed in time to meet the February 21 comment deadline. The data obtained thus far for the MSGPNewAugusta biomass stoker unit have been analyzed and 105 daily averages added to the 2119 daily averages representing four biomass stokers already analyzed by EPA.

Response: The additional data for TNBewaterNewsprint were not submitted and will not be incorporated into the EPA ICR Database. For a response to the additional data provided for MSGPNewAugusta, please see comment EPA-HQ-OAR-2002-0058-3465-A1, excerpt 26.

Commenter Name: Ashok K. Jain

Commenter Affiliation: National Council for Air and Stream Improvement, Inc. (NCASI)

Document Control Number: EPA-HQ-OAR-2002-0058-3505-A1

Comment Excerpt Number: 35

Comment: For PC-fired units, NCASI obtained 3 years duration of CO CEM data (2009, 2010 and 2011) from the VASmurfitStone Westpt unit that was used to calculate the 10-day rolling average floor of 28 ppm @3% O₂. Using the additional data, NCASI estimates the 99% UPL value would rise from 28 to 32 ppm @3% O₂, and the alternate limit rises from 35 to 67 ppm @3% O₂. As pointed out in the previous section 6a, the alternate limit based on determining the maximum 10-day rolling average in the data used to set the floor is much more defensible than a UPL-based limit.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3688-A2, excerpt 3.

Commenter Name: James Pew

Commenter Affiliation: Earthjustice, Clean Air Council, Partnership for Policy Integrity

Document Control Number: EPA-HQ-OAR-2002-0058-3511-A1

Comment Excerpt Number: 66

Comment: PM emissions at existing facilities are commonly controlled with ESPs and baghouses. Emissions test data from the McNeil biomass plant in Vermont shows that filterable PM can be controlled well. [See submittal for Table 3-1. Summary of Particulate Matter Test Results.]

Response: The provided emissions data do not pertain to any known facility that is subject to the NESHAP for Industrial, Commercial, and Institutional Boilers and Process Heaters at Major Sources. In fact, the permit for the McNeil biomass plant indicate that the facility is an area source of HAP. Thus, these data were not incorporated into the EPA ICR Databases.

Commenter Name: Stephen E. Woock

Commenter Affiliation: Weyerhaeuser Company

Document Control Number: EPA-HQ-OAR-2002-0058-3523-A1

Comment Excerpt Number: 24

Comment: EPA lists this unit (ES-017 WFB) at the Weyerhaeuser Dodson mill as a top performer for PM in the *Stoker/sloped grate/other unit designed to burn wet biomass* subcategory. EPA has in its database for this re-proposal two tests with average PM data of 0.00333 (2002 test) and 0.035 (2007 test). Two separate stack tests completed in 2010 and summarized in the table below put these tests in perspective, demonstrating an order-of-magnitude variability which shows the need for EPA to take stack test performance and perhaps, control technology performance over time into account. This unit could not reliably meet the proposed PM limit of 0.029 for wet biomass stokers based on the units test data, yet EPA has designated this unit as a top performer in that subcategory. The 2010 test reports are submitted as attachments to these comments (see attachments).

test run date and average PM emissions in lb/mmBtu:

- 2002/0.0033 (3 run test)
- 2007/0.035 (3 run engineering test)
- May 2010/ 0.0320 (3 run engineering test)
- July 2010/0.029 (4 run compliance test)

Response: The additional emissions testing data for the specified combustion unit have been incorporated into the EPA ICR Databases.

Comment: The accompanying data was collected at the Steam Center at Jackson Lab in Bar Harbor, Maine. [See DCN EPA-HQ-OAR-2002-0058-3658-A3] The plant was commissioned in Sept 2011. The setting is a laboratory campus bordering in the Acadia National Park. The plant complies with both State and Federal emissions requirements based on proximity to the Park. The facility will consume approximately 14,000 tons of pelletized biomass per year and replace over 1,250,000 gallons of #2 heating oil. The data is provided to illustrate the following:

- Frequency of steam loads below maximum fire rates
- Variations of steam load in daily operations
- Variations in CO levels due to firing rates and fuel.

Response: This facility is not a major source of hazardous air pollutant (HAP) emissions. Thus, the data from this facility were not incorporated into the EPA ICR Databases.

Comment: MSU has reviewed their calendar year 2010 CO CEMS data on our CFB unit and also recently collected CO emissions data on the three (3) PC units using a portable CEMS. This information is attached for your review. [See submittal EPA-HQ-OAR-2002-0058-XXXX for data provided by the commenter] The data for the CFB boiler shows that hourly CO emissions vary quite significantly. In fact, at the typical steam load for the CFB boiler, the majority of the hourly CO data is above the proposed 59 parts per million (ppm) standard. The data for the MSU PC units also show that CO tends to go above the proposed standard at normal operating loads, with a considerable increase when using SNCR control.

Response: The additional CO emissions data for the four combustion units specified have been incorporated into the EPA ICR Databases.

Comment: Attachment 3: Chevron U.S.A. Inc., Kapolei Hawaii Refinery PM Boiler Stack Test Results.

The Chevron U.S.A. Inc., Kapolei Hawaii Refinery (Chevron) contracted with URS Corporation (URS) to perform measurements of particulate matter (PM) emissions from two identical boilers recently commissioned at the refinery. The boilers may be fueled by low sulfur fuel oil (LSFO) or refinery fuel gas (RFG), and are not equipped with air pollution control devices (APCD) to

control PM emissions. The boilers are manufactured by Foster Wheeler and are rated at 99 MMBtu/hr. Chevron requested that URS perform preliminary testing for PM/PM10 emissions to assess the performance of the boilers.

U.S. EPA Methods 5 and 17 are typically designed to measure total filterable PM emissions (PM-FIL), or PM emissions of all particle sizes. The primary difference between U.S. EPA Methods 5 and 17 is that Method 5 employs an out-of-stack filter heated to 248±25°F, while Method 17 employs an in-stack filter that collects PM at the temperature of the stack gas. However, both methods do not allow for quantification of various particle sizes (PM10-FILT, PM2.5-FILT).

Under certain sampling conditions, U.S. EPA Method 201A may be used to measure PM-FILT emissions. First, the stack must be equipped with a sampling port diameter of 4-6", depending on the type of in-stack filter used. Second, there must be no entrained water droplets in the stack gas. Both boilers (5 & 6) met these conditions.

U.S. EPA Method 201A was used with an in-stack cyclone and filter to separate PM larger than 10 µm from the PM10-FILT sample fraction and PM2.5-FILT sample fraction with the addition of a second in-stack cyclone and filter (see Figure 1). In addition, U.S. EPA Method 201A was combined with U.S. EPA Method 202 to measure "back-half" condensable PM (PM-CON).

[See submittal for Figure 2 for summary of PM test results.]

Response: EPA requested an emissions testing report for the additional test data for this facility, but the reports were unable to be provided. As such, the additional emissions data cannot be verified and have not been incorporated into the EPA ICR Databases. The facility does not plan to obtain a report for the additional emissions data.

Comment: Remove Wauna from the Liquid inventory; it is no longer permitted to use liquid fuel.

The GP Wauna Pulp and Paper Mill – Boiler Number EU-33 is no longer permitted to burn liquid fuels and therefore should be removed from the floor calculation for the heavy liquid subcategory. The Oregon Title V Operating Permit# 04-0004 has been modified to prohibit the burning of fuel oil in this unit. Find attached in Appendix B, the EPA request to remove this source from the inventory and Page 27 of 78 from the operating permit where burning of fuel oil specifically prohibits in the boiler. [See submittal for Appendix B]

Facility: ORGeorgiaPacificWaunaMill Boiler: EU33 - Power Boiler

Response: The EPA ICR Databases have been updated to show that the specified combustion unit is no longer permitted to combust liquid fuels.

Commenter Name: Paul Noe

Commenter Affiliation: American Forest & Paper Association (AF&PA) et al.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 58

Comment: During our examination of the units in the liquid fuel subcategories, we discovered that several of the units that were considered are either no longer in operation or are no longer permitted to burn liquid fuels. Among these are:

- ORGeorgiaPacificWauna-EU 33 (fuel oil has been removed as a permitted fuel for this unit in the facilities Title V permit),
- SCGPChemRussellville-FOBoiler (This facility is no longer in operation and the unit is being dismantled), and
- NCDomtar-66-25-2050 (The No. 1 Package Boiler is no longer in operation and has been removed from the NC site).

These units should not be used in liquid unit floor calculations.

Response: For responses to the specified data corrections pertaining to SCGPChemRussellville and ORGeorgiaPacificWaunaMill, please see DCN EPA-HQ-OAR-2002-0058-3465-A1, Excerpts No. 24 and 25, respectively. EPA confirmed with NCDomtar that the specified

combustion unit has been permanently shut down; the EPA ICR Databases have been updated to reflect that this unit has been permanently shut down.

Commenter Name: Temple-Inland

Commenter Affiliation: Carole J. Stapper

Document Control Number: EPA-HQ-OAR-2002-0058-3423

Comment Excerpt Number: 1

Comment: In the proposed rule, there were several changes in boiler subcategories, including a separate subcategory created for biomass suspension burners that resulted in a short term CO limit of 58 ppm @ 3% O₂. The best performer for this subcategory is the Temple-Inland boiler at the Thomson Particleboard Plant (Facility ID GATempleinlandThomson, Unit ID BW-B001). Three stack test reports were submitted to EPA for BW-B001 (1/30/03, 12/7/04, and 12/3/08); however, it appears that the December 2004 test was not included in the floor analysis due to a concern that the CO data was not generated according to EPA Method 10. After further review, it appears that the stack test data provided to EPA was not for the December 2004 compliance test conducted on BW-B001, but was instead an "Investigative Emission Test Report" dated January 2005 that did not include CO testing at the boiler. To correct the record, Temple-Inland is submitting the "Compliance Emission Test Report Boiler/ESP B001" dated December 2004. As noted in the [See DCN EPA-HQ-OAR-2002-0058-3423.1 (page 3-3)], Method 10 was used for this stack test; therefore, we are requesting that these data be incorporated into the floor analysis.

Response: The reported emissions testing data have been updated accordingly in the EPA ICR Databases and will be factored into future MACT floor analyses.

Commenter Name: Traylor Champion

Commenter Affiliation: Georgia-Pacific LLC (GP)

Document Control Number: EPA-HQ-OAR-2002-0058-3465-A1

Comment Excerpt Number: 22

Comment: Currently, in its Boiler MACT database, EPA shows that GP has two process heaters identified as being affected sources under Boiler MACT. We believe these units should not be affected emissions sources under Boiler MACT because these units are currently regulated as an affected source subject to the requirements under the Plywood and Composite Wood Products (PCWP) MACT (40 CFR Part 63 Subpart DDDD). As noted in §63.7491(h) of the proposed Boiler MACT rule, these units would not be subject to this regulation if already subject to another MACT standard. The facilities are identified in the Boiler MACT emissions database as VAGeorgiaPacificBrooknealGladys and WVGPMtHopeOSB; and these units should be removed from EPA's emissions source database. The following is a detailed description of the facilities and the basis GP has utilized in determining these units are not subject to Boiler MACT: GP has two unique oriented strand board (OSB) facilities that use an integrated wood-fired heat source serving the dual function of supplying the heat required in the flake drying process and also heating thermal oil for the press. At each facility, these integrated wood-fired heat sources consist of a 240 MMBtu/hr Wellons Energy System, 3 rotary flake dryers, and 6 air-to-air heat exchangers all interconnected (see enclosed process flow diagram below). Heat for the drying system is provided by the Wellons Energy System. The combustion gases generated in

the Wellons Energy System are routed to an air-to-air heat exchanger (Primary Air Heater, one per dryer) to heat ambient air for use in that dryer. As needed to maintain dryer operating conditions, approximately 15% of the combustion gases entering the primary air heater can be sent directly to the dryer without going through the heat exchanger. These combustion gases come in direct contact with the process material. The heated ambient air and combustion gases are sent to each dryer where they are used to both convey the flakes through the dryer and to remove the moisture from the flakes. The dry flakes from each dryer are pneumatically conveyed to a cyclone collector where they are removed from the gas stream. The moisture laden dryer exhaust (process gases) from the cyclone is routed to another air-to-air heat exchanger (Recuperator, one per dryer) where it is re-heated to prevent condensation prior to being sent back to the Wellons Energy System for use as combustion air.

This system also includes a thermal oil heat exchanger where the combined combustion gases/process gases from the Wellons Energy System are used to indirectly heat thermal oil for use in the process. The combustion/process gases routed through the thermal oil heat exchanger represent a relatively small proportion of the heat source output (less than 20% of total heat output), and are re-combined with the combustion/process gases used in the drying process prior to entering a dry electrostatic precipitator before exhausting to the atmosphere.

GP urges EPA to:

a. **Remove the two units identified in the comments** (VAGeorgiaPacificBrooknealGladys and WVGPMtHopeOSB) from the Boiler MACT emissions source database.

Response: The EPA agrees that the specified combustion units are subject to 40 CFR Part 63, Subpart DDDD. The units have been removed from the major source inventory of industrial, commercial, and institutional boilers and process heaters.

Commenter Name: Sarah E. Amick

Commenter Affiliation: National Council for Air and Stream Improvement, Inc. (NCASI)

Document Control Number: EPA-HQ-OAR-2002-0058-3505-A1

Comment Excerpt Number: 22

Comment: The GATempleInlandThomson BW B-001 boiler had the lowest Method 10 CO test result for boilers in the biomass suspension burner subcategory. Although Version 7.0 of the emissions database had three Method 10 tests for this unit, there is a note regarding the 12/7/04 test:

“This is not actually a Method 10 test but an average CEMS reading, not appropriate to use this test to assess variability and CEMS average is much larger than test average; do not use for baselines or floors.”

The company has submitted the 12/7/04 compliance test report (not previously submitted to EPA) that shows Method 10 procedures were followed. The company has also submitted a 2010 test report not previously provided to EPA.

Using EPA’s UPL calculation methodology for all Method 10 test runs results in a 99% UPL of 11,300 ppm at 3% O₂ and a 99.9% UPL of 13,400 ppm at 3% O₂. EPA should use all available data for this unit to set the final new and existing source CO limits for this subcategory.

Response: The EPA has reviewed the provided test report and agrees with the commenter's assertion that the data follows the appropriate Method 10 procedures and guidelines. The EPA ICR Databases have been updated accordingly, and the December, 2004, compliance test data will be factored into future MACT floor analyses.

Commenter Affiliation: American Forest & Paper Association (AF&PA) et al.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 59

Comment: Some of our members have solid fuel units that have been misclassified, either by fuel type or design subcategory, or the operation is closed. The individual member companies are submitting comments to EPA to identify these mis-classifications and other circumstances. EPA should also consider the final NHSM rule when determining which units that are currently in the CISWI database need to be moved to the Boiler MACT database. We believe many more materials are fuels (and not waste) than EPA has initially determined. These changes will affect not only floor setting but also cost and emissions impacts estimates.

Response: The final inventory of major source industrial, commercial, and institutional boilers and process heaters was developed simultaneously with the NHSM and CISWI standards. Sources determined to be combusting non-hazardous materials that are solid waste were removed from the major source industrial, commercial, and institutional boiler and process heater inventory. The methodology used to develop the inventory of major source industrial, commercial, and institutional boilers and process heaters is described in the January, 2011 memorandum from ERG to EPA entitled, "Development of Baseline Emission Factors for Boilers and Process

Heaters and Commercial, Industrial, and Institutional Facilities." Comments on fuels that shall (or shall not) be classified as solid waste pertain to the Identification of Non-Hazardous Materials That Are Solid Waste rulemaking and are out of scope for this boiler rulemaking.

Document Control Number: EPA-HQ-OAR-2002-0058-3522-A1

Comment Excerpt Number: 7

Comment: The PM test data for the Foster Wheeler boiler at the Twin Falls facility was not a permit compliance test requirement. As a result, it's important to recognize that this test was not approved by the state agency including all appropriate *QA/QC* procedures. It is recommended that only performance test quality data be utilized when developing Boiler MACT emission standards.

Response: The EPA reviewed the test report for the specified emissions testing conducted by the facility and notes that the test passed the basic *QA/QC* procedures. The EPA does not recognize any technical reason for dismissing the results of tests not conducted for compliance purposes if basic *QA/QC* procedures are conducted.

Commenter Name: Stephen E. Woock

Commenter Affiliation: Weyerhaeuser Company

Document Control Number: EPA-HQ-OAR-2002-0058-3523-A1

Comment Excerpt Number: 19

Comment: EPA lists this unit (SN-45) at the Weyerhaeuser Dierks mill as a top performer for both CO and PM in the *Dutch ovens/pile burners designed to burn biomass/bio-based solid* subcategory. We believe this unit is a *Fuel Cell* and should be listed in that subcategory.

In the re-proposed rule EPA has the following three definitions:

Dutch oven means a unit having a refractory-walled cell connected to a conventional boiler setting. Fuel materials are introduced through an opening in the roof of the dutch oven and burn in a pile on its floor. Fluidized bed boilers are not part of the dutch oven design category.

Pile burner means a boiler design incorporating a design where the anticipated biomass fuel has a high relative moisture content. Grates serve to support the fuel, and underfire air flowing up through the grates provides oxygen for combustion, cools the grates, promotes turbulence in the fuel bed, and fires the fuel. The most common form of pile burning is the dutch oven.

Fuel cell means a boiler type in which the fuel is dropped onto suspended fixed grates and is fired in a pile. The refractory-lined fuel cell uses combustion air preheating and positioning of secondary and tertiary air injection ports to improve boiler efficiency. Fluidized bed, dutch oven, pile burner, hybrid suspension grate, and suspension burners are not part of the fuel cell subcategory. The Dierks SN-45 combustion unit is a 4-cell unit with secondary and tertiary air injection points. Combustion air is preheated. These are key features of a Fuel Cell in the re-proposal definition.

The Dierks SN-45 combustion unit is a 4-cell unit with secondary and tertiary air injection points. Combustion air is preheated. These are key features of a Fuel Cell in the re-proposal definition.

Response: The EPA ICR Databases have been updated to reflect that the specified combustion unit should be classified as a Fuel Cell designed to combust biomass/bio-based solid fuels rather than a Dutch Oven/Pile Burner.

Commenter Name: Bruce A. Steiner

Commenter Affiliation: American Coke and Coal Chemical Institute (ACCCI)

Document Control Number: EPA-HQ-OAR-2002-0058-3547-A2

Comment Excerpt Number: 9

Comment: EPA's current database is insufficient to understand emissions from coke oven gas-fired sources. Of the three units identified in the EPA database as coke oven gasfired, two have been confirmed as burning petroleum coke, a solid fuel, and not coke oven gas. These data must be excluded from any gaseous fuel analysis. The only remaining emissions data in the EPA dataset for coke oven gas-fired units comes from a source test snapshot of a byproduct coke plant in West Virginia that uses a desulfurization system. This limited data from a single source cannot adequately represent the variability inherent in the coke oven gas-fired sources identified by EPA within the Gas 2 subcategory. However, the data can, and do, indicate significant differences between coke oven gas emissions and other Gas 2 process gases.²⁷

[Footnote]

(27) For a discussion of these differences, we direct you to the comments of the American Petroleum Institute and the National Petrochemical Refiners Association, which reveal significant differences in the emission characteristics among the Gas-2 fuels.

Response: Since the two units burning petroleum coke were not specified, no changes were made to the EPA ICR Databases.

Commenter Name: Christopher Coleman
Commenter Affiliation: HOVENSA LLC. , Hess Corporation
Document Control Number: EPA-HQ-OAR-2002-0058-3673-A2
Comment Excerpt Number: 1

Comment: Until very recently, HOVENSA L.L.C. ("HOVENSA") operated a crude oil petroleum refinery on the island of St. Croix, United States Virgin Islands (USVI), a territory of the United States. Subsidiaries of Hess Corporation and Petroleos de Venezuela each own 50% interests in the facility. The refinery has a permitted crude oil refining capacity of 525 thousand barrels of oil per day (BOPD) but had reduced that capacity to approximately 350 BOPD in April 2011 and shut down the remaining capacity in February, 2012. The facility provided petroleum products to the eastern seaboard of the United States, and accounted for a substantial percentage of the transportation and heating fuels supplied to the entire region, particularly for the Caribbean, Florida and the Mid-Atlantic and New England.

Response: The EPA ICR Databases have been updated to reflect that the specified facility is permanently shut down.

Commenter Name: Douglas Emerson et al.
Commenter Affiliation: American Crystal Sugar Company et al.
Document Control Number: EPA-HQ-OAR-2002-0058-3675-A2
Comment Excerpt Number: 4

Comment: In addition to the exclusion of certain data, it was also noted that errors were present in the data included in the 2008 survey database for those boilers that were included. Specifically, under Appendix B-6e: Unit Rankings for Filterable PM from Stoker Coal/Solid Fossil Fuel Units (Recommended Option), information presented for MNAmericanCrystalCrockston Boiler 1 indicates three (3) boiler tests and a final emission rate of 0.001733 lb/MMBtu, which results in a Number 4 overall ranking for this unit and placing it in the Top 12 Percent. A review of the Emission Test Spreadsheet submitted to the EPA in EPA Docket Center (EPA/DC) October of 2008 under provisions of Section 114 of the Clean Air Act indicate only one test was performed for Boiler 1 and the submitted emission rate was 0.0037 lb/MMBtu, which would result in a ranking of approximately Number 15.

Whether the differences between reported data and what appears in the 2008 survey database is a result of errors and omissions, or there was some quality control or statistical evaluation to review data entries, the process must be transparent and reviewed by stakeholders of the proposed rule. Any statistical evaluation used to exclude certain data is of vital importance with regard to transparency due to the variable operation of industrial boilers.

Response: Due to an error in the reported combustor ID attributed to each of the three reported particulate matter tests, all of the data were being attributed to Boiler #1. After a review of the reported emissions testing data, the EPA agrees that only one test was conducted on Boiler #1. The emissions data reported from a test conducted on 11/2/2005 have been attributed to Boiler #2. The emissions data reported from a test conducted on 11/3/2005 have been attributed to Boiler #3.

Comment: An example of a questionable categorization is CraftMaster's (PACraftmaster) No3 Boiler that fires biomass through a combination of Air-swept Stokers firing wet biomass (20.7% of heat input in 2011), Suspension Burners firing dry biomass (60.7%), and Natural Gas (18.6%). Suspension Burners used by CraftMaster are similar to pulverized coal burners. (Historically the fraction of annual heat input from the suspension burners has been higher but was down recently because of lower process steam demand due to the severely depressed market conditions in the building products industry.) Per the "CO CEMS MACT Floor Analysis (November, 2011),"USEPA has classified the No3 Boiler in the "Stoker/ Sloped Gate/ Other" combustor design subcategory firing wet biomass based on the hierarchy. However, the air-swept stokers provided only about 1/5 of the heat input in 2011. The primary firing method in 2011 was

the suspension burners with 3/5 of the heat input. Then under the hierarchy approach the primary firing method employed is not considered by USEPA in establishing what subcategory a unit is in. We believe the No3 Boiler would be more accurately classified in the "Suspension Burner" biomass subcategory for compliance purposes. Also we believe the No3 Boiler CO CEMS data should not be considered in the CO CEMS MACT Floor for the wet biomass "Stoker/ Sloped Gate/ Other" combustor design subcategory. Most of the heat input was from the suspension burners and no CO CEMS data was generated while the unit was fired on $\geq 90\%$ stoker firing.

Response: The No. 3 Boiler at the facility has been reclassified as a Suspension Burner in the EPA ICR Databases.

9C. QA of Test reports

Commenter Name: Vickie Woods

Commenter Affiliation: Division of Air Quality, North Carolina Department of Environment and Natural Resources (NCDENR)

Document Control Number: EPA-HQ-OAR-2002-0058-3663-A2

Comment Excerpt Number: 15

Comment: QA. EPA performed a Data Quality Review of Best Performers for PM, Hg, HCl, CO, and Dioxin/Furan Emissions for the MACT database.

Given its fundamental importance, several NC DAQ staff are assigned to observe emission tests to ensure protocols are followed and review the ensuing reports to verify data quality. Likewise, it is worthwhile for EPA to collect copies of all of the emission test reports for the best performing units in order to perform additional quality assurance. It is not surprising this level of review resulted in multiple changes to the emission data set, invalidation of some emission tests, improved the quality of the industry provided data, and enhanced the confidence of the responsible agency on their official determinations.

Response: The EPA thanks the commenter for their support.

9Z. Other

Commenter Name: Vickie Woods

Document Control Number: EPA-HQ-OAR-2002-0058-3663-A2

Comment Excerpt Number: 14

Comment: New emission data. EPA received additional data to incorporate into MACT database, including 36 Hg test runs, 168 PM test runs, 24 dioxin/furan test runs, 133 CO test runs, 63 HC1 test runs, and 22 TSM test runs.

NC DAQ supports the use of additional emission data, fuel analyses, CO CEMS data, and corrections to data and to descriptions of combustion units for incorporation into the MACT database.

Response: The EPA thanks the commenter for their support.

Commenter Name: Lorraine Gershman

Commenter Affiliation: American Chemistry Council (ACC)

Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1

Comment Excerpt Number: 24

Comment: In addition, fuel variability data should be collected for all units setting new source floors and factored into the calculated emission limits. Industrial boilers operate over a variety of conditions and fire a variety of fuels, so adequate consideration of variability is important in setting achievable emission limits.

Response: Fuel variability was factored into the calculated MACT floor emission limits for new sources when available data warranted it. The mercury, HCl, and TSM floors for liquid units and TSM for coal units incorporates fuel analysis variability.

Comment Excerpt Number: 2

Comment: After review of the "Survey Database containing Results of the 2008 Questionnaire for Boilers, Process Heaters, & Other Combustion Units (ICR No. 2286.01) (version 3)" posted on the EPA website at <http://www.epa.gov/ttn/atw/boiler/boilerpg.html>, it has come to our attention that there is a significant amount of error in the small population of data reviewed by us. This has far reaching and serious ramifications considering the conclusions that can be drawn from the review. If a small sample population of reviewed sources reflects a large amount of error, it can only be representatively assumed that a larger sample population would also contain a high degree of error. Considering these parallels, especially in light of the uniform data collection procedures used by the EPA to collect and process the initial data, there is a possibility of serious erroneous conclusions and subsequent proposed emission limitations in the proposed rule.

The sample population reviewed includes data submitted by three sugar beet processing companies, which include American Crystal Sugar Company, Michigan Sugar Company and MinnDak Farmers Cooperative.

Response: EPA has made substantial revisions to the database since the June, 2010 proposed rule. These revisions have been based on specific corrections identified and submitted by facilities, corrections based on internal review of emissions testing reports, and additional data submissions received since the June, 2010 proposal. These substantial changes are discussed in the original and updated versions of the January 2011 memorandum from Graham Gibson, ERG, to EPA entitled "Handling and Processing of Corrections and New Data in the EPA ICR Databases".

Commenter Name: Richard D. Garber
Commenter Affiliation: Boise Inc.
Document Control Number: EPA-HQ-OAR-2002-0058-3686-A2
Comment Excerpt Number: 24

Comment: EPA should review and correct problems in the data that are being used to establish the MACT "floor" for various subcategories, including the wet biomass stoker category.

Boise understands that additional CO stack test CEM data has been provided to EPA for boilers that would make up the MACT floor since the December 23, 2011 proposed rule. We also understand that detailed AF&PA and NCASI comments have been submitted that point to various floor units that are inappropriately included in the floor for several subcategories.

Because development of the floor emission levels is a difficult and complex process, and because it is absolutely critical to Boise and others in the regulated community that the floor be established correctly for legal and technical reasons, and because the floor units should be able to achieve continuous compliance with the proposed standards at all times, we respectfully request that EPA carefully consider the detailed comments submitted by NCASI and AF&PA on this issue.

Response: For response to issues with the EPA ICR Databases containing problematic or erroneous data, please see DCN EPA-HQ-OAR-2002-0058-3675-A2, Excerpt No. 2. The additional CO emissions data provided by the additional commenters have been incorporated into the EPA ICR Databases.

Commenter Name: Dean C. DeLorey
Commenter Affiliation: The Amalgamated Sugar Company LLC (TASCO)
Document Control Number: EPA-HQ-OAR-2002-0058-3522-A1
Comment Excerpt Number: 6

Comment: The Amalgamated Sugar Company LLC would like to further clarify some of the emissions stack test data provided to EPA as part of the Boiler MACT Survey. The survey was originally completed in October 2008. Trace metal data (HCl, Hg, other metals) was based on very limited stack testing. This data would likely be considered as poor quality in accordance with EPA AP-42 criteria.

Response: EPA has made substantial revisions to the database since the June, 2010 proposed rule. These revisions have been based on specific corrections identified and submitted by facilities, corrections based on internal review of emissions testing reports, and additional data submissions received since the June, 2010 proposal. These substantial changes are discussed in the original and updated versions of the January 2011 memorandum from Graham Gibson, ERG, to EPA entitled "Handling and Processing of Corrections and New Data in the EPA ICR Databases".

Rule Language Corrections

10A. Rule Language: Definitions (Existing)

Commenter Name: Felix Mestey, on behalf of Donald R. Schregardus

Commenter Affiliation: Clean Air Act Services Steering Committee, Department of Defense (DoD)

Document Control Number: EPA-HQ-OAR-2002-0058-3427

Comment Excerpt Number: 8

Comment: EPA should revise the “unit designed to burn...” definitions to prevent overlap. Currently the definition of “*unit designed to burn liquid subcategory*” overlaps with “*unit designed to burn gas 2 (other) subcategory*.” For example: consider a unit that: 1) burns gas 1 fuel and liquid fuel at times other than periods of gas curtailment or supply interruption and/or burns liquid more than 48 hours for testing and/or burns liquid for other non-testing purposes; and 2) burns less than 10% liquid on an annual basis. This unit is clearly not in the “*unit designed to burn gas 1 subcategory*.” But it does meet the definitions of both a “*unit designed to burn liquid subcategory*” and a “*unit designed to burn gas 2 (other) subcategory unit*.” It meets the “*unit designed to burn liquid subcategory*” definition because it burns “any” liquid fuel and no solid fuels in combination with gaseous fuel. It meets the “*unit designed to burn gas 2 (other) subcategory unit*” definition because 1) it is not in the gas 1 subcategory, and 2) burns “any” gaseous fuels in combination with less than 10% liquid fuels as well as less than 10% coal/solid fossil fuel and less than 10% biomass. To prevent overlap and misapplication, EPA should consider revising the definition of “*unit designed to burn gas 2 (other) subcategory unit*” as follows:

Alternative 1:

Unit designed to burn gas 2 (other) subcategory includes any boiler or process heater that is not in the unit designed to burn gas 1 subcategory and burns any gaseous fuels either alone or in combination with less than 10 percent coal/solid fossil fuel, and less than 10 percent biomass/bio-based solid fuel on an annual heat input basis, and less than 10 percent no liquid fuels on an annual heat input basis with the exception of liquid fuels burned for periodic testing not to exceed a combined total of 48 hours during any calendar year, or during periods of gas curtailment or gas supply interruptions.

Alternative 2:

Unit designed to burn gas 2 (other) subcategory includes any boiler or process heater that is not in the unit designed to burn gas 1 subcategory and burns any gaseous fuels either alone or in combination with less than 10 percent coal/solid fossil fuel, less than 10 percent biomass/bio-based solid fuel, and less than 10 percent liquid fuels on an annual heat input basis any other “unit designed to burn” subcategory. [Note: or specifically list all of the other “unit designed to burn” subcategories].

Response: The EPA agrees with the commenter and has clarified the definition of unit designed to burn gas 2 (other) subcategory. It was the EPA's intent in the proposed rule to require units

firing liquid fuels in combination with gas 1 fuels that did not meet the thresholds for liquid fuel allowed in the unit designed to burn gas 1 subcategory to be captured in the unit designed to burn liquid subcategory.

For clarification, the unit designed to burn gas 2 (other) subcategory definition has been revised to reflect that the units in this subcategory do not burn liquid fuels, with the exception of liquid fuels burned under the testing, curtailment, and gas supply emergency thresholds. The definition has been revised to read: "Unit designed to burn gas 2 (other) subcategory includes any boiler or process heater that is not in the unit designed to burn gas 1 subcategory and burns any gaseous fuels either alone or in combination with less than 10 percent coal/solid fossil fuel, and less than 10 percent biomass/bio-based solid fuel on an annual heat input basis, and no liquid fuels. Gaseous fuel boilers and process heaters that burn liquid fuel for periodic testing of liquid fuel, maintenance, or operator training, not to exceed a combined total of 48 hours during any calendar year, are included in this definition. Gaseous fuel boilers and process heaters that burn liquid fuel during periods of gas curtailment or gas supply emergencies of any duration are also included in this definition." This definition is consistent with the unit designed to burn gas 1 and unit designed to burn liquid subcategories.

Document Control Number: EPA-HQ-OAR-2002-0058-3427

Comment Excerpt Number: 10

Comment: The definition of energy assessment will be different in the major and area source rules if the terms “boilers” and “process heaters” are used and if the rule table references are included. The following shows how the definition in the major source rule should be changed for consistency. This also reflects our conclusion that it is not necessary to limit the term to a table in the rule because the term is used throughout the rule.

Energy assessment means the following ~~only as this term is used in Table 3 to for the~~ emission units covered by this subpart.:

(1) ~~The~~ Energy assessment for facilities with affected boilers and process heaters using less than 0.3 trillion Btu (TBtu) per year heat input will be 8 technical labor hours in length maximum, but may be longer at the discretion of the owner or operator of the affected source. The boiler system(s) and any on-site energy use system(s) accounting for at least 50 percent of the energy output will be evaluated to identify energy savings opportunities, within the limit of performing an 8-hour energy assessment.

(2) ~~The~~ Energy assessment for facilities with affected boilers and process heaters using 0.3 to 1.0 ~~trillion Btu per~~ TBtu/year will be 24 technical labor hours in length maximum, but may be longer at the discretion of the owner or operator of the affected source. The boiler system(s) and any on-site energy use system(s) accounting for at least 33 percent of the energy output will be evaluated to identify energy savings opportunities, within the limit of performing a 24-hour energy assessment.

(3) ~~It~~The ~~E~~energy assessment for facilities with affected boilers and process heaters using greater than 1.0 ~~trillion Btu per~~ TBtu/year, the boiler system(s) and any on-site energy use system(s) accounting for at least 20 percent of the energy output will be evaluated to identify energy savings opportunities.

Response: EPA appreciates the commenter's input. The definition of Energy assessment has been revised accordingly for consistency between the major and area source rules.

Comment Excerpt Number: 15

Comment: Clarify the Definition of Metal Process Unit.

Metal process furnaces are a subset of "*Process Heaters*" covered by the rule. However, the current definition for *Metal process furnace* could be misinterpreted more broadly to also include furnaces that transfer heat directly to process material and are potentially regulated under another NESHAP. Alcoa- Warrick thus requests that EPA clarify the existing definition as follows:

Metal process furnaces are a subset of process heaters that includes natural gas-fired annealing furnaces, preheat furnaces, reheat furnaces, aging furnaces, heat treat furnaces, and homogenizing furnaces.

Response: EPA appreciates the commenter's input. The definition of Metal Process furnaces has been revised accordingly.

Comment Excerpt Number: 3

Comment: EPA again changed the liquid fuel definition in the December 23, 2011 reconsidered NESHAP Subpart JJJJJ to include the addition of vegetable oil.

Liquid fuel includes, but is not limited to, distillate oil, residual oil, any form of liquid fuel derived from petroleum, on-spec used oil, liquid biofuels, biodiesel, and vegetable oil.

As noted above, the addition of liquid biofuels was included in NESHAP Subpart JJJJJ liquid fuel definition previous to this reconsideration, per the comment submitted by Darling International Inc. (NRA member).

The December 23, 2011 reconsidered NESHAP Subpart DDDDD included the addition of subcategories for light liquid and heavy liquid fuels in §63.7575.

Light liquid includes distillate oil, biodiesel or vegetable oil.

However, EPA clearly took an "easy way" out by throwing processed fats in with the liquid fuel definition in NESHAP Subpart JJJJJ and assumed intended inclusion of light liquid definition that was unexpected and unintended by the NRA, without fully vetting the impact on the liquid fuel regulations, or the impact on processed fat-fired units. EPA has acknowledged acting in haste to finalize these regulations by the Court-imposed deadline.⁶

The proposed definition of "liquid fuel" is fundamentally similar in both NESHAP Subpart JJJJJ (75 FR 31931) and NESHAP Subpart DDDDD (75 FR 32064), specifically delineating "distillate oil, residual oil, on-spec used oil, biodiesel, and vegetable oil" in each definition. EPA has not indicated that the subsequent inclusion of "liquid biofuels" to the definition of "liquid fuel" was intentional for NESHAP Subpart JJJJJ only. For the purposes of this comments letter, the NRA assumes that EPA intended for liquid biofuels to also be considered a "light liquid" as defined under §63.7575 in the reconsidered rule.

[Footnote 6: Court ordered EPA to issue the final rule by February 21, 2011.]

Response: The definition of "Liquid fuel" as far back as the 2004 Boiler MACT (since vacated) has contained the phrase ""includes, but is not limited to," The definitions generally listed the the most prevalent ones. Based on comments the definition has been revised to add certain liquid fuel to clarify some applicability or implementation issue. In any case, the source category has always included, but was not limited to, boilers fired by mixed or other fuels.

Comment Excerpt Number: 1

Comment: There are inconsistencies between the Area Source Rule, Major Source Rule, and CISWI Rule definitions. The EPA is proposing several definitions in the area source boiler rule, major source boiler rule (both under consideration separately), and CISWI rule that are designed to clarify the applicable fuels under the appropriate section of the Clean Air Act (CAA) regulating a combustion device (i.e., Section 112 or 129). NESCAUM notes that there are inconsistencies between the area source rule, major source rule, and CISWI rule, and requests that the EPA harmonize the definitions between the rules so there is no ambiguity as to which rule a source is subject. For example, the following definitions for liquid fuel are inconsistent between the three rules:

1. In the proposed area source boiler rule, liquid fuel is defined as follows:

Liquid fuel includes, but is not limited to, distillate oil, residual oil, any form of liquid fuel derived from petroleum, on-spec used oil, liquid biofuels, biodiesel, and vegetable oil.

2. In the proposed major source boiler rule, liquid fuel is defined as follows:

Liquid fuel includes, but is not limited to, distillate oil, residual oil, onspec used oil, biodiesel and vegetable oil.

3. Under the CISWI and NHSM rules, liquid fuel is classified under “traditional fuel” as follows (excerpted as noted):

Traditional fuels means materials that are produced as fuels and are unused products that have not been discarded and therefore, are not solid wastes, including: (1) ... fossil fuels (e.g., coal, oil and natural gas)...; and (2) alternative fuels developed from virgin materials that can now be used as fuel products, including used oil which meets the specifications outlined in 40 CFR 279.11....

NESCAUM understands that all of these definitions are intended to encompass all non-waste liquid fuels that the EPA has deemed to be traditional fuels when burned in a combustion device and should be regulated under Section 112. NESCAUM recommends that the definitions be harmonized to all say the same thing (i.e., reference 40 CFR 279.11 for defining used oil) to the extent possible and list the same examples (i.e., list liquid biofuels and vegetable oil in all three definitions).

Response: See the response to comment EPA-HQ-OAR-2002-0058-3476-A1, excerpt 3 for definition of liquid fuels in the major source rule. Definition of traditional fuels in the CISWI and NHSM rules are outside the scope of this comment response document. To the extent that this comment was submitted to the dockets for CISWI and/or NHSM it will be addressed in those response to comment documents.

Comment: The definition of "annual heat input" is unclear because compliance demonstrations are an ongoing requirement. The definition should be revised as follows:

Annual heat input means the heat input for the 12 months preceding the **initial** compliance demonstration.

If it was intended that annual heat input be determined every year, the definition should be on a calendar basis and compliance time provisions need to be added where new requirements are triggered by changes in the annual heat input value (i.e., a BPH changes subcategory).

Response: We disagree that the definition be revised to include "initial" because that would imply "once in always in" that subcategory. The subcategory are based on the annual heat input prior to the compliance demonstration.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 135

Comment: Since there is no logical reason to single out specific subtypes of water heaters for applicability within the universe of water heaters that are not part of the source category, we recommend that EPA revise the water heater definition to exclude the capacity limitation. Including water heaters within the applicability of the rule would also impose very high regulatory compliance costs on users and regulatory authorities for units with insignificant emissions.

EPA attempted to address this concern by adding the following sentence to the definition in the proposed rule: "Hot water boilers (i.e., not generating steam) combusting gaseous or liquid fuel with a heat input capacity of less than 1.6 million Btu per hour are included in this definition." This addition has only created additional confusion as to what types of units meet this definition. Therefore, we recommend EPA revise the definition of hot water heater to read as follows:

Hot water heater means a closed vessel in which water is heated by combustion of gaseous or liquid fuel and is withdrawn for use external to the vessel at pressures not exceeding 160 pounds per square inch gauge (psig), including the apparatus by which the heat is generated and all controls and devices necessary to prevent water temperatures from exceeding 250°F (121°C) at or near the heater outlet.

Alternatively, EPA should reword the definition to clarify that units that are EITHER less than 120 gallons OR less than 1.6 MMBtu/hr meet the definition of a water heater, as follows:

Hot water heater means a closed vessel with a capacity of no more than 120 U.S. gallons or a heat input capacity of no more than 1.6 million Btu per hour in which water is heated by combustion of gaseous or liquid fuel and is withdrawn for use external to the vessel at pressures not exceeding 160 psig, including the apparatus by which the heat is generated and all controls and devices necessary to prevent water temperatures from exceeding 210 degrees Fahrenheit (99 degrees Celsius). Hot water heater also means a tankless unit that provides on demand hot water.

Response: Based on various comments, the definition of "Hot water heater" has been revised to read:

Hot water heater means a closed vessel with a capacity of no more than 120 U.S. gallons in which water is heated by combustion of gaseous, liquid, or biomass/bio-based solid fuel and is withdrawn for use external to the vessel. Hot water boilers (i.e., not generating steam) combusting gaseous, liquid, or biomass fuel with a heat input capacity of less than 1.6 million Btu per hour are included in this definition. The 120 U.S. gallon capacity threshold to be considered a hot water heater is independent of the 1.6 MMBtu/hr heat input capacity threshold for hot water boilers. Hot water heater also means a tankless unit that provides on demand hot water.

Commenter Name: Arthur N. Marin

Commenter Affiliation: Northeast States for Coordinated Air Use Management (NESCAUM)

Document Control Number: EPA-HQ-OAR-2002-0058-3506-A1

Comment Excerpt Number: 25

Comment: In the proposed definition of hot water heaters discussed earlier, the EPA lists “gaseous or liquid fuel” but not biomass. NESCAUM suggests that the definition also include biomass-fueled units. Without that exclusion, some very small units in the Northeast will fail to be exempted from the rule despite their negligible impact on HAP emissions. NESCAUM recommends the following revision to the definition:

Hot water heater means a closed vessel with a capacity of no more than 120 U.S. gallons in which water is heated by combustion of gaseous, liquid, or biomass fuel and hot water is withdrawn for use external to the vessel. Hot water boilers (i.e., not generating steam) combusting gaseous, liquid, or biomass fuel with a heat input capacity of less than 1.6 million Btu per hour are included in this definition.

Response: EPA appreciates the commenter's input. The definition of "Hot water heater" has been revised accordingly to include biomass.

Comment Excerpt Number: 134

Comment: We agree that hot water heaters should be exempted from the rule as proposed (63.7491).

We agree that there should be some objective standard to distinguish hot water heaters from steam generators. An easily verifiable and rational method for distinction is on a mechanical design basis. Water heaters are intended generally for personal and domestic use, as well as for local heating purposes, and not for industrial purposes. All types of industrial, commercial, and institutional facilities incorporate individual water heaters throughout the facility, particularly in separated locations where use of a common steam or heating system is not economically justified for the low energy input required. By their application, water heaters operate on a very cyclic and inconsistent basis, with typically very low resultant HAP emissions. Imposing a limitation on water volume capacity is arbitrary and neuters the point that these units are not listed in the source category regardless of size.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3521-A1, excerpt 135.

Commenter Name: Tangela Niemann

Commenter Affiliation: Texas Commission on Environmental Quality (TCEQ)

Document Control Number: EPA-HQ-OAR-2002-0058-3594-A3

Comment Excerpt Number: 13

Comment: The definition for *hot water heater* in §63.7575 includes provisions regarding maximum pressure and temperature conditions for a unit to qualify as a hot water heater; however, the EPA has proposed to remove the same provisions from the definition of a hot water

heater in §63.11237 for 40 CFR 63 Subpart JJJJJ (76 FR 80547). The EPA has not provided any rationale why a more specific definition is needed for major sources under 40 CFR 63 Subpart DDDDD than for area sources under 40 CFR 63 Subpart JJJJJ. The definition of a *hot water heater* should be consistent between the two rules. However, the TCEQ recommends keeping the provision in §63.7575 that includes tankless water heaters in the definition of *hot water heater* in 40 CFR 63, Subpart DDDDD. In separate comments submitted concurrently on the EPA's proposed revisions to 40 CFR 63 Subpart JJJJJ, the TCEQ suggested that tankless water heaters should be included in the proposed revised definition of *hot water heater* in §63.11237. Additionally, the EPA needs to clarify whether the requirement that hot water boilers must be less than 1.6 MMBtu/hr heat input capacity threshold to qualify as a hot water heater is considered independent of the 120 gallon capacity threshold.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3521-A1, excerpt 135. Comments and edits related to the definition of hot water heaters in the area source rule will be addressed in that separate rulemaking docket.

Commenter Name: Lorraine Gershman

Commenter Affiliation: American Chemistry Council (ACC)

Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1

Comment Excerpt Number: 151

Comment: THE HOT WATER HEATER DEFINITION SHOULD BE REVISED

ACC agrees that hot water heaters should be exempted from this rule as indicated in § 63.7491. However, EPA proposes to define hot water heater as follows:

ACC concurs that there should be some objective standard to distinguish hot water heaters from steam generators. An easily verifiable, and rational method, for distinction is on a mechanical design basis. The ASME Code, Section IV- Rules for Construction of Heating Boilers, is applicable to hot water heating boilers and is, in our opinion, the standard that should be used to define a hot water heater consistent with industry standards. The ASME Code, Section IV is applicable to: —(a) steam boilers for operation at pressures not exceeding 15 psi; (b) hot water heating boilers and hot water supply boilers for operating at pressures not exceeding 160 psi and/or temperatures not exceeding 250°F, at or near the boiler outlet."

Response: See the response to comment EPA-HQ-OAR-2002-0058-3521-A1, excerpt 135.

Commenter Name: Lorraine Gershman

Commenter Affiliation: American Chemistry Council (ACC)

Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1

Comment Excerpt Number: 152

Comment: ACC does support the inclusion of the heat input capacity limitation and inclusion of tankless water heaters in the definition, and recommends that EPA revise the definition of hot water heater to read as follows:

Hot water heater means a closed vessel in which water is heated by combustion of gaseous or liquid fuel and is withdrawn for use external to the vessel at pressures not exceeding 160 pounds per square inch gauge (psig), including the apparatus by which the heat is generated and all controls and devices necessary to prevent water temperatures from exceeding 250°F (121°C) at or near the heater outlet. Hot water boilers (i.e., not generating steam) combusting gaseous or liquid fuel with a heat input capacity of less than 1.6 million Btu per hour are included in this definition. Hot water heater also means a tankless unit that provides on demand hot water.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3521-A1, excerpt 135.

Commenter Name: Lorraine Gershman

Commenter Affiliation: American Chemistry Council (ACC)

Document Control Number: EPA-HQ-OAR-2002-0058-3510-A1

Comment Excerpt Number: 153

Comment: Alternatively, if EPA feels size thresholds are warranted, ACC suggests reorganizing the proposed definition for clarity. EPA should reword the definition of hot water heater to make it clear that a hot water heater is "a closed vessel with a capacity of no more than 120 U.S. gallons or with heat input no more than 1.6 million Btu/hr and is withdrawn for use external to the vessel at pressures not exceeding 160 psig, including the apparatus by which the heat is generated and all controls and devices necessary to prevent water temperatures from exceeding 210 degrees Fahrenheit (99 degrees Celsius). Hot water heater also means a tankless unit that provides on demand hot water."

Response: See the response to comment EPA-HQ-OAR-2002-0058-3521-A1, excerpt 135.

Commenter Name: Russell A. Wozniak

Commenter Affiliation: The Dow Chemical Company

Document Control Number: EPA-HQ-OAR-2002-0058-3449-A1

Comment Excerpt Number: 34

Comment: Dow supports EPA's proposed expanded definition of the term hot water heater. Specifically, Dow supports EPA's proposal to include hot water boilers (i.e., not generating steam) combusting gas or liquid fuel with a heat input capacity of less than 1.6 million Btu per hour. These are insignificant sources that should be treated as a hot water heater for the purpose of this rule.

Response: The EPA thanks the commenter for their support.

Commenter Name: David A. Buff, Golder Associates Inc.

Commenter Affiliation: Florida Sugar Industry (FSI)

Document Control Number: EPA-HQ-OAR-2002-0058-3504-A1

Comment Excerpt Number: 9

Comment: The FSI agrees with the proposed change to the definition of hybrid suspension grate boilers, which now includes the following sentence: "The fuel combusted in these units exceed[s] a moisture content of 40 percent on an as-fired basis." Section 63.7575; 76 F.R.80652.

This value is appropriate because the moisture content of bagasse typically ranges from approximately 48 percent to 55 percent. However, hybrid suspension grate boilers also fire other fuels, such as No. 6 fuel oil, as supplemental fuel or for startup, shutdown and malfunction. Accordingly, this definition should be revised to read: "The *biomass* fuel combusted in these units exceeds a moisture content of 40 percent on an as-fired basis."

Response: The EPA agrees with the commenter. The definition of hybrid suspension grate boilers has been revised accordingly.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 130

Comment: As quoted immediately above, the Gas 2 subcategory is defined to permit a unit to burn up to "10 percent liquid fuels on an annual heat input basis," and we have recommended that EPA make a conforming change to the definition of the Gas 1 subcategory. EPA has proposed to divide the "unit designed to burn liquid" subcategory into two sub-subcategories, but it has failed to make an important and necessary technical correction to the definition of that subcategory. As SOCMA pointed out in its comments on the June 2010 proposed rule,⁵⁷ the "unit designed to burn liquid subcategory" is defined to include "any boiler or process heater that burns *any* liquid . . ." § 63.7575 (emphasis added). The definition goes on to allow gaseous fuel boilers to burn liquids for periodic testing, maintenance and operator training (for up to 48 hours) and for periods of gas curtailment or supply emergencies, *id.*, but it does not contain a generic exemption for gaseous fuel boilers that burn less than 10% liquids on an annual heat input basis. As a result, a Gas 2 unit that burned 5% liquid fuels would be included in *both* the Gas 2 and liquid subcategories. A Gas 1 unit redefined as we propose would face the same problem. Accordingly, as EPA makes other technical corrections to the current rule, it should also revise the definition of the unit designed to burn liquid subcategory to provide that it "includes any boiler or process heater that burns more than 10 percent liquid fuel . . ." ⁵⁸

[Footnote 57: See SOCMA comments (EPA-HQ-OAR-2002-058-2926), at 3.]

[Footnote 58: With that change, the definition might no longer need the exemption for testing, maintenance and training. It probably should maintain the exemption for curtailment and supply emergencies, however.]

Response: See the response to comment EPA-HQ-OAR-2002-0058-3427, excerpt 8.

Commenter Name: Felix Mestey, on behalf of Donald R. Schregardus

Commenter Affiliation: Clean Air Act Services Steering Committee, Department of Defense (DoD)

Document Control Number: EPA-HQ-OAR-2002-0058-3427

Comment Excerpt Number: 9

Comment: Several definitions in the area source rule differ from the definitions in the major source rule. Some differences are appropriate due to the differences in the scope of the rules and the subcategories used. However, in many cases the definitions could and should be identical.

Fuel type means each category of fuels that share a common name or classification. Examples include, but are not limited to, bituminous coal, sub-bituminous coal, lignite, anthracite, biomass, distillate oil, residual oil. Individual fuel types received from different suppliers are not considered new fuel types.

Response: The EPA appreciates the commenter's input. Definitions, as appropriate, have been revised accordingly for consistency between the major and area source rules.

Commenter Name: Felix Mestey, on behalf of Donald R. Schregardus

Commenter Affiliation: Clean Air Act Services Steering Committee, Department of Defense (DoD)

Document Control Number: EPA-HQ-OAR-2002-0058-3427

Comment Excerpt Number: 11

Comment: The area source rule has separate definitions for commercial boiler and institutional boiler. The major source rule has a single definition for commercial/institutional boiler. It does not matter which approach is used, but these definitions could be the same in both rules. Currently the definitions in the area source rule contain more examples of commercial and institutional establishments. At a minimum, the examples should be consistent and the combined definition in the major source rule could be revised as follows. *Commercial/institutional boiler means a boiler used in commercial establishments or institutional establishments such as medical centers, nursing homes, research centers, institutions of higher education, elementary and secondary schools, libraries, religious establishments, and governmental buildings, hotels, restaurants, and laundries to provide steam and/or hot water.*

EPA should consider either a) replacing the combined definition for commercial/institutional boiler in the major source rule with the separate definitions used in the area source rule, or b) replacing the separate definitions in the area source rule with the revised version of the combined definition shown above.

Response: The EPA has revised the definition of commercial/institutional boiler for consistency with the area source rule. Revisions to the definitions of commercial boiler and institutional boiler in the area source rule are discussed in a separate response to comment document (see Docket ID. No EPA-HQ-OAR-2006-0790) for the area source rule.

Commenter Name: Felix Mestey, on behalf of Donald R. Schregardus

Commenter Affiliation: Clean Air Act Services Steering Committee, Department of Defense (DoD)

Document Control Number: EPA-HQ-OAR-2002-0058-3427

Comment Excerpt Number: 12

Comment: EPA should also change the following definitions to reflect the change to the term “periods of natural gas curtailment and gas supply emergencies” to “periods of gas curtailment and gas supply interruption.”

Unit designed to burn gas 1 subcategory includes any boiler or process heater that burns only natural gas, refinery gas, and/or other gas 1 fuels; with the exception of liquid fuels burned for periodic testing not to exceed a combined total of 48 hours during any calendar year, or during periods of gas curtailment and gas supply emergenciesinterruption.

Unit designed to burn liquid subcategory includes any boiler or process heater that burns any liquid fuel, but less than 10 percent coal/solid fossil fuel and less than 10 percent biomass/bio-based solid fuel on an annual heat input basis, either alone or in combination with gaseous fuels. Gaseous fuel boilers and process heaters that burn liquid fuel for periodic testing of liquid fuel, maintenance, or operator training, not to exceed a combined total of 48 hours during any calendar year or during periods of maintenance, operator training, or testing of liquid fuel, not to exceed a combined total of 48 hours during any calendar year are not included in this definition. Gaseous fuel boilers and process heaters that burn liquid fuel during periods of gas curtailment or gas supply emergenciesinterruption of any duration are also not included in this definition.

Response: The EPA appreciates the commenter's input. The definitions have been revised accordingly for consistency.

Commenter Name: Arthur N. Marin

Commenter Affiliation: Northeast States for Coordinated Air Use Management (NESCAUM)

Document Control Number: EPA-HQ-OAR-2002-0058-3506-A1

Comment Excerpt Number: 11

Comment: NESCAUM agrees that temporary boilers should be exempted from both the major and area source boiler rules. Subjecting these units to strict requirements beyond management practices is impractical. NESCAUM supports the establishment of a 12 month threshold, above which a unit may no longer be considered temporary. Many commercial buildings that use temporary boilers during construction, however, require more than 12 months to complete construction, and as such, NESCAUM recommends that the EPA amend the definition of temporary boilers to allow owners or operators of a facility to petition for an extension. NESCAUM believes this process is needed to allow proper flexibility within the rule so as not to require stringent controls on units that are temporary. NESCAUM specifically recommends that the second condition in the definition of a temporary boiler be changed as follows:

(2) The boiler or a replacement remains at a location for more than 12 consecutive months, unless the regulating agency approves an extension. An extension may be granted by the regulating agency upon petition by the owner or operator of a unit specifying the basis for such a request. Any temporary boiler that replaces a temporary boiler at a location and performs the same or similar function will be included in calculating the consecutive time period.

Response: The EPA appreciates the commenter's input. The definition has been revised accordingly.

Commenter Name: Matthew Todd

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 175

Comment: In the "temporary boiler" definition, paragraph (2) excludes a boiler or a replacement that "remains at a location for more than 12 consecutive months." And further specifies that "Any temporary boiler that replaces a temporary boiler at a location and performs the same or similar function will be included in calculating the consecutive time period."

The second sentence language creates a problem because there is no time period associated with the replacement. It is not unusual for a temporary boiler to be used for short periods during turnarounds that recur several years apart. Under the proposal, these boilers would not be considered temporary, because each boiler replaces the previous one and performs the same function, even though there is a multi-year gap between the occurrences. We believe that replacements that occur after a gap of at least one year should not be considered consecutive for the purposes of this definition and the language of paragraph (2) should be revised to reflect that situation.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3506-A1, excerpt 11.

Commenter Name: Shawn Good

Commenter Affiliation: Pennsylvania Chamber of Business and Industry

Document Control Number: EPA-HQ-OAR-2002-0058-3671-A2

Comment Excerpt Number: 5

Comment: EPA proposes to exempt temporary boilers, as was done in the final rule for major sources. We agree that temporary boilers should be exempted from both rules if they are to be exempted from any. However, we believe that the definition of temporary boilers should include emergency use boilers or safety related boilers. Such consideration has been provided for other MACT source categories as IC engines. Further, EPA should clarify whether "temporary" means use for start-up as well as back-up purposes.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3506-A1, excerpt 11. The term "temporary," to clarify, refers to portable/rental boilers.

Document Control Number: EPA-HQ-OAR-2002-0058-3521-A1

Comment Excerpt Number: 138

Comment: The proposed definition of "daily block average" requires that monitoring results from periods of startup and shutdown be included in the average.

"Daily block average means the arithmetic mean of all valid emission concentrations or parameter levels recorded when a unit is operating measured over the 24-hour period from 12 a.m. (midnight) to 12 a.m. (midnight)."

A startup and shutdown period exception must be added to the definition of "daily block average" since sources are exempt from meeting emission standards and opacity and operating parameter limits during these periods.

This same exemption must be added to the definition of "30-day rolling average." EPA should specify that the 30-day rolling average includes the previous 720 hours of valid operating data. Valid operating data excludes hours during startup and shutdown as well as unit down time.

Response: The EPA agrees with the commenter and has revised the definitions of daily block average and 30-day rolling average accordingly. The definition of daily block average has been clarified as follows:

Daily block average means the arithmetic mean of all valid emission concentrations or parameter levels recorded when a unit is operating measured over the 24-hour period from 12 am (midnight) to 12 am (midnight), except for periods of startup and shutdown or downtime.

The definition of 30-day rolling average has been clarified as follows:

30-day rolling average means the arithmetic mean of the previous 720 hours of valid operating data. Valid data excludes hours during startup and shutdown, data collected during periods when the monitoring system is out of control as specified in your site-specific monitoring plan, while conducting repairs associated with periods when the monitoring system is out of control, or while conducting required monitoring system quality assurance or quality control activities, and periods when this unit is not operating. The 720 hours should be consecutive, but not necessarily continuous if operations were intermittent.

Comment Excerpt Number: 18

Comment: The proposed rule describes TSM as the combination of the following metallic hazardous air pollutants: As, Be, Cd, Cr, Pb, Mn, Ni, and Se. However, combination is not defined. Please clarify the definition of TSM including the term "combination".

Response: It is the EPA's intent that total selected metals (TSM) includes the aggregate of the identified individual metallic hazardous air pollutants. Therefore, we have revised the definition of TSM as follows:

Total selected metals means the sum of the following metallic hazardous air pollutants: arsenic, beryllium, cadmium, chromium, lead, manganese, nickel and selenium.

Document Control Number: EPA-HQ-OAR-2002-0058-3668-A2

Comment Excerpt Number: 14

Comment: In §63.7575, "Dry Scrubber" is defined to include sorbent used in fluidized bed boilers. Elsewhere in the proposed rule, EPA uses the terms "sorbent injection." Purdue asks EPA to confirm that the use of in furnace limestone in CFB boilers is indeed "sorbent injection" as well as a "dry scrubber" in the proposed Boiler MACT.

Response: The EPA has revised the definition of Minimum sorbent injection rate to clarify that the use of in furnace limestone in a circulating fluidized bed boiler would be considered "sorbent injection" for the purposes of the final rule. See the response to comment EPA-HQ-OAR-2002-0058-3674-A, excerpt 11 for more information.

Commenter Name: Matthew Todd

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 38

Comment: The proposed definition of "unit designed to burn gas 1 subcategory" provides for a liquids exception for "periodic testing not to exceed a combined total of 48 hours during any calendar year." However, the same exception in the "unit designed to burn liquid subcategory" is referenced and described as "Gaseous fuel boilers and process heaters that burn liquid fuel for periodic testing of liquid fuel, maintenance, or operator training, not to exceed a combined total of 48 hours during any calendar year." Because operator training and maintenance are important reasons for occasionally having to fire liquids on a BPH that primarily fires gas 1, the 48 hour exception in the gas 1 subcategory definition should be revised to match the description in the liquids subcategory definition.

The proposed "boiler" definition includes the production of hot water. The proposed "process heater" definition includes the production of hot water to be used as a process heat transfer material. Thus, units that produce hot water as a process heat transfer medium are both boilers and process heaters. The boiler definition should be revised to exclude the production of hot water for use as a process heat transfer medium.

Response: The EPA acknowledges that boilers or process heaters that fall into the unit designed to burn gas 1 subcategory may have a need to burn liquid fuels for operator training or maintenance. Therefore, the subcategory definition has been updated as follows:

Unit designed to burn gas 2 (other) subcategory includes any boiler or process heater that is not in the unit designed to burn gas 1 subcategory and burns any gaseous fuels either alone or in combination with less than 10 percent coal/solid fossil fuel, and less than 10 percent biomass/bio-based solid fuel on an annual heat input basis, and no liquid fuels. Gaseous fuel boilers and process heaters that burn liquid fuel for periodic testing of liquid fuel, maintenance, or operator training, not to exceed a combined total of 48 hours during any calendar year, are included in this definition. Gaseous fuel boilers and process heaters that burn liquid fuel during periods of gas curtailment or gas supply emergencies of any duration are also included in this definition.

This definition is consistent with other subcategory definitions under the final subpart. Additionally, the EPA agrees with the commenter that the definitions of boiler and process heater requires clarification for units producing hot water as a process heat transfer material but we disagree that the definition of boiler should be revised. The definition of process heater has been updated as follows:

Process heater means an enclosed device using controlled flame, and the unit's primary purpose is to transfer heat indirectly to a process material (liquid, gas, or solid) or to a heat transfer material (e.g., glycol or a mixture of glycol and water) for use in a process unit, instead of generating steam. Process heaters are devices in which the combustion gases do not come into direct contact with process materials. A device combusting solid waste, as defined in §241.3 of this chapter, is not a process heater unless the device is exempt from the definition of a solid waste incineration unit as provided in section 129(g)(1) of the Clean Air Act. Process heaters do not include units used for comfort heat or space heat, food preparation for on-site consumption, or autoclaves. Waste heat process heaters are excluded from this definition.

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 53

Comment: Tune-up is defined in proposed §63.7575 as "adjustments made to a boiler in accordance with procedures supplied by the manufacturer (or an approved specialist) to optimize the combustion efficiency." The term "approved specialist" is undefined. It is also unclear whose approval is required. As we discuss elsewhere, most BPH are not "manufactured" and thus there are no applicable manufacturer's procedures. Therefore most of the tune-up procedures will be developed by specialists. It would impose unreasonable burdens to require approval of this multitude of specialists, since they will be numerous, frequently changing, and there is no objective set of criteria for evaluating a person's adequacy. The "approval" requirement should be deleted from the tune-up definition.

Response: The EPA acknowledges the commenter's concerns. However, the EPA's intent in the proposed rule was to require owners and operators of units required to perform an annual tune-up to meet the requirements specified in 40 CFR 63.7540(a)(10). Therefore, the definition of tune-up has been revised to read, "Tune-up means adjustments made to a boiler or process heater in accordance with the procedures outlined in §63.7540(a)(10)."

Commenter Name: Matthew Todd

Commenter Affiliation: American Petroleum Institute (API) and American Fuel and Petrochemical Manufacturers (AFPM)

Document Control Number: EPA-HQ-OAR-2002-0058-3677-A2

Comment Excerpt Number: 54

Comment: The tune-up definition refers to boilers and not process heaters. If, as indicated elsewhere, EPA intends to apply the tune-up requirements to process heaters, that should be indicated in the definition.

Response: See the response to comment EPA-HQ-OAR-2002-0058-3677-A2, excerpt 53. By changing the definition to be based on the required procedures, the definition applies to both boilers and process heaters, as originally intended by the Agency.
