DETERMINATION OF EL-107\(^1\) AND/OR ITS SOIL METABOLITE\(^2\) IN SOIL

AM-AA-CA-3042-AC-755

PRINCIPLE

EL-107 and its soil metabolite are extracted from soil by refluxing with methanol-water. An aliquot of the extract is purified by liquid-liquid partitioning and alumina column chromatography. Detection and measurement require HPLC with UV detection. EL-107 and its metabolite are collected as separate samples from the alumina column and measured using different mobile phase solutions.

REAGENTS

1. Methanol, reagent-grade
2. Methanol/water, 80:20 (v/v)
3. Sodium chloride solution, 5-percent aqueous
4. Dichloromethane, reagent-grade
5. Sodium sulfate, anhydrous, methanol washed and dried
6. Alumina, Alcoa F-20 (deactivated with water, 4 percent)
7. Ethyl acetate, reagent-grade
8. Dichloromethane/ethyl acetate, 80:20 (v/v)
9. Dichloromethane/methanol, 99:1 (v/v), 98:2 (v/v), 97:3 (v/v)
10. HPLC mobile phase: methanol/water, 70:30 (v/v) for EL-107; methanol/water, 60:40 (v/v) for metabolite (Solvents must be HPLC quality, filtered, and degassed.)

APPARATUS

1. Sample grinding and blending equipment
2. Reflux apparatus with water-cooled condenser

\(^1\) \textit{N-[3-(1-Ethyl-1-methylpropyl)-5-oxazolyl]-2,6-dimethoxybenzamide}, Serial No. 121607

\(^2\) \textit{N-[3-(1-Hydroxy-1-methylpropyl)-5-oxazolyl]-2,6-dimethoxy-}
\textit{benzamide}, Serial No. 201469

107****/DF**75/ESDSS?/US/****/121
3. Rotary vacuum evaporator with water bath set at 40-45°C

4. Chromatographic columns, 25 cm x 14 mm i.d., equipped with stopcocks

5. High-performance liquid chromatograph equipped with UV detector capable of operation at 0.01 AUFS at 254 nm

STANDARD PREPARATION

Prepare separate standards for EL-107 and its soil metabolite.

1. Stock standard solution (50 mcg/ml) -- Accurately weigh about 10 mg of reference standard. Transfer it to a 200-mL volumetric flask and dilute to volume with methanol. Mix well.

2. Working standard solution (1.25 mcg/ml) -- Dilute the stock solution with methanol/water to obtain a solution containing 1.25 mcg/ml and mix well. (Use methanol/water in the same proportions as the mobile phase. See REAGENTS, Step 10.)

3. Standard curve -- Prepare standard solutions over the range of 1.25 to 0.156 mcg/ml by diluting aliquots of the working standard solution with methanol/water in the same proportions as the mobile phase.

Note: The stock standard solution is stable for at least two months if kept refrigerated. The 1.25 mcg/ml standard and standard curve solutions should be prepared fresh weekly.

PROCEDURE

A. Preparation of Soil Samples

Soil samples should be blended as necessary to yield homogeneous material. Dry silica sand (about equal weight) may be added if the soil is too moist to flow freely.

B. Extraction of EL-107 and Its Soil Metabolite From Soil

1. Weigh 50 g of soil into a 500-mL refluxing flask.
2. Add 200 mL of methanol/water, 80:20.
3. Add a water-cooled condenser and heat to reflux for one hour.
4. Allow to cool to room temperature and allow solids to settle.
5. Transfer 100 mL of the supernatant solution to a 250-mL separatory funnel.
6. Add 50 mL of 5-percent aqueous sodium chloride solution.
7. Extract by shaking with three 70 ml portions of dichloromethane. Allow the phases to separate and drain the lower layer through a layer of anhydrous sodium sulfate (previously washed with 10-15 ml dichloromethane) into a 250-ml boiling flask. (Do not allow any water into the flask containing the dichloromethane extract.)

8. Rinse the sodium sulfate with additional dichloromethane.

9. Evaporate the sample solution on a rotary vacuum evaporator with water bath temperature at 40-45°C. If water droplets remain, add small portions of dichloromethane and repeat evaporation.

C. Purification

1. Prepare an alumina column for each sample as follows:
   a. Tamp a pledget of glass wool to the bottom of the column with a stirring rod.
   b. Add 1320.5 ml of standardized alumina (See section E). Tap the sides of the column gently to settle alumina. Note: The alumina must be added to the columns in a reproducible manner to assure a consistent elution pattern for all samples within a set.
   c. Add about 1.5 cm of anhydrous sodium sulfate, layering it carefully to avoid disturbance of the alumina surface.
   d. Wash the column with 30 ml dichloromethane, draining the solvent to the top of the sodium sulfate layer.

2. Transfer the sample residue to the column using two 5-ml portions of dichloromethane, allowing each addition to pass into the adsorbent. Rinse the boiling flask with 25 ml dichloromethane and add it to the column, rinsing down the sides of the column. Allow the solvent to drain to the alumina surface. Discard the eluate.

3. Wash the column with 50 ml of 80:20 dichloromethane/ethyl acetate. Discard the eluate.

5. Add 50 ml of 99:1 dichloromethane/methanol and collect the eluate in a 125-ml boiling flask. This fraction should contain EL-107.

6. Wash the column with 20 ml of 98:2 dichloromethane/methanol. Discard the eluate.

7. Add 75 ml of 97:3 dichloromethane/methanol and collect the eluate in a 125-ml boiling flask. This fraction should contain the soil metabolite.
Note: The solvent volumes used in steps 3 through 7 are dependent on the column profile and are suggested as a guideline. A column profile should be run when the procedure is introduced into the laboratory and when a new batch of alumina is used. See section E, Standardization of Alumina, for determination of the column profile.

8. Evaporate the eluate from step 5 and/or step 7 by rotary vacuum evaporation.

9. Dissolve the residue in 1.0 ml of methanol/water in the same proportions as the appropriate mobile phase and proceed with HPLC analysis.

D. Standard Recovery and Control Samples

A standard recovery sample of 0.025 ppm and a control sample as assayed with each set of experimental samples. The standard recovery sample is prepared by adding 1.0 ml of the appropriate 1.25 meg/ml standard solution to 50.0 g of control soil. If control soil is unavailable, a system recovery is run which simulates the 0.025 ppm recovery level. Recovery and control samples are assayed exactly as experimental samples.

E. Standardization of Alumina

1. The alumina, as received, is deactivated prior to use by the addition of 4 percent (v/v) water, followed by tumbling in a closed container for 30 minutes. Allow the material to stand for two hours prior to use. Keep storage container tightly closed.

2. Prepare an alumina column as described in step C.1.

3. Evaporate to dryness; 1.0 ml of the appropriate 1.25 meg/ml working standard solution and transfer the residue to the column with two 5 ml portions of dichloromethane. Wash with 25 ml dichloromethane and discard washings.

4. Elute with two 25 ml portions of 80:20 dichloromethane/ethyl acetate, collecting each fraction in a separate boiling flask.

5. Elute with three 25 ml portions of 99:1 dichloromethane/methanol, collecting each fraction in a separate boiling flask.

6. Elute with 20 ml of 98:2 dichloromethane/methanol; collect fraction in a boiling flask.

7. Elute with four 25 ml portions of 97:3 dichloromethane/methanol, collecting each fraction in a separate boiling flask.

8. Evaporate the samples in steps 4, 5, 6 and 7 to dryness using rotary vacuum evaporation.
9. Dissolve the residues in 1.0 ml of methanol/water in the same proportions as the appropriate mobile phase and proceed with HPLC analysis.

10. From the resulting chromatograms, determine which column fractions contain EL-107 or its metabolite. Collect the corresponding fractions when assaying experimental samples.

F. High-Performance Liquid Chromatography

1. HPLC pump: Capable of delivering a constant flow rate with pulseless operation

2. UV detector: Capable of operation at 0.01 AUFS at 254 nm

3. Injector: Fixed loop or constant volume injector

4. Recorder: Compatible with detector

5. Analytical column: 25 cm x 4.6 mm i.d. Spherisorb ODS II, 5 μm

6. Guard column: Co. Pelle ODS, 30-38 μm, or equivalent packing or equivalent pellicular packing

7. Operating conditions:

   Mobile phase:
   a. methanol/water, 70:30 for EL-107
   b. methanol/water, 60:40 for soil metabolite

   Flow rate: 1 ml/min

   Injection volume: 70 μl

   Retention time of EL-107: approx. 7.0 minutes
   Retention time of soil metabolite: approx. 5.5 minutes

   Note: These parameters may require slight adjustments for optimum sensitivity.

G. Measurement

1. Assay standard curve solutions, control, standard recovery, and experimental samples using the HPLC conditions described for EL-107 or its metabolite.

2. Measure the peak height of the EL-107 or metabolite peak for each injection. If the peak height of any sample is not within the range of the standard curve, appropriate dilutions should be made for reassy by HPLC.

3. Plot the peak heights versus concentration for the standard curve on linear graph paper or perform linear regression analysis on a scientific calculator.
4. Using the peak heights of the experimental samples, standard recoveries, and control, determine the concentration in mcg/ml of each from the standard curve plot.

H. Calculation

1. Standard Recovery

\[ \text{% Recovery} = \frac{\text{mcg/ml (from std curve)}}{200 \text{ ml}} \times \frac{1 \text{ ml}}{100 \text{ ml}} \times 100 \]

\[ \text{mcg added} \times \text{100 ml} \]

2. Experimental Samples

\[ \text{ppm EL=107 or metabolite} = \frac{\text{mcg/ml (from std curve)}}{200 \text{ ml}} \times \frac{1 \text{ ml}}{\text{g Sa}} \times \frac{100 \text{ ml}}{\text{percent std recovery}} \times \frac{1}{\text{dilution factor}} \times 100 \]

* dilution factor only necessary if sample required further dilution.
