

# Webinar on “Technical Guidance on Tracking Visibility Progress for the Second Implementation Period of the Regional Haze Rule”

Brett Gantt and Brian Timin  
February 20, 2019

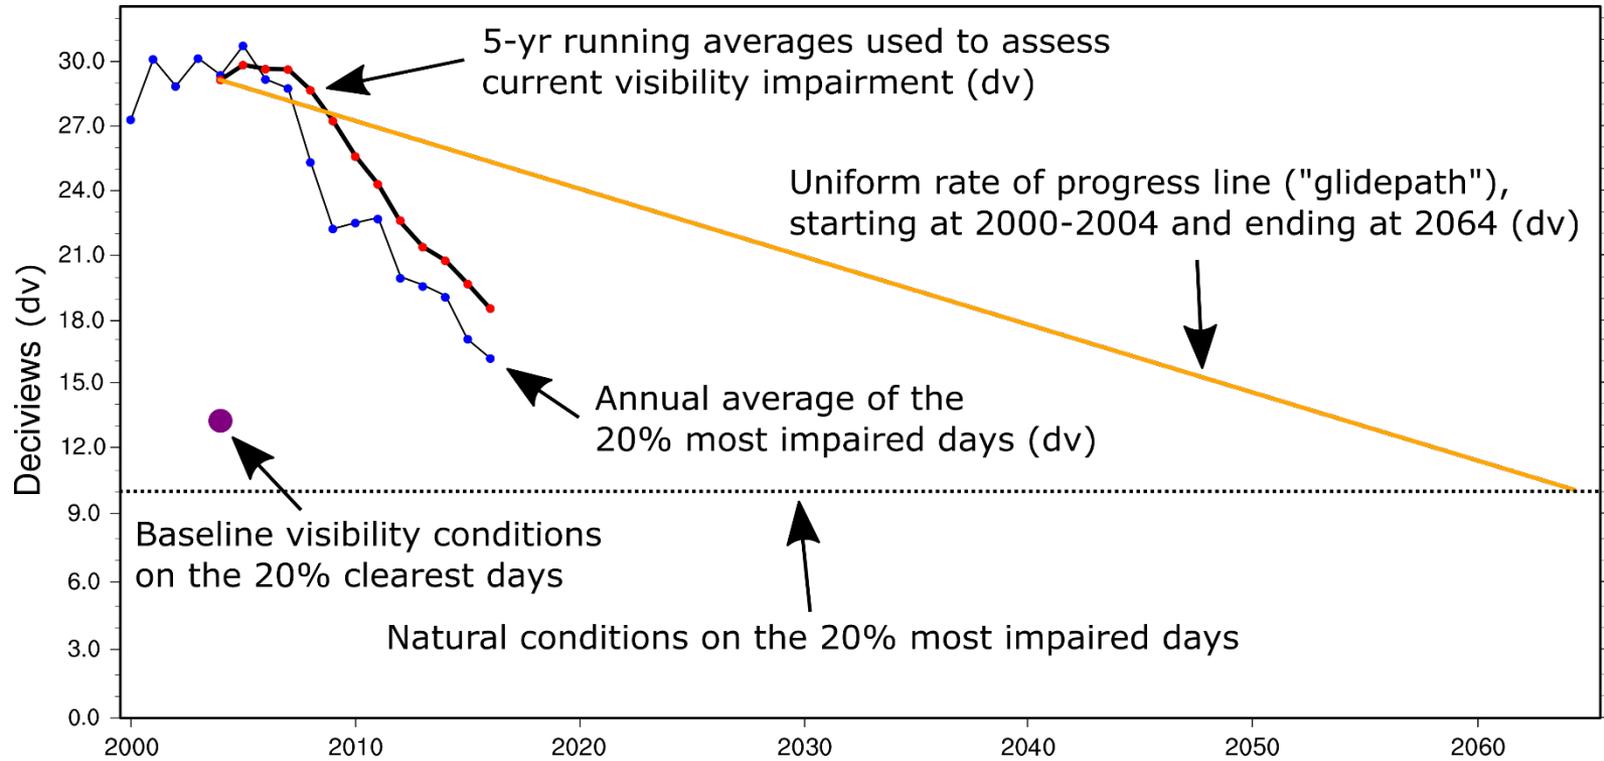

# Visibility Tracking Metric and International Adjustment

- ▶ The guidance was released on December 20, 2018 and fulfills a commitment in EPA's Regional Haze Reform Roadmap
  - <https://www.epa.gov/visibility/technical-guidance-tracking-visibility-progress-second-implementation-period-regional>
- ▶ The 2017 Regional Haze Rule revisions require a revised approach to tracking visibility improvements over time.
  - The guidance finalizes a recommended methodology to develop baseline and current visibility conditions, and natural conditions on the most impaired and clearest days at Class I areas.
- ▶ The 2017 Regional Haze Rule also includes a provision that allows states to propose an adjustment to the uniform rate of progress (URP) glidepath to account for anthropogenic international sources (and prescribed fires).
  - The guidance describes recommended tools and methods to develop optional URP adjustments

# Motivation for Changing the Tracking Metric

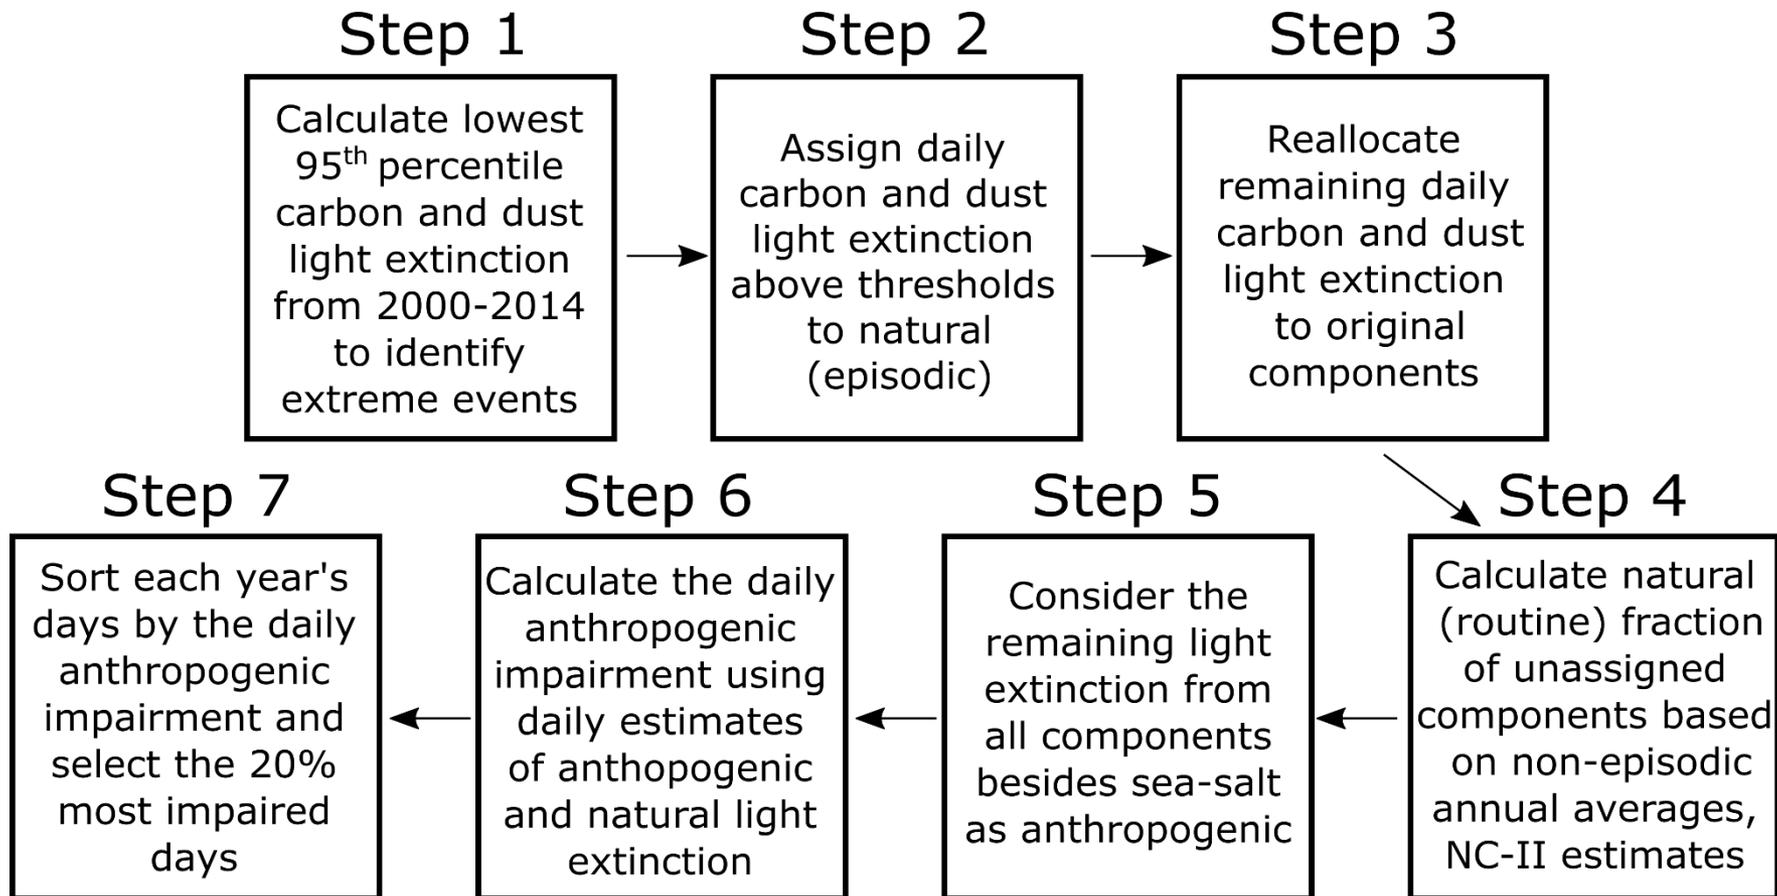

- ▶ In the 2017 Regional Haze Rule revisions, the EPA clarified that states select the 20 percent most impaired days, i.e., the days with the most impairment from *anthropogenic* sources, for the purposes of calculating baseline, current visibility conditions, and natural visibility conditions.
- ▶ In the first implementation period, the most impaired days were simply the 20% haziest days
  - In the eastern U.S., these days typically had high sulfate/nitrate extinction from anthropogenic sources
  - In the western U.S., these days occasionally had high extinction from organic carbon and coarse matter whose sources include wildfires and dust storms (sometimes from outside of the U.S.)
    - Even with a 5-year rolling average, one year with frequent impacts from wildfires or dust storms could affect the entire trend at some sites
- ▶ This guidance finalizes the recommended changes to the visibility tracking metric to focus on anthropogenic contributions

# Uniform Rate of Progress Diagram

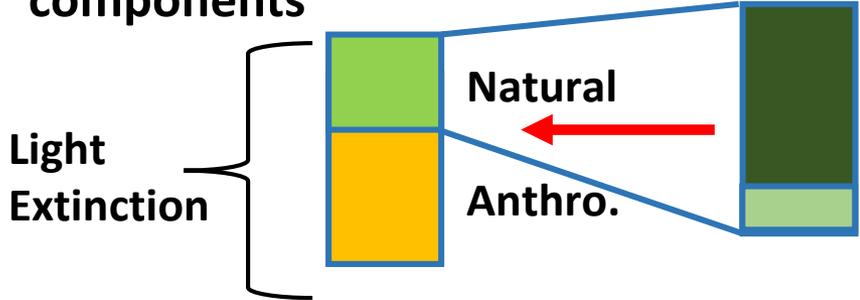

In the Regional Haze Rule, the URP framework is used to track and present visibility progress over time

# Recommended Metric Flow-chart

# Recommended Metric Simplified (Steps 1-2)

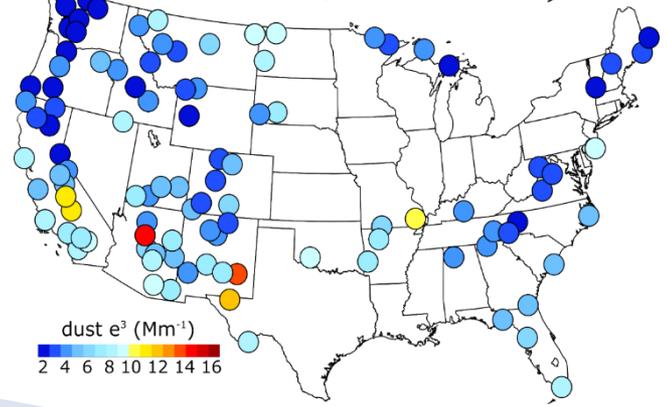

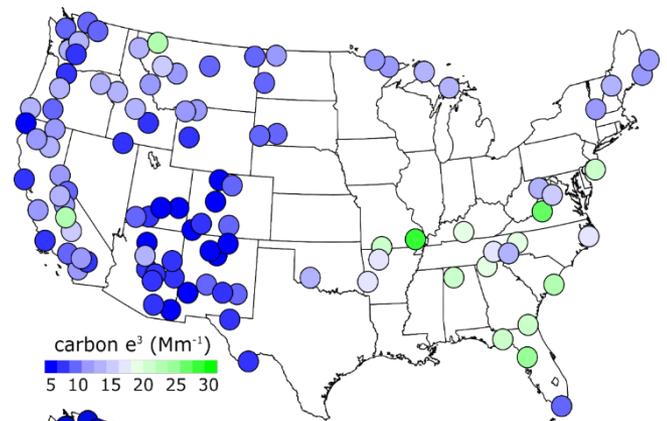

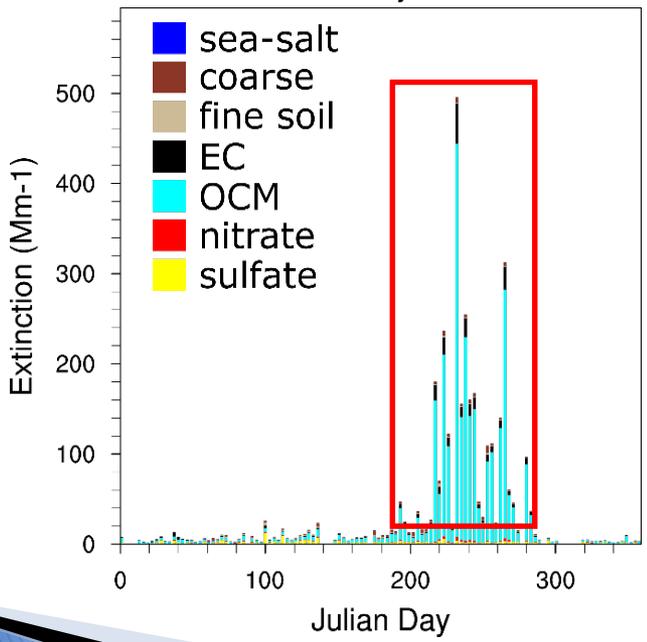

- Split each day of IMPROVE data into natural and anthropogenic extinction components

**Episodic** = site-specific daily dust and carbon > site's lowest annual 95<sup>th</sup> percentile values between 2000-2014

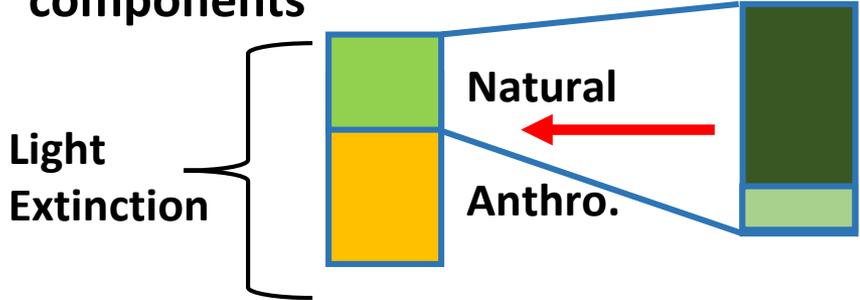

**Routine** = all sea-salt; daily fraction of avg. NC-II dust, carbon, sulfate, and nitrate in proportion to the non-episodic portion of measured values

Sawtooth NF, ID in 2012

# Recommended Metric Simplified (Steps 3-4)

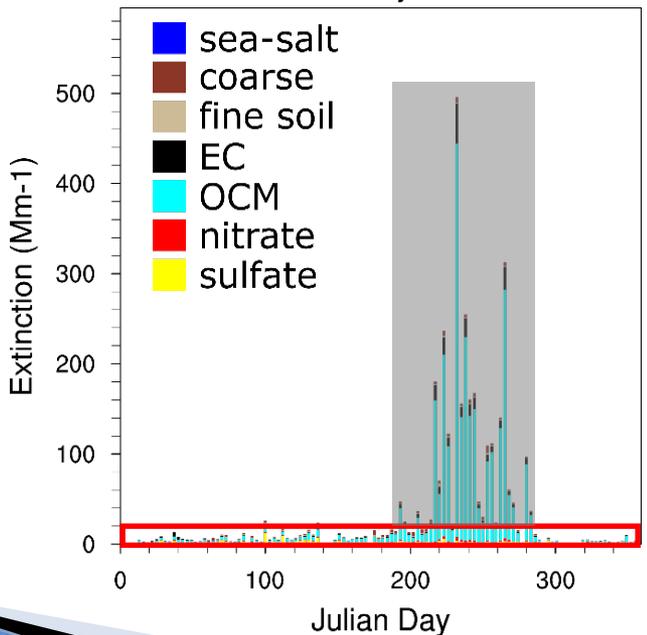

- Split each day of IMPROVE data into natural and anthropogenic extinction components

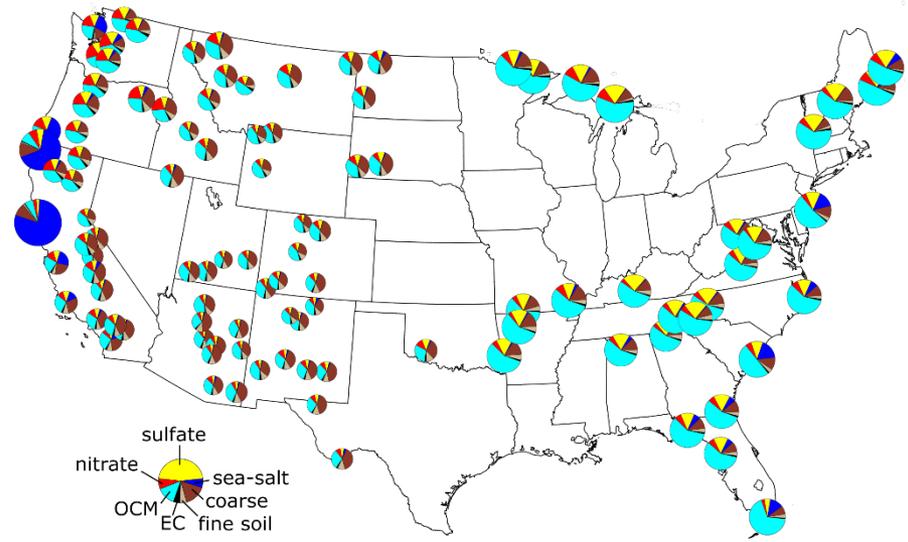

**Episodic** = site-specific daily dust and carbon > site's lowest annual 95<sup>th</sup> percentile values between 2000-2014

**Routine** = all sea-salt; daily fraction of avg. NC-II dust, carbon, sulfate, and nitrate in proportion to the non-episodic portion of measured values

Sawtooth NF, ID in 2012

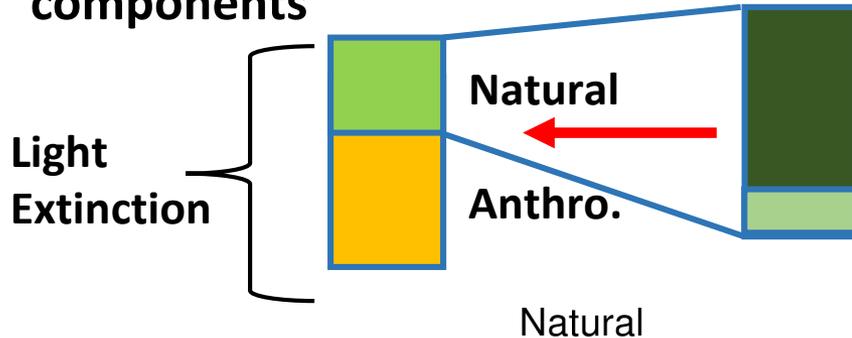

NC-II average conditions

$$\text{natural(routine)} = \frac{\text{daily extinction} \times \text{NC-II estimate}}{\text{non-episodic annual average}}$$

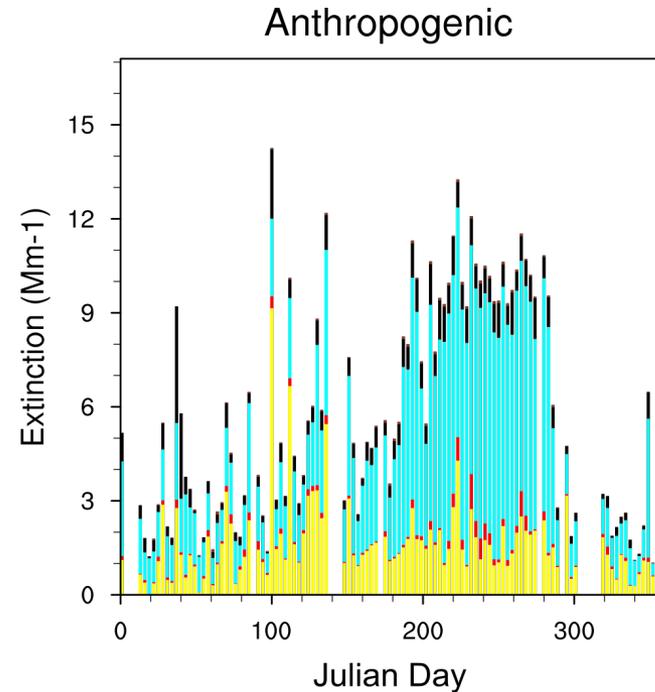

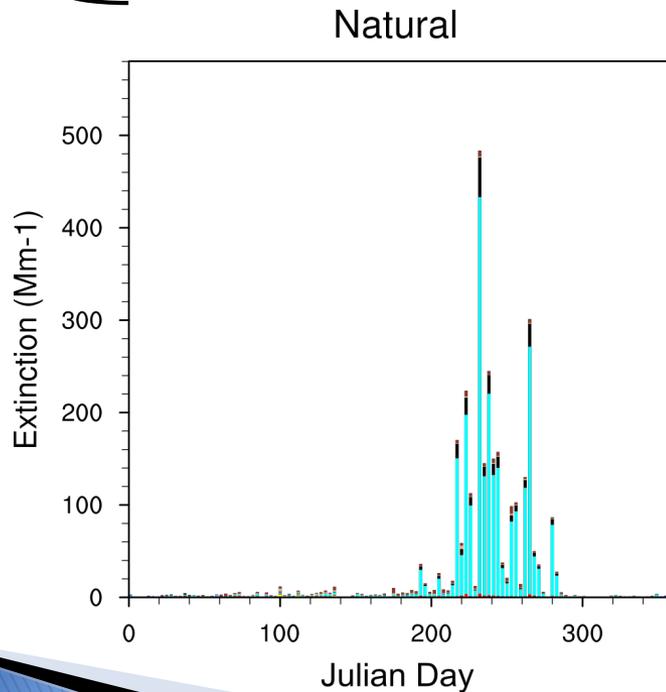

# Recommended Metric Simplified (Step 5)

- Split each day of IMPROVE data into natural and anthropogenic extinction components

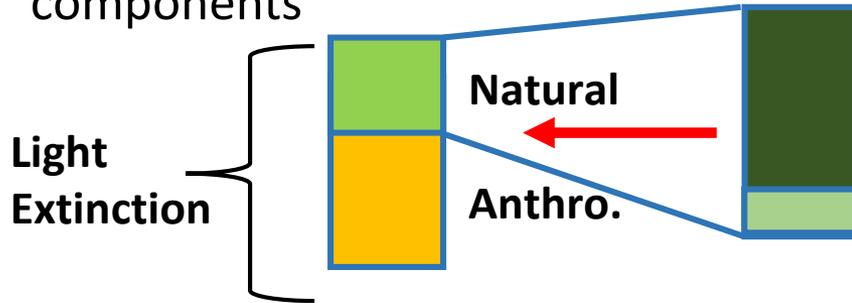

**Episodic** = site-specific daily dust and carbon > site's lowest annual 95<sup>th</sup> percentile values between 2000-2014

**Routine** = all sea-salt; daily fraction of avg. NC-II dust, carbon, sulfate, and nitrate in proportion to the non-episodic portion of measured values

# Recommended Metric Simplified (Step 6)

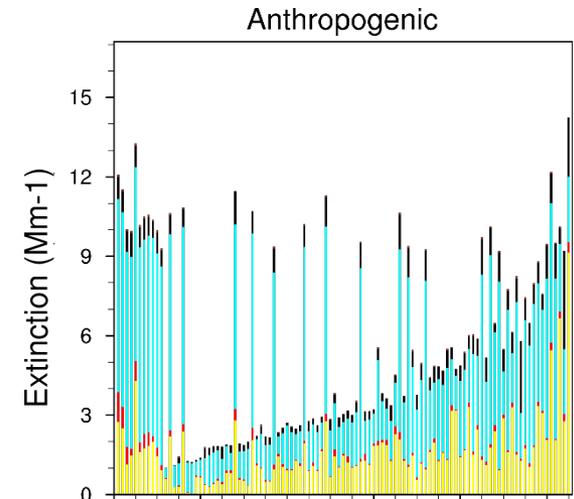

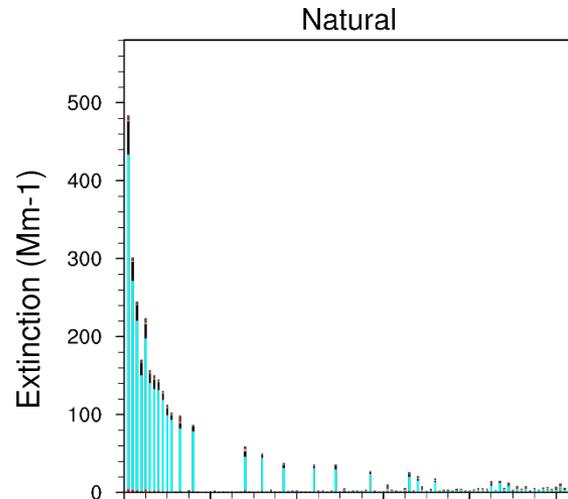

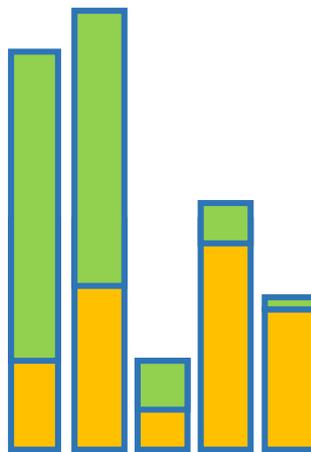

- Split each day of IMPROVE data into natural and anthropogenic extinction components

**Episodic** = site-specific daily dust and carbon > site's lowest annual 95<sup>th</sup> percentile values between 2000-2014

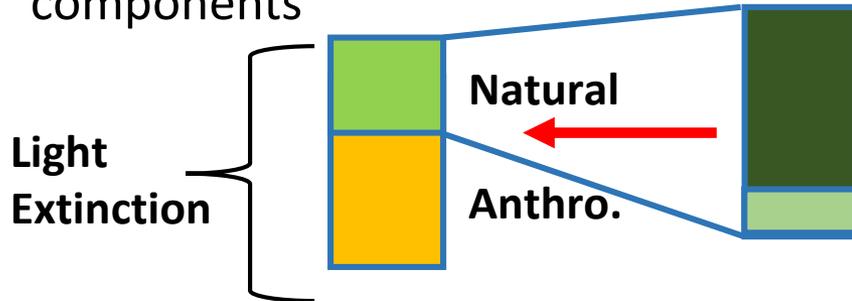

**Routine** = all sea-salt; daily fraction of avg. NC-II dust, carbon, sulfate, and nitrate in proportion to the non-episodic portion of measured values

- Sort days by  $dv_{\text{Total}} - dv_{\text{Nat}}$  (proportional to Anthro/Nat extinction) to identify the "most impaired" days:

# Recommended Metric Simplified (Step 7)

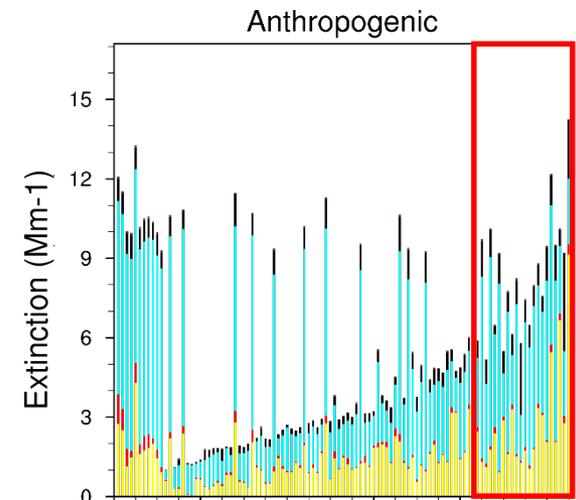

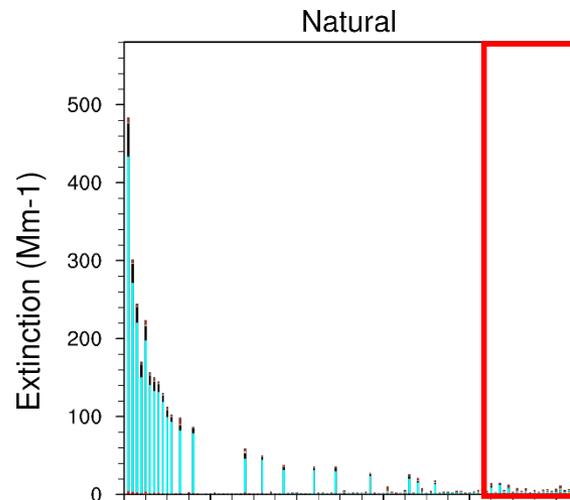

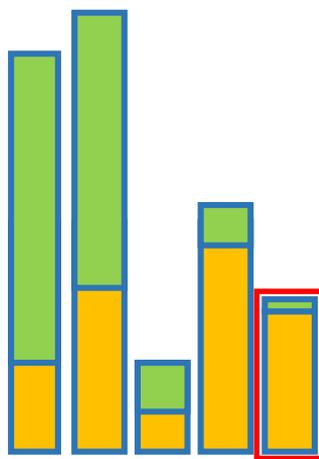

- Split each day of IMPROVE data into natural and anthropogenic extinction components

Episodic = site-specific daily dust and carbon > site's lowest annual 95<sup>th</sup> percentile values between 2000-2014

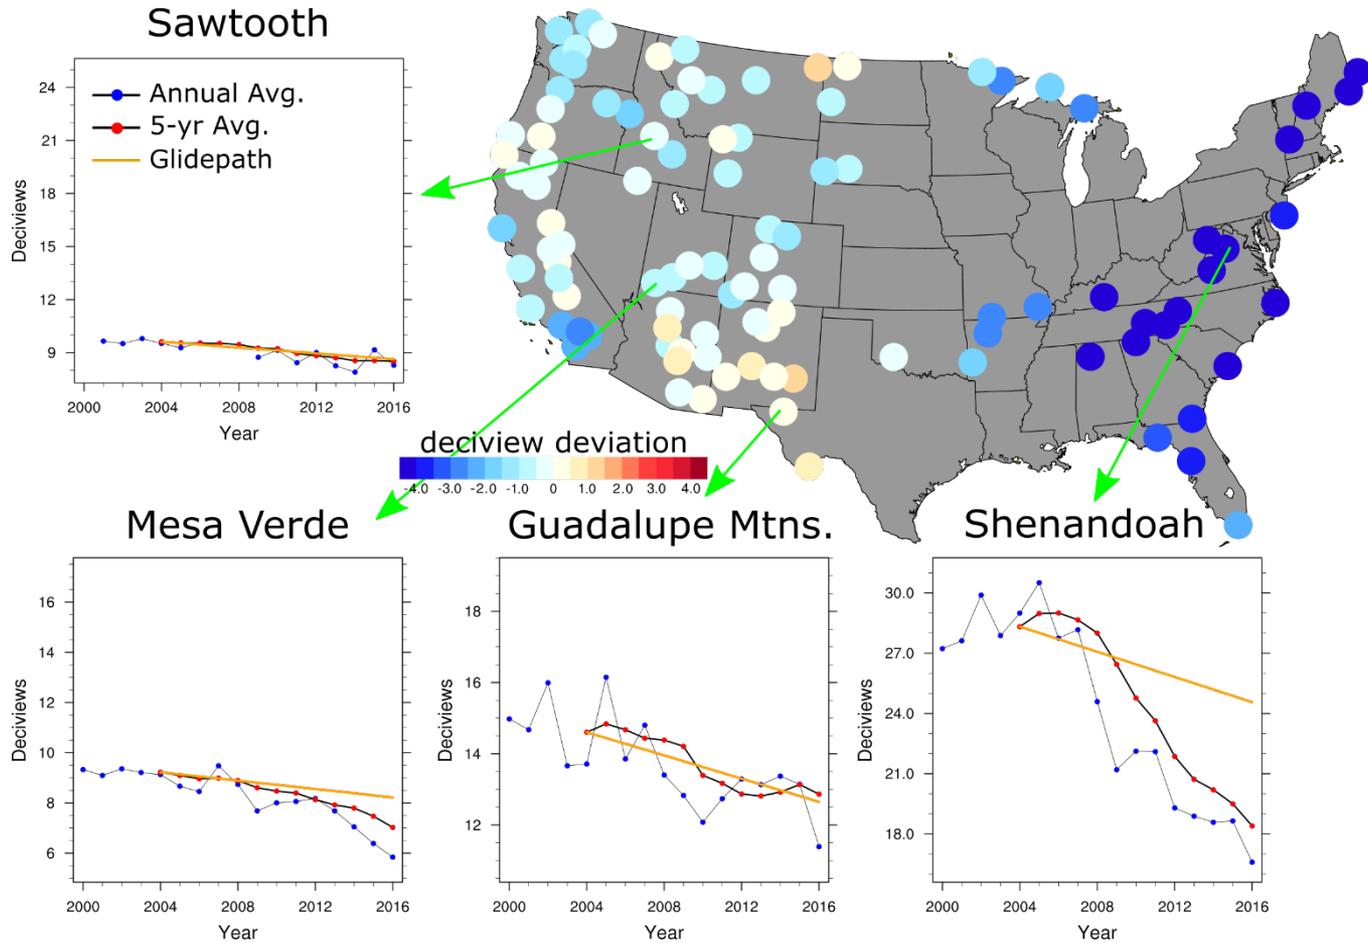

Routine = all sea-salt; daily fraction of avg. NC-II dust, carbon, sulfate, and nitrate in proportion to the non-episodic portion of measured values

- Sort days by  $dv_{\text{Total}} - dv_{\text{Nat}}$  (proportional to Anthro/Nat extinction) to identify the "most impaired" days:

- Select the 20% most impaired days

# 2012–2016 Glidepath Deviation (20% most impaired days)

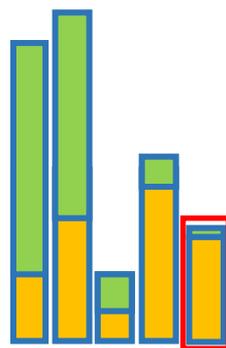

# Major Comments to 2016 Draft Guidance

- ▶ **The extreme episodic event threshold is too high/low**
  - Some commenters identified sites where they claimed the threshold value was too low because it was closer to the peak of the distribution than the tail
  - Other commenters identified sites where the threshold allowed smaller wildfires to be considered partially anthropogenic
  - We retained the threshold recommended in the draft guidance because:
    - This threshold seems to be acceptable for most IMPROVE sites
    - The guidance makes it clear that states can choose a different threshold if they explain why another method is more appropriate for their individual Class I areas

# Major Comments to 2016 Draft Guidance

- ▶ **Sorting of days should use the anthropogenic extinction rather than the recommended delta-deciview approach**
  - We retained the sorting method recommended in the draft guidance because:
    - We found that sorting by anthropogenic extinction was much more sensitive to the anthropogenic/natural split and inadvertently included more wildfire/dust storms in the selected days
    - Sorting by the delta-deciview approach selects the days where cuts in anthropogenic emissions can have the largest visibility impact

Recommended Approach   Anthropogenic Extinction

# Recommended Metric Summary

- ▶ Compared to the metric used in the first implementation period:
  - In the eastern U.S.: little difference between metrics
  - In the western U.S.: many sites that were above the URP in 2012–2016 are now at or below the URP with the recommended metric
    - Days selected as the 20% most impaired tend to have:
      - Lower extinction
      - Wider distribution across seasons
      - Higher fractions of sulfate and nitrate, much lower organic carbon
- ▶ States can easily download data using the recommended EPA methodology by going to the following website:  
<http://views.cira.colostate.edu/fed/QueryWizard/Default.aspx> and choosing the “IMPROVE aerosol, RHR III” dataset

# International Adjustment

# International Adjustment

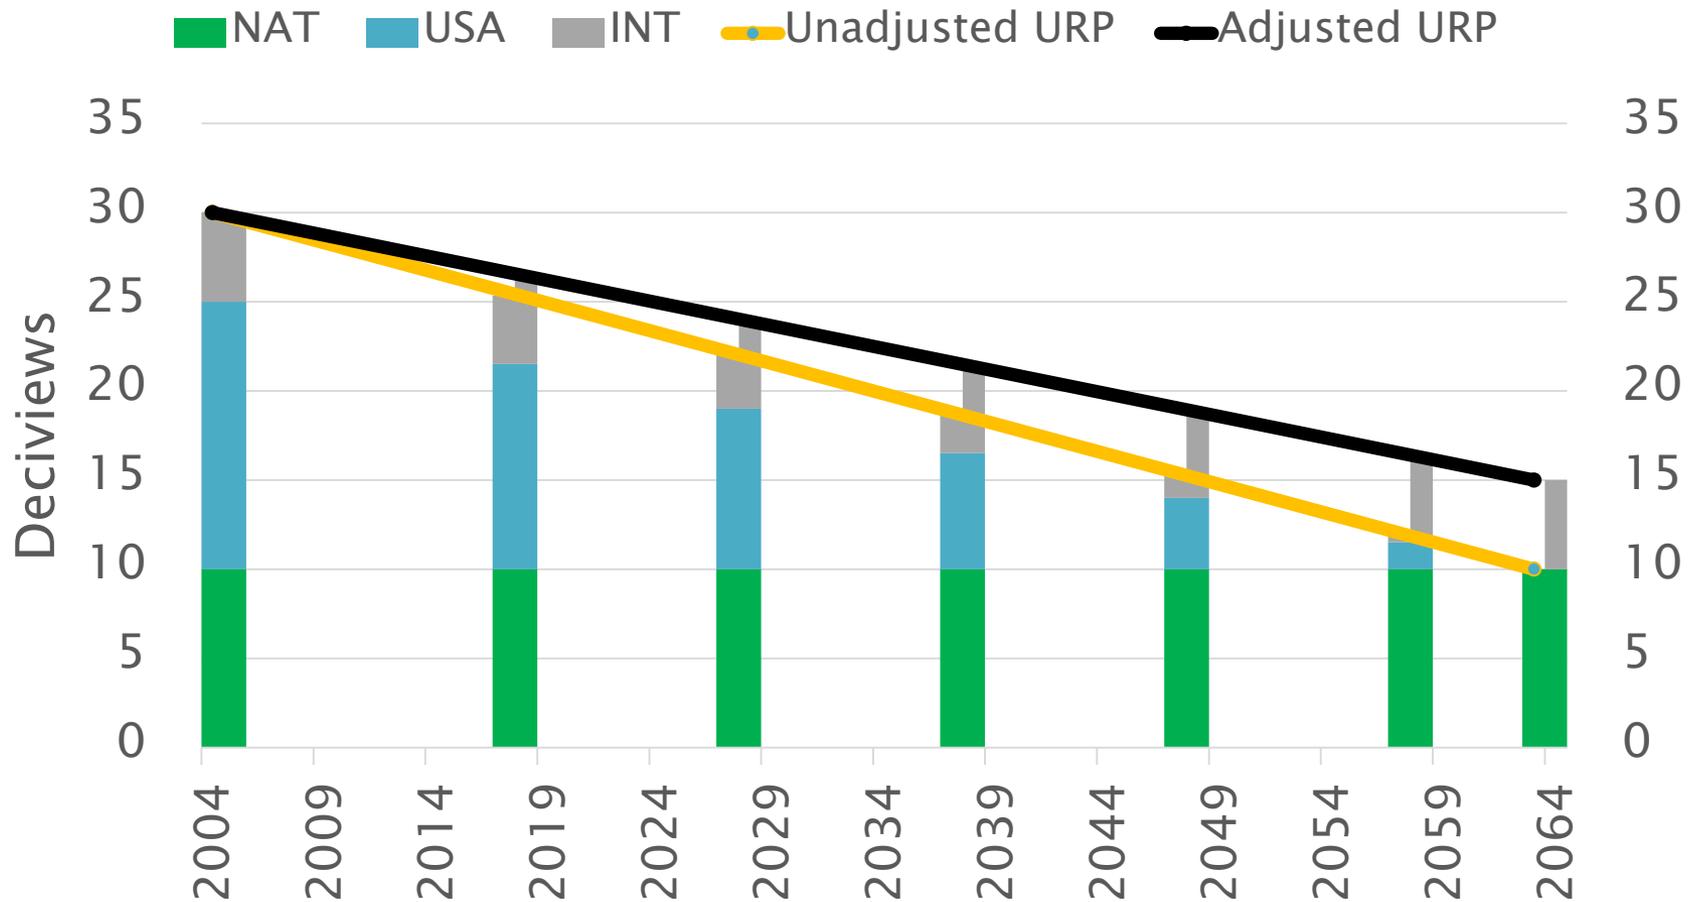

- ▶ The 2017 RHR allows states to adjust the *endpoint* of the URP glidepath upwards to account for international **anthropogenic** impacts (and prescribed fires)
  - 51.308(f)(1)(vi)(B): *As part of its implementation plan submission, the State may propose (1) an adjustment to the uniform rate of progress for a mandatory Class I Federal area to account for impacts from anthropogenic sources outside the United States and/or (2) an adjustment.... to account for impacts from wildland prescribed fires....*
- ▶ This guidance provides technical information, and recommendations on procedures and considerations for making URP adjustments

# International Adjustment Guidance

## Contents

- ▶ Background on rule language
- ▶ Year selection for quantifying international visibility impacts
- ▶ Modeling to estimate anthropogenic international visibility impacts
  - Recommended types of models
  - Modeling techniques
  - Additional considerations

# Adjusting the URP Glidepath

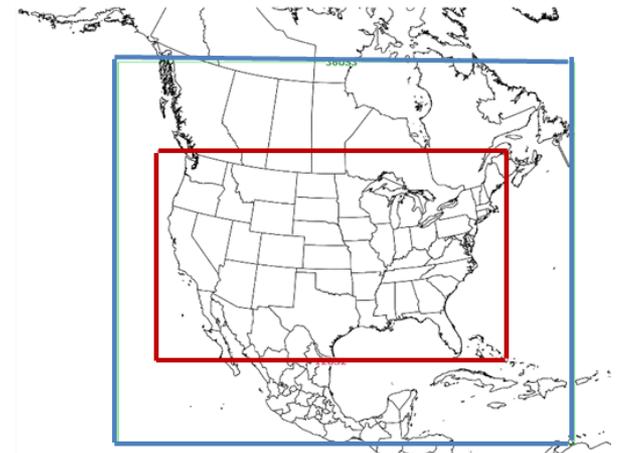

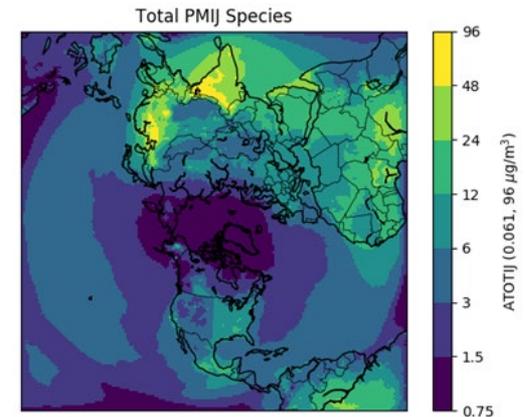

# What Year To Model?

- ▶ Year selection for quantifying international visibility impacts
  - International emissions and trends, especially outside North America, are uncertain
    - Recommend modeling “recent” year or if high quality projected emissions are available, 2028
      - “Recent year” may depend on available data
        - Most common recent modeling for 2011, 2014, and 2016
      - 2028 international emissions trends may be uncertain, especially for some source sectors and regions
    - Recommend “iterative” process of updating the international emissions and adjustment in each subsequent regional haze implementation period

# Modeling International Adjustment

- ▶ Tools to estimate impacts
  - Photochemical models
    - Global/hemispheric models
    - Regional models
  - Quantification of international impacts
    - Zero-out modeling
      - Simulations with and without international anthropogenic emissions
    - Source apportionment models
      - Tracking international anthropogenic impacts

# Other Modeling Issues

- ▶ Consistency between global and regional models
  - Aim for consistency between global/hemispheric and regional model emissions, chemical species, and meteorology inputs
- ▶ Model performance evaluation of regional and global/hemispheric models
  - Important to evaluate both regional and global/hemispheric models
- ▶ Post-processing model results and calculating visibility impacts
  - Calculate PM concentration impacts on the observed 20% most impaired days at Class I areas
  - Convert concentration to extinction and then calculate delta deciviews
    - $\Delta dv = 10 \ln \left( \text{bext}_{\text{natural conditions}} + \text{bext}_{\text{international anthropogenic}} \right) / \text{bext}_{\text{natural conditions}}$
- ▶ Defining “international” vs. US emissions
  - Aircraft
  - Off-shore shipping
- ▶ Upcoming EPA regional haze modeling will help inform further details on the modeling and adjustment process

# Updated EPA Regional Haze Modeling Summer 2019

- ▶ New 2016 based modeling platform with emissions projections to 2028, including sector-based source apportionment
  - 2028 projected deciviews and glidepath estimates
  - Estimate of international anthropogenic contributions
  - Model Improvements
    - New 2016 and 2028 emissions from the State/EPA platform collaborative
    - Regional model improvements
      - Updates to CAMx
      - Larger regional domain (including 36km outer domain)
    - Updated boundary conditions
      - Hemispheric CMAQ and/or GEOS-Chem
  - EPA will continue to work collaboratively with MJOs, states, and FLMs to make further emissions and modeling improvements
