ABSTRACT

The Texas Mining Industry, in addition to oil and gas, produces crushed rocks. Operations always involve water, either as an input or current water use in the various sectors of the mining industry: (1) hydrocarbons (oil and gas), (2) lignite and coal, (3) crushed rock and sand and gravel (collectively known as aggregate), and (4) other substances. Oil and gas make up most of the dollar value and compose a significant fraction in terms of volume with the aggregate category (Table 1). Oil and gas are produced from almost every county in the state (Fig. 1a), whereas lignite mines are located in a narrow band in the middle of the state (Fig. 1c) and parallel to the coast (Kylie, 2008; Kylie and Chitt, 2008). Sand and gravel are exploited mostly along rivers (Fig. 1d). Crushed-stone quarries are present mostly in the footprint of the Edwards Limestone. The objective of a recent study performed

#### INTRODUCTION

Mineral resources in Texas fall into four categories: (1) hydrocarbons (oil and gas), (2) lignite and coal, (3) crushed rock and sand and gravel (collectively known as aggregate), and (4) other substances. Oil and gas make up most of the dollar value and compose a significant fraction in terms of volume with the aggregate category (Table 1). Oil and gas are produced from almost every county in the state (Fig. 1a), whereas lignite mines are located in a narrow band in the middle of the state (Fig. 1c) and parallel to the coast (Kylie, 2008; Kylie and Chitt, 2008). Sand and gravel are exploited mostly along rivers (Fig. 1d). Crushed-stone quarries are present mostly in the footprint of the Edwards Limestone. The objective of a recent study performed

## ENVIRONMENTAL Science & Technology

### Water Use for Shale-Gas Production in Texas, U.S.

Jean-Philippe Nicolet and Bridget R. Scanlon

Bureau of Economic Geology, Jackson School of Geosciences, The University of Texas at Austin, 10100 Burnet Road, Building 130, Austin, Texas 78758, United States

Supporting Information

**ABSTRACT:** Shale-gas production using hydraulic fracturing of mostly horizontal wells has led to considerable controversy over water resource and environmental impacts. The study objective was to quantify net water use for shale-gas production using data from Texas, which is the dominant producer of shale gas in the U.S. with a focus on three major plays: the Barnett Shale (~15,000 wells, mid-2011), Texas-Haynesville Shale (300 wells), and Eagle Ford Shale (1000 wells). Past water use was estimated from well-completion data, and future water use was extrapolated from past water use constrained by shale-gas resources. Cumulative water use in the Barnett totaled 145 Mm<sup>3</sup> (2000–2011). Annual water use represents ~9% of water use in Dallas (population 1.3 million). Water use is younger (2008–mid-2011) plays, although less (63 Mm<sup>3</sup> Texas-Haynesville, 18 Mm<sup>3</sup> Eagle Ford), is increasing rapidly. Water use for shale gas is <1% of statewide water withdrawals; however, local impacts vary with water availability and competing demands. Projections of cumulative net water use during the next 50 years in all shale plays total ~4350 Mm<sup>3</sup>, peaking at 145 Mm<sup>3</sup> in the mid-2020s and decreasing to 23 Mm<sup>3</sup> in 2060. Current freshwater use may shift to brackish water to reduce competition with other uses.

#### INTRODUCTION

Natural gas has spurred intense interest in reducing greenhouse gases and enhancing energy security. Natural gas production estimates that are much lower than those from oil and coal: 30%–40% lower for CO<sub>2</sub>, 80% for NO<sub>x</sub>, and ~100% for SO<sub>2</sub>, particulate, and mercury.<sup>1</sup> Natural gas is used widely for industrial (13%), electric power (27%), residential (23%), commercial (14%), and other purposes (mean 2000–2010).<sup>2</sup> Production of natural gas from hydrocarbon-rich shale is referred to as shale gas. Shale contains gas in micropores, fractures, and adsorbed onto organic matter. Conventional gas has been produced from permeable geologic formations for decades; however, within the past decade, advances in directional drilling, combined with breakthrough in gas fracturing in Texas, have allowed large-scale expansion of gas production from low-permeability shale formations at depths of ~1 km. Shale gas resources differ from typical oil and gas reservoirs in that the shale serves as the source rock, reservoir, and seal. Although shale wells in older plays, such as the Barnett, and exploratory wells in newer plays are vertical (Supporting Information, A), most wells are currently drilled vertically almost to the depth of the shale formation, then deviated to the horizontal and drilled laterally within the shale. Fracturing involves injection of water containing chemical additives and proppant (e.g., sand) under high pressure to fracture the shale.<sup>3</sup> Early expansion of shale-gas production was restricted primarily to the Barnett Shale in Texas, which was the main producer in the 2000s, accounting for 60% of shale-gas production in the U.S. in 2007–2008;<sup>4</sup> however, shale gas is

currently produced in 22 of the 50 states, and production increased by an annual average rate of ~50% between 2006 and 2010.<sup>5</sup> Shale-gas production is projected to increase from 23% of U.S. natural gas production in 2009 to 47% by 2035.

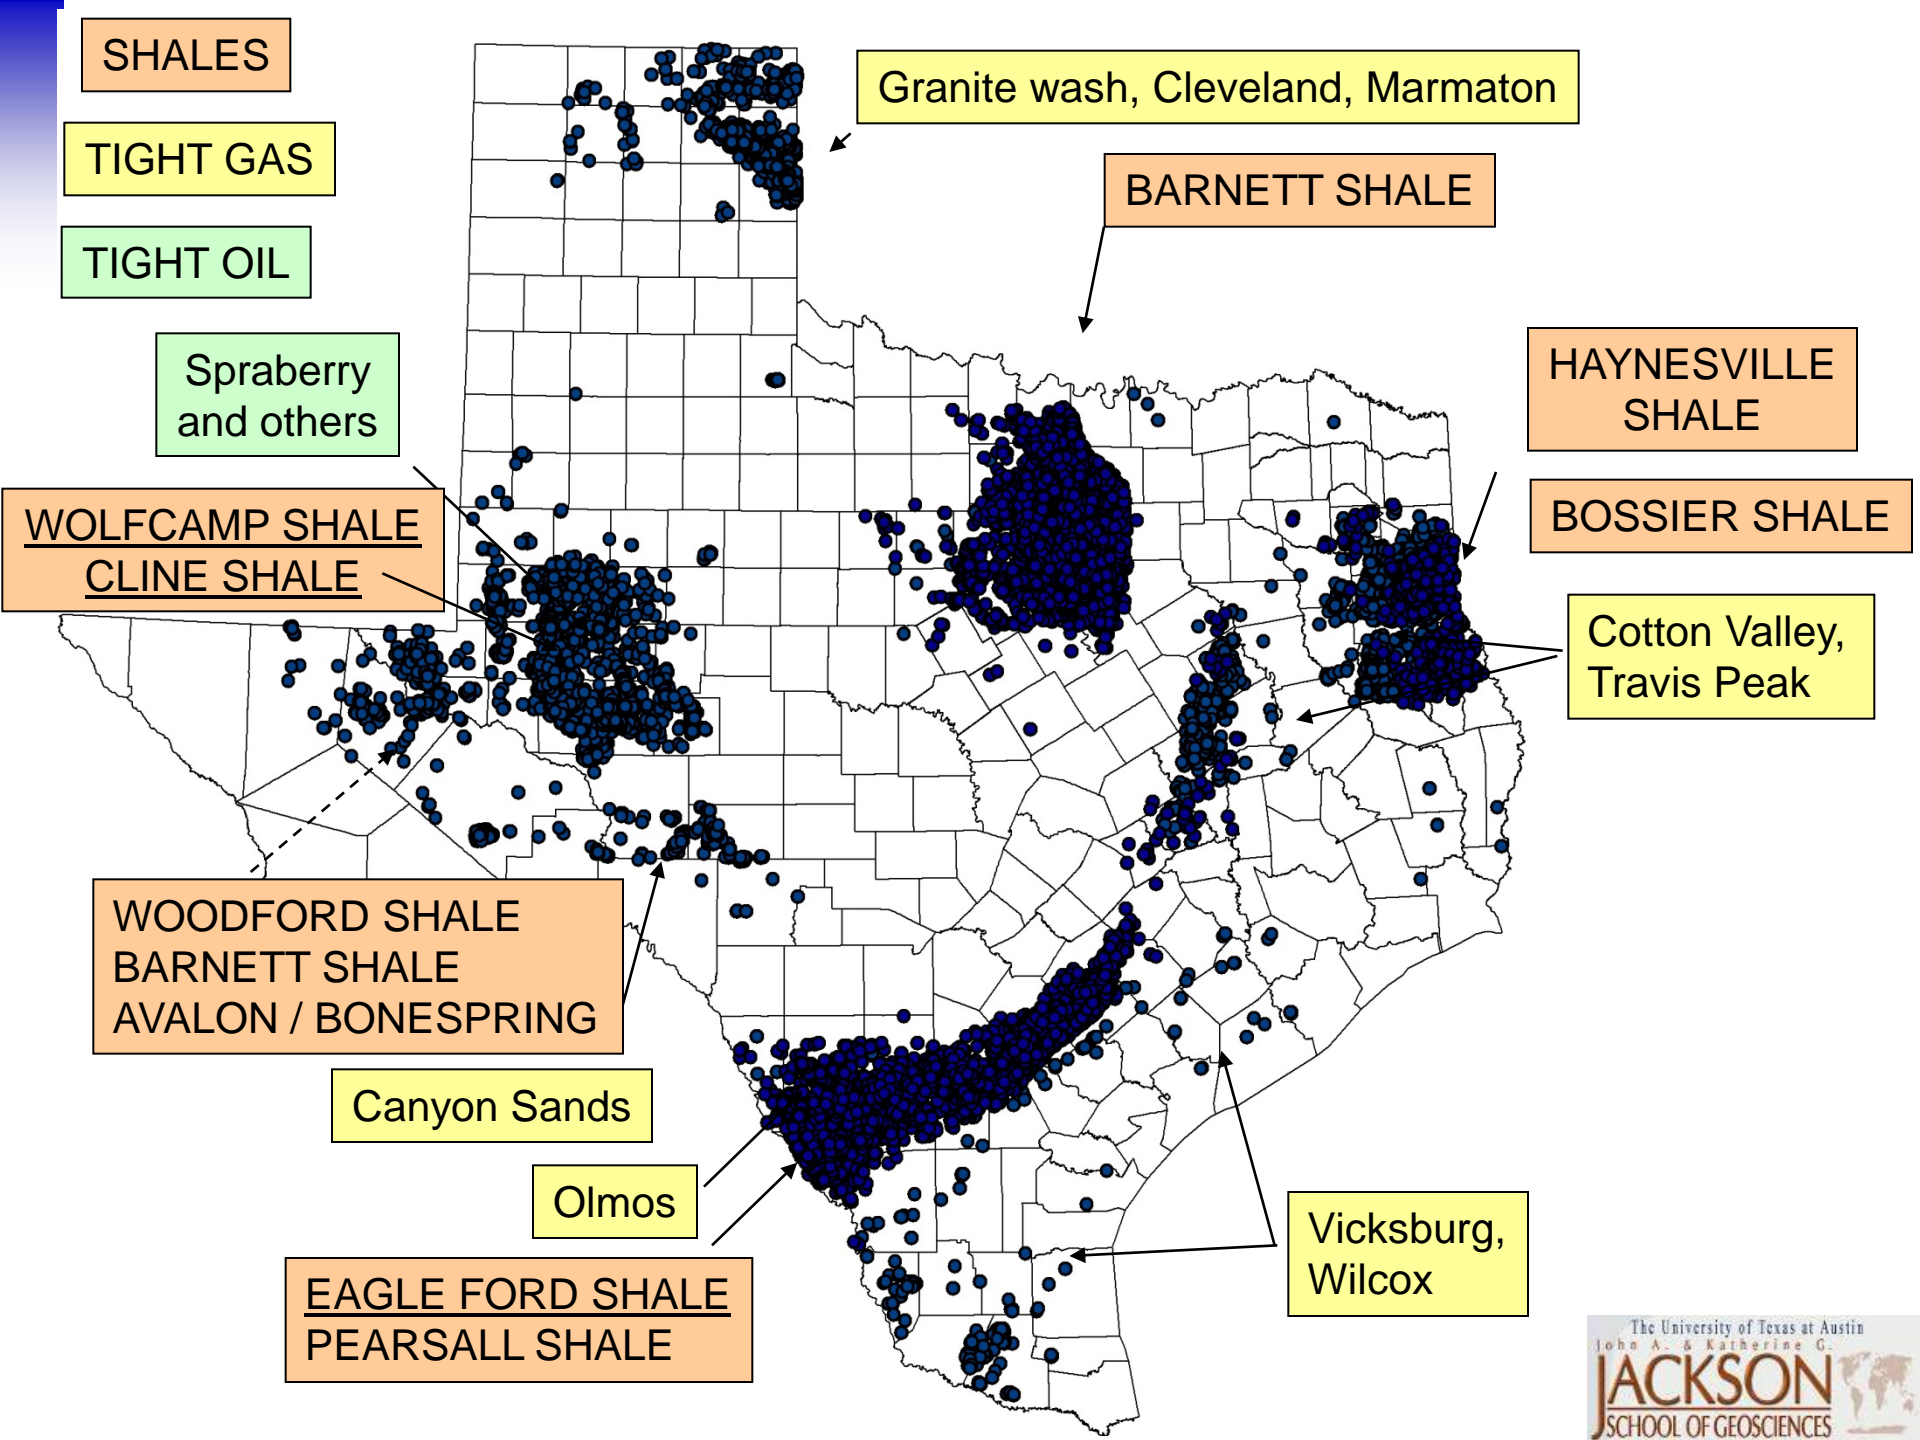

Energy and water production are interdependent in the shale-gas context: there is a strong correlation between water quantity and gas production (Supporting Information, B). Most studies of water resource impacts from shale-gas exploration and production have focused on effects of finding on water quality; however, some studies also emphasize impacts on water quantity.<sup>6–11</sup> Few published studies quantify water use for shale-gas production and their environmental impacts.<sup>12–14</sup> Water use for hydraulically fracturing wells varies with the shale gas play; the operator, well depth, number of fracturing stages, and length of laterals. To date, generally fresh water (total dissolved solids <1000 mg/L) has been used for fracturing, sourced from surface water or groundwater, depending on local availability. The commonly used polyacrylamide additives (friction reducers) function best in fresh water.<sup>15</sup>

Impacts of water production for shale-gas development depend on water availability in the region and competing demands for water from other users. Limited water availability in certain regions may restrict shale-gas production. Impacts range from declining water levels at the regional<sup>16–18</sup> or local<sup>19</sup>

## Historical Water Use Estimates

Each year the Texas Water Development Board conducts an annual survey of ground and surface water use by municipal and industrial entities within the state of Texas. The information obtained is then utilized by the Texas Water Development Board for Water Resources Planning. The historical water use estimates are subject to revision as additional data and corrections are made available to the TWDB.

Please read [Frequently Asked Questions](#) for more information on water use survey estimates and GPCDs and how they are derived.

For more information, please contact [Water Use Survey Team](#).
