We note that these costs reflect a snapshot estimate in time and are likely to increase, particularly due to the significant challenges and delays utilities are facing in their supply chains, which are contributing to an unprecedented shortage of the most basic machinery and components essential to ensure the continued reliability of the electric grid. Electric cooperatives are waiting a year, on average, to receive distribution transformers. Additionally, lead times for large power transformers have grown to more than three years. And orders for electrical conduit have been delayed five-fold to 20 weeks with costs ballooning by 200 percent year-over-year. As a result, new projects are being deferred or canceled, and electric cooperatives are concerned about their ability to respond to major storms due to depleted stockpiles. We expect these supply chain challenges to persist with the increased demand for electrification projects being incentivized by the U.S. federal government. All these delays will likely impact the cost and timing of charging infrastructure buildout needed to support the HDV fleet electrification envisioned in this proposed rule. [EPA-HQ-OAR-2022-0985-1515-A1, p. 4]

Organization: Transfer Flow, Inc.

Even the Federal Energy Regulatory Commission (FERC) has warned that a rapid transition to electric vehicles would be devastating to the country's electric grid reliability.18'19 [EPA-HQ-OAR-2022-0985-1534-A1, p. 4]

18 https://robertbryce.substack.com/p/epa-v-the-grid?utm_source=substack&utm_medium=email

Organization: Truck Renting and Leasing Association (TRALA)

Shifting all U.S. vehicles to battery electric would demand more than 40% of the country's current electricity production according to a recent study by the American Transportation Research Institute (ATRI). 5 Installing charging equipment at truck stop parking locations across the U.S. alone could cost upwards of $35 billion based on a per-unit cost of $112,000.6 Overall vehicle electricity demands will vary widely by state based upon vehicle populations, types, usage rates, and other factors. Figure 1 depicts the wide range in vehicle power demands anticipated if a 100% transition were to occur today. [EPA-HQ-OAR-2022-0985-1577-A1, pp. 4-5] [Refer to Figure 1 on p. 5 of docket number EPA-HQ-OAR-2022-0985-1577-A1]

5 Charging Infrastructure Challenges for the U.S. Electric Vehicle Fleet, American Transportation Research Institute (December 2022).

6 Id.

The U.S. Energy Information Administration projects electricity consumption byi the transportation sector will increase from 12 billion kWh in 2021 to more than 145 billion kWh in 2050.7 The electric power sector will have decades to meet that demand but in the near-term experts say possible constraints will need to be addressed. Even at a relatively slow transitional pace, there will be challenges on the grid such as can trucks and cars demanding electricity at the same time and located in the same geographic area be supported under existing power loads? [EPA-HQ-OAR-2022-0985-1577-A1, p. 5]

2. EPA does not adequately consider potential grid reliability impacts.

As part of its evaluation of potential economic impacts to the welfare of Americans and businesses, EPA must assess grid reliability impacts stemming from the proposed rule's forced electrification of the HD transportation sector. Reliance on BEVs for freight transport may have unintended, negative consequences, especially in relation to the electricity generation sector. In addition, EPA needs to accurately predict the number of additional chargers that will be needed to support the anticipated HD BEV population, which will require DC fast chargers ("DCFC"). At present, charging and re-fueling infrastructure are inadequate to meet the country's freight transport needs. Moreover, most of America's existing DCFC and prospective installations are first and foremost intended to service light-duty passenger vehicles and do not include the commercial depot charging systems necessary to support electric HDV fleets. [EPA-HQ-OAR-2022-0985-1566-A2, p. 37.]

ZEV mandates like the proposed rule also present significant risks to grid reliability and the stability of the transportation sector. Transitioning truck stops into BEV charging hubs will require massive power, on a scale that has been likened to the power required by a small town178 or sports arena.179 Yet EPA's analysis of electrical grid impacts is weak. [EPA-HQ-OAR-2022-0985-1566-A2, pp. 37 - 38.]

178 https://www.autoblog.com/2022/11/26/electric-vehicle-charging-stations-could-use-as-much-power-as-a-small-town-by-2035-and-the-grid-isn-t-ready/

179 https://www.bloomberg.com/news/articles/2022-11-14/tesla-s-electric-semis-are-coming-and-trucks-stops-aren-t-ready

EPA expects that the proposed standards will drive an increase in electricity demand and generation across the U.S.180 [EPA-HQ-OAR-2022-0985-1566-A2, p. 38.]

180 EPA's HD Phase 3 GHG Proposal at 25983.

EPA estimates an increase in electricity consumption in response to this proposal of 7.8 Terawatt-hours (TWh) in 2028 (a 0.2 percent increase), 18 TWh in 2030 (a 0.5 percent increase), 48 TWh in 2035 (a 1.2 percent increase), 72 TWh in 2040 (a 1.8 percent increase) and 98 TWh in 2050 (a 2.5 percent increase)."181 [EPA-HQ-OAR-2022-0985-1566-A2, p. 38.]

181 DRIA at 430.

EPA does not expect grid reliability to be adversely affected by this increase in electricity demand and generation, as long as charging behavior is carefully managed.182 This begs the question who would manage charging behavior, by what authority, and based on what standards or criteria. In the absence of any specific and credible information about how charging behavior will be managed, it is unreasonable for EPA to assume that it will be. [EPA-HQ-OAR-2022-0985-1566-A2, p. 38.]

182 DRIA at 70-71.

In its analysis of electric grid reliability, EPA refers to a 25% increase in electrical demand that occurred over 1992 to 2021 and concludes that since the increase in demand occurred ¡§without any adverse effects on electric grid reliability or electricity generation capacity shortages, "grid reliability is not expected to be adversely affected by the modest increase in electricity demand associated with HD BEV charging."183 However, this glib assessment overlooks the vast increase in inexpensive natural gas occurring during this period which made it possible to meet the increased demand without compromising reliability. It also overlooks the potential impacts to electrical grid costs and reliability from EPA's recently proposed New Source Performance Standards for GHG emissions from power plants.184 [EPA-HQ-OAR-2022-0985-1566-A2, p. 38.]

183 EPA's HD Phase 3 GHG Proposal at 25983.

184 88 Fed. Reg. 33240 (May 23, 2023).

Considering the regional and temporal nature of the PEV charging load, the recent trends of seasonal strain on grid reliability, and the increasing replacement of baseload generation with intermittent renewable sources, EPA's comparison to a national trend occurring over the past three decades is not particularly meaningful. [EPA-HQ-OAR-2022-0985-1566-A2, p. 38.]

EPA also acknowledges that "how the additional electricity demand from BEVs will impact the grid will depend on the time of day that charging occurs, the type or power level of charging, and the use of onsite storage and vehicle-to-grid (V2G) or other vehicle-grid integration technology, among other considerations."185 EPA explains that most of the electric power grid is owned and operated by the private industry, with Federal, state, local, Tribal and territorial governments playing significant role in enhancing the reliability of the electric power grid.186 While EPA is neither the expert in nor holds responsibility for the reliability of the electrical power grid, the agency offers suggestions for accommodating the increased electricity demand, such as:

- Grid operators incorporating automated load management or power control systems to dynamically limit total charging load;187 and
- EVSE station operators incorporating onsite battery storage or onsite renewable generation to reduce demand on the grid.188
- EPA does not account for the cost of either suggestion in its DRIA nor to any other safeguards to protect grid reliability. [EPA-HQ-OAR-2022-0985-1566-A2, pp. 38 - 39.]

185 DRIA at 70.

186 EPA's HD Phase 3 GHG Proposal at 25983.

187 DRIA at 71.

188 DRIA at 71.

EPA asserts that it has statutory authority to adopt technology-forcing standards for reducing emissions from motor vehicle tailpipes. CAA Section 202(a) does not authorize the agency to force grid operators to manage electrical loads in completely new ways, or to dictate vehicle charging behavior to fleet owners and independent vehicle operators. Yet EPA must account for the costs and impacts on the grid in the RIA for the rule and consider such costs and impacts and the availability and reliability of the grid. [EPA-HQ-OAR-2022-0985-1566-A2, p. 39.]

4. EPA fails to recognize existing grid reliability concerns.

EPA's analysis of impacts to the electrical power grid overlooks existing grid reliability issues such as the following: [EPA-HQ-OAR-2022-0985-1566-A2, p. 40.]

The North American Electric Reliability Corporation's (NERC's) "2023 Summer Reliability Assessment" warns that two-thirds of North America is at risk of energy shortfalls this summer during periods of extreme demand. While there are no high-risk areas in this year's assessment, the number of areas identified as being at elevated risk has increased. The assessment finds that, while resources are adequate for normal summer peak demand, if summer temperatures spike, seven areas — the U.S. West, SPP and MISO, ERCOT, SERC Central, New England and Ontario — may face supply shortages during higher demand levels.192 [EPA-HQ-OAR-2022-0985-1566-A2, p. 40.]

192 NERC, "2023 Summer Reliability Assessment" (May 17, 2023), https://www.nerc.com/news/Headlines%20DL/Summer%20Reliability%20Assessment%20Announcement%20May%202023.pdf

NERC's "2022-2023 Winter Reliability Assessment" warned that a large portion of the North America BPS was at risk of insufficient electricity supplies during peak winter conditions, including Texas RE-ERCOT, MISO, SERC-East, WECC-Alberta, NPCC-Maritimes, NPCC-New England.193 [EPA-HQ-OAR-2022-0985-1566-A2, p. 40.]

193 NERC, "2022-2023 Winter Reliability Assessment" (November 2022), https://www.nerc.com/pa/RAPA/ra/Reliability%20Assessments%20DL/NERC_WRA_2022.pdf

NERC's "2022 Long Term Reliability Assessment" identifies three high risk areas – MISO, NPCC-Ontario, and the California/Mexico part of WECC – that are projected to not have adequate electricity supply to meet demand forecasts associated with normal weather over the 10-year assessment period. Several other areas are identified as having elevated risk, i.e., meeting the resource adequacy criteria for normal forecasted conditions but at risk of shortfall in extreme conditions. These areas include the U.S. West—CA/MX, Western Power Pool (WPP), and the Southwest Reserve Sharing Group (SRSG), Texas RE-ERCOT, SPP and New England. Specific recommendations from NERC to manage the risks include considering "the impact that the electrification of transportation, space heating, and other sectors may have on future electricity demand and infrastructure."194 [EPA-HQ-OAR-2022-0985-1566-A2, pp. 40 - 41.]

194 NERC, "2022 Long-Term Reliability Assessment" (December 2022), https://www.nerc.com/pa/RAPA/ra/Reliability%20Assessments%20DL/NERC_LTRA_2022.pdf

As California has faced rolling blackouts and historic energy prices, Governor Newsom in his May 2022 state budget proposal, has pivoted to the use of traditional fuel infrastructure to ensure system reliability to protect against outages. Approximately one week after the California Air Resources Board approved its "Advanced Clean Cars II" rule prohibiting sales of new ICEV passenger cars in California by 2035, Governor Gavin Newsom issued a statewide request for electric vehicle owners to refrain from charging their vehicles in order to prevent blackouts.195 Significant investments in charging/fueling infrastructure will also be needed. The CEC has projected that an additional 157,000 chargers will be needed to support California's anticipated electric HD population in 2030—all of these will be DCFC, representing 9,100 additional job-years of dedicated workforce requirements, compounding timeline feasibility challenges. CEC further projects that the HDV charging network will see loads "in excess of 2,000 MW around 5 p.m. on a typical workday," further exacerbating the existing gap between net peak energy demand and existing generation. [EPA-HQ-OAR-2022-0985-1566-A2, p. 41.]

195 https://www.nytimes.com/2022/09/01/us/california-heat-wave-flex-alert-ac-ev-charging.html

Twelve states expressed concerns regarding electrical grid and utility impacts in their DOT-approved state EV Infrastructure Deployment Plans, as summarized below. While the plans primarily focus on infrastructure to be installed along designated alternative fuel corridors, the concerns relating to grid and utility impacts are similarly applicable to depot and truck parking stations. EPA has not accounted for these concerns in its analysis. [EPA-HQ-OAR-2022-0985-1566-A2, p. 41.] [See the table of State Concern on page 41 of docket number EPA-HQ-OAR-2022-0985-1566-A2.]

Additionally, within California there are significant challenges to be overcome in order to build the infrastructure necessary to support freight electrification under the CARB Advanced Clean Trucks and Advanced Clean Fleets rules. The California Public Utilities Commission (CPUC) recently identified the need for an accelerated electrical infrastructure deployment as a challenge for forecasting and planning, with approximately three years lead time needed for statewide planning efforts to be completed and infrastructure authorized.208 Indeed, in the six priority corridors alone, which doesn't account for more rural routes, California would need between 556 and 1,832 public BEV charging stations by 2040.209 For comparison, California currently has approximately 5,000 retail diesel stations statewide as of 2021.210 As a result, there are risks that could negatively impact MD and HD adoption including uncertainty regarding long-term electricity rate, delayed construction of distribution/transmission infrastructure, and differences in charging behavior from what was assumed in the planning stages (which would result in an infrastructure buildout that doesn't align with actual charging behavior).211 Clearly, there will be significant shortfall in resources in California alone to meet the needs of the freight electrification push, let alone the entire nation, as contemplated by the instant proposed rule. [EPA-HQ-OAR-2022-0985-1566-A2, p. 43.]

An American Transportation Research Institute report from 2022 estimated that full national electrification of light-duty and medium/heavy-duty vehicles would require a 26% and 14% increase in power supply respectively.4 For a more regional perspective, a National Grid Report co-authored by Calstart, RMI and others looked at charging needs along major highways in Massachusetts and New York.5 Based on current truck traffic and the goal of having all light-duty and medium/heavy-duty vehicles be electric by 2035 and 2045 respectively, the report stated that "in 10 years more than a quarter of sites studied will require the same amount of power as an outdoor sports stadium to meet charging demand, with some requiring the same power as a small town within the next two decades." [EPA-HQ-OAR-2022-0985-1606-A1, p. 8]

c. Electricity Generation and Grid Readiness

Transitioning to zero-emission transportation offers a unique challenge to the energy companies that will need to ensure they have ample electricity supply to match EV-driven demand. At minimum, this will require investments in the electricity distribution system to enable the deployment of electric vehicle charging equipment. In some instances, this may also require investing in new energy generation sources and associated distribution system infrastructure to accommodate major EV centers like heavy-duty vehicle depots or co-locate other necessary amenities. [EPA-HQ-OAR-2022-0985-2429-A1, p. 29]

However, this is not the first time electricity providers have navigated increases in electricity demand brought on by new technologies: similar spikes accompanied the mass adoption of now-standard appliances like refrigerators and in-home air conditioners. Still, it will be important to ensure that providers and government agencies can work within their regulatory frameworks to test solutions and upgrade the grid to prepare for future demand increases accompanying greater EV adoption. [EPA-HQ-OAR-2022-0985-2429-A1, p. 29]

This section will discuss the growing energy demands of widespread EV adoption and new potential hotspots for energy demand. It will also use case studies to highlight how electricity providers are preparing for this transition. These case studies showcase solutions that have the potential to revolutionize energy consumption and highlight how electricity providers support customer EV adoption through incentive programs, building infrastructure, and other initiatives. [EPA-HQ-OAR-2022-0985-2429-A1, pp. 29 - 30]

The grid's ability to handle millions of additional EVs hinges on utilities' proactive planning capacity. Granting utilities the flexibility to make proactive upgrades to the electrical grid and facilitate transportation electrification will require careful planning and coordination between regulators and stakeholders. [EPA-HQ-OAR-2022-0985-2429-A1, p. 30]

Regulatory certainty will allow utilities to make the investments necessary to facilitate a smooth EV transition. To invest proactively, rather than in response to firm load, energy providers will need clear insight into multi-year schedules for customer electrification, approval from regulators to recover costs, and/or flexibility to serve loads with non-wire alternatives. [EPA-HQ-OAR-2022-0985-2429-A1, p. 30]

Robust EPA emission standards will provide the regulatory certainty needed to not only ensure vehicle manufacturers continue to invest in EV technologies, but that the entire supply chain supporting the transition to electrification will have a clearer picture of how to plan capital expenditures today to meet the increased demand over the coming years. [EPA-HQ-OAR-2022-0985-2429-A1, p. 30]

i. Anticipated impacts to electricity providers from increased EV deployment

In 2021, the U.S. fleet of electric vehicles used 6.1 terawatt hours (TWhs) of electricity to travel 19.1 billion miles.125 That accounted for just 0.15% of the total national energy generation that year.126 In 2022, the United States produced 4,243 TWhs of electricity.127 To meet the demand of transportation electrification, more generation will be needed to service EVs and electrified vehicle technologies. One estimate suggests it would take roughly 800 to 1,900 TWh of electricity to power all vehicles if they were electric.128 It is important to remember, however, that this new demand will not occur all at once but rather more gradually as EVs continue to displace ICEVs. While achievable, meeting this increase in electricity demand will require significant strategy as electric providers transition to renewable, carbon free resources. [EPA-HQ-OAR-2022-0985-2429-A1, p. 30]

125 "Assessment of Light-Duty Plug-in Electric Vehicles in the United States, 2010–2021," Argonne National Lab, November 2022 https://publications.anl.gov/anlpubs/2022/11/178584.pdf

126 “Monthly Energy Review May 2023,” EIA, https://www.eia.gov/totalenergy/data/monthly/pdf/sec7_3.pdf

128 “How much electricity would it take to power all cars if they were electric?,” USAFacts, (May 15, 2023) accessed June 13, 2023 https://usafacts.org/articles/how-much-electricity-would-it-take-to-power-all-cars-if-they-were-electric/

The key to meeting these energy requirements will be the expansion of renewable energy resources but also the addition of new, zero-emission and low-emission load-following resources like advanced nuclear, carbon capture, long-term energy storage, and green hydrogen. In 2022, electricity generated from renewable sources surpassed coal for the first time in U.S. history.129 At the same time, electricity providers are looking at ways to add low-cost energy storage to increase the availability of non-dispatchable renewable generation such as solar and wind. Currently, renewable energy generates about 20% of all electricity production in the U.S, and renewable sources like solar and wind are expected to account for the majority of new utility-scale electricity generation going forward.130,131 Already, available renewable energy resources in the U.S. are estimated to amount to more than 100 times the nation’s current electricity needs.132 [EPA-HQ-OAR-2022-0985-2429-A1, pp. 30 - 31]

129 “U.S. renewable electricity surpassed coal in 2022,” Associated Press, (March 28, 2023), accessed June 4, 2023 https://apnews.com/article/renewable-energy-coal-nuclear-climate-change-dd4a0b168fe057f430e37398615155a0

130 “Renewable Energy,” Department of Energy, accessed June 4, 2023 https://www.energy.gov/eere/renewable-energy

132 “Renewable Energy Resource Assessment Information for the United States,” Department of Energy, accessed June 4, 2023 https://www.energy.gov/eere/analysis/renewable-energy-resource-assessment-information-united-states

133 “Yes, the grid can handle EV charging, even when demand spikes,” Yale Climate Connections, (March 23, 2023) accessed June 4, 2023 https://yaleclimateconnections.org/2023/03/yes-the-grid-can-handle-ev-charging-even-when-demand-spikes/

Power generation is only one of the considerations when preparing for 100% transportation electrification. In particular, the industry needs to develop its ability to precisely manage demand in real time, including by accurately predicting when and where increases in demand will occur. [EPA-HQ-OAR-2022-0985-2429-A1, p. 31]

It is important to note that energy demand is not constant. Instead, it consists of relatively predictable peaks and troughs throughout the day. High demand consistently occurs between 5:00 PM and 8:00 PM each day, as customers return home, turn up their climate control systems, begin cooking dinner, and turn on other devices.133 System demand peak is typically between 5:00-6:00 PM during the summer, and 7:00-8:00 AM in the winter. As such, EV charging poses minimal impacts to the winter peak hours but could increase summer peaks without managed charging. [EPA-HQ-OAR-2022-0985-2429-A1, p. 31]

ii. Utility-specific planning underway

The following collection of case studies demonstrates how electricity providers in ZETA's membership are preparing for the EV transition and highlights some of their groundbreaking initiatives to support EV adoption in the United States. It should be noted that each provider operates within a regulatory framework that is unique to the state in which it serves. The cases outlined below do not represent the entire portfolio of EV-related products and services offered by these providers. [EPA-HQ-OAR-2022-0985-2429-A1, p. 31]

These examples include programs that exist across the EV supply chain, with earlier examples covering infrastructure planning programs and later examples focusing on programs to engage with EV drivers on their charging needs. [EPA-HQ-OAR-2022-0985-2429-A1, p. 32]

1. Pacific Gas & Electric

As California's largest electric provider, PG&E continues to play an important role in advancing electric vehicle adoption in support of the state's broad climate goals. PG&E works in collaboration with the California Energy Commission and California Public Utilities Commission to plan and approve grid infrastructure upgrades to support this shift to zero-emission transportation. [EPA-HQ-OAR-2022-0985-2429-A1, p. 32]

With nearly 500,000 EVs sold in its service area—one in every seven of all EVs on the road throughout the nation—expansion of PG&E's EV charging network in Northern and Central California is critical to support the State's transition to a clean transportation future. Over the last half-decade, the provider has deployed more than 5,000 EV charging ports across its service area. Additionally, it offers a variety of resources to help accelerate EV adoption among customers, and PG&E is working collaboratively with vehicle manufacturers to develop vehicle grid-integration technologies. [EPA-HQ-OAR-2022-0985-2429-A1, p. 32]

Grid planning requires precise forecasts to ensure electric infrastructure is available to support future demand. Pre-existing electricity demand (load) forecasts did not provide the geographical granularity needed to best plan for grid investments. PG&E could allocate the load to residential charging locations; however, larger charging loads that are often not associated with existing service points—such as public charging systems—lacked a methodology to be accounted for in long-term forecasting efforts. Without the ability to identify future EV demand with geographic and temporal accuracy, PG&E was limited in its ability to plan future grid capacity. [EPA-HQ-OAR-2022-0985-2429-A1, p. 32]

Lacking a long-term geospatial forecasting methodology, PG&E was primarily dependent on customer requests for service to inform where EV load would materialize. This reliance on customer requests led PG&E to reactively develop capacity solutions to serve load requests. Given the long lead times often associated with capacity projects and the relatively fast pace at which customers wish to build EV charging infrastructure, there would be instances where energization timelines exceeded the requested energization date from customers. This can occur with large load applications associated with public DCFC charging stations or large fleets, which have the potential to exceed the maximum capacity of existing electrical infrastructure in those areas. [EPA-HQ-OAR-2022-0985-2429-A1, p. 32]

Identifying a need for a more proactive approach, PG&E set out to improve its forecasting abilities to increase the clarity of where and when EV loading is most likely to materialize. This enables PG&E to build capacity in advance of service applications being received.

Although research indicates that customer preference for EVs is increasing, and there are many regulations and incentives which further support the transition to EVs, there are still uncertainties around the pace of adoption. This impacts how the EV load will manifest on the electric grid. For this reason, a solution capable of supporting a variety of forecast scenarios was necessary for success. PG&E commissioned a multi-faceted project focused on three common categories of EV charging load: 1) public DCFC & Level 2 charging stations, 2) residential EV charging, and 3) fleet charging. [EPA-HQ-OAR-2022-0985-2429-A1, pp. 32 - 33]

Detailed analysis and machine learning modeling and testing were applied to each of these focus areas to predict where EV charging is most likely to occur. These analyses were performed at the premise level and resulted in over 5 million potential growth points across PG&E's service territory that were integrated into existing distribution planning software. This created a dynamic tool that can adapt to a variety of forecast inputs, such as system-level adoption forecasts, EV charging behaviors, and charging infrastructure assumptions. These scenarios can be integrated into PG&E's distribution planning processes. [EPA-HQ-OAR-2022-0985-2429-A1, p. 33]

Developing a solution that was easily integrated into existing distribution planning processes and software was critical for successful implementation. Involving PG&E forecasting and asset planning teams in the development of the EV forecasting tool, as well as reviewing and approval of the major inputs and assumptions used to develop forecast scenarios, ensured alignment in the scenarios generated. [EPA-HQ-OAR-2022-0985-2429-A1, p. 33]

In figure 7 above, the difference in magnitude of localized EV load in the year 2035 can be seen in a relatively low EV adoption scenario (2020 California Energy Commission (CEC) Integrated Energy Policy Report (IEPR Mid)) and a higher policy-based scenario based on the California Air Resources Board (CARB) Multiple Source Strategy (MSS) forecast. Grid planners can use this tool to investigate and solve for circuit level impacts of EV load growth. [EPA-HQ-OAR-2022-0985-2429-A1, p. 34.] [See Docket Number EPA-HQ-OAR-2022-0985-2429-A1, page 34, for Figure 7. This Figure was redacted]

Using varying EV forecast scenarios, PG&E was able to assess the localized grid impacts from high EV adoption scenarios that are better aligned with state transportation electrification goals and policies. PG&E assessed how various levels of EV adoption, as well as the impacts that changing charging behaviors (such as on vs. off-peak charging), can have on grid needs. Early analysis has indicated that off-peak charging can reduce near-term grid constraints. In the future, this may lead to new circuit peaks and capacity constraints that must be addressed. [EPA-HQ-OAR-2022-0985-2429-A1, p. 34]

Results from these analyses were helpful in advocating for approval of higher transportation electrification forecasts with regulators and the state energy commission, which are ultimately used for electric grid planning. PG&E has also used these forecasts to produce directional assessments of the resources needed to support capacity investments included in their long-term capital planning. PG&E continues to work to improve its forecasting and planning capabilities. Still, the solutions implemented to date have enabled a more robust approach that will allow PG&E to continue to support its customers' electrification transition. [EPA-HQ-OAR-2022-0985-2429-A1, pp. 34 - 35]

2. Vistra

Electricity generators are making the transition to low- and no-carbon-emitting sources of energy as quickly as possible in response to investor, regulator, policymaker, and customer expectations. This transition is backed by a strong business case for doing so, as renewables and battery storage systems are able to compete effectively with fossil fuel generation and provide benefits to the power grid. The International Energy Agency expects renewable energy resources to provide 18% of the world's power by 2030, up from 11.2% in 2019.134 However, certain renewable energy sources—such as solar and offshore/onshore wind—are dependent on weather conditions and the time of day. This means deploying these resources at scale will require accompanying battery technology to ensure electric grid reliability. [EPA-HQ-OAR-2022-0985-2429-A1, p. 35]

134 "Modern renewables," IEA, accessed June 4, 2023 https://www.iea.org/reports/sdg7-data-and-projections/modern-renewables

Energy storage allows for the integration of more intermittent resources by storing electricity until it is needed. It also augments existing energy generation by allowing excess energy to be produced when low demand is stored until demand peaks. Energy storage can provide benefits beyond emissions reduction, including cost-savings for consumers, reliability, and backup and startup power during extreme events. [EPA-HQ-OAR-2022-0985-2429-A1, p. 35]

Vistra operates the Moss Landing Energy Storage Facility in California, the largest of its kind in the world, and is pursuing an expansion that will bring 750 MW online in the second quarter of 2023.135 This facility is particularly valuable in California, where the swift transition to renewable energy, paired with a constantly growing demand for electricity, illustrates the need for reliability in the electric grid and the role energy storage can play. As of 2021, non-hydroelectric renewables provide approximately 35% of California's electricity, and electricity demand has increased due to a variety of factors, including severe weather events, widespread electrification, and electric vehicle deployment.136 This combination was put to the test in September 2022, when the state faced its most extreme September heat event in recorded history. This weather event put unprecedented strain on the electric grid and set records for electricity demand. To the surprise of many, the lights stayed on. During that event, batteries, including Vistra's Moss Landing facility, provided about 4% of supply—over 3,360 MW, more than the Diablo Canyon nuclear power plant (the state's largest electricity generator)—during the peak demand, averting rolling blackouts. A report from the California Independent System Operation (CAISO) following the September 2022 event specifically highlighted the increase in energy storage resources as a key factor that supported the grid's reliability.137 As a comparison, the August 2020 heat wave, which occurred when California's energy storage resources were few and far between, resulted in rolling blackouts over multiple days. [EPA-HQ-OAR-2022-0985-2429-A1, pp. 35 - 36]

135 "Vistra Announces Expansion of World's Largest Battery Energy Storage Facility," Vistra, accessed June 4, 2023 https://investor.vistracorp.com/2022-01-24-Vistra-Announces-Expansion-of-Worlds-Largest-Battery-Energy-Storage-Facility

136 "2021 Total System Electric Generation," California Energy Commission, accessed June 5, 2023 https://www.energy.ca.gov/data-reports/energy-almanac/california-electricity-data/2021-total-system-electric-generation

137 "California ISO posts analysis of September heat wave," California ISO, accessed June 5, 2023 http://www.caiso.com/Documents/california-iso-posts-analysis-of-september-heat-wave.pdf

Recognizing that the replacement of fossil fuel-powered assets with zero-carbon resources is not a one-to-one exchange, Vistra is working to maintain reliability by using energy storage and installing zero-carbon investments on the sites of retired or soon-to-be-retired fossil fuel plants. This also ensures that communities do not lose key energy supplies or ongoing tax revenue. Vistra is also focused on ensuring that existing zero-carbon generation remains online, such as the Comanche Peak Nuclear Power Plant in Texas, which is currently going through the Nuclear Regulatory Commission's relicensing process to continue operations through 2053. This high-performing plant is able to produce power—rain, snow, or shine—increasing grid reliability for Texans and making it a keystone generator for the Electric Reliability Council of Texas (ERCOT) grid. Alongside the transition to cleaner generation resources, Vistra has been able to maintain reliability for its consumers and ensure that individuals and businesses are able to keep their lights on, even during extreme weather events. During Winter Storm Uri in Texas in 2021, Vistra's plants produced between 25-30% of the power on the grid during the storm, far beyond its ~18% market share. [EPA-HQ-OAR-2022-0985-2429-A1, p. 36]

As the energy supply mix shifts toward low- and zero-carbon resources, energy storage will fill the reliability gap and allow that mix to evolve more reliably and flexibly. The Inflation Reduction Act provides new tax incentives for investment in energy storage technologies and resources to support the R&D of advanced and long-duration energy storage technologies. These investments will enable the deployment of utility-scale energy storage and add reliability to the grid, no matter what the future energy generation mix looks like. It is crucial that the United States continues to make the transition to a carbon-neutral economy and electric grid in a way that ensures the continued reliability of the grid at a reasonable cost to consumers. [EPA-HQ-OAR-2022-0985-2429-A1, p. 36]

3. Southern California Edison: Preparing the Grid for EV Adoption

About 40% of the nation's electric vehicles, more than 1.3 million, have been sold in the state of California. More than 430,000 of those are in SCE's service area alone. Many have expressed doubts that the grid is ready for the energy demand created by the need to charge so many EVs, but electric power companies, including SCE, are keeping up with increasing levels of adoption. [EPA-HQ-OAR-2022-0985-2429-A1, p. 36] In anticipation of growing EV demand in Southern California, SCE is continuously taking the steps to upgrade the grid and promote customers' transition to electric transportation and proactively solve near-term issues, while also undertaking long-term investments to ensure the grid is ready for all levels of anticipated electrification adoption. [EPA-HQ-OAR-2022-0985-2429-A1, p. 37]

Solving near-term challenges

One way SCE is addressing the near-term issues is its Power Service Availability (PSA) initiative for Transportation Electric service

- SCE is focusing on (1) improving its internal processes to streamline interconnection, (2) engaging fleet operators to better understand their plans for electrification, (3) improving its ability to forecast and assess the impacts of transportation electrification (TE) growth, and (4) leveraging new technologies as grid infrastructure solutions
- Because some projects require more time than others to build, SCE is encouraging fleet owners to engage with the utility early in the process so that SCE can better understand and plan for the fleets' needs [EPA-HQ-OAR-2022-0985-2429-A1, p. 37]

SCE is also improving how we partner with customers to meet their needs.

- This includes streamlining buildout, developing deeper customer engagements that include rate planning and load management education, and right-sizing grid solutions to meet the expected charging demand growth in both the near and long term. These efforts will provide more innovative and customer-focused solutions. [EPA-HQ-OAR-2022-0985-2429-A1, p. 37]

In addition to customer project deployment, SCE has also pushed to accelerate EV adoption through customer-side infrastructure programs such as Charge Ready for light-duty vehicles.

- Through its Charge Ready program, SCE installs, maintains, and covers installation costs for charging infrastructure while participants own, operate, and maintain the charging stations. For those ready to invest in EV charging for medium- and heavy-duty vehicles, SCE's Charge Ready Transport program similarly offers low- to no-cost site upgrades to support the installation. The program provides funding to help electrify semi-trucks, buses, and delivery vehicles, among others. Through its Charge Ready programs, SCE has installed more than 3,000 charging ports throughout its service area and is targeting 30,000 charging ports by 2026. [EPA-HQ-OAR-2022-0985-2429-A1, p. 37]

SCE's Transportation Electrification Advisory Services program is also available for commercial customers considering electric transportation options.

- On top of offering educational webinars and workshops, the program also offers to develop site-specific EV-readiness studies to help determine the feasibility of proposed projects and grant writing assistance to help customers secure zero-emission vehicle grants. [EPA-HQ-OAR-2022-0985-2429-A1, p. 37]

Long-term Planning and investing in the grid for TE

SCE is improving the value of EV adoption forecasts used for grid planning by assessing where, when, and how much EVs are likely to charge.

- SCE led the West Coast Clean Transit Corridor Initiative, composed of nine other electric utilities and two agencies representing more than two dozen municipal utilities, to conduct a multi-phase and multi-year research study to forecast EV truck populations and determine the proper number and size of highway charging sites. Subsequent phases of this initiative are supporting internal planning operations across the participating utilities.
- SCE developed a new forecasting approach for Medium-Duty / Heavy Duty (MDHD) vehicles for the recent General Rate Case (GRC) Application.
    - Because MDHD electrification is still nascent, current forecasting methodologies that are based (in part) on historical adoption are insufficient
    - For the GRC, SCE's new forecasting methodology leverages MDHD fleet industry data to more accurately predict MDHD electrification adoption and corresponding grid needs
    - SCE (and the IOUs) are collaborating with CPUC on a new "Freight Infrastructure Planning" (FIP) Framework to further address planning for MDHD
- SCE is working to expand the current distribution planning forecast window from 10 years to 20 years. Developing and implementing an interagency-sponsored forecast that spans 20 years for distribution will bring benefits, such as:

- Identifying long lead time projects that are needed beyond the 10-year horizon
    - Identifying important land acquisition needs
    - Informing how the development of infrastructure may need to be levelized to practically achieve the scale of development required by achieving state ZEV policies and GHG targets
- SCE has proposed robust investments in its GRC application to support TE adoption and load growth.
    - The investments proposed are designed to ensure long-lead infrastructure projects (such as new or expanded substations) will be completed when load growth arrives. The plan especially focuses on high TE locations: freight corridors, fleet hubs, Port of Long Beach, etc.
    - Specific TE-focused projects include: [EPA-HQ-OAR-2022-0985-2429-A1, p. 38.] [See Docket Number EPA-HQ-OAR-2022-0985-2429-A1, pages 38-39, for Figure of TE-focused projects]

4. Con Edison

Con Edison is helping to accelerate New York State's transition to clean transportation and EV adoption through grid and customer investments that support buildout of a widespread charging network. The Company's PowerReady Program provides incentives to connect thousands of new public and private charging stations to the electric grid. Authorized by the New York State Public Service Commission's July 2020 Order Establishing Electric Vehicle Infrastructure Make-Ready Program and Other Programs, the program offsets the electric infrastructure costs associated with installing chargers for light-duty EVs, including cars and small vans. To date, nearly 4,000 Level 2 and 175 DCFC chargers have been installed under the program, with the goal of installing 18,539 Level 2 and 457 DCFC chargers by 2025, with the potential for significant expansion of the program budget and goals as recently recommended by the New York State Department of Public Service Staff. The Company provides a similar pilot program for medium- and heavy-duty (MHD) vehicles, and a full-scale program is being considered in the recently launched New York State proceeding to address barriers to MHD charging infrastructure (MHD Proceeding). [EPA-HQ-OAR-2022-0985-2429-A1, p. 39]

Along with these infrastructure incentive programs, Con Edison also offers the SmartCharge New York managed charging program that provides incentives for personal drivers to charge outside of grid peak periods and the Company is launching a commercial managed charging program later this year including eligibility for all fleets, public stations, and multi-unit dwellings. SmartCharge New York is discussed below as an example of how managed charging can help mitigate the impact of EV charging on the grid. [EPA-HQ-OAR-2022-0985-2429-A1, p. 39]

An essential step in EV charger buildout is interconnection with the grid. Con Edison has developed dedicated teams that support the growing number of EV charging interconnections, including those that provide load evaluation, engineering review, project queue management, and incentive deployments. The Company is implementing multiple efforts to improve the customer experience and speed interconnection timelines and will continue to identify and implement efficiencies and improvements. For example, the Company provides pre-application advisory services for fleets and other customers to evaluate site feasibility and understand electric fueling costs, automates internal processes such as service rulings for smaller stations, and is coordinating with permitting agencies to identify and resolve challenges. Con Edison provides load-serving capacity maps to help those seeking to install EV charging infrastructure identify suitable sites with adequate grid capacity. [EPA-HQ-OAR-2022-0985-2429-A1, pp. 39 - 40]

While Con Edison is supporting installation of increasing numbers of EV chargers under its programs today, the Company is also working to evolve its robust planning processes to prepare for the ramp in clean transportation loads. These loads are expected to drive significant grid impacts in New York State and ambitious emissions regulations will further accelerate an already rapidly growing EV market, with the exact timing in the inflection point unknown. The timeline to install EV chargers is relatively short compared to that of other new customer infrastructure, such as a new building, while the buildout of utility-side grid infrastructure to meet the significant increase in demand from EV chargers requires longer timelines, sometimes of 5 to 7 years. A proactive grid planning process to meet near-term needs and build out the grid in advance to support long-term growth in the deployment of EVs is being considered in the New York State MHD Proceeding. Con Edison, along with other NY State Utilities, filed comments proposing a proactive utility infrastructure planning framework to prepare the grid in advance of future transportation electrification needs. [EPA-HQ-OAR-2022-0985-2429-A1, p. 40]

SmartCharge New York Managed Charging Case Study

In 2017, Con Edison launched SmartCharge New York program with the goal of instilling gridbeneficial charging behavior in parallel with the upswing in electric vehicle adoption. The goal was to influence driver behavior at the inflection point of transitioning from combustion-engine fueling to electric battery charging and have drivers default to grid-optimizing charging activity. Program participants received a free cellular-enabled device that plugs into the vehicle's diagnostic port that allowed Con Edison to track time, energy, and power consumed when charging in the utility's service territory. Incentives encourage drivers to 1) avoid charging during the system peak (2 PM to 6 PM) during summer weekdays from June to September, and 2) charge overnight from 12 AM to 8 AM. Incentives were initially paid off-bill through gift cards to the customer's business of choice, such as Amazon, Starbucks, or Home Depot. [EPA-HQ-OAR-2022-0985-2429-A1, p. 40]

As electric vehicle adoption continues to rise, managing charging behavior will grow increasingly important in maintaining a healthy and reliable grid. Since its inception, the SmartCharge New York program has evolved to meet customer needs and program objectives. Starting in 2023 for example, the program was overhauled to allow participation through a mobile application and payments are now issued through Venmo or Paypal, in line with participant feedback. This shift also changed the way the program collects data, favoring more cost-effective vehicle onboard telematics or networked electric vehicle supply equipment such as a Wi-Fi-enabled charger or charging cable. This enables the program to scale efficiently with the market and give a greater number of drivers insight into their behavior and how that activity translates to incentive earnings. [EPA-HQ-OAR-2022-0985-2429-A1, pp. 40 - 41]

In light of the EPA announcement of its heavy-duty and light/medium-duty proposed emissions standards, Con Edison released the following statement:

"Con Edison applauds the Environmental Protection Agency's efforts to rev up the market for electric vehicles, which will improve the air in the communities we serve and help in the fight against climate change. A rapid shift to mass EV adoption looks more achievable all the time, with vehicle options expanding and new charging stations being built across New York City and Westchester County, including locations that serve the needs of disadvantaged communities. Con Edison will continue to support the EV market's development through investment in the grid and by offering a range of programs, from incenting new chargers to managing the grid impact by rewarding drivers for charging overnight."138 [EPA-HQ-OAR-2022-0985-2429-A1, p. 41]

138 "Con Edison Supports Effort to Encourage Electric Vehicle Adoption," Con Edison Media Relations, (April 12, 2023) accessed June 5, 2023 https://www.coned.com/en/about-us/media-center/news/2023/04-12/con-edison-supports-effort-to-encourage-electric-vehicle-adoption

5. SRP

When EVs were still in the early stages of adoption, SRP recognized the importance of exploring ways to identify EV households and analyze their charging behavior in order to help prepare for greater EV uptake in the future. It was also important to begin engaging customers who were EV drivers in order to understand their interests and their charging patterns and assess ways to influence charging behaviors. [EPA-HQ-OAR-2022-0985-2429-A1, p. 41]

In 2014, SRP launched "EV Community" (EVC)—a program that offers customers a $50 bill credit for each EV they register (up to two vehicles per household)—as a means to incentivize EV drivers to identify themselves and engage with SRP. Participants provide basic information about the electric vehicle and the type of charger they use. This provides a way for SRP to learn more about EV customers and their charging behavior and needs while offering them an incentive to help support EV growth in the region. There are currently more than 7,500 customers enrolled in the program. [EPA-HQ-OAR-2022-0985-2429-A1, p. 41]

While EVC members only account for a small number of total EV households, they are a fair overall representation of the EV customer base since all price plans are included, as well as households with one vs. two EVs. The program offers SRP a good platform for analysis, including the type of cars they drive (PHEV, BEV, brand, etc.) and the charge levels they use. In addition, SRP found that EVC members are willing to share information and are eager to participate in future pilot programs. [EPA-HQ-OAR-2022-0985-2429-A1, p. 42]

The EVC program also provides SRP with a method and channel to promote their Electric Vehicle Price Plan, a special time-of-use pricing plan which offers EV drivers the most opportunity to save on EV charging costs by charging during super off-peak times (between 11 PM and 5 AM). Load research has shown that this program has been highly effective at shifting EV charging loads away from peak periods. [EPA-HQ-OAR-2022-0985-2429-A1, p. 42]

The EVC program has helped SRP plan and prepare the grid for widespread EV adoption by enabling them to:

- Anticipate load growth. A pilot study with EVC members that monitors their EV driving and charging behavior through data telematics devices enables SRP to estimate typical consumption and charging load profiles per EV.
- Understand the impacts of EV charging on the grid. EVC data is used to model the impacts of EV charging on the electric grid, identify when transformers and wires may need to be upgraded, and understand when and how customers need to charge.

- Recruit for Managed Charging pilot programs. The EVC program and channel have enabled SRP to recruit participants for additional Managed Charging pilot programs to test other active control technologies to control EV charging load on the grid.
- Survey participants for insights. EVC members are surveyed regularly to get more data on their charging behaviors, including their use of home, workplace, and public charging and their satisfaction with EVs overall.
- Engagement. EVC participants receive regular newsletters and other communications with EV-related information. [EPA-HQ-OAR-2022-0985-2429-A1, p. 42]

6. Duke Energy

Electric fleet commitments are increasing as companies with ambitious sustainability goals work to decarbonize operations. Fleet owners are also seeking ways to take advantage of the cost savings available by transitioning to EVs. However, programs for fleet electrification and managed charging options are still limited to date. [EPA-HQ-OAR-2022-0985-2429-A1, p. 42]

When transitioning to an electric fleet, it is important that fleet managers understand the full scope of charging multiple vehicles while maintaining fleet operations and that larger MHDVs bring with them additional factors to consider. Fleet owners who have electrified fleets without consulting experts or an electric provider have likely been experiencing avoidable operational and technological issues. Long-term energy cost and performance risk are also potential issues for fleets and can hinder mainstream fleet electrification technology development if not managed correctly. [EPA-HQ-OAR-2022-0985-2429-A1, pp. 42 - 43]

Duke Energy's significant experience and large customer base make it well-positioned to design and implement fleet electrification and charging programs. Duke Energy is building a first-of-its-kind performance center that will model and accelerate the development, testing, and deployment of zero-emission light-, medium-, and heavy-duty commercial electric vehicle EV fleets. The site will be located in North Carolina at Duke Energy's Mount Holly Technology and Innovation Center and incorporate microgrid integration. [EPA-HQ-OAR-2022-0985-2429-A1, p. 43]

The fleet electrification center will provide a commercial-grade charging experience for fleet customers evaluating or launching electrification strategies—reinforcing reliability, clean power, and optimization by integrating solar, storage, and microgrid controls software applications. The center will be connected to both the Duke Energy grid—charging from the bulk electric system—and to 100% carbon-free resources through the microgrid located at Mount Holly. This project is the first electric fleet depot to offer a microgrid charging option. [EPA-HQ-OAR-2022-0985-2429-A1, p. 43]

In addition to fleet charging, the site will also function as an innovation hub, allowing Duke Energy to collect data around charger use, performance, management, and energy integration with various generation resources. It will also allow for the development of managed charging algorithms for fleets connected to the bulk power system or integrated with renewables and storage—which can be utilized to minimize the upgrades needed to the distribution system, easing the transition to electrifying fleets. Identifying EV charging technologies and how they may be used to power any type of fleet with vehicles (ranging from class 1) will help develop a model to show the industry a clear, integrated, and cost-effective path to fleet electrification. [EPA-HQ-OAR-2022-0985-2429-A1, p. 43]

Duke Energy is teaming up with Daimler Truck North America and Electrada on this important work. Electrada, an electric fuel solutions company, is providing funding for research and demonstration efforts. For fleets seeking to electrify, Electrada invests all required capital “behind the meter” and delivers reliable charging to the fleet’s electric vehicles through a performance contract, eliminating the complexity and risk that fleets face in transitioning to this new source of fuel. Electrada’s investment in the depot allows Duke Energy to focus on programs that simplify adoption for electric fleet customers and distribution system performance to support the predictable addition of electric load over time. [EPA-HQ-OAR-2022-0985-2429-A1, p. 43]

By the end of 2023, fleet operators will be able to experience a best-in-class, commercial-grade fleet depot integrated with energy storage, solar, and optimization software. Moving to zero-emission vehicles in this sector allows North Carolina to seize the large economic potential of the transition and generate billions in net benefits for the state. Projects like Duke Energy’s fleet performance center will be key for fleet owners across the state to take advantage of the cost savings of transitioning to electric vehicles. That said, fleet owners exploring electrification should engage their electricity provider early and often to identify and address site-specific considerations. As fleet electrification accelerates, it will be important for electricity providers and policymakers to identify best practices to proactively plan for fleet electrification, including readying the distribution grid. [EPA-HQ-OAR-2022-0985-2429-A1, pp. 43 - 44]

7. Xcel Energy

Xcel Energy is committed to electrifying all of its light-duty fleet and 30% of its medium and heavy-duty fleet by 2030, equating to over 2,500 EVs. It’s part of their vision to be a net-zero energy provider by 2050 and enable one out of five vehicles to be electric in the areas they serve by 2030. This will save customers $1 billion annually on fuel by 2030 and deliver cleaner air for everyone. [EPA-HQ-OAR-2022-0985-2429-A1, p. 44]

With a fleet that includes iconic bucket trucks, all-terrain service vehicles, and a host of pickup trucks and pool cars across eight states, achieving these goals will be no small feat, but an important one. There are notable hurdles, yet evolving technology presents solutions. [EPA-HQ-OAR-2022-0985-2429-A1, p. 44]

Electrifying the Marquee Fleet Vehicle

Xcel Energy is the first electric provider in the nation to add an all-electric bucket truck to its fleet. The truck features two electric sources: one for the drivetrain and one for the lift mechanism. It has a 135-mile driving range and can operate the bucket for an entire workday on a single charge. Crews are collecting data from real working conditions in Minnesota and Colorado that will be used to inform further improvement to the vehicle’s technology and operation. [EPA-HQ-OAR-2022-0985-2429-A1, p. 44]

Optimizing Charging to Minimize Grid Impacts

To support a growing electric fleet, over 1,200 EV chargers must be brought into service by 2030, which will result in an electric load increase of 71 megawatts. Charge management techniques enable low-cost charging for this growing electric fleet. It’s a sophisticated approach to optimize charging times by using time-of-day and grid demand efficiencies and builds on the expertise Xcel Energy has developed through offering managed charging programs to customers in multiple states. [EPA-HQ-OAR-2022-0985-2429-A1, p. 44]

For fleets, overnight charging schedules make the most sense. Demand and rates are lower, and renewable wind sources are ample at that time. Yet, fast charging outside of these time periods may be required to help larger vehicles make it through a workday. This is when charging schedules need to be customized and highly specific. [EPA-HQ-OAR-2022-0985-2429-A1, p. 45]

Enabling Cleaner Service Calls Through Bucket Truck Technology

Xcel is also taking immediate action on other high-impact emission reduction opportunities, using technologies such as electric power take-off, idle mitigation, and solar systems to power jobsite tools.

- Electric power take-off (ePTO) - An ePTO system is a device that uses battery power. It's similar to an EV, but instead of moving the vehicle down the road, it powers equipment and tools to avoid engine idling at the job site. These devices are recharged by plugging into the same chargers that EVs use.
- Idle mitigation - An idling truck can consume 1.5 gallons of gas each hour. Idle mitigation on Xcel Energy's utility bucket trucks works by automatically shutting down the gas-powered engine when the vehicle is not in use or when the engine is idling for too long. This helps to reduce emissions and conserve fuel. [EPA-HQ-OAR-2022-0985-2429-A1, p. 45]

Fleet Electrification Solutions for Customers

Xcel Energy's experience and expertise with fleet electrification doesn't stop with their own fleet. They have developed a mix of customer programs across service areas to support fleet electrification for businesses and communities. These customer-centric solutions enable sophisticated planning, lower upfront costs with various rebates and incentives, and minimize impacts to the grid. [EPA-HQ-OAR-2022-0985-2429-A1, p. 45]

Xcel's approach for commercial EV fleet development includes:

- Advisory services: Xcel offers a "white-glove service" to meet customers where they are on their electrification journey by guiding them through customized planning for their infrastructure needs. For fleet operators, this includes a free assessment to help them determine the best path to electrify their fleet and advise them on future electric fleet considerations such as charging best practices.
- Infrastructure installation: Xcel designs and builds EV supply infrastructure to support charging station installations at minimal to no cost to customers.
- Equipment recommendations and rental options: Xcel also provides recommendations for charging equipment and offers customers the option to purchase their own qualifying vehicle chargers or rent them at a monthly fee that includes installation and maintenance.
- Grid continuity: Xcel designs long-term clean energy resource and distribution plans to consider the future impact of new EV load to ensure ongoing grid stability, reliability and affordability.
- Equitable opportunities: Xcel supports EV adoption in higher emissions communities and income-qualified neighborhoods through rebates and incentives. This includes facilitating

the electrification of carshare, refuse trucks, school buses, paratransit vehicles, and other fleets operating in these disproportionately impacted communities. [EPA-HQ-OAR-2022-0985-2429-A1, pp. 45 - 46]

Fleet electrification is a key component of Xcel Energy's larger vision, which includes enabling zero-carbon transportation by 2050 across our eight-state service footprint. This long-term strategy balances affordability with sustainability across the entire grid. It's why Xcel is dedicated to assisting fleet managers across the ecosystem in providing fleet electrification solutions that empower and inspire a clean energy future while also leading by example. [EPA-HQ-OAR-2022-0985-2429-A1, p. 46]

iii. Transmission

A critical part of ensuring a smooth transition to an electrified heavy-duty sector will be a robust build out of high-voltage transmission lines. Doing so will also enable increased penetration of renewables into the grid mix, helping to further improve the environmental and climate benefits of electric vehicles. While progress in this space has historically been slow and bogged down by procedural delays, there are some signs of progress. In April 2023, the U.S. Bureau of Land Management approved a 732-mile transmission line, which will carry wind energy from Wyoming through to Nevada.139 Also in April 2023, a Maine court granted approval to restart work on the 145-mile New England Clean Energy Connect project, which will carry hydropower from Canada to New England.140 The line is expected to carry up to 1,200 megawatts of power. [EPA-HQ-OAR-2022-0985-2429-A1, p. 46]

139 "US approves $3bn Wyoming-Nevada power line," (April 12, 2023) accessed May 15, 2023 https://www.power-technology.com/news/us-approves-3bn-wyoming-nevada-power-line/#:~:text=The%20US%20BLM%20has%20given,blustery%20Wyoming%20through%20to%20Nevada.&text=US%20officials%20on%20Tuesday%20gave,running%20from%20Wyoming%20to%20Nevada

Electricity transmission is also a key focus of the Biden-Harris Administration. In May 2023, the administration published its plan to decrease permitting timelines for new transmission projects, among other key items.141 Also in May 2023, the U.S. Department of Energy proposed a rule on designating National Interest Electric Transmission Corridors.142 There will also be a role for Congress to play in improving transmission permitting times and this is a policy area where some bipartisan support exists. 142 88 FR 30956

EPA Summary and Response:

Summary:

EPA received many comments about the nation's power supply and its ability to support the demand from increased adoption of HD BEV (AFPM, EC, EDF). CFDC focused concern on the power demand of HD plus LD BEV while power plant policy is proposed that could reduce electricity supply and increase cost. AFPM, Arizona State Legislature, Clean Fuels Development Coal., National Ass'n of Rural Electric Cooperatives stated that EPA had failed to account for the combined impact of various EPA rules when assessing the issue of grid reliability (adequacy). These rules (many of which are proposed) include not only the parallel rule concerning GHG emission standards from LDV, but also the proposed rule for CO2 emissions from electricity generating units, the cross-state air pollution rule, the proposed rule for discharge to navigable waters for steam electric units (Clean Water Act), and the proposed rule to control leakage and other releases from of historic surface impoundments used to manage waste from coal combustion (Resource Conservation and Recovery Act). Some commenters stated that our power supply has insufficient margin now and that increased demand from this policy and other energy related policy actions drive additional risk. ASL shares FERC concern that dispatchable energy could be removed from the grid too quickly. NTEA focused on the long lead times for adding power generation and questioned if the policy adoption rates can be supported. Concerns were raised regarding the power supply quantity, quality, stability, and transmission losses.

Many responses referenced reports by NERC (North American Electric Reliability Corporation) and specific comments on summer 2023 reserve margins (AFPM, ASL, CFDC, TRALA, Valero). Valero also shares NERC's concern with winter 2022/2023 reliability and NERC's 2022 long term reliability assessment. AFPM also points out that regional issues exist as the southwest US appears most at risk when generation capacity is compared to BEV load added. Commenters maintained that the power increase to support HD BEVs is not 2.8% as estimated by EPA but was higher, some values going as high as 14% (Arizona State legislature, ATA per ATRI) and 40% power increase for LD plus HD. Note: ATRI 14% and 40% is driven by full fleet electrification (100% adoption) which is significantly higher than the EPA adoption scenario. NRECA asserted that generation needs to increase 170% along with a three-fold increase in the transmission grid by 2050 (although this is total anticipated need, not need attributable to the proposed vehicle GHG standards). Valero states that past success with increasing power generation, including the increase of 25% in the near past in a period comparable to the roll out of the Phase 3 rule cited by EPA, are not analogous since those improvements were enabled by inexpensive natural gas which is no longer an option due to emissions restrictions. AFPM raises concern with adding generation capacity quickly enough due to time for permitting and approvals, supply chain issues, and availability of skilled workers. Other commenters agreed that the power needed for an HD Phase 3 rule is a relatively small share of the national electricity demand, that the annual demand growth is same or less than the last few decades, and that power generating capacity will not be a constraint. These comments came from the electric utility sector (EEI), from regulated entities themselves (DTNA, EMA), from NGOs (EDF, MFN, CATF), and from affected States (CARB). CATF analysis shows the HD BEV proposal (NPRM) to drive 0.5% average annual load growth while the 31 years up to 2021 has seen 1,1 percent growth with 10 of those years over 2% growth. Thus, EMA stated "[t]he overall impact of MDHV charging demand on the grid is minimal and is well under forecasted margins published in the NREC Long-Term Reliability Assessment from December 2022. "EMA Comments at Exh. 1 p. 29. EEI states that "Electricity companies can accommodate increased demand" attributable to the modest EV growth projected in the rule. Daimler states that it "generally agrees with EPA's assessment that scale-up of electric power generation is not likely to significantly limit the development of BEV electric vehicle charging infrastructure." (Daimler did, however, estimate increased demand on the national grid attributable to the proposed rule slightly larger than EPA's estimate—3.9% above 2021 levels rather than the 2.8% EPA estimated.) To the same effect, see Comments of Advance Energy United, Electrification Coalition, ZETA. These commenters posited modest increase in demand on the national grid attributable to the proposed rule (1% over 2021 grid demand) (ICCT) to 3.9% (DTNA). They indicated that these increases were modest in comparison with historic increases in grid capacity. While CARB agrees that HD BEV demand can be met, they recognize that private utilities, government, and public utilities commissions will need to work together and be cognizant of all new demand to ensure that adequate power is available. MFN was not concerned with power delivery but rather the carbon intensity of the power being supplied. MFN highlights the need for sustainable power across the US to ensure that HD BEV use is delivering net benefits. ZETA supported the deployment of renewable energy resources as well as nuclear, carbon capture, and green hydrogen. Comments by MFN regarding projected emissions from electricity generation are covered in RTC 13, health benefits in RTC 15, and LCA in RTC 17. Energy Innovation shared analysis (Drive Clean Scenario) that specifies what a 90 percent clean grid looks like that would be capable of handling 2% annual demand growth. They found, "the U.S. would need to install on average 105 GW of new wind and solar and 30 GW of new battery storage each year—nearly four times the current deployment rate. Even with additional electric loads in the DRIVE Clean Scenario, grid modeling found a 90 percent clean grid would be dependable without coal plants or new natural gas plants by 2035. The grid model also found that during normal periods of generation and demand, wind, solar, and batteries provide 72 percent of total annual generation, while hydropower and nuclear provide 16 percent… The increased electrification and pervasive renewable energy and battery storage deployments require investments mainly in new transmission spurs connecting renewable generation to existing high-capacity transmission, rather than new investments in bulk transmission".

AEU, ESC, ZETA pointed to potential measures to assist generation by reducing peak demand, such as time of use rates, managed charging, demand response technologies, stationary batteries, and vehicle-to-grid technologies. Advanced Energy Solutions, CARB, Energy Innovation, Energy Strategy Coalition mentioned utilities are investing in part because of benefits EVs "can provide to grid reliability". Other comments (EC, ESC, EDF) likewise promote HD BEV as a way to support the grid during times of shortfall or shutdown by using V2G. These comments promote HD BEV as assisting with peak power, backup power, or simply freeing up power with charging flexibility.

A smaller number of commenters like AFPM maintain that there could also be shortages of electricity transmission capacity. NAM asserts that, per a draft DOE report, the electrical transmission infrastructure would need to grow 57% for LD, MD, and HD BEV. Commenters AFPK and National Rural Electrical Cooperative Ass'n raised concerns such as a threefold increase in transmission by 2050. AFPM raises concern that required infrastructure may not be available by 2027. They shared data from DOE that the time for a typical interconnection project, from initial request to commercial operation, is 5 years. EDF's report from Analysis Group showed that the small growth needed would not be an issue for the transmission infrastructure. Commenter ZETA, pointed to recent regulatory actions approving several large-scale regional transmission expansions, plus Administration actions to expedite such expansions. MFN reports that MISO is working on total energy needs and timing of annual peaks that could change due to HD BEV adoption.

Response:

A. Response to Comments Relating to Overall Demand and Reliability

EPA performed emissions and power modeling with MOVES as described in RIA Chapter 4.2. HD BEV adoption rates (aligned with the modeled potential compliance pathway) are applied to determine future power demand. This power demand is distributed geographically based on current registrations and future expectations due to external forces like ACT. MOVES supports granularity down to the county level. Power demand as determined by MOVES is then input to IPM to determine how the power will be generated and transmitted. IPM takes into consideration EGU additions and retirements. Concerns with specific geographic areas (like that expressed by AFPM) are addressed as IPM showed all areas to have adequate generation and transmission. IPM also understands that reserve margins must be maintained to protect grid adequacy. The power demand increase from HD BEVs will be at levels that have been handled by the electricity power sector for decades.

EPA acknowledges the quantified estimates from the utility industry, regulated entities, NGOs, and other expert commenters, all of which corroborate EPA's conclusion that demand from the Phase 3 rule is minimal and does not pose issues of grid reliability. Moreover, all of these entities provided quantified estimates of demand which are quite similar to EPA's. Note further that these estimates are for 2055, when there has been full fleet turnover and hence maximum demand impact on the grid. The increased demand as the Phase 3 program commences is roughly an order of magnitude less. See RTC Section 7 (Distribution) above; that same section documents that there also will be only minor incremental increases in daily demand attributable to standards somewhat more stringent from the standpoint of energy demand than the Phase 3 rule. EPA agrees with this assessment from the Energy Strategy Coalition (speaking for some of the nation's largest utilities, public power authorities and generators of electricity from renewable, nuclear, and gas-fired sources): "[d]emand for electricity will increase under both the HDV Proposal and recently-proposed multi-pollutant standards for light-duty and medium-duty vehicles ("LMDV Proposed Rule"), but the electricity grid is capable of planning for and accommodating such demand growth and has previously experienced periods of significant and sustained growth." The Edison Electric Institute, the trade association for the nation's investor-owned utilities, agrees: "As EPA also notes, the increase in electricity use resulting from the Proposed Rule also will be modest, increasing electricity end-use by less than 3 percent in 2055. On a macro-level, meeting the increased energy usage from electric truck adoption as contemplated in the Proposed Rule will not be a significant challenge for the electric power sector." [577] Moreover, this comment, as well as the others summarized above, evaluated the impact of EPA's proposed rule, which in its initial model years was somewhat more stringent than the final rule; demand on the grid is correspondingly slightly lower with the final rule. EPA further believes that these comments from the electric utility industry representatives serve as a response to commenter Valero, which comment posited that historic growth rates were predicated on availability of inexpensive natural gas, and that similar historic growth should not be assumed.

EPA also notes that many of the comments appear to discuss general information about the grid as opposed to impacts of the Phase 3 Rule, and therefore are of limited, if any relevance. For example, NRECA's claim of a 170% increase by 2050 appears to reflect their estimate of total

[577] Comments of Edison Electric Institute at 7.

demand increases across the entire economy, not demand associated with this rule. ATA and ATRI's estimate of 14% increase due to heavy-duty BEVs and 40% due to light- and heavy-duty BEVs reflects estimate in total demand associated with all 267 million light- and heavy-duty vehicles in the light- and heavy-duty fleets being electrified, as opposed to the orders of magnitude less electrification in the EPA modeled compliance pathways.[578] NERC reviews of our national and regional power supply, which do not directly address issues associated with vehicle electrification and any associated grid impacts, continue to appropriately identify issues and identify government and industry actions that can mitigate national power supply risk. Similarly, the testimony by a FERC Commissioner referenced in several comments (Transfer Flow, ASL) did not address potential grid impacts from electrification in the transportation sector and so is not directly relevant to the issues discussed here of demand posed by EPA transportation sector and other rules affecting the grid, or to EPA's analysis thereof.

As EPA noted at proposal, and as many commenters emphasize, many opportunities exist for optimization due to placement of both distributed and dispatchable power sources, as well as stationary batteries as the nation adds power supply. EPA notes the comment of the Energy Strategy Coalition that these measures create a distinct incentive for utility investment. EPA notes further that its estimate of grid demand is conservative because EPA included only the most basic of mitigative measures.

B. Response to Comments Relating to Impact of EPA Vehicle Rules and other Potential EPA Rules Affecting the Power Sector

EPA has also carefully evaluated the potential impact on grid resource adequacy or reliability posed by various recent and projected EPA rules implementing the Clean Air Act: the LDMD multi-pollutant rule establishing GHG and criteria pollutant emission standards for light and medium duty vehicles, proposed emission limits and guidelines for CO2 emissions from new and existing fossil-fueled fired electricity generating units (CAA section 111 (d))(proposed), the cross-state air pollution rule (CAA section 110 (a)(2)(D)) (88 FR 36654) (June 5, 2023)(final)), and the Mercury and Air Toxics Risk and Technology Review proposed rule (section 112 (d)(6)).[579] In response, we used power sector modeling to estimate emissions from electric power plants for loads associated with vehicle electrification as well as to assess generation resource adequacy and grid reliability of the rapidly-transitioning electric grid. For resource adequacy, we considered the combined projected resource adequacy impacts of this Phase 3 rule

[578] ATRI, Charging infrastructure Challenges for the U.S. Electric Vehicle Fleet (Dec. 2022) at 16-17.

[579] Commenters also referred to the proposed rule for management of coal combustion residuals under subtitle D of the Resource Conservation and Recovery Act. This proposed rule would only apply to residuals managed in inactive surface impoundments at inactive electric utilities; to closed surface impoundments, closed landfills and inactive landfills at operating utilities; and closed landfills and to inactive landfills at sites with a legacy surface impoundment at utilities not generating power. 88 FR 31982, 31984 (May 18, 2023), No closures are projected for the proposed rule for those operating facilities that would be affected. 88 FR at 32028-29..At this preliminary stage, EPA does not see that this rule (assuming it is finalized as proposed) would have any adverse impact on grid reliability or resource adequacy.

Commenters also referred to the proposed rule implementing sections 301 and 304 of the Clean Water Act, which proposed rule would further limit discharge of toxic metals and other pollutants from coal-fired power. 88 FR 181824 (March 29, 2023). EPA projected a single plant closure attributable to this proposed rule (assuming it is finalized as proposed). 88 FR at 18834. At this preliminary stage, EPA does not see that this rule would have adverse impacts on grid resource adequacy or reliability. Our IPM modeling, described in the text, also reflects this proposed rule and EPA's Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles (LMDV))) (collectively "Vehicle Rules") to demonstrate that the impacts of both the Vehicle Rules alone and combined with other anticipated EPA actions related to the EGU sector "Power Sector Rules" result in anticipated power grid changes that adversely affect resource adequacy or grid reliability. .

Specifically, we considered whether the Vehicles Rules alone and combined with the Power Sector Rules would result in anticipated power grid changes such that they 1) respect and remain within the confines of key National Electric Reliability Corporation (NERC) assumptions, [580] 2) are consistent with historical trends and empirical data, and 3) are consistent with goals, planning efforts and Integrated Resource Plans (IRPs) of industry itself.[581] We demonstrate that the effects of EPA's vehicle and power sector rules do not preclude the industry from meeting NERC resource adequacy criteria or otherwise adversely affect resource adequacy. This demonstration includes explicit modeling of the impacts of the Vehicle Rules, an additional quantitative analysis of the cumulative impacts of the Vehicles Rules and the Power Sector Rules, as well as a review of the existing institutions that maintain grid reliability and resource adequacy in the United States. We conclude that the Vehicles Rules, whether alone or combined with the Power Sector Rules, satisfy these criteria and are unlikely to adversely affect the power sector's ability to maintain resource adequacy or grid reliability.

Beginning with EPA's modeling of the Vehicle Rules, we used EPA's Integrated Planning Model (IPM), a model with built-in NERC resource adequacy constraints, to explicitly model the expected electric power sector impacts associated with the two vehicle rules. IPM is a state-of-the-art, peer-reviewed, multi-regional, dynamic, deterministic linear programming model of the contiguous U.S. electric power sector. It provides forecasts of least cost capacity expansion, electricity dispatch, and emissions control strategies while meeting energy demand and environmental, transmission, dispatch, and resource adequacy constraints. IPM modeling we conducted for the Vehicle Rules includes in the baseline all final rules that may directly impact the power sector, including the final Good Neighbor Plan for the 2015 Ozone National Ambient Air Quality Standards (NAAQS), 88 FR 36654 (August 4, 2023).

EPA has used IPM for over two decades, including for prior successfully implemented rulemakings, to better understand power sector behavior under future business-as-usual conditions and to evaluate the economic and emissions impacts of prospective environmental policies. The model is designed to reflect electricity markets as accurately as possible. EPA uses the best available information from utilities, industry experts, gas and coal market experts, financial institutions, and government statistics as the basis for the detailed power sector

---

[580] NERC was designated by FERC as the Electric Reliability Organization (ERO) in 2005 and, therefore, is responsible for establishing and enforcing mandatory reliability standards for the North American bulk power system. Resource Adequacy Primer for State Regulators, 2021, National Association of Regulatory Utility Commissioners (https://pubs.naruc.org/pub/752088A2-1866-DAAC-99FB-6EB5FEA73042).

[581] Our analysis of the proposed Power Sector Rules is based on the modeling conducted for proposals. We believe this analysis is a reasonable way of accounting for the cumulative impacts of our rules affecting the EGU sector, including the proposed Power Sector Rules, at this time. Our cumulative analysis of the Vehicles and Power Sector Rules supports this final rule, and it does not reopen any of the Power Sector Rules, which are the subject of separate agency proceedings. Consistent with past practice, as subsequent rules are finalized, EPA will perform additional power sector modeling that accounts for the cumulative impacts of the rule being finalized together with existing final rules at that time.

modeling in IPM. The model documentation provides additional information on the assumptions discussed here as well as all other model assumptions and inputs. EPA relied on the same model platform at final as it did at proposal, but made substantial updates to reflect public comments. Of particular relevance, the model framework relies on resource adequacy-related constraints that come directly from NERC. This includes NERC target reserve margins for each region, NERC Electricity Supply & Demand load factors, and the availability of each generator to serve load across a given year as reported by the NERC Generating Availability Data System. Therefore, the model projections for the Vehicle Rules are showing compliance pathways respecting these NERC resource adequacy criteria. These NERC resource adequacy criteria are standards by which FERC, NERC and the power sector industry judge that the grid is capable of meeting demand. Thus, we find that modeling results demonstrating that the grid will continue to operate within those resource adequacy criteria supports the conclusion that the rules will not have an adverse impact on resource adequacy, which is an essential element of grid reliability.

EPA also considered the cumulative impacts of the Vehicle Rules together with the Power Sector Rules, which as noted above are several recent proposed rules which would regulate the EGU sector. In a given rulemaking, EPA does not generally analyze the impacts of other proposed rulemakings, because those rules are, by definition, not final and do not bind any regulated entities, and because the agency does not want to prejudge separate and ongoing rulemaking processes. However, some commenters on this rule expressed concern regarding the cumulative impacts of these rules when finalized, claiming that the agency's failure to analyze the cumulative impacts of the Vehicle Rules and its EGU-sector related rules rendered this rule arbitrary and capricious. In particular, commenters argued that renewable energy could not come online quickly enough to make up for generation lost due to fossil sources that may retire, and that this together the increasing demand associated with the Vehicle Rules would adversely affect resource adequacy and grid reliability. EPA conducted additional analysis of these cumulative impacts in response to these comments. Our analysis finds that the cumulative impacts of the Vehicle Rules and Power Sector Rules is associated with changes to the electric grid that are well within the range of fleet conditions that respect resource adequacy, as projected by multiple, highly respected peer-reviewed models. In other words, taking into consideration a wide range of potential impacts on the power sector as a result of the IRA and Power Sector Rules (including the potential for much higher variable renewable generation), as well the potential for increased demand for electricity from both this rule and the Phase 3 Heavy-Duty GHG rule, EPA found that the Vehicle Rules and proposed Power Sector Rules are not expected to adversely affect resource adequacy and that EPA's rules will not inhibit the industry from its responsibility to maintain a grid capable of meeting demand without disruption. [582]

Finally, we note the numerous are existing and well-established institutional guardrails at the federal- and state-level, as well as non-governmental organizations, which we expect to continue to maintain resource adequacy and grid reliability. These well-established institutions – including the Federal Energy Regulatory Commission (FERC), state Public Service Commissions (PSC), Public Utility Commissions (PUC), and state energy offices, as well as NERC and Regional Transmission Organization (RTO) and Independent System Operator (ISO) – have been in place for decades, during which time they have ensured the resource adequacy and reliability of the

[582] See "Resource Adequacy Analysis Technical Memorandum for Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles - Phase 3 ," available in the docket for this rulemaking.

electric power sector. As such, we expect these institutions to continue ensuring that the electric power sector is safe and reliable by ensuring that owners of electric power generators will not retire electric power plants in a haphazard or disruptive manner. We also note that EPA's proposed Power Sector rules include built-in flexibilities that accommodate a variety of compliance pathways and timing pathways, all of which helps to ensure the resource adequacy and grid reliability of the electric power system.[583] In sum, the power sector analysis conducted in support of this rule indicates that the Vehicle Rules, whether alone or combined with the Power Sector Rules, are unlikely to affect the power sector's ability to maintain resource adequacy and grid reliability.[584]

C. Response to Comments Relating to Impacts on Transmission

With respect to new transmission, the need for new transmission lines associated with the LMDV and HDP3 rules between now and 2050 is projected to be very small, approximately one percent or less of transmission. Nearly all of the projected new transmission builds appear to overlap with pre-existing transmission line right of ways (ROW), which makes the permitting process simpler. Approximately 41-percent of the potential new transmission line builds projected by IPM have already been independently publicly proposed by developers. The approximate regional distribution of the potential new transmission line builds are:

- 24% in the West (excluding Southern California), which are largely Federal lands, that are more-easily permittable for new transmission builds;
- 21% in the desert Southwest, which are largely Federal lands, that are more-easily permittable for new transmission builds;
- 14% in the Midwest;
- 9% for each of the Northeast, Mid-Atlantic, and Southeast and Mid-Atlantic regions; and
- 5% for each for Southern California and New York State/City regions.[585]

We note further that with respect to impacts on transmission, the federal government has limited authority to direct transmission system planning, although there are a myriad of programs and efforts underway that will help support improvements to the grid and provide reliability benefits. While there is congestion and delays in transmission buildout, utilities and other actors have other ways to improve reliability, by deploying Grid Enhancing Technologies (GET) and Storage As Transmission Asset (SATA).

For example, two 230-kV transmission lines used by PPL Electric Utilities, in Pennsylvania, were found to be approaching their maximum transmission capacity in 2020. As a result, the utility paid more than $60 million in congestion fees in the winters of 2021-2022 and 2022-2023. Rather than rebuilding or reconductoring the two transmission lines, which would have cost tens of millions of dollars, the utility spent under $300 thousand installing dynamic line rating (DLR) sensors, which helped the utility to rebalance each of the two transmission lines and allowed them to reliably carry an additional 18 percent of power [586]

[583] As noted above, EPA is not prejudging the outcome of any of the Power Sector Rules.
[584] "Resource Adequacy Analysis Technical Memorandum for Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles - Phase 3" available in the docket for this rulemaking.
[585] See Multi-Pollutant Emission Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Regulatory Impact Analysis at 5-22 (2024).
[586] PPL's Dynamic Line Ratings Implementation: https://www.energypa.org/wp-content/uploads/2023/04/Dynamic-Line-Ratings-H-Lehmann-E-Rosenberger.pdf

DOE recently announced several programs and projects to reduce transmission congestion include the interconnection queue backlog.[587] Examples of such programs and projects include DOE's Interconnection Innovation e-Xchange (i2X), which aims to increase data access and transparency, improve process and timing, promote economic efficiency, and maintaining grid reliability; FERC Order 2023, discussed in an earlier comment response, which provides generator interconnection procedures and agreements to address interconnection queue backlogs, improve certainty, and prevent undue discrimination for new technologies; and DOE's Grid Resilience and Innovation Partnerships (GRIP) program,[588] with $10.5 billion in Bipartisan Infrastructure Law funding to develop and deploy Grid Enhancing Technologies (GET), such as Dynamic Line Ratings (DLR) and Advanced Power Flow Controllers (APFC). To facilitate upgrading and rebuilding transmission lines, DOE issued a Notice of Proposed Rulemaking to update its National Environmental Policy Act ("NEPA") implementing regulations. DOE also conducted the National Transmission Planning Study to designate areas experiencing electricity transmission constraints or congestion as National Interest Electric Transmission Corridors (NIETCs). In February 2024, DOE announced a Request for Proposals (RFP) for the second round of the Transmission Facilitation Program, a revolving fund supported by the Bipartisan Infrastructure Law to help overcome financial hurdles facing large-scale new and upgraded transmission lines.

The capacity of existing electric power transmission lines can also be increased by a process known as reconductoring, in which existing transmission lines, typically with steel cores, are replaced with higher capacity composite conductors. Since the process makes use of existing transmission towers, it typically does not require additional rights of way. As such, new generation capacity can be rapidly added, which serves to improve resource adequacy. For example, American Electric Power, a Texas-based transmission utility, replaced the aging conventional conductors of a 240 miles transmission line with advanced composite core conductors from 2012-2015[589] The reconductoring resulted in an approximate doubling of the previous transmission line capacity and was accomplished while the 345-kilovolt transmission lines remained energized.[590]

Energy storage projects can also be used to help to reduce transmission line congestion and are seen as alternatives to transmission line construction in some cases.[591] These projects, known

as Storage As Transmission Asset (SATA),[592] can help to reduce transmission line congestion, have smaller footprints, have shorter development, permitting, and construction times, and can be added incrementally, as required. Examples of SATA projects include the ERCOT Presidio Project,[593] a 4 MW battery system that improves power quality and reducing momentary outages due to voltage fluctuations, the APS Punkin Center,[594] a 2 MW, 8 MWh battery system deployed in place of upgrading 20 miles of transmission and distribution lines, the National Grid Nantucket Project,[595] a 6 MW, 48 MWh battery system installed on Nantucket Island, MA, as a contingency to undersea electric supply cables, and the Oakland Clean Energy Initiative Projects, a 43.25 MW, 173 MWh energy storage project to replace fossil generation in the Bay area. [596],

FERC has issued various orders to address interconnection queue backlogs, improve certainty, and prevent undue discrimination for new technologies.[597,598] FERC Order 2023, for example, requires grid operators to adopt certain interconnection practices with the goal of reducing interconnection delays. These practices include a first-ready, first-served interconnection process that requires new generators to demonstrate commercial readiness to proceed, and a cluster study interconnection process that studies many new generators together.[599]

Through such efforts, the interconnection queues can be reduced in length, transmission capacity on existing transmission lines can be increased, additional generation assets can be brought online, and electricity generated by existing assets will be curtailed less often. These factors help to improve overall grid reliability.

EPA Summary and Response: DER

Summary:

Commenters (AFPM, Clean Fuels Development, NRECA) shared concern that removing dispatchable energy too quickly from our power generation arsenal, while adding distributed energy resources (DER), will lead to shortfalls and reliability concerns when DER like solar and wind are not able to generate sufficient power. These commenters maintained that the agency's proposed rule under CAA section 111 addressing CO2 emissions from Electricity Generating

Units would reduce supply due to intermittent power provided by renewables, while the vehicle electrification rules would at the same time increase grid demand. (e.g., Arizona State Legislature, AFPM.) Other commenters welcomed distributed energy resources, shared ways that they add grid reliability, and added ways to leverage their strengths and mitigate their weaknesses. As noted above, for example, MFN explained how demand from vehicle electrification could smooth out a "negative valley" potentially posed by storage issues associated with increased use of renewable sources. Energy Innovation noted that a grid powered by increased use of renewables can readily accommodate demand posed by vehicle electrification.

Response:

We respond to comments about the cumulative impacts of the 111 proposed rule and this rule in our prior response. Here, we focus on DER. DER utilization has the potential to provide clean sustainable power. They can be positioned throughout the grid, helping to reduce power transmission across the grid. The decreased power transmission drives reduced power loss as well as minimizes cost of the transmission hardware. EPA understands that DER cannot always generate power at the same time that it is required. Mitigating actions like stationary batteries and temporal electricity rates will help to leverage DER and increase grid resilience. In addition, dispatchable power may be reduced but we do not expect it to be eliminated. As demand vs power available is managed, the life of some existing dispatchable energy could be extended while other appropriate dispatchable power may be added. DER, when combined with stationary batteries, can help optimize existing grid infrastructure. The stationary battery is able to absorb power when supplied by the DER and then deliver the energy when required by the HD BEV, greatly reducing demand placed on the grid. The stationary battery is critical to optimize capture of the DER output (as the HD BEV is not always charging) and providing power to the BEV as the DER is not always providing output. EPA's analysis of potential impacts on grid (both generation and distribution) is conservative in that it does not consider future DER. That is, we find that the additional generation and distribution associated with this rule can be met even if no additional DER are deployed. The potential for DER deployment is an additional strategy for supporting the charging infrastructure associated with this rule. Future sources of electricity generation, including DER from renewables, are reflected in the EGU emission factors calculated from IPM runs but those DER are not modeled in the TEIS to reduce distribution build out. See RIA section 4.2.4.2.

7.2 Resilience

Comments by Organizations

Organization: Alliance for Vehicle Efficiency (AVE)

Grid reliability

In the Proposal, EPA states that BEV trucks will have a negligible impact on the nation's electrical grid.20 Unfortunately, it cannot be assumed that the U.S. grid will always be reliable. There is growing evidence that fleet owners may be less likely to purchase BEVs without improved grid reliability.21

- The average annual number of weather-related power outages increased by roughly 78% during 2011-2021, compared to 2000-2010.
- From 2000-2021, there were 1,542 weather-related power outages, an average of four per day.
- The states with the most reported weather-related power outages were the heavy trucking corridors of Texas, Michigan, California, North Carolina, and Pennsylvania.22 [EPA-HQ-OAR-2022-0985-1571-A1, p. 8]

[EPA-HQ-OAR-2022-0985-1571-A1, p. 8]

Organization: Missouri Farm Bureau (MOFB)

Further, MOFB is greatly concerned that the proposed rule contains zero language regarding what impact it will have on the severely aged and inadequate electric grid. In 2020, the U.S. experienced 180 major electrical disruptions, up from fewer than two dozen in 2000.9 In this proposed rule, EPA fails to illustrate how electricity will actually be delivered to thousands of new charging stations that will be built in the near future, and what impact this action will have upon every other aspect of our lives, much of which relies on the constant delivery of electricity. [EPA-HQ-OAR-2022-0985-1584-A1, p. 2]

9 America’s Power Grid Is Increasingly Unreliable - WSJ, accessed June 14, 2023.

In addition, but not separable from this conversation, MOFB is especially concerned with the future buildout of electric transmission lines that will be needed to carry the proposed rule’s mandates into fruition. Unfortunately, and all too often, farmers and ranchers hear others say that their land is needed for the ‘public’s benefit.’ Government agencies and renewable energy advocates often forget that farmers and ranchers are part of the ‘public’ as well, and need to be fairly compensated for the continued buildout of transmission lines through their private property which will take away the critical farm and ranch land necessary to run their businesses for generations to come. [EPA-HQ-OAR-2022-0985-1584-A1, p. 3]

Organization: Transfer Flow, Inc.

Even the Federal Energy Regulatory Commission (FERC) has warned that a rapid transition to electric vehicles would be devastating to the country’s electric grid reliability.18’19 [EPA-HQ-OAR-2022-0985-1534-A1, p. 4]

18 https://robertbryce.substack.com/p/epa-v-the-grid?utm_source=substack&utm_medium=email

19 https://www.washingtonexaminer.com/policy/energy-environment/ev-push-threatens-to-strain-power-grids-and-threaten-reliability

Organization: Truck Renting and Leasing Association (TRALA)

The Federal Energy Regulatory Commission (FERC) expressed great concern for the state of the nation's energy infrastructure, and vulnerabilities to cybersecurity attacks, physical threats, and extreme weather. In May 2023, during a congressional hearing, FERC Chairman Philips informed the Senate Committee on Energy and Natural Resources, 'We face unprecedented challenges to the reliability of our nation's electric system,' and that, 'Our country urgently needs more energy infrastructure of all kinds.'4 Exacerbating pressure to our energy grid, power production from previously reliable electric generation sources has diminished. [EPA-HQ-OAR-2022-0985-1577-A1, p. 4]

4 Full Committee Hearing to Conduct Oversight of FERC: Hearing before the Senate Committee on Energy and Natural Resources, 118th Cong. (2023) (testimony of Willie L. Phillips).

Power Outages Have Potential to Significantly Impact Goods Movement

States, particularly in the western U.S., are repeatedly learning what happens during brownout or blackout periods. The truck renting and leasing industry relies on critical components to provide services, vehicles, and energy sources – one missing element results in lost revenue, disruptions to the supply chain, and essential products not being delivered throughout the economy. [EPA-HQ-OAR-2022-0985-1577-A1, p. 7]

Monitoring electric power generation and transmission are critical and difficult in the short and long-term, let alone over a decade out and beyond under Phase 3. The North American Electric Reliability Corporation (NERC) closely monitors and forecasts the nation's power needs. NERC is predicting two-thirds of North America could face elevated risks of blackouts during extreme weather this summer alone. 11 (See Figure 2). [EPA-HQ-OAR-2022-0985-1577-A1, p. 7] [Refer to Figure 2 on p. 7 of docket number EPA-HQ-OAR-2022-0985-1577-A1]

11 2023 Summer Reliability Assessment, North American Electric Reliability Corporation (May 2023).

NERCs attributes geographical grid strain to a variety of factors including increased peak demands; planned nuclear refurbishment outages; wildfire risks to transmission networks; shortages of distribution transformers; new environmental rules restricting power plant emissions for coal-fired generators in 23 states; hurricanes and extreme storms; supply chain issues presenting maintenance and summer preparedness challenges and delays in some new resource additions; and unseasonable temperatures coinciding with generator unavailability to just name a few.12 [EPA-HQ-OAR-2022-0985-1577-A1, p. 8]

12 Id.

Power outages can create obvious concerns for anyone who owns, rents, or leases a ZEV. Generators can supply back-up power but for a fleet accustomed to Direct Current (DC) fast-charging, generators will need to be substantially sized and will come at a steep price. Back-up energy storage has its limitations as well given its temporary energy banking capabilities. Unfortunately, electricity availability challenges create on-going questions and hesitation for an industry being mandated to rely almost exclusively on a new energy source to move the nation's freight consistently and reliably. Meanwhile, grid reliability risk is exacerbated by a rule that also forces ZEV technology on vocational vehicle applications that are required to build and maintain critical infrastructure. Converting all vehicle applications at once to BEVs compounds risk factors that could make overall implementation more problematic. [EPA-HQ-OAR-2022-0985-1577-A1, p. 8]

EPA Summary and Response

Summary:

The electricity grid must be reliable in that it performs consistently well due to adequacy of generation and transmission as covered in 7.1. The grid must also be reliable in that the existing infrastructure (generation, transmission, distribution) keeps working during extreme weather events (snow/ice storms, hurricanes, other high wind speed events, wildfires). The grid reliability received a range of comments. Many of these comments deal with extreme weather, it's impact on the grid, and its possible impact on HDBEV users. Some comments turn the tables and speak to the possible benefits of using BEV to back up the grid in times of challenge. Power outage frequency, level, and the impact to critical areas has been increasing per comments by AVE and MFB. ASL points out the peak number of power outages in 2020. AFPM and TRALA comment that fleets must keep operating to generate income but that power outages could keep fleets from operating for days at a time and cause those fleets significant cost. AFPM suggests that fleets will require expensive back up power systems consisting of generators and/or stationary batteries. CFDC comments cover NERC statements from their Long-Term Risk Assessment and from a NERC paper, Electric Vehicle Dynamic Charging Performance explaining how grid disturbances, combined with BEV charging could have catastrophic consequences. Similarly, the Arizona State legislature cited a Summer 2023 Reliability Study of the North American Electric Reliability Corp. which described grid reliability issues already being experienced in various regions of the country largely due to extreme weather. Transfer Flow and ASL comment that FERC warns of a rapid transition being devasting to the grid and that the US is heading for a reliability crisis and resource adequacy crisis. AmFree shared concerns that HD BEV power needs could shorten the life of transformers. Other comments (AEU, EC, ESC, EDF, MFN) promote HD BEV as a way to support the grid during times of shortfall or shutdown via load management or by using V2G. Energy Strategy Coalition (ESC) gave examples of investments in charging infrastructure driven by the grid reliability benefits. They also shared trials being conducted regarding both load management and V2G technologies. EDF and MFN promote the value in using school buses for grid reliability fromV2G and provides information on pilot programs in process. These comments promote HD BEV as assisting with peak power, back up power, or simply freeing up power with charging flexibility.

Response:

Available data suggests risk to grid reliability due to extreme weather events is increasing (the greater frequency and severity of extreme weather events being a predicted consequence of climate change, see 74 FR at 66497, 66498, 66524-25 (endangerment finding for section 202(a), the endangerment to which GHG emissions from HDVs contribute and which the Phase 3 rule addresses). As TRALA and others state, there will be times when grid infrastructure is damaged, and HD BEV cannot get the power they need to recharge. While this is a small part of any given calendar year, fleets should be aware of this risk when making vehicle choices. Power outages in the U.S. are infrequent, occurring about 1.4 times per customer annually and typically lasting between 2-5 hours (EIA, Average duration of total annual electric power interruptions, United States (2013-2020) 2023). The effect of power outages on electric vehicle owners is expected to be similar to that of non-electric vehicle drivers. Neither driver will be able to "fuel" during power outages, as gasoline pumps are electric powered. However, electric vehicles can provide their owners with residential power for a limited time. Moreover, electric vehicle chargers that are attached to distributed energy resources, such as homes or businesses with solar and/or stationary battery storage, would be unaffected by power outages and, thereby, can continue to provide charge for electric vehicles via its independent capacity. In fact, electric vehicles could be used to power gasoline pumps during electric power outages. Given that the physical extent of typical power outages tends to be relatively small, electric vehicle drivers, as well as conventional vehicle drivers, can be expected to drive out of the outage area and to unaffected charging or refueling stations, should it become necessary. EPA does not add the cost of backup power systems (batteries or generators) as suggested by AFPM. Backup power is a reliability opportunity for fleet owners but is not required. Stationary batteries also provide the opportunity to optimize charging costs by slowly drawing power from the grid during the best rates and then charging trucks quickly. The cost / benefit analysis for backup power is best left to individual fleets. Fleets should also consider that many severe weather events also block roads that would affect the operation of vehicles generally, and they also shut down gas and diesel stations or disrupt other petroleum or renewable fuel distribution infrastructure that would particularly affect vehicles with ICE. Note that EPA also does not model these costs either, including the additional costs to fleets with ICE (but not BEVs) associated with disruptions in liquid fuel distribution infrastructure. Fleet owners may even benefit by having emergency electrical power available from their HD BEV when the grid has been damaged. EPA is not mandating HD BEV, and its modeled compliance pathway posits a majority of ICE vehicles in the fleet even in 2032, so fleets that see electricity reliability as insufficient will be free to stay with other propulsion systems or purchase back up power systems.

AmFree shares concern that integration of HD BEV could drive shortened life of transformers. The article they cite makes use of a previous article ("Impacts of plug-in hybrid electric vehicles on a residential transformer using stochastic and empirical analysis" (Razeghi, 2014)[600]) for this statement. Although the source article is for residential PEV, their highlights apply to any properly designed electricity distribution system and support our case for HD BEV adoption: Catastrophic failure of distribution transformers due to ZEV charging is unlikely, Off-peak charging results in prolonged transformer life, ZEV demand is manageable for transformers even if multiple vehicles exist.

There is also a general comment going to issues of overall grid reliability and not to the relevant question of whether demand posed by the Phase 3 rule could pose an issue to grid reliability and resilience. As we explained in RTC section 7.1 and earlier section, we can reasonably show that no such adverse impacts will occur. With respect to the general issues raised in the comment, CFDC brings up the challenge that is imposed by severe heat or cold ambient temperatures hitting a portion of the country. The NERC report it cites speaks to long term reliability of the generation and transmission systems with respect to handling unusually high loads occasioned by extreme weather events by supplying all of the energy demanded. Concerns raised by the report show that NERC is raising awareness such that timely actions can

[600] Razeghi, Ghazal. "Impacts of plug-in hybrid electric vehicles on a residential transformer using stochastic and empirical analysis". Highlights in April 15, 2014; https://www.sciencedirect.com/science/article/pii/S0378775313019320

be aligned. EPA applauds NERCS executive summary[601] that states, "Reliably integrating inverter-based resources (IBR), which include most solar and wind generation, onto the grid is paramount. Over 70% of the new generation in development for connecting to the BPS over the next 10 years is solar, wind, and hybrid (a generating source combined with a battery)." That executive summary further states, "As new resources are introduced and older traditional generators retire, careful attention must be paid to power system and resource mix reliability attributes. Within the 10-year horizon, over 88 GW of generating capacity is confirmed for retirement through regional transmission planning and integrated processes. Effective regional transmission and integrated resource planning processes are the key to managing the retirement of older nuclear, coal-fired, and natural gas generators in a manner that prevents energy risks or the loss of necessary sources of system inertia and frequency stabilization that are essential for a reliable grid." NERC's strategy is properly aligned with EPA's IPM modeling that, as described in section 7.1, recognizes these EGU changes. With these changes the electricity generation will continue to not only align with needs but have the proper resource adequacy for events such as extreme temperatures.

CFDC also comments on NERC's paper on dynamic charging performance[602]. They are correct that the paper explains how, if left unchecked, infrequent bulk power system disturbances could interact with charging EVs (with future expected significant increase in EV charging loads) and cause blackouts or power interruptions. The paper shows that NERC and the Western Electricity Coordinating Council (WECC) supports and has a MOU with the California Mobility Center (CMC) and their EV Grid Reliability Working Group. CFDC comments also fail to share that DOE and the national labs provided help with dynamic load modeling back in 2010 when this issue, fault-induced delayed voltage recovery (FIDVR), was dealt with successfully in relation to loads from residential air conditioners. The paper provides multiple actions to prevent this EV charging scenario from occuring. It shows that EVSE that behave in a grid friendly manner exist today suggesting that modest changes will allow all EVSE to respond as needed.

Commenter Transfer Flow states that "[e]ven the Federal Energy Regulatory Commission (FERC) has warned that a rapid transition to electric vehicles would be devastating to the country's electric grid reliability." They cite as support a blog by Robert Bruce, and a newspaper article from the Washington Examiner which proved to be inaccessible. In fact, it is clear from the cited blog that the testimony of several FERC Commissioners before the Senate Environment and Public Works Committee did not mention electrification of the transportation sector (or mention any EPA rule), but rather dealt with challenges facing the grid generally. As explained in RTC section 7.1 above, the Phase 3 rule is not associated with demands on the grid that would cause significant adverse impacts to grid reliability, in the view (and analysis) not only of EPA but of trade associations representing major segments of the electric utility industry. EPA consequently views this comment as a mischaracterization.

Commenter Missouri Farm Bureau notes that farmers and other landowners should be compensated should additional transmission lines be needed which require installation on private property. EPA is projecting minimal (about 1%) need for additional transmission capacity that

[601] NERC. 2022 Long Term Reliability Assessment. December 2022.
https://www.nerc.com/pa/RAPA/ra/Reliability%20Assessments%20DL/NERC_LTRA_2022.pdf
[602] NERC. Electric Vehicle Dynamic Charging Performance Characteristics during Bulk Power System Disturbances. https://www.nerc.com/comm/RSTC/Documents/Grid_Friendly_EV_Charging_Recommendations.pdf

will use existing right of ways as a result of the Phase 3 rule as explained earlier. Review of energy pricing modeling (IPM conducted by ICF) with the increased loads shows no cost increase due to transmission congestion. The stable prices are a clear indicator that transmission is adequate. In addition, as the grid develops and DER are added, many DER will be logically situated closer to demand and decrease transmission stress. Additional DER with location optimization can help minimize buildout of electricity transmission and distribution but this scenario was not applied in the TEIS.

8 Hydrogen Infrastructure

8.1 Hydrogen Infrastructure Readiness and Lead Time

Comments by Organizations

Organization: Alliance for Vehicle Efficiency (AVE)

Hydrogen infrastructure

According to the Department of Energy (DOE), only 59 hydrogen fueling stations operate across the U.S. and there are approximately 50 stations under construction. DOE is bringing together federal agencies, automakers, hydrogen providers, fuel cell developers, and additional stakeholders to support the growth of hydrogen as a transportation option. [EPA-HQ-OAR-2022-0985-1571-A1, p. 8]

Bringing significant numbers of hydrogen trucks into production will incentivize the building of more hydrogen stations. By removing any CO2 penalty on hydrogen engine trucks, EPA can help lead the way to developing the necessary infrastructure. [EPA-HQ-OAR-2022-0985-1571-A1, p. 8]

Organization: American Free Enterprise Chamber of Commerce (AmFree) et al.

Hydrogen Refueling Stations. Although much of the available data focuses on charging infrastructure for battery-electric vehicles, the state of hydrogen refueling is even worse. According to EPA, every step of this supply chain is underdeveloped. Clean hydrogen production is at "nearly zero today," Draft RIA at 82, and even accounting for tax incentives and federal funding, the Department of Energy predicts that clean hydrogen will only be "emerging" for heavy-duty vehicles during the timeframe of the proposed rule, id. at 83. There are also no large-scale pipelines for distribution, which means that hydrogen will have to be delivered from central production facilities by truck until at least 2031. Id. at 84. And the number of public refueling stations will have to increase many times over to make the use of fuel-cell vehicles possible—let alone preferred— for the fleet owners expected to adopt this technology. See id. at 85 ("[W]e considered FCEVs in the technology packages for select applications that travel longer distances and/or carry heavier loads[,] . . . includ[ing] coach buses, heavy-haul tractors, sleeper cab tractors, and some day cab tractors."). Currently, there are only 58 public hydrogen refueling stations in the entire country, 57 of them are in California, and most are designed for light-duty vehicles. See Alternative Fueling Station Counts – Public; 88 Fed. Reg. at 25,999 (noting that the existing public stations are "primarily for light-duty vehicles").6 [EPA-HQ-OAR-2022-0985-1660-A1, p. 47]

6 There are also 16 private en-route stations. See Dep't of Energy, Alternative Fuels Data Ctr., Alternative Fueling Station Counts by State (Private), https://tinyurl.com/4xc8jfcs (last accessed June 14, 2023). These are not generally accessible to the public.

And this ignores many of the upstream problems with hydrogen. While the feedstock for hydrogen is abundant, it takes a huge amount of energy to produce. Using electricity to generate hydrogen loses about a third of the power input as compared to transmitting it into the grid. There are further losses when hydrogen is consumed by the fuel cells. Even if hydrogen is readily available, there are still problems to solve because of hydrogen's propensity for embrittling metal. Because of embrittlement, existing infrastructure is incapable of handling hydrogen and that problem with continue to plague new infrastructure, exacerbating the safety issues discussed below. American Institute of Physics, Hydrogen Embrittlement Creates Complications for Clean Energy Storage, Transportation, ScienceDaily (Oct. 6, 2020), www.sciencedaily.com/releases/2020/10/201006114309.htm. And even if the hydrogen is safely onboard, hydrogen suffers from some of the same energy density problems that plague electric batteries. Hydrogen itself is very light, but compressing or liquifying hydrogen requires very high-pressure tanks, which weigh far more than the hydrogen they contain. Jody Muelaner, Comparing EV Battery and Fuel Cell Energy Density, Battery Power Tips (Nov. 18, 2021), https://www.batterypowertips.com/comparing-ev-battery-and-fuel-cell-energy-density-faq/. After accounting the tank, the gravimetric energy density of hydrogen is much lower than diesel, making liquid fuels a better fit for heavy-duty vehicles. Id. [EPA-HQ-OAR-2022-0985-1660-A1, pp. 47 - 48]

Despite the extraordinary challenges that lie ahead for hydrogen refueling, EPA provides little by way of solutions. The agency notes that there are tax incentives and federal funding designed to increase the production and distribution of clean hydrogen, but it identifies only one tax credit—the "Alternative Fuel Refueling Property Credit"—aimed at increasing the number hydrogen refueling stations. Draft RIA at 19–20, 85. As discussed above, that tax credit is limited to infrastructure in low-income or non-urban area census tracts and is capped at $100,000—a small fraction of the amount needed to construct a public station, which is estimated to cost between $9 and $45.5 million. Id. at 19–20, 86. Moreover, EPA does not identify any current private investment plans in the refueling industry other than noting that the West Coast Collaborative's Alternative Fuel Infrastructure Corridor Coalition is "actively considering buildout of a network for medium- and heavy-duty vehicles throughout the western states" and has received 153 project proposals for hydrogen stations. Id. at 86. Under these circumstances, emissions standards premised on the adoption of fuel-cell vehicles as soon as 2030 are not feasible. [EPA-HQ-OAR-2022-0985-1660-A1, p. 48]

Organization: American Trucking Associations (ATA)

Hydrogen refueling

EPA assumes that hydrogen fuel technology will become the predominant technology of choice for line-haul fleets by 2030 when long-haul tractor percentage sales requirements begin. EPA's cost analysis relies on the availability of hydrogen fuel stations and low-cost green hydrogen. Today, there are 57 hydrogen refueling stations in the United States, almost all of them in California. To support hydrogen-fuel adoption in line-haul tractors, stations must be built on interstate freight corridors. [EPA-HQ-OAR-2022-0985-1535-A1, p. 19]

Organization: BorgWarner Inc.

BorgWarner appreciates the Administration's support for EV charging and hydrogen infrastructure.

BorgWarner applauds the Administration's support for EV charging and hydrogen infrastructure. More infrastructure support is needed, however, for the HD, MD, and other commercial vehicles to help these segment's shift to an electrified and hydrogen-powered future. We urge federal agencies to align resources and goals to leverage the shared endeavors to decarbonize the transportation sector. [EPA-HQ-OAR-2022-0985-1578-A1, p. 4.]

A key factor for expanding infrastructure is private sector charging support. Fleet owners will need to not only bear higher costs for new ZEV vehicles, but also the charging and refueling equipment as well. More support for these commercial facilities is crucial. Many products are available to help fleet owners navigate this transition and we hope more federal and state incentives will be forthcoming. BorgWarner is currently working with customers to install needed charging stations. [EPA-HQ-OAR-2022-0985-1578-A1, p. 4.]

Organization: California Air Resources Board (CARB)

The NPRM requests comments on lead time considerations related to the development of HD hydrogen fueling infrastructure. Based on the CEC's experience, LD hydrogen refueling stations on average take around two years to build. Post-pandemic, construction times have slowed, and costs have increased, although this may be temporary. For MD/HD refueling stations, refueling station construction times seem similar. For example, the CEC's Center for Transportation and the Environment drayage project constructed a hydrogen station near the Port of Oakland, capable of fueling 30 class 8 trucks. The project was approved in July 2021 and is expected to be commissioned in September 2023. This timeline includes time lost to some permitting challenges. A number of entities are developing and offering rapid deployment mobile or transportable hydrogen dispensing solutions that can lessen the site preparation and permitting challenges in some cases or provide a bridge during the construction of permanent hydrogen stations.177,178,179,180 Even with those challenges, U.S. EPA's proposal provides adequate lead time, including for its more stringent alternative standards. [EPA-HQ-OAR-2022-0985-1591-A1, pp.48-49]

Phased approach: Building the next level of implementation detail into this strategy, the infrastructure needs assessment illustrates that infrastructure, while a near-term challenge, will not be the limiting factor on meeting steeper penetration rates. This is due to the unique phased and geographically targeted way infrastructure is most likely to deploy. Indeed, CALSTART's findings show the network benefits of this clustered and phased rollout, which matches ZE-MHDV penetration volumes with first-launch regions, will create charging network efficiencies in deployment volume and utilization that can support more ZE-MHDVs than EPA's approach assumes.37 [EPA-HQ-OAR-2022-0985-1656-A1, p. 18.]

37 Phasing In U.S. Charging Infrastructure, CALSTART, June 2023

The analysis considers that deployment will first occur where it makes sense, not everywhere.38 That is, priority areas will be a focus of most private investment in the near term, and prioritization will inform the coordination of several of the factors critical in reducing lead times for the installation of infrastructure, developing the grid, and making costs more predictable. [EPA-HQ-OAR-2022-0985-1656-A1, p. 18.]

c. EPA should more fully incorporate the extent to which BIL incentives will hasten the buildout of FCEV refueling infrastructure.

EPA should also consider the hydrogen hubs program currently being run by the Department of Energy and how it may accelerate the building of necessary hydrogen infrastructure, which could in turn expedite FCEV market growth. Hydrogen hubs are a key tool for demonstrating the full value chain of clean hydrogen, including production, connective infrastructure, and end-use in new off-taker markets, including HDVs. The BIL appropriates $8 billion for at least 4 regional clean hydrogen hubs, $1 billion for the Clean Hydrogen Electrolysis Program, and $500 million for the Clean Hydrogen Manufacturing Initiative. Furthermore, the National Alternative Fuel Corridors Program has $2.5 billion for charging alternative fuel infrastructure along major highways in the U.S., and the Port Infrastructure Development Program set aside $2.3 billion for port infrastructure, including hydrogen refueling infrastructure for drayage trucks and trains that service the port. Additionally, the Biden Administration recently published its final U.S. National Clean Hydrogen Strategy and Roadmap,295 which details plans to substantially increase U.S. hydrogen production. It outlines “pathways for clean hydrogen to decarbonize applications [that] are informed by demand scenarios for 2030, 2040, and 2050 with strategic opportunities for 10 million metric tons (MMT) of clean hydrogen annually by 2030, 20 MMT annually by 2040, and 50 MMT annually by 2050.”296 The DOE and other agencies are working with national laboratories and industry through a program called the 21st Century Truck Partnership to use hydrogen and medium and heavy-duty trucks and buses to reduce harmful emissions.297 [EPA-HQ-OAR-2022-0985-1640-A1, pp. 67 - 68]

295 U.S. DOE, U.S. National Clean Hydrogen Strategy and Roadmap (2023), https://subscriber.politicopro.com/f/?id=00000188-8c84-db64-afd9-9fbd2ad70000&source=email.

296 Id. at 1.

297 Id. at 32.

In total, this $14.3 billion has led to an explosion of hydrogen activity, much of it centered around massive hubs that will be scattered across the country.298 Heavy-duty trucking will likely move between hubs, stopping in regions across the U.S. to refuel with clean hydrogen.299 Hubs will help to kick start the market, increasing the chance of realizing the cost reductions discussed previously, which in turn will help more quickly boost FCEV stocks in U.S. truck fleets. The synergy we expect to see between the hubs and the developing FCEV market is an additional reason EPA should consider FCEV technology as feasible before 2030, giving cause to further strengthen the proposed rule. [EPA-HQ-OAR-2022-0985-1640-A1, p. 68]

298 CATF, Hydrogen Hubs Map, https://www.catf.us/us-hydrogen-hubs-map/, (last visited June 6, 2023).

299 Anna Menke & Emily Kent, CATF, The outlook for U.S. hydrogen hubs: Who's applying and what they could achieve (Mar. 29, 2023), https://www.catf.us/2023/03/outlook-us-hydrogen-hubs/.

Organization: Daimler Truck North America LLC (DTNA)

EPA's assumptions about the timing for hydrogen-fueled vehicles to become cost-competitive are unreasonable.

Like EPA, DTNA believes that hydrogen-fueled vehicles, whether FCEV or hydrogen combustion technologies, will be the primary pathway for decarbonizing segments that are more challenging to electrify, including long-haul HHD applications where weight sensitivities or dwell times prohibit BEV adoption, and applications where electrical infrastructure is cost-prohibitive. However, EPA's assumption that FCEVs will be available in significant volumes starting in 2030128 is overly optimistic based on the current state of the technology and infrastructure. DTNA believes that FCEVs will not see significant market penetration until at least 2032. [EPA-HQ-OAR-2022-0985-1555-A1, p. 58]

128 See Proposed Rule, 88 Fed. Reg. at 25,973 ('Though fuel cell technology is still emerging in HD vehicle applications, FCEVs are a viable ZEV technology for heavy-duty transportation and will be available in the 2030 timeframe.').

Relying on its assumptions regarding calculated payback periods and adoption rates, the Agency input into its HD TRUCS tool values that reflect significant FCEV uptake in 2032, with more than half of new Class 8 coach buses and regional day cab tractors indicated as FCEVs, as shown in Table 18 below. Even if EPA's assumptions of TCO and adoption rates turn out to be true (which is doubtful, as discussed in Sections II.B.3.a and II.B.3.b of these comments), EPA should incorporate an infrastructure scalar into the equation used to calculate the Phase 3 CO2 standards to reflect the current state of hydrogen infrastructure buildout, and it must regularly review the state of this infrastructure and adjust the scalar accordingly to ensure standard feasibility, as discussed in Section II.C of these comments. [EPA-HQ-OAR-2022-0985-1555-A1, p. 58] [Refer to Table 18 on p. 59 of docket number EPA-HQ-OAR-2022-0985-1555-A1]

DTNA is optimistic about the future of hydrogen refueling infrastructure. Hydrogen infrastructure can leverage some synergies from the nation's existing petroleum infrastructure and is not hindered by the process and policy hurdles that pose challenges for electric infrastructure development (as discussed in Sections I.B.4 and II.B.3.f of these comments). Because hydrogen producers are not subject to utility-style regulation, the scale and pace of capital investments for hydrogen infrastructure serving the transportation sector will be largely driven by the free market and business cases, making for potentially more flexible and faster development as compared to the electricity utility sector. [EPA-HQ-OAR-2022-0985-1555-A1, p. 59]

In addition, as EPA notes in the Proposed Rule, DOE is supporting the development of at least four clean hydrogen hubs through 2026 and there are numerous corridor-pending AFCs, where public hydrogen stations will be separated by no more than 100 miles.130 According to DOE's Alternative Fuels Locator, however, as of May 2023 there are only two areas of the country with 'ready corridor' designations for hydrogen, extending from the San Francisco Bay Area along I-80 toward Reno, Nevada, and in Southern California from Santa Barbara to San Diego, reflected in Figure 8 below.131 These corridor designations note only distances between stations, and do not indicate whether or not these stations would be accessible to all types of

HDVs. It is also likely that as FCEV technology develops, current gaseous hydrogen stations may need to undergo a conversion to liquid hydrogen to serve medium- and heavy-duty applications. [EPA-HQ-OAR-2022-0985-1555-A1, p. 59] [Refer to Figure 8 on p. 60 of docket number EPA-HQ-OAR-2022-0985-1555-A1]

130 See Proposed Rule, 88 Fed. Reg. at 25,944; 25,999.

131 See DOE, Alternative Fuels Data Center,'Alternative Fueling Station Locator,' https://afdc.energy.gov/stations/#/corridors?fuel=HY&state=CA.

Hydrogen infrastructure in the United States is currently insufficient to enable the FCEV volumes that EPA projects in the 2030 - 2032 timeframe. 55% of new day cab tractors, 25% of new sleeper cab tractors, and 15% of new heavy haul day cabs clearly cannot be constrained to operating around the California corridors and four hydrogen hub locations pictured above. Such a constraint would have significant consequences for fleet operations and goods movement. Further, the pace of infrastructure development outside of these corridors and hubs cannot be accurately predicted. [EPA-HQ-OAR-2022-0985-1555-A1, p. 60]

EPA Request for Comment, Request #19: We request comment on our approach that focuses primarily on BEVs, which currently are more prevalent in the HD vehicle market, and whether there are additional vehicle types that should be evaluated as FCEVs along with BEVs.

- DTNA Response: DTNA agrees in principle with EPA's primary focus on BEVs at this time, as these vehicles are more prevalent in the market. EPA should not consider FCEVs until at least MY 2032, due to the current state of the technology and refueling infrastructure. EPA also should not project ZEV uptake for any vehicle types outside of the BEV and FCEV categories included in the Proposed Rule. [EPA-HQ-OAR-2022-0985-1555-A1, p. 161]

EPA Request for Comment, Request #60: We request comment on lead time considerations related to the development of HD hydrogen fueling infrastructure.

- DTNA Response: According to the DOE's Alternative Fuels Data Center, there are currently very few 'Ready Corridor' designations for hydrogen fueling stations (meaning that there are enough stations on the corridor to support travel with a minimum distance of 150 miles between hydrogen stations). The designated 'Ready Corridors' that do exist are located in California, and it is unclear whether stations at these locations are accessible to all types of HDVs. There is currently no data to accurately predict the pace of hydrogen infrastructure expansion, but it is unlikely that significant infrastructure to enable regional and long haul applications will be built out by 2030, when EPA projects that the fuel is first expected to be cost-competitive, as discussed in Section II.B.3 of these comments. [EPA-HQ-OAR-2022-0985-1555-A1, p. 170]

EPA Request for Comment, Request #61: EPA requests comment on what, if any, additional information and data EPA should consider collecting and monitoring during the implementation of the Phase 3 standards; we also request comment on whether there are additional stakeholders EPA should work with during implementation of the Phase 3 standards and what measures EPA should include to help ensure success of the Phase 3 program, including with respect to the important issues of refueling and charging infrastructure for ZEVs.

- DTNA Response: See DTNA Response to Request # 60, above. [EPA-HQ-OAR-2022-0985-1555-A1, p. 170]

Organization: Energy Innovation

IV. THE COMBINED IMPACT OF FEDERAL, STATE, AND PRIVATE INVESTMENTS ON INFRASTRUCTURE DEPLOYMENT WILL HELP MEET THE NEEDS OF AN INCREASINGLY ELECTRIFIED HDV FLEET OVER THE NEXT DECADE.

The EPA notes that "[u]ncertainty about ZEV technology, charging infrastructure technology and availability for BEVs, or hydrogen refueling infrastructure for FCEVs, may affect ZEV adoption rates. As ZEVs become increasingly more affordable and ubiquitous, we expect uncertainty related to these technologies will diminish over time."42 We concur with this assessment and recognize that vehicle adoption must occur apace with infrastructure deployment. [EPA-HQ-OAR-2022-0985-1604-A1, p. 19]

Organization: MEMA

Infrastructure Success is Critical

While MEMA urges EPA to consider other propulsion systems, we believe it is imperative to address infrastructure challenges that will limit the success of a zero-emission vehicle fleet. [EPA-HQ-OAR-2022-0985-1570-A1, p. 8.]

We note the timelines forecasted by the U.S. DOE for deployment of nationwide hydrogen production, distribution and delivery are several years, almost a decade, behind the EPA estimates for production of vehicles fueled by hydrogen (H2ICE or FCEV). The recently released DOE paper titled "U.S. National Clean Hydrogen Strategy and Roadmap"6 shows, in its generation and distribution studies, significant gaps in regional production and availability of hydrogen through 2050. While it may be possible for national production of clean hydrogen to reach the 50 million metric ton (MMT) capability noted in the paper, we call attention to figures 7, 8(a), 8(b) and 23, which show an infrastructure yet to emerge, and one that as forecasted is not likely able to support HD trucking effectively. Furthermore, the timelines for growth of hydrogen generation and distribution, pages 70-75, do NOT ALIGN with EPA forecast of vehicle production. We note this gap so that it may be addressed, and hydrogen-powered trucks manufactured using MEMA member technology will have the fuel they will need to deliver the service they are built for. Left unattended, the national hydrogen infrastructure could lag vehicle production by almost a decade. In practical terms, such mismatch will result in loss of consumer confidence and low- to no-sales of hydrogen fueled trucks, leading to few financially and technologically feasible options for fleets obliged to upgrade or replace existing diesel trucks. [EPA-HQ-OAR-2022-0985-1570-A1, pp. 8 - 9]

6 https://www.hydrogen.energy.gov/pdfs/us-national-clean-hydrogen-strategy-roadmap.pdf

Organization: National Association of Manufacturers

In addition to building out the transmission system to accommodate a substantial increase in electric vehicle usage, accompanying hydrogen fueling stations will need to be matched with hydrogen fuel cell vehicle rollout, which will be accelerated under this proposed rule. We cannot unlock the full market potential of zero emissions vehicles without the appropriate infrastructure. [EPA-HQ-OAR-2022-0985-1649-A2, p. 2]

Organization: PACCAR, Inc.

PACCAR is working diligently to develop ZEVs for the future, but the necessary supporting infrastructure must be in place before widespread ZEV market penetration and adoption. Planning, developing, and implementing the charging infrastructure required to support battery electric trucks is a major initiative. The hydrogen refueling infrastructure is also not well developed. EPA's proposed standards are premised on the infrastructure being established and functional. EPA should facilitate the feasibility of the regulation by including a mechanism to adjust the applicable standards to correlate with the progress of the necessary infrastructure development and readiness. [EPA-HQ-OAR-2022-0985-1607-A1, p. 2]

Organization: Schneider National Inc.

Hydrogen is assumed to become the sleeper technology solution.

- Schneider is currently testing hydrogen technology. However, the lack of existing hydrogen infrastructure and equipment will make implementing this technology challenging within the timeframe proposed by the EPA. As of today, there are approximately six (6) existing hydrogen fueling locations in the country (all in southern California). [EPA-HQ-OAR-2022-0985-1525-A1, p. 3]

Organization: South Coast Air Quality Management District (South Coast AQMD)

Finally, while most sites installing infrastructure are focused on their local needs (e.g., site installation, local utility distribution infrastructure, etc.), when implemented at scale, additional generation/production and transmission/transportation of electricity and hydrogen will be needed, in many cases across state lines. The federal government can continue to facilitate these interstate connections to ensure a streamlined market that will encourage the rapid growth of zero emissions vehicles. Key factors in the adoption of zero emissions vehicles is the actual price that end consumers will pay for electricity and hydrogen as well as a reliable supply of both, especially in comparison to conventional fossil fuels. The federal government can play a role in driving down the cost to consumers as well as ensuring stable and reliable fuel supplies to the extent that they cross state lines. [EPA-HQ-OAR-2022-0985-1575-A1, p. 4]

Organization: Truck and Engine Manufacturers Association (EMA)

- The envisioned level of deployment of ZEV trucks also will require the construction of approximately 700 hydrogen refueling stations across the country by 2032, at an aggregate cost of approximately $5.25 billion, not including any of the costs for the hydrogen manufacturing or distribution systems. As a point of reference, there are currently just six (6) operational MHD hydrogen refueling stations in California. [EPA-HQ-OAR-2022-2668-A1, p. 13]

5. The Critical Importance of Infrastructure Readiness

Even if the more reasonable outputs from EMA's HD TRUCS are used to frame the final Phase 3 standards, there is no doubt that the infrastructures to power the ZEVs must be in place for any Phase 3 rule to be implementable. For trucking fleets to operate BEVs or FCEVs, whether a few or many, adequate battery-recharging or hydrogen-refueling infrastructures will be needed to power the ZEVs. Without sufficient infrastructures in place in time to meet the needs of the ZEVs implicitly required by EPA's GHG Phase 3 regulation, the rule will be destined to fail. [EPA-HQ-OAR-2022-0985-2668-A1, p. 43]

The NPRM and HD TRUCS incorrectly assume that all commercial BEVs will be depot-charged at night, and that any commercial ZEVs that need to operate further from home will be FCEVs. The NPRM also assumes that trucking fleets will be able to devote up to 30% of each vehicle's cargo carrying capacity for batteries large enough to provide enough power for the vehicle's entire daily work. If a commercial vehicle cannot carry enough batteries to complete its daily work, or if it must travel too far from its home terminal, the NPRM assumes that a FCEV will be used instead of a BEV. Of course, those FCEVs will require an entirely separate infrastructure of hydrogen-refueling stations, which still needs to be designed and developed. [EPA-HQ-OAR-2022-0985-2668-A1, pp. 45 - 46]

The hydrogen needed to fuel FCEVs (and hydrogen-fueled internal combustion engines, or H2-ICEs) may need to be a compressed gas (3,500 – 10,000 psi) or a cryogenic liquid (-423° F). As this time, it is not clear which type of hydrogen will be most cost-effective to produce, distribute and deliver to MHD ZEVs. Manufacturers are able to produce vehicles with either type of on-board storage tanks; the technology choice will be determined by fleet customers and the readiness of the infrastructures. Therefore, the necessary whole-of-government initiative also should: (i) determine what type of hydrogen infrastructure is needed, (ii) identify where the hydrogen-refueling stations will be needed, and (iii) ensure that the investments for the necessary hydrogen-refueling infrastructure will be in place in time (i.e., by 2030) to power the MHD FCEVs required by the GHG Phase 3 rule. [EPA-HQ-OAR-2022-0985-2668-A1, p. 46]

EPA has established as a foundational premise of the NPRM that the necessary battery-recharging and hydrogen-refueling infrastructures will be developed in time to meet the needs of the MHD ZEVs that the GHG Phase 3 rule will require manufactures to sell. However, there is a significant chance that EPA's key premise – what really amounts to little more than a stated aspiration – may prove fundamentally wrong, a prospect that would completely undermine this rulemaking. Accordingly, a massive and focused whole-of-government initiative must come together very quickly to ensure the development of the necessary ZEV-truck infrastructures in time. [EPA-HQ-OAR-2022-0985-2668-A1, p. 46]

The current lack of the much-needed whole-of-government initiative already may be chilling investments in the development of necessary battery-recharging and hydrogen-refueling infrastructures. Without clarity about whether long-distance commercial vehicles will be BEVs or FCEVs, investors may be hesitant to commit capital to develop the infrastructure for one of the technologies. For example, clarity is needed regarding whether the required public stations will deliver electricity or hydrogen. Without a long-term technology path identified, investors may be sitting on the sidelines. Similarly, if hydrogen will be part of the solution, clarity is needed to identify whether it will be a compressed gas or cryogenic liquid. Until that hydrogen infrastructure direction is clear, more investors may stay on the sidelines. [EPA-HQ-OAR-2022-0985-2668-A1, p. 46]

Truck manufacturers are doing their part by developing all of the potential ZEV technologies: BEVs, compressed hydrogen-fueled FCEVs, cryogenic hydrogen-fueled FCEVs, compressed hydrogen-fueled H2-ICEs, and cryogenic hydrogen-fueled H2-ICEs. However, without adequate assurances that the appropriate infrastructures will be in place in time, fleets simply will not purchase any of those types of ZEVs. Thus, developing the necessary infrastructures represents the most complicated, most expensive, and longest lead-time challenge to transition the U.S. trucking industry to ZEVs. Without an effective whole-of-government initiative focused on understanding, developing and ensuring those infrastructures, there may be little chance that the GHG Phase 3 rule will be successful. Consequently, clear links between the phase-in of the Phase 3 rule and the phase-in of the requisite infrastructure must be established, monitored, and acted on if misalignment among the respective phase-ins is detected. [EPA-HQ-OAR-2022-0985-2668-A1, pp. 46 - 47]

In that regard, EMA recommends that EPA work with other agencies, departments and stakeholders to establish clear annual benchmarks for assessing progress in the deployment of the necessary ZEV-truck infrastructures. For example, using the data developed by ICCT, Ricardo, NREL and others, EPA could determine the top 100 counties across the country where the greatest numbers of ZEV-trucks will be deployed under the Phase 3 and ACT regulations by 2032. For each of those counties, benchmarking assessments could be made of the number of BEV-recharging and FCEV-refueling stations that will need to be installed on an annual basis to support the annually increasing deployment of the anticipated numbers of ZEV-trucks in each of those counties. Each year, evaluations could be made on a county-by-county basis to determine whether and how the actual pace of installation of ZEV-truck recharging/refueling stations is keeping up with the benchmark numbers of necessary recharging/refueling stations. If it is determined that the aggregate actual progress in infrastructure development is falling behind the benchmark rates of progress by, for example, 20% or more, the phase-in schedule of the Phase 3 standards could be deferred by one or more years as deemed appropriate by EPA, perhaps in consultation with other agencies and departments. [EPA-HQ-OAR-2022-0985-2668-A1, p. 47]

The foregoing is just an example of the type of direct linkage that needs to be made between the implementation of the Phase 3 rule and the implementation of the fundamentally necessary ZEV-truck infrastructure. Without that type of linkage, there is no real prospect for the proposed rule to stand. To the contrary, much like a one-legged stool, it will be preordained to collapse. [EPA-HQ-OAR-2022-0985-2668-A1, p. 47]

Organization: Truck Renting and Leasing Association (TRALA)

TRALA requests EPA conduct annual reviews to ascertain whether charging infrastructure, power demands, and hydrogen fuel (when/if available), will satisfy the needs for all ZEVs in every state to meet trucking’s charging and hydrogen needs. If the status of charging or hydrogen fueling infrastructure identifies significant gaps that would impede truck mobility in any state, EPA should not implement subsequent milestone year requirements until identified fueling gaps are operational in keeping pace with vehicle needs. [EPA-HQ-OAR-2022-0985-1577-A1, p. 8]

Organization: Valero Energy Corporation

Major hydrogen production and distribution infrastructure would need to be put in place before FCEVs would even be serviceable. “[A]nalysis [also] suggests that the infrastructure for the hydrogen pathway is generally costlier than battery electric," with hydrogen transport facing "the largest cost-penalty in the near-term."113 It is estimated that the capital cost for a single hydrogen filling station is $1.5 to $2.0 million.114 Moreover, there are currently no hydrogen fuel cell tractor-trucks commercially available in North America or Europe to confirm their true cost or economic viability.115 [EPA-HQ-OAR-2022-0985-1566-A2, p. 25]

113 Hall, Dale and Lutsey, Nic, ICCT White Paper, "Estimating the Infrastructure Needs and Costs for the Launch of Zero-Emission Trucks" at 18 (August 2019). https://theicct.org/sites/default/files/publications/ICCT_EV_HDVs_Infrastructure_20190809.pdf

115 Sharpe, Ben & Basama, Hussein, ICCT Working Paper 2022-09, "A meta-study of purchase costs for zero-emission trucks" at 12 (February 2022), https://theicct.org/wp-content/uploads/2022/02/purchase-cost-ze-trucks-feb22-1.pdf.

The transition of a large and complex transportation system to a BEV or FCEV technology is a massive undertaking, requiring the establishment of new manufacturing, assembly and supply chains; build-out of new charging/fueling infrastructure; interface with public utilities; re-conception of fuel distribution logistics; and ultimate design of end-of-life resource recovery strategies. Renewable diesel, on the other hand, can utilize existing infrastructure (i.e., pipelines, terminals, and retail distribution supply chains), requiring far less investment when compared against BEV charging and FCEV hydrogen fueling build-out. [EPA-HQ-OAR-2022-0985-1566-A2, p. 25.]

Organization: Volvo Group

Of course, the availability of hydrogen (H2) fueling infrastructure is even further behind that for battery electric vehicles and thus Volvo Group does not believe the requisite charging and hydrogen fueling infrastructure will develop sufficiently on a year-over-year basis to support penetrations of the magnitude EPA has determined in its stringency setting. We urge the agency to include a provision in the Phase 3 regulation tying manufacturer compliance to minimum infrastructure availability and density thresholds. Without some such mechanism it is beyond OEMs' capacity to control their own compliance with the regulation. [EPA-HQ-OAR-2022-0985-1606-A1, p. 9]

EPA Summary and Response:

Summary:

We received several comments on the topic of hydrogen infrastructure. Some commenters were optimistic and provided support for their view. AVE noted that producing hydrogen trucks, including H2 ICEVs, will incentivize the building of new stations. They suggested removing a CO2 penalty on H2 ICEVs could help make this happen. AVE and CATF expressed awareness of DOE efforts to bring stakeholders together to support the growth of hydrogen as a transportation option. CATF pointed out that a $14.3 billion federal investment via the BIL and IRA in clean hydrogen production, alternative fuel corridors, ports, and the 21st Century Truck Partnership is expected to heavily influence the market. They suggested that much of the investment is centered around regional hydrogen hubs; there is opportunity for trucks to travel between hubs, and expected synergies between hydrogen hubs and FCEVs can launch the markets more than EPA anticipates, making FCEVs feasible before 2030. CARB agreed there is enough infrastructure lead time based on experience with building LD hydrogen refueling stations in the California. They shared an example of a hydrogen station for HD vehicles near the Port of Oakland expected to move from approval to commissioning in just over two years, despite permitting challenges. They cited numerous entities developing mobile refueling solutions that could provide a fueling option “bridge” during the construction of permanent stations.

Energy Innovation suggested that uncertainty could diminish over time as the technology becomes more ubiquitous. CALSTART noted that infrastructure may be a near-term challenge, but it will not be a limiting factor since it is likely to deploy in a phased or geographically targeted way. They cited a paper specific to charging infrastructure.

Other commenters were more cautious about the readiness and availability of hydrogen infrastructure. Several indicated there are few existing hydrogen refueling stations for HD FCEVs—mostly in California—and stated that it is overly optimistic to expect buildout of a national network by 2030. AmFree noted that hydrogen refueling infrastructure is nascent compared to BEV charging infrastructure. They said that in the NPRM, EPA did not offer solutions to the myriad of upstream problems with hydrogen refueling. They pointed out that hydrogen production is energy-intensive and raised concerns about issues such as metal embrittlement, safety related to the delivery of hydrogen, and the low gravimetric density of hydrogen. They stated that the impact of the Alternative Fuel Refueling Property Credit, which EPA referenced in the NPRM, is limited given that a public station can cost between $9 and $45.5 million. AmFree also said that EPA did not sufficiently identify current private investment plans, thus indicating that FCEVs by 2030 are not feasible. Valero said that a transition to BEV or FCEV technology is a massive undertaking, particularly given that there is little now, and transitioning to a fuel like renewable diesel would require far less investment. Schneider noted that a lack of infrastructure will make it hard to implement HD FCEV technology. EMA estimated that 700 hydrogen refueling stations will be needed by 2032, compared to six for HD FCEVs in place in California now.

Several commenters identified refueling infrastructure challenges that need to be addressed. ATA said that stations must be built along interstate freight corridors to support line-haul tractors. MEMA observed a lag between EPA’s forecast of vehicle production and timelines for hydrogen production in the U.S. National Clean Hydrogen Strategy and Roadmap, which they say could result in a loss of consumer confidence if left unchecked. Energy Innovation and the National Association of Manufacturers called for a coordinated rollout of FCEVs and hydrogen refueling stations. Borg-Warner and EMA suggested that more support for commercial facilities is necessary, and they urged Federal agencies to align resources and goals to ensure that buildout happens in a coordinated fashion and at a necessary pace. South Coast AQMD highlighted a federal role to facilitate infrastructure development across state lines.

Industry commenters anticipated lead time issues beyond their control. Daimler stated that there are good reasons to be optimistic about the future of hydrogen. They pointed out that hydrogen infrastructure can leverage synergies from existing petroleum infrastructure and is not hindered by the process and policy hurdles that pose challenges for BEV infrastructure development, such as utility rate proceedings, but they also stated that there are still too many unknowns to ensure adequate coverage in the 2030 to 2032 timeframe. Daimler, PACCAR, and Volvo suggested adjusting the standards based on the pace of infrastructure deployment. TRALA and EMA joined their calls to regularly evaluate infrastructure. EMA also highlighted numerous uncertainties about the future of hydrogen in transportation—with regards to the form of the fuel (gaseous vs liquid), location of stations, and investments—and called for a clear long-term technology path with annual benchmarks for assessing progress towards deploying infrastructure.

Response:

For more on how we accounted for hydrogen infrastructure uncertainties in assessing corresponding technologies and developing the technology packages for the modeled potential compliance pathway for the final rule and for responses about suggested post-rule actions, including the concept of including an infrastructure scalar, please refer to RTC Chapters 2 and 3. For a discussion of H2 ICEVs and related comments, please see RTC Section 9. For discussion about upstream emissions impacts of hydrogen, please see RTC Section 13.

We agree with commenters who suggested that federal investment can encourage the buildout of hydrogen refueling stations for HD FCEVs. EPA has seen progress since the NPRM on the implementation of BIL and IRA funding and other provisions to incentivize the establishment of a clean hydrogen market in the United States that could offer $140 billion in revenues and 700,000 jobs by 2030,[603] as described in more detail in RIA Chapters 1.3 and 1.8. For example, in June 2023, the U.S. National Clean Hydrogen Strategy and Roadmap was finalized[604] Also in June 2023, DOE updated Clean Hydrogen Production Standard (CHPS) guidance that establishes a target for lifecycle (defined as “well-to-gate”) GHG emissions associated with hydrogen production.[605] In October 2023, DOE announced the selection of seven Regional Clean Hydrogen Hubs (H2Hubs) in different regions of the country that will receive a total of $7 billion to kickstart a national network of hydrogen producers, consumers, and connective infrastructure while supporting the production, storage, delivery, and end-use of hydrogen, expected to catalyze nearly $50 billion in additional hydrogen investment.[606] In December 2023, the Treasury Department and Internal Revenue Service proposed regulations to offer income tax credit of up to $3 per kg for the production of qualified clean hydrogen at a qualified clean hydrogen facility

(Section 45V), as established in the IRA.[607,608] In January 2024, DOE selected a consortium to design and implement a $1 billion initiative to offer "demand pull" for H2Hubs.[609] Also in January 2024, DOE announced $98 million in grants to start build and enhance up to ten hydrogen fueling stations for HD freight trucks in Texas, California, and Colorado.[610] Furthermore in March 2024, DOE announced $750 million for 52 projects to dramatically reduce the cost of clean hydrogen and help advance electrolysis technologies and improve manufacturing and recycling capabilities for clean hydrogen systems and components.[611]

Meanwhile, several processes are getting started at the federal level that demonstrate that federal agencies are taking steps to align resources and facilitate infrastructure development in a coordinated manner. For example, consistent with EMA's recommendation for a whole-government initiative relating to hydrogen production and deployment, a Hydrogen Interagency Taskforce (HIT) has been established across 11 federal agencies to implement the U.S. National Clean Hydrogen Strategy and Roadmap.[612] There is a HIT workgroup goal to support the establishment of 10 million metric tons per year (MMT/yr) of new, clean supply and end use by 2030, 20 MMT per year by 2040, 50 MMT per year by 2050. And in March 2024, the U.S. released a National Zero-Emission Freight Corridor Strategy[613] that, "sets an actionable vision and comprehensive approach to accelerating the deployment of a world-class, zero-emission freight network across the United States by 2040. The strategy focuses on advancing the deployment of zero-emission medium- and heavy-duty vehicle (ZE-MHDV) fueling infrastructure by targeting public investment to amplify private sector momentum, focus utility and regulatory energy planning, align industry activity, and mobilize communities for clean transportation."[614] The strategy has four phases. The first phase, from 2024-2027, focuses on establishing freight hubs defined "as a 100-mile to a 150-mile radius zone or geographic area

centered around a point with a significant concentration of freight volume (e.g., ports, intermodal facilities, and truck parking), that supports a broader ecosystem of freight activity throughout that zone."[615] The second phase, from 2027-2030, will connect key ZEV hubs, building out infrastructure along several major highways. The third phase, from 2030-2045, will expand the corridors, "including access to charging and fueling to all coastal ports and their surrounding freight ecosystems for short-haul and regional operations."[616] The fourth phase, from 2035-2040, will complete the freight corridor network. This corridor strategy provides support for the development of HD ZEV infrastructure that corresponds to the modeled potential compliance pathway for meeting the final standards. This kind of certainty can allow industry and other stakeholders to develop emissions reduction solutions that work best for them related to details such as the form of the fuel (e.g., gaseous or liquid) or the location of stations.

We also agree with commenters that the availability of HD FCEVs for select vehicle applications in early market volumes by MY 2030, as discussed in RTC Section 5.1, can further incentivize the deployment of hydrogen refueling stations.[617,618] In consideration of comments, we assessed infrastructure needs and lead time (see RIA Chapter 1.8.3), including California's experience with building stations for FCEVs and the suggestion that mobile fueling can help fill gaps as fleets start to adopt HD FCEVs (see RIA Chapter 1.8.3.2). And we re-evaluated our assumptions about the retail price of hydrogen (see RTC Section 8.2 and RIA Chapter 2.5.3.1), in consultation with DOE, along with FCEV technology-related costs (see RIA Chapter 2.5.2). Based on all of these factors, our assessment is that early market buildout of a hydrogen refueling station network to support the updated FCEV adoption levels in the modeled potential compliance pathway is feasible in the 2030 to 2032 timeframe.

We are not suggesting that a full national hydrogen infrastructure network needs to be in place by 2030 or even by 2032, as implied by a few commenters, and specifically note that a full national hydrogen infrastructure network is not needed to accommodate the demand that we posit for FCEVs in our modeled potential compliance pathway. First, we project that manufacturers would choose to adopt FCEVs for a limited number of longer-range HD vehicles (HD TRUCS coach bus 18 and tractors 41, 45, and 79), that such inclusion in the HD TRUCS analysis does not begin until MY 2030, and that even then we project FCEVs for these limited number of vehicle types only at modest adoption rates. For example, in MY 2032, we project that there would need to be roughly 10,000 FCEVs sold, an adoption rate of 25 percent of long-haul tractors would be ZEVs (Preamble Table II-4), and that just over 2 percent of new HD vehicle sales would be FCEVs with most of them being long-haul tractors.

Second, as explained in RIA Chapter 1.8.3.5, through BIL and IRA incentives and private investment spurred by H2Hubs, we conclude there is opportunity to concentrate HD FCEV hydrogen demand from the modeled potential compliance pathway in priority areas. Secure and

617 Since at least 2014, a coordinated rollout has been a stated objective of California's program to install hydrogen fueling stations, for instance—to establish fueling capacity of their station network ahead of hydrogen fuel demand.

618 CARB. "Annual Evaluation of Fuel Cell Electric Vehicle deployment and Hydrogen Fuel Station Network Development". June 2014. Available online: https://ww2.arb.ca.gov/sites/default/files/2020-10/ab8_report_final_june2014_ac.pdf.

sufficient demand from local or regional anchor fleets would offer certainty that could help lower infrastructure costs in targeted regions and enable expansion over time. This strategy is supported in the literature, which includes regional analyses that demonstrate that infrastructure buildout can start in targeted regions. Similar to BEVs, as explained in RTC 7.1 above, the infrastructure needed to meet this initial demand will likely be centered in a discrete sub-set of states and counties where freight activity is concentrated. Thus, the select vehicle applications for which we project FCEV adoption could start traveling within or between regional hubs in this timeframe where hydrogen development is prioritized initially. For example, the projects that recently received more than $90 million to deploy public hydrogen fueling stations along corridors in Texas, California, and Colorado could be candidates for initial deployment.[619,620] We agree with commenters who pointed out that uncertainty can diminish over time as these technologies are adopted and near-term challenges are resolved.

We note further, as commenter DTNA points out, that hydrogen infrastructure development might have certain advantages over BEV infrastructure that favor its rapid deployment such as existing petroleum infrastructure that can be leveraged in some instances and fewer potential policy and process challenges (e.g., associated with utility commission regulations).

We agree with commenters that federal investment alone is insufficient (nor is it intended to be all-encompassing). For example, as noted by AmFree, the impact of the Alternative Fuel Refueling Property Credit of up to $100,000 may be limited given the cost of a public station. NREL estimates that a station can cost nearly ~$4 million to up to ~$40 million, depending on its size and use.[621] Thus, we have also assessed private investment and coordination spurred by the federal investment for hydrogen infrastructure buildout. See RIA Chapters 1.8.3.2. According to Cipher's Clean Technology Tracker, as of September 2023, there is $45.752 billion in total clean hydrogen production investment in the United States,[622] with 1 percent in projects that are in operation (close to $500,000), 7 percent ($3.2 million) under construction, and a majority still classified as announced.[623] DOE has started tracking announcements of domestic electrolyzers and fuel cell manufacturing facilities. So far, over $1.8 billion has been announced in over 10 new and expanded facilities with the capacity to manufacture over 10 GW of electrolyzers per year.[624] We anticipate that private investment strategies will become clearer over time after the rule is finalized as policy and process details start to settle. We expect this rule will provide

greater certainty to the market to support timely development of hydrogen refueling stations, which could consequently allow industry to capture more of the 45V tax credit potential to produce clean hydrogen.

We acknowledge the perceived differences noted by MEMA between FCEV projections in the NPRM and the U.S. National Clean Hydrogen Strategy and Roadmap (Roadmap).[625] EPA's analysis for the NPRM was based on similar information and assumptions as the Roadmap report, as our agencies have coordinated on this issue.

- The Roadmap report notes that at $4 per kg, the scenario analysis has shown that 10 to 14 percent of all MHD trucks would demand about 5 MMT per year of hydrogen by 2040 and up to 8 MMT per year by 2050.[626] The NPRM referred to the same Ledna report but focused more on the technology-based potential of specific use cases for HD FCEVs at $4 per kg that resulted in less than 1 MMT hydrogen demand by 2032. The timeframes are not inconsistent since hydrogen production is expected to ramp up quickly through 2035 and beyond. In the final rule, we revised our hydrogen price so that it is further in line with DOE's Ledna analysis and Liftoff reports (see RIA Chapter 2.5.3.1).
- MEMA pointed to Figures 7, 8(a), 8(b), and 23 in the Roadmap, suggesting that they show an infrastructure yet to emerge. However, none of these Figures deal with infrastructure availability during the rule's timeframe: Figure 7 concerns present conditions, Figure 8 deals with clean hydrogen production, and Figure 23 displays current hydrogen and natural gas national pipeline networks. They are not projections of the future given that there is $9.5 billion of federal investment available to kickstart the clean hydrogen market, along with an all-of-government Roadmap in place to guide the private and intergovernmental process. We do agree that hydrogen infrastructure for trucking is at an earlier stage.
- MEMA also suggested that the timelines for growth of hydrogen generation and distribution on pages 70 to 75 of the Roadmap do not align with EPA forecasts. As outlined in RIA Chapter 1.8.3.6, our assessment is that a scenario for early market buildout of hydrogen refueling stations is in line with the Roadmap timeline:
    - Page 70 of the Roadmap report includes an action to, "deploy scalable hydrogen fueling stations to support early fleet markets, such as heavy-duty trucks and buses" in 2026 to 2029, which is before the introduction of FCEVs in the modeled potential compliance pathway of the final rule.
    - Page 71 of the Roadmap report includes an action to, "deploy at least two Regional Clean Hydrogen Hubs, demonstrating hydrogen use in hard-to-decarbonize sectors (e.g., industry and heavy-duty transport)" in 2026 to 2029," likewise consistent with timeline for FCEV introduction that we project in our modeled potential compliance pathway.
    - As mentioned on pages 73-74 of the Roadmap, long-haul heavy-duty trucks (for example) are part of the "first wave" of hydrogen end uses. As noted above, our

[625] U.S. Department of Energy, Hydrogen Program. "DOE National Clean Hydrogen Strategy and Roadmap". June 2023. Available online: https://www.hydrogen.energy.gov/library/roadmaps-vision/clean-hydrogen-strategy-roadmap, https://www.hydrogen.energy.gov/docs/hydrogenprogramlibraries/pdfs/us-national-clean-hydrogen-strategy-roadmap.pdf.
[626] See page 19 and Figure 12 of the Roadmap report.

modeled compliance pathway likewise projects HD FCEV use for only a limited percentage of longer-range vehicle types.

We recognize that these plans will represent increases in hydrogen infrastructure, and our assessment, in consultation with relevant federal agencies, is that our projections are supported and correspond to our measured approach in our modeled compliance pathway for FCEVs. EPA is also committed to ensuring the Phase 3 program is successfully implemented and, as described in preamble Section II.B.2.iii, in consideration of concerns raised regarding inherent uncertainties about the future, we are including a commitment to monitor progress on infrastructure development in the final rule.

AmFree pointed out that hydrogen refueling infrastructure is nascent compared to BEV charging infrastructure. In December 2023, DOE announced plans to spend $59 million to advance research, development, demonstration, and deployment of technologies for HD FCEV stations.[627] There is global momentum to continue to develop technologies to deliver hydrogen to FCEVs as well. For example, in May 2023, European Union states reached an agreement to build hydrogen refueling stations in all major cities at 200 km intervals along core highway networks, including for HD FCEVs, starting in 2030.[628]

AmFree also raised certain issues regarding uncertainties relating to transport and management of hydrogen. Specifically, they indicated that there are issues of metal embrittlement, safety related to the delivery of hydrogen, and the low gravimetric density of hydrogen, which they said EPA failed to address. We understand that hydrogen can permeate cracked steel pipes and cause metal embrittlement. If left unattended, leakage or explosions are possible. DOE's Liftoff report refers to embrittlement in relation to pipelines. They indicate that, "like all pipelines (natural gas, ammonia, etc.), hydrogen pipelines are designed around codes and standards to ensure safety and account for unique properties of the molecule)" and indicate that proper monitoring and maintenance can reduce risk.629,630 We are not aware of major concerns about metal embrittlement related to HD FCEVs but address a range of FCEV and hydrogen safety issues in RTC Section 5.2 and RIA Chapter 1.7.4. In short, the entire hydrogen

value chain—from production to distribution and end use—is regulated to address safety concerns.631,632

Regarding the density of hydrogen, please note that in RIA Chapter 1.8.1, we say that hydrogen has low energy density (i.e., volumetric density), so it must be compressed or liquified for use, but high specific energy (i.e., gravimetric density), with about 2.5 to 3 times the energy content per unit of mass than gasoline or diesel.[633] We recognize that hydrogen tanks can add weight (see RTC Section 5) and volume (see RTC Section 5.3), but our assessment at this time is that neither pose constraints on the feasibility of HD FCEVs as they are evaluated in HD TRUCS.

8.2 Hydrogen Fuel Costs

Comments by Organizations:

Organization: American Trucking Associations (ATA)

ICCT's analysis of hydrogen pricing and refueling indicates a lack of cost competitiveness before 2035, while EPA's preferred proposal would require 10 percent of the line-haul market to be ZEV in 2030 with hydrogen-fuel cell winning out.26 [EPA-HQ-OAR-2022-0985-1535-A1, p. 19]

> 26 The International Council on Clean Transportation, Near-Term Infrastructure Deployment to Support Zero-Emission Medium-and Heavy-Duty Vehicles in the United States, pgs. 16-17 May 2023.

"Our renewable hydrogen price projections of $8/kg-$10/kg in 2040 means there will be very few cases of lower cost of ownership for hydrogen long-haul trucks over their battery-electric counterparts. Hydrogen trucks could become cost-competitive in the late 2030s, if hydrogen became significantly lower than our central estimate. However even with median hydrogen prices as low as $3, we find no significant business case for hydrogen trucks before 2035 due to lower technology maturity." [EPA-HQ-OAR-2022-0985-1535-A1, p.19]

Organization: Clean Air Task Force et al.

b. EPA is correct that hydrogen prices will continue to fall.

As the hydrogen market grows, economies of scale will likely help bring the levelized cost of hydrogen in line with EPA projections of $4/kg by 2030. Two key areas where costs are expected to drop are electricity and electrolyzers, which have the potential over time, according to a report from the International Renewable Energy Agency, "to cut hydrogen costs by 80%."290 If this occurs, it will be due to reductions in electrolyzer cost, increasing electrolyzer capacity factors as more renewables come online, increasing electrolyzer durability that results in

lifetimes closer to 20 years rather than 10, increasing electrolyzer efficiency (greater than 70 percent by lower heating value), and electricity costs falling into the $20/MWh range. If all of those things come to pass, hydrogen production costs, not including transport, storage, and dispensing, could fall under $2/kg in 2030. [EPA-HQ-OAR-2022-0985-1640-A1, p. 66]

290 Int'l Renewable Energy Agency, Making the breakthrough: Green hydrogen policies and technology costs 10-11, figs. 1-2 (2021), https://www.irena.org/publications/2020/Dec/Green-hydrogen-cost-reduction.

291 Energy Transitions Comm'n, Making the Hydrogen Economy Possible: Accelerating Clean Hydrogen in an Electrified Economy 45 (2021), https://energy-transitions.org/wp-content/uploads/2021/04/ETC-Global-Hydrogen-Report.pdf.

The UC Davis report292 used to model market penetration also included a model-based projection for the cost of hydrogen that is broken down into production costs as well as transport, storage, and dispensing costs. This analysis uses SERA to analyze the hydrogen supply chain for a range of scenarios and sensitivity cases. Those scenarios look at both natural gas with carbon capture and electrolyzer-based production methods for the 2025 to 2035 timeframe and find a cost of $5–$6/kg at the pump in 2030. This analysis assumes that delivery trucks would be used for local distribution (distances less than 32 miles) and pipelines would be used for longer distances (up to 625 miles). The hydrogen production costs in 2030 are projected to be $2–$4/kg and the transport, storage, and dispensing costs $2–$3/kg, where the larger volumes handled in the pipeline scenarios resulted in cheaper production costs but more expensive distribution. [EPA-HQ-OAR-2022-0985-1640-A1, p. 67]

292 Fulton et al., § 6.1.

It is important to note that all three of these analyses do not include the effect of the hydrogen production tax credit in the IRA.293 Taking that into account, all three would see the cost of hydrogen at or below the $4/kg level projected by EPA. As such, $4/kg by 2030 is achievable assuming the hydrogen and FCEV markets ramp up as expected and industry participants along the supply chain make full use of available incentives. States are aiding this process by adopting laws that further incentivize the use of hydrogen for heavy-duty vehicles.294 [EPA-HQ-OAR-2022-0985-1640-A1, p. 67]

293 See 26 U.S.C. § 45V (providing a tax credit of up to $3 per kilogram of clean hydrogen produced)

294 For example, Colorado recently passed a law that provides tax credits for the use of hydrogen, including in heavy-duty vehicles. See H.R. 1281, 2023 Leg., Reg. Sess. (Colo. 2023), https://leg.colorado.gov/sites/default/files/2023a_1281_signed.pdf.

Organization: Daimler Truck North America LLC (DTNA)

DTNA agrees with EPA's projection that hydrogen may potentially be cost-competitive as a fuel by 2030, but this projection must be regularly evaluated as the market develops. In addition, there is not sufficient data to accurately project the rate of hydrogen station proliferation now, seven years before the fuel is expected to be cost-competitive. The existing petroleum network required several decades to build, and it is likely hydrogen will need additional time before becoming available nationwide to enable hydrogen-fueled regional and long-haul applications. For this reason, the availability of hydrogen fueling infrastructure must be factored in to the infrastructure scalar that DTNA proposes be included in EPA's CO2 stringency calculations, as discussed below in Section II.C of these comments. [EPA-HQ-OAR-2022-0985-1555-A1, p. 60]

Hydrogen pricing cannot be accurately forecasted, thus the hydrogen price inputs used in HD TRUCS must be reviewed as the market develops. Today, hydrogen dispensed at California hydrogen stations costs as much as $17.00 per kilogram. EPA projects that the cost of hydrogen will fall to $4.00 per kilogram in 2030 and beyond, whereas ICCT projected the 2030 green hydrogen price to be $9.86 per kilogram. Using ICCT's analysis, hydrogen-fueled vehicles will not achieve cost parity with comparable ICE vehicles until after 2040. While DTNA is optimistic that the price of hydrogen will fall, the Company does not believe that the future costs of hydrogen can be accurately projected to inform adoption rate and CO_2 stringency at this time.

Organization: Dana Incorporated

EPA should also conduct studies to analyze the impact of new federal incentives on the cost of producing hydrogen, which could play an important role for long-haul trucks. [EPA-HQ-OAR-2022-0985-1610-A1, p. 2.]

Organization: International Council on Clean Transportation (ICCT)

ASSUMPTIONS REGARDING THE RETAIL PRICE OF HYDROGEN EPA references Argonne National Laboratory's BEAN model for a $4/kg hydrogen retail price in 2030 and references the DOE's Liftoff report for a $4-$5/kg hydrogen price in 2030, and stating both values incorporate IRA incentives from the Inflation Reduction Act in their prices (Islam et al., 2022; Murdoch et al., 2023). However, both citations source the hydrogen price from a cost parity analysis done by NREL published prior to the passage of the Inflation Reduction Act (Ledna et al., 2022). This NREL study analyzed the required retail hydrogen price for fuel-cell electric vehicles, including buses and long-distance trucks, to reach total cost of ownership parity with diesel comparators. The hydrogen price at which the vehicles reach cost parity, determined to be $4-$5/kg, was referenced as the 'willingness to pay' fuel price in the DOE's Liftoff report. Therefore, the $4/kg hydrogen price used by EPA cannot reflect the real market. It is more appropriate to take a bottom-up approach to understand what fleet owners would pay at the hydrogen refueling station. [EPA-HQ-OAR-2022-0985-1553-A1, p. 15]

Islam, E. S., Vijayagopal, R., & Rousseau, A. (2022). A Comprehensive Simulation Study to Evaluate Future Vehicle Energy and Cost Reduction Potential (ANL/ESD-22/6). Transportation and Power Systems Division, Argonne National Laboratory. https://anl.app.box.com/s/qc3nov3w25qmxs20b2m2wmru0gadp83z

Murdoch, H., Munster, J., Satyapal, S., Rustagi, N., Elgowainy, A., & Penev, M. (2023). Pathways to Commercial Liftoff: Clean Hydrogen. U.S. Department of Energy. https://liftoff.energy.gov/wpcontent/uploads/2023/05/20230523-Pathways-to-Commercial-Liftoff-Clean-Hydrogen.pdf

Ledna, C., Muratori, M., Yip, A., Jadun, P., & Hoehne, C. (2022). Decarbonizing Medium- & Heavy-Duty On-Road Vehicles: Zero-Emission Vehicles Cost Analysis. National Renewable Energy Laboratory. https://doi.org/10.2172/1854583

A bottom-up analysis would estimate all the potential costs along the hydrogen supply chain that would contribute to the final retail price. The main cost components are hydrogen production, hydrogen distribution, and hydrogen dispensing. EPA references three studies for the production cost of green hydrogen, including a past study from ICCT. Among the three studies cited, only the Rhodium Group's cost ($0.39/kg -$1.92/kg) considered the hydrogen production tax credit (PTC) under the Inflation Reduction Act. However, that report simply subtracted $3/kg (the maximum value of the hydrogen PTC) from its estimated green hydrogen production cost without PTC ($3.39-$4.92 /kg). This is not how the PTC works in the real world. To reflect the impact of the PTC accurately, it is necessary to apply a discounted cash flow (DCF) model that evaluates the annual incomes and expenses at a hydrogen production plant. This cash flow analysis would determine the amount of annual tax liability by the hydrogen producer with and without the PTC. Similarly, the DOE’s Liftoff report provided a range for green hydrogen production cost of $1.5/kg - $3.4/kg without the PTC and a less than or equal to $0.4/kg cost with PTC, explaining that, ‘$0.40/kg is when the PTC is applied in a given year / point-in-time and clean hydrogen costs can go negative. However, if investors apply a discounted cash flow DCF) to calculate the value of the credit (10-years) over 25+ year asset life, the value of the credit will fall from $3/kg (point-in-time) to ~$1.4/kg (applying DCF on the value of the PTC)’. [EPA-HQ-OAR-2022-0985-1553-A1, p. 15]

A more recent ICCT study estimated the retail green hydrogen price considering the PTC and using a DCF model (Slowik et al., 2023). This analysis follows the detailed provisions in the Inflation Reduction Act to best reflect the impact of the PTC. Specifically, the 10-year tax credit starts in 2023 and ends in 2030, meaning that only producers that started operating early in 2023 would receive the full 10-year credits while plants start in 2030 would only receive 2 years of PTC out of the plant’s lifetime of 30 years. Besides the $3/kg clean hydrogen PTC, the $0.026/kWh PTC for renewable electricity is also included, since the two are allowed to be combined under the Act. In addition, the PTCs for clean hydrogen are refundable for the first five years of operation per ‘direct pay’ provision under section 6417 of the Act. Further, tax ‘transferability’ under section 6418 was also included, where both renewable electricity and clean hydrogen producers are eligible to sell their unused tax credits to a buyer who has the tax value of the credit will fall from $3/kg (point-in-time) to ~$1.4/kg (applying DCF on the value of the PTC)’. [EPA-HQ-OAR-2022-0985-1553-A1, p. 15]

value of the credit will fall from $3/kg (point-in-time) to ~$1.4/kg (applying DCF on the value of the PTC)’. [EPA-HQ-OAR-2022-0985-1553-A1, p. 15]

value of the credit will fall from $3/kg (point-in-time) to ~$1.4/kg (applying DCF on the value of the PTC)’. [EPA-HQ-OAR-2022-0985-1553-A1, p. 15]

burden. The ICCT result shows that the PTCs would reduce the levelized production cost of green hydrogen by $2/kg for a plant start in 2023, decreasing to $0.3/kg for a plant start in 2030. [EPA-HQ-OAR-2022-0985-1553-A1, p. 15]

Slowik, P., Searle, S., Basma, H., Miller, J., Zhou, Y., Rodríguez, F., Buysse, C., Minjares, R., Kelly, S., & Pierce, L. (2023). Analyzing the impact of the Inflation Reduction Act on electric vehicle uptake in the United States. International Council on Clean Transportation. https://theicct.org/publication/ira-impactevs- us-jan23/

For hydrogen distribution and dispensing costs estimates of $1/kg-$2/kg EPA references two reports (Rustagi et al., 2018; Satyapal, 2022). However, the numbers cited are based on very optimistic scenarios with aggressive fuel-cell electric vehicle market uptake, high-volume hydrogen supply and refueling, and advanced research and development accomplishment. In contrast, the same DOE 2018 document that is referenced by EPA (Rustagi et al., 2018) projected distribution and dispensing cost of $4.2/kg-$4.9/kg in 2025, which is more realistic.

The ICCT analysis of the Inflation Reduction Act assumed a $4.6/kg cost in 2030, decreasing to $2/kg in 2050, based on an Argonne National Laboratory study of prices in the United States and an impact assessment of the Alternative Fuel Infrastructure Regulation in the EU (European Commission, 2021; Reddi et al., 2017). Taking all of this into consideration, ICCT estimates about $9.5/kg retail fueling price in 2030, assuming green hydrogen and meeting the 700-bar pressure requirement and high hydrogen purity requirement by the FCEV. This estimate taken from Slowik et al., 2023 is significantly greater than the price used in the EPA rule. [EPA-HQ-OAR-2022-0985-1553-A1, p. 16]

Organization: MEMA

g) Hydrogen needs support to reach Total Cost of Ownership (TCO) parity with conventional technology. Hydrogen is not expected to have good TCO unless it gets to $5/gal and then it will need deployment at stations.

EPA Summary and Response:

Summary:

We received a range of comments on hydrogen fuel costs. CATF highlighted several reports that indicate large potential for the hydrogen price to rapidly drop with economies of scale, particularly on the production side. For example, they cited a UC Davis study for California, which estimated a potential retail price for green hydrogen of $5 to 6 per kg in 2030, where production costs are projected to be $2 to $4 per kg and distribution and dispensing costs could fall to $2 to $3 per kg. They noted that, after taking hydrogen production tax credit incentives into account, the estimates from all three studies would fall within the range of EPA's proposal. They pointed to reductions in electricity price and the cost of electrolyzers as two main factors that could impact hydrogen production prices. CATF also noted that states such as Colorado are adopting laws that further incentivize the use of hydrogen in HD vehicles.

Several commenters expressed concern about the hydrogen price assumption in the NPRM or said that prices cannot be predicted at this time. ATA and OEMs pointed to ICCT's analysis, which indicated that FCEVs would not be cost-competitive before 2035 due to low technology maturity. ICCT said that it is better to conduct a bottom-up analysis that considers hydrogen fuel production, distribution, and dispensing that uses a model to properly account for potential tax credit benefits to understand what fleet owners would pay at hydrogen refueling stations. They showed how they did this to estimate a final retail price for green hydrogen (at 700 bar and to meet high purity needs of FCEVs) in 2030 of $9.50/kg, which is over twice the price that EPA projected in the NPRM. They said that the DOE reports we referenced in the proposed rule include a "willingness to pay" that reflects the total price at which FCEVs could reach cost parity with diesel vehicles, which cannot reflect the real market.

DTNA agreed that hydrogen may be cost-competitive by 2030 but asserted that progress needs to be regularly evaluated as the market develops. They stated there is not sufficient data to project station buildout nationwide to enable regional and long-haul applications. They noted that the petroleum fueling network took several decades to build. DTNA shared the high price of hydrogen in California now and pointed to ICCT's report that found that HD FCEVs will not reach cost parity with comparable ICE vehicles until after 2040. They suggested including an infrastructure scalar to adjust the stringency of the standards based on the pace of buildout.

MEMA suggested that hydrogen would need to get to a price of $5 per kg to reach TCO parity with conventional technology, and then the fuel will need to be deployed at stations.

Dana suggested that EPA should conduct studies to analyze the impact of federal incentives on the cost of producing hydrogen.

Response:

EPA discusses the issue of hydrogen cost in detail in RIA Chapter 2.5.3.1, which includes a review of literature that addresses the ICCT paper mentioned by several commenters. We note here in summary that, after further consideration, including of public comment and in consultation with DOE, our initial estimate of a retail hydrogen price of $4 per kg in 2030 in the proposal was adjusted higher in this final rule to $6 per kg in 2030 and dropping to $4 per kg in 2035. This is intended to reflect a price that fleet owners would pay at hydrogen refueling stations.

To evaluate our estimates further, and in response to comments, the National Renewable Energy Laboratory (NREL) conducted a bottom-up analysis that explores the potential range of levelized costs of dispensed hydrogen (LCOH) from hydrogen refueling stations for HD FCEVs in 2030. The authors conclude that the overall system LCOH for stations in 2030 is estimated to range from ~$3.80/kg-H2 to ~$13/kg-H2.[634] This cost range is not the same as a retail price, but we assume that any retail markup at the station is minimal, given that gas and diesel fuel retailers

[634] Bracci, Justin, Mariya Koleva, and Mark Chung. "Levelized Cost of Dispensed Hydrogen for Heavy-Duty Vehicles". National Renewable Energy Laboratory. NREL/TP-5400-88818. March 2024. Available online: https://www.nrel.gov/docs/fy24osti/88818.pdf.

generally make very little selling fuel.[635,636] Importantly, it does not consider any tax incentives or other state or federal incentive policies that may further reduce the retail price that consumers see at a fueling station in 2030. Therefore, we conclude that our retail price of hydrogen is within a reasonable range of anticipated values. MEMA suggested that hydrogen would need to be $5 per kg to get to a total cost of ownership (TCO) parity with conventional technology. ICCT noted that the National Clean Hydrogen Strategy and Roadmap[637] and Liftoff Report[638] identify a willingness to pay (or threshold price) for clean hydrogen of $4 to $5 per kg for commercial trucks and buses. We acknowledge that our revised hydrogen price projection for the final rule of $6 per kg in 2030 is above $5 per kg and that our projection of $5.20 per kg in 2032 is still slightly above the threshold price (see RIA Chapter 2.5.3.1). Importantly, however, our projections indicate that the price would fall below $5 per kg by 2033 and thus the use of hydrogen would become more at parity with diesel fuel within one to two years of HD FCEV vehicle ownership. RIA Chapter 2.9.2 includes our payback calculations to determine the number of years that it will take for the annual operational savings of a ZEV to offset the incremental upfront purchase price of a BEV or FCEV. This analysis shows that when purchased in 2030, two of the four HD FCEVs in the modeled potential compliance pathway pay back in less than 10 years[639] and, when purchased in 2032, all four HD FCEVs pay back in four to seven years due to operational savings. See RIA Chapter 2.12 for a related TCO analysis.

CATF asserted that hydrogen prices will continue to fall, and possibly lower than we projected in the proposed rule by 2030. We agree that many factors are at play that will ultimately impact the price and recognize that the potential hydrogen market is larger than the transportation sector, as outlined in RIA Chapter 1.8.3.5. According to the U.S. National Strategy, long-haul heavy-duty trucks are within the “first wave” of hydrogen market development in the U.S.[640] There are BIL and IRA incentives in place to develop seven H2Hubs that could start to produce clean hydrogen and deliver it to end uses during the timeframe of the rule, possibly in addition to the 10 million metric tons that is produced annually today.[641] This includes up to $4 billion in tax credits for the manufacturing of hydrogen production equipment

and fuel cells, among other technologies.[642,643] As suggested in DOE's Liftoff report, "as fleets begin to transition to clean hydrogen, a reinforcing feedback loop could occur in which hydrogen infrastructure catalyzes more FCEV production, and thus—more FCEV production leads to lower cost vehicles, more customer demand, and more widely scaled, lower-cost hydrogen infrastructure" as challenges such as those identified by commenters can be overcome.[644] This final rule provides greater certainty to early market HD FCEV participants who can initiate market development so that lower hydrogen fuel costs are realized by MY 2030.

DTNA said that there is insufficient data to project hydrogen station buildout and related pricing, noting that California's price for hydrogen is currently high. We understand that the hydrogen price in California spiked recently, from an average of $14.95 per kg in the second quarter of 2022 to $36 per kg in August 2023. According to the State, causes include supply chain constraints, hydrogen supply disruptions, and equipment failures, and the State is taking actions to address these issues, some of which are still related to COVID-19 pandemic-related slowdowns.[645] S&P Global found that key challenges affecting hydrogen supply and prices in California reflect an immature FCEV fueling infrastructure market. According to data collected by S&P Global, fuel availability and price volatility have not been issues for transit bus FCEVs because transit agencies structure long-term fixed hydrogen price supply contracts to meet their needs. Transit agencies require more fuel and more station operations and maintenance (O&M) so are less risk-prone than smaller stations for light-duty vehicles.[646] We expect that as hydrogen production develops to meet higher levels of demand required by HD FCEVs, there will be fewer issues with supply. Another challenge identified in California is the equipment failures at stations. California issued a solicitation to support O&M, along with a manufacturing grant to produce hydrogen refueling equipment, and they entered into a contract to conduct surveys to investigate issues further.[647] DOE is also funding efforts to advance research, development, demonstration, and deployment of technologies for HD FCEV stations and to address station

reliability issues.[648,649] We expect equipment failures will decrease over time as both manufacturers and operators of equipment gain experience with it while bringing it to scale. The modeled potential compliance pathway in the final rule includes an early market level of FCEV adoption, which allows for growth in technology maturity before and during the 2030 to 2032 timeframe and prior to more widespread adoption in later years. We anticipate that infrastructure concerns can be addressed to meet the needs of an early market HD FCEV fleet by 2030.

DTNA also noted that the petroleum network took decades to build. MEMA suggested that prices need to be cost-effective prior to station deployment. As discussed in RTC Section 8.1, we are not suggesting that a full national hydrogen infrastructure network needs to be in place by 2030 or even by 2032, and specifically note that a full national hydrogen infrastructure network is not needed to accommodate the demand that we posit for FCEVs in our modeled potential compliance pathway. EPA does believe, however, that a full infrastructure network for hydrogen can be achieved over the coming decades. To help accomplish this goal, the U.S. released a National Zero-Emission Freight Corridor Strategy[650] in March 2024 that, "sets an actionable vision and comprehensive approach to accelerating the deployment of a world-class, zero-emission freight network across the United States by 2040. The strategy focuses on advancing the deployment of zero-emission medium- and heavy-duty vehicle (ZE-MHDV) fueling infrastructure by targeting public investment to amplify private sector momentum, focus utility and regulatory energy planning, align industry activity, and mobilize communities for clean transportation."[651] The strategy has four phases. The first phase, from 2024-2027, focuses on establishing freight hubs defined "as a 100-mile to a 150-mile radius zone or geographic area centered around a point with a significant concentration of freight volume (e.g., ports, intermodal facilities, and truck parking), that supports a broader ecosystem of freight activity throughout that zone."[652] The second phase, from 2027-2030, will connect key ZEV hubs, building out infrastructure along several major highways. The third phase, from 2030-2045, will expand the corridors, "including access to charging and fueling to all coastal ports and their surrounding freight ecosystems for short-haul and regional operations."[653] The fourth phase, from 2035-2040, will complete the freight corridor network. This corridor strategy provides support for the development of HD ZEV infrastructure that corresponds to the modeled potential compliance

Comments by Organizations

Organization: American Free Enterprise Chamber of Commerce (AmFree) et al.

E. EPA Failed To Consider Alternatives

EPA also unreasonably ignored alternative solutions to the proposed heavy-duty emissions standards. Agencies are required, as part of any reasoned decision-making process, to consider all “significant and viable and obvious alternatives” to their proposed action. Dist. Hosp. Partners, 786 F.3d at 59 (citation omitted); see Spirit Airlines, Inc. v. DOT, 997 F.3d 1247, 1255 (D.C. Cir. 2021) (“[T]he failure of an agency to consider obvious alternatives has led uniformly to reversal.” (quoting Yakima Valley Cablevision, Inc. v. FCC, 794 F.2d 737, 746 n.36 (D.C. Cir. 1986))). [EPA-HQ-OAR-2022-0985-1660-A1, p. 67]

Here, EPA failed to consider any alternatives that did not fall within the narrow category of tailpipe-emissions standards. The agency instead considered only whether emissions standards of varying level of stringency or with differing phase-in periods may be appropriate alternatives. See 88 Fed. Reg. at 26,082–83. But tailpipe-emissions standards are not the only means available to achieve EPA’s stated goal of “reduc[ing] GHG air pollution from” heavy-duty vehicles. Id. at 25,928. [EPA-HQ-OAR-2022-0985-1660-A1, p. 67]

For instance, in its parallel proposed rule on emissions standards for light and medium-duty vehicles, EPA asserted that it has authority to impose fuel controls—though it requested comment only on whether fuel controls should be used in the future as a “complement” to emissions standards, rather than as an alternative to them. 88 Fed. Reg. at 29,397–98. But the heavy-duty rule at issue here does not address fuel controls as an alternative at all. That omission violates the requirement of reasoned decisionmaking.12 Cf. Am. Radio Relay League, Inc. v. FCC, 524 F.3d 227, 242 (D.C. Cir. 2008) (remanding where agency did not “consider responsible alternatives to its chosen policy and . . . give a reasoned explanation for its rejection of such alternatives” (citation omitted)). EPA’s failure to consider any non-emissions-standard-based alternatives to the proposed rule renders the proposed rule arbitrary and capricious. [EPA-HQ-OAR-2022-0985-1660-A1, p. 67]

12 We do not at this time express any view on any particular fuel-control measure, and any regulation incorporating such measures would first have to be proposed for public comment. See 42 U.S.C. § 7607(d). We simply note the proposed rule’s failure to address this alternative.

Organization: American Highway Users Alliance

In addition, EPA seems to have given little or no consideration to incentives for lower emission liquid fuels as part of the solution to reducing lifecycle emissions from heavy-duty vehicles. Such fuels are already in the marketplace; increasing their use would appear to be achievable. Policy approaches to help encourage the production of lower emission liquid fuels could offer near-term emissions reductions from existing vehicles, potentially at a lower cost to society. Yet, EPA's proposal in this docket focuses on electrification as the sole means of reducing emissions from heavy-duty vehicles. [EPA-HQ-OAR-2022-0985-1550-A1, p. 3]

Greater use of lower-emission liquid fuels should be part of the overall approach to reducing emissions from heavy-duty vehicles.

As noted earlier, the discussion in the NPRM seems to have given little or no consideration to the potential gains in emissions reductions that medium- and heavy-duty fleets could achieve through greater use of lower emission fuels. Fuels produced with lower emission renewable feedstocks and traditional fuels produced with lower carbon intensities, such as in association with carbon capture and sequestration, exist today and are scalable with the right policy support. Greater use of these fuels could help progress emission reductions from existing fleets while refueling infrastructure, recharging infrastructure and critical mineral supply chains develop. [EPA-HQ-OAR-2022-0985-1550-A1, p. 8]

Even with the accelerated fleet turnover the EPA's proposed standards seek, millions of medium and heavy-duty vehicles with internal combustion engines will remain on the roads in the coming decades. Instead of pursuing policies that focus on a sole technology pathway for achieving transportation-related emissions reductions, EPA should allow for multiple technology pathways – including pathways that recognize how to improve the overall lifecycle carbon intensity for existing vehicles and fuels. This might include linked, carbon-intensity based vehicle and fuel standards that enable consumers to retain the preference for engine type, while still participating in societal aims to achieve emissions reductions. [EPA-HQ-OAR-2022-0985-1550-A1, p. 8]

Organization: American Petroleum Institute (API)

As noted by the American Trucking Associations (ATA), in testimony before the U.S. Senate Committee on Environment and Public Works8:

When battery electric vehicles are not the answer, federal support should refrain from playing favorites, and instead assist in the buildout of alternative fuel facilities. Proposals for hydrogen infrastructure for trucks need to ensure that the infrastructure is in place where that technology best fits in supply chains. Where lifecycle emissions can be reduced by deploying renewable diesel and renewable natural gas, those fuel stocks need to be available for trucking. [EPA-HQ-OAR-2022-0985-1617-A1, p. 8.]

8 U.S. Senate Committee on Environment and Public Works, hearing on "The Future of Low Carbon Transportation Fuels and Considerations for a National Clean Fuels Program", February 15, 2023 (https://www.epw.senate.gov/public/index.cfm/2023/2/the-future-of-low-carbon-transportation-fuels-and-considerations-for-a-national-clean-fuels-program).

Bio and renewable fuels, such as renewable diesel, renewable natural gas, and biodiesel can and should be considered as part of an "all-of-the-above" approach to decarbonization of the transportation sector, including biocircularity. Especially for HD vehicles (and other hard-to-abate sectors) which may not be EV-ready or have infrastructure available, renewable fuels can serve as a lower emission and cost option that is readily available. As previously noted, API members are currently investing heavily in renewable fuel production – continued investment and development will increase the available volumes of such fuels in the marketplace and allow them to serve both as a viable lower carbon solutions leading up to the start of the Phase 3 program, throughout implementation, and beyond. Further, key findings of a study prepared for the Diesel Technology Forum showed results (for the scenarios considered in the study) of cumulative GHG reductions that were up to three times greater than BEVs for ICEVs fueled with 100 percent renewable diesel, and reductions from vehicles fueled with biodiesel blends were on par with BEV reductions.9 [EPA-HQ-OAR-2022-0985-1617-A1, p. 8]

9 "Environmental Benefits of Medium- and Heavy-Duty Zero Emission Vehicles Compared with Clean Bio- & Renewable-Fueled Vehicles 2022-2032," prepared for Diesel Technology Forum by Stillwater Associates LLC, July 19, 2022.

Further, EPA's LCA modeling for the proposal is based on biocircularity with atmospheric CO2 consumed by biomass, resulting in zero tailpipe carbon emissions if the combusted biofuels were made from renewable biomass. The agency is thus not taking the source of carbon into account, and is classifying all carbon tailpipe emissions as the same related to their atmospheric GHG impact. For example, the agency should have considered in its analysis that a Class 7/8 ICEV run on 100% Renewable Diesel made from used cooking oil would have a greater than 70 percent tailpipe carbon reduction. EPA's approach is not consistent with other existing EPA policies (e.g., the Renewable Fuel Standard). [EPA-HQ-OAR-2022-0985-1617-A1, pp. 8 - 9]

Organization: American Soybean Association (ASA)

Through this rulemaking process, ASA urges EPA to recognize and maintain robust opportunities for biomass-based diesel to make immediate carbon reductions in the heavy-duty market now and in the future; and to consider the potential economic and environmental impacts that the proposed Phase 3 rule may have on farmers through continued use of readily available technologies and slower pace for implementation of new regulations. [EPA-HQ-OAR-2022-0985-1549-A1, p. 1]

Biomass-Based Diesel Impacts As the federal government seeks to address climate change both today and in the long-term, biomass-based diesel will remain an important tool in the toolbox in both existing diesel engines and new ultra-low carbon liquid fuel engine technologies. Carbon emissions continue to accumulate, and increased utilization of biomass-based diesel and other biofuels can help mitigate increasing emissions occurring at present. The Intergovernmental Panel on Climate Change notes in its sixth assessment report that using existing low carbon technologies is a crucial component to avoiding catastrophic temperature increases, stating that 'biodiesel and renewable diesel fuels…could offer important near-term reductions' for several technologies, including buses, rail, and long-haul trucking.3 [EPA-HQ-OAR-2022-0985-1549-A1, p. 3]

3 Jaramillo, P., Ribeiro, S.K., et al. (2022). Transport. In IPCC, 2022: Climate Change 2022: Mitigation of Climate Change. Contribution of Working Group III to the Sixth Assessment Report of the Intergovernmental Panel on Climate Change. (https://report.ipcc.ch/ar6wg3/pdf/IPCC_AR6_WGIII_FinalDraft_Chapter10.pdf)

Of note, government and corporate entities around the country are already utilizing biomass-based diesel as an opportunity to achieve lower emissions. For example, New York City requires all 11,000 city fleet vehicles to use biomass-based diesel—from the police department and fire department to the department of sanitation and off-road equipment vehicles. Other cities, like Washington, D.C., are also transitioning their fleets to biomass-based diesel. In 2018, D.C. used 120,000 gallons of biomass-based diesel in its vehicle fleet, which resulted in 1,000 fewer tons of greenhouse gas emissions. In 2020, the D.C. Department of Public Works announced it would begin running 17 garbage trucks on B100, or 100% biomass-based diesel—an 86% greenhouse gas emissions reduction from a traditional petroleum-fueled garbage truck. The results are so clear that the city plans to double the size of its B100 vehicles in the next year. Through funds granted by EPA's Diesel Emissions Reduction Act program, D.C. Water Authority is expanding its use of B100 to 31 vehicles where it also benefits worker health. [EPA-HQ-OAR-2022-0985-1549-A1, p. 3]

Soy farmers are proud of the success of biomass-based diesel—not only for the new market opportunities the fuel created for farmers, but also for being able to grow a clean energy solution right in soybean fields. In fact, many soybean growers are using biomass-based diesel in their own farming equipment. Soybean oil represents about half the feedstock used to produce biomass-based diesel and, according to analysis by Clean Fuels Alliance America, biomass-based diesel has led to a savings of 143.8 million metric tons of carbon since 2010. [EPA-HQ-OAR-2022-0985-1549-A1, p. 3]

Given the current boom in the biomass-based diesel sector, the continued development of more efficient heavy-duty vehicles employing ICE technology that can utilize renewable fuels will encourage purchase of newer model year technology and retirement of older trucks with higher emissions in the agricultural hauling sector. New ZEV technologies are not yet widely accepted in rural America, based on cost and infrastructure considerations mentioned earlier. However, powertrain ICEs that can run on biomass-based diesel can provide real GHG emissions reductions today. ASA believes that ensuring continued pathways for these technologies will lead to increased utilization in the agricultural sector. [EPA-HQ-OAR-2022-0985-1549-A1, p. 3]

Organization: American Trucking Associations (ATA)

Fleets are evaluating and implementing cost-effective options to reduce emissions. Biodiesel is a traditional plug-in fuel that yields lower carbon emissions. More recently, renewable diesel has emerged as a desirable carbon reduction option, producing near-zero tailpipe emissions when combined with the newest engine technologies. Fleets are also operating renewable natural gas and propane-powered vehicles in locations where fueling infrastructure is established. These fuel-based options present more cost-effective solutions and should be encouraged under the proposed regulation. A crediting system that prorates the annual expansion of lower carbon fuel use across new conventional vehicle sales is needed to capture existing carbon reduction efforts. This system would help account for fleet efforts to purchase conventional or alternative fueled vehicles rather than only ZEVs. [EPA-HQ-OAR-2022-0985-1535-A1, p. 13]

Organization: Anonymous Public Comment

There should be provisions in the rule for the handling of biofuels and/or synthetic fuels ("efuels") in GHG emission calculations. Phasing out fossil fuels for ICEVs while phasing in renewable fuels/efuels could be just as effective in achieving climate goals as a shift to so-called "zero-emission" vehicles, possibly even more so. In fact, even if 100% of new vehicle sales are BEV by 2035, or any other date for that matter, it could potentially be counterproductive from an environmental perspective. ICEVs will be on the road for decades even if new ICEVs are effectively banned by regulation, and those vehicles would be contributing to significantly reduced GHG emissions with bio/efuels, while still in use. The European Union just adopted a provision to allow new ICEVs to be sold after 2035 if efuels are used exclusively to fuel the vehicles, in spite of efforts to "ban" ICEVs after 2035. Some consideration of biofuels/efuels should be adopted. [EPA-HQ-OAR-2022-0985-1773]

According to Argonne National Laboratory (ANL), efuels produced by the Fischer-Tropsch (FT) process can be carbon NEGATIVE from a well-to-wheels perspective if the system is properly configure (https://pubs.acs.org/doi/10.1021/acs.est.0c05893). Some FT biofuels can also be carbon negative with CCS (e.g., https://velocys.com/2019/10/10/negative-emission-fuel-agreement/), or by sequestering carbon produced as a byproduct from the process (https://www.greencarcongress.com/2023/04/20230415-terrastar.html). There are no pathways in ANL's GREET model for BEVs to be carbon negative, not even with 100% renewable electricity. If GHG emission reduction is really the goal, these fuels should be given top priority from a regulatory perspective. It should also be pointed out that FT ediesel fuel has very low upstream (well-to-tank) criteria pollutant air emissions according to ANL's GREET model. The Renewable Fuel Standard (RFS) could be used as a mechanism for phasing out fossil-based fuels in favor of biofuels/efuels. Alternatively, the U.S. could follow the European model and allow only ICEVs that use efuels/biofuels exclusively to be produced post 2035. [EPA-HQ-OAR-2022-0985-1773]

Organization: Barry Supranowicz

I am pleased that the EPA is taking important steps to address global warming pollution from trucks, but the heavy-duty vehicle standard needs to do much more to put us on a path to eliminate all tailpipe emissions from new vehicles by 2035. [EPA-HQ-OAR-2022-0985-2252]

Black, Asian America, and Latin American communities and other marginalized communities living in high traffic areas have suffered the health impacts of diesel trucks for too long. Now is the time to set us on a path to eliminate toxic tailpipe emissions from trucks. [EPA-HQ-OAR-2022-0985-2252]

Technology currently exists in the US (see PLUG) to supply green-energy produced hydrogen and oxygen as fuels for the trucking industry (as opposed to gray- or fossil fuel-based hydrogen-oxygen of which would continue to foster pollution of our air). We need to move forward in mandating green-energy produced hydrogen-oxygen fuel cell powered big rigs. Fact is, not only do green hydrogen-oxygen fuel cell powered trucks offer zero pollution power plants to move things around - they offer to said trucking industry vastly reduced costs for fuel purchases and thereby reduced costs for goods and services - making those manufacturing-trucking industries more competitive in their offerings of goods and services. Green hydrogen-oxygen use for hydrogen-oxygen fuel cell powered power plants for trucks and businesses offers much lower costs for energy-power production (compared to fossil fueled power plants) from a infinite (for human purposes) supply of said power through accessing that hydrogen-oxygen from our oceans. Fossil fueled power plants arise from limited and dwindling oil in our earth surface, a resource increasingly more difficult and expensive to acquire, not to even consider the pollutive effects of fossil fuel acquisition-extraction-refinement-transport-and usage - costs that arise in future time from fossil fuel extraction-use and making fossil fuels even more expensive. [EPA-HQ-OAR-2022-0985-2252]

The EPA has the power to accelerate the deployment of zero-emission vehicles. Please finalize the strongest possible rule to deliver clean air. The clock is ticking, and zero-emission trucks will save lives. [EPA-HQ-OAR-2022-0985-2252]

I strongly urge the EPA to adopt requirements that would address the disproportionate health impacts for marginalized communities living near freight corridors and accelerate the rollout of zero-emission trucks. Thank you for your consideration. [EPA-HQ-OAR-2022-0985-2252]

Organization: Chevron

4. The role of biofuels

Recent data from the EPA Moderated Transaction System shows 2022 annual production of approximately 2.0 billion gallons of biodiesel, an additional 2.0 billion gallons of renewable diesel, and 700 million gallons equivalents of renewable natural gas. These renewable fuels represent over 8% of the total diesel demand in the U.S. In California, biodiesel and renewable diesel together supplied 34% of total diesel demand in the state. Renewable fuels are contributing significantly to GHG reduction in today's market using existing infrastructure. The heavy-duty GHG standards should recognize the potential for additional GHG reduction from the existing vehicle fleet using these renewable fuels. [EPA-HQ-OAR-2022-0985-1552-A1, pp.5-6]

We believe there is ample feedstock, oilseed crush capacity, and fuel production capacity to achieve an additional 500 million gallons per year of advanced biofuels through the end of 2025, as outlined in Chevron's comments7 earlier this year for EPA's proposed regulations for the Renewable Fuel Standard. The majority of these advanced biofuels will be made up of renewable diesel and biodiesel. [EPA-HQ-OAR-2022-0985-1552-A1, p.6]

7 Docket ID No. EPA-HQ-OAR-2021-0427, Chevron Comment Letter in response to Renewable Fuel Standard Program Proposed Rule: Standards for 2023-2025 and Other Changes. Available here: EPA-HQ-OAR-2021-0427-0553

Several of our trade association partners highlight investments to expand lower carbon intensity biofuels that are playing a key role today to reduce emissions from the hard to electrify transportation sector. We reference the comments filed by Clean Fuels Alliance America and the Natural Gas Vehicles for America noting advances in expanding biodiesel, renewable diesel, and renewable natural gas supply. [EPA-HQ-OAR-2022-0985-1552-A1, p.6]

Additionally, Chevron is investing in capabilities to increase the supply of biofuels. In 2022, Chevron acquired Renewable Energy Group (now Chevron REG) a leading biodiesel and renewable diesel fuel producer. Chevron REG is scheduled to complete the expansion of the renewable diesel facility in Geismar, LA in 2024 that will triple capacity to 340 million gallons of lower carbon intensity renewable diesel. [EPA-HQ-OAR-2022-0985-1552-A1, p.6]

Chevron announced a collaboration with Corteva to introduce winter canola that will produce lower carbon intensity feedstocks. Chevron has invested in CoverCress to develop and introduce small winter oilseeds that will also produce lower carbon intensity feedstocks. A Chevron joint venture with Bunge, a leading oilseed processor, will expand crush capacity to yield greater access to lower carbon intensity feedstocks. [EPA-HQ-OAR-2022-0985-1552-A1, p.6]

Chevron is also partnering with CalBio Energy, Brightmark and dairy farmers to market and produce renewable natural gas, which is used as compressed natural gas (CNG) for vehicle fueling. In January of 2023, Chevron acquired full ownership of Beyond6 with its network of 55 CNG stations across the United States. [EPA-HQ-OAR-2022-0985-1552-A1, p.6]

Finally, Chevron is forming creative alliances with partners such as Walmart, Cummins, and Raven SR to develop alternative heavy-duty fuel and technology options. All of the above technology pathways and commercial ventures are important contributors to reduce lifecycle and tailpipe emissions from new vehicles and from the existing truck fleet and should be incorporated into a strategy to reduce GHG emissions from heavy-duty trucks. [EPA-HQ-OAR-2022-0985-1552-A1, p.6]

Organization: Clean Fuels Alliance America (Public Hearing Testimony)

[*From Hearing Testimony, May 2, 2023*] On behalf of Clean Fuels members, thank you for the opportunity to testify on the immediate benefits of biodiesel and renewable diesel have and will continue to bring as we de-carbonize the heavy-duty sector. Biodiesel and renewable diesel are among the cleanest and lowest carbon fuels available today to help reduce greenhouse gas emissions and are available now to meet President Biden's near- and long-term climate goals, particularly in the hard-to-decarbonize heavy-duty sector. We appreciate EPA's acknowledgement that the internal combustion engine will continue to play an important role in the markets that Clean Fuels member serve. Low-carbon liquid fuels are the lowest cost option towards decarbonization that can be used in every diesel-fueled application and every engine technology. The heavy-duty sector will continue to rely on liquid fuels for decades to come. Clean Fuels has a long history of working with users, fleets, and the OEM community to conduct technically-credible research that validates the performance and positive impacts of biodiesel when used in existing and future diesel engines. To date, the utilization of increasing volumes of ultra-low carbon liquid fuels, like biodiesel and renewable diesel, reduces greenhouse gas emissions by more than 70 percent on average, directly and immediately reducing GHG emissions from the vehicles that use our fuels. Our fuels reduce more than just greenhouse gas emissions. Biodiesel and renewable diesel also reduce criteria pollutants from existing diesel engines, reduce health and environmental impacts in major trucking corridors, warehouse distribution centers, and other diesel hotspots close to major population sectors. This means that using these fuels today can lower healthcare costs and costs for all populations living in and near these areas including, minority, low-income, and indigenous populations. Through our continued partnership with Trinity Consultants, Clean Fuels quantified the health benefits and corresponding economic savings from converting petroleum-based diesel to 100-percent biodiesel at 23 sites across the country. This research finds that switching to 100-percent biodiesel can provide immediate community health improvements, including more than 436,000 fewer reduced asthma cases per year, more than 137,000 few sick days per year, nearly 9,400 less cancer cases, the prevention of more than 885 premature deaths, over $7.4 four billion in avoided healthcare costs annually, and a 45-percent reduction in cancer risk. And legacy heavy-duty trucks, such as older semis, use B100. The immediate benefits of B100 usage can bring -- cannot be underscored enough, especially for disadvantaged communities when you consider the longer, full, useful life requirements of existing diesel engines and the decades-old take to pursue across-the-board electrification and other decarbonization strategies. Clean Fuels looks forward to working with EPA to continue to optimize the immediate benefits of biodiesel and renewable diesel to decarbonize the heavy-duty sector today and in the years to come. Thank you. [EPA-HQ-OAR-2022-0985-2666, Public Hearing Testimony, Day 1]

Organization: Clean Fuels Alliance America

Low carbon liquid fuels are the lowest cost option toward decarbonization that can be used in every diesel fueled application and every engine technology. It cannot be overlooked that the heavy-duty sector will continue to rely on the internal combustion engines when you consider the longer full useful life requirements of existing diesel engines and the decades it will take to pursue across the board electrification and other decarbonization strategies. As a result, EPA cannot discount the immediate benefits biodiesel and renewable diesel have and will continue to bring as we decarbonize the heavy-duty sector. [EPA-HQ-OAR-2022-0985-1614-A1, pp. 1 - 2]

Our fuels reduce more than just greenhouse gas emissions. Biodiesel and renewable diesel also reduce criteria pollutants from existing diesel engines, reducing health and environmental impacts in major trucking corridors, warehouse distribution centers and other diesel hot spots close to major population sectors. This means that using these fuels today will also lower health care impacts and costs for all populations living in and near these areas including minority, low-income, and indigenous populations. [EPA-HQ-OAR-2022-0985-1614-A1, p. 2]

We ask that EPA adjust the performance-based standards to reflect a more appropriate and feasible mix of technologies available in the time-frame proposed to meet the revised standards recognizing that EPA will still achieve both carbon reductions and environmental justice benefits using biodiesel and renewable diesel in the heavy-duty sector. [EPA-HQ-OAR-2022-0985-1614-A1, p. 2]

II. Proposed CO2 Emission Standards

We appreciate EPA's acknowledgement of the role the internal combustion engine will continue to play in the heavy-duty market. The heavy-duty trucking sector alone will be reliant on liquids fuels until at least 2050 with the assumed average lifetime of 15 years. [EPA-HQ-OAR-2022-0985-1614-A1, p. 2]

The Ultra-Low Emissions Diesel Engines (ULEDEs) produced under the "Control of Air Pollution from New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards" are substantially cleaner than New Technology Diesel Engines (NTDE) in the market today and will approach near-zero regulated emissions of PM, NOx, unburned hydrocarbons, and carbon monoxide.3 Low-carbon liquid fuels will address the emissions of PM, NOx, unburned hydrocarbons, and carbon monoxide in existing engines. Using renewable fuels in existing internal combustion engines will remain an important option for decarbonizing the transportation sector. In addition, these fuels continue to make improvements in emissions, are readily available nationwide, have known predictable performance, and other known operating characteristics such as higher cetane rating and improved lubricity, which help prolong engine life. Biodiesel burns cleaner, reduces harmful emissions, and helps eliminate injector and fuel system deposits, which can extend maintenance intervals. [EPA-HQ-OAR-2022-0985-1614-A1, p. 2]

3 U.S. Environmental Protection Agency. Control of Air Pollution from New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards, EPA-HQ-OAR-2019-0055, 88 FR 4296 (January 24, 2022), available at https://www.federalregister.gov/d/2022-27957

Meeting clean air demands does not require switching to a zero-emissions vehicle. Biodiesel and renewable diesel are drop-in alternatives, achieving valuable carbon reductions today at a relatively low cost.4 These fuels offer owners, users, and fleet operators of heavy-duty vehicles affordable, low-carbon solutions to immediately improve the sustainability of their operations. These cleaner fuels are available now and can be used in every diesel fueled application and every engine technology. Nearly all medium- and heavy-duty original equipment manufacturers (OEMs) support using biodiesel blends of 20% or more in the vehicles they produce, and the vast majority of OEMs support the use of biodiesel blends up to 20%. For those that do not, warranties cannot be voided or impacted in any way using biodiesel, due to existing federal law.5 [EPA-HQ-OAR-2022-0985-1614-A1, pp. 2 - 3]

4 Source: Frank, J. et al. Quantifying and comparing the cumulative greenhouse gas emissions and financial viability of heavy-duty transportation pathways for the Northeastern, United States. Fuel, 323, 124243, Sep. 2022. https://doi.org/10.1016/j.fuel.2022.124243. See Table 4.

5 Magnuson-Moss Warrant Act, P.L. 93-637

When compared to other decarbonization strategies such as zero emissions and specifically electrification approaches, which require both new vehicles and infrastructure to realize the benefits, biodiesel and renewable diesel remain the lowest cost option. [EPA-HQ-OAR-2022-0985-1614-A1, p. 3]

Organization: ClearFlame Engine Technologies

ClearFlame supports a strong Final Rule that accelerates the decarbonization of the all vehicles in the heavy-duty truck sector in a manner that will meet the ambitious goals of the Biden Administration's Transportation Decarbonization Blueprint (the 'Blueprint').Integrating our recommendations and proposed solutions into the Final Rule will align the Phase 3 GHG standards 3 More specifically, the Blueprint stated that we will need to deploy a range of solutions to meet our climate goals, including biofuels and e-fuels (collectively referred to as 'Sustainable Liquid Fuels' or 'SLFs'), electric vehicles, and hydrogen-powered vehicles. and the Final Rule with the Blueprint. [EPA-HQ-OAR-2022-0985-1654-A2, p. 2]

3 The U.S. National Blueprint for Transportation Decarbonization: A Joint Strategy to Transform Transportation (the 'Blueprint').

We are pleased to see EPA acknowledge that there will be no 'one-size-fits-all' approach to future heavy-duty vehicles and engines, and that it expects to see a mix of engine technologies as part of the solution set.5 Our goal in submitting these comments is to support EPA by proposing changes to the Final Rule that better aligns with the Administration's Blueprint, especially with respect to ethanol, the most common SLF. [EPA-HQ-OAR-2022-0985-1654-A2, p. 2]

5 Proposal at 25932.

A Final Rule that is silent on ethanol and other SLFs – that does not even create a certification pathway for engines that dedicated to ethanol usage – will stifle innovation in this sector, send a signal to America's farms and rural communities that they will not participate in the exciting economic opportunities presented by a decarbonized transportation future, and result in a longer, slower, less cost-effective transition from petroleum-fueled, internal combustion engine ('ICE') vehicles in the long-haul truck sector. [EPA-HQ-OAR-2022-0985-1654-A2, p. 2]

Currently, of the three strategies highlighted in the Blueprint to decarbonize our future trucks, the Proposal only incentivizes electric vehicles and hydrogen vehicles. However, the Blueprint concluded that, in the long-haul truck sector, biofuels and other SLFs will be a 'large, long-term' opportunity that is even greater than the market opportunity for battery-electric vehicles (‘BEVs’).6 We believe that the Blueprint’s recognition of the large, long-term opportunity of biofuels and other SLFs in the long-haul truck sector should be embodied In the Final Rule. [EPA-HQ-OAR-2022-0985-1654-A2, p. 3]

6 The U.S. National Blueprint for Transportation Decarbonization: A Joint Strategy to Transform Transportation, see page 5, Figure B

The Clean Air Act authorizes EPA to integrate the type of fuel into the Phase 3 GHG emission standards. [EPA-HQ-OAR-2022-0985-1654-A2, p. 4]

This Proposal is based on authority granted to EPA under Clean Air Act Section 202(a).8 Section 202(a)(1) gives EPA authority to establish emissions standards for ‘any air pollutant from any class or classes of new motor vehicles or new motor vehicle engines.’ On numerous occasions, EPA has found that carbon dioxide (CO2) and other GHG emissions have significant impacts that endanger public health and welfare.9 Thus, we agree that EPA is authorized to proceed with this Proposal to establish Phase 3 GHG standards for heavy-duty engines pursuant to Section 202(a)(1) of the Clean Air Act. [EPA-HQ-OAR-2022-0985-1654-A2, p. 4]

8 42 U.S.C. 7521(a)(1).

9 See Proposal, p. 25928, footnote 4.

As EPA knows, GHG pollution is a global problem. Unlike pollutants that trigger asthma emergencies, heart attacks, or other local health impacts, it does not matter whether GHG emissions reductions occur at the tailpipe of a vehicle or from the shift from high-carbon petroleum to low-carbon SLFs like ethanol. From the perspective of carbon pollution, the location of these reductions is irrelevant. Thus, it makes sense to create a Final Rule that reduces the total GHG emissions impact of America’s future heavy-duty vehicles as much as possible, as quickly as possible, wherever possible, and as cost-effectively as possible. Doing so makes it more likely that the Final Rule will be a success. [EPA-HQ-OAR-2022-0985-1654-A2, p. 4]

Section 202(a)(3)(A)(ii) authorizes EPA to look beyond the basic engine to set its engine or vehicle emission standards. Specifically, it states that, ‘in establishing classes or categories of vehicles or engines for purposes of regulations under this paragraph, the Administrator may base such classes or categories on gross vehicle weight, horsepower, type of fuel used, or other appropriate factors.’10 (emphasis added). [EPA-HQ-OAR-2022-0985-1654-A2, p. 4]

10 42 U.S.C. 7521(a)(3)(A)(ii)

In the case of a dedicated alternative fuel engine, the type of fuel used is an inherent part of the engine system. In such an engine, the engine cannot be separated from fuel that powers it. The fuel must be considered in determining whether the engine meets the relevant emission standard. Indeed, EPA’s GEM has a fuel input for natural gas, because the agency recognizes that it is impossible to consider the emissions performance of a natural gas engine (and thus, whether such an engine should receive its certificate of conformity) separate and apart from the natural gas fuel that powers it. Similarly, it is appropriate – even imperative – that EPA establishes a certification pathway for a class or category of dedicated alternative fuel engines. It would be counter-productive if EPA simultaneously acknowledges that a low-carbon SLF like ethanol should be an important component of the Administration’s Blueprint, yet fails to provide a certification pathway that acknowledges and integrates the GHG benefits of such a dedicated alternative fuel engine that uses ethanol or other low-carbon SLF. [EPA-HQ-OAR-2022-0985-1654-A2, pp. 4-5]

EPA Should Update its Certification Pathways and GEM Inputs in the Final Rule to Specifically Integrate ethanol and other SLFs [EPA-HQ-OAR-2022-0985-1654-A2, p. 5]

In response to EPA's request for comment on the need to 'include additional GHG-reducing technologies and/or higher levels of adoption rates of existing technologies for ICE vehicles' in the Final Rule,11 and EPA's proposal to update 40 CFR 1036.505 to clarify that 'when certifying vehicles with GEM, for any fuel type not identified in Table 1 of 40 CFR 1036.550, the manufacturer would identify the fuel type as diesel fuel for engines subject to compression-ignition standards,'12 we strongly urge EPA to include an engine certification pathway for all fuels that it reasonably expects to see used in dedicated alternative fuel engine.13 Today, new engines have to be certified using the GEM. GEM assumes that the only fuels to be used by heavy-duty engines are gasoline, diesel, and natural gas. EPA recognizes that the absence of a fuel-specific approach for hydrogen will chill investment or technology development and recognizes that the emissions performance of a hydrogen-fueled engine cannot be separated from the hydrogen fuel that powers it. Thus, it is seeking comment to determine how to create a certification pathway for internal combustion engines that are fueled by hydrogen.14 [EPA-HQ-OAR-2022-0985-1654-A2, p. 5]

11 Proposal at 25961.

12 Proposal at 26022.

13 To avoid confusion and to be consistent with EPA's traditional terminology (see., e.g., EPA's Part 1065 requirements for Alternative Fuel Engine Conversions), we are using the phrase 'alternative fuel' throughout these comments, rather than the Blueprint's use of the phrase 'SLF.' However, for the purposes of our comments and recommendations, these terms are interchangeable.

14 Proposal at 26024.

EPA's Final Rule must similarly provide a mechanism for certifying dedicated ethanol and other dedicated alternative fuel engines. Failure to do so would be arbitrary and capricious as a legal matter, chilling as an investment matter, scientifically unsound from a GHG perspective, and extremely short-sighted from the perspective of creating a program to reduce GHGs at scale, as quickly and as cost-effectively as possible. [EPA-HQ-OAR-2022-0985-1654-A2, pp. 5-6]

Creating a certification pathway for dedicated alternative fuel engines that run on ethanol is not just critical to the success of ClearFlame, it is the scientifically and technically correct way to treat our engines, as well as other dedicated ethanol engines that may follow once EPA has sent this market signal to the OEMs that their dedicated ethanol engines will provide emissions certification benefits that are in sync with their real-world climate benefits. [EPA-HQ-OAR-2022-0985-1654-A2, p. 6]

The current system treats the ethanol-fueled engine as though it were actually dirtier than diesel from a carbon perspective, because GEM treats a dedicated ethanol engine as though it is running on high-carbon diesel fuel (in contrast to a CNG engine, which is not treated by GEM as though it is running on diesel). By treating a dedicated ethanol engine as though it was running on diesel, the resulting GEM calculations yield an unintended negative outcome that has no bearing in reality - modeled emissions that are actually ‘even dirtier than diesel,’ despite their obviously different contributions to climate change. [EPA-HQ-OAR-2022-0985-1654-A2, p. 6]

This ‘ethanol penalty’ happens (1) because GEM does not take the biogenic nature of ethanol emissions into account, (2) it does not take the lower carbon Intensity of ethanol into account, and (3) it does not take other combustion differences (like heating value and H/C ratio) between ethanol and diesel into account. Taken together, this means that the GEM output masks the climate benefit of the ethanol fuel choice, compared to diesel. Leading climate research indicates that these errors result in overestimating the climate impact of ethanol by 3x.15 [EPA-HQ-OAR-2022-0985-1654-A2, p. 6]

15 GEM currently estimates emissions from ethanol vehicles to be approximately 1.5 times worse than diesel. However, GREET, based on national average, calculates ethanol to have 50% of the emissions impact of diesel. Based on this information, GEM overestimates the climate impact of an ethanol-fueled engine by 3x (1.5/.5).

GEM currently estimates emissions from ethanol vehicles to be approximately 1.5 times worse than diesel. However, GREET, based on national average, calculates ethanol to have 50% of the emissions impact of diesel. Based on this information, GEM overestimates the climate impact of an ethanol-fueled engine by 3x (1.5/.5). EPA should create a fuel input for ethanol within GEM, which would account for its heating value, H/C ratio, and biogenic carbon ratio. This would enable GEM to accurately account for the different combustion properties and decarbonization benefits of a compression-ignition engine that has been designed to run exclusively on ethanol. [EPA-HQ-OAR-2022-0985-1654-A2, p. 6]

While it would be possible to achieve the same goal by adding a conversion or correction factor to the calculation of GEM emissions, a fuel-specific fuel Input (such as is being considered for hydrogen) is highly preferred to ensure GEM consistency across the various fuels that will power future heavy-duty vehicles.16 [EPA-HQ-OAR-2022-0985-1654-A2, pp. 6-7]

16 Adding such an after-the-fact conversion or correction factor to GEM could enable EPA to correctly estimate that actual, real world GHG benefits of switching from diesel to ethanol. However, this approach would not send the same market signal that a fuel-specific input does—a market signal enjoyed by engine makers that use natural gas and, presumably soon, hydrogen. That said, using the Argonne National Laboratory GREET model, we estimate a truck operating solely on E98 ethanol (i.e., 98% ethanol) would receive a 32% conversion factor, which would account for the two GHG advantages of ethanol, i.e., its lower heating value and significantly lower carbon intensity. See Argonne National Laboratory, The Greenhouse gases, Regulated Emissions, and Energy use in Technologies Model (‘GREET’), accessible at https://greet.es.anl.gov/.

We note that EPA has requested comment on whether the agency ‘should add specifications for alternative test fuels, like methanol, and fuels other than carbon-containing fuels like hydrogen and ammonia, to 40 CFR part 1065, subpart H (‘Subpart H’).’17 Currently, 40 CFR 1065.701(c) allows the use of test fuels that are not specified in Subpart H, but only with EPA’s prior written approval.18 [EPA-HQ-OAR-2022-0985-1654-A2, p. 7]

17 Proposal at 26025.

18 40 CFR 1065.701(c). See also Id. at Table 1.

The current approach enables a company like ClearFlame to request approval to use as an alternative test fuel any of the following if we meet EPA’s criteria: (1) E98 that meets ASTM D4806 (i.e., uses gasoline as its denaturant), (2) another form of E98 that does not use gasoline as its denaturant, or (3) ethanol that includes 5% water (as would result from the output of an unaugmented distillation process). However, this approach does not guarantee that EPA will approve any of these fuels as an alternative test fuel. [EPA-HQ-OAR-2022-0985-1654-A2, p. 7]

This approach adds an unnecessary layer of uncertainty into our product development, our test plans, and even the expectations of our potential investors and customers. Since EPA's intent in Subpart H seems to be to encourage innovators to develop new, low-emission technologies using a wide range of alternative fuels, it should add specifications for all SLFs that are likely to be used in future engine technologies that are developed to meet the standards and requirements of the Final Rule, including the three examples cited above. [EPA-HQ-OAR-2022-0985-1654-A2, p. 7]

Currently, the relevant section of 40 CFR part 1065, subpart H limits the use of high-blend ethanol as a test fuel to E51-83 fuel that meets the specifications of ASTM D5798.19 We request that EPA adds specifications for high-blend ethanol for each of the examples that we have outlined above: (1) E98 that meets ASTM D4806 (i.e., uses gasoline as its denaturant), (2) another form of E98 that does not use gasoline as its denaturant, and (3) ethanol that includes 5% water (as would result from the output of an unaugmented distillation process). [EPA-HQ-OAR-2022-0985-1654-A2, pp. 7-8]

19 See 40 CFR Part 1065.725.

EPA Should Treat Ethanol as Carbon-Neutral at the Tailpipe in the Final Rule, just as it treats BEVs and FCVs [EPA-HQ-OAR-2022-0985-1654-A2, p. 8]

In its Proposal, EPA proposes to treat future battery-electric vehicles and hydrogen-fueled vehicles as carbon-neutral at the tailpipe.20 This disregards any upstream or life cycle emissions that are associated with the power generation necessary to charge BEVs or the source or amount of energy that is used to generate the hydrogen that is used in any hydrogen-fueled ICE or fuel cell vehicles. [EPA-HQ-OAR-2022-0985-1654-A2, p. 8]

20 Proposal at 26022.

In its Final Rule, EPA should also treat a heavy-duty engine that is designed to operate solely on ethanol as carbon-neutral at the tailpipe. Why? Because the carbon emissions from an ethanol-fuel engine are 100% biogenic, i.e., they derive from photosynthesis pulling carbon from the atmosphere in the natural carbon cycle. Stated another way, biogenic carbon does not contribute to the process of moving carbon from the lithosphere to the atmosphere (e.g. extracting fossil-based carbon from deep underground). Since these emissions do not derive from fossil fuels, they do not contribute to climate change at the point of combustion in the engine. And thus, just like battery-electric and hydrogen-fueled vehicles, dedicated ethanol engines and vehicles should be treated as carbon-neutral at the tailpipe because they are not contributing to global climate change at the tailpipe. [EPA-HQ-OAR-2022-0985-1654-A2, p. 8]

To be as scientifically sound as possible, the Phase 3 GHG standards should focus on reducing the human-generated (or anthropogenic) climate impacts from America's future trucks and buses by reducing anthropogenic GHG emissions from their engines. To achieve this goal, EPA should recognize that biogenic and anthropogenic carbon are different in how –and even whether—they contribute to climate change. Renewable SLFs like ethanol reduce overall GHGs from heavy-duty transportation by keeping the carbon from petroleum diesel out of the atmosphere—in the ground, where it should stay. [EPA-HQ-OAR-2022-0985-1654-A2, p. 8]

Failure to recognize the difference between biogenic and anthropogenic emissions would yield an outcome that is not scientifically sound and that seems arbitrary and capricious. It would yield an outcome where a hydrogen-fueled engine that is derived from coal combustion could be certified at a lower emissions level than a dedicated ethanol engine that is derived from a low-carbon (or even carbon-negative) feedstock. [EPA-HQ-OAR-2022-0985-1654-A2, p. 8]

It is worth noting that EPA already has a policy of treating certain biogenic carbon as carbon-neutral in stationary sources. In 2018, EPA adopted a policy of treating carbon emissions resulting from the combustion of biomass from managed forests at stationary sources as carbon-neutral.21 [EPA-HQ-OAR-2022-0985-1654-A2, p. 9]

21 See U.S. Environmental Protection Agency, policy statement, accessed on April 30, 2023 at https://www.epa.gov/sites/default/files/2018-04/documents/biomass_policy_statement_2018_04_23.pdf.

Given that EPA has requested comment on whether to include additional GHG-reducing technologies for ICE vehicles in its technology assessment for the Final Rule, we do not believe that EPA would need to publish an additional Notice of Proposed Rule Making or other procedural step to integrate our recommendations.31 [EPA-HQ-OAR-2022-0985-1654-A2, p. 12]

31 Proposal at 25961.

Organization: Diesel Technology Forum (DTF)

One can reasonably conclude that both the acquisition of new ICEV and continued use of ICEV in the existing fleet in the commercial trucking sector will continue at significant levels for several decades at least. [EPA-HQ-OAR-2022-0985-1618-A1, p. 4]

As such, we believe EPA has failed to fully consider the GHG mitigation potential and factors related to the expanded use of renewable biobased diesel fuels in the extensive population of existing and expected future ICEVs that will be in service for decades to come. The resulting GHG mitigation impacts from the potential for use of the renewable biofuels on the levels of stringency in GHG standards proposed and the timing for their implementation as well as other factors has not been considered, as discussed further below. [EPA-HQ-OAR-2022-0985-1618-A1, p. 4]

III. The Proposal Fails to Consider the Current and Future Utilization of Biobased Diesel Fuels as A Decarbonization Strategy for The Sector, And Its Resulting Implications for All Aspects of The Proposed Rule.

While the proposed rule focuses on establishing emissions standards that govern future new vehicles, the justification of all the aspects of the rule is based on the hazards of greenhouse gases and the EPA’s duty to reduce them. EPA notes in its arguments that

“Despite the significant emissions reductions achieved by previous rulemakings, GHG emissions from HD vehicles continue to impact public health, welfare, and the environment. The transportation sector is the largest U.S. source of GHG emissions, representing 27 percent of total GHG emissions. Within the transportation sector, heavy-duty vehicles are the second largest contributor to GHG emissions and are responsible for 25 percent of GHG emissions in the sector.4 [EPA-HQ-OAR-2022-0985-1618-A1, p. 4]

4 Inventory of U.S. Greenhouse Gas Emissions and Sinks: 1990–2020 (EPA–430–R–22–003, published April 2022).

Use of low-carbon renewable fuels is recognized as a proven means to reduce GHG emissions of the transportation sector. In EPA's February 2023 proposed Renewable Fuel Standard (87 Fed Reg 80585) EPA notes that

"This proposed rule is projected to reduce GHG emissions, which would benefit communities with environmental justice concerns who are disproportionately impacted by climate change…" [EPA-HQ-OAR-2022-0985-1618-A1, p. 5]

In the current proposal however, EPA provides only a single passing mention of biobased diesel fuels (biodiesel and renewable diesel) (88 Fed Reg 25951)

"Manufacturers have responded to standards over the past decade by continuing to develop and deploy a wide range of technologies, including more efficient engine designs, transmissions, aerodynamics, and tires, air conditioning systems that contribute to lower GHG emissions, as well as vehicles based on methods of propulsion beyond diesel- and gasoline fueled ICE vehicles from mild hybrids and alternative fuels (such as natural gas, biodiesel, renewable diesel, methanol, and other fuels), as well as various levels of electrified vehicle technologies from mild hybrids, to strong hybrids, and up through batery electric vehicles and fuel cell electric vehicles." [EPA-HQ-OAR-2022-0985-1618-A1, p. 5]

EPA has failed to factor in the use of biobased diesel fuels and their overall impact on reducing GHG from this sector during the timeframe of the proposed rule. According to the Energy Information Administration, in 2022, U.S. refiners produced 71,879,000 barrels of biodiesel and renewable diesel combined, in addition to over 10,000,000 barrels imported. [EPA-HQ-OAR-2022-0985-1618-A1, p. 5]

By definition as an Advanced Biofuel, biodiesel and renewable diesel reduce C02 emissions by at least 50 percent compared to petroleum diesel fuel. Depending on feedstocks, the use of these fuels reduces greenhouse gas emissions by as much as 85%. [EPA-HQ-OAR-2022-0985-1618-A1, p. 5]

Given the significant role of renewable biobased diesel fuels today and projections for future growth, the Agency's failure to consider the GHG mitigation potential of the use of these fuels in the trucking sector ICEV undermines the analysis and justification for proposed future standards and other aspects of this proposed rule. These biobased diesel fuels currently meet about 4% of the nation's on-road diesel demand, and 38% in California. Biobased diesel fuels have generated more cumulative Low-Carbon Fuel Credits (42% of total since 2013) than other transportation fuels. [EPA-HQ-OAR-2022-0985-1618-A1, p. 5]

Many aspects of the proposed Phase 3 GHG rule should be reevaluated by factoring in current and future potential for GHG mitigation through the use of low carbon fuels, including the overall role of ICEV using renewable fuels in helping the US achieve climate goals, the need for the rule, the timing of the implementation of the rule, the stringency of GHG standards adopted and other factors. [EPA-HQ-OAR-2022-0985-1618-A1, p. 5]

Research completed by Stillwater Associates for the Diesel Technology Forum in July 2022 evaluated options for reducing greenhouse gas emissions from commercial vehicles in 10 northeastern states over the ten-year period 2022-2032:

- Medium and heavy-duty trucks operating in 10 Northeastern states (Connecticut, Delaware, Massachusetts, Maryland, Maine, New Jersey, New York, Pennsylvania, Rhode Island, and Vermont) that have adopted California's low emission (LEV) and zero emission vehicle (ZEV) regulations were studied by Stillwater Associates for the Diesel Technology Forum.
- An analysis was undertaken to analyze the environmental benefits attainable from three strategies in the 2022-2032 period; electrification, accelerated fleet turnover and use of biodiesel and renewable diesel fuel.
- The considerable benefits of using low-carbon renewable biobased diesel fuels were evident from this analysis. As these fuels can be used in all diesel vehicles today, fueling the diesel vehicles in the study with 100% renewable diesel resulted in three times larger cumulative GHG reductions by 2032 than the EV scenarios. Using B20 – a 20% blend of biodiesel with 80% petroleum diesel – provided about the same cumulative GHG reduction. [EPA-HQ-OAR-2022-0985-1618-A1, pp. 5 - 6.] [See the Figure, HD Scenarios 2022-2023 GHG Reductions, on page 6 of docket number EPA-HQ-OAR-2022-0985-1618-A1, pp.5-6]

Beyond GHG emissions, the research also highlighted impacts of an advanced diesel vs. electrification strategy on regional air quality as well, finding that the business-as-usual case replacing pre-2007 model year diesel vehicles which lacked diesel particulate filters with advanced technology diesel vehicles provided the largest particulate matter (PM) reduction. This is due to new technology diesel engines' 98% PM reductions compared to EVs' 95% PM reduction assuming power from the U.S. Grid Mix. [EPA-HQ-OAR-2022-0985-1618-A1, p. 6]

As for nitrogen oxides (NOx) emissions, EVs have 98.5% lower NOX than pre-2007 diesel vehicles on a per mile basis, and 2010 and later MY vehicles have 79% less NOx emissions than a 2007 diesel model. However, when replacing a diesel medium and heavy-duty vehicle with an EV and evaluated on an annual miles driven basis, the NOx benefit is diminished. EVs are generally deployed on shorter routes and have a shorter range of operation than that of a comparable diesel vehicle, with about 87% of the mileage on a daily basis. Given this mileage difference, NOx emission reductions for a fleet transitioning to EV will be less than the business-as-usual turnover from older generation diesel to advanced technology with selective catalytic reduction (SCR) systems that reduce NOx by 98%. [EPA-HQ-OAR-2022-0985-1618-A1, p. 6]

On a cumulative fleet conversion cost basis, turning over a medium and heavy-duty fleet of 10,000 vehicles in the 10-state region over to EV carries a price tag more than three times higher than the equivalent cost for new technology diesel vehicles. The incremental EV cost for Class 7/8 vehicles is $250,000 for the vehicle and $45,000 for charging infrastructure. [EPA-HQ-OAR-2022-0985-1618-A1, pp. 6-7]

The full study and supporting infographic are appended to these comments. They are also available for View and downloading as follows:

- View the full study at https://dieselforum.egnyte.com/dl/MWHPcRW4e6

- View and download the infographic at https://dieselforum.egnyte.com/dl/fZ9UzT4y6h [EPA-HQ-OAR-2022-0985-1618-A1, p. 7.] [See the Appendix on pages 8-42 of docket number EPA-HQ-OAR-2022-0985-1618-A1.]

Organization: Energy Vision

Energy Vision, a leading NGO in the clean energy sector, is submitting these comments in strong support of EPA's goal of decarbonizing the US economy as quickly as possible. However, our research shows that the country could achieve greater climate benefits on a much faster timeline through an amendment to the proposed Greenhouse Gas Phase 3 regulations: one that would indefinitely allow heavy-duty vehicles fueled by renewable natural gas (RNG), often a net carbon-negative fuel. [EPA-HQ-OAR-2022-0985-1576-A1, p. 1]

Reasons for Allowing RNG-Fueled Heavy-Duty Vehicles in EPA Phase 3 Regulations

- Measuring greenhouse gas emissions on a lifecycle basis – meaning from all aspects of production, transportation, and end-use – is the gold standard. This methodology was developed by Argonne National Laboratory and is utilized by a number of states with progressive climate laws. By contrast, a tailpipe 'zero emissions' requirement measures just a slice of the whole picture. Having zero tailpipe emissions is misguided as a criterion when the consideration that matters most to the global climate is getting total lifecycle emissions down to zero – or negative, as with renewable natural gas (RNG). [EPA-HQ-OAR-2022-0985-1576-A1, p. 1]
- RNG is the lowest carbon fuel available today. Energy Vision has found that the greatest environmental benefits accrue from converting the methane biogases emitted by decomposing organic wastes into RNG, also known as biomethane. When greenhouse gas emissions from RNG as transportation fuel are compared to diesel on a lifecycle basis, RNG from food waste, manure, and wastewater is deeply carbon-negative. This means that more carbon is captured in producing the gas (in the form of potent methane) than is ever released by combusting it (as far less potent CO2). RNG also has 90% fewer NOx emissions and 60% fewer particulate emissions than diesel; both are very damaging to health and disproportionately affect environmental justice communities. [EPA-HQ-OAR-2022-0985-1576-A1, pp. 1-2]
- It is essential to decarbonize the economy as quickly as practicable. EPA's objectives are critical in doing so, but RNG-fueled heavy-duty vehicles are a vital part of the solution. These vehicles are not technically zero-emission, but as noted above, on a lifecycle basis, they are actually net carbon negative, which is even better from a climate perspective. Put another way, even if all vehicles were to become battery electric tomorrow, there would still be a continuous flow of organic wastes – food waste, manure, wastewater, etc. – all over that must be disposed of and would be emitting methane as they decompose. By capturing that methane to produce RNG and displace the dirtiest vehicle fuel – diesel – our country would maximize climate benefits right away. [EPA-HQ-OAR-2022-0985-1576-A1, p. 2]
- Incentivizing the capture and use of methane that is otherwise escaping into the atmosphere or being flared is essential for the US to meet its climate goals. Organic waste generates a large portion of US methane emissions. Landfills accounted for approximately 16.9% in 2021 (the third largest source); when wastewater treatment, composting, anaerobic digestion, and manure management are added, that proportion

rises to over 28% – almost as much as the 29% from the oil and gas industry. The US has committed to reducing its methane emissions 30% from 2020 levels by 2030, so putting that methane to use for RNG production is a win-win. [EPA-HQ-OAR-2022-0985-1576-A1, p. 2]

- RNG technology is already well-established, high-performing, and available today, with over 50,000 trucks running on it. RNG broke a new record in 2022, making up 69% of all on-road fuel used in natural gas vehicles. There is sufficient feedstock for RNG to power a quarter of the nation's heavy-duty trucks. It's slightly more expensive for trucks to use a modern, efficient natural gas engine than a diesel engine but vastly less than a battery electric truck, which currently often retails for over twice as much as a diesel truck. While total cost of ownership for battery electric trucks is expected to come down in the years ahead, relying solely on a technology that is largely unproven in the heavy-duty on-road sector is unwise and misguided. [EPA-HQ-OAR-2022-0985-1576-A1, p. 2]
- The two leading market-based programs for transportation decarbonization in the U.S. – EPA's very own Renewable Fuel Standard and California's Low Carbon Fuel Standard – both treat RNG favorably. The vast majority of the 250+ domestic RNG projects operating today send at least a portion of their fuel to the heavy-duty on-road vehicle market. Yes, potential demand for RNG will always outpace supply, particularly for stationery (non-road) applications. But much of the success we have tracked over the past decade in seeing this country's waste-derived methane put to beneficial use has been tied to investors' and developers' ability to see the direct link between supply and demand. Eliminating RNG's eligibility for use in trucks and buses within the next decade may seriously undermine efforts to drastically reduce unchecked methane emissions. [EPA-HQ-OAR-2022-0985-1576-A1, p. 2]
- Europe provides a noteworthy example of including – even mandating – RNG (aka 'biomethane') in its transport sector. The European Union (EU) measures greenhouse gases on a lifecycle basis, and biomethane is among its accepted renewable energy sources. This includes the EU-wide carbon Emissions Trading System, where biomethane production generates valuable credits that higher-carbon producers must purchase to offset their emissions. Furthermore, the EU has set a legally binding mandate for aggregate annual production and usage of biomethane by member-states: 35 billion cubic meters (bcm) by 2030. This builds upon its previous target for renewables to cover at least 14% of the transport sector by 2030, with sub-targets for advanced biofuels and biogas to reach 1% by 2025 and 3.5% by 2030. By 2024, EU countries must separately collect organic waste, which should help scale up biomethane production. A whole host of EU financing mechanisms are available to help meet this 35 bcm target by 2030 as well. [EPA-HQ-OAR-2022-0985-1576-A1, pp. 2-3]
- RNG can also be used as a sustainable feedstock – 'bio-intermediate' – for producing other low- and no-carbon gaseous and liquid fuels that will be essential for economy-wide decarbonization. This includes production of sustainable aviation fuel, methanol and hydrogen without the use of any fossil fuels, since organic waste will continue to be generated. [EPA-HQ-OAR-2022-0985-1576-A1, p. 3]
- Battery electric trucks may have zero tailpipe emissions, but on a lifecycle basis, they actually do have significant emissions (and human rights concerns) from mining lithium and cobalt abroad – such as in the Democratic Republic of Congo and China – as well as from transportation and manufacturing; they also have troublesome battery disposal

issues. Additionally, the batteries necessary to power a Class 8 truck are heavy, in turn increasing wear on the tires, brakes, and the roads, all of which cause fine particulate emissions. Some studies have even found particulate emissions from these non-tailpipe sources on battery electric heavy-duty vehicles to be higher than what diesel trucks emit (tailpipe and non-tailpipe). [EPA-HQ-OAR-2022-0985-1576-A1, p. 3]

- EPA projects that the proportion of battery electric trucks in the heavy-duty sleeper cab category will rise from 0% in 2029 to 10% in 2030, 20% in 2031, and 25% in 2032. Those figures seem unrealistic, but even at face value they leave the vast majority of these sleeper cabs still presumably using diesel for at least the next decade, and likely much longer. However, allowing RNG-fueled heavy-duty vehicles to count indefinitely under Phase 3 regulations would lead to much faster adoption and massive greenhouse gas reductions starting now, rather than waiting many years to make a difference. [EPA-HQ-OAR-2022-0985-1576-A1, p. 3]

On a final note, we want to underscore that we are totally supportive of the development of battery electric technology and infrastructure for heavy-duty vehicles. It will take many years for the US to scale up electric vehicle charging infrastructure for heavy-duty trucks; to improve electric vehicle technology for heavy-duty models and thus their performance; and to eventually reduce costs through economies of scale. In the meantime, trucking fleets can make a big difference in emissions by switching to RNG-fueled trucks now, at reasonable cost and reliable availability. Knowing that RNG-fueled trucks would be allowed indefinitely in the Phase 3 rules would give fleet owners the certainty they seek, likely leading to a major increase in RNG usage, at least until battery electric becomes a realistic option for many of these fleets performing an essential service that is the lifeblood of our economy. In any case, RNG will never be able to cover all diesel usage – even at full theoretical production from all feedstocks, it could displace perhaps 20% of total diesel usage in the US. But to exclude it entirely from eligibility under the EPA Phase 3 regulations would be a grave mistake. [EPA-HQ-OAR-2022-0985-1576-A1, p. 3]

Organization: Hexagon Agility Inc.

Vehicles with internal combustion engines running on renewable fuels should be given credit under the Proposed Rule. [EPA-HQ-OAR-2022-0985-1507-A1, p. 1]

We request that as part of EPA's GHG emission standards analysis, EPA further investigate the emissions reduction efficacy of renewable natural gas as it compares to other fuel types – including electricity. As indicated in the graph below, and as further described in the following link (Clean Energy Fuels - How sustainability goals become reality), RNG is the only fuel with a negative carbon intensity. Indeed, RNG captures harmful methane that would otherwise be released into the atmosphere, and repurposes it as a clean fuel that quickly and effectively decarbonizes the heavy duty sector. [EPA-HQ-OAR-2022-0985-1507-A1, pp. 2-3] [See the graph on p. 2 of docket number EPA-HQ-OAR-2022-0985-1507-A1]

We believe that a wider and more agnostic approach to clean fuel technologies will allow the market to determine whatever technology is best for a particular interest, while ensuring GHG reductions are achieved over time. Remember, internal combustion architecture in the heavy-duty sector has a 100+ year track record, whereas their electric counterparts have only a roughly 3-to-5-year history. [EPA-HQ-OAR-2022-0985-1507-A1, p. 2]

Heavy duty vehicles with renewable natural gas-powered internal combustion engines (‘ICE’) and hydrogen ICE engines effectively allow for massive reductions in greenhouse gases, particularly in the in the 10L to 15L heavy duty segment. Currently, battery electric and fuel cell heavy duty vehicles do not replace their ICE and HICE counterparts on a 1:1 basis due to energy storage capacity. Future iteratives may be able to replace these, however today they cannot. Thus, achieving GHG emission reductions in this sector can only be accomplished through utilization of ICE vehicles running on clean and renewable fuels. [EPA-HQ-OAR-2022-0985-1507-A1, p. 2]

Hexagon Agility has the unique perspective of offering products within all fields of the clean energy marketplace and therefore is keenly aware of the state of that marketplace. Renewably fueled low emission heavy-duty vehicles are available, cost-effective, safe and reliable. Indeed, Hexagon Agility has over two decades of experience with natural gas fuel systems and storage. Medium- and heavy-duty trucks using renewable fuel remain one of the most cost-effective remedies to address greenhouse gas and NOx emissions, especially in the near-term. Low NOx technologies (i.e., trucks with 0.02 gram per brake horsepower (g/bhp-hr) engines) are certified by CARB as 90 percent cleaner than diesel and are available today to help achieve emissions goals on time. Moreover, medium- and heavy-duty trucks running on RNG are only continuing to improve, with CARB recently certifying the lowest NOx engine ever. Simply put, these trucks, specifically in classes 4 through 8, are commercially available and technologically feasible and therefore should be evaluated and included in the Proposed Rule. [EPA-HQ-OAR-2022-0985-1507-A1, p. 2]

Practicality and cost-effectiveness support inclusion of ICE vehicles running on clean fuels in the Proposed Rule. [EPA-HQ-OAR-2022-0985-1507-A1, p. 2]

Hexagon Agility’s products have proven real-world reliability, having been used on over 60,000 commercial vehicles for more than 20 years, logging billions of miles. Common examples of vehicles utilizing our RNG fueling systems are refuse trucks, transit buses and line haul trucks. These customers have predictable routes, demand high vehicle up-time & reliability while logging high miles and long days. These companies are highly sensitive to vehicle lifecycles and total cost of ownership (TCO). [EPA-HQ-OAR-2022-0985-1507-A1, p. 3]

Currently, by taking a tailpipe only approach, EPA is really demanding a fuel cell and electrification-only solution. This position will cause substantial up-front financial investment for customers while being the highest risk option in terms of up-time and TCO, considering vehicles are not replaced on a 1:1 basis. This will also drive all consumer goods up during a time of inflation and threatened recession. There are faster and lower cost pathways to protecting public health and driving carbon emissions down. As EPA is aware, low NOx technologies are available today and have a proven track-record as a critical and cost-effective emissions reduction strategy. It is imperative to fully consider faster and lower cost pathways to attaining cleaner air for the public health. [EPA-HQ-OAR-2022-0985-1507-A1, p. 3]

Organization: Lubrizol Corporation (Lubrizol)

Lubrizol believes that vehicle owners and fleets in the heavy-duty vehicle sector will use a range of fuels and technologies to meet their future operational and environmental needs. Thus, we are pleased to see EPA acknowledge that it expects to see Original Engine Manufacturers

(“OEMs”) use an array of technologies to meet the requirements of the Final Rule. Lubrizol strongly encourages EPA to promulgate a Final Rule that will advance all three strategies highlighted in the Biden administration’s Transportation Decarbonization Blueprint (the “Blueprint”), i.e., Sustainable Liquid Fuels (“SLFs”), Battery-Electric Vehicles (“BEVs”), and Hydrogen.2 While there is exciting progress being made to develop heavy-duty engines and vehicles that will operate on electricity and hydrogen, the majority of new heavy-duty vehicles will continue to use internal combustion engines (“ICE”) for many years to come. This will be especially true in the heavier vehicle classes in the heavy-duty vehicle market.3 [EPA-HQ-OAR-2022-0985-1651-A2, p. 2.]

2 The U.S. National Blueprint for Transportation Decarbonization: A Joint Strategy to Transform Transportation (the “Blueprint”). Accessed on June 11, 2023 at The U.S. National Blueprint for Transportation Decarbonization: A Joint Strategy to Transform Transportation | Department of Energy. See, e.g., page 5, Figure B and similar references elsewhere in the Blueprint.

3 Lubrizol notes that, even in California and the other states that adopt California’s Advanced Clean Transportation (“ACT”) rule (collectively, the “ACT States”), most new trucks sold in 2035 will still be ICE vehicles fueled by petroleum diesel fuel, absent any further changes in state or federal fuel policy. More specifically, manufacturers who certify Class 2b-8 chassis or complete vehicles with combustion engines will be required to sell zero-emission trucks as an increasing percentage of their annual sales in the ACT States from 2024 to 2035. By 2035, zero-emission truck/chassis sales will need to be 55% of Class 2b – 3 truck sales, 75% of Class 4 – 8 straight truck sales, and 40% of truck tractor sales in the ACT States.

In the segments of the market that will continue to rely on ICE technologies, we note that the Blueprint described SLFs as a “large, long-term opportunity” for long-haul heavy trucks. In fact, the Blueprint found that SLFs represent an even greater opportunity in this market segment than BEVs. We agree with this assessment, and we encourage EPA to integrate the potential market growth of biofuels, e-fuels, and other SLFs into its Technology Assessment, certification pathways, and other relevant aspects of the Final Rule. We believe that doing so will maximize and accelerate the emissions reduction potential of ICE vehicles. [EPA-HQ-OAR-2022-0985-1651-A2, p. 2]

2) The Final Rule Should Include Certification Pathways for all emerging ICE Technologies

The Proposal acknowledges that further ICE technology development is likely to be needed to meet the requirements of the Final Rule. For example, it notes the likely use of hybrid and hydrogen-fueled ICE vehicles. Lubrizol anticipates that there will be additional ICE technology development, including dedicated SLF engines, as well as new technologies for engines and vehicles that will continue to operate on traditional petroleum diesel fuel. The Final Rule should include certification pathways for each of these technologies and fuels, as well as flexibility to enable the certification of new technologies that have not been developed yet. [EPA-HQ-OAR-2022-0985-1651-A2, p. 5]

We strongly urge EPA to update its Greenhouse Gas Emissions Model (“GEM”) inputs to account for the full range of fuels that are likely to power these emerging engine technologies. In particular, limiting the GEM fuel inputs to gasoline, diesel, and natural gas masks the potential emissions benefits of engines that are developed as dedicated SLF engines. Creating GEM inputs for each SLF that may be used will create additional incentives for innovation and investment in dedicated SLF-fueled ICE vehicles, which will help ensure that the Final Rule meets its goals as fully, as expeditiously, and as cost-effectively as possible. In addition, it will help the lubricant industry develop appropriate lubricants and oils for these engines by ensuring that we have appropriate information when setting our performance specifications. [EPA-HQ-OAR-2022-0985-1651-A2, p. 5]

4) Lubrizol supports consideration for the creation of a diesel deposit control standard similar to 40 CFR 1090.260

As warranty and useful life requirements are extended, it is imperative that in-use practices for vehicles maintain emission and GHG performance as ‘like-new” as possible. Deposits and wear within the fuel system can lead to a significant deterioration of emissions and efficiency through mechanisms such as:

- External injector tip deposits
- Internal injector deposits
- Fuel injection system wear [EPA-HQ-OAR-2022-0985-1651-A2, p. 6]

Modern engines operate at much higher injection pressures, their fuel injectors have tighter passages and tolerances, and injection strategies may include several injections per single piston stroke. Extremely small deposits on the tip of the injector can dramatically alter fuel flow affecting emissions. This is particularly critical in engines where the injector tip is subjected to combustion related soot combined with high in-cylinder temperatures and pressures. Internal deposits can affect the response of the injector needle, also leading to higher emissions. Increased particulates can accelerate the rate of particulate filter soot accumulation (plugging), which leads to more regenerative cycles and decreased fuel economy. [EPA-HQ-OAR-2022-0985-1651-A2, p. 6]

In the US diesel market, different from many other countries, the average detergent additive level is very low. In fact, most of the diesel fuel sold contains no diesel detergent, even though it is known and demonstrated that the usage of diesel detergent is an effective way to keep the engines clean or even clean them up (depending on the treat rate). Clean engines generate less emissions than a dirty one and the use of detergent additives can extend that performance throughout their serviceable lives. Thus, we request the EPA consider the creation of a diesel deposit control standard similar to 40 CFR 1090.260. [EPA-HQ-OAR-2022-0985-1651-A2, p. 7]

Organization: Lynden Incorporated

Limiting Renewable Fuel Options

Lynden understands that the proposed rule is considered technology neutral, however mandating ‘Zero-Emission Vehicles’ becomes a de-facto ban on the internal combustion engine, limits viable options, and fails to consider renewable fuels and other currently available technologies that are able to significantly reduce emissions. [EPA-HQ-OAR-2022-0985-1470-A1, p. 1]

For example,

- Engines manufactured after 2010 are 25% more fuel efficient and cut NOx (nitrous oxide) and PM (particulate matter) by over 90% compared to older engines. Replacing these older engines that remain in operation, estimated at 47%, would be the most cost effective and reliable solution for reducing CO2, PM, and NOX emissions.

- Renewable diesel, manufactured from biological feedstocks, emits 56% less CO2 than traditional diesel and 38% less CO2 than a battery electric truck when considering the full lifecycle emissions of vehicle production, use, and disposal.1
- Renewable Natural Gas provides negative carbon emissions by capturing methane from agricultural biogas and landfills. However, these ‘carbon negative’ trucks are not considered ‘zero-emissions’ under the rule.
- Some of the high-horsepower engines that we rely on to haul very heavy loads in Alaska are being phased out of production because of the inability to meet emission standards. Using lower horsepower engines will require more trips and result in more overall emissions. [EPA-HQ-OAR-2022-0985-1470-A1, pp. 1-2]

1 American Transportation Research Institute (May 2022). Understanding the CO2 Impacts of Zero-Emission Trucks. Understanding the CO2 Impacts of Zero-Emission Trucks – TruckingResearch.org

The proposed standards will not only increase the cost, weight, and complexity of compliant diesel engines, they will force engine manufacturers to subsidize ‘Zero Emission Vehicles’ by further increasing the cost of diesel and natural gas engines. By reducing our options and making diesel engines more expensive, the most cost effective and reliable solutions for reducing emissions: replacing pre-2010 engines with modern engines combined with the option to use renewable diesel and renewable natural gas becomes artificially less economical and even further out of reach. [EPA-HQ-OAR-2022-0985-1470-A1, p. 2]

Recommendations:

- Assist small fleets and owner-operators to replace pre-2010 diesel engines with modern diesel engines.
- Take into account the lifecycle emissions of fuels such as renewable diesel, renewable natural gas, and electrical generation as well as vehicle operation, production, and disposal. [EPA-HQ-OAR-2022-0985-1470-A1, p. 5]

Organization: MEMA

Renewable fuels, such as hydrogen, ethanol, renewable natural gas (RNG) and carbon-neutral renewable diesel are viable, proven pathways to lower emissions in the trucking sector almost immediately. We are concerned the EPA has dismissed alternate fuel options, and as a result is missing opportunities for greater emissions reductions. We refer the EPA to the U.S. DOE alternate fuels data center for detailed examples of how alternate fuels can reduce vehicle emissions.’ Several studies and programs run by Argonne National Laboratory also point to reduced emissions through alternate fuels.2 EPA should include more analysis of these alternatives and do more to encourage investment and deployment of these technologies. We note CARB recognizes renewable diesel fuel3 and allows it to be used for compliance with certain regulations. EPA should consider similar provisions. [EPA-HQ-OAR-2022-0985-1570-A1, p. 5]

2 https://www.anl.gov/taps/fuels

3 See § 2449.1(f) of the CARB In-Use Off-Road Diesel-Fueled Fleets Regulation https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2022/off-roaddiesel/ord15dayatta-1.pdf

Trucks that use alternative, lower-carbon fuels can help advance EPA climate goals while also contributing to national security by lowering our dependence on foreign oil. Additionally, encouragement and investment in carbon-neutral fuels will also positively impact existing vehicles already on the road. [EPA-HQ-OAR-2022-0985-1570-A1, p. 5]

Organization: Missouri Farm Bureau (MOFB)

MOFB urges EPA to thoroughly consider an all-of-the-above approach, and not overlook the important role home-grown biofuels can and should play in this policy discussion. According to a 2021 study conducted by the U.S. Department of Energy and published by Argonne National Laboratory, ethanol has 52 percent less greenhouse gas (GHG) emissions than gasoline.2 In addition, biodiesel and renewable diesel reduce GHG emissions 50-80 percent when compared to petroleum diesel, depending on the feedstock used.3 Meanwhile, the proposed rule will upend the transportation sector to 'achieve significant reductions in GHG emissions' to achieve a mere 17-18 percent decrease in GHG emissions.4 EPA should look to Missouri and the heartland of America as a key part of the solution, instead of the approach taken by its proposed rule, which will surely prop up the economies of foreign countries – namely China's - instead of our own. EPA should acknowledge that higher utilization of biofuels can occur today with the majority of vehicles on our nation's roadways, rather than attempting to replace all of the internal combustion engines being driven by Americans on a daily basis. [EPA-HQ-OAR-2022-0985-1584-A1, pp. 1-2]

Organization: National Association of Convenience Stores (NACS), NATSO, and SIGMA

The Proposed Rule Blunts Innovation and Competition.

EPA's effort to mandate a shift to EV technologies directly disincentivizes new technology that could maximize diverse investments and achieve near-term and long-term emission reduction goals. Indeed, EPA's proposal risks zeroing out new innovations in emissions reductions for ICE vehicles. Because there is no way for manufacturers to comply based on ICE vehicles alone, they would not achieve a return on new investments for and in developing that technology. Finalizing regulations that push people to that conclusion will cause truck manufacturers to miss an opportunity for innovative emissions reductions. Climate research has consistently emphasized the importance of near-term emissions reductions relative to future reductions.23 More efficient diesel engines coupled with low-carbon, biomass-based diesel can reduce emissions immediately. [EPA-HQ-OAR-2022-0985-1603-A1, p. 9]

23 See G. Cornelis van Kooten, Patrick Withey, and Craig M.T. Johnston, BIOMASS AND BIOENERGY 151 'Climate Urgency and the Timing of Carbon Fluxes,' (August 2021) available at https://doi.org/10.1016/j.biombioe.2021.106162. ('The current climate emergency dictates that immediate action is required to mitigate climate change, which implies that carbon fluxes occurring 20 or more years from now are too late to have any mitigative effect.')

As just one example, there have been increasingly innovative technologies surrounding expanded natural gas vehicle ('NGV') production in recent years. But the Proposed Rule fails to provide the automotive sector with any meaningful incentive to continue developing such technology or similar vehicles that can effectively rely on renewable natural gas ('RNG'). The latest data available from the California Low Carbon Fuel Standard Program indicates that the average carbon intensity of bio-CNG (compressed natural gas) sold in 2020 was -5.85gC)2e/MJ.24 In the coming years, the carbon intensity of RNG is expected to be even lower as greater amounts of low-carbon dairy gas is produced and used in NGVs. This is especially important in light of market considerations for HD vehicles in particular. [EPA-HQ-OAR-2022-0985-1603-A1, p. 9]

24 California Air Resources Board, Low Carbon Fuel Standard Program, LCFS Pathway Certified Carbon Intensities (2023) available at https://ww2.arb.ca.gov/resources/documents/lcfs-pathway-certified-carbon-intensities.

Further, existing alternative fuel incentives—such as the Renewable Fuel Standard ('RFS') and biofuel blending and alternative fuel infrastructure tax credits—have allowed truckstops and other fuel retailers to offer less expensive, lower carbon fuels to our customers, while also supporting investments in renewable fuel production.25 The incentives Congress established over the past few decades have caused the displacement of significant volumes of petroleum-based fuel with renewable fuels. [EPA-HQ-OAR-2022-0985-1603-A1, p. 9]

25 Importantly, renewable fuels significantly reduce carbon dioxide emissions through the lifecycle of heavy-duty vehicles without requiring truck drivers to cover the upfront costs of a battery-electric truck, which costs roughly twice as much as a comparable diesel-powered truck. See Todd Dills, OVERDRIVE, 'Cutting through Heavy-Duty E-Trucks Hype: 7 in 10 Owner-Ops Show 'Zero' Interest in Electric Powertrain Techs,' (Dec. 15, 2021) available at https://www.overdriveonline.com/equipment/article/15286428/cutting-through-the-heavyduty-etrucks-hype.

Recent estimates indicate that renewable diesel reduces carbon intensity by 65% compared to petroleum-based diesel.26 Increased utilization of renewable fuels could lead to significant emissions reductions by improving the emissions profiles not only of new vehicles but existing vehicles as well. The Proposed Rule surrenders the market's ability to deliver near-term emissions savings by imposing a top-down, hurried transition to one technology. [EPA-HQ-OAR-2022-0985-1603-A1, p. 10]

26 U.S. Dep't of Energy, 'Renewable Diesel' (2023) available at https://afdc.energy.gov/fuels/renewable_diesel.html.

Organization: National Corn Growers Association (NCGA)

As producers of the primary feedstock for low-carbon ethanol and users of heavy-duty vehicles, we support a final rule that will allow all solutions to accelerate decarbonization of the heavy-duty vehicle sector. The final rule should follow the direction of the Biden Administration's Transportation Decarbonization Blueprint (Blueprint), which directly stated that we need to deploy a range of solutions to meet our climate goals, including ethanol and other sustainable biofuels and e-fuels, clean electricity, and clean hydrogen. More specifically, in the long-haul truck sector, the Blueprint concluded that these Sustainable Liquid Fuels (SLFs) will be a 'large, long-term' opportunity that is even greater than the market opportunity for battery-electric vehicles in the long-haul truck sector.1 [EPA-HQ-OAR-2022-0985-1622-A1, p. 1]

1 The U.S. National Blueprint for Transportation Decarbonization: A Joint Strategy to Transform Transportation, see page 5, Figure B

The final rule should send a clear signal to innovators who seek to use ethanol to reduce the GHG emissions of future trucks that will still rely on traditional internal combustion engines. Unfortunately, as currently proposed, the Phase 3 GHG standards will hamper – if not wholly preclude—the use of affordable and readily available low-carbon ethanol to decarbonize the hard-to-electrify long-haul truck market. Further, it risks creating a chilling precedent for ethanol's potential to decarbonize even harder-to-electrify nonroad engines used in agriculture, construction, mining, locomotives, and marine engines. [EPA-HQ-OAR-2022-0985-1622-A1, p. 1]

EPA's Final Rule must provide a mechanism for certifying dedicated ethanol and other dedicated alternative fuel engines. Currently, a dedicated ethanol engine must certify its emissions as though it were a diesel-fueled engine. This penalizes ethanol in two ways: First, it overlooks the real-world difference between biogenic and anthropogenic carbon, and thereby treats ethanol as dirty as fossil diesel fuel from a climate perspective. Second, it ignores other attributes of ethanol that should be incorporated into EPA's Greenhouse Gas Emissions Model that are different than diesel fuel. Together, these two penalties mask the climate benefit of a dedicated ethanol engine, compared to diesel, and overestimates the climate impact of ethanol by threefold.2 [EPA-HQ-OAR-2022-0985-1622-A1, p. 1]

2 GEM currently estimates emissions from ethanol vehicles to be approximately 1.5 times worse than diesel. However, using national averages, GREET calculates ethanol to have 50% of the lifecycle emissions impact of diesel. Based on this information, GEM overestimates the climate impact of an ethanol-fueled engine by 3x (1.5/.5).

EPA has proposed to treat future battery-electric vehicles and hydrogen-fueled fuel cell vehicles as carbon-neutral at the tailpipe. EPA should also treat a dedicated ethanol engine as carbon-neutral because the carbon emissions from such an engine will be 100 percent biogenic, i.e., they derive from photosynthesis pulling carbon from the atmosphere in the natural carbon cycle. These emissions will not be derived from fossil fuels, and they will not contribute to climate change at the point of combustion in the engine. For these reasons, dedicated ethanol vehicles should be treated as carbon-neutral at the tailpipe. [EPA-HQ-OAR-2022-0985-1622-A1, p. 2]

Fixing the 'ethanol penalty' in EPA's current certification structure will enable SLFs to do their job decarbonizing America's hard-to-electrify long-haul trucks as envisioned by the Administration's Blueprint. The GEM calculations for a dedicated ethanol engine yield a perverse outcome that has no bearing in reality - modeled emissions that are actually 'even dirtier than diesel,' despite their obviously different contributions to climate change. Without fixing the ethanol penalty in the final Phase 3 rule, it will be impossible for ethanol, and likely other SLFs, to provide the 'large, long-term decarbonization opportunity' that the Administration's Blueprint hopes for. [EPA-HQ-OAR-2022-0985-1622-A1, p. 2]

Correcting this penalty in the final rule will:

- Make the overall program more scientifically robust.

- Avoid the unintended climate backsliding that would result from a rule that disincentivizes—if not precludes—investment in SLF-based engines that will help accelerate decarbonization of hard-to-electrify vehicles.
- Provide a certification pathway that is aligned with Blueprint's prioritization of SLFs for long-haul trucking and consistent with EPA's authority under Title II of the Clean Air Act, as well as the Agency's proposed treatment of battery-electric and hydrogen-fueled fuel cell vehicles.
- Reward American innovation and create new economic opportunities for the many farm and rural communities that produce the fuels that will be used in future compression-ignition engines that are designed to operate exclusively on SLFs like low-carbon ethanol; and
- Result in faster, greater, more cost-effective decarbonization, air quality, and related health benefits overall. [EPA-HQ-OAR-2022-0985-1622-A1, p. 2]

The bottom line is that to meet its decarbonization goals, EPA must finalize a rule that sends the right market and regulatory signals to encourage and reward performance-based innovation that delivers near-term, cost-effective emission reductions at scale. This includes sending the signal that dedicated ethanol-fueled engines will be rewarded for their decarbonization potential, rather than treating them as dirty as diesel from the perspective of tailpipe climate impacts. [EPA-HQ-OAR-2022-0985-1622-A1, p. 2]

Organization: Natural Gas Vehicles for America (NGVAmerica)

EPA must act now to adopt regulations that reward, credit, or account for the emission reductions provided by biofuels. Without this requested action, eventually there could be no new natural gas vehicles or other biofuel vehicles, and consequently no use of biofuels in transportation unless they are used to produce electricity for electric vehicles. To continue to certify and sell new natural gas vehicles, the current and proposed approach means that natural gas vehicle manufacturers will eventually be forced to subsidize electric vehicle truck sales to offset their tailpipe greenhouse gas emissions. This factor combined with regulations adopted by California and approved by EPA that mandate the sale of zero-tailpipe vehicles eventually will force manufacturers to stop offering natural gas trucks despite delivering substantial criteria pollutant and greenhouse gas emission reductions, and supplying a significant portion of the on- and off-road vehicles that will not be able to be electrified. This will have a negative impact on emission reductions and will be extremely financially detrimental to businesses that have invested in and employ workers in supporting the use of natural gas in transportation. [EPA-HQ-OAR-2022-0985-1522-A1, p. 2]

Numerous studies and analyses support the conclusion that there are significant environmental benefits associated with powering natural gas vehicles with RNG to displace petroleum motor fuels. Many of these studies support the conclusion that RNG fueled vehicles offer superior benefits to electric vehicles. To be fair, that should not be a requirement for equitable treatment. It should not be the job of RNG advocates to prove that RNG is superior to electricity or hydrogen, or that it is more cost-effective, or more readily deployable, or doesn't rely on rare earth minerals, etc. [EPA-HQ-OAR-2022-0985-1522-A1, p. 3]

EPA must stop favoring one technology over others by relying on outdated methods of certifying vehicles and engines. There is not a single environmental journal that would publish a paper or study that evaluates greenhouse gas emissions by only looking at tailpipe emissions or tank to wheel emissions. They would not do it because it is not defensible and would be an absurd comparison. The same is true for retaining greenhouse gas vehicle regulations that only look at tailpipe emissions. It is no longer rational, defensible, or equitable. [EPA-HQ-OAR-2022-0985-1522-A1, p. 3]

As noted in the introduction, data from California's Low Carbon Fuel Standard (LCFS) program demonstrates how clean and low carbon these RNG fueled heavy-duty vehicles truly are. The most recent data confirms that the average carbon intensity (CI) value of California's bio-CNG is negative 99 gCO2e/MJ and has been negative for three consecutive years. In California, 97 percent of the natural gas consumed or credited to on-road transportation fuel in 2022 was renewable natural gas. Nationally the percentage was 69 percent in 2022 including fuel used in California. California continues to be a critical market for natural gas vehicles, but it is noteworthy that nearly 50 percent of the RNG reported in 2022 was for use in areas outside of California. [EPA-HQ-OAR-2022-0985-1522-A1, p. 3]

RNG Supply Can Support Additional NGV Uptake Here and Abroad

The International Energy Agency's (IEA) World Energy Outlook 2022 projects that, under its different scenarios to 2050, renewable biogases (hydrogen and others) reach more than 400 billion cubic meters (bcm) by 2050; around 65 percent of that (260 bcm) is biomethane.5 The World Biogas Association's far more aggressive outlook estimates that biomethane could substitute 993 to 1380 bcm of natural gas, equivalent to 26-37 percent of the current natural gas consumed globally.6 European authorities recently set a target of achieving 35 bcm of biomethane by 2030.7 That target is roughly the energy equivalent of 8.9 billion diesel gallons. The European target is notable in that if achieved it would represent a ten-fold increase in production levels in less than ten years.8 [EPA-HQ-OAR-2022-0985-1522-A1, p. 5]

5 International Energy Agency, World Energy Outlook, Chapter 8, Outlook for Gaseous Fuels pp. 370, 377, and 380.

6 https://www.worldbiogasassociation.org/wp-content/uploads/2019/09/WBA-execsummary-4ppa4_digital-Sept-2019.pdf

7 European Parliament supports 35 bcm biomethane target in EU Gas Package (gasworld.com)

8 EBA: 30% increase in European biomethane plants since 2021 | Bioenergy Insight Magazine (bioenergy-news.com)

Part of the reason NGV advocates are confident there are ample supplies is that the RNG industry and technology associated with it is very mature and existing domestic resources have not been fully exploited. Another reason is that NGVs are expected to make up a portion of the on-road market but not totally displace all gasoline or diesel vehicles. For example, NGVAmerica projects that successful future commercialization of NGVs in the heavy-duty market segment, specifically Class 8 trucks, in the U.S. could begin to displace between 10 – 15 percent of annual sales in the next several years. [EPA-HQ-OAR-2022-0985-1522-A1, pp. 5 - 6]

If NGVs sales attain and maintain a level of 10 – 15 percent of new Class 8 sales, over the next decade that could result in several hundred thousand Class 8 NGV trucks consuming the equivalent of roughly 3 – 3.5 billion diesel gallon equivalents of fuel. Based on projections developed by the America Gas Foundation and other organizations, this level of fuel consumption -- even if the vehicles were operated 100 percent on biomethane -- would represent only a small portion of the available RNG supplies projected to be available in the U.S. As noted above, natural gas vehicles operating on blends considerably less than 100 percent still offer significant greenhouse gas benefits. [EPA-HQ-OAR-2022-0985-1522-A1, p. 6]

Various reports include projections of U.S. renewable natural gas supply. The most recent is a 2019 report prepared by ICF for the American Gas Foundation.9 Based on the projections in that report and shown below, there is more than sufficient potential supply of RNG to meet the demand posed by on-road NGVs. NGVs today consume approximately 75 trillion Btu per year (tBtu/y) and based on NGVAmerica's projections could grow to about 485 tBtu/y by 2035. This amount is far below what the AGF report projects is possible in the future. [EPA-HQ-OAR-2022-0985-1522-A1, p. 6.] [See Docket Number EPA-HQ-OAR-2022-0985-1522-A1, pages 6-7, for referenced figures.]

9 AGF 2019 RNG Study Full Report - FINAL 12-18-2019 (1).docx (gasfoundation.org)

EPA Must Amend its Proposal to Account for Benefits of Biofuels

NGVAmerica is not alone in making the case that EPA must amend its proposal. Other organizations including the refinery industry, independent fuel retailers, and the ethanol industry have argued that EPA must make a course correction and following through on its prior commitment to do so. [EPA-HQ-OAR-2022-0985-1522-A1, p. 7]

In 2012, EPA10 committed to sunset the use of the 0 g/mi allowance for electric vehicles as explained below:

EPA is finalizing the full net upstream GHG emissions approach for the compliance treatment for EV/PHEV/ FCVs beyond the per-company vehicle production threshold caps in MYs 2022–2025. EPA is not adopting any type of ‘‘phase-in’’, i.e., the compliance value will change from 0 g/mi to the full net upstream GHG emissions value once a manufacturer exceeds the cap. EPA believes that the levels of the per company vehicle production caps in MYs 2017–2025 are high enough to provide a sufficient incentive such that any production beyond those caps should use the full net upstream GHG emissions accounting. [EPA-HQ-OAR-2022-0985-1522-A1, p. 7]

10 2012-21972.pdf (govinfo.gov)

The preamble to that rule included the following discussion aptly summarizing the opposition to the use of the 0 g/mi standard.

Two automakers opposed the use of 0 g/mi. Honda ‘‘believes that EPA should separate incentives and credits from the measurement of emissions. Honda believes that without accounting for the upstream emissions of all fuels, inaccurate comparisons between technologies will take place * * *. EPA's regulations need to be comprehensive and transparent. By zeroing out the upstream emissions, EPA is conflating incentives and credits with proper emissions accounting.’’ EcoMotors International ‘‘encourages EPA to drop the 0 g/mile tailpipe compliance value.’’ Environmental advocacy groups also opposed the 0 g/ mi compliance treatment. The Natural Resources Defense Council claimed that 0 g/mi ‘‘undermines’’ the pollution and technology benefits of the program. Along with other environmental groups, the American Council for an Energy Efficient Economy also opposed 0 g/mi, but added that ‘‘[m]ost important, however, is that a zero-upstream treatment of plug-in vehicles not be continued indefinitely, and that full upstream accounting be applied to these vehicles by a date certain.

EPA's proposed treatment of EVs largely accomplishes this, so we strongly support that aspect of the proposal.'' The American Petroleum Institute argued that ''[i]gnoring the significant contribution of (and extensive compilation of published literature on) upstream CO2 emissions from electricity generation, defies principles of transparency and sound science and distorts the market for developing transportation fuel alternatives. It incentivizes the electrification of the vehicle fleet with a pre-defined specific and costly set of technologies whose future potential is not measured with the same well-to-wheels methodology against that of advanced biofuels or other carbon mitigation strategies.'' Organizations advocating fuels other than electricity also opposed the use of 0 g/mi. [EPA-HQ-OAR-2022-0985-1522-A1, p. 8]

Despite the expressed views, EPA nevertheless retained the 0 g/mi standard. In defense of continuing to retain the 0 g/mi treatment and providing multiplier credits, EPA stated that:

EPA believes that it is both reasonable and appropriate to accept some short-term loss of emissions benefits in the short run to increase the potential for far-greater game-changing benefits in the longer run. The agency believes that these multipliers may help bring some technologies to market more quickly than in the absence of incentives. [EPA-HQ-OAR-2022-0985-1522-A1, p. 8]

The European Biogas Association eloquently explained why the EU Commissions rules should account for well-to-wheel emissions and their explanation is worth including here:

The current "tank-to-wheel" approach does not compare the different technologies appropriately because it ignores emissions associated with the production of the fuel. It does not recognise the positive contribution of renewable fuels such as biomethane to climate protection, and thus biases one technology over others without a climate protection rationale. [EPA-HQ-OAR-2022-0985-1522-A1, p. 8]

The revised CO2 regulation should propose technology-neutral solutions to reduce emissions in an accelerated and cost-effective way. It should avoid one-size-fits-all options that could prove insufficient in the long-term and may lead to a slow, unfair and costly emissions reduction process. [EPA-HQ-OAR-2022-0985-1522-A1, p. 8]

The CO2 regulation should be amended to ensure an integrated transition that picks no single green technology over others and leaves no-one behind. All alternative fuels are necessary if transport decarbonisation is to be delivered at pace.11 [EPA-HQ-OAR-2022-0985-1522-A1, pp. 8 - 9]

11 SMART CO2 STANDARDS FOR LEAN MOBILITY (europeanbiogas.eu)

The Frontier Economics report similarly offers an excellent case for ensuring proper treatment and inclusion of biomethane.

Our analysis shows that gas mobility can help to contribute to reducing GHG emissions in road transport at comparably low system cost. As gas mobility – in contrast to other drivetrain technologies which are less mature – is readily available on vehicle, infrastructure and fuel supply levels and thus quickly scalable now, it can contribute to ambitious early GHG emission reduction by 2030 at low cost.

- Technological diversification. The immense challenge and high urgency for the mobility sector to achieve emissions reductions does not allow for cherry picking of individual technologies. Rather, we have to go "all-in" by enabling as many options to contribute as possible.

- Freedom of choice and competition of technologies. The heterogeneity of mobility applications with many individual factors determining the most efficient technology in each case rules out any central planning approach – there is no "one size fits all" solution.
- Keeping options open. There is a high degree of uncertainty around the optimal technology options in the future. Regulation therefore should avoid prematurely ruling out any pathway (e.g. by banning combustion engines which may in the future be fuelled by renewable or low-carbon fuels or gases). [EPA-HQ-OAR-2022-0985-1522-A1, p. 9]

We fervently believe that the Administration's decarbonization and clean air goals will only be achieved by focusing on a multi-technology approach that includes cost-effective carbon-negative solutions like RNG trucks that can begin accruing and compounding significant clean air and carbon reductions right away. We, therefore, respectfully request that EPA provide credits for natural gas vehicles based on the well-to-wheel benefits of the consuming natural gas which increasingly includes larger amounts of RNG. We also believe that any additional incentives finalized in this rulemaking to offer aid in the commercialization of electric vehicles or fuel-cell vehicles should be extended to NGVs based on the extraordinary emission reduction potential of these vehicles. [EPA-HQ-OAR-2022-0985-1522-A1, pp. 9 - 10]

Developing a Credit Mechanism for Biofuels

For greenhouse gas emissions, NGVAmerica previously requested that EPA use the 0.15 factor for greenhouse gas emissions to give credit to manufacturers for RNG use and to create an efficient method of calculating the benefit of renewable natural gas until EPA moves to adopt a well-to-wheels regulatory approach for all fuels, or until EPA can develop a detailed assessment and emission factor specific to RNG use. A benefit of the 0.15 factor is that it is consistent with the fuel efficiency credits and has been used in the past in EPA's regulations. [EPA-HQ-OAR-2022-0985-1522-A1, p. 11]

Given the recent state of developments and based on the increasing amount of carbon negative RNG that is being used in transportation, a factor of 0.15 may not adequately represent the credit that is warranted for RNG use. A factor of 0.15 would represent an 85 percent reduction and therefore is not carbon neutral or carbon negative. Developing a precise factor based on WTW comparisons of different fuels is complicated for various reasons: moving baseline targets; year-over-year changes in fuel mix; truck lifetimes, etc. That is probably part of the reason that EPA decided to abandon developing factors for electric vehicles and retained the 0 g/mi factor. [EPA-HQ-OAR-2022-0985-1522-A1, p. 11]

One solution might be to adopt a similar approach for NGVs as has been adopted for electric vehicles. Such a concept has been developed and is explained in the attached European Biogas and NGVA Europe documents. NGVA Europe has proposed using a carbon correction factor (CCF) that treats biomethane as having a carbon content of zero, and then providing an emission offset related to the percentage of biomethane distributed in a country. In the example provided in the NGV Europe document, 10 percent displacement with biomethane equates to a CCF discount of 10 percent that is applied to a vehicle's tailpipe emissions of CO2. In the case of the U.S., the CCF for 2022 would be 69 percent if the national average were used or 97 percent if the California average were used and credits were assigned based on state registration of motor vehicles. [EPA-HQ-OAR-2022-0985-1522-A1, pp. 11 - 12]

One limitation of this approach is the fact that if RNG levels go up in the future manufacturers selling trucks today would not receive the full benefit of future increases, and thus the credit or CCF used would underrepresent the benefit of their trucks. This could be addressed by periodically revising the levels of RNG use projected to occur during a vehicle's lifetime and using that level of displacement to offset emissions. EPA previously proposed a similar concept for electric vehicles that would have based emissions on future EIA forecasts of renewable electricity. [EPA-HQ-OAR-2022-0985-1522-A1, p. 12]

(6) Federal agencies should work with state authorities to ensure that transportation policies include performance metrics and consider a variety of different technologies as opposed to only promoting specific technologies regardless of their cost; [EPA-HQ-OAR-2022-0985-1522-A1, p. 13]

Organization: POET

Renewable fuels, such as bioethanol, already significantly reduce lifecycle carbon emissions relative to fossil fuels. POET and other companies are exploring ways to further reduce those lifecycle emissions. Bioethanol may soon achieve net-zero, or even net-negative, lifecycle emissions by utilizing carbon capture, renewable power for process energy and biomass for process heat at bioethanol plants, as well as requiring the use of climate-smart farming practices by our producers. Renewable fuels will be particularly critical in decarbonizing heavy-duty internal combustion engine ('ICE') vehicles that will remain on the road for the next several decades. EPA's proposed GHG standards should credit vehicles that use renewable fuels to reduce their net GHG emissions. [EPA-HQ-OAR-2022-0985-1528-A1, pp. 1-2]

Renewable fuels are a well-proven technology. Many federal and state programs, such as the federal Renewable Fuel Standard ('RFS') and California's Low Carbon Fuel Standard ('LCFS'), among others, support the production of significant quantities of low-carbon renewable fuels. Renewable fuels are also key to the Administration's renewable energy policies. They receive funding and tax credits under the recently enacted Bipartisan Infrastructure Law ('BIL') and Inflation Reduction Act ('IRA'). The U.S. National Blueprint for Transportation Decarbonization, which EPA co-authored, also calls for more renewable fuels as one of its many decarbonization strategies.1 EPA's Proposed Rule should align with those policies by incorporating renewable fuels. [EPA-HQ-OAR-2022-0985-1528-A1, p. 2]

1 The U.S. National Blueprint for Transportation Decarbonization (Jan. 2023), available at https://www.energy.gov/sites/default/files/2023-01/the-us-national-blueprint-for-transportation-decarbonization.pdf.

EPA Should Revise the Proposed Rule to Credit Lifecycle Emissions Reductions from Renewable Fuels.

The Proposed Rule should credit renewable fuels and their lifecycle GHG emissions reductions as an additional technology pathway for meeting EPA's emissions reduction standards. EPA's focus on ZEVs ignores that renewable fuels are available now to significantly reduce emissions from ICE vehicles. This is critical because, even under the most optimistic ZEV projections, ICE vehicles, especially heavy-duty ICE vehicles, are expected to remain on the road for decades. Renewable fuels offer one of the best solutions to decarbonizing those legacy ICE vehicles. [EPA-HQ-OAR-2022-0985-1528-A1, p. 4]

Incorporating renewable fuels will have myriad benefits.

i. Renewable fuels significantly reduce carbon emissions on a lifecycle basis and may soon achieve net-zero or net-negative emissions. [EPA-HQ-OAR-2022-0985-1528-A1, p. 4]

The carbon-reducing benefits of renewable fuels are immense. Bioethanol, for instance, reduces lifecycle GHG emissions by at least 46 percent relative to fossil transportation fuels.8 This figure represents the latest scientific research on land-use impacts, energy consumption, and other processes that affect carbon emissions from bioethanol production.9 Other renewable transportation fuels achieve similarly significant and, in some cases, even greater lifecycle emissions reductions relative to fossil fuels.10 [EPA-HQ-OAR-2022-0985-1528-A1, p. 4]

8 See Scully MJ, Norris GA, Alarcon Falconi TM, MacIntosh DL. 2021a. Carbon intensity of corn ethanol in the United States: state of the science. Environmental Research Letters, 16(4), pp. 043001. The 46 percent reduction figure relates to typical corn starch ethanol on an energy-adjusted basis. Cellulosic ethanol that is currently being produced is associated with even greater reductions, and corn starch ethanol may also have greater benefits when its octane value is accounted for.

9 See generally id.

10 See, e.g., U.S. EPA, Proposed Rule, Renewable Fuel Standard (RFS) Program: Standards for 2023-2025 and Other Changes, 87 Fed. Reg. 80582, 80611 (Dec. 30, 2022).

POET and others are pursuing ways to reduce lifecycle emissions of renewable fuels even further. By deploying carbon capture and storage technologies, switching to renewables such as wind and solar for process energy at production facilities, utilization of renewable biomass rather than natural gas for process heat, and encouraging farmers to implement climate-smart farming practices, renewable fuel producers would reduce the carbon footprint of their processes even further and may even achieve net-negative lifecycle emissions—removing carbon from the total atmospheric carbon load. [EPA-HQ-OAR-2022-0985-1528-A1, p. 5]

POET is taking bioethanol production in this direction. For example, it is taking concrete steps towards reducing bioethanol's carbon footprint by working to capture and store the concentrated biogenic carbon dioxide emitted during bioethanol production. EPA has recognized the immense benefits of this approach. In its most recent proposed RFS rulemaking, EPA observed:

- Corn ethanol facilities produce a highly concentrated stream of CO_2 that lends itself to carbon capture and sequestration (CCS). CCS is being deployed at ethanol plants and has the potential to result in negative emissions at the ethanol production facility, especially if mills with CCS use renewable sources of electricity and other advanced technologies to lower their needs for thermal energy.11 [EPA-HQ-OAR-2022-0985-1528-A1, p. 5]

11 U.S. EPA, Draft Regulatory Impact Analysis: RFS Standards for 2023-2025 and Other Changes, at 175.

By POET's calculations, bioethanol production could achieve significant emissions reductions from such measures, and could even achieve net-negative emissions. The latest scientific assessments assign bioethanol a carbon intensity of 51.4 gCO_2/MJ.12 POET estimates that sequestering the biogenic carbon dioxide byproduct of bioethanol production would reduce bioethanol's carbon intensity by 30 gCO_2/MJ. Switching to renewable electricity for process energy at bioethanol plants would reduce bioethanol's carbon intensity by another 5 gCO_2/MJ. And climate-smart farming practices could lower bioethanol's carbon intensity by at least an additional 30 gCO2/MJ. The Proposed Rule should encourage these developments by crediting renewable fuels for vehicles. [EPA-HQ-OAR-2022-0985-1528-A1, p. 5]

12 Scully et al., supra note 8.

Renewable fuels are a proven technology in a growing industry.

Renewable fuels are proven technology with a sophisticated regulatory incentive system and a well-developed industry. That industry is also growing. This is due in part to existing federal and state programs, including the RFS, California's LCFS, and Oregon's Clean Fuel Standard. It is also due in part to the industry's genuine desire, and proven track record, to use biofuels to reduce our dependence on fossil fuels and combat climate change. EPA can rely on the existing incentive programs in the same way it relies on the BIL and IRA—which also promote biofuels—when assessing technology pathways in the Proposed Rule. The existing programs have given EPA years of real-world evidence showing how renewable fuels have succeeded in reducing and replacing fossil transportation fuels at scale. [EPA-HQ-OAR-2022-0985-1528-A1, pp. 5-6]

Beyond innovation in renewable fuels themselves, other companies are making significant carbon-reducing advancements for heavy-duty vehicles. ClearFlame Engine Technologies, for example, is deploying fleets of bioethanol-powered heavy-duty vehicles.13 And Remora, another heavy-duty vehicle company, designs carbon capture and sequestration systems that are fitted to semi-trucks and capture carbon emitted directly from those vehicles as they travel.14 Those technologies greatly reduce carbon emission from heavy-duty vehicles. They, too, deserve a boost from the Proposed Rule. Ignoring them, in fact, would run counter the very purpose of utilizing 202 to address greenhouse gas emissions. Instead of encouraging these incredibly promising greenhouse gas reduction technologies, the EPA approach would move towards eliminating them from the marketplace by treating those technologies the same as engines that utilize traditional fossil fuel. [EPA-HQ-OAR-2022-0985-1528-A1, p. 6]

13 ClearFlame Engine Technologies, https://clearflame.com/about/ (last visited June 16, 2023).

14 Remora, https://remoracarbon.com/vision/ (last visited June 16, 2023).

Renewable fuels crediting would give vehicle manufacturers more options to comply and make for a more durable emissions reduction program. [EPA-HQ-OAR-2022-0985-1528-A1, p. 6]

Adding a renewable fuel crediting mechanism would also make it more feasible for automakers to meet EPA's stringent standards. Renewable fuels would further diversify the pathways for manufacturers to comply with the proposed standards. This would be especially important in places, particularly rural areas with lower population densities, where battery-electric and hydrogen infrastructure will be difficult to develop and may not be cost-effective. Renewable fuels would serve as a viable alternative to attain significant heavy-duty vehicle emissions reductions in such areas. [EPA-HQ-OAR-2022-0985-1528-A1, p. 6]

EPA and the National Highway Traffic Safety Administration ('NHTSA') have experience with exactly this type of crediting. In prior iterations of EPA's 202 standard, and in the existing NHTSA fuel economy standards, 'flexible fuel vehicles' ('FFVs') receive compliance benefits because they can run on alternative fuels such as E85.15 This ability to utilize lower greenhouse gas fuels is adjusted by an 'F Factor' that represents how much renewable fuel is actually used in the real world.16 EPA should re-introduce crediting for vehicles that can utilize higher blends of renewable fuels, and should expand the program to include technologies other than just FFVs. [EPA-HQ-OAR-2022-0985-1528-A1, pp. 6-7]

15 49 CFR 523.2 (definition of dual-fuel vehicle includes flexible fuel vehicles); 49 CFR 536.10 (indicating that dual-fuel vehicles can earn credits under the standards); 2017 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions and Corporate Average Fuel Economy Standards, 77 Fed. Reg. 62624 (Oct. 5, 2012) (providing that FFVs could generate credits under the standards).

16 40 CFR 600.510-12(k).

Crediting vehicle engines that run on biofuels would also create a more durable program. Enabling a broader suite of technologies could avoid supply chain and other problems that are plaguing industry generally and threatening to undermine the Proposed Rule as currently structured. EPA should take a broader, more diversified approach to guard against other unforeseen events that may affect the flow of critical materials in the international economy. [EPA-HQ-OAR-2022-0985-1528-A1, p. 7]

Finally, a broader set of technologies may protect the rule from being withdrawn by future administrations. Biofuels enjoy broad bipartisan support, as evidenced by the recent debt ceiling negotiations between members of Congress.17 Both Republicans and Democrats in the House of Representatives successfully pressed for the removal of provisions in an early version of the debt ceiling bill that would have cut biofuels subsidies, and Congress remained steadfast in including important biofuels incentives that should not be undermined by the Proposed Rule.18 A rule that moves the needle too far toward one or two technologies risks political pushback if those technologies lose public support. [EPA-HQ-OAR-2022-0985-1528-A1, p. 7]

EPA Should Credit Renewable Fuels for Their Lifecycle Emissions Reductions or By Treating the Biogenic Emissions from Renewable Fuels as Zero-Emissions Sources.

Because carbon dioxide differs from other air pollutants, a different regulatory approach is warranted. EPA's crediting programs, like the Proposed Rule, should include renewable fuels because they replace fossil fuels, reducing their use and the need to extract and burn them. Although renewable fuels emit carbon when burned, those emissions are biogenic: the carbon dioxide naturally recirculates when the plants and other biomass sources absorb the carbon dioxide as they grow. The result is no net increase in atmospheric carbon. The more we can rely on fuels utilizing biogenic carbon, the less we will need to use fossil fuels that increase the atmosphere's total carbon load. [EPA-HQ-OAR-2022-0985-1528-A1, p. 10]

This phenomenon is widely recognized by lifecycle greenhouse gas models such as the GREET model developed and maintained by Argonne National Laboratory. EPA regularly utilizes lifecycle greenhouse gas modeling in its implementation of the RFS. EPA could utilize the Argonne GREET model and its own experience with lifecycle assessments to establish nationwide average carbon intensity scores for renewable fuels. Vehicles that utilize those fuels could be credited based on the degree of GHG reductions compared to fossil fuels and a factor that represents real-world use of renewable fuels in the vehicle (an ‘F Factor’). [EPA-HQ-OAR-2022-0985-1528-A1, p. 10]

To the extent EPA does not wish to examine lifecycle emissions in detail, an alternative approach could be to assign zero tailpipe emissions to renewable fuels because their biogenic emissions are canceled out by the carbon intake of biofuels feedstocks. Such an approach would be consistent with EPA’s lack of consideration of lifecycle emissions associated with ZEVs. EPA already largely assumes zero tailpipe emissions for renewable fuels when determining whether to approve new RFS production pathways for biofuels.30 EPA also considers ‘biogenic CO2 emissions resulting from the combustion of biomass from managed forests at stationary sources for energy production as carbon neutral,’ per the agency’s 2018 statement of policy.31 Additionally, the California Air Resources Board (‘CARB’) treats biogenic emissions as carbon neutral under its cap-and-trade regulations. Under CARB’s regulations, CO2 emissions from certain biomass-derived fuels (biogenic solid waste; waste pallets, crates, dunnage, manufacturing and construction wood wastes, tree trimmings, mill residues, and range land maintenance residues; all agricultural crops and waste; and certain wood and wood wastes) do not count towards an entity’s compliance obligations.32 The same assumptions could apply here.[EPA-HQ-OAR-2022-0985-1528-A1, pp. 10-11]

32 Cal. Code Regs. tit. 17, 95852.2.

U.S. EPA Fails to Account for the Potential of Ethanol and Other Renewable Fuels to Achieve GHG Reductions from HD Vehicles as Alternatives to Electric and Hydrogen Vehicles [EPA-HQ-OAR-2022-0985-1528-A1, p. 31]

Although HD BEVs, FCEVs, and H2-ICE vehicles have zero tailpipe emissions of CO2, they are still sources of CO2 emissions because of the emissions associated with fossil fuels used to produce the electricity or hydrogen used to power them. It then follows that the magnitude of the effective CO2 emissions from these vehicles will not be zero and will in fact vary depending on the source of that electricity or hydrogen. In contrast, while HD vehicles fueled by ethanol or other renewable biofuels fuels will have tailpipe CO2 emissions, they may have lower overall effective CO2 emissions than electric or hydrogen vehicles. This is because there may be less fossil fuel used in their production and the fact that the CO2 emitted at the tailpipe will ultimately be removed from the atmosphere by the growing of the next generation of feedstock plants. [EPA-HQ-OAR-2022-0985-1528-A1, p. 31]

Given that the purpose of the Proposed Rule is to reduce GHG emissions is to ‘further reduce GHG air pollution from highway heavy-duty engines and vehicles across the United States’ and not to mandate the use of HD ZEVs, U.S. should consider the addition of provisions in the Proposed rule that would lead to greater substitution of ethanol and other fuels for gasoline and diesel used in conventional vehicles These would include creating appropriate tailpipe GHG credit provisions for new HD vehicles designed to operate on ethanol blends above E10 and up to E99 that recognize the renewable nature of ethanol and similar provisions for HD vehicles capable of operating on other renewable fuels. An obvious advantage of this approach is that it would provide vehicle and engine manufacturers with compliance options other than overreliance on HD ZEV technology that may or may not be accepted in the marketplace and help to ensure that substantial reductions in HD GHG emissions are actually realized by the Proposed Rule. [EPA-HQ-OAR-2022-0985-1528-A1, p. 31]

Organization: South Dakota Department of Agriculture and Natural Resources (DANR)

Biofuels

The proposed emissions standards and the effort to use regulations to essentially mandate EV use ignores the benefits of continued use of renewable biofuels to power our vehicles. South Dakota's primary industry is agriculture, and we are the nation's fifth-largest ethanol producer. Ethanol is clean burning, renewable fuel used in our existing vehicle fleet allowing our citizens to travel across our state safely and reliably. Instead of working to mandate EV use, DANR recommends EPA look for ways to support the continued production and use of renewable biofuels. [EPA-HQ-OAR-2022-0985-1639-A2, p. 3]

South Dakota is a rural state with a small population, wide open spaces, and clean air. South Dakota is in full compliance or attainment with all federal criteria pollutants and the proposed emissions standards will not significantly improve our air quality. However, by essentially mandating EV use, they will limit the ability of our citizens to live and work in rural South Dakota. [EPA-HQ-OAR-2022-0985-1639-A2, p. 3]

Organization: Truck Renting and Leasing Association (TRALA)

Continued EPA Support is Needed for the Use of Low-Carbon Fuels

TRALA requests EPA support and incentivize the continued use of lower carbon intensity fuels throughout the coming decades instead of limiting itself to zero-emission technology pathways that reduce CO2 at tailpipe under the proposed rule. By way of example, data from California's Low Carbon Fuel Standard (LCFS) program demonstrates how clean and low-carbon emitting Renewable Natural Gas (RNG) fueled HD vehicles truly are. Recent data confirms that the average carbon intensity value of California's bio-compressed natural gas has been characterized as being a negative carbon fuel for three consecutive years. [EPA-HQ-OAR-2022-0985-1577-A1, p. 22]

Renewable diesel fuel is another low carbon alternative. Drop-in renewable diesel fuels, produced from forest residues or wood waste feedstock via thermochemical conversion technologies, could also potentially reduce GHG emissions more than 75% despite the varying energy efficiency of the conversion routes and feedstocks used.28 [EPA-HQ-OAR-2022-0985-1577-A1, p. 22]

28 Journal of Sustainable Energy & Fuels, Decarbonization potential of on-road fuels and powertrains in the European Union and the United States: a well-to-wheels assessment, (Published Sept. 1, 2022) (Decarbonization potential of on-road fuels and powertrains in the European Union and the United States: a well-to-wheels assessment - Sustainable Energy & Fuels (RSC Publishing).

Transitioning to a zero-emissions future is not about flipping a switch. Such unprecedented efforts will not occur overnight and must consider the fact that internal combustion engines will remain necessary for the trucking industry nationwide for decades to come. EPA has the opportunity to support the continued growth and use of low-carbon alternative fuels within the scope of this rulemaking. TRALA therefore recommends that EPA adopt a regulation that rewards, credits, and accounts for the emission reductions provided by biofuels and other low-carbon fuel options. Without the inclusion of biofuels and other low-carbon fuels under Phase 3, the agency is picking technology winners and losers as in the nation’s transportation mix. [EPA-HQ-OAR-2022-0985-1577-A1, p. 23]

Organization: Urban, William

The industry upheaval and Herculean infrastructure requirements associated with battery and hydrogen powered trucks could be reduced by 80% while fulfilling 80% of clean air goals with clean fuels such as Dimethyl ether. Dme requires no more complicated storage arrangements or moderate pressure needs than propane. It uses existing ICE designs with a different fuel system. Those in authority need to ask themselves why this is not a no-brainer. [EPA-HQ-OAR-2022-0985-1686.html, p. 1]

Organization: Volvo Group

Incorporation of emission reductions realized from renewable fuels

In January of this year, the Biden Administration released its National Blueprint for Transportation Decarbonization which emphasizes the importance of battery electric, hydrogen, and sustainable liquid fuels for reaching a net-zero economy in 2050. The report notes that renewable diesel fuels are “already being developed using standards to ensure they are safe for use and are fully compatible with existing vehicle fleets and fueling infrastructure and minimize emissions in their full life-cycles” while going on to say that “even greater opportunities lie ahead to leverage existing industrial infrastructure by converting petroleum refineries and other facilities for sustainable fuel production.”8 [EPA-HQ-OAR-2022-0985-1606-A1, p. 13]

8 U.S. Departments of Energy, Transportation, Housing and Urban Development, and U.S. Environmental Protection Agency (2023, January). The U.S. National Blueprint for Transportation Decarbonization, A Joint Strategy to Transform Transportation. Accessed on 14 June 2023 at https://www.energy.gov/sites/default/files/2023-01/the-us-national-blueprint-for-transportation-decarbonization.pdf.

Renewable diesel fuel is a 100% drop in fuel that can use the existing diesel distribution system. When used, it can reduce GHG emissions 50-85% or even more compared to petroleum diesel and while also reducing nitrogen oxide (NOx), particulate matter (PM) and other emissions. One of the biggest challenges to greater renewable diesel use has been its availability; however according to a recent Today in Energy article by the U.S. Energy Information Agency, eight new renewable diesel refineries recently began production which could result in more of a doubling of available supply by 2025.9 [EPA-HQ-OAR-2022-0985-1606-A1, p. 13]

9 U.S. Energy Information Administration. https://www.eia.gov/todayinenergy/detail.php?id=55399

With such growth in volumes, the lack of needed infrastructure investments and the significant levels of emission reductions, it seems counter to the administration’s own

Decarbonization Blueprint not to account for the significant contribution renewable diesel can play in meeting the reductions being sought through the Phase 3 proposal. According to a study released by the Diesel Technology Forum last year, it was found that "accelerating fleet turnover and use of renewable and biodiesel fuels can deliver significantly more benefits (3X) that outweigh those possible from EVs in the region in the study period."10 [EPA-HQ-OAR-2022-0985-1606-A1, p. 13-14]

10 Unknown (2022, July 22). Research Finds More Emissions Benefits at Lower Cost from Accelerated Fleet Turnover and Use of Bio- and Renewable Fuels than Switching to Electrified Medium and Heavy-Duty Trucks. Waste Advantage Magazine. Accessed 14 June 2023 at https://wasteadvantagemag.com/research-finds-more-emissions-benefits-at-lower-cost-from-accelerated-fleet-turnover-and-use-of-bio-and-renewable-fuels-than-switching-to-electrified-medium-and-heavy-duty-trucks/

While we recognize new mechanisms to account and verify the reductions gained through use of renewable diesel would be required, it is certainly no more difficult than trying to ensure the development or expansion of an entirely new vehicle fueling infrastructure that, depending on the power source, may not offer significantly more full life-cycle emission reductions. Achieving our mutual greenhouse gas reduction goals and keeping to no more than 1.5 degrees Celsius (C) increase in global warming will require an "all of the above" approach to emissions reductions. The Volvo Group is investing heavily in zero-emission powertrains and while we want to enable an environment for their utilization, we also want to see emissions reduced in the most cost-effective and quickest way for the benefit of our customers and the country. [EPA-HQ-OAR-2022-0985-1606-A1, p. 14]

Organization: Westport Fuel Systems

Emissions reductions can be achieved with a variety of fuels. The use of renewable, and low carbon fuels such as renewable natural gas (RNG) and hydrogen in internal combustion engines, particularly in the heaviest of vehicle classes, can result in significant reductions in carbon emissions. In our comments, we respectfully encourage the EPA to re-examine its stance on setting CO2 emissions standards for vehicles using tailpipe only emissions. While this may be a viable approach for lighter duty vehicles and some class 8 trucks where many electric models are commercially available and costs are more competitive with conventionally fuelled vehicles due to a mix of incentives and lower costs, this may not be the case for the heavy-duty class 8 sleeper cab segment. In this segment, despite the expected gains in electrification, there is still a need for alternative advanced technology options that can provide the power density and efficiency provided by internal combustion engines, using low carbon fuels. We urge the EPA to recognize the benefits of advanced internal combustion technologies using renewable gaseous fuels, including those with pilot fuels, and their ability to significantly reduce emissions in this segment. Adoption of hydrogen combustion technologies can reduce CO2 emissions by 90% or more. [EPA-HQ-OAR-2022-0985-1567-A1, p. 2]

Long haul road freight is recognised as one of the most challenging transport sectors to decarbonise due to the demanding use profiles, and the pressures of cost competitiveness. [EPA-HQ-OAR-2022-0985-1567-A1, p. 2]

There is considerable expectation that Battery Electric Vehicle (BEV) and Hydrogen Fuel Cell Electric Vehicle (FCEV) technologies can provide the solutions to a future sustainable road freight sector within the next decade, and the trajectory of many US policy initiatives is presumptive of these technologies being ubiquitous across the freight fleet. However, there are applications in heavy-duty long-haul vehicles, specifically long-haul class 8 sleeper cabs, where performance characteristics may not be fully served by these technologies. [EPA-HQ-OAR-2022-0985-1567-A1, p. 2]

While battery electric and fuel cell technologies can play a role, based on our analysis, the most cost-effective approach to decarbonising freight must include a central role for Internal Combustion Engines (ICE), fuelled by RNG or hydrogen (). ICE solutions using Westport Fuel Systems' HPDITM fuel system technology can significantly reduce emissions both at the tailpipe and across the lifecycle. As such, changes to policy frameworks that recognise more than the singular metric of tailpipe emissions will enable a greater diversity of solutions. This approach will better suit the diverse needs of the freight sector, and deliver faster, larger, CO2 reductions, at the lowest cost. [EPA-HQ-OAR-2022-0985-1567-A1, p. 2]

Providing a Level Playing Field for Advanced ICE Technologies

Westport supports a technology neutral performance-based approach to emission reductions and requests that the EPA move further to provide equal compliance pathways for hydrogen combustion technologies. [EPA-HQ-OAR-2022-0985-1567-A1, p. 5]

Although the EPA seeks to make this proposed ruling technology agnostic, the developing policy landscape is moving sharply towards incentives and other subsidies for BEV and FCEVs based on zero tailpipe emissions.3 While incentives are not part of this Rule, they do play a role in influencing the greater policy environment. Companion or complementary regulations, such as the ACT Advanced Clean Truck Act in California and the Inflation Reduction Act, have factored into the decision-making process in the Phase 3 rulemaking around vehicle deployment rates and costing and increasing stringency of emissions. This policy direction prioritizes vehicles with zero tailpipe emissions over other low emissions technologies, including those that use RNG or other carbon neutral or negative fuels. Part of the policy direction to recognize the full impacts of transportation emissions is accounting for well to wheels analysis, the other is to ensure that other technologies are measured on not only emissions but also on cost effectiveness metrics. [EPA-HQ-OAR-2022-0985-1567-A1, p. 5]

3 Clean Vehicle Tax Credits in the Inflation Reduction Act of 2022 https://crsreports.congress.gov/product/pdf/IN/IN11996. The IRA defines "qualified vehicles" for purposes of incentives as "draws electricity from a battery has the capacity to be recharge or is propelled by power derived from certain fuel cells.

EPA Summary and Response:

Summary:

A group of commenters urged EPA to develop a standard that provides certification pathways which recognize environmental benefits of various biofuels (e.g., Clean Fuels Alli., NGV America, Diesel Tech. Forum, Missouri Farm Bur., Westport). These commenters touted biofuels' benefits, including:

- ICE vehicles will remain, and biofuels are a means of curbing their GHG emissions
- biofuels are available now, and are highly cost effective, and do not require supportive infrastructure, meaning that benefits can commence immediately rather than in MY 2027;

- use of biofuels could provide reductions while critical mineral supply chains are developed;
- criteria pollutant emissions are lower than from diesel vehicles;
- biofuels are an especially good alternative for vehicles which are not natural ZEV candidates, such as Class 8 sleeper tractors.

Many of these comments urged EPA to establish standards on a lifecycle basis, and maintained that so measured, CO2 (and, for one commenter, Diesel Tech. Forum, criteria pollutant) emissions would be less. Several of these commenters cited a study of Stillwater Associates from July 2022 asserting that switching to 100% renewable diesel would have three times more CO2 emissions reductions than the BEV scenarios, that MY 2021 diesel engines have greater PM reductions than BEVs, and that NOx reductions need to be determined on a miles traveled basis instead of a per vehicle basis. (API, Volvo, Diesel Tech. Forum). Commenters' views of what should count as lifecycle emissions went not just to upstream production and fuel/electricity generation, but to battery disposal, and overseas mining emissions and other actions. (Energy Vision, Lynden Renewable Fuels, POET). Commenters also noted steps now being taken to reduce upstream emissions related to processing of biofuels, as well as to reduce the carbon intensity of the biofuels themselves. (NACS, POET.)

Others pointed to regulatory and policy support for a biofuel-based compliance pathway. They pointed to the Administration's Blueprint for Decarbonisation, which mentions biofuels and lifecycle reductions favorably, to EPA's 2018 Policy Statement regarding CO2 emissions from combustion of biomass in managed forests as carbon neutral (Clean Flame, citing U.S. Environmental Protection Agency, policy statement,[654] POET), and more generally, to the CAA RFS program, and CARB cap-and-trade program (which counts biofuel emissions as zero) and Low Carbon Fuel standard (MEMA, POET, Energy Vision).

A group of commenters stressed the benefits of Renewable Natural Gas, stating that it is derived from captured methane, a potent GHG, and emitted as the less potent CO2. (TRALA, Lynden Renewable Fuel, Energy Vision, Hexagon Agility.) In addition, other commenters maintained that EPA was improperly ignoring the difference between anthropogenic emissions (from fossil fuels) and biogenic emissions (from plants). The asserted difference by these commenters is that plants remove CO2 from the ambient air, so their later combustion nets out as zero, unlike the case with fossil fuels. (Clean Flame, National Corn Growers Ass'n.) MFN, on the other hand, noted that natural gas fueled vehicles have significantly higher VOC emissions than conventional vehicles (including methane emissions), although slightly lower PM emissions (without needing filters), and lower NOx emissions.

Commenters had various suggestions on how to account for biofuels in a certification pathway. In addition to suggesting EPA develop standards on a lifecycle basis, commenters recommended the following:

- developing a Utility Factor on a case-by-case basis representing the amount of time the vehicle runs on some type of biofuel (POET)
- update GEM to recognize fuel types in addition to the three (gasoline, diesel, CNG) now recognized (Lubrizol)

[654] *Available at* https://www.epa.gov/sites/default/files/2018-04/documents/biomass_policy_statement_2018_04_23.pdf.

- include some type of credit mechanism for biofuels (Natural Gas Veh. For America)
- adopt the same approach as the Flexible Fuel Vehicle standards (POET)

Commenter Urban states that EPA should consider use of dimethyl ether (without further explication).

The American Free Enterprise Chamber of Commerce (Am Free) asserted that EPA's failure to consider use of biofuels is arbitrary, violating the principle that agencies must consider reasonable alternatives as part of a process of reasoned decision-making. This commenter also stated that EPA asserted in the parallel light duty proposed rule that it has authority to impose fuel controls though its requested comment on whether fuel controls should be used in the future as a "complement" to emissions standards (though the commenter conceded that EPA did not request comment on such controls as an alternative to emissions standards), and that this further indicated arbitrariness in the heavy-duty proposal.

American Petroleum Institute stated that "EPA's approach is not consistent with other existing EPA policies (e.g., the Renewable Fuel Standard)".

American Soybean Association stated that the standards should still provide a pathway for ICE that can run on biomass-based diesel, since it will lead to increased utilization of these engines in the agricultural sector.

Clean Fuels Alliance America commented that emissions warranties cannot be voided or impacted because of the use of biodiesel blends.

Lubrizol commented that they support consideration for the creation of a diesel deposit control standard similar to 40 CFR 1090.260.Lynden Incorporated commented that high-horsepower engines are being phased out because of the inability to meeting emissions standards. Lynden and NGVAmerica stated that the emission standards will force manufacturers to subsidize ZEV by increasing the cost of engines. Lynden also recommended that EPA should assist small fleets in replacing pre-2010 diesel engines with modern diesel engines.

National Association of Convenience Stores (NACS), NATSO, and SIGMA, commented that the proposed standards risk zeroing out new innovations in emissions reductions from ICE vehicle, because the standards cannot be met with ICE vehicles alone.

<u>Response:</u>

Implicit (or in some cases, explicit) in many of these comments is that the proposed standard in some manner mandates use of ZEVs. It does not. See Sections I and II of the preamble and RTC 2. In short, the final standards are numerical performance-based standards, and can be met in any manner a regulated entity (i.e. manufacturer) sees fit that achieves compliance with that numerical standard. In assessing a modeled potential compliance pathway that includes a technology mix of ICE vehicle technologies and ZEV technologies, EPA was demonstrating that the final standards were feasible and appropriate; EPA was not requiring that manufacturers utilize that modeled potential compliance pathway. This is the Agency's approach for all of its CAA Title 2 standards, following the template set forth initially by the D.C. Circuit in *NRDC v. EPA*, 655 F. 2d at 332, and echoed many times since in succeeding rules and court opinions. EPA is not mandating the use of the technology included in the technology packages for this compliance pathway, just as EPA has not mandated the technology included in such technology packages in prior rules (and which manufacturers have previously either only partially or not at all adopted in complying with previous rule standards). See generally responses in RTC section 2.1, which notes further that there are many additional examples of compliance pathways to meet the final standards open to manufacturers. See also additional example potential compliance pathways that support the feasibility of the final standards in preamble Section II.F, which include a suite of technologies ranging from ICE engine, transmission, drivetrain, aerodynamics, and tire rolling resistance improvements, to the use of low carbon fuels like CNG and LNG, to hybrid powertrains (HEV and PHEV) and H2-ICE. Low carbon fuels, like CNG and LNG, may be accounted for subject to certain requirements if the use of the fuel results in lower CO_2 emissions in the vehicle exhaust. This similarly applies to biofuels, if the use of the fuel results in lower CO_2 vehicle exhaust emission. However, to use fuels (including biofuels) as part of the engines and vehicles certification, the manufacturer is required to get approval from the EPA and one of the requirements of this approval is that the manufacturer must show that the vehicle and engine only use the specific fuel when operating in-use.[655]

EPA's Phase 3 GHG standards are CO_2 vehicle exhaust emission standards, and EPA considers all comments asserting that EPA must, or should, set or determine compliance with such standards in a manner other than measuring (directly or via GEM) vehicle exhaust CO_2 emissions as comments asserting that EPA must, or should, consider life cycle assessment. For EPA's response to comments on life cycle assessment, see RTC section 17.1. EPA recognizes that changes to fuel requirements can result in changes in emissions but disagrees that such changes are within the scope of this rulemaking or that EPA is required to consider them as alternatives to this rulemaking, which is concerned with vehicle and engine standards under CAA section 202(a). The CAA has a separate and distinct set of requirements for engaging in fuels regulations and EPA has not at this point undertaken the requisite analyses to regulate GHGs under CAA section 211(c). Indeed, section 211(c)(2)(A) provides that fuel may not be regulated to control harmful air pollution except after "consideration of other technologically or economically feasible means of achieving emissions standards under section [202]." Thus, it is entirely appropriate (if not required) for the Administrator to take the technologically and economically feasible steps of this rule before undertaking further controls on fuels to address emissions reduction. In light of this statutory structure, with very different regulatory programs for vehicles standards under section 202 and fuels standards under section 211, EPA disagrees that it is required to consider fundamentally altering this rulemaking from a vehicles rulemaking to a fuels rulemaking. "While an agency must consider and explain its rejection of 'reasonably obvious alternative[s],' it need not consider every alternative proposed nor respond to every comment made. Rather, an agency must consider only 'significant and viable' and 'obvious' alternatives."[656] At this point, given that the EPA has not met the statutory prerequisites for new fuels controls, much less proposed new fuels controls, the adoption of new fuels controls is not a viable alternative. EPA of course continues to separately implement the RFS program, which also has the goal of promoting lower GHG fuels, and the most recent renewable fuel volume standards require the largest volumes of renewable fuels to date to be used for transportation.[657] Similarly, in response to the specific comments on using a utility factor to account for the relative use of non-biofuels and biofuel (for example diesel and biodiesel), the comment that a credit mechanism should be created to account for the LCA, and the comment to adopt the same

[655] *See* the response to the ClearFlame comments in this RTC Section 9.1.
[656] *Nat'l Shooting Sports Found., Inc. v. Jones*, 716 F.3d 200, 215 (D.C. Cir. 2013) (citations omitted).
[657] *See* 88 FR 44468 (July 12, 2023).

approach as the Flexible Fuel Vehicle standards, we disagree that such changes are within the scope of this rulemaking.

Regarding the comment on biogenic emissions, EPA notes that ever since the section 202 Endangerment Finding was made, it has considered GHG pollution as being comprised of six well-mixed gases (one of which is CO2), based on their properties and behaviors in the atmosphere that are relevant to the climate change problem, including characteristics and attributes related to radiative forcing, chemical reactivity, and atmospheric lifetime. As EPA stated, in reiterating this position in the 2016 Endangerment Finding for GHG Emissions from Aircraft, "[i]n the record for the 2009 Endangerment Finding, the Agency stated that 'all CO2 emissions, regardless of source, influence radiative forcing equally once it reaches the atmosphere and therefore there is no distinction between biogenic and non-biogenic CO2 regarding the CO2 and the other well-mixed GHGs within the definition of air pollution that is reasonably anticipated to endanger public health and welfare."[658] EPA finds it appropriate to continue this policy of treating all vehicle exhaust CO_2 emissions equivalently, since once they have been emitted to the atmosphere the CO2 molecules have equivalent impacts on the climate, regardless of the origin and constitution of the fuel prior to combustion.

EPA has reviewed the Stillwater Associates study from July 2022, stating that switching to 100% renewable diesel will provide three times the CO_2 reductions as can be achieved from ZEVs, and determined that the information it provides is not applicable to the vehicle tailpipe standards being set in this rule. First, the final standards in this rule are for new vehicles, so comparing the emissions reductions from the rule to a scenario where 100% of the nation's diesel is switched to renewable diesel is not an apples-to-apples comparison. Second, the upstream emissions modeling performed in the Stillwater Associates study doesn't reflect the impacts of the IRA on emissions from EGUs, which is significant. RIA Chapters 4.1 and 4.2.4 contain more discussion regarding changes in EGU emissions over time driven by economic conditions, Congressional action such as the IRA, and other finalized rules by EPA and others affecting power sector emissions. EPA's power sector model, IPM, models significant reductions in GHG emissions from EGUs in future years. This makes the study's conclusions outdated. Finally, see also RTC section 17.1 for EPA's response to comments regarding life cycle assessment.

In response to the claim that "new technology diesel engines '98% PM reductions compared to EVs' 95% PM reduction assuming power from the U.S. Grid Mix," we first note that EPA is setting GHG emission standards for HD vehicles in this rulemaking, though we also analyze impacts of the rule, including impacts on non-GHG emissions. See Section II.G.4 of the preamble for EPA's consideration of such impacts. Additionally, this commenter's assertion doesn't reflect the impacts of the IRA on emissions from EGUs, which is significant. RIA Chapters 4.1 and 4.2.4 contain more discussion regarding changes in EGU emissions over time.

We disagree with the comment that NOx reductions need to be determined on a miles traveled basis instead of a per vehicle basis. The comment is based on the assumption that ZEV have lower VMT than ICE vehicles, which is not consistent with feasibility assessment that was conducted for the rule. See RIA Chapter 2.5.1 on how we sized the powertrain components of

[658] *See* 81 FR 54422 (August 15, 2016).

ZEV, which includes the sizing of the battery, to meet the duty cycle requirements for each of the 101 vehicle IDs in HD TRUCS.

Regarding the comments that changes to GEM are needed for fuels other than gasoline and diesel to be recognized in GEM, GEM is configured to accept inputs for all carbon-containing fuels. GEM has explicit inputs for gasoline, diesel, natural gas, liquefied petroleum gas, dimethyl ether, and high-level ethanol-gasoline blends. In Table 1 of 40 CFR 1036.550, EPA specifies the reference fuel properties for these fuel types.[659] In addition, footnote "a" to Table 1 of 40 CFR 1036.550 allows for manufacturers to seek approval for reference fuel properties that are not listed in Table 1 of that section. 40 CFR 1036.505 contains the instruction for how manufacturers must generate fuel maps for input in GEM and, with the final addition described in Section III.C of the preamble, specifies that for any fuel type not listed in Table 1 of 40 CFR 1036.550 manufacturers are required to identify the fuel type as diesel fuel for engines subject to compression-ignition standards and as gasoline for engines subject to spark-ignition standards. Thus, the test procedures set out in 40 CFR 1036.505 and 40 CFR 1036.550, allow for carbon-mass-specific net energy content of all carbon containing fuels to be accounted for in GEM. See also our further response to commenter Clear Flame below.

Regarding Am Free's comment comparing the light duty proposal, first, the discussion in the light and medium duty proposal to which the commenter refers dealt with PM control, not with GHG emissions. The light-duty proposal is multi-pollutant; the heavy-duty rule only sets GHG emission standards. Moreover, all the light and medium duty preamble announces is the possibility of a different rulemaking at a later date and requests comments on potential approaches for that rulemaking, not as part of the light duty rulemaking at issue. EPA consequently does not agree that EPA took a meaningfully different approach in the two rules.[660]

Regarding the supply of critical materials, see our response in RTC section 17.2. and Preamble section II.D.2.ii.c.

Clean Fuels Alliance America's comment is outside the scope of this final rule; see existing 40 CFR 1068.115.

The comment from Lubrizol on the consideration for the creation of a diesel deposit control standard is outside the scope of this final rule.

We disagree with the Lynden Incorporated comment that high-horsepower engines are being phased out because of the inability to meet emissions standards. EPA's HD GHG engines standards are work specific and the engine duty cycles are denormalized with the torque curve of the engine, so higher horsepower engines have higher cycle work over the duty cycles, which results in lower CO_2 emission than their lower horsepower counterparts.

We also disagree with the comment from Lynden and NGVAmerica that the emission standards will force manufacturers to subsidize ZEV by increasing the cost of engines. Our analysis include in Preamble Section II and RIA Chapter 2 shows payback periods under the modeled potential compliance pathway that are acceptable for heavy-duty vehicle purchasers.

---

[659] Under 40 CFR 1037 (e.g., 1037.520(f)), manufacturers are required to followi the 40 CFR 1036 regulations on test procedures, including fuel mapping and related requirements.
[660] *See generally* 88 FR 29397-98.

The comment from Lynden that recommended EPA should assist small fleets in replacing pre-2010 diesel engines with modern diesel engines is out of scope for this rule.

We disagree with the comment from National Association of Convenience Stores (NACS), NATSO, and SIGMA, that the proposed standards risk zeroing out new innovations in emissions reductions from ICE vehicle, because the standards cannot be met with ICE vehicles alone. As discussed in Preamble Section II and RIA Chapter 2.11, the standards are performance-based and manufacturers could meet the standards with the use of hydrogen engines, hybrids, natural gas engines and improvements to ICE vehicles.

Response to Individual Comments

Comment:

ClearFlame Engine Technologies stated that the proposal to update 40 CFR 1036.505 to clarify that "when certifying vehicles with GEM, for any fuel type not identified in Table 1 of 40 CFR 1036.550, the manufacturer would identify the fuel type as diesel fuel for engines subject to compression-ignition standards" is not sufficient to provide an engine certification pathway for all fuels that are reasonably expected for use in dedicated alternative fuel engines. They state that GEM assumes that the only fuels to be used by heavy-duty engines are gasoline, diesel, and natural gas and EPA must provide a mechanism for certifying dedicated ethanol and other dedicated alternative fuel engines, as it is the scientifically and technically correct way to treat these engines. They state that GEM treats a dedicated ethanol engine as though it is running on high-carbon diesel fuel (in contrast to a CNG engine, which is not treated by GEM as though it is running on diesel). They state that treating a dedicated ethanol engine as though it was running on diesel fuel results in GEM calculations that yield an unintended negative outcome because GEM:

(1) Does not take the biogenic nature of ethanol emissions into account.

(2) Does not take the lower carbon Intensity of ethanol into account.

(3) Does not take other combustion differences (like heating value and H/C ratio) between ethanol and diesel into account.

ClearFlame Engine Technologies believes that GEM currently estimates emissions from ethanol vehicles to be approximately 1.5 times worse than diesel, while GREET, based on national average, calculates ethanol to have 50% of the emissions impact of diesel. They state that, thus, GEM overestimates the climate impact of an ethanol-fueled engine by 3x (1.5/.5). They would like EPA to create a fuel input for ethanol within GEM, which would account for its heating value, H/C ratio, and biogenic carbon ratio. They state that this would enable GEM to accurately account for the different combustion properties and decarbonization benefits of a compression-ignition engine that has been designed to run exclusively on ethanol.

They state that 40 CFR 1036.505 and 40 CFR 1065.701(c)(1) enables a company to request approval to use the following alternative test fuels with EPA approval:

(1) E98 that meets ASTM D4806 (i.e., uses gasoline as its denaturant).

(2) Another form of E98 that does not use gasoline as its denaturant.

(3) Ethanol that includes 5% water (as would result from the output of an unaugmented distillation process).

ClearFlame Engine Technologies requested that EPA add specifications for high-blend ethanol for each of the examples outlined above, to provide certainty to the certification process.

ClearFlame Engine Technologies stated that "possible to achieve the same goal by adding a conversion or correction factor to the calculation of GEM emissions, a fuel-specific fuel Input (such as is being considered for hydrogen) is highly preferred".

They also commented that 40 CFR part 1065, subpart H limits the use of high-blend ethanol as a test fuel to E51-83 fuel that meets the specifications of ASTM D5798.19 and request a high-blend ethanol E98 fuels.

Response:

ClearFlame Engine Technologies requested updates to 40 CFR 1036.505 to allow GEM to treat a dedicated ethanol engine in a manner different than an engine running on diesel. EPA made changes to the base fuel properties within GEM to allow for accounting for the carbon content of E85 fuel via a test procedure technical amendment finalized in 2022.[661] We also note that the footnote "a" in Table 1 to Paragraph (b)(4) of § 1036.550—Reference Fuel Properties allows for approval of other fuels. This allows a manufacturer to request other fuels, like E98, and to account for its carbon mass fraction differences. In this scenario, with a preapproved E98 fuel, the fuel map would be preprocessed with the E98 fuel properties, which would eliminate the commenter's asserted need for any changes to GEM with respect to the ability to generate accurate results for an E98 fuel.

Regarding their comment on well-to-tailpipe emissions, see our response above in this section of the RTC and see RTC chapter 17.1 for our response on life cycle assessment.

EPA is not adding additional reference fuel properties in Table 1 of 40 CFR 1036.550 at this time and this request is outside the scope of this final rule. Please see our response above in this section of the RTC regarding what Table 1 already includes in the existing regulation. Under the existing regulations, the mechanism exists for manufacturers to request approval by EPA for use of these fuels in 40 CFR 1036.550 and 40 CFR 1065.701(c)(1). In addition, equation 4 of 40 CFR 1036.535, already accomplishes the correction for fuels that are not in Table 1 of 40 CFR 1036.550 that was suggested by ClearFlame Engine Technologies. In response to the comment that 40 CFR part 1065, subpart H limits the use of high-blend ethanol, preventing the use of E98 fuels, this is simply not the case. While 40 CFR 1065 subpart H does not directly list E98 as a fuel, 40 CFR 1065.701(c) provides a process to allow a manufacturer to obtain approval for any fuel, provided it meets the qualifications in 40 CFR 1065.701(c)(1).

9.2 Phase 2 Vehicle and Engine Technologies

Comments by Organizations

Organization: Alliance for Vehicle Efficiency (AVE)

In 2012, EPA saw fit to incentivize near zero technologies and embraced their role to support ZEVs while achieving significant GHG reductions. [EPA-HQ-OAR-2022-0985-1571-A1, p. 2]

“EPA believes that these temporary regulatory incentives are justified under CAA section 202(a) as they promote the commercialization of technologies that have, or of technologies that can be critical facilitators of next-generation technologies that have, the potential to transform the light-duty vehicle sector by achieving zero or near-zero GHG emissions and oil consumption, but which face major near-term market barriers.” 1 [EPA-HQ-OAR-2022-0985-1571-A1, p. 2]

1 Federal Register / Vol. 77, No. 199 / October 15, 2012, at 62811

The enormous challenges of decarbonizing the heavy-duty vehicle market will take decades and require all available technologies. AVE encourages EPA to seek additional pathways to incentivize the near-term introduction of as many advanced technologies as possible into future heavy-duty trucks. Prior to the effective implementation of this Proposal, nearly one million Class 8 trucks will be produced. These vehicles will be on American roads for well over 20 years. By expanding the definition of ZEVs even slightly, EPA can ensure greater emission reductions for decades. [EPA-HQ-OAR-2022-0985-1571-A1, p. 2]

Recognizing the challenges of decarbonizing Class 8 trucks, the European Union now includes HD vehicles that emit not more than 5 g/(t.km) or 5 g/(p.km) of CO2 as ZEVs.3 AVE encourages EPA to adopt the EU’s amended standard. Doing so will allow for greater emission reductions in the heavy-duty sector and faster penetration of already commercialized technologies. [EPA-HQ-OAR-2022-0985-1571-A1, p. 2]

3 https://climate.ec.europa.eu/eu-action/transport-emissions/road-transport-reducing-co2-emissions-vehicles/reducing-co2-emissions-heavy-duty-vehicles_en#incentive-mechanism-for-zero--and-low-emission-vehicles-zlev

Organization: Advanced Engine Systems Institute (AESI)

AESI supports the EPA proposal to reduce GHG emissions from heavy-duty trucks by setting performance standards that drive the improved efficiency of diesel ICE engines while accelerating the introduction of electric and hydrogen powertrains. AESI believes that certain critical engine and powertrain technologies, which were not economically viable or fully developed 10 years ago and are not considered in EPA’s proposed Phase 3 GHG standards, can be further deployed to reduce the GHG emissions of combustion engines. HD hybrid powertrains, and hydrogen ICE have seen significant advances during the past few years. These technologies are cost effective and can deliver substantial GHG emission reductions. EPA should account for recent data regarding the performance of these carbon reduction technologies in the final rule. [EPA-HQ-OAR-2022-0985-1600-A1, p. 1]

A just released study by the International Council on Clean Transportation (ICCT) finds that ‘cost effective ICE efficiency improvements remain important to the de-carbonization of the HD sector.’ AESI agrees with that conclusion. HD Hybrid powertrains, with existing incentives, can deliver up to a 31% GHG reduction in vocational vehicles and 25% in long haul at a small fraction of the cost of an HD BEV powertrain. It is essential that EPA conduct technical analysis and encourage deployment of these cost-efficient Hybrid powertrains, which can provide an important short-term solution to the de-carbonization of long-haul freight, our most difficult sector challenge in MY 2027-2032. [EPA-HQ-OAR-2022-0985-1600-A1, pp. 1-2]

Organization: California Air Resources Board (CARB)

b. Plug-in Hybrid Technologies

Affected page: DRIA 181

Plug-in hybrid technologies are a bridge technology which offers advantages and disadvantages versus pure BEVs. Plug-in hybrid electric vehicles (PHEV) offer greater flexibility than BEVs and can be operated in a similar manner to existing ICE vehicles today. However, the additional complexity of simultaneously including both ICE and BEV powertrains in each PHEV adds cost versus BEV powertrains, and operational savings from PHEVs are already expected to be lower than for BEVs due to higher fuel and maintenance expenses further reducing potential cost effectiveness. Applications with low daily mileage but occasional high mileage trips such as utility applications may be well served by PHEVs before a full transition to ZEV technologies. Certain recent federal funding opportunities may further support rollout of PHEVs. PHEVs freight vehicles are expected to come to market in the near future before 2027 by manufacturers such as Hyliion.90 ZE-capable PHEV technology is already being fielded in emergency response vehicles in the U.S. by at least three fire apparatus manufacturers.91 Diesel and compressed natural gas PHEVs are also available today in streetsweepers.92 Vehicles using these types of powertrains can address parts of the market which might otherwise default to ICE vehicles in the early years of implementation. Market interest in freight applications of hybrid and PHEV systems is further underscored by explorations of trailer-based hybrid systems to add regenerative braking and plug-in energy to whatever conventional (or ZEV) tractor is connected.93,94,95,96,97,98,99,100 Electrification on board conventional ICE HDVs is already anticipated to increase significantly with the addition of higher voltage chassis electrical systems (48-Volt and above), the announced usage of electric exhaust heaters, and the broad component availability of electric exhaust heaters, electrically heated mixers, and electrically heated catalysts.101,102,103 One manufacturer already announcing electric exhaust heaters for their medium heavy-duty engine (HDE) offering has seen historic market share >85 percent for class 8 engines under 10L104 and similarly dominates the medium HDV market outside of HD pickups and vans.105,106,107,108,109,110 Another example illustrative of existing LD powertrains that could be applicable to launching PHEV technology up into the lightest end of the HD range is the RAM gasoline pickup, which has applied a default 48-Volt mild hybrid on their largest engine offering since MY 2019.111 Adding as little at as 15 kWh of energy storage to any of these types of mild hybrids (less than two-thirds the size of an original Nissan Leaf battery and still smaller than an electric Smart ForTwo battery112) could trigger the IRA commercial vehicle tax credits, likely covering the entire incremental cost of such storage and the cost of the entire hybrid system itself.113 Putting moderate amounts of stored energy on a vehicle (e.g. the 15 kWh needed to qualify for IRA tax credits) can also unlock other non-propulsion user benefits like replacing Auxiliary Power Units, providing export power on jobsites and robustly underpinning the power needs of advanced driver assistance systems. As discussed further in the

HDVs with ICE Technologies in Part I. Section C.2. below, U.S. EPA did not assume significant market penetration of PHEVs in setting the proposed Phase 3 GHG standards. Given these aligned technology availability, user and manufacturer interests and favorable economic drivers, CARB staff suggests U.S. EPA reflect expected PHEV market conditions more accurately (and strengthen stringency accordingly) based on projecting a significant fraction of vehicle sales as PHEVs, a fraction that could foreseeably approach the remaining non-ZEV share of the market. [EPA-HQ-OAR-2022-0985-1591-A1, pp.34-36]

VI. Hybrid Certification and Test Procedures

Hybrids are essential to the success of EPA's Phase 3 Greenhouse Gas proposal. Hybrids can bridge the gap between conventional internal combustion engines and future zero emissions technology. They are not as dependent on the electrical grid as battery electric vehicles and are a technology that fleets can use today. Below we have identified several significant EPA certification and compliance barriers that make hybrids much more challenging to certify than either internal combustion engines or fully electric vehicles. [EPA-HQ-OAR-2022-0985-1598-A1, p. 11]

EPA streamlining heavy-duty hybrid certification and compliance requirements would improve the durability of Phase 3 by providing another viable path toward compliance, directionally decreasing the likelihood that the Phase 3 standards would need to be delayed should the recharging infrastructure not be ready. Hybrids can achieve early success by decreasing GHGs during a period in which the recharging infrastructure is still growing toward supporting the shorter range of fully electric vehicles. Hybrids also maximize the use of critical battery materials to achieve greater GHG reductions with a greater number of vehicles. Heavy-duty vehicles will evolve from hybrids to fully electric, and manufacturers should be able to leverage all technology options, without today's disproportionate heavy-duty hybrid certification and compliance barriers. Streamlining and eliminating the certification and compliance barriers for hybrids will also allow manufacturers to take advantage of hybrid credits which will incentivize additional development and further production. Lastly, if the certification and compliance barriers to hybrids are not streamlined, EPA's Phase 3 rule will be at the mercy of the status of the nation's electric grid and heavy-duty BEV charging infrastructure. [EPA-HQ-OAR-2022-0985-1598-A1, p. 11]

Organization: Daimler Truck North America LLC (DTNA)

EPA Request for Comment, Request #11: We request comment on whether we should include additional GHG-reducing technologies and/or higher levels of adoption rates of existing technologies for ICE vehicles in our technology assessment for the final rule.

- DTNA Response: DTNA believes it is inappropriate to add additional GHG technologies at this time.[EPA-HQ-OAR-2022-0985-1555-A1, p. 160]

EPA Request for Comment, Request #52: We request comment on ICE vehicle technologies that could support more stringent standards than those proposed (in both tractor and vocational sections)

- DTNA Response: DTNA believes it is inappropriate to require additional GHG technologies for ICE vehicles at this time. [EPA-HQ-OAR-2022-0985-1555-A1, p. 167]

Organization: Diesel Technology Forum (DTF)

a. Hybrid diesel engine technology is readily available, cost efficient (compared to BEVs and FCVs), and can make a significant impact on fuel consumption reduction and CO2 reduction now.

In the proposed rule, the utility of hybrid powertrains as a compliance strategy has not been fully considered. Newer data is being established by SwRI as part of their Clean Hybrid Electric Diesel Engine (CHEDE), a consortium of leading manufacturers and suppliers. Results indicate that particularly for Class 7 trucks (the smallest class of HD trucks), used primarily as garbage trucks, street sweepers, straight trucks such as for furniture delivery, when hybrid technology is incorporated, they can significantly reduce CO2 due their stop-and-go duty cycle. [EPA-HQ-OAR-2022-0985-1618-A1, p. 3]

In the case of hybrids, EPA notes (88 Fed. Reg 25896) that tax credit eligibility of a "qualified commercial clean vehicle" is limited to those powered to a significant extent by a battery-powered electric motor, thereby excluding hybrid powertrains that utilize ICE while including plug-in hybrid electric vehicles. Unfortunately, the IRA legislation failed to take a technology-neutral approach for eligibility in incentivizing investments in all technologies that can substantially reduce GHG, instead favoring only battery-based and electrified technology. [EPA-HQ-OAR-2022-0985-1618-A1, pp. 3 - 4]

This unfortunate defect in the credit eligibility in the legislation does not however preclude EPA from factoring in greater credit and other provisions for ICE vehicles that utilize hybrid electric powertrains in its Phase 3 rule which we strongly encourage. Given the fact that ICE powertrains will continue to play a major role in the commercial trucking sector for decades to come, having more of the future trucks outfitted with hybrid technology would translate into lower GHG emissions perhaps sooner than fuel cell electric or battery electric vehicles. The earlier the technology is adopted, the more impact it can have. [EPA-HQ-OAR-2022-0985-1618-A1, p. 4]

Organization: Eaton

3. GHG regulations need to be based on data, include evaluations of recent technologies, allow multiple pathways for achieving emissions reduction, and remain technology-neutral

While the NPRM describes high penetration of Zero-Emissions Vehicles (ZEV) as the path to achieve low GHG emissions, there are also uncertainties such as infrastructure availability, clean electrical energy or Hydrogen production, robust and affordable Battery Electric Vehicles (BEV) or Fuel Cell Electric Vehicle (FCEV) technology. Therefore, the Phase 3 rule needs to also consider technologies that lower emission for ICE powertrains, based on technology progress since Phase 2 that is not in conflict with the recent low NOx rules. Since 2017, Eaton and other suppliers have developed an array of technologies based on conventional, robust and very cost-effective components, ranging between ICE improvements and hybridization, with reductions in the range of 5% to 50% lower GHG while achieving 2027 EPA NOx limits (in both certification test environment as well as real-world cycles). [EPA-HQ-OAR-2022-0985-1556-A1, p. 2]

The Phase 2 GHG rule proved to be a great success. The rule included engine and vehicle-level standards that drove technology improvements that are currently in production, while additional improvements are planned for production through 2027. Examples include high compression ratio engines, waste heat recovery, cylinder thermal insulation, reduced friction losses, improved aerodynamics, and efficient transmissions to name a few. The industry is on path to achieve the upcoming 2024 and 2027 Phase 2 GHG goals on time. However, the technology landscape has also changed since the Phase 2 regulations were adopted in 2016. In addition to the advent of BEV and FCEV trucks and the deployment of many technologies evaluated for Phase 2, other significant changes in ICE-based powertrains are as follows: [EPA-HQ-OAR-2022-0985-1556-A1, p. 2]

1. GHG benefits associated with compliance with 2027 Low NOx limits

Low NOx technologies were developed for meeting new NOx regulations in 2025 – 2027, that in isolation increase CO2 emissions through increased backpressure of larger catalysts and increased energy for faster heat-up of the catalysts. However, by balancing the trade-off between CO2 and NOx, the ICE and Aftertreatment systems can in fact achieve simultaneously CO2 reductions while achieving the new stringent NOx limits. Eaton components such as Variable Valve Actuation (VVA) and electrical and/or fuel based aftertreatment heater, in conjunction with advanced catalysts and aftertreatment architectures, have demonstrated 1.5% CO2 savings of Federal Test Procedure (FTP) as shown in Figure 1 and up to 5.1% on the Low Load Cycle (LLC), as seen in Figure 2. These results were achieved at the Southwest Research Institute and are published in [1]. [EPA-HQ-OAR-2022-0985-1556-A1, p. 3.] [See Docket Number EPA-HQ-OAR-2022-0985-1556-A1, page 3, for Figures 1 and 2.]

1. McCarthy, J. Jr., Zavala, B. and Matheaus, A., “Technology Levers for Meeting 2027 NOx and CO2 Regulations,” SAE 2023-01-0354, 4/20/2023

2. GHG benefits associated with improved ICE air handling

At the engine level, Eaton has developed and demonstrated technologies that reduce GHG such as Cylinder Deactivation (CDA) and variable Miller cycles, and pairing Exhaust Gas Recirculation (EGR) Pumps with High Efficiency Turbochargers that improve engine open cycle efficiency.

For example, CDA achieves 40% CO2 reductions at idle, and more importantly, 1% CO2 reductions on the 55 mph GHG cycle illustrated in Figure 3 and described in 2017 [2], with further improvements in the meantime. [EPA-HQ-OAR-2022-0985-1556-A1, p. 3.] [See Docket Number EPA-HQ-OAR-2022-0985-1556-A1, page 3, for Figure 3.]

2. McCarthy, J., Jr., "Cylinder Deactivation Improves Diesel Aftertreatment and Fuel Economy for Commercial Vehicles," 17th Stuttgart International Symposium, Vol. 2, pp. 175-202, 3/15/2017

In [3], significant CO2 savings are found on real world driving cycles due to cylinder deactivation: 6% reduced CO2 on the Low Load Cycle, 3% on Orange County Transit Authority cycle, 8% on the New York Bus Cycle and 5% on the Beverage cycle. Finally, CDA offers a 4% to 35% fuel / CO2 savings on the Port Drayage Cycle as shown in Figure 4 and described in [4]. [EPA-HQ-OAR-2022-0985-1556-A1, p. 3.] [See Docket Number EPA-HQ-OAR-2022-0985-1556-A1, page 4, for Figure 4.]

3. Reinhart, T., Matheaus, A., Sharp, C., Peters, B., Pieczko, M. and McCarthy, J. Jr., 'Vibration and emissions quantification over key drive cycles using cylinder deactivation.' Int. J. Powertrains, Vol. 9, No. 4, pp. 315–344, Nov. 16, 2020

4. Joshi, M., Gosala, D., Allen, C., Srinivasan, S., Ramesh, A., VanVoorhis, M., Taylor, A., Vos, K., Shaver, G., McCarthy, J. Jr., Farrell, L. and Koeberlein, E., "Diesel Engine Cylinder Deactivation for Improved System Performance over Transient Real-World Drive Cycles," SAE 2018-01-0880, 4/3/2018

The EPA proposes a 1.5 "intelligent controls" adjustment factor in GEM for engines that include full CDA during coasting where both exhaust and intake valves are closed, justifying it as similar in effect to neutral coasting estimated at 1.5% CO2 reduction. However, the full effect of CDA on CO2 is more significant, as this approach also prevents the cooling of the aftertreatment system through idle flow during coasting, thus avoiding additional fuel spent on thermal management after coasting, as illustrated in Figure 3. On the 55 mph cycle, this effect was measured as 1% incremental fuel or CO2 reduction. Given the significant benefits at low load illustrated in Figure 4, we believe a 2.5 GEM "Intelligent controls" adjustment factor is a conservative adjustment for CDA that includes all cylinders deactivated during coasting. [EPA-HQ-OAR-2022-0985-1556-A1, p. 4]

The ICE has seen improvements for the boosting and EGR systems for reducing CO2 that were not included in Phase 2 GHG assessments. Replacing the production turbocharger, normally designed to also flow EGR for today's engines, with a high efficiency turbocharger while using an EGR pump to flow EGR shows a 5% improvement in fuel economy and CO2 as shown in Figure 5. Significant GHG reductions were measured, up to 5.5% at A-speed, 6.2% at-B speed and 5.3% at C-speeds on the SET test. For the HD FTP, the combination of high efficiency turbocharger and EGR pump showed a 1.7% to 3.6% savings of CO2 [5]. These CO2 gains are additive to the gains from CDA. [EPA-HQ-OAR-2022-0985-1556-A1, p. 4.] [See Docket Number EPA-HQ-OAR-2022-0985-1556-A1, page 4, for Figure 5.]

5. Bitsis, D.C., Matheaus, A., Hopkins, J. and McCarthy, J. Jr., "Improving Brake Thermal Efficiency Using High Efficiency Turbo and EGR Pump While Meeting 2027 Emissions," SAE 2021-01-1154, 9/21/2021

Overall, the technologies developed and tested by Eaton improve ICE GHG emissions in the range of 3% – 7%. Our ICE partners have demonstrated the potential for an additional 3% improvement through their ICE technologies such as higher compression ratios, reduced thermal loss in the cylinder and reduced friction loss. For example, The Volvo Supertruck II showed that up to 1.4% BSFC improvement (i.e., 1.4% CO2 improvement) with optimum LIVC timing [6] on its path for a low CO2 powertrain. [EPA-HQ-OAR-2022-0985-1556-A1, p. 4]

6. McLaughlin, S., Bond, E. and Li, J., “Volvo SuperTruck 2 Pathway to Cost-Effective Commercialized Freight Efficiency,” DOE Annual Merit Review, 6/24/2021.

3. GHG benefits associated with micro- and mild-hybrids (48V systems)

Eaton has demonstrated micro- and mild-hybridization enabled by 48V technology, in the form of 48V energy recovery and management systems that achieve additional 5% – 8% GHG reductions at the vehicle level, by enabling engine-off while coasting (1.5% benefit), anti-idle and hoteling modes (up to 6% benefit for sleepers), and efficient electrical accessories (1.5% benefit), while recovering the energy for these systems from the vehicle dynamics (braking and coasting) [7]. It should be noted that 48V technology is also a key enabler for enhanced value-adding performance, such as electrical HVAC and/or automated and driver assist functions. These results corroborate well with the major US OEM’s demonstrations in the SuperTruck II program. [EPA-HQ-OAR-2022-0985-1556-A1, p. 5]

7. Hergart, C and Brown, M., “Development and Demonstration of Advanced Engine and Vehicle Technologies for Class 8 Heavy-Duty Vehicle (SuperTruck II),” DOE Annual Merit Review, 6/21/2018.

4. GHG benefits associated with hybridization

Eaton has recently demonstrated HD Hybrid technology (HEV) using 600 – 800V technology that improves GHG emissions by 9% on tractor certification cycles and 13%-19% on the vocational cycles, while enabling both anti-idle and hoteling function. The model predictions [8] were recently verified at Oak Ridge National Laboratory on TRL 4 hardware on the powertrain test cell, and TRL 5 was recently achieved in vehicle, with significantly improved performance (acceleration and grade-ability). A similar approach is deployed in the market in Europe by Scania since 2022. [EPA-HQ-OAR-2022-0985-1556-A1, p. 4]

8. Patil C., Thanom W., Dykes E., Kreucher J., Genise T., “Model-based Assessment of Fuel Economy and Performance of a Switchable P2/P3 Hybrid Powertrain for Heavy Truck”, In Proceedings of the Ground Vehicle Systems Engineering and Technology Symposium (GVSETS), NDIA, Novi, MI, Aug. 10-12, 2021.

HEV technology also improves productivity through both faster acceleration (40% reduction in time to road speed), 2x or better grade-ability improvement, and the ability to drive at controlled low speed. It also enables ultra-low NOx emissions (e.g., less than 10 mg NOx/ kWh) by eliminating the high emissions cold start conditions. With a battery pack in the range of 100 kWh, the plug-in hybrid (PHEV) version achieves as much as 25% – 50% GHG reduction. The increased productivity further lowers GHG emissions, though not measured on certification cycles. [EPA-HQ-OAR-2022-0985-1556-A1, p. 5]

HEV and PHEV technologies are particularly attractive for the Class 7 and Class 8 vehicles, in applications such as long-haul freight and performance vocational segments that are the hardest to decarbonize due to the massive energy requirements (750 kWh – 1,200 kWh daily energy needs) and where the lack of an ubiquitous MW-level charging or Hydrogen refueling infrastructure is a formidable barrier to operations. MD BEV applications are already achieving penetration in the market and that creates a supply chain and an infield support structure that can be readily leveraged by HD HEV and PHEV trucks. Such powertrains are in fact composed of

HD ICE mated with MD BEV electrical equipment (150 – 250 kW) and batteries (50- 150 kWh). [EPA-HQ-OAR-2022-0985-1556-A1, p. 5]

Figure 7 illustrates the significant CO2 reduction that are possible. An HEV powertrain in line haul can reduce CO2 by 15% while an urban vocational PHEV can reduce it by 52%. These reductions do not increase NOx, rather, Eaton has shown that it can further reduce NOx to less than 10 mg / hp-hr (vs the 35 mg standard). Improvements in the ICE with cylinder deactivation, EGR pumping etc are not included in this HEV analysis and would further improve CO2. Figure 7 also uses simplified powertrain cost estimates based on ACT Research recent modeling [9], with battery costs estimated at $200/kWh (at pack level, but also considering one battery per truck), and $40,000 BEV incentives quoted by the EPA analysis in the NPRM, prorated based on range for PHEV applications. This analysis shows that the significant GHG reductions (including hoteling and anti-idle credits) are also cost-effective, in some cases being cost neutral to the baseline Diesel ICE powertrain. In this example, the difference between PHEV and HEV is just the battery size (100 kWh vs 30 kWh). [EPA-HQ-OAR-2022-0985-1556-A1, pp. 5 - 6.] [See Docket Number EPA-HQ-OAR-2022-0985-1556-A1, page 6, for Figure 7.]

9. ACT Research Co, "Charging Forward 2024 – 2040 Decarbonization Forecast & Analysis", draft April 2023

Consider multiple pathways to achieve the proposed CO2 emissions level, including ICE improvements and technology packages not considered in Phase 2 and especially the reduction associated with low voltage (48V) and high voltage hybrids. There are multiple pathways for internal combustion-based powertrains to achieve 10-15% GHG reduction in long haul applications and 15-25% reduction in vocational applications, while HEV and PHEV technology enable 25 – 50% GHG reduction, all while still achieving stringent NOx levels for 2027 and beyond. Considering these pathways re-affirms the technology-neutral nature of the rule and allows the market and technology innovation to find the best solutions mix to achieve the proposed emissions goals, while creating and maximizing the economic benefit and reducing compliance cost. [EPA-HQ-OAR-2022-0985-1556-A1, p. 7]

Simplify the Phase 2 certification methodology for PHEV. HEV and PHEV technologies can play significant roles in reducing CO2 and are viable alternative paths for applications that are hard to fully electrify. For PHEV, the current methodology (described in Phase 2) relies on both a Powertrain test and a complex formula to determine the number of charge depleting and charge sustaining cycles per application. The Agency could simplify the latter procedure in the final rule or technical amendments, for example, by defining default utility factor curves for specific applications. [EPA-HQ-OAR-2022-0985-1556-A1, p. 7]

Organization: Howmet Wheel Systems

Comments on Aerodynamics

The Draft Regulatory Impact Analysis for Greenhouse Gas Emissions and Fuel Efficiency Standards for Heavy-Duty Vehicles – Phase 3 ('DRIA') cites "extensive description of aerodynamic improvements for Class 8 tractors" done in previous phases of the regulation. It also describes updated tractor aerodynamic designs from several manufacturers developed as part of the Department of Energy's SuperTruck program that demonstrate aerodynamics that are better than those used in existing MY 2027 standards' Heavy-Duty Greenhouse Gas – Phase 2 technology package for high roof sleeper cab tractors in MYs beyond 2027. 6 [EPA-HQ-OAR-2022-0985-1599-A1, p. 5]

6 “Draft Regulatory Impact Analysis: Greenhouse House Emissions Standards for Heavy-Duty Vehicles – Phase 3,” U.S. Environmental Protection Agency, https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P10178RN.pdf, April 2023.

Howmet agrees with EPA’s focus on aerodynamics, and we note that the state of technology and product offerings supports this focus. As noted previously, Alcoa® Wheels Aerodynamic Steer and Drive Cover Solutions provides an aerodynamic solution that minimizes drag and delivers significant fuel savings which enables commercial transportation customers to secure a combined savings of 1.35 gallons of fuel per 1,000 miles and can be applied at the factory. The drive system’s unique inspection window allows for a clear view of all wheel end components, enabling an operator to conduct safety checks without removing the wheel cover. [EPA-HQ-OAR-2022-0985-1599-A1, p. 5]

Howmet agrees with EPA’s assessment that there is an opportunity for further improvements and increased adoption of factory installed aerodynamic technologies through MY 2032 and believes that wheel covers should be considered as part of that overall aerodynamic design technology package. We further appreciate that the DRIA recognizes both the CO2 emission reduction benefits of improved aerodynamics as well as additional consideration that aerodynamics plays a role in extending the range of ZEV tractors. [EPA-HQ-OAR-2022-0985-1599-A1, p. 5]

Organization: International Council on Clean Transportation (ICCT)

ICE EFFICIENCY TECHNOLOGIES BEYOND THOSE REQUIRED UNDER THE PHASE 2 PROGRAM [EPA-HQ-OAR-2022-0985-1553-A1, p. 16]

ADDITIONAL ICE TECH PACKAGES CAN DELIVER PAYBACK WITHIN TWO YEARS This section is ICCT’s response to EPA’s request for comment on whether to include additional GHG-reducing technologies and/or higher levels of adoption rates of existing technologies in the proposed Phase 2 GHG standards. For the purposes of setting the stringency of the rule, EPA does not assume the adoption of new technologies to improve the efficiency of internal combustion engine (ICE) vehicles beyond those already being deployed to meet the Phase 2 standards. In our view, the proposal can deliver greater benefits with minimal cost by revising the stringency of the proposed standards to reflect the deployment of additional commercially available and cost-efficient technologies like those considered in the Phase 2 standard that manufacturers have not found necessary to deploy. The ICCT conservatively estimates that incorporating such additional technologies in the stringency of its rule – not including engine technology improvements – would generate an additional 537 million tonnes of cumulative CO2 emissions avoided between 2020 and 2050. [EPA-HQ-OAR-2022-0985-1553-A1, p. 16]

Several technologies are available to improve ICE vehicle efficiency beyond what is required to meet existing Phase 2 greenhouse gas standards. In recently published research, ICCT identified significant efficiency improvement potential from a list of technologies with a two-year payback period across tractor and vocational regulatory categories (Buysse et al., 2021; Ragon, Buysse, et al., 2023). EPA considered some of these technologies in its Phase 2 rulemaking, but only a few were incorporated into the stringency of the Phase 2 rule. These technologies are available to further increase ICE vehicle efficiency and should be reflected in the stringency of the Phase 3 final standards. [EPA-HQ-OAR-2022-0985-1553-A1, p. 16]

Buysse, C., Sharpe, B., & Delgado, O. (2021). Efficiency technology potential for heavy-duty diesel vehicles in the United States through 2035. International Council on Clean Transportation. https://theicct.org/publication/efficiency-technology-potential-for-heavy-duty-diesel-vehicles-inthe-united-states-through-2035/

Ragon, P.-L., Buysse, C., Sen, A., Meyer, M., Benoit, J., Miller, J., & Rodríguez, F. (2023). Potential benefits of the U.S. Phase 3 Greenhouse Gas Emissions Regulation for Heavy-Duty Vehicles. International Council on Clean Transportation. https://theicct.org/publication/hdv-phase3-ghg-standards-benefits-apr23/

Our research suggests a potential improvement in ICE vehicle efficiency of up to 23% in the highroof sleeper cab vehicle category, reflecting both engine and non-engine improvements. Table 2 shows the efficiency improvement potential of each identified technology. [Refer to Table 2, Two-Year Payback ICE Vehicle Technology Potential Sleeper Cab, on p. 17 of docket number EPA-HQ-OAR-2022-0985-1553-A1] The largest contributions are from engine improvements, followed by aerodynamics, tires, and predictive cruise control. Without engine improvements (e.g., hybridization, alternative fuel injection systems, etc.), a smaller efficiency improvement up to 13% can still be realized. These percentages assume no contribution from trailer technologies such as trailer tires, aerodynamics, or weight reduction. [EPA-HQ-OAR-2022-0985-1553-A1, p. 16]

Our research also suggests a potential ICE vehicle efficiency improvement of up to 31% exists for a diesel-fueled Class 6 multi-purpose vocational vehicle. Table 3 shows the efficiency improvement potential of each technology. [Refer to Table 3, Two-Year Payback ICE Vehicle Technology Potential Class 6-7, on p. 17 of docket number EPA-HQ-OAR-2022-0985-1553-A1] The largest contributions are from engine improvements, followed by stop-start, weight reduction, and tires. Without improving engine technology, efficiency improvements of up to 20% can still be realized. [EPA-HQ-OAR-2022-0985-1553-A1, p. 17]

We identified meaningful efficiency packages across a range of vehicle types. Across tractor regulatory categories, we identified 11%–13% in unrealized efficiency improvements, as well as 6% for heavyhaul tractors. Across vocational vehicle categories, we identified 15%–20% in unrealized efficiency improvements. Original equipment manufacturers (OEMs) like Navistar and Volvo Trucks currently offer ICE products with technology options similar to the ones listed (Advances In International® LT® Series And RHTM Series Drive Improved Fuel Efficiency And Uptime, 2019; Volvo Trucks Makes Latest-Generation D13 Turbo Compound Engine Standard in All VNL 740, 760 and 860 Models, 2020). The benefits of the rule would be greater by encouraging the industry-wide adoption of these technologies. [EPA-HQ-OAR-2022-0985-1553-A1, p. 17]

EPA uses projected ZEV adoption as the sole determinant when setting the MY 2028 – MY 2032 GHG standards and neglected cost-effective ICE vehicle technology efficiency improvements. EPA can revise the stringency of its standards to reflect industry-wide ICE vehicle efficiency improvements that are additional to ZEV adoption alone. This would enable unrealized ICE efficiency improvements to be incorporated into the final stringency, while retaining OEMs' flexibility in achieving compliance. Table 4 gives suggested stringency levels based on ICE vehicle efficiency improvements for EPA to consider [Refer to Table 4, ICE Technology Potential for HD Vehicles, on p. 18 of docket number EPA-HQ-OAR-2022-0985-1553-A1.] These efficiency potential projections are described in more detail in Ragon et al. (2023). The use of these technology improvements can only strengthen the EPA proposal if they are treated as additional technologies – not complementary technologies – to the deployment of zero-emission vehicles. We encourage EPA to treat them as such in order to maximize the cost-effective reduction of greenhouse gas emissions achieved from the rule. [EPA-HQ-OAR-2022-0985-1553-A1, pp. 17-18]

Ragon, P.-L., Buysse, C., Sen, A., Meyer, M., Benoit, J., Miller, J., & Rodríguez, F. (2023). Potential benefits of the U.S. Phase 3 Greenhouse Gas Emissions Regulation for Heavy-Duty Vehicles. International Council on Clean Transportation. https://theicct.org/publication/hdv-phase3-ghg-standards-benefits-apr23/

Beyond the technology improvements outlined in Table 2 and Table 3, OEMs are demonstrating additional technology packages to improve ICE efficiency in vehicle prototypes. The U.S. Department of Energy's SuperTruck Program acts as a testbed for innovative technology packages to improve the freight efficiency of tractor trailers. Launched in 2010, the first phase of the program aimed to develop and demonstrate long-haul tractor trucks that achieve 50% improvement in overall freight efficiency. By 2016, all SuperTruck I participant OEMs reported efficiency improvements ranging from 80% to 116%. (Adoption of New Fuel Efficient Technologies from SuperTruck, 2016). Through the program, the OEMs developed and validated technologies like improved aerodynamics, low rolling resistance tires, and engine downsizing, and deployed them in their commercial products (Park, 2022). [EPA-HQ-OAR-2022-0985-1553-A1, p. 18]

Park, J. (2022, January 24). Is SuperTruck Worth the Money? Truckinginfo. https://www.truckinginfo.com/10160190/is-supertruck-worth-the-money

All the major tractor-trailer OEMs (Peterbilt/Cummins, Daimler, Navistar, Paccar, and Volvo) are participating in the second phase of the program, SuperTruck II (Bashir, 2022; Bond & Li, 2022; Dickson & Mielke, 2022; Meijer, 2022; Zukouski, 2022). The second phase doubles the vehicle freight efficiency improvement target to 100% compared with a 2009 baseline and emphasizes cost-effective technologies. All participating OEMs are reporting the development of final trucks that exceed 125% of efficiency improvements, and their designs incorporate 48V mild hybrid, electrification of auxiliary systems, improved aerodynamics, and enhanced waste heat recovery. Organization: Manufacturers of Emission Controls Association (MECA)

Component suppliers have continued to innovate, and many technologies that were not even considered as compliance options in the Phase 2 rule are now likely to be deployed on limited engine families in 2024 and more broadly in 2027. Furthermore, engine efficiency technologies – such as cylinder deactivation, advanced driven turbochargers, and hybridization – have also been demonstrated in combination with advanced aftertreatment technologies on heavy-duty diesel engines. Testing has shown the ability of these engine technologies to be optimized to reduce both GHG and criteria pollutant emissions including NOx. [EPA-HQ-OAR-2022-0985-1521-A1, p. 4]

Cylinder Deactivation

Cylinder deactivation (CDA) is an established technology on light-duty vehicles, with the primary objective of reducing fuel consumption and CO2 emissions. This technology combines hardware and software computing power to, in effect, "shut down" some of an engine's cylinders, based on the power demand, and keep the effective cylinder load in the more efficient portions of the engine map reducing fuel consumption. Based on decades of experience with CDA on passenger cars and trucks, CDA is now being adapted to heavy-duty diesel engines. On a diesel engine, CDA is programmed to operate differently than on gasoline engines, with the goal of the diesel engine running hotter in low load situations by having the pistons that are firing do more work. This programming is particularly important for vehicles that spend a lot of time in creep and idle operation modes. During low load operation, the use of CDA results in exhaust temperatures increasing by 50°C to 100°C to maintain effective conversion of NOx in the SCR [1]. In some demonstrations, CDA has been combined with a 48V mild hybrid motor with launch and sailing capability to extend the range of CDA operation over the engine, and this may deliver multiplicative CO2 reductions from these synergistic technologies [2,3]. In another study, CDA combined with an electric heater or fuel burner has been shown to reduce NOx as well as CO2 to levels below the capabilities of each technology individually [4]. CDA has also been synergistically combined with high efficiency turbochargers, and an electrically driven

EGR pump to yield an additional 1.7 to 3.6% reduction in CO_2 [5]. [EPA-HQ-OAR-2022-0985-1521-A1, p. 4]

We support the provision in the proposed rule of a 1.5% GEM credit for engines that include full CDA during coasting where both exhaust and intake valves are closed. As presented above, CDA and other advanced engine and powertrain technologies are still developing and often in combination to synergistically yield higher values of CO_2 reduction. As a result, EPA should allow manufacturers to request variable GEM credit values for CDA and for other engine and powertrain technologies based upon the submission of performance data. [EPA-HQ-OAR-2022-0985-1521-A1, p. 5]

Advanced Turbochargers

Advances in turbochargers are providing a variety of available design options enabling lower CO_2 emissions by improving thermal management capability, such as: i) state of the art aerodynamics, ii) electrically actuated wastegates that allow exhaust gases to by-pass the turbocharger to increase the temperature in the aftertreatment, and iii) advanced ball bearings to improve transient boost response. More advanced turbochargers are designed with a variable nozzle that adjusts with exhaust flow to provide more control of intake pressure and optimization of the air-to-fuel ratio for improved performance (e.g., improved torque at lower speeds) and fuel economy. These variable geometry turbochargers (VGT), also known as variable nozzle turbines (VNT) and variable turbine geometry (VTG), also enable lower CO_2 emissions through improved thermal management capability to enhance aftertreatment light-off. Finally, modern turbochargers have enabled engine and vehicle manufacturers the ability to downsize engines, resulting in fuel savings without sacrificing power and/or performance. [EPA-HQ-OAR-2022-0985-1521-A1, p. 5]

The latest high-efficiency turbochargers are one of the more effective tools demonstrated in the DOE SuperTruck program [6]. In addition to affecting the power density of the engine, turbochargers play a significant role in NOx and CO_2 regulations compliance. Continuous improvement in turbocharger technology is making it possible to run very lean combustion (high air/fuel ratios), which reduces CO_2, particulate and engine-out NOx. [EPA-HQ-OAR-2022-0985-1521-A1, p. 5]

[6]. Navistar, "Final Scientific/Technical Report for SuperTruck Project: Development and Demonstration of a Fuel-Efficient, Class 8 Tractor & Trailer Engine System," 2016.

Turbo-compounding

Turbo-compounding is a variant of turbocharger technology that allows for the energy from the exhaust gas to be extracted and mechanically added to the engine crankshaft. Alternatively, waste exhaust energy can also be extracted by using an electric turbine to recover the waste exhaust energy electrically (see Driven Turbochargers) and used to increase primary turbocharger response and efficiency or to power other electric vehicle systems. [EPA-HQ-OAR-2022-0985-1521-A1, p. 5]

Mechanical turbo-compounding has been employed on some commercial diesel engines, and EPA estimated penetration to reach 10% in the U.S. by the time the Phase 2 GHG Regulation is fully implemented in 2027 [7]. An early 2014 version of a turbo-compound-equipped engine was used during the first stage of testing at SwRI under the CARB HD Low NOx Test Program, and the results from this engine with advanced aftertreatment have been summarized in several SAE technical papers [8, 9, 10]. While turbo-compounding has the potential to reduce fuel consumption, it can result in lower exhaust temperatures that can challenge aftertreatment performance. Therefore, it is important to consider turbo-compound designs that incorporate bypass systems during cold start and low load operation or electrically driven turbo-compounding systems where the unit can be placed after the aftertreatment system. Henry, "Achieving Ultra Low NOx Emissions Levels with a 2017 Heavy-Duty On-Highway TC Diesel Engine - Comparison of Advanced Technology Approaches", SAE Technical Paper 2017-01-0956, https://doi.org/10.4271/2017-01-0956, SAE International Journal of Engines, vol. 10, no. 4, pp. 1722-1735, 2017.

Driven turbochargers

Driven turbochargers can be used to control the speed of the turbomachinery independently of the engine's exhaust flow and vary the relative ratio between engine speed and turbo speed. Driven turbochargers may be utilized for several reasons, including performance, efficiency, and emissions. Considered an 'on-demand' air device, a driven turbocharger also receives transient power from its turbine. During transient operation, a driven turbocharger will behave like a supercharger and consume mechanical or electrical energy to accelerate the turbomachinery for improved engine response. At high-speed operation, the driven turbocharger will return mechanical or electrical power to the engine in the form of turbo-compounding, which recovers excess exhaust power to improve efficiency [11]. This cumulative effect lets a driven turbocharger perform all the functions of a supercharger, turbocharger, and turbo-compounder. [EPA-HQ-OAR-2022-0985-1521-A1, p. 6]

[11]. Suelter, B., Itou, T., Waldron, T., and Brin, J., "Optimizing Steady State Diesel Efficiency and Emissions Using a SuperTurboTM on an Isuzu 7.8L Engine," SAE Technical Paper 2019-01-0318, 2019, https://doi.org/10.4271/2019-01-0318.

NOx emission control uniquely benefits from the application of driven turbochargers in several ways, including the ability to decouple EGR from boost pressure, reduce transient engine-out NOx, and improve aftertreatment temperatures during cold start and low load operation. [EPA-HQ-OAR-2022-0985-1521-A1, p. 6]

Bypassing a driven turbine can provide quick temperature rises for the aftertreatment while still delivering the necessary boost pressure to the engine through supercharging, which also increases the gross load on the engine to help increase exhaust temperature [11]. Testing has shown that routing engine exhaust to the aftertreatment by bypassing a turbocharger is one of the most effective methods to heat up the aftertreatment [2]. [EPA-HQ-OAR-2022-0985-1521-A1, p. 6]

Electrification: Mild Hybridization

In the near future, 48-volt mild hybrid electrical systems and components are expected to make their way onto medium and heavy-duty vehicles. These 48-volt systems can be found on many light- duty vehicle models (primarily in Europe) from Mercedes, Audi, VW, Renault and PSA. In the U.S., FCA is offering a 48-volt system on the RAM 1500 pick-up and the Jeep Wrangler under the eTorque trademark. Because the safe voltage threshold is 60 volts, which is especially important when technicians perform maintenance on the electrical system, 48-volt systems are advantageous from an implementation standpoint. From a cost perspective, 48-volt systems include smaller starter and wire gauge requirements, offering cost savings from a high voltage architecture of a full hybrid. The U.S. Department of Energy's SuperTruck II program teams employed 48-volt technologies on their vehicles to demonstrate trucks with greater than 55% brake thermal efficiency. A recent study demonstrated through model-based simulations that a 48-volt technology package combined with advanced aftertreatment can achieve a composite FTP emission level of 0.015 g/bhp-hr [3]. [EPA-HQ-OAR-2022-0985-1521-A1, p. 6]

[3]. Dhanraj, F., Dahodwala, M., Joshi, S., Koehler, E. et al., "Evaluation of 48V Technologies to Meet Future CO2 and Low NOx Emission Regulations for Medium Heavy-Duty Diesel Engines," SAE Technical Paper 2022-01-0555, 2022, https://doi.org/10.4271/2022-01-0555.

Similar to the passenger car fleet, truck OEMs are considering replacing traditional mechanically driven components with equivalent or improved electric versions to gain efficiency. Converting electrical accessories from 12-volts to 48-volts reduces electrical losses and this is particularly advantageous for components that draw more power, such as pumps and fans. The types of components that may be electrified include electric turbos, electronic EGR pumps, AC compressors, electrically heated catalysts, electric cooling fans, oil pumps and coolant pumps, among others. Another technology that 48-volt systems could enable is electric power take-offs rather than using an engine powered auxiliary power unit or idling the main engine during hoteling while drivers rest. MECA members supplying commercial 48V components for commercial vehicles believe that the technology may be feasible to apply to a limited number of engine families by 2024, and it is likely to see greater penetration by 2027, especially on Class 8 line-haul where full hybridization is less practical. [EPA-HQ-OAR-2022-0985-1521-A1, pp. 6 - 7]

Mild hybridization covers a range of configurations, but a promising one includes an electric motor/generator, regenerative braking, electric boost and advanced batteries. Stop/start deployment also provides a thermal management benefit to the aftertreatment by preventing cooling airflow through the aftertreatment during hot idle conditions. In this way, 48-volt mild hybridization is complementary technology to CDA and start-stop capability, allowing the combination of multiple technologies on a vehicle to yield synergistic benefits to reduce CO2 by an additional 5-8% at the vehicle level by enabling engine-off while coasting (1.5% benefit), anti-idle and hoteling modes (up to 6% benefit for sleepers), and efficient electrical accessories (1.5% benefit), while recovering the energy for these systems from the vehicle dynamics (braking and coasting) [12, 13]. By shutting off the engine at idle or motoring using start/stop, micro hybrid technology can help to reduce CO2 while maintaining aftertreatment temperature by avoiding the pumping of cold air through the exhaust. Capturing braking energy and storing it in a small battery for running auxiliary components when the engine is off offers another CO2 reducing strategy for OEMs to deploy. [EPA-HQ-OAR-2022-0985-1521-A1, p. 7]

[12]. M. Dorobantu, "Affordable Simultaneous Emissions and Efficiency Improvements from an Integrated Powertrain Systems Perspective", 2019 SAE Government and Industry Conference.

[13]. Hergart, C and Brown, M., "Development and Demonstration of Advanced Engine and Vehicle Technologies for Class 8 Heavy-Duty Vehicle (SuperTruck II)," DOE Annual Merit Review, 6/21/2018.

In lighter medium-duty applications, advanced start-stop systems have been developed that use an induction motor in a 48-volt belt-driven starter-generator (BSG). When the engine is running, the motor, acting as a generator, will charge a separate battery. When the engine needs to be started, the motor then applies its torque via the accessory belt and cranks the engine instead of using the starter motor. The separate battery can also be recharged via a regenerative braking system. In addition to the start-stop function, a BSG system can enhance fuel economy even during highway driving by cutting off the fuel supply when cruising or decelerating. Such systems can also be designed to deliver a short power boost to the drivetrain. This boost is typically 10 to 20 kW and is limited by the capacity of the 48V battery and accessory belt linking the motor to the crankshaft. New designs are linking the BSG directly to the crankshaft and allowing additional power boost of up to 30kW to be delivered, giving greater benefits to light and medium commercial vehicles [2]. [EPA-HQ-OAR-2022-0985-1521-A1, p. 7]

[2]. MECA, "Technology Feasibility for Heavy-Duty Diesel Trucks in Achieving 90% Lower NOx Standards in 2027," 2020. Online at https://www.meca.org/wp-content/uploads/resources/MECA_2027_Low_NOx_White_Paper_FINAL.pdf.

Electrification: Full hybridization and electric vehicles

Full hybrid configurations are currently found on a growing number of models of light-duty passenger cars and light trucks in the U.S. and a limited number of medium-duty trucks and urban buses. These include models that can also be plugged-in (PHEVs) to enable electric operation for a determined "all- electric" range (AER). A full hybrid (HEV) can enable enhanced electrification of many of the components described above for mild hybrid vehicles as the higher voltages allow for more parts to be electrified and to a larger degree. Full hybrids also employ larger electric motors and batteries, which support greater acceleration capability and regenerative braking power. Full hybrid and plug-in hybrid vehicles have made the highest penetration into vocational applications such as parcel delivery, beverage delivery and food distribution vehicles because they can take advantage of regenerative braking in urban driving [14] and operate from a central location. Model predictions of HD HEV 600-800V technology recently verified at Oak Ridge National Laboratory [15] have shown that GHG emissions reductions of 9% on tractor certification cycles and 13%-19% on the vocational cycles, while enabling both anti-idle and hoteling function. [EPA-HQ-OAR-2022-0985-1521-A1, pp. 7 - 8]

[14]. CARB, "Draft Technology Assessment: Heavy-Duty Hybrid Vehicles," 2015.

[15]. Patil C., Thanom W., Dykes E., Kreucher J., Genise T., "Model-based Assessment of Fuel Economy and Performance of a Switchable P2/P3 Hybrid Powertrain for Heavy Truck", In Proceedings of the Ground Vehicle Systems Engineering and Technology Symposium (GVSETS), NDIA, Novi, MI, Aug. 10-12, 2021.

We expect to see the increasing application of strong / parallel and serial hybrids combined with a low NOx engine to reduce CO2 emissions in several vocational applications. Integrated electric drivetrain systems, consisting of a fully qualified transmission, motor and power electronics controller, are now commercially available. With power levels of over 160kW and the ability to meet high torque requirements, these systems enable electrification of medium-duty commercial vehicles. There is also an increasing number of electric drivetrain solutions up to and over 300kW that are suitable for Class 8 vehicles that can be used with either hybrid [16], battery or fuel cell power sources [2]. Organization: MEMA

MEMA and its members support the objectives of the agency to improve national air quality through improvements to heavy duty trucks. The supplier industry directly manufactures vehicle components and systems that enable the transformation of the transportation sector to more environmentally friendly vehicles. The industry also supports advancements in internal combustion engine technologies, needed to serve the vocational and long-haul sectors where zero-tailpipe emission vehicles are not yet feasible due to weight, load, and infrastructure limitations. [EPA-HQ-OAR-2022-0985-1570-A1, p. 1]

Lightweighting Will Continue to be Important and Should be Encouraged. Lightweighting is an important part of the overall strategy for improving vehicle emissions performance. The use of lighter weight materials (high strength steel, aluminum, plastics, polymer composites, carbon fiber, magnesium, etc.) and designs - otherwise known as mass reduction or lightweighting - continues to be an important cost-effective strategy in meeting emissions reduction standards. Lightweighting is well-recognized to increase trucking efficiency and there are three primary ways that this occurs:

- By lowering rolling resistance, less energy is needed to start the vehicle moving and then overcome the friction of its contact with the road.
- By allowing carriers to add more cargo to each truck, which reduces the number of trucks on the road and/or trips that need to be made.
- By facilitating the adoption of other efficiency and emissions reductions technologies higher payloads through utilization of heavier components for battery, fuel cell, and efficient engines as well as other emissions reductions, improvements are possible, and can negate the concerns about the added weight of those technologies.

Furthermore, lightweighting also includes the unsprung mass of suspension and brake components as well as, but not limited to, wheels. The North American Council for Freight Efficiency's Confidence Report on Lightweighting noted that the aluminum wheel is the, "...single most effective product for saving weight on both a tractor and trailer." [EPA-HQ-OAR-2022-0985-1570-A1, p. 13]

11 North American Council for Freight Efficiency, 'Confidence Report on Lightweighting,' January 10, 2021 https://nacfe.org/wp-content/uploads/2021/02/Lightweighting-Confidence-Report-Feb2021.pdf

We commend EPA for continuing to recognize the contributions of wheel-related weight reductions and non-wheel-related weight reductions to the agency's overall emissions reductions goals. This is reflected in Table 6 to ci 1037.520 and Table 8 to ci 1037.520 of the proposed rule which provide specific vehicle weight reduction credit inputs. The NPRM relies on prior assumptions around lightweighting that were part of the Regulatory Impact Analysis for Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles - Phase 2 as the weight reduction credits for Phase 2 appear to have been extended to Phase 3. [EPA-HQ-OAR-2022-0985-1570-A1, p. 13]

EPA should recognize that suppliers have introduced new technologies and products since the Phase II rule was finalized in 2016 and seek comments from suppliers to update the agency's assumptions around weight reduction inputs to reflect the latest available technologies on the marketplace. For example, lightweight forged aluminum wheel producers have continuously improved their product offerings to the heavy-duty truck, bus, and trailer markets. More recent generations of products - introduced to the market since the Phase 2 was promulgated - offer weight savings of nearly 10% as compared to similar steer or dual-drive, and wide base wheels which were part of the analysis EPA previously conducted. [EPA-HQ-OAR-2022-0985-1570-A1, p. 13]

Recommendation: EPA should continue to grant credit for lightweighting and weight reduction and update GHG Ph2 assumptions on lightweighting in the GHG Ph3 GEM model. [EPA-HQ-OAR-2022-0985-1570-A1, p. 13]

Organization: Moving Forward Network (MFN) et al.

7.3.1. Assessing the impact of CNGVs

There is no clean or safe natural gas fuel source. Natural gas based options are false solutions, with upstream and downstream pollution impacts for frontline and fenceline communities from production, distribution, etc., and the ensuing infrastructure required for the fuel. To assess the harms from these vehicles, we rely upon data from EPA's heavy-duty in-use test program and required emissions tests. For fuel efficiency, we assume that these vehicles are just as energy-efficient as their diesel-fueled alternatives. This is an optimistic assessment, as EPA notes that CNGVs can be expected to be 5-15 percent less efficient (81 FR 73925), but differences in required emissions control to meet newly finalized federal standards could reduce this efficiency gap in the future. [EPA-HQ-OAR-2022-0985-1608-A1, p. 47]

To assess the impacts of NGVs, we utilize the default values in GREET to assess the upstream emissions associated with the production and distribution of methane. EPA's HDIUT shows that CNGVs today emit lower levels of NOX but significantly higher levels of VOCs than modern diesel trucks. There are also modest increases in PM2.5 emissions since CNGVs can meet current particulate matter standards without the need for particulate filters found on modern diesel vehicles. We anticipate little improvement to current CNGVs to meet future NOX standards; therefore, we assumed that emissions would be the lesser of current values or the future in-use requirements for NOX, PM2.5, and VOC. [EPA-HQ-OAR-2022-0985-1608-A1, p. 47]

We also used data from the HDIUT program to correct for the direct emissions of greenhouse gases—while EPA intended for CNGVs to reduce excess methane emissions beginning with the Phase 1 program, manufacturers have instead been taking advantage of the credit program to offset these additional methane reductions with CO2 credits (81 FR 73925). We assume this trend will continue and use hydrocarbon speciation data to assign a relationship between direct VOC and CH4 emissions, 104 converting CH4 into CO2-equivalent greenhouse gas emissions consistent with the global warming potentials used in GREET. [EPA-HQ-OAR-2022-0985-1608-A1, p. 47-48]

104 Section 3.6 in EPA. Speciation of total organic gas and particulate matter emissions from onroad vehicles in MOVES3. EPA-420-R-22-017. (2022). https://www.epa.gov/system/files/documents/2022-07/420r22017.pdf.

9.1.1. Compression-ignition engine technologies (diesel)

EPA appropriately identifies manufacturers' plans to deploy new engines in order to meet the 2027 NOX standards finalized last year. 88 Fed. Reg. at 25958. However, in its analysis, the Agency inappropriately freezes the progress of diesel engines at the bare minimum requirements on the books today, with no improvement required beyond the 2027 Phase 2 diesel engine standards and no assumed improvement in any truck technology beyond 2027 Phase 2 ICE vehicle requirements. This is inconsistent with both the literature and the Agency's own analysis of what is possible in the 2027-2032 time period. [EPA-HQ-OAR-2022-0985-1608-A1, p. 65]

In its Phase 2 regulation, EPA identified multiple pathways and approaches to achieving the Phase 2 diesel engine regulations (Phase 2 FRIA 2.7.10 and 2.7.11). In assessing what is achievable, the Agency relied significantly upon manufacturer-submitted data from the

SuperTruck research program in partnership with the Department of Energy (Phase 2 FRIA 2.7.5). However, the second phase of the SuperTruck program has far exceeded the level of efficiency deployed in the data EPA relied upon, particularly for engines: the Navistar and Cummins/Peterbilt teams were able to demonstrate 55 percent brake-thermal efficiency (BTE), compared to the 50 percent target for the first phase, while Daimler, Volvo, and PACCAR all demonstrated over 50 percent BTE, with a clear pathway towards the 55 percent target. 116 The PACCAR team's progress is particularly illuminating, as they undertook an additional challenge to meet "ultra low NO X " targets consistent with EPA's recent regulation as part of their overall efficiency effort, indicating that these levels of thermal efficiency are not incompatible with achieving the 2027 standards. [EPA-HQ-OAR-2022-0985-1608-A1, p. 65]

Eaton partnered with the PACCAR team in the development of its SuperTruck II truck, and they have demonstrated that it is possible to outperform simultaneously the 2027 NOX standards and the Phase 2 CO2 standards through a number of different aftertreatment and powertrain combinations. 117 A recent research paper by Eaton demonstrates various combinations of control technologies manufacturers can tune CO2 and NOX emissions over different regulatory cycles to develop a technology package that is suitable for compliance, including packages that can achieve CO2 reductions beyond Phase 2 while meeting EPA's future 2027 standards. 118 [EPA-HQ-OAR-2022-0985-1608-A1, p. 66]

117 Dorobantu, M. Eaton considerations on MD/HD GHG Phase 3. Presentation, OIRA-Eaton meeting, March 23. (2023). https://www.reginfo.gov/public/do/eoDownloadDocument?pubId=&eodoc=true&documentID=215442

118 McCarthy, J., et al. Technology levers for meeting 2027 NOX and CO2 regulations. SAE Technical Paper 2023-01-0354. (2023). https://doi.org/10.4271/2023-01-0354.

One of the strategies deployed by Eaton is a 48V electric heater, which could be deployed easily with a 48V mild hybrid powertrain, again illustrating the complementary technology packages available to manufacturers. The 48V mild hybrid powertrain can not just power accessories, including those related to emissions control, but it can also help reduce engine-out NOX. This was also demonstrated through testing by FEV as a strategy particularly relevant to

MHDVs, whose engines are required to meet tighter NOX standards than those of HHDVs. 119 [EPA-HQ-OAR-2022-0985-1608-A1, p. 66]

119 Fnu, D., et al. Application of 48V mild-hybrid technology for meeting GHG and low NOX regulation for MHD vehicles. SAE Technical Paper 2023-01-0484. (2023). https://doi.org/10.4271/2023-01-0484.

9.1.2. Spark-ignition technologies (gasoline)

A significant opportunity for increased improvement lies in spark-ignition (SI) engines, for which Phase 2 required no engine improvements beyond the 2016 SI engine standard. The weakness in EPA's Phase 2 targets for SI engines and vehicles is apparent in looking at the compliance credits to-date, particularly for Ford Motor Company, the largest SI engine supplier. Ford has run a credit surplus in every year of the vocational engine program, but this surplus exploded in MY2020 with the release of its latest 7.3L V8 engine, codenamed "Godzilla." 120 Even though the engine platform is relatively low-tech (naturally aspirated, pushrod V8), utilizing variable cam timing and a variable-displacement oil pump, it's a significant improvement in efficiency. The engine was also designed with fuel economy at load in mind for applications like towing. A smaller engine built on the same platform replaced the older base engine in 2023, no doubt increasing Ford's over compliance. [EPA-HQ-OAR-2022-0985-1608-A1, p. 66]

120 EPA. Final Phase 1 EPA Heavy-Duty Vehicle and Engine Greenhouse Gas Emissions Compliance Report (Model Years 2014-2020). (2022). Appendix B: Individual Manufacturer Detailed Credit Summaries. https://nepis.epa.gov/Exe/ZyPDF.cgi/P1016962.PDF?Dockey=P1016962.pdf.

General Motors is not standing still, either—their fifth-generation small-block V8 platform is getting a next-generation update to a 5 percent improvement over the current generation, 121 and the current generation is already a credit generator for its heavy-duty vehicles under the Phase 2 program. 122 No further details are available about the heir to the current iron-block direct-injection L8T variant found in its heavy-duty offerings, but again this underscores the significant amount of fuel efficiency still available from heavy-duty gasoline engines. [EPA-HQ-OAR-2022-0985-1608-A1, pp. 66 - 67]

122 U.S. EPA. Final Rule for Phase 2 Greenhouse Gas Emissions Standards and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles. (2022). https://www.epa.gov/regulations-emissions-vehicles-and-engines/final-rule-phase-2-greenhouse-gas-emissions-standards

9.1.4. Non-powertrain technologies

In the Phase 2 regulation, EPA identified numerous improvements to every class of heavy-duty vehicle which could be applied in the timeframe of the rule (through 2029), including non-engine technologies to reduce road load regardless of the propulsion source. Most of these technologies were not exhausted in setting the standards. Given the longer timeframe of this rule (through 2032) and the steady increase from 2021-2029 for which EPA applied these technologies, EPA should naturally have continued to assume a steady increase in such technology adoption over the course of the Phase 3 rule, particularly since they are largely powertrain agnostic and thus affected neither by the 2027 NOX rule nor a transition to electric trucks. [EPA-HQ-OAR-2022-0985-1608-A1, p. 68]

As EPA identified in Phase 2, many of these are evolutionary technologies that have gradually improved over time: aerodynamics, rolling resistance, weight reduction, accessory load reduction, etc. There are also technologies which have seen a gradual increase in market share that is likely to continue, such as 6x2 axles and neutral idling. [EPA-HQ-OAR-2022-0985-1608-A1, p. 68]

Below, we've summarized a simple extrapolation of EPA's Phase 2 GEM analysis, wherein we assume no changes to the 2027 engine or transmission but have simply extrapolated the continuous evolution of improvements to vehicles from 2021-2029, through 2032, for each regulatory class at the pace EPA adopted in finalizing the Phase 2 regulation, and run these technology deployment scenarios through EPA's GEM Compliance model. As can be seen by Tables 4 and 5, even without the improvements identified above or any wholesale shifts in the market, ICE-powered trucks would be expected to improve by up to 8.4 percent by 2032 just by continuing the same pace of improvement from Phase 2 with already-identified technologies. This is the barest of minimal level of improvement EPA should assume ICEVs are capable of in Phase 3 because it doesn't reflect synergies with improvements identified above for gasoline and diesel-powered vehicles that would be deployed to achieve 2027 NOX standards such as 48V hybridization and cylinder deactivation. [EPA-HQ-OAR-2022-0985-1608-A1, p. 68]

Any improvement in ICEVs not considered by EPA in setting its standards is a one-to-one decrease in the market share of ZEVs needed for compliance. If manufacturers continue at the pace set by the Phase 2 program, with no additional changes to reflect the increase in available technology, EPA's Phase 3 proposal would yield at least 7 percent fewer electric trucks in the regulatory timeframe (27.0 percent compared to 29.2 percent for 2027-2032). Since these technologies were already identified by EPA in setting the Phase 2 standards, they are all available at scale by 2027—if manufacturers instead accelerated the pace to the 2032 levels identified, this alone would lead to a 16.9 percent reduction in electric trucks required (24.3 percent compared to 29.2 percent for 2027-2032). For comparison, EPA's weaker alternative is based on a 21.3 percent reduction (23.0 percent compared to 29.2 percent for 2027-2032). Thus, just by ignoring its own Phase 2 analysis, EPA's rule could lead to electric truck deployment comparable to the proposed weaker alternative. 127 [EPA-HQ-OAR-2022-0985-1608-A1, p. 68.] [See Table 4, Phase 2-based Tractor-Trailer Improvement and Table 5, Phase 2-based Tractor-Trailer Improvement located on p. 69 of docket number EPA-HQ-OAR-2022-0985-1608-A1.]

127 It is crucial to emphasize that this exercise ignores other aspects of EPA's rule which will also lead to a reduced share of electric trucks, including the current, inappropriate treatment of H 2 ICEVs as 0 g/ton-mile vehicles.

Organization: Odyne Systems LLC

Ensure that PHEV systems can be easily qualified to provide credits if they significantly improve driving fuel economy by increasing mpg by over 40% compared to non-electrified propulsion systems, regardless of whether PHEV systems use parallel or series configurations.

Odyne encourages the EPA to continue to focus on GHG reductions rather than specific powertrain configurations. Some PHEV systems can be effectively integrated into medium and heavy-duty chassis without modifications to exhaust systems or engine control systems and without major powertrain modifications, significantly improving fuel efficiency while minimizing increases in vehicle manufacturing costs. [EPA-HQ-OAR-2022-0985-1623-A1, p. 4]

Organization: PACCAR, Inc.

PACCAR requests that EPA clarify its cylinder deactivation proposal. EPA proposes to credit vehicles with engines that include full cylinder deactivation during coasting at a rate of 1.5 percent under "Intelligent Controls" in the Greenhouse Gas Emissions Model (GEM). EPA should clearly define "full cylinder" in this context by specifying that "full" refers to the scenario where both the intake and exhaust valves are closed, and not deactivation of all cylinders. [EPA-HQ-OAR-2022-0985-1607-A1, p. 10]

Organization: Strong Plug-in Hybrid Electric Vehicle (PHEV) Coalition

EPA, the DOE or the national labs should conduct a comparative analysis on PHEV and BEV costs with a stakeholder input or working group and collect more data from truck makers as part of the final regulation. [EPA-HQ-OAR-2022-0985-1647-A2, p. 2]

EPA should consider a scenario in the final rulemaking that reduces the total costs. Specifically, this new scenario should include a modest number of PHEV trucks as that will impact the cost analysis by reducing the cost of charging infrastructure, the amount of critical minerals and by using BEV batteries in strong PHEVs (see appendices C and D in this letter.) Further, a modest amount of bidirectional charging for BEVs and PHEVs should be included as this has a positive total cost of ownership and further reduces costs. [EPA-HQ-OAR-2022-0985-1647-A2, p. 2]

Summary of our main recommendations

1) We understand that utility factor (UF) data is available for EPA to calculate the UF for light-duty PHEVs. But due to lack of product, this is not possible for heavy-duty PHEVs. For this reason, we support EPA's proposal that this be done on a case-by-case basis by EPA using data from a truck manufacturer. We also support EPA not including the upstream GHG emissions from battery manufacturing in this rule. However, there are very substantial benefits in reduced GHG from battery manufacturing emissions for a plug-in hybrid electric truck having a much smaller battery than a long-range battery electric truck as well as other environmental and supply chain benefits. Based on this, we recommend that this large benefit of PHEV trucks be considered informally when EPA is determining the utility factor for a truck manufacturer and that EPA should not be conservative when determining the UF for the plug-in hybrid electric truck. See Appendix C for additional details on the GHG reduction benefits of smaller batteries and a comparison of GHG emissions from long-range BEVs and strong PHEVs. [EPA-HQ-OAR-2022-0985-1647-A2, pp. 4 - 5] [[See Docket Number EPA-HQ-OAR-2022-0985-1647-A2, pages 13-14, for Appendix C]]

4) EPA, the DOE or the national labs should conduct an analysis on the value and feasibility of PHEVs as a platform for low-carbon alternative fuels (e.g., adequate supply of feedstocks) including whether to allow PHEVs with 85% or more low carbon liquid biofuels blended with gasoline or diesel to be treated as zero-emission vehicles (ZEVs) in future regulations and incentives. [EPA-HQ-OAR-2022-0985-1647-A2, p. 2]

9) EPA should take special care in the final regulation to encourage work trucks that idle most of the day (power take-off operations) as PHEVs, especially strong PHEVs are a good candidate for this market and some of the only PHEV trucks in class 4-8 so far.2 This may require modifying the test cycles to capture the long-duration times that these trucks use batteries to power their booms and other equipment. [EPA-HQ-OAR-2022-0985-1647-A2, p. 3]

2 For example, utility trucks made by Odyne or the former EDI.

10) The EPA should encourage manufacturers to share anonymized actual data from the Strong PHEVs so that in future years, the EPA can make informed decisions based upon real world data. [EPA-HQ-OAR-2022-0985-1647-A2, p. 3]

3) In the longer term, EPA, the DOE or the national labs should conduct a comparative analysis on PHEV and BEV costs with a stakeholder input or working group). PHEVs can be made in a less costly manner than shown in most analyses. Technical maturity, engineering advances, supply chain issues, changes in mineral prices, war and scale-up issues are impacting the costs of BEV and PHEV up-front and operating costs. Today, costs are rapidly changing, especially for batteries. In addition, Argonne National Lab's recent report8 shows that PHEVs are less expensive than BEVs for cars, and our experts at Strong PHEV coalition assert that several additional technical modifications can lower the cost of PHEVs that most analyses do not consider. We think this likely applies to plug-in hybrid trucks but recognize that more analysis is needed. A common mistake we find in reports is not understanding the difference between a strong PHEV and other PHEVs because a strong PHEV can use the same batteries as a BEV which results in significant cost savings. See Appendix D for a more detailed explanation. [EPA-HQ-OAR-2022-0985-1647-A2, p. 6] [[See Docket Number EPA-HQ-OAR-2022-0985-1647-A2, page 15, for Appendix D]]

8 https://www.anl.gov/argonne-scientific-publications/pub/167396

4) In the longer term, EPA, the DOE or the national labs should conduct an analysis on the value of PHEVs as a platform for low-carbon alternative fuels including whether to allow PHEVs with 85% or more low carbon liquid biofuels blended with gasoline to be treated as zero-emission vehicles (ZEVs) in future EPA regulations. The issue to be studied is feedstock availability in the long run for both diesel and gasoline substitutes that could be used in PHEVs to make them have lower life cycle emissions. Related environmental issues could be studied. Justification: Some biomass feedstocks used in gasoline can't or won't be used in diesel or jet fuel powered transportation. This should result in large amounts of unused feedstocks because biomass feedstocks for spark-ignited engines will not be needed in the long run (e.g.,2050). However, using some of these existing feedstocks would make future PHEVs have even lower full fuel cycle GHG emissions than they have today. Strong plug-in hybrid cars and light trucks using gasoline already can have lower GHG than long range electric cars and light trucks due to the GHG emissions from battery manufacturing and the slightly poorer fuel economy of long-range BEVs. (See appendix C in this letter). [EPA-HQ-OAR-2022-0985-1647-A2, p. 6]

6) In order to show additional ways that costs can be reduced and that hard-to-reach markets are served, we respectfully request that EPA develop a scenario in the final rulemaking that reduces the total costs. Specifically, this new scenario should include a modest number of PHEV trucks as that will impact the cost analysis by reducing the cost of charging infrastructure, the amount of critical minerals and by using BEV batteries in strong PHEVs. This scenario could

reduce the number of BEVs and FCEVs by a small amount (say 10% collectively) and be instead served by a mix of Strong PHEV trucks and other PHEV trucks. The PHEV battery costs should be based on using BEV batteries as explained in appendix D in this letter. The use of away-from-home DC fast chargers should be modestly reduced, and the cost of the PHEV including total cost of ownership should be based on work by Argonne national lab for light-duty PHEVs.9 [EPA-HQ-OAR-2022-0985-1647-A2, p. 7]

9 Ibid

Finally, bidirectional charging using DC off-board chargers should be assumed in our recommended alternative cost analysis for a reasonable percentage of BEVs and PHEVs in order to further reduce the total cost of ownership. [EPA-HQ-OAR-2022-0985-1647-A2, p. 7]

10) The EPA should encourage manufacturers to share anonymized actual data from Strong PHEVs so that in future years, the EPA can make informed decisions based upon real world data. Strong PHEV trucks are further behind in commercialization compared to BEV trucks and fuel cell EV trucks, so more data would be useful to EPA. [EPA-HQ-OAR-2022-0985-1647-A2, p. 8]

Benefits of Strong PHEVs

Allowing PHEV trucks to be in the proposed regulation helps low-income truck drivers (class 2b - 8)

- The flexible nature of Strong PHEV trucks and cars makes them an important solution for low-income drivers of used PHEV trucks and cars. Many drivers need flexibility in their choice of vehicle because they either change residences often, change jobs often, work two or more jobs or live in areas where charging at night is difficult. This applies to some vocational vehicles that park at home, or commercial businesses that don’t have easy access to charging or that move relatively often. In addition, we understand that low-income drivers in the California Clean Cars for All program preferred PHEVs (e.g., Volt and BMW i3 REX) over BEVs and we think this will hold true for PHEV trucks. Eventually used PHEV trucks will enter the market and they will be attractive to low- and moderate-income owners and renters of trucks. Small businesses often rent their home base or move their business and a PHEV truck provides needed flexibility for this hard-to-reach market segment. [EPA-HQ-OAR-2022-0985-1647-A2, p. 9]

Because of the urgency of the climate and air pollution crises worldwide and the challenges of predicting consumer acceptance, it is important to take an all-hands-on-deck approach and have multiple types of zero-emission truck technologies in the final regulation including Strong PHEVs.

- Strong PHEVs offer more options for consumers which means a faster path to zero CO2 worldwide.
- Many areas of the world are relying on EPA’s leadership to commercialize new zero carbon solutions to transportation such as Strong PHEVs.
- The longer-term goal should be PHEVs with 100% zero carbon electricity generation for almost all of their electric miles, and advanced biofuels or other ultra-low carbon fuel for the remaining miles.
- The experience of the last fifteen years has shown that many residential and commercial users of vehicles will first adopt a PHEV instead of a BEV. In addition, we believe that

long range PHEVs are a no-regrets solution for EPA to encourage in the long term. In other words, uncertainty in speed of adoption of battery EVs and fuel cell EVs, especially by fast followers and late adopters, requires agencies such as EPA to be fuel and technology neutral in their regulations.

- We believe the uncertainty in CARB's report on 2045 fuel neutrality10 argues for EPA to be broad minded and nimble in adopting regulations, plans and incentives to reach the 2045 carbon neutrality goal and implies long-term use of low carbon fuels with Strong PHEVs. In addition, reaching very high levels of ZEV sales in the next decade frees up large amounts of biofuels for use in spark-ignited and compression-ignited engines such as the strong PHEVs allowed in the proposed rule. [EPA-HQ-OAR-2022-0985-1647-A2, pp. 9 - 10]

10 E3 report for CARB at 11. " Many key uncertainties remain around the achievement of carbon neutrality in California. One of these uncertainties is the optimal use and deployment of zero-carbon fuels in hard-to-electrify sectors, including certain high temperature industrial processes, heavy-duty long-haul trucking, aviation, trains and shipping. These fuel uses may be met with a combination of fossil fuels, hydrogen, synthetic zero-carbon fuels or biofuels. It is still uncertain how the relative costs of these technologies will evolve over time. As the cost of wind and solar decline, the cost of renewable hydrogen production is also falling, making hydrogen a more attractive solution than biofuels for some applications. The market for sustainable biofuels remains nascent, making it uncertain how much sustainable biomass supply will be available, and what the best uses for these biomass resources will be through mid-century." https://ww2.arb.ca.gov/resources/documents/achieving-carbonneutrality-california-final-report-e3

Allowing PHEV trucks in the HDV regulation provides a better solution especially for commercial vehicles that provide services during major catastrophes and daily emergencies.

- Because Strong PHEV trucks are dual fuel that means they are particularly suited to provide services for society to recover from wildfires, earthquakes, hurricanes, floods, riots, and other catastrophes, as well as provide needed services in more typical daily emergencies (e.g., police, ambulance, fire, power outage recovery). PHEVs for some of their fleet provide the flexibility they need to deal with catastrophes and emergencies as public servants. CARB's Advanced Clean Truck program recognized this by providing exemptions for emergency vehicles, and this emphasizes the need for dual fuel vehicles that can provide the flexibility that some fleets need.
- Because PHEVs and Strong PHEVs are dual fuel vehicles, they provide truck owners who also sometimes use their truck for personal use or who park their work truck at home with a second fuel to travel in case of emergencies. Further, many PHEVs will come with vehicle-to-load and vehicle-to-building technology that will allow emergency power for their home or a few appliances. [EPA-HQ-OAR-2022-0985-1647-A2, p. 10]

Strong PHEV trucks are an excellent solution for many parts of the world and a long commercialization period is needed to scale up this technology.

- In addition, we believe that at least some truck manufacturers will find a better business case to reach scale and get higher levels of vehicle adoption by producing both PHEVs and BEVs than only producing battery electric vehicles. Such a result is good for truck and car maker competition, for consumers and the planet. [EPA-HQ-OAR-2022-0985-1647-A2, p. 10]

Strong PHEV trucks are an excellent solution for the unique needs of rural areas, mountainous areas and cold weather areas.

- Strong PHEV trucks are potentially a better option for the portion of the US and other countries that cover small and mid-size towns where trip distances (when needed) exceed urban megacity regions.
- Strong PHEVs do well compared to other ZEVs in mountainous areas or cold weather regions around the world because they are dual fuel vehicles and technology exists to make the second fuel ultra-low carbon.
- While many trips in these regions are local, fleet vehicles do take long distance trips, including to remote areas, where charging is lacking or inadequate. Mountainous terrain and very cold weather both significantly reduce the range of battery EVs, but PHEVs are not impacted. Even California's recently adopted Advanced Clean Fleet regulation defers compliance for government fleets in 25 of the State's 58 "low population counties." This is an acknowledgement that the State's rural counties will not have the infrastructure to support ZE trucks and buses in the near term. [EPA-HQ-OAR-2022-0985-1647-A2, p. 10]

Strong PHEVs are needed in this regulation for trucks that tow or haul for work or recreation.

- Due to the large energy requirements of towing, Strong PHEVs are better than other ZEVs. In addition, Strong PHEVs as dual fuel vehicles offer advantages when towing over mountains and rural areas where charging or hydrogen refueling is not common or not feasible from a business case perspective. (Many class 2b vehicles serve as both work and personal transportation and this is a relatively large class of vehicles.) Mountain grades are particularly known for reducing the all-electric range of battery EVs, but PHEVs are dramatically less impacted and/or have better access to refueling.
- Larger trucks may not tow but face the same issue in mountainous terrain when hauling a full payload and would benefit from a strong PHEV truck. [EPA-HQ-OAR-2022-0985-1647-A2, p. 11]

Allowing Strong PHEV trucks to be eligible should result in less need and cost for away-from home charging stations for commercial fleets.

- Strong PHEVs do not need public charging and can rely on fleet-only or, in some cases, home-only charging which reduces the societal cost (e.g., grid upgrades, public incentives for charging stations). For example, this translates to less expense for and impact on the grid including new transformers, distribution feeders and substations compared to battery EVs. PHEVs reduce the need for fast charge stations and potentially for other types of away-from-home charging stations.
- Strong PHEVs charging in residential or fleet applications have less cost to the grid because they typically charge at home or depots at lower kW levels than battery electric vehicles. [EPA-HQ-OAR-2022-0985-1647-A2, p. 11]

Allowing Strong PHEV trucks to be eligible will help with several scale-up issues including reducing the pressure to quickly scale up away-from-home and depot DC fast chargers and facilities for battery production and mineral extraction.

- Strong PHEVs do not need public charging (depot or home only charging is adequate) and use smaller batteries which means more efficient use of mineral resources especially in the near-term. See Appendix C in this letter. [EPA-HQ-OAR-2022-0985-1647-A2,

p. 11] [[See Docket Number EPA-HQ-OAR-2022-0985-1647-A2, pages 13-14 for Appendix C]]

Allowing Strong PHEV trucks to be eligible can help fleet operators avoid a weight penalty

- For trucks and buses, large battery packs will add weight (a weight penalty). For the fleet operator, they will likely have to purchase a larger truck - such as a Class 4 instead of a Class 3, in order to have the same payload. This becomes a bigger issue in use cases such as class 8 refuse haulers where lack of payload means second truck will be need to be purchased (two trucks replacing the original truck). [EPA-HQ-OAR-2022-0985-1647-A2, p. 11]

Allowing Strong PHEV trucks to be eligible will help reach skeptical consumers and other late adopters.

- Strong PHEVs provide the flexibility that is key to convincing the hard-to-convince fleets to adopt advanced technology. Many consumers for political or personal reasons are very skeptical about BEVs and FCEVs, but we have found that Strong PHEVs appeal to them. [EPA-HQ-OAR-2022-0985-1647-A2, p. 11]

We support the more stringent electric range, emission control and testing requirements placed on PHEVs in regulations in general, including, but not limited to, new requirements to limit high power cold starts, increase minimum all electric range, require higher engine turn-on speeds in order to meet the US06 driving cycle test, more stringent requirements on particulate matter. These requirements enable Strong PHEVs to have very low criteria pollutants over their lifetime and improve the consumer driving experience. [EPA-HQ-OAR-2022-0985-1647-A2, p. 12]

Regarding the reduced GHG benefit of manufacturing smaller batteries, we do not have data for large trucks (PHEVs vs BEVs), but we believe the analyses below for light-duty PHEVs and BEVs show this benefit and it should apply to large trucks. Strong PHEV battery utilization maximizes value of battery manufacturing and materials capacities. PHEV trucks, especially, Strong PHEV trucks, can electrify most daily commuting miles while occasionally using some gasoline, while BEVs have a lot of battery capacity that only gets “used” on very long trips. We assert that this could be considered wasted or underutilized lithium and other battery minerals. Thus, because PHEVs use their batteries more, the USA gets more EV miles per tonne of lithium by driving PHEVs and Strong PHEVs as shown below. [EPA-HQ-OAR-2022-0985-1647-A2, p. 13. Refer to the graph on p. 13 of docket number EPA-HQ-OAR-2022-0985-1647-A2.]

For light-duty PHEVs, our coalition has found that many researchers incorrectly find that PHEVs are high cost compared to BEVs. However, Argonne National Lab’s recent report16 shows that light-duty PHEVs are less expensive than BEVs for cars, and our experts at Strong PHEV coalition assert that several additional technical modifications can lower the cost of PHEVs that most analyses do not consider. We think this likely applies to plug-in hybrid trucks but recognize that more analysis is needed. For example, A common mistake we find in reports is not understanding the difference between a strong PHEV and other PHEVs because a strong PHEV can use the same batteries as a BEV which results in significant cost savings. The chart below shows how a light-duty PHEV should use the same batteries as a BEV and not have to use a special low-volume production battery with a different (higher) power to energy ratio. We believe this finding should translate to class 2b to 8 trucks, and that most PHEV trucks will need BEV batteries. [EPA-HQ-OAR-2022-0985-1647-A2, p. 15.] [Refer to the graph on p. 15 of docket number EPA-HQ-OAR-2022-0985-1647-A2.]

16 See footnote 7.

Organization: U.S. Tire Manufacturers Association (USTMA)

USTMA appreciates that the proposed HD Phase 3 regulations consider the ongoing technological innovation in the HD vehicle space.2 USTMA advocates and supports technologies that improve fuel economy but not when there are unintended consequences that can affect driver safety and tire performance as explained below. [EPA-HQ-OAR-2022-0985-1635-A1, p. 2]

2 88 Fed. Reg. 25926 at 25930 (April 27, 2023)

The NPRM states, “The proposed standards do not mandate the use of a specific technology, and EPA anticipates that a compliant fleet under the proposed standards would include a diverse range of technologies (e.g., transmission technologies, aerodynamic improvements, engine technologies, battery electric powertrains, hydrogen fuel cell powertrains, etc.). The technologies that have played a fundamental role in meeting the Phase 2 GHG standards will continue to play an important role going forward as they remain key to reducing the GHG emissions of HD vehicles powered by internal combustion engines.”3 [EPA-HQ-OAR-2022-0985-1635-A1, p. 2]

3 88 Fed. Reg. 25926 at 25932 (April 27, 2023)

USTMA supports aerodynamic improvements in fleets. However, recent evolutions in vehicle aerodynamic designs and emissions equipment have created conditions that contribute to heat build-up in tires and that can adversely impact tire performance. It is critical to closely monitor and manage tire heat-contributing factors that are within the operator’s control. [EPA-HQ-OAR-2022-0985-1635-A1, pp. 2 - 3]

To improve fuel economy, OEM and aftermarket manufacturers recently have introduced aerodynamic body features on their vehicles such as ground clearance air dams and side fairings. These aerodynamic features may have the unintended consequence of reducing airflow in the fender wells, which prevents the dissipation of heat and increases tire operating temperatures. These recent developments in truck technology have resulted in an increase in the number of tire claims related to heat damage. The tire industry has been evaluating tire performance on late model vehicles equipped with certain newer aerodynamic configurations and found both front fender well and tire operating temperatures to be significantly higher than ambient air temperatures. [EPA-HQ-OAR-2022-0985-1635-A1, p. 3]

Testing conducted by some USTMA members at equivalent tire operating conditions concluded that these higher than ambient air temperatures associated with certain newer aerodynamic configurations significantly decreases tire performance across multiple products and manufacturers, which is further impacted by more severe operating conditions that increase internal tire operating temperatures. For years, the tire industry has warned that operating tires over-loaded, under-inflated, or at high speeds could cause excessive heat to build up in tires. Factors contributing to tire heat are additive and due to the introduction of aerodynamic technologies, the list of factors is expanding. The tire industry believes that recent aerodynamic technology and these more severe operating conditions create an unprecedented high heat environment that substantially contributes to reducing the life span of tires on certain vehicles. [EPA-HQ-OAR-2022-0985-1635-A1, p. 3]

EPA Summary and Response:

Summary:

A group of commenters noted that further improvements to ICE engine and vehicle fuel efficiency are feasible, cost effective, and readily available. These commenters, for the most part, did not specify what numeric standards predicated on ICE vehicle and engine improvements would be, with the exception of several commenters urging that standard stringency be increased to reflect feasible improvements to ICE vehicle fuel efficiency (ICCT, MFN and others, quantifying those improvements; see summaries and responses in RTC chapter 2.4).

Many commenters spoke to the advantages of hybridization (including both strong hybrids and PHEVs). In addition to dramatically improved fuel efficiency compared to diesel vehicles, which commenters estimated at 31% for vocational vehicles and 25% for long haul tractors (Advanced Engine Systems Inst., Eaton) and 5-50% reductions when combined with other improvements, commenters noted:

- Much lower purchase price than ZEVs since a much smaller battery is needed (Strong Plug-In Hybrid Coalition)
- Significantly less supportive electrical infrastructure needed, and so easier and quicker to implement (Cummins)
- A good fit for applications like Class 8 tractors, work vehicles with long idle times, and stop and go duty cycles for which ZEVs are less suitable (Diesel Technology Forum, Eaton, Strong Plug-In Hybrid Coalition)
- A good alternative for lower income purchasers (Strong PHEV Coal.)
- Useful in areas or conditions for which ZEVs are either less suitable or unlikely to be adequately supported, including rural areas and cold weather areas (Strong PHEV Coal.)
- There is no cargo capacity penalty, unlike BEVs (Strong PHEV Coal.)
- Battery capacity is used more efficiently than a BEV (Strong PHEV Coal. (using a EV mile per ton of lithium ratio)
- Considered on a lifecycle basis, CO_2 emissions may be less than a BEV due to less resources expended in battery production (Strong PHEV Coal.)
- A potential bridge technology, especially given that some may be eligible for the commercial vehicle tax credit (CARB)

These commenters had a number of suggestions as to how hybrid performance could be reflected in a Phase 3 standard. These included:

- Acknowledging that there is insufficient data to develop a Utility Factor for HDV hybrids, either include a case-by-case factor based on user engineering judgment, or include a credit for PHEV with long documented battery ranges, possibly reflecting the lifecycle advantages of PHEVs in either that Utility Factor or credit (Strong PHEV Coal.)
- Include either credits or some other type of incentive for hybrids (Diesel Tech. Forum)

Some of these commenters urged modifications to the current hybrid certification regime:

- Streamline the testing regime (Odyne, Cummins)
- Simplify the Phase 2 formula, for example by defining a utility factor curve (Eaton)
- Increase the GEM credit for ePTO (Odyne, Strong PHEV Coal. (urging modification of test cycles to capture the long duration times when the batteries are in use)

Strong PHEV Coalition voiced its support for the following test protocols: “the more stringent electric range, emission control and testing requirements placed on PHEVs in regulations in general, including, but not limited to, new requirements to limit high power cold starts, increase minimum all electric range, require higher engine turn-on speeds in order to meet the US06 driving cycle test, more stringent requirements on particulate matter”, noting further that “[t]hese requirements enable Strong PHEVs to have very low criteria pollutants over their lifetime and improve the consumer driving experience.”

Commenters also mentioned other engine and vehicle improvements available now. Engine improvements included cylinder deactivation (including in combination with Miller cycle engines) (Eaton), high efficiency turbo charging with EGR (Eaton), 48V mild hybrid (ICCT, MECA, MFN), and lightweighting (MEMA). Several commenters mentioned improvements available from use of advanced aerodynamic technologies (Howmet, ICCT), although USTMA commented that new vehicle technologies should consider unintended consequences for driver safety and tire performance. Specifically, USTMA described concerns with aerodynamic designs and emissions equipment creating conditions that may contribute to heat build-up in tires and may adversely impact tire performance. USTMA indicated aerodynamic features such as ground clearance air dams and side fairings may reduce air flow in fender wells resulting in increased tire operating temperatures.

Several of these commenters requested changes to the way some of these technologies are credited in GEM. MEMA indicated that the Phase 2 assumption on lightweighting reflected in GEM need updating (“EPA should recognize that suppliers have introduced new technologies and products since the Phase II rule was finalized …and seek comments from suppliers to update the agency’s assumptions around weight reduction inputs to reflect the latest available technologies on the marketplace. For example, lightweight forged aluminum wheel producers have continuously improved their product offerings to the heavy-duty truck, bus, and trailer markets. More recent generations of products - introduced to the market since the Phase 2 was promulgated - offer weight savings of nearly 10% as compared to similar steer or dual-drive, and wide base wheels which were part of the analysis EPA previously conducted”, recommending that “EPA should continue to grant credit for lightweighting and weight reduction and update GHG Ph2 assumptions on lightweighting in the GHG Ph3 GEM model”). Eaton provided information to support their assertion that cylinder deactivation is also not properly assessed in GEM, recommending a 2.5 “intelligent control” adjustment factor rather than the current factor of 1.5.

ICCT and MFN asserted that various engine and vehicle improvements should be reflected in standard stringency. MFN stated that even just assuming further year-over-year improvements equivalent to those in Phase 2 through MY 2027, there should be a further 8.4% improvement reflected in the Phase 3 standard stringency. MFN also noted the ready availability of improvements for SI engines, stating that Phase 2 required no engine improvements beyond the 2016 SI engine standard.

AVE commented that “By expanding the definition of ZEVs even slightly, EPA can ensure greater emission reductions for decades.” DTNA responded to EPA’s request for comment on whether EPA should include additional GHG-reducing technologies of existing technologies for ICE vehicles in our technology assessment for the final standards, that DTNA believes it is inappropriate to add additional GHG technologies at this time.

PACCAR commented that in the proposed changes to 40 CFR 1037.520(j)(1), EPA should clearly define “full cylinder”.

Strong PHEV Coalition commented that the battery costs for PHEVs should be the same as BEVs and that we should include the benefits of bidirectional charging in our TCO. Investigate use of strong PHEVs with low carbon fuels, including the possibility that this combination should be considered zero emission, and, generally, distinguish strong PHEVs from other PHEVs (Strong PHEV Coal.)

Response:

We agree with the comments that there are technologies other than ZEVs that can be used to meet the final standards. Regarding the stringency of the final standards, EPA has undertaken a balanced and measured approach to setting performance-based standards under our CAA section 202(a)(1)-(2) authority. See Preamble Section II and RTC 2. In short, the final standards can be met in any manner a regulated entity (*i.e*. manufacturer) sees fit that achieves compliance with that numerical standard. In assessing a modeled potential compliance pathway that includes a technology mix of ICE vehicle technologies and ZEV technologies, EPA was demonstrating that the final standards were feasible and appropriate; EPA was not requiring that manufacturers utilize that modeled potential compliance pathway. In fact, as discussed in Preamble Section II.F.4, we have assessed additional example potential compliance pathways that support the feasibility of the final standards, which include a suite of technologies ranging from ICE engine, transmission, drivetrain, aerodynamics, and tire rolling resistance improvements, to the use of low carbon fuels like CNG and LNG, to hybrid powertrains (HEV and PHEV) and H2-ICE. See also responses in RTC 9.1 and 2.1 further responding to the explicit or implicit incorrect assertion that the Phase 3 rule mandates use of ZEVs.

As for the comment related to recognizing the emissions performance of hybrid powertrains, the current procedures in Subpart F of 40 CFR 1036 provide such a pathway. These procedures rely on a powertrain test procedure that EPA has refined over the years. The procedure defines how to generate a fuel map for use in GEM for both hybrid and plug-in hybrid powertrains. While the commenters’ request for the future addition of hybrid powertrain utility factors is not within the scope of this rulemaking, we agree that the future addition of EPA- defined utility factor curves could be an improvement to the procedure and are committed to working with stakeholders to consider defining these curves in the future. In the meantime, as commenters acknowledge, the test procedures allow for manufacturers to get approval for a utility factor curve. In addition, the powertrain test procedure may be used to demonstrate the criteria pollutant performance of hybrids on the FTP, SET, and LLC duty cycles. As for comments on streamlining the powertrain test procedures, EPA continually works towards developing improved, less burdensome test procedures and intends to continue to work with manufacturers and stakeholders towards that end, including in future rulemaking actions. See RTC Section 24 and Preamble Section III.C for more information on powertrain testing.

In response to the commenters that EPA should increase the GEM credit for ePTO through changes in the duty cycle, we didn't propose changes to or reopen the duty cycles so this comment is out of scope in this final rule.

With respect to the comments on credit multipliers for hybrids, please see Preamble Section III.A and response to comment Section 10.3.1.

As for the comments that engine and vehicle improvements are available now, the test procedures in 40 CFR 1037.520 and Subpart F of 40 CFR 1036 provide a pathway for manufacturers to get credit for the use of these technologies. These test procedures are designed to capture the performance of many different technologies from engine improvements to vehicle lightweighting and technologies that reduce the aerodynamic drag of vehicles. As noted above, nothing in the Phase 3 rule precludes compliance strategies utilizing these technologies.

We do not agree with commenters advocating for more stringent standards reflecting further improvements to ICE vehicles and engines beyond the Phase 2 2027 improvements in our modeled compliance pathway, as our assessment is that manufacturers do not have the resources to pivot between different technology improvement strategies within the lead time provided by the Phase 3 program (e.g., the modeled potential compliance pathway versus an additional example potential compliance pathway discussed in Preamble Section II.F.4). See also RTC Section 2.4.

Regarding the comments from MEMA that EPA should update the credit for lightweighting, we provide a pathway in the existing regulations for manufacturers to seek approval for such cases. 40 CFR 1037.520(e)(5) states: "You may ask to apply the off-cycle technology provisions of § 1037.610 for weight reductions not covered by this paragraph (e)."

As for the comment from Eaton that the 1.5% credit doesn't reflect the full CO2 reduction of cylinder deactivation, we note the existing fuel mapping test procedures in 40 CFR 1036.540 and 40 CFR 1036.545 are test procedures that can be used and are designed to capture the CO2 benefits from integrating multiple technologies, like the use of CDA (cylinder deactivation, the technology noted in the comment) to minimize additional fuel for thermal management.

EPA agrees with USTMA regarding the need to maintain safe tire operation with the use of HD vehicle emission reduction technologies; however, USTMA did not provide specific data or describe specific emission reduction technologies that result in safety issues.

In response to AVE comment on expanding the definition of ZEV, EPA is not defining ZEV in our regulations in this rulemaking and the final rule is not requiring ZEVs, but rather is setting performance-based standards.

Regarding DTNA's comment, see discussion in Preamble Section II.G as well as our response in RTC Section 2.4 responding to comments advocating for more stringent standards than those proposed.

We agree with PACCAR's comment that "full cylinder" should be clarified and have finalized changes to 40 CFR 1037.520(j)(1), to clearly define "full cylinder". See Preamble Section III.C.3.viii for more information.

In response to the comments on critical minerals, see RTC Section 17.2.

We agree with Strong PHEV Coalition that the costs for batteries in PHEVs should be the based on the cost of batteries in BEVs and have included this approach in our assessment of those technologies in our additional example potential compliance pathways supporting the feasibility of the final CO_2 standards in RIA Chapter 2.11. We agree with Strong PHEV Coalition that bidirectional charging and related technologies may offer numerous benefits and potentially save money for fleets, as discussed further in RIA Chapter 1.6.4, RTC 6.4 and RTC Section 7. We did not quantitatively include these benefits in our analysis for the rule so to the extent that fleets monetize such benefits, our costs analysis may be considered conservative.

In response to the comment from Strong PHEV Coalition that PHEVs should be considered zero emissions if fueled with low carbon fuels see our response to LCA in RTC 9.1 and RTC 17.

Finally, existing 40 CFR 1037.610 provides a pathway for manufactures to seek approval for alternative test procedures for technologies that are not reflected in GEM and that will result in measurable, demonstrable, and verifiable real-world CO2 emission reductions.

9.3 H2 ICE Vehicles

Comments by Organizations

Organization: Alliance for Vehicle Efficiency (AVE)

AVE seeks stronger support for hydrogen engine platforms as a way for the U.S. to meet its environmental goals. [EPA-HQ-OAR-2022-0985-1571-A1, p. 5]

AVE supports EPA's recognition of hydrogen internal combustion engines (H2-ICE) as emitting zero CO2 at the tailpipe. Still, EPA is limiting support for this technology in propulsion systems "…where a diesel pilot is used for combustion."14 This limitation is not reasonable given that CO2 emissions from pilot ignition are minimal. More importantly, EPA should recognize that advanced aftertreatment solutions, emission control technology, and selective catalytic reduction systems exist to further reduce tailpipe emissions to almost untraceable levels where a diesel pilot is used. [EPA-HQ-OAR-2022-0985-1571-A1, p. 5]

14 Federal Register / Vol. 88, No. 81 / Thursday, April 27, 2023 / at 26021

H2-ICE is ideal for high load and high utilization vehicle applications where BEV or fuel cell solutions cannot meet the long haul, heavy load requirements or the need for quick refueling. H2-ICE trucks have an advantage over BEVs in operating within long range fleet conditions because it can haul heavier loads for longer periods of time. [EPA-HQ-OAR-2022-0985-1571-A1, p. 5]

Furthermore, H2-ICE technology is more mature and economically feasible, so it is a fast-to-market propulsion solution, ready to be rapidly deployed in high volume. H2-ICE has the ability to quickly transform the heavy-duty marketplace at many weight classes as a scalable retrofit to existing internal combustion engines overcoming enormous costs to fleet owners. H2-ICE is a zero-tailpipe emission technology. By including H2-ICE in its clean transportation strategy, the EPA will create demand that will nurture and grow the developing hydrogen fuel market, which in turn, will help accelerate hydrogen fuel cell adoption. [EPA-HQ-OAR-2022-0985-1571-A1, p. 5]

When analyzing predictions for U.S. energy consumption through 2050, support for H2-ICE deployment becomes more prescient. According to the U.S. Energy Information Administration, U.S. petroleum consumption will continue to increase by nearly 13% from 2021 levels (see chart below). The best pathway forward is by supporting all GHG reducing technologies. [EPA-HQ-OAR-2022-0985-1571-A1, p. 6.] [See Docket Number EPA-HQ-OAR-2022-0985-1571-A1, page 6, for the referenced chart.]

We recommend that EPA fully analyze how H2-ICE can dramatically offer faster more cost-effective compliance with future standards. H2-ICE technology is being developed and deployed all over the world and has the opportunity to bring significant manufacturing growth and investment to the U.S. [EPA-HQ-OAR-2022-0985-1571-A1, p. 6]

Organization: American Council for an Energy-Efficient Economy (ACEEE)

H2-ICEVs are likely to provide smaller efficiency gains over diesel vehicles than H2-FCEVs provide and could even result in GHG emissions increases relative to diesel well into the time frame of the Phase 3 rule, as indicated by Table 2.28 Yet EPA states in the proposal that, “a new technology under development that would reduce GHG emissions from heavy-duty vehicles with ICEs is hydrogen-fueled internal combustion engines (H2–ICE)” (FR 25960). EPA’s enthusiasm is premature. [EPA-HQ-OAR-2022-0985-1560-A1, p. 14.]

28 GREET does not currently include HD H2-ICEs. We obtained the (rough) values shown in Table 2 for such a vehicle by scaling the diesel combination truck values by E10/liquid H2 LD (SI) ICE vehicle ratios from GREET 2022.

EPA should not incentivize hydrogen-fueled vehicles without strong evidence that hydrogen fuel for transportation will be clean in the foreseeable future. For H2-ICEVs in particular, for which intrinsic efficiency advantages are modest, actual GHG benefits may be negative, and potential future benefits are based largely on changes to the fuel rather than to the vehicle, the zero-upstream incentive is inappropriate. It would offer manufacturers the same compliance benefit for an H2-ICEV as for a BEV or FCEV but require only relatively small changes to the engine, as described At FR 25960. The fact that H2-ICEVs produce NOx makes conferring ZEV benefits on them all the more inappropriate. Low-carbon hydrogen-fueled vehicles are best incentivized through performance-based standards. [EPA-HQ-OAR-2022-0985-1560-A1, pp. 14 - 15.]

Organization: American Petroleum Institute (API)

While still in the early stages of development and prove out, hydrogen-based vehicles (FCEVs and H2-ICE) are a promising technology that many stakeholders are considering. API members are engaged in hydrogen projects to support development of hydrogen focused technology. Companies are partnering with HD OEMs to explore commercial business opportunities to build demand for commercial vehicles and industrial applications powered by hydrogen. Demonstration projects target hard-to-abate applications like rail and marine, with a goal to develop viable large-scale businesses and advance a thriving hydrogen economy. [EPA-HQ-OAR-2022-0985-1617-A1, p. 8.]

Organization: BorgWarner Inc.

BorgWarner supports hydrogen engine development and expanding hydrogen infrastructure.

BorgWarner supports efforts to accelerate development of the hydrogen transportation sector. We are concerned, however, that regulations may not go far enough to allow the technology to develop quickly. EPA should support both H2FC and H2ICE platforms because they complement the overall deployment of hydrogen infrastructure. H2FC and H2ICE address different vehicle use cases; however, both utilize the same hydrogen infrastructure. [EPA-HQ-OAR-2022-0985-1578-A1, p. 3]

Both technologies currently have market challenges. The cost of H2FC is still quite high and needs more time before reaching price competitiveness. Currently, the H2ICE market is nearly nonexistent in the U.S. because of the lack of refueling infrastructure and H2ICE product is not yet released commercially. It is also facing headwinds as California and EPA regulations do not presently recognize H2ICE as a zero-tailpipe emissions technology. [EPA-HQ-OAR-2022-0985-1578-A1, p. 3]

EPA's proposal is inclusive of H2ICE in its clean transportation strategy, however, EPA is proposing strict limitations based on pure hydrogen as the fuel, as well as counting trace amounts of tailpipe CO2. [EPA-HQ-OAR-2022-0985-1578-A1, p. 3]

Hydrogen has one of the lowest lifecycle emissions of any powertrain option when using renewable hydrogen. Certain stakeholders may be concerned that H2ICE does not result in 100% zero tailpipe emissions. There are, however, new technologies, such as aftertreatment in higher performing selective catalytic reduction (SCR) systems, emissions controls, and air-fuel controls, which can nearly eliminate particulate matter and remaining tailpipe emissions to background levels. [EPA-HQ-OAR-2022-0985-1578-A1, p. 4]

The H2ICE market is maturing in other regions of the world, where policymakers recognize H2ICE as a viable and critical technology to address air quality and environmental issues. The U.S. is already losing its innovation leadership for hydrogen trucks and will continue to miss this opportunity if H2ICE is not included in the clean transportation transformation. [EPA-HQ-OAR-2022-0985-1578-A1, p. 4]

A heavy-duty vehicle powered by a hydrogen combustion engine will produce close to zero CO2 when compared to current Class 8 trucks. By comparison, natural occurring processes in nature like a human breathing produce a limited amount of CO2 (1kg per day of CO2 for average human) or decaying plants (plants release ½ the CO2 they absorb in total life). [EPA-HQ-OAR-2022-0985-1578-A1, p. 4]

Currently, there are no on-road demonstration vehicles being supported in the U.S. that can help regulators fully understand and assess H2ICE as a solution to meeting climate goals. We recommend the EPA incentivize and partner with technology providers to demonstrate H2ICE's capabilities and GHG emissions reductions. [EPA-HQ-OAR-2022-0985-1578-A1, p. 4]

Defining vehicle emissions exclusively at the tailpipe creates a de facto technology mandate and excludes technologies that could make a timely real-world difference in CO2 emissions. As stated above, H2ICE is a cost-effective advanced technology that is under development and more ready to be rapidly deployed in high volumes to make an impact on the environment. [EPA-HQ-OAR-2022-0985-1578-A1, p. 6]

BorgWarner supports EPA’s decision to include H2ICE as a clean vehicle technology. An additional benefit of H2ICE is how the technology can be readily adapted from existing systems and therefore, could be used as a strategy to significantly decrease CO2 faster for the current HD fleet and help advance the development of fuel cell vehicles. [EPA-HQ-OAR-2022-0985-1578-A1, p. 6]

Organization: California Air Resources Board (CARB)

3. HDVs with Hydrogen Internal Combustion Engine (H2 ICE)

Affected pages: 25960-25961 and 26022

The NPRM is proposing to include vehicles with engines using fuels other than carbon-containing fuels as another potential technology to meet Phase 3. U.S. EPA is proposing to amend 40 CFR 1037.150(f) to include H2 ICE as a zero-tailpipe emission technology and exempt H2 ICE technologies from CO2-related emission testing. [EPA-HQ-OAR-2022-0985-1591-A1, p.43]

CARB staff asks that U.S. EPA consider that manufacturers may respond to Phase 3 by making H2 ICE instead of deploying HD ZEVs. Although H2 ICE engines have near zero CO2 tailpipe emissions, their NOx emissions are of concern as is the sustainability of their use of finite supplies of low carbon hydrogen. As indicated above, California needs significant NOx and CO2 reductions to meet its air quality and climate goals and hence is taking rigorous actions that will accelerate the deployment of HD ZEVs. Since federal certified trucks sold outside of California contribute about 50 percent of the total HD trucks NOx emissions in California, standards applicable in other States (including U.S. EPA’s standards) nonetheless remain crucially important, and California would benefit from greater deployment of ZEVs elsewhere. In addition, H2 ICE engines are less efficient than FCEVs, meaning they will require substantially greater amounts of hydrogen needed to perform the same amount of work over real-world duty cycles. This additional hydrogen will result in greater upstream GHG emissions. U.S. EPA should consider requiring quantification of H2 ICE hydrogen fuel use via fueling map disclosure, just as it does for all previous combustion fuels, a requirement which is necessary for U.S. EPA and others to properly assess the upstream GHG emissions from H2 ICE technologies. U.S. EPA has existing precedent for measuring vehicle energy usage even if the energy carrier does not contain carbon as seen in the plug-in hybrid and ZE LDV test procedures. Hydrogen should not be given a special exemption in HD for its lack of carbon when similar metrics are already reported for electricity and hydrogen used on-board a LDV. U.S. EPA CO2 standards should intentionally account for potential H2 ICE adoption rates by including estimated costs and emissions impacts of this projected H2 ICE technology for use to meet the Phase 3 emission standards in the final rulemaking. It appears that U.S. EPA’s small assumed technology penetrations of H2 ICE do not analyze the possibility of such technology potentially becoming the default approach for certain high energy demand sectors for which industry is promoting H2 ICE with statements like “These [H2 ICE] engines look like engines, they sound like engines, and fit where engines normally fit.”141 More than one HDV manufacturer is public about bringing H2 ICE class 8 engines in the 2027 timeframe,142,143 and development continues on other similarly sized engines.144,145,146 U.S. EPA should conduct sensitivity analysis of the emissions risks should industry elect to produce many H2 ICEs. U.S. EPA should also consider commensurate production caps to limit such potential risks, particularly if U.S. EPA is not going to fully assess those risks at this time. [EPA-HQ-OAR-2022-0985-1591-A1, pp.43-44]

Organization: Cummins Inc.

Hydrogen engines will help ready the infrastructure and market for fuel cells by creating demand for hydrogen before fuel cells are commercially ready. [EPA-HQ-OAR-2022-0985-1598-A1, p. 9]

Organization: Daimler Truck North America LLC (DTNA)

Treatment of H2-ICE Vehicles. DTNA supports EPA’s proposal to deem tailpipe CO2 emissions from vehicles with H2-ICE to be zero and not to require GHG emission testing for such engines or their input to vehicle certification applications.23 EPA rightly recognizes that these engines emit nearly zero CO2, with any CO2 almost entirely from ambient environmental sources. DTNA supports these proposed changes as a minimum step to help enable H2-ICE penetration. [EPA-HQ-OAR-2022-0985-1555-A1, p. 17]

23 See id. at 25,960; 26,022 (proposing changes to 40 C.F.R. § 1037.150(f) to specify that tailpipe CO2 emissions from vehicles with engines fueled with neat hydrogen ‘are deemed to be zero’).

The Company also agrees with EPA’s decision not to include H2-ICE vehicles in the technology packages that form the basis of its CO2 standard stringency proposal. Not only is this technology still in the development stage, but its increased costs, fleet hesitance to adopt alternative powertrain solutions, and most importantly, the lack of available fueling infrastructure will limit the early rollout of H2-ICE vehicles to customers and applications best suited to them. [EPA-HQ-OAR-2022-0985-1555-A1, p. 17]

In addition, many of the potential early adopters of H2-ICE technology are the same ones that EPA assumes will adopt other ZEV technologies. As explained in these comments, the ZEV penetration rates assumed in the Proposed Rule are likely already overly-optimistic and unobtainable. Proposing additional CO2 standard stringency to reflect anticipated H2-ICE vehicle proliferation would thus be inappropriate. While it is possible that H2-ICE vehicles will displace BEVs and fuel cell electric vehicles (FCEVs) over the long-term, particularly in applications for which BEVs and FCEVs are not well-suited, the timeframe for such a shift is not at all certain, thus it would be unreasonable to base the proposed CO2 standards on significant H2-ICE penetration at this time. [EPA-HQ-OAR-2022-0985-1555-A1, p. 17]

EPA can and should further reduce regulatory burdens for H2-ICE technologies by making changes to how H2-ICE vehicles are certified, as detailed below in Section IV.A of these comments. [EPA-HQ-OAR-2022-0985-1555-A1, p. 18]

This rulemaking presents an important opportunity to foster innovation and accelerate penetration of innovative technologies with zero CO2 emissions and near-zero NOx emissions such as H2-ICE engines. [EPA-HQ-OAR-2022-0985-1555-A1, p. 77]

H2-ICE technology provides an important pathway to rapid penetration of vehicles with effectively zero CO2 emissions and near-zero NOx emissions. This rulemaking presents an opportunity for EPA to encourage innovation in alternate fuel engine development generally, and H2-ICEs specifically. Currently H2-ICE new technology is in the primitive proof-of-concept stage of innovation, and regulatory pathways are needed to bring this new near-zero CO2 and NOx technology to the market. Such technology could bring carbon-neutral transportation to sectors that are not currently ripe for battery or fuel-cell applications, given the current state of technology development. It could also create a use-case for widespread hydrogen fueling, which could spur the development of hydrogen infrastructure and lay the groundwork for future fuel cell vehicles, which would rely on the same infrastructure. The Company also believes that H2-ICE is a favorable technology, even in the long term, for vehicles with high power demands and high daily mileage requirements (which BEVs and FCEVs may not serve well). DTNA's vision for H2-ICE applicability in a zero-emissions future is illustrated in Figure 10 below: [EPA-HQ-OAR-2022-0985-1555-A1, p. 77] [Refer to Figure 10 on p. 77 of docket number EPA-HQ-OAR-2022-0985-1555-A1]

Importantly, this technology can be implemented more rapidly, using existing products, processes, and technical expertise. In concept, H2-ICEs are very similar to existing combustion engines and can leverage the extensive technical expertise manufacturers have developed with existing products—in many cases, using the same components for many key systems. Similarly, these products can be built on the same assembly lines, by the same workers and with existing supply chains already in place, preventing costly plant retooling and preserving good-paying American manufacturing jobs. H2-ICEs thus have an important role to play in facilitating the ZEV transition with minimal supply chain and economic disruptions. [EPA-HQ-OAR-2022-0985-1555-A1, p. 77]

Although H2-ICE technology is promising, it is in an infant state, and near-term penetration potential is relatively low. By developing a regulatory framework that facilitates H2-ICE development, EPA could speed the adoption of such technology. This could be achieved by eliminating regulatory obstacles to market introduction of H2-ICEs. Specifically, EPA should use the opportunity presented in this rulemaking to create a favorable regulatory environment for these engines by providing relief in areas such as DF testing, GHG certification and testing requirements (under Parts 1036 and 1037), and expensive diagnostic requirements. [EPA-HQ-OAR-2022-0985-1555-A1, p. 78]

H2-ICE is a promising concept, with effectively zero CO2 emissions and extremely low criteria pollutant emissions. [EPA-HQ-OAR-2022-0985-1555-A1, p. 78]

DTG has performed a concept study of H2-ICE by converting a diesel engine to adapt all the relevant hardware components to accommodate H2 combustion. The results are shown in Figure 11. Along with effectively zero CO2 emissions, near-zero NOx emissions are also possible with H2-ICE innovative technology. Engine-out NOx levels are extremely low when compared to diesel emissions, and the temperatures created are extremely favourable for adapting existing SCR aftertreatment technologies—leading to further NOx reductions. [EPA-HQ-OAR-2022-0985-1555-A1, p. 78] [Refer to Figure 11 on p. 78 of docket number EPA-HQ-OAR-2022-0985-1555-A1]

Similarly, when measured at the tailpipe, CO2 emissions from these vehicles are extremely low—two orders of magnitude lower than a conventionally-fueled heavy duty engine. Figure 12 below shows a typical breakdown of CO2 emissions as measured at the tailpipe of an H2-ICE. Most of these emissions are ambient in nature (e.g., from the ambient air, or from the carbon content of urea) and do not represent a net increase of CO2 to the environment. EPA already allows the removal of background CO2 from emissions calculations; in these conditions, H2-ICE engines are as close as practical to zero, and are competitive with BEVs and FCEVs from a total carbon lifecycle perspective. Accordingly, DTNA supports EPA's proposal to declare H2-ICE engines as zero CO2. [EPA-HQ-OAR-2022-0985-1555-A1, p. 78] [Refer to Figure 12 on p. 79 of docket number EPA-HQ-OAR-2022-0985-1555-A1]

Other regulatory bodies already provide regulatory relief for H2-ICE engines, incentivizing their adoption. [EPA-HQ-OAR-2022-0985-1555-A1, p. 79]

As manufacturers move aggressively towards decarbonization, global consistency in the regulatory approach to ZEVs is essential to provide the certainty and predictability necessary to spur investment, especially in markets that are likely to adopt such technologies first. European Union (EU) regulators have already recognized the advantages of H2-ICE engines, and the EU framework provides a path for these engines to be certified as 'zero-emission heavy-duty vehicles' by defining such vehicles as follows:

- 'Zero-emission heavy-duty vehicle' means a heavy-duty vehicle without an internal combustion engine, or with an internal combustion engine that emits less than 1 g CO 2 /kWh as determined in accordance with Regulation (EC) No 595/2009 and its implementing measures, or which emits less than 1 g CO 2 /km as determined in accordance with Regulation (EC) No 715/2007 of the European Parliament and of the Council and its implementing measures.146 [EPA-HQ-OAR-2022-0985-1555-A1, p. 79]

  146 See Regulation (EU) 2019/1242, Art. 3(11) (June 20, 2019).

It is also expected that the EU regulations will be further updated to more explicitly recognize these engines as a zero-emission technology. Such recognition provides significant benefits for manufacturers by reducing regulatory burdens, as well as development and certification costs, and by otherwise incentivizing commercialization. [EPA-HQ-OAR-2022-0985-1555-A1, p. 79]

Similarly, CARB ZEV standards for passenger cars and light-duty trucks already recognize extremely low-emissions from H2-ICEs, providing a mechanism for manufacturers to generate credits for producing such vehicles that can be applied towards their ZEV sales obligations:

- (E) Credit for Hydrogen Internal Combustion Engine Vehicles. A hydrogen internal combustion engine vehicle that meets the requirements of subdivision 1962.2(c)(2) and has a total range of at least 250 UDDS miles will earn an allowance of 0.75, which may be in addition to allowances earned in subdivision 1962.2(c)(3)(A), and subject to an overall credit cap of 1.25.147 [EPA-HQ-OAR-2022-0985-1555-A1, p. 80]

  147 See 13 CCR § 1962.2(c)(3)(E).

We recommend that EPA recognize, as CARB and the EU have, the potential of H2-ICE engines to play an important role in the zero-emission transition, and to take further steps to reduce regulatory burden and incentivize manufacturers to introduce this technology. As a global manufacturer with deep roots in U.S. and European markets, Daimler Truck AG and DTNA support global alignment in recognizing H2-ICE as a zero-emission technology. [EPA-HQ-OAR-2022-0985-1555-A1, p. 80]

DTNA supports EPA's proposal to declare neat H2-ICE as zero-CO2. EPA could further reduce manufacturer burden, and thereby accelerate the penetration of zero-CO2 technologies in the commercial truck sector, by removing the most costly and onerous engine certification requirements. [EPA-HQ-OAR-2022-0985-1555-A1, p. 80]

Currently the market for H2-ICE technology, especially in the near-term, is limited. Since H2 infrastructure does not exist in any significant quantity, it is expected that manufacturers will face difficulties recouping their H2-ICE investment costs, and a high regulatory burden may prevent manufacturers from bringing these technologies to market. [EPA-HQ-OAR-2022-0985-1555-A1, p. 80]

In the Proposed Rule, EPA proposes to declare H2-ICE products as zero-CO2 without the need to perform costly GHG testing—for engine regulations or for their input to vehicle certification. EPA rightly recognizes that these engines emit nearly zero CO2, with any CO2 almost entirely from ambient environmental sources. DTNA supports these proposed changes as a minimum step to help enable H2-ICE penetration. [EPA-HQ-OAR-2022-0985-1555-A1, p. 80]

By making additional changes to how H2-ICE vehicles are certified, EPA could further reduce regulatory burdens in a manner that would help to ensure the success of these new technologies, enabling immediate carbon reductions at low cost and while preserving American jobs. [EPA-HQ-OAR-2022-0985-1555-A1, p. 80]

First, we recommend that EPA recognize vehicles powered by H2-ICEs as effectively zero-emission, placing them in a category similar to BEVs and FCEVs, which do not require costly certification, demonstration, diagnostic, and compliance requirements. The Company does not believe such compliance obligations have any value with respect to H2-ICE emissions performance, since the engines already emit effectively no CO2, NOx, PM, and other constituent pollutants of concern—even in degraded or failed states, based on the fundamental physics governing this combustion cycle and fuel. ZEV recognition for these products would significantly incentivize their production, as they would qualify for emissions credits and advanced credit multipliers in the same manner as BEVs and FCEVs. [EPA-HQ-OAR-2022-0985-1555-A1, p. 80]

Alternatively, if EPA decides to continue to require H2-ICEs to be certified under its program for traditional combustion engines, we recommend that EPA significantly reduce the certification burden by making the following modifications to its certification requirements:

- Reduced DF validation burden and Durability requirements.
    - DF validation is extremely expensive and burdensome, and carries a several-year lead-time to complete for new technologies.
    - EPA could allow manufacturers to attest to durability and useful life requirements.
    - EPA could consider an assigned DF for criteria pollutants for H2-ICE engines.
    - EPA could consider a reduced Useful Life standard for H2-ICE in the HHD category, consistent with how SI engines in the LHD and MHD categories are treated. [EPA-HQ-OAR-2022-0985-1555-A1, p. 81]
- Simplified OBD regulation.
    - The development and demonstration of an OBD system, as required in EPA's Section 1036.110, is extremely time consuming, expensive, and risky for manufacturers.
    - It also drives significant material cost to the engine, as sensors are added purely for the purpose of diagnostic requirements.
    - The combustion mechanisms of an H2-ICE mean that, even in a failed condition, increased emission potential is extremely limited. CO2, PM, and hydrocarbon emissions are effectively zero in any combustion regime with H2 fuel, and even in the case of a failed catalyst, engine-out NOx emissions are extremely low with this technology. The value of an OBD system in an H2-ICE-powered vehicle is extremely limited—especially when considered in light of its cost.
    - EPA could reduce this burden by requiring the OBD system only to detect circuit faults and failed actuators—which make up the vast majority of real world failures—and avoid requirements for threshold diagnostics and rationality checks which add cost and complexity and are onerous to develop and demonstrate.
    - At a minimum, EPA should allow manufacturers to propose an alternate monitoring plan for H2-ICE engines, avoiding monitors for failures which good engineering judgement shows a significant impact to emissions is unlikely or impossible. If a manufacturer can demonstrate, either with good engineering judgement, or with testing, that a particular failure mode cannot cause the engines emissions to exceed the thresholds regulated in 1036.110, the EPA should exempt the manufacturer from monitoring for those failure modes.[EPA-HQ-OAR-2022-0985-1555-A1, p. 81]

EPA has an important opportunity in this rulemaking to encourage the development of technologies with effectively zero CO2 emissions today, in applications that might not otherwise be ripe for ZEV penetration in the foreseeable future. DTNA recommends that EPA work with manufacturers to determine the best path to enable these technologies. [EPA-HQ-OAR-2022-0985-1555-A1, p. 81]

EPA Request for Comment, Request #42: We welcome comment, including additional data, on our approach and assessment of HD ICE vehicle M&R costs.

- DTNA Response: See DTNA Response to Request # 20, above. [Refer to section 2 of this comment summary] [EPA-HQ-OAR-2022-0985-1555-A1, p. 165]

EPA Request for Comment, Request #70: We request comment on this proposed revision to include H2 ICE in 40 CFR 1037.150(f).

- DTNA Response: DTNA supports EPA's proposal to include H2-ICE engines in 40 CFR 1037.150(f), as discussed in Sections II and IV.A. of these comments. [EPA-HQ-OAR-2022-0985-1555-A1, p. 172]

Organization: Environmental Defense Fund (EDF)

c) H2 ICE vehicles emit NOx and should not be considered full ZEVs.

While BEVs and FCEVs do not generate any intended emissions at the tailpipe, H2-ICE vehicles still emit nitrogen oxides (NOx) and should be required to employ aftertreatment devices analogous to those required for diesel engines (primarily SCR). Even if EPA considers H2-ICE vehicles as a carbon-free technology, they should not be considered a full ZEV. [EPA-HQ-OAR-2022-0985-1644-A1, 86]

Organization: Manufacturers of Emission Controls Association (MECA)

Hydrogen-Fueled Internal Combustion Engines

Another promising technology that is being commercialized to both reduce the NOx and carbon footprint of heavy-duty vehicles is the hydrogen internal combustion engine (H2ICE). These engines, when coupled with advanced NOx aftertreatment, have the potential to meet the MY 2027 NOx limits while emitting zero tailpipe carbon emissions when operated on hydrogen fuel and zero lifecycle carbon emissions when operated on renewable green hydrogen. There is broad industry support for internal combustion engines fueled with clean hydrogen and most engine manufacturers and component suppliers are conducting significant development work and testing with ongoing on-road demonstrations in Europe and North America. H2ICEs are attractive options for commercial trucking where challenges exist in applying current BEV or H2FC technology. [EPA-HQ-OAR-2022-0985-1521-A1, pp. 8 - 9]

One of the main benefits of H2ICE is their lower upfront capital costs due to the leveraging of existing investments in manufacturing capacity in engines, emission controls and powertrain as well as vehicle servicing. H2ICE vehicles share many components with today's diesel and natural gas-powered vehicle fleet, including the base engine, installation parts, powertrain components and aftertreatment system architectures. Furthermore, H2ICE can borrow technology from currently available natural gas engines, such as cylinder heads, ignition systems, fuel injection, turbochargers, cooled exhaust gas recirculation (EGR), and engine control unit/software, among others. Nearly all on-road and off-road engine OEMs, along with their suppliers, are developing H2ICE for commercial introduction in the MY 2026-2027 timeframe. [EPA-HQ-OAR-2022-0985-1521-A1, p. 9]

Suppliers of on-vehicle hydrogen storage tanks are looking at this H2ICE transition technology to grow the manufacturing capacity for 350 bar and 700 bar high pressure hydrogen tanks and bring down their costs. This will accelerate the introduction of fuel cell trucks that will rely on the same high pressure fuel tanks and hydrogen infrastructure that they will share with H2ICE trucks. Truck and engine manufacturers are targeting the introduction of H2ICE trucks at least 10 years before fuel cell trucks will become cost competitive. The early introduction of H2ICE trucks will help to accelerate the build-out of the hydrogen infrastructure and allow fleets to seamlessly transition from operating H2ICE trucks to operating fuel cell trucks in their fleet. [EPA-HQ-OAR-2022-0985-1521-A1, p. 9]

Organization: MEMA

Furthermore, EPA should support both hydrogen fuel cell technology and H2ICE because they complement the overall deployment of hydrogen infrastructure. FCEV and H2ICE address different vehicle use cases; however, both utilize the same hydrogen infrastructure. [EPA-HQ-OAR-2022-0985-1570-A1, p. 5]

MEMA supports EPA's proposal to include H2ICE in the GEM model credited as a zero CO2 technology. MEMA believes H2ICE has potential as another technology that fits within a performance-based standard regulatory framework to decarbonize applications that are more challenging to electrify from a performance standpoint. H2ICE holds promise as a bridge technology to encourage building out hydrogen infrastructure that will be shared with FCEV applications. [EPA-HQ-OAR-2022-0985-1570-A1, p. 15]

We also note that the California Air Resources Board has few exceptions, most temporary, for ICE in its Advanced Clean Fleets' program and ask EPA to encourage CARB to respect technological limitations and provide more exceptions beyond case-basis. [EPA-HQ-OAR-2022-0985-1570-A1, p. 15]

Recommendation: EPA should retain the technology multiplier for FCEV and include H2ICE in the GEM model with zero CO2 emissions. EPA should also encourage CARB to find space for H2ICE within its ZEV mandate regulatory structure which is set up to allow exemptions from conventional ICE to fill technology readiness gaps. [EPA-HQ-OAR-2022-0985-1570-A1, p. 15]

Organization: Moving Forward Network (MFN) et al.

EPA must not allow alternative combustion fuels ("false solutions") to be included in their zero-emission definition. Instead, EPA should adhere to the precautionary approach, which turns traditional environmental policy on its head. Instead of asking, "How much harm is allowable?" the precautionary approach asks us to consider, "How little harm is possible?" The precautionary approach urges a full evaluation of available alternatives to prevent or minimize harm. 90 [EPA-HQ-OAR-2022-0985-1608-A1, p. 38]

90 Rachel's Democracy & Health News (formerly Rachel's Environment & Health News). #770 -- Environmental Justice and Precaution, May 29, 2003. (July 31, 2003). http://web.archive.org/web/20071219020722/http://www.rachel.org:80/bulletin/index.cfm?issue_ID=2359 any discussion must include specific parameters.

Since the Agency focuses solely on reducing CO2 the Agency focuses solely on reducing CO2 and not cumulative impacts and other pollutants, harmful technologies like hydrogen combustion technologies and natural gas remain options. Although hydrogen combustion technology may not produce CO2 when combusted, it does produce other pollutants, including nitrogen oxide (NOx) emissions. [EPA-HQ-OAR-2022-0985-1608-A1, p. 38]

Unfortunately, the Agency's proposal does not appropriately take into account the impact hydrogen combustion engines will have on the communities this rule is meant to protect. For example, EPA's proposal accounts for hydrogen ICE vehicles as having zero tailpipe emissions, even though upstream emissions from the production and distribution of hydrogen can be significant. This is particularly concerning because 99 percent of hydrogen is produced from fossil fuels, and only 0.02 percent of hydrogen produced today is green hydrogen (derived from using 100% renewable energy to split hydrogen from water molecules). 91 [EPA-HQ-OAR-2022-0985-1608-A1, p. 38]

91 Sasan Sadaat and Sara Gersen. Reclaiming Hydrogen for a Renewable Future. (August 2021). p. 21-30. https://earthjustice.org/sites/default/files/files/hydrogen_earthjustice_2021.pdf.

Additionally, hydrogen (despite the color; blue, green, etc.) itself can indirectly contribute to greenhouse gas emissions through leakage from within its infrastructure system throughout the various lifecycle stages (e.g., storage, refueling, and transportation stages). According to a 2022 study on the climate consequences of hydrogen leakage, hydrogen leakage may significantly diminish the climate benefits linked to hydrogen. In fact, if leaks are high …fossil-derived hydrogen may initially yield more warming than would the use of the fossil fuel system it replaces. 92 There was a study by the International Council on Clean Transportation (ICCT) that analyzed the life cycle greenhouse gas emissions of hydrogen across eleven hydrogen pathways. This study found that a wide range of carbon intensities exist and also found that some methods have an even greater carbon intensity than diesel fuel (e.g., coal gasification). 93 [EPA-HQ-OAR-2022-0985-1608-A1, p. 38]

92 Ilissa B. Ocko and Steven P. Hamburg. Climate consequences of hydrogen emissions. Atmos. Chem. Phys. V. 22. Iss. 14. p. 9349–9368. (2022). https://doi.org/10.5194/acp-22-9349-2022

93 ICCT. Life Cycle Analysis of Greenhouse Gas Emissions of Hydrogen, and Recommendations for China. (October 19, 2022). https://theicct.org/publication/china-fuels-lca-ghgs-hydrogen-oct22/

EPA should apply the precautionary principle when thinking about compliance pathways and structure this regulation to provide certainty that alternative, safer, and more environmentally friendly and truly zero-emissions options for transportation are applied. A pathway to ensure this could be by incentivization of EVs powered by increasingly renewable electricity. Another such regulatory design strategy is a multipollutant rule which would set vehicle emissions standards not just for greenhouse gas emissions, as proposed, but for NOX and PM2.5 as well. This is the strategy currently deployed by the administration for light- and medium-duty vehicles (88 FR29184-446), and a design for a heavy-duty program easily integrated into the agency's current regulatory structure was presented to EPA as part of the EO 12866 process for the Phase 3 GHG rule. 94 [EPA-HQ-OAR-2022-0985-1608-A1, p. 39]

94 Union of Concerned Scientists. EO 12866 Meeting 2060-AV50. UCS - Multipollutant HDV proposal - 2023-03-15.pdf. (March 15, 2023). https://www.reginfo.gov/public/do/eoDownloadDocument?pubId=&eodoc=true&documentID=213242.

Regardless of the hydrogen fuel type (green, blue, or otherwise), it is clear that combustion-based hydrogen technology allows for direct and unintended consequences and harm to environmental justice communities as a heavy-duty vehicle fuel source. [EPA-HQ-OAR-2022-0985-1608-A1, p. 39]

In addition, it appears that EPA did not account for emissions from petroleum refineries in analyzing the scenarios due to potential uncertainty about refinery behavior due to reduced diesel demand. However, leaving out the potential benefits from reduced demand for diesel (and reduced refining of petroleum producers needed) undercuts the overall emission reduction benefits (and climate and public health benefits) from switching to battery electric trucks on an increasingly cleaner grid. In contrast, emissions from hydrogen that may largely be produced by SMR technologies at refineries (even with the Inflation Reduction Act investments) would also not be captured in EPA's analysis. EPA's assumptions that the historical investments from Congress will lead to a shift to cleaner hydrogen production pathways as well as manufacturer compliance through ZEVs is insufficient, especially since the proposed rule structure doesn't include upstream emissions accounting - which would provide increased certainty that compliance would occur through truly clean technologies. The basis for this assumption alone is wholly insufficient, and the Agency must finalize a version of the rule that appropriately addresses this and discourages compliance by using technologies that will continue to pollute communities and harm the public. [EPA-HQ-OAR-2022-0985-1608-A1, p. 39]

EPA's current, ill-conceived crediting of H 2 ICEVs as 0 g/ton-mile is inconsistent with these vehicles' climate and public health impact, as noted in Section 7.3.2. When fueled by today's dominant source of hydrogen (as identified by EPA, DRIA Figure 1-11), H2 ICEVs have virtually no climate benefit over a Phase 2 diesel vehicle, and there is no public health benefit regardless of the source of the fuel. This suggests that EPA's current regulatory approach to H2 ICEVs is misguided and misaligned with the Agency's requirement under the Clean Air Act to "establish emission standards for air pollutants from new motor vehicles or new motor vehicle engines, which, in the Administrator's judgment, cause or contribute to air pollution that may reasonably be anticipated to endanger public health or welfare." [EPA-HQ-OAR-2022-0985-1608-A1, p. 39]

While we do not support using natural gas as a fuel source, we note that EPA acknowledged the need for an assessment process that could better account for lifecycle impacts. To assess the path forward for H 2 ICEVs, the Agency should consider its approach to natural gas vehicles in Phase 2. In that case, the Agency conducted a thorough lifecycle analysis of CNGVs and LNGVs to assess the full lifecycle harms compared to diesel (Phase 2 FRIA, Chapter 13). EPA then adopted specific test procedures for CNGVs and LNGVs to mitigate the upstream harms from the vehicles (81 FR 73931). Finally, EPA adopted standards that "in essence, applies a one-to-one relationship between fuel efficiency and tailpipe CO2 emissions for all vehicles, including natural gas vehicles" (81 FR 73524). In the case of hydrogen combustion, EPA is now proposing to break with its prior approach. Given the evidence on the lifecycle impacts of H 2 ICEVs, EPA should instead hew to a model that treats energy efficiency of the gaseous fuel equivalently for combustion vehicles. In this way, manufacturers could still submit a fuel map (g/s), and then for certification purposes, the g/s hydrogen would be converted to an energy-equivalent consumption of gasoline or diesel, depending on the intended service class and engine cycle (40 CFR § 1036.140). The CO2 rates for certification would then be based on the rates for the diesel or gasoline-equivalent engine, using the respective CO2 rates for diesel or gasoline. [EPA-HQ-OAR-2022-0985-1608-A1, p. 40]

EPA already allows manufacturers to use fuel flow rate as a determinant in establishing CO2 measurements, so this alteration fits within EPA's well-established Phase 2 test procedures. This would simply adopt a corrective factor for use within GEM for vehicle certification to more accurately reflect the relative emissions impacts of H 2 ICEVs with other combustion-powered vehicles. [EPA-HQ-OAR-2022-0985-1608-A1, p. 40]

To account for tailpipe pollution from combustion vehicles, we have used data traces from the GEM-modeled truck runs to obtain information about engine loads. For today's diesel vehicles, we have largely relied upon the updated MOVES model to reflect the latest real-world information for levels of pollution at different engine operating conditions. For future combustion vehicles, we have accounted for the real-world emissions required under the in-use standards for EPA's latest emissions standards for heavy-duty engines, including additional emissions allowance under the temperature adjustment and interim adjustment. These tailpipe emissions are considered over the average lifetime of the vehicle, accounting for differences in warranty and lifetime requirements for emissions controls but acknowledging, as EPA's MOVES model does, that emissions control equipment is susceptible to tampering and mal-maintenance, particularly outside the mandated warranty period. Obviously, for electric trucks, tailpipe emissions remain zero throughout the vehicle's entire lifetime. To assess upstream emissions from the grid, we use the latest version of EPA's eGRID model (eGRID2021). For future grid emissions, we rely primarily on modeling done by the National Renewable Energy Laboratory (NREL) for its Cambium project. 100 For all sources of energy, we use the latest version of the GREET model to estimate the upstream emissions of all pollutants of concern. 101 [EPA-HQ-OAR-2022-0985-1608-A1, p. 43-44]

7.3. Emissions of gaseous-fuel powered trucks

BEVs are not the only non-diesel technology considered by EPA in the proposed rule—hydrogen is identified as a potential alternative fuel, either through vehicles powered by hydrogen internal combustion engines (H 2 ICEVs) or through fuel cell electric vehicles (FCEVs). Additionally, combustion vehicles powered by compressed methane (compressed natural gas vehicles, or CNGVs) are an alternative considered in the Agency's Phase 2 and Phase 3 rulemakings. [EPA-HQ-OAR-2022-0985-1608-A1, p. 47]

7.3.2. Assessing the impact of hydrogen-powered vehicles

While there are no direct tailpipe emissions from FCEVs, H2 ICEVs emit both NOx and PM2.5 directly. The available data indicate that such engines will need emissions controls (at the very least, exhaust gas recirculation 105) to achieve the required level of emissions for combustion engines finalized last year, just as their diesel counterparts. Thus we assume, as in the case for future diesel vehicles, that direct emissions will exactly achieve the real-world requirements of those standards. [EPA-HQ-OAR-2022-0985-1608-A1, p. 48]

105 Section 7.1.1 in North American Council for Freight Efficiency (NACFE). Hydrogen trucks: Long haul's future? (2023). https://nacfe.org/research/electric-trucks/hydrogen/.

There are additional impacts from hydrogen throughout its life cycle–from creation, storage, transportation, and waste–and those impacts remain uncertain. The infrastructure for developing this fuel is likely to put already overburdened communities at risk based on the historical precedent of other fueling infrastructure. To assess the impacts of hydrogen-fueled trucks, we utilize the default values in GREET, as above, to assess the upstream emissions associated with the production and distribution of hydrogen. [EPA-HQ-OAR-2022-0985-1608-A1, p. 48]

In order to assess the potential harms or benefits of hydrogen-powered trucks, we consider two different possible sources for hydrogen representing the predominant source of hydrogen today, produced from cracked methane gas and a more sustainable form of hydrogen, produced from electrolysis and powered by solar energy. For both of these cases, we have assumed the hydrogen is produced in central plants, which is the dominant method of producing hydrogen today. This hydrogen must then also be compressed and transported for sale. [EPA-HQ-OAR-2022-0985-1608-A1, p. 48]

For efficiency, we assume that H2 ICEVs will achieve the same level of energy efficiency as a Phase 2 diesel truck—while this may be optimistic since the thermal efficiency of an Otto-cycle engine is significantly less than a compressed-ignition engine, the limited data on H 2 ICEVs does seem to indicate this as reasonable. 106 For the efficiency of the fuel cell, we use the vehicle-level efficiency of the BEV (i.e., excluding charger-related losses) and assume a fuel cell efficiency of 60 percent based on data from light-duty FCEVs. 107 [EPA-HQ-OAR-2022-0985-1608-A1, p. 48]

106 Section 7.1.1 in NACFE. (2023).

107 Kurts, J. et al. Fuel cell electric vehicle durability and fuel cell performance. Technical report NREL/TP-5400-73011. (2019). https://www.nrel.gov/docs/fy19osti/73011.pdf.

Greenhouse gas emissions and public health impacts for drayage trucks are summarized in Figure 6. These data make clear that not only does the production method of hydrogen matter, but the type of vehicle in which it is deployed is critical in determining the harms of that fuel. Most importantly, if H2 ICEVs are fueled on hydrogen from natural gas, they would provide virtually no benefit to the climate over a Phase 2-compliant diesel vehicle, and the public health impacts from such a vehicle could actually be worse. Consistent with EPA's approach in Phase 2, CNGVs are found to be roughly comparable to diesel trucks in terms of greenhouse gas emissions. [EPA-HQ-OAR-2022-0985-1608-A1, p. 49] [Refer to Figure 6, Comparison of drayage trucks powered by different fuels on p. 49 of docket number EPA-HQ-OAR-202-1608-A1.]

When it comes to the greenhouse gas emissions from hydrogen-powered trucks, today's dominant form of hydrogen is virtually indistinguishable from diesel: the only climate benefit from FCEVs comes as the result of the substantial improvement in efficiency resulting from an electric powertrain, and for H2 ICEVs there is almost no climate benefit whatsoever over Phase 2. Regarding public health, the adverse impacts of fossil fuel extraction are notable—for H2 ICEVs powered by hydrogen generated from methane, the public health outcomes are actually worse than diesel. Even if hydrogen for these vehicles were made from electrolysis powered by solar energy, the processing steps involved in compressing and distributing the fuel would still yield significant harm such that for an H2 ICEV the direct impacts would be just as harmful as a future diesel truck. The lack of tailpipe emissions and more efficient use of hydrogen mitigate some of these factors in an FCEV, which shows an emissions profile more comparable to a BEV. However, even in an FCEV there is a more than a two-fold increase in harm if the hydrogen is generated from methane as opposed to solar-powered electrolysis. [EPA-HQ-OAR-2022-0985-1608-A1, p. 49]

It is clear from this analysis that H2 ICEVs are no better than diesel trucks when it comes to public health and has no climate benefits over Phase 2 vehicles when fueled by the dominant source of hydrogen today. Their treatment under the Phase 3 program should be comparable to other combustion vehicles rather than vehicles that lack tailpipe emissions (see Section 6.4). [EPA-HQ-OAR-2022-0985-1608-A1, p. 50]

9.1.3. Hydrogen combustion engines

EPA has acknowledged the existence of vehicles powered by hydrogen combustion engines (H2 ICEVs), but the agency has misstated the emissions impacts of these vehicles. As noted earlier, H 2 ICEVs emit PM 2.5, contrary to the Agency's assertion. 123 This is a critical oversight because of the importance of particulate matter with respect to public health. While gaseous H 2 fuel lacks hydrocarbons, there is a significant body of research on hydrogen combustion showing that particulate matter is generated in the combustion process, most likely from the lubricants. 124 In fact, in-cylinder direct injection of hydrogen, which avoids the substantial power losses of pre-cylinder injection and enhances the efficiency of the engine, can lead to even greater PM 2.5 emissions than a gasoline engine. 125 [EPA-HQ-OAR-2022-0985-1608-A1, p. 67]

123 H2–ICE is a technology that produces zero hydrocarbon (HC), carbon monoxide (CO), and CO2 engine-out emissions. 88 Fed. Reg. at 25960.

124 Miller, A.L., et al. Role of lubrication oil in particulate emissions from a hydrogen-powered internal combustion engine. Environ. Sci. Technol. V. 41. No. 19. (2007). p. 6828-6835. https://doi.org/10.1021/es070999r.

125 Thawko, A., and L. Tartakovsky. The mechanism of particle formation in non-premixed hydrogen combustion in a direct-injection internal combustion engine. J. Fuel. V. 327. (2022). p. 125187. https://doi.org/10.1016/j.fuel.2022.125187.

Cummins, the largest engine manufacturer in the United States, has announced plans to bring a direct-injection engine to market in the timeframe of EPA's proposed rule. 126 Yet, the Agency has excluded them from its analysis. As the Agency astutely acknowledges, manufacturers have a predilection towards the deployment of H2 ICEVs: they take advantage of assets that are already being utilized for the production of diesel engines. 88 Fed. Reg. at 25960. As a recent ICCT report shows, H2 ICEVs have a total cost of ownership advantage over FCEVs under low hydrogen prices. Given the clear incumbency advantage for the combustion platform vis-à-vis manufacturers' investments, it is likely that, even under a hydrogen price where FCEVs offered a theoretical TCO advantage, manufacturers may neglect to give purchasers such a choice, particularly when there is no regulatory advantage. [EPA-HQ-OAR-2022-0985-1608-A1, p. 67]

Organization: Northeast States for Coordinated Air Use Management (NESCAUM) and the Ozone Transport Commission (OTC)

Hydrogen Internal Combustion Engines

Hydrogen internal combustion engines are listed as a potential technology for compliance with the GHG standards. We request that EPA further evaluate the disbenefits associated with using hydrogen-fueled ICEs. NOx emissions related to hydrogen combustion should be more fully evaluated prior to finalizing the rule. We note that with the persistent ground-level ozone problems in the Northeast Corridor and other urban areas across the country where on-road transportation emissions dominate the NOx emissions inventory, NOx emissions from hydrogen combustion in ICEs can delay progress towards achieving ozone air quality standards. In addition, hydrogen-fueled ICE vehicles will use considerably more hydrogen than FCEVs and have greater leakage potential of hydrogen within the fueling infrastructure. Because of this, there can be significant issues with hydrogen ICEs related to use of scarce resources of low carbon hydrogen and greater upstream emissions associated with the production and transport of hydrogen. We request EPA evaluate these issues prior to finalizing the rule and institute production caps for hydrogen-fueled ICEs if the issues cannot be fully evaluated.[EPA-HQ-OAR-2022-0985-1562-A1, p. 13-14]

Organization: Westport Fuel Systems

Westport supports the reduction of transportation emissions and is continually working to create products that reduce emissions, especially in hard to decarbonize sectors, such as long-haul heavy-duty applications. We understand the importance of setting standards on CO2 emissions but stress the importance of creating a level playing field and leaving space for a variety of technologies including those that utilize combustion technologies. [EPA-HQ-OAR-2022-0985-1567-A1, p. 1]

Compared to a reference diesel heavy-duty truck, analysis of purely tailpipe CO2 (Tank To Wheel, TTW) yields the expected 100% reduction via FCEV. The H2 HPDI ICE vehicle exhibits very high tailpipe CO2 reductions (93% to 95%) but falls short of the zero tailpipe CO2 metric used in the majority of policies due to the use of small quantities of diesel for ignition, the use of which is fundamental to the high efficiency and power density of H2 HPDI compared to H2 spark ignition ICE. [EPA-HQ-OAR-2022-0985-1567-A1, p.4]

Due to the high efficiency of HPDI, H2 HPDI can deliver equivalent CO2 reductions as fuel cell vehicles, though even with green hydrogen neither technology results in zero CO2 on a Well to Wheel basis including vehicle manufacturing emissions. [EPA-HQ-OAR-2022-0985-1567-A1, p. 4]

While the transition to battery electric vehicles or fuel cell electric may be appropriate in some lighter vehicle classes, it is not yet viable for Class 8 sleeper cabs. Flexibility to acknowledge the benefits of advanced combustion technologies is needed to create space for low emissions vehicles in this segment. In the Rule, the EPA has addressed hydrogen combustion ICEs and has acknowledged CO2 emissions benefits from mono fuel hydrogen engines, however it has not defined the role of Hydrogen ICE technologies that utilize pilot fuel. [EPA-HQ-OAR-2022-0985-1567-A1, p. 5]

To fully recognize the benefits of hydrogen ICE vehicles in reducing heavy duty truck emissions, we propose the following options and their details for consideration and further discussion.

1. Adopt the European Union proposed definition of ZEV, which encompasses hydrogen combustion engines and vehicles.

OR

2. Recognize vehicles with less than 10% energy use as a pilot fuel perform the same as monofuel hydrogen combustion engines and designate them as having zero CO2 emissions.

OR

3. Create a new category for near zero emissions heavy-duty vehicles that are powered by internal combustion engines and pilot fuel of less than 10%. [EPA-HQ-OAR-2022-0985-1567-A1, p. 5]

1. The EU Approach to Hydrogen Combustion Heavy Duty Vehicles

In February 2023, as part of the review of its CO2 Standards for heavy-duty vehicles, the European Commission has proposed the following definition of zero-emission heavy-duty vehicle:

‘zero-emission heavy-duty vehicle’ means a heavy- duty motor vehicle with not more than 5 g/(t.km) or 5 g/(p.km) of CO2 emissions as determined in accordance with Article 9 of Regulation (EU) 2017/2400. [EPA-HQ-OAR-2022-0985-1567-A1, p. 6]

which is a change from the previous limit of 1 g CO2/kWh. This change was proposed because it was found that due to the “heterogenous structure of the total truck fleet”, it wasn’t “possible to fully predict whether for all niche uses, technological developments will be quick enough to ensure that zero-emission tailpipe technology is a viable choice.” The importance of this is to highlight that some flexibility in regulation is being proposed to allow for future technologies that may be needed to accommodate different vehicle types and uses, and that a one size fits all approach may not be in the best interest of reducing overall emissions. This designation also impacts the ability of vehicles to qualify for incentives. [EPA-HQ-OAR-2022-0985-1567-A1, p. 6]

Access to the ZEV label is critical to the customer value proposition. The proposed ZEV definition will provide regulatory and economic support to a wider portfolio of technologies, leading to higher market adoption of high performing, CO2 reducing solutions in the new vehicle market. It offers the potential for heavy-duty vehicles powered by different H2 ICE technologies, including both monofuel hydrogen and H2 HPDI engines, to be considered as ZEV. [EPA-HQ-OAR-2022-0985-1567-A1, p. 6]

For the European market, regulatory approaches are also being developed for the type-approval of hydrogen combustion engines, both monofuel hydrogen and H2 HPDI which is being considered as a type of dual fuel engine “Type 1A” according to UNECE Regulation 49 (R49). This is a specific designation for engine technologies that use less than 10% diesel fuel over parts of the test cycle and do not idle on diesel nor have a diesel operational mode. The operation of H2 HPDI equipped engines share many similarities with that of monofuel, especially in regard to power output being purely determined by control of hydrogen injection. [EPA-HQ-OAR-2022-0985-1567-A1, p. 6]

Table 1 below has been provided to illustrate a comparison of the attributes of a Hydrogen monofuel ICE and H2 HPDI based on an EU analysis on EU vehicle classes but still provides relevant information for the EPA. [EPA-HQ-OAR-2022-0985-1567-A1, p. 6.] [See Docket Number EPA-HQ-OAR-2022-0985-1567-A1, page 7, for Table 1.]

Preliminary testing of the H2 HPDI product has so far been conducted using European engine test cycles and protocols. As Table 1 illustrates, initial testing using European test cycles has estimated that CO2 emissions are reduced by approximately 93% to 95% relative to diesel engines. Tailpipe emissions including aftertreatment are estimated to be 30-40 g/kWh. Of note, the Well to Wheel CO2 reduction relative to diesel is the same as for hydrogen monofuel ICE engines. It is also expected to be very similar to FCEVs. [EPA-HQ-OAR-2022-0985-1567-A1, pp. 6 - 7]

Additional preliminary data has established that the system exhibits attributes that are equivalent or better than monofuel engines in key areas, such as higher efficiency, power density and equivalent well to wheel CO2 reductions as monofuel engines (the higher efficiency of H2 HPDI compensates for the WTW CO2 impacts of the pilot fuel). [EPA-HQ-OAR-2022-0985-1567-A1, p. 7]

Going back to the EPA Rule, Westport estimates that on average vehicles equipped with the H2 HPDI system will be more that 90% lower than the MY 2032 fleet target for the Class 8 vehicle class as illustrated in the proposed rule. Further testing using appropriate US test cycles must be conducted for more accurate results. [EPA-HQ-OAR-2022-0985-1567-A1, p. 7]

2. Recognize Hydrogen ICE Vehicles with less than 10% Pilot Fuels as Zero CO2 Emissions in the Same Way As Monofuel Hydrogen ICE [EPA-HQ-OAR-2022-0985-1567-A1, p. 8]

The EPA in the Phase 3 Rule has addressed the development of mono fuel hydrogen combustion technologies but has not provided a pathway for evaluating other combustion technologies such as those that use pilot fuels. [EPA-HQ-OAR-2022-0985-1567-A1, p. 8]

In the Rule, monofuel hydrogen combustion engines using “neat’ hydrogen are considered to have no engine out emissions and it is being proposed that their tailpipe emissions are “deemed to be zero” for CO24. Westport proposes that this treatment be extended to other hydrogen combustion technologies including those with pilot fuels of 10% or less. [EPA-HQ-OAR-2022-0985-1567-A1, p. 8]

4 See: Phase 3 Proposed Rule, page 26022, section ii. Vehicles With Engines Using Fuels Other than Carbon Containing Fuels and page 25958, Section II, D.1. Technologies to Reduce GHG Emissions From HD Vehicles With ICEs

Given the low emissions expected from H2 HPDI, as illustrated by preliminary results in Table 1 above, it would be reasonable to also consider it as a monofuel (zero CO2) vehicle given the pilot fuel energy used is less than 10% and does not significantly impact CO2 emissions. Remaining combustion emissions are dealt with through aftertreatment systems. [EPA-HQ-OAR-2022-0985-1567-A1, p. 8]

3. Work with Other Agencies to Create a Near Zero Emissions Technology Category for Hydrogen ICEs with Pilot Fuel for the Class 8 Segment [EPA-HQ-OAR-2022-0985-1567-A1, p. 8]

In response to providing feedback that emissions should be less stringent for some market segments where high energy content is needed for certain applications, we urge the EPA to consider the benefits of creating a new class of emission reducing vehicles, "near zero emissions technologies", which would include hydrogen internal combustion engines with diesel pilot to be considered on par with Zero Emissions Vehicles in the Class 8 segment. Broadening the ZEV definition to create a "carve out" for specific vehicle segments such as Class 8, where few options are available until 2032 (25% deployment rate) will allow more technologies with very low CO2 emissions to be recognized as viable technologies in other regulatory and legislative incentive programs (like those implemented by CARB and the IRA) that Phase 3 helps to inform. This action could accelerate the transition of these heavy fuel users away from diesel fuel faster than the proposed timeline of 2030 where EPA shows a 10% adoption rate and 2030 with a 25% rate in this segment. These targets if accurate still leave the remainder of vehicles in this class (75%+) using non-ZEV technologies in 2032. [EPA-HQ-OAR-2022-0985-1567-A1, p. 8]

The H2 HPDI system, having less than 10% diesel, contributes nominally to CO2 emissions. Westport has longer term plans to further reduce the percentage of pilot fuel over time. [EPA-HQ-OAR-2022-0985-1567-A1, p. 9]

The EPA has proposed the introduction of "Neat" hydrogen monofuel vehicles and has combined dual fuel (mixed fuels that contain carbon) and pilot diesel engines5 to determine test procedures. [EPA-HQ-OAR-2022-0985-1567-A1, p. 9]

5 See: Phase 3 Proposed Rule, page 26021, xi. Updates to 40 CFR Part 1036 definitions.

Pilot diesel ignition, such as used in the H2 HPDI is less than 10% of fuel use and thus CO2 and criteria emissions are substantially lower than a diesel ICE vehicle or a traditional dual fuel vehicle. HPDI technology uses diesel for ignition only and it is not mixed with hydrogen as a blend. The CO2 emissions resulting from pilot ignition is considered nominal overall. H2 HPDI cannot operate on diesel fuel alone at any time other than service mode. [EPA-HQ-OAR-2022-0985-1567-A1, p. 9]

Future testing on a full U.S. cycle with mixed loads will be needed to further optimize the system. However, in the interim period before 2032, any technology with at least 90 % reductions in CO2 emissions should be recognized as contributing significantly to emissions reductions efforts and should be considered as near zero. A similar approach was adopted by California relating to low NOx engines, which were given consideration as "near zero" NOx and had access to deployment incentives. Access to incentives has been a key factor in the deployment of all alternative technologies in many markets. [EPA-HQ-OAR-2022-0985-1567-A1, p. 9]

The EPA has already recognized that H2 ICE engines share similar components and can leverage existing manufacturing capabilities and supply chains to produce these products, in addition requiring simpler and smaller aftertreatment systems.6 More hydrogen powered vehicles will also help to build out fuelling infrastructure. [EPA-HQ-OAR-2022-0985-1567-A1, p. 9]

6 See: Phase 3 Proposed Rule, page 25960, Section II, D.1. Technologies to Reduce GHG Emissions From HD Vehicles With ICEs

H2 HPDI has the potential to be production-ready and deployed relatively quickly, given natural gas versions of this technology are commercially available in Europe today. The emissions reduction potential of this technology can be realized sooner than 2030 when EPA projections estimate a ZEV adoption rate of 10% of vehicles in sleeper cab tractors with 15% in 2031 and 25% in 2032. [EPA-HQ-OAR-2022-0985-1567-A1, p. 10]

Development of a US Test Protocol for Pilot Ignited Engines such as H2 HPDI

We encourage the EPA to engage in further discussions and analysis on the benefits of Hydrogen combustion technologies and develop a test protocol for the type approval of pilot ignited engines such as H2 HPDI. [EPA-HQ-OAR-2022-0985-1567-A1, p. 10]

The EPA has proposed changes to engine test procedures 40 CFR part 1037 for certain highway heavy duty engines in 40 CFR parts 1036 and 1065. To our knowledge, there are currently no test procedures for a product like H2 HPDI. As mentioned earlier, in the EU there is a task force focused on H2 ICE, including H2 pilot ignited hydrogen CI engines, to aid in the development of procedures for testing hydrogen combustion engines. It is important to have applicable testing procedures and protocols specifically for hydrogen combustion that recognize that testing is different from procedures established for natural gas or diesel engines and vehicles. In addition, guidelines for equipment may need to be established, because the same equipment used in testing procedures for diesel and natural gas may not be sensitive enough to detect the low emissions produced by hydrogen combustion. In absence of a test procedure, it may not be possible to homologate and commercialize engines equipped with an H2 HPDI fuel system. [EPA-HQ-OAR-2022-0985-1567-A1, p. 10]

EPA Summary and Response:

Summary:

AVE, API, BorgWarner, DTNA, MECA, MEMA, and Westport Fuel Systems commented in support of the changes to 40 1036.150(f) and 40 1037.150(f) deeming CO2 emissions zero for engines fueled with neat hydrogen. In addition, some commenters stated that EPA did not go far enough to support H2-ICE and should deem CO2 emissions zero for engines fueled with neat hydrogen that also have a diesel pilot. These comments included comments from DTNA that we should follow the EU framework, that defines a CO2 emissions level to qualify the engines are deemed to be zero CO2. Westport Fuel Systems commented that engines with less than 10% energy coming from carbon -containing fuels also should be deemed to be zero.

Westport also commented that access to the ZEV label is critical to the customer value proposition. Westport also commented that they are not aware of any test procedures for a product like H2 HPDI (high pressure direct injection).

MEMA supports including H2ICE as a technology with zero CO2 emissions and suggested that EPA add an H2-ICE credit multiplier, similar to FCEV. MEMA also requested that EPA “encourage CARB” to include H2ICE in its regulatory program.

DTNA commented that standards should not be based on the use of H2-ICE, since there is too much uncertainty on the adoption of H2-ICE.

DTNA comments included specific changes to the Deterioration Factor (DF) and On Board Diagnostic (OBD) requirements for H2-ICE. For DF the commenter requested EPA allow manufacturers to attest to durability and useful life requirements, that EPA assigned the DF for criteria pollutants, and that EPA revise our regulations to include a reduced useful life standard.

For OBD, DTNA commented that EPA should simplified the OBD requirements in 40 CFR 1036.110. They suggest that EPA could reduce this burden by requiring the OBD system only to detect circuit faults and failed actuators, and avoid requirements for threshold diagnostics and rationality checks. DNTA also commented that EPA should allow manufacturers to propose an alternate monitoring plan for H2-ICE engines.

CARB and MFN commented that they do not support treating H2-ICE as zero emissions technology.

EDF commented that even if EPA considers H2-ICE vehicles as a carbon-free technology, they should not be considered a full ZEV.

CARB commented that including H2 ICE as ZEVs for GHGs even though they're not ZEVs for criteria pollutants, could become a default option, which is not great for California. CARB also commented that hydrogen engines are less efficient than FCEVs which could have upstream impacts. CARB commented that EPA should consider requiring fuel maps for H2-ICE to allow for tracking of hydrogen production. CARB commented that EPA consider production caps for H2-ICE that are deemed to have zero CO2 emissions.

MFN doesn't support treating H2-ICE as zero emissions technology. MFN commented that hydrogen itself can indirectly contribute to greenhouse gas emissions through leakage from within its infrastructure system and throughout the various lifecycle stages (e.g., storage, refueling, and transportation stages). With further regard to lifecycle emission impacts, MFN notes that 99 percent of hydrogen is produced from fossil fuels, and only 0.02 percent of hydrogen produced today is green hydrogen (derived from using 100% renewable energy to split hydrogen from water molecules). MFN goes on to cite an ICCT study that analyzed the life cycle greenhouse gas emissions of hydrogen across eleven hydrogen pathways. MFN states that this study found that a wide range of carbon intensities exist and also found that some methods have an even greater carbon intensity than diesel fuel (e.g., coal gasification). See ICCT. Life Cycle Analysis of Greenhouse Gas Emissions of Hydrogen, and Recommendations for China. (October 19, 2022). https://theicct.org/publication/china-fuels-lca-ghgs-hydrogen-oct22/. . MFN further indicated that Steam Methane Reforming – i.e., using fossil fuels to generate hydrogen – is high GHG emitting and that EPA's assumptions that IRA incentives would result in so-called green hydrogen (MFN's terminology) are overly sanguine. MFN commented that EPA acknowledged the need for an assessment process that could better account for lifecycle impacts of natural gas and commented that to assess the path forward for H2 ICEVs, the Agency should consider its approach to controlling refueling and evaporative emissions from natural gas vehicles in Phase 2.

NESCAUM commented that hydrogen-fueled ICE vehicles will use considerably more hydrogen than FCEVs and have greater leakage potential of hydrogen within the fueling infrastructure. NESCAUM commented that because of this, there can be significant issues with hydrogen ICEs related to use of scarce resources of low carbon hydrogen and greater upstream emissions associated with the production and transport of hydrogen. ACEEE noted that H2-ICEVs have modest efficiency advantages at best. They believe the zero-upstream incentive is inappropriate since benefits are largely based on the carbon intensity of the hydrogen, not to mention the NOx. They suggest that low-carbon hydrogen-fueled vehicles are best incentivized through performance-based standards.

Response:

As explained in Preamble Sections I and II and RTC Section 2, the final standards can be met in any manner a regulated entity (i.e. manufacturer) sees fit that achieves compliance with that numerical standard. In assessing a modeled potential compliance pathway that includes a technology mix of ICE vehicle technologies and ZEV technologies, EPA was demonstrating that the final standards were feasible and appropriate; EPA was not requiring that manufacturers utilize that modeled potential compliance pathway. In fact, as discussed in Preamble Section II.F.4, we have assessed additional example potential compliance pathways that support the feasibility of the final standards, which include a suite of technologies ranging from ICE engine, transmission, drivetrain, aerodynamics, and tire rolling resistance improvements, to the use of low carbon fuels like CNG and LNG, to hybrid powertrains (HEV and PHEV) and H2-ICE. See also responses in RTC 9.1 and 2.1 further responding to the explicit or implicit incorrect assertion that the Phase 3 rule mandates use of ZEVs. Thus. OEMs have many different potential technology mixes that can utilize to achieve compliance with the final Phase 3 standards, including a mix of technologies that includes H2-ICE. Regarding NOx emissions from H2-ICE, the HD 2027 Low NOx Rulemaking set NOx and other criteria pollutant standards (40 CFR 1036.104) that all HD engines must meet. Manufacturers of H2-ICE will be required to demonstrate that the engines meet the part 1036 standards, including the criteria pollutant standards set in the HD2027 final rule, and thus H2ICE engines will be required to be equipped with advanced emissions control devices for both PM and NOx.

Several comments, notably MFN's, stressed the potential adverse environmental implications of H2 ICE vehicles if upstream emissions are taken into account and hydrogen production is fossil fuel based. EPA is reasonably projecting that the IRA will work as intended in incentivizing the production of clean hydrogen. Additionally, we have conducted a comparative analysis of the potential impacts of various hydrogen production methods in our assessment of emissions impacts of the Phase 3 rule. More specifically, our emissions inventory modeling assumes that hydrogen fuel produced for the HD FCEVs in our modeled potential compliance pathway would be produced via grid electrolysis as a simplifying assumption.[662] To further analyze the environmental implications of future methods of hydrogen production, for the FRM, we also performed a comparative analysis to assess how emissions between multiple alternative hydrogen production pathways could compare. RIA Chapter 4.8. We concluded that "[r]elative to the emission inventory impacts presented earlier in this chapter…, we therefore expect that an emission inventory impacts analysis which assumes more hydrogen produced via SMR to estimate decreased upstream GHG emissions in earlier years and increased upstream GHG emissions in further out years. Given that these are offsetting trends and given the uncertainty inherent in projecting how the hydrogen needed to fuel FCEVs will be produced, we feel that our modeling assumption that all hydrogen will be produced via grid electrolysis does not meaningfully skew the overall GHG emission inventory impacts attributable to the final standards."

[662] *See* RIA Chapter 4.3.

We disagree with CARB's comment that EPA should consider requiring fuel maps for H2-ICE to allow for tracking of hydrogen production, as at this time our assessment is that there are more direct ways to track hydrogen production for use in vehicles. As for setting production caps for H2-ICE that are deemed to have zero CO2 emissions, we are finalizing performance-based standards for CO_2 and so disagree with an approach that would limit a particular technology beyond meeting such performance-based standards.

Regarding the various comments that upstream emissions associated with hydrogen production should be reflected in the standards themselves, as opposed to emissions modeling for assessing the impacts of the final rule, please see our response to comments on life cycle assessment in RTC 17.1. We also note that we disagree with any assertion that we should treat only H2 ICE technology differently for purposes of assessing lifecycle emissions.

Regarding comments on hydrogen leakage, commenters did not provide data and we do not have data on the leakage rate of FCEVs versus H2-ICEVs.

Regarding the comment from Westport on labeling vehicles with H2 ICEs, we are finalizing performance-based standards, not setting a ZEV mandate, and we are not defining the term ZEV in 40 CFR 1037. Regarding the comments on available test procedures for H2 HPDI engines, we are finalizing changes to 1065 to address this issue. See Preamble Section III.C.5 for more information on engine testing and certification with fuels other than carbon-containing fuels.

Regarding comments that H2-ICE is not as efficient, with respect to hydrogen use, as a FCEV, we reiterate that the Phase 3 GHG standards are CO2 vehicle exhaust emission standards. We acknowledge that a recent study by FEV identified that a Class 8 tractor with a 500-mile range using an H2-ICE powertrain would use 84 kg of H2 while a fuel cell electric vehicle would use 77 kg of H2. We account for the difference in efficiency between FCEVs and vehicles with H2-ICEs in our assessment of H2-ICE vehicles, as described in RIA Chapter 2.11.

We disagree with the comments that EPA should encourage H2-ICE that are also fueled with a carbon containing fuel by deeming CO_2 emissions from these engines to be zero. As with the EU proposal and the proposal from Westport Fuel systems, this designation would need to be based on results from testing. For example, we cannot determine that an engine will have CO_2 emission below a certain threshold or have less than 10% of its fuel come from carbon containing fuels without testing that engine. In addition, the final changes to 40 CFR 1036.150(f) and 40 CFR 1037.150(f) are not defining these H2-ICE engines/vehicles that use neat hydrogen as zero emissions engines/vehicles, but rather are providing an option for manufacturers to be exempt from testing these engines/vehicles for certain pollutants. As explained in Preamble Section III.C, this testing exemption for certain pollutants can be clearly defined for engines that use neat hydrogen, as the fuel does not contain carbon (e.g., zero engine-out CO2 emissions). Finally, the test procedures in 40 CFR 1036, 40 CFR 1037, and 40 CFR 1065 define how to test engines that are fueled with a mix of hydrogen and carbon containing fuels, so the test procedures provide a pathway for the CO_2 reduction from these engines to be credited at certification. EPA's approach of deeming emissions for certain pollutants at a specific level is reasonably reserved for technologies where it is clear, without additional testing, that the emissions are zero or near zero.

We disagree with the comment from MEMA that an advanced technology credit multiplier should apply to H2-ICE. As noted in Section III.A.2 of the final rule preamble, the proposal regarding Phase 2's credit multipliers was limited to evaluating whether to end their existing Phase 2 phase out date earlier or leave existing end date in place. We did not propose or request comment on extending credit multipliers to apply for other technologies under the Phase 2 program (and did not reopen that aspect of the Phase 2 multipliers) and did not propose or request comment on including credit multipliers as part of the Phase 3 program for any technology. Thus, these comments requesting new multipliers are out of scope for this final rule.

Regarding the comment from DTNA that the standards should not be based on the use of H2-ICE technology in addition to ZEV technologies included in the proposals compliance pathway to support the feasibility of the Phase 3 standards, please see our response in RTC Section 9.2 regarding the stringency of the final performance-based standards. See also RIA I and Preamble Section II regarding our assessment of H2-ICE technology in supporting the feasibility of the Phase 3 final standards.

Comments from DTNA that the DF and OBD requirements should be streamlined/reduced for H2-ICE are outside the scope of this final rule, however we also note that we disagree. Both the DF and OBD requirements are in place for engines to ensure that engines meet the criteria pollutant standards in 40 CFR 1036. Specifically, the DF requirements provide a means for manufacturers to demonstrate that the emissions standards will be met through useful life. The OBD requirements are in place such that malfunctions in the emissions control systems are detected and fixed quickly. As mentioned by other commenters, even H2-ICE that use neat hydrogen do emit certain pollutants, including but not limited to NOx and PM, so the requirements in 40 CFR 1036 remain critical for their intended purposes. The comments that EPA should reduce the useful life for H2-ICE are out of scope as we didn't propose or request comment on any changes to the useful life for engines under the emissions standards in 40 CFR 1036.

For addition information on the final changes to 40 CFR 1036.150(f) and 40 CFR 1037.150(f), see Preamble Section III.C.2.xviii and Section III.C.3.ii, respectively.

9.4 Other Technologies

Comments by Organizations

Organization: American Chemistry Council Fuel Additives Task Group (FATG)

The FATG supports EPA's recognition that multiple technologies can lead to a reduction in greenhouse gas emissions and supports the use of performance-based standards. The longevity of the internal combustion engines (ICE) of the current commercial fleets means that they, and carbon-based liquid fuels, will continue to play an important role in the transportation needs of the United States. There is ongoing research to continue to improve the thermal efficiency of diesel internal combustion engines3. There is also an increasing diversity of fuels in the distillate market and biobased and renewable fuels are growing in usage to help reduce the carbon intensity of the fuel pool. Fuel additives have and will continue to play a vital role in the optimization of the fuel and engine system combination with the aim of reducing carbon emissions. [EPA-HQ-OAR-2022-0985-1573-A1, p. 1]

3 DOE, "The Road Ahead Toward a Net-Zero-Carbon Transportation Future" Co-Optima Findings and Impact FY15-FY21. link

Fuel Additive Benefits

Fuel additives provide benefits to the environment and the consumer4. Additive technologies help enhance desired performance capabilities and suppress undesirable properties in fuel, which in turn leads to improved function and performance. Diesel additives have been used for almost 100 years at all points in the diesel distribution system, from the refinery, through pipelines and terminals, to the distributors, fleets, and aftermarket end users. These additives allow fuel producers, distributors, and marketers to not only meet certain basic specification requirements5 for engines, but also to provide additional protection to critical distribution and vehicle components, and to improve the overall performance of the fuel powering the diesel engine. [EPA-HQ-OAR-2022-0985-1573-A1, pp. 1 - 2]

4 Additive Technical Committee, “Fuel Additives: Use and Benefits,” Document 113, September 2013. link

5 For example ASTM D975, EN590.

The most common performance-enhancing additives for diesel and biomass based diesel and blends currently used in the United States include cold flow improvers, lubricity improvers, injector, and fuel system detergents6.

- In regions with low winter temperatures, cold flow improvers help with pour point and filter blocking issues associated with all fuels and blends.
- Refineries employ corrosion inhibitors to help protect storage tanks and pipelines against corrosion to prevent asset leakage during transport, lubricity improvers to help protect engine components against wear, and conductivity improvers to help safely move fuel through the supply chain minimizing risk of Static Discharge Ignition.
- Diesel detergents can help avoid deposits during normal operation of equipment associated with diesel and renewable duels. [EPA-HQ-OAR-2022-0985-1573-A1, p. 2]

6 ACC FATG, “FATG Diesel Additives and Fuel Issues.” 2018. link

Fuel additives help to optimize the functional efficiency of the internal combustion engine leading to the reduction of fuel consumption. Often, additive suppliers combine these and other components into customized multi-functional diesel additive packages in order to simplify additives injection and storage needs. [EPA-HQ-OAR-2022-0985-1573-A1, p. 2]

Organization: American Chemistry Council Product Approval Protocol Task Group (PAPTG)

Engine and driveline lubricants are an important component of heavy duty vehicle design and have been demonstrated to impact fuel economy and durability performance. To help ensure that vehicle performance remains as close to the design and certification level as possible, ACC suggests that EPA include language in the proposed standard which recognizes and highlights the importance of using the appropriate OEM or industry certified lubricants in factory fill and service fill (aftermarket) applications. [EPA-HQ-OAR-2022-0985-1574-A1, p. 1]

Organization: Lubrizol Corporation (Lubrizol)

Each of the Blueprint’s strategies can yield extremely low-carbon performance. However, the lifecycle emissions of each technology should be considered and integrated into the Final Rule. We are concerned about the unintended consequences of a “tailpipe-only” approach that neglects upstream emissions and other emissions impacts of future engines and vehicles. Our concern is equally valid, whether the technology is an ICE vehicle operating on petroleum diesel, an ICE vehicle operating on a SLF, an ICE vehicle operating on hydrogen, a battery-electric vehicle, or fuel cell vehicle. The end goal should be a heavy-duty vehicle market that emits as few GHGs as possible, on a lifecycle basis. [EPA-HQ-OAR-2022-0985-1651-A2, p. 2]

As we have noted in our comments on prior EPA rule-makings, Lubrizol remains concerned about real-world, in-use emission levels over the full useful life of the engines and vehicles we serve. We encourage EPA to include provisions in the Final Rule that will help ensure that the appropriate fuel additives and lubricants are used throughout the useful life of future engines and vehicles that will be manufactured to meet the requirement of the Final Rule in years to come. [EPA-HQ-OAR-2022-0985-1651-A2, p. 3]

1) The Final Rule Should Help Ensure that the Highest Quality Lubricants Are Used Throughout Useful Life

Lubrizol is committed to ensuring that OEMs have the engine, axle, and transmission lubricants and oils that they will need to ensure that their engines will meet the final Phase 3 GHG standards, both for certification purposes and throughout their useful life. [EPA-HQ-OAR-2022-0985-1651-A2, p. 3]

Compared with prior generations of internal combustion engines (“IC engines”), future IC engines will operate with extremely high temperatures, high pressure, high shear, and other extremely sensitive operating environments. In order to operate efficiently, durably, and with low emissions, these IC engines will need to use the appropriate engine oil or lubricant at all times throughout their useful life. [EPA-HQ-OAR-2022-0985-1651-A2, p. 3]

Using the wrong lubricant can impact the engine’s performance and durability, as well as the performance and durability of the vehicle’s emissions control systems and Emissions-Related Components.4 Numerous studies have been done in the past that highlighted the relationship between lubricant composition and emission system durability. It can be expected that lubricant compatibility will become even more important when the next generation of emission control systems and Emissions-Related Components is deployed to meet the Phase 3 GHG standards, especially in combination with the new NOx standards that will be in place, starting in MY 2027. [EPA-HQ-OAR-2022-0985-1651-A2, p. 3]

4 The list of “Emissions-Related Components” is contained in 40 C.F.R. Park 1068, Appendix I.

Under Section 207 of the Clean Air Act, OEMs are required to provide emissions-related warranties.5 These warranties are typically limited to the Emissions-Related Components that are listed in 40 C.F.R. Part 1068, Appendix I. However, using the appropriate lubricant or oil is critical to the performance of many of the components on the Appendix I list.6 Thus, while we recognize that these warranties would not require specific oils or lubricants to be used, we do believe that OEMs can and should require their customers to use the same or higher quality oil or lubricant that was used by the OEM in its certification testing as part of their warranty requirements to protect their Emissions-Related Components. This can be accomplished by adding lubricants or engine oils to the list of covered components in the proposed new language for 40 C.F.R. Section 1037.120(c).7 Indeed, the new language directs emission-related warranties to covers other added emission-related components to the extent they are included in an OEM’s application for certification, as well as any other components whose failure would increase a vehicle's CO_2 emissions. Because the use of a sub-standard lubricant or engine oil would deviate from the lubricant or oil used in the OEM's certification application and could lead to increased CO_2 emissions, it should not be allowed to be used under the OEM's emissions-related warranties. [EPA-HQ-OAR-2022-0985-1651-A2, pp. 3 - 4.]

5 Proposal at 25949, citing 42 U.S.C. 7541.

6 Appendix A to these comments provides a list of references to studies that review the impact of lubricants and oils on the performance of various emission control technologies and "Emission-Related Components." [See Docket Number EPA-HQ-OAR-2022-0985-1651-A2, pages 8-9, for Appendix A.]

7 Proposal at 26124-26125. "The emission-related warranty also covers other added emission-related components to the extent they are included in your application for certification, and any other components whose failure would increase a vehicle's CO_2 emissions."

Lubrizol strongly urges EPA to include language in the Final Rule that will achieve this goal. For example, EPA could require emissions-related warranties to include regular service intervals for oil changes, as well as require that engines are consistently using the appropriate higher-performing lubricant oil for each particular engine - at all times throughout its useful life. Such specified lubricants would provide the engine with the appropriate level of performance, engine protection, and protection of emission control technology, according to objective characteristics as determined by the OEMs. These characteristics could be in the form of an OEM performance specification or an industry category defined by an entity like the American Petroleum Institute (API) or the European Automobile Manufacturers' Association (ACEA), along with a maximum viscosity level. (As we have stated in previous comment letters, and to be clear, Lubrizol does not suggest that EPA should specify particular lubricant brands or servicing locations as a warranty requirement.) [EPA-HQ-OAR-2022-0985-1651-A2, p. 4]

OEMs already use these higher performing lubricants in the development and certification of their powertrain systems. They rely on them to demonstrate that their engines will meet EPA's requirements throughout the full useful life of their engines and emissions systems. By requiring OEMs to take steps to ensure that the same category and maximum viscosity level that is used for certification and initial fill is used when the vehicle is serviced to maintain vehicle powertrains, engines, emission control technologies, and Emissions-Related Components," EPA will help ensure that engines maintain their emissions durability throughout their useful life, thereby helping to ensure that real world emissions remain at the levels EPA seeks to achieve in the Final Rule. [EPA-HQ-OAR-2022-0985-1651-A2, p. 4]

In addition, Lubrizol urges EPA to require OEMs to communicate important maintenance information related to engine oils and lubricants to their customers in three ways. [EPA-HQ-OAR-2022-0985-1651-A2, p. 4]

First, EPA should require OEMs to include maintenance information related to engine oils and lubricants in their owner's manuals. The owner's manual is relied upon by heavy-duty vehicle owners or operators to describe appropriate engine maintenance, applicable warranties, and any other information related to operating or maintaining the engine or vehicle. By requiring information about the minimum lubricant and oil performance specifications in the owner's manual, EPA will be taking an important step towards reducing mal-maintenance, better service experiences for independent repair technicians, specialized repair technicians, owners who repair their own equipment, and possibly vehicle inspection and maintenance technicians. Most important, we believe that this step will provide greater assurance of long-term in-use emission reductions by reducing likelihood of occurrences of tampering. [EPA-HQ-OAR-2022-0985-1651-A2, pp. 4 - 5]

Second, Lubrizol urges EPA to require lubricant specification information on an engine label that is placed at the appropriate place in the engine compartment. The agency has had similar requirements in the past, such as when EPA required vacuum hose diagrams to be included on the emission labels. [EPA-HQ-OAR-2022-0985-1651-A2, p. 5]

Third, both the owner's manual and engine label should include an internet link that would enable owners or operators to obtain this information online. For example, manufacturers could include a Quick Response Code or "QR Code" in the owner's manual and on the emission label that would direct repair technicians, owners, and inspection and maintenance facilities to a website which provides critical emissions systems information at no cost. This information should include engine-specific lubricant requirements, including the recommended lubricant, service intervals, and other relevant information that is necessary to ensure that the correct high-performing lubricant is used throughout the engine's useful life. Providing this information will help ensure that the engine and emissions control systems are adequately protected during all modes of operation throughout their useful lives. [EPA-HQ-OAR-2022-0985-1651-A2, p. 5]

Organization: Odyne Systems LLC

Odyne supports efforts by the EPA to reduce medium and heavy-duty vehicle GHG emissions. [EPA-HQ-OAR-2022-0985-1623-A1, p. 1]

Ensure delegated assembly can be used to transfer credits to truck chassis OEMs by intermediate or final stage manufacturers that install emissions reduction components and systems, such as PHEV and ePTO systems.

Trucks are built in a multi-stage manufacturing process. Chassis manufacturers may not be aware of the final application or truck configuration when the truck is built initially, making it difficult to know whether to install an ePTO. Later in the vehicle manufacturing process, after the application has been determined, intermediate-stage or final-stage manufacturers may install ePTO or PHEV systems that reduce GHGs. To encourage the installation of ePTO and PHEV systems on incomplete vehicles at other vehicle manufacturing stages, the regulatory benefits for those systems need to accrue to the chassis OEM through delegated assembly provisions or some other method. [EPA-HQ-OAR-2022-0985-1623-A1, p. 3]

Ensure that testing requirements for ePTO systems are effective and streamlined to encourage greater use of ePTO technology. Streamlined, effective, and affordable verification requirements will help ePTO system manufacturers sell systems enabling trucks to meet more stringent GHG regulations. Required test procedures that are too expensive, narrow, or complex can unnecessarily impede the sale and use of effective emission-reducing products for trucks. [EPA-HQ-OAR-2022-0985-1623-A1, p. 4]

Increase credits for ePTO systems that reduce GHG and NOx emissions over a wider variety of use cases and duty cycles.

Electric power take-off systems that reduce emissions over a wider variety of use cases and duty cycles should be given greater regulatory benefit over less capable systems. Specifically, charge-depleting ePTO systems that also reduce emissions through hybrid ePTO operation once batteries become depleted should be given greater regulatory credit than systems that don't effectively function if not plugged in or if batteries become depleted. Some ePTO systems will not provide GHG reductions if not plugged in or if batteries need recharging in the field due to depletion from atypically large amounts of energy use at worksites or extended mutual aid events where the grid is unavailable. [EPA-HQ-OAR-2022-0985-1623-A1, p. 4]

Organization: Volvo Group

NOx regulation impacts on engine greenhouse gas emissions

With respect to the engine standards, EPA's stringency setting for the 2027 model year did not provide any consideration for EPA's new NOx standards within the Clean Trucks Plan finalized in December of last year. This regulation includes an 82.5% greater stringency in NOx in 2027 in addition to increased useful life and warranty periods, resulting in the need to provide a significantly higher margin on certified engine levels to meet those extended useful life periods. [EPA-HQ-OAR-2022-0985-1606-A1, p. 14]

Reductions in NOx have a direct impact on greenhouse gas emissions for compression ignition combustion engine technology. NOx can be mitigated with on-engine technologies or aftertreatment devices. Engine based NOx reduction is achieved by reducing peak temperature during combustion, inherently less efficient combustion by modifying fueling such as retarding timing or increasing exhaust gas recirculation. Aftertreatment systems have grown in volume significantly also, requiring advanced reductant mixing geometries and complex packaging, all increasing exhaust backpressure which further decreases engine efficiency. Additionally, the aftertreatment system must be warmed to enable chemical reactions to reduce NOx, and the warming of the catalyst via any means requires fuel energy. [EPA-HQ-OAR-2022-0985-1606-A1, p. 14]

The key technology required to achieve 2027 NOx emission levels could increase actual fuel consumption up to 25% for some applications, with vehicles in all applications experiencing some level of increased fuel consumption. Today's diesel engines are very advanced in technology and further refinements are planned. However, many OEMs are approaching 50% brake thermally efficient capable engines and are near the theoretical limit of the capabilities of a combustion engine. Therefore, any further engine specific requests for reduction in greenhouse gas emissions or increase in fuel economy will not be reliable, cost effective or even theoretically possible if we maintain the requirement to comply with ultra-low NOx emission requirements. [EPA-HQ-OAR-2022-0985-1606-A1, p. 14]

In summation, Volvo Group firmly supports EPA's proposal not to promulgate additional engine standards beyond the 2027 model year standards finalized with Phase 2. We believe this is justified given the Clean Trucks Plan's significant impact on fuel economy and greenhouse gas performance that will need to be clawed back just to meet the Phase 2 MY 2027 National Highway Traffic Safety Administration (NHTSA) and EPA fuel economy (FE) and greenhouse gas standards. Additionally, as the Phase 2 and proposed Phase 3 benefits are calculated solely on a complete vehicle level, separate engine standards provide no additional benefit; rather they artificially inflate costs and unreliability by forcing technologies onto the engine, as opposed to allowing manufacturers to utilize potentially lower cost and risk technologies on the vehicle that provide the same, or greater benefit. [EPA-HQ-OAR-2022-0985-1606-A1, p. 14-15]

EPA Summary and Response:

Summary:

A number of commenters noted the importance of fuel additives and high quality lubricants to the performance of both ICE and ZEV vehicles. (American Chemistry Council Fuel Additives Task Force, American Chemical Council Product Approval). Lubrizol made the same points, but offered detailed suggestions of how use of high quality lubricants could be incorporated into the commercial, and potentially regulatory, warranty process. Specifically,

"Under Section 207 of the Clean Air Act, OEMs are required to provide emissions-related warranties.5 These warranties are typically limited to the Emissions-Related Components that are listed in 40 C.F.R. Part 1068, Appendix I. However, using the appropriate lubricant or oil is critical to the performance of many of the components on the Appendix I list. Thus, while we recognize that these warranties would not require specific oils or lubricants to be used, we do believe that OEMs can and should require their customers to use the same or higher quality oil or lubricant that was used by the OEM in its certification testing as part of their warranty requirements to protect their Emissions-Related Components. This can be accomplished by adding lubricants or engine oils to the list of covered components in the proposed new language for 40 C.F.R. Section 1037.120(c)… Because the use of a sub-standard lubricant or engine oil would deviate from the lubricant or oil used in the OEM's certification application and could lead to increased CO2 emissions, it should not be allowed to be used under the OEM's emissions-related warranties."

Lubrizol then offered suggestions as to how EPA could effectuate this goal:

"EPA could require emissions-related warranties to include regular service intervals for oil changes, as well as require that engines are consistently using the appropriate higher-performing lubricant oil for each particular engine - at all times throughout its useful life. Such specified lubricants would provide the engine with the appropriate level of performance, engine protection, and protection of emission control technology, according to objective characteristics as determined by the OEMs. These characteristics could be in the form of an OEM performance specification or an industry category defined by an entity like the American Petroleum Institute (API) or the European Automobile Manufacturers' Association (ACEA), along with a maximum viscosity level.

In addition, Lubrizol urges EPA to require OEMs to communicate important maintenance information related to engine oils and lubricants to their customers in three ways:

"First, EPA should require OEMs to include maintenance information related to engine oils and lubricants in their owner's manuals.. ..

Second, Lubrizol urges EPA to require lubricant specification information on an engine label that is placed at the appropriate place in the engine compartment. The agency has had similar requirements in the past, such as when EPA required vacuum hose diagrams to be included on the emission labels. …

Third, both the owner's manual and engine label should include an internet link that would enable owners or operators to obtain this information online."

Odyne requested that EPA's delegated assembly rules or some other methods be used to transfer credits to truck chassis OEMs by the intermediate or final assembler where ePTO or PHEV are installed. Odyne described that chassis manufacturers may not be aware of the final application or truck configuration before they ship the chassis for the next stage of manufacturing, and that downstream or secondary manufacturers are in a better position to determine the application and decide whether to install ePTO or PHEV systems that reduce GHG emissions. Odyne advocated for allowing those secondary manufacturers to gain regulatory benefits from installing ePTO and PHEV systems to encourage greater use of those technologies.

Odyne stated that required test procedures are too expensive, narrow, or complex, which can unnecessarily impede the sale and use of emission-reducing products for trucks. Odyne advocated for more effective and streamlined testing requirements to encourage greater use of ePTO technology.

Odyne also noted that some ePTO and PHEV systems are able to effectively reduce GHG and NOx emissions even when their battery is depleted, and that these systems should have more credit-generating recognition than ePTO and PHEV systems which are less effective in depleted battery mode.

Volvo supported EPA's proposal not to increase the Phase 2 engine standards, noting that increased engine standards stringency would be especially problematic given the need to achieve the recent HD2027 NOx standards.

Response:

Lubrizol's comment is out of scope. We note that their comment suggests that they would like to ensure more frequent oil changes, but EPA's minimum maintenance intervals do not serve that purpose. Rather, we are specifying *minimum* maintenance intervals to prevent the manufacturers from creating unrealistic expectations for maintenance from users beyond what is necessary for maintenance and at intervals that would be less likely to occur in-use. Furthermore, we also note that lubricants are a consumable product and are not considered to be components.

Regarding the comments on the importance of fuel additives and high-quality lubricants, the existing requirements in 40 CFR 1037.135(c)(7) require the label to include this information: "Identify any requirements for fuel and lubricants that do not involve fuel-sulfur levels."

In addition, existing 40 CFR 1036.135(d) and 40 CFR 1037.135(d), state that the label may include any additional information to ensure that the engine and vehicle will be properly maintained.

With these existing requirements we believe that users have the information needed to ensure that the correct fuel additive and lubricants are used. While outside the scope of this rulemaking, we also note that we disagree that lubricants should be included in the list of covered components in 40 CFR 1037.120(c).

Regarding commenters requests for revisions to delegated assembly or other provisions, these requested revisions are outside the scope of this rulemaking. We note that, under the current regulations, EPA adopted provisions for delegated assembly at 40 CFR 1037.621 and for partially complete vehicles at 40 CFR 1037.622 in recognition of multiple manufacturers sequentially producing vehicles in a certified configuration. In all cases, we depend on the certifying manufacturer to properly account for all emission-related features in the documentation for certification. This includes nine months after the end of the model year to track all adjustments and additions at different stages of manufacturing before delivery to the ultimate purchaser, resulting in a credit report that properly describes how the certifying manufacturer complies with emission standards. In the case of delegated assembly at 40 CFR 1037.621, the original manufacturer ensures that secondary manufacturers take necessary steps to finish vehicle assembly in a way that conforms to the original manufacturer's plans as documented in their compliance demonstration. In the case of provisions for partially complete vehicles at 40 CFR 1037.622, we allow original manufacturers to shift all the compliance obligations to a secondary manufacturer. In either case, the certifying manufacturer has the obligation to comply based on the final vehicle configuration. We note that any future consideration of revisions to the existing provisions would likely involve evaluation of requirements needed to ensure EPA could accurately quantify credits for incremental technology improvements and have compliance oversight to ensure that the secondary manufacturer is properly executing their responsibilities for the emission controls they are adding. For example, without certification there would be no mechanism for recalling defective systems.

EPA adopted the current test procedures through a rulemaking process that included engagement with and consideration of submitted comments from stakeholders. The procedures as adopted are targeted to achieve effective measurements for evaluating the performance of vehicles and vehicle systems in determining whether vehicles meet emission standards. Odyne expressed dissatisfaction with EPA's published procedures, but failed to make any specific suggestions. We continue to be open to feedback on suggested changes to measurement procedures for potential consideration in future rulemakings.

10.1 General ABT

Comments by Organizations

Organization: Advanced Engine Systems Institute (AESI)

EPA should maintain the off-cycle credit procedures that encourage innovation in technology, opening additional pathways which include increasingly cost-effective solutions that have not been validated yet in the market. [EPA-HQ-OAR-2022-0985-1600-A1, p. 2]

Organization: Allergy & Asthma Network et al.

EPA Should Ensure Real-World Benefits

We have also noted that even when vehicle manufacturers comply with the rules on paper, there remains the possibility of cheating or tampering with emissions controls for any non-zero-emission vehicle. The stronger the final standards and the more of a nationwide transition to zero-emission heavy-duty vehicles results from them, the lower the possibility of tampering with gas- or diesel-powered vehicle pollution controls. [EPA-HQ-OAR-2022-0985-1532-A1, p. 4]

Organization: American Council for an Energy-Efficient Economy (ACEEE)

EPA should ensure that credits from Phase 2 do not undermine the Phase 3 standards

Manufacturers' credits carried over from the Phase 2 program could substantially affect the efficacy of Phase 3. The proposal states: "In considering feasibility of the proposed standards, EPA also considers the impact of available compliance flexibilities on manufacturers' compliance options" (FR 26002). Yet EPA has not offered any projection of the credit balances to be carried over from Phase 2 to Phase 3, much less indicated how these credits might affect the levels of electrification achieved or the potential for backsliding on ICEV emissions under the proposed standards. [EPA-HQ-OAR-2022-0985-1560-A1, p. 17]

For the final rule, EPA should present its analysis of likely credit balances in Phase 3 and adjust the stringency of the standards accordingly to ensure they deliver the intended CO2 reductions and technology advancement under the program. [EPA-HQ-OAR-2022-0985-1560-A1, p. 17]

Organization: California Air Resources Board (CARB)

2. Standards for Qualifying Small Businesses

Affected pages: 26022 and 26124 (1037.150(c))

The NPRM proposes the following language:

"(v) Small manufacturers may bank emission credits only by certifying all their vehicle families within a given averaging set to the Phase 3 standards that apply for the current model year." [EPA-HQ-OAR-2022-0985-1591-A1, p.27]

CARB staff suggests adding the limitation that small manufacturers certified to the Phase 3 custom chassis standards are not eligible to bank credit. The existing Phase 2 GHG regulation does not allow manufacturers who certify to the custom chassis standards to bank or trade emission credits. Therefore, this limitation should also apply to small manufacturers certified to the custom chassis standards. Banking credit under an exemption allowing the weaker custom chassis standards could inadvertently create windfall credits from vehicles that would barely meet or not at all meet the governing vocational standards if that same vehicle were produced by a large manufacturer. While allowing flexibility for the small manufacturers, CARB staff encourages U.S. EPA to not erode the stringency of the program by also awarding bankable credits on top of the direct flexibility of the custom chassis provision. [EPA-HQ-OAR-2022-0985-1591-A1, p.27]

Organization: Clean Air Task Force et al.

2. The averaging, banking, and trading program continues to be an important way for manufacturers to maintain flexibility in meeting EPA's greenhouse gas emission standards.

Like its Phase 1 and Phase 2 HD GHG emission standards, and standards for certain criteria HD emissions dating back to 1985, EPA's proposed standards rely on an ABT approach allowing manufacturers to meet the standards by averaging emissions across subcategories of their HD vehicles. EPA has employed similar approaches in certain standards issued under section 202 of the Clean Air Act since 1983, including in its light-duty vehicle GHG standards beginning in 2010. Given its longstanding use of this approach under section 202, EPA's proposal emphasizes that EPA is "not reopening the general availability of ABT" or the general structure of the compliance provisions it uses to enforce and implement the ABT approach. 88 Fed. Reg. at 25952 n.211; id. at 26008 n.567. [EPA-HQ-OAR-2022-0985-1640-A1, p. 16]

We agree with EPA's determination that there is no reason to reopen the question whether it is permissible to use an ABT approach under section 202. EPA has not only repeatedly used ABT in section 202 standards but also repeatedly explained that ABT is consistent with and gives full effect to the requirements of section 202 as well as the Clean Air Act's compliance and enforcement provisions applicable to standards issued under section 202. Under such circumstances, it is eminently reasonable for EPA not to reconsider a question that has been settled for decades. See Growth Energy v. EPA, 5 F.4th 1, 13 (D.C. Cir. 2021).

Organization: Colorado Department of Transportation et al

- EPA requested comment on the use of credits, including consideration of a program similar to CARB's ACT credit provisions. Aligning with the ACT rule can help ensure consistency, and avoid weakening the effectiveness of the rule. [EPA-HQ-OAR-2022-0985-1530-A1, pp. 2-3]

Organization: Eaton

While existing technologies offer multiple pathways to compliance, the EPA should maintain the off-cycle credits procedures that encourage innovation in technology, opening additional pathways and allow for increasingly cost-effective solutions that have not been validated yet in the market or not yet realized. As was the case with previous regulations, once the first generation of new technology was introduced, driven by increasingly stringent limits, the market learned and quickly corrected issues while also significantly reduced costs. Therefore, it is key to the success of the regulations to maintain flexibility in the form of ABT credits as well as off-cycle credits. [EPA-HQ-OAR-2022-0985-1556-A1, p. 6]

Organization: Environmental Defense Fund (EDF)

b) EPA Properly Decided Not to Reopen its Longstanding Use of Averaging, Banking, and Trading in its Rules

EPA has used an ABT approach in standards for light- and heavy-duty vehicles since the 1980s, including the Phase 1 and Phase 2 medium- and heavy-duty GHG rules that this proposal builds upon.28 Within this decades-long history, EPA has repeatedly explained why such an approach is reasonable and consistent with the text of Section 202.29 Based on EPA's settled and longstanding use of ABT in its Section 202 rules and ABT's well-established basis in the statute, the agency's decision not to reopen "the general availability of ABT" is reasonable.30 [EPA-HQ-OAR-2022-0985-1644-A1, p. 14]

28 76 Fed. Reg. 57106, 57127-28 (Sept. 15, 2011) (HD Phase 1 GHG standards); 81 Fed. Reg. 73428, 73495 (Oct. 25, 2016) (HD Phase 2 GHG standards).

29 See, e.g., 55 Fed. Reg. 30584, 30593-94 (1990) (EPA explaining in the context of its 1990 programs for HD banking and trading of NOx and particulate matter why it "continues to believe . . . that trading and banking are consistent with the statutory aims").

30 88 Fed. Reg. 25952 n. 211.

Organization: Manufacturers of Emission Controls Association (MECA)

Off-Cycle Provisions for Innovative Technologies

MECA strongly supports the generation of credits through the off-cycle provisions for innovative technologies so manufacturers can deploy all possible technologies to address the CO2 emission limits. The value of the credits must be verified by actual technology testing submitted to EPA. We believe that in the absence of advanced technology credit multipliers, a broader range of advanced technologies will see greater implementation by manufacturers to ensure their compliance. For this reason, MECA believes off-cycle provisions should be retained as an option under a performance-based regulatory framework. [EPA-HQ-OAR-2022-0985-1521-A1, p. 10]

Organization: Navistar, Inc.

Navistar supports EPA's proposal to include ABT provisions, which provides manufacturers the flexibility necessary to meet the proposed GHG standards.

Averaging, banking and trading ('ABT') provisions provide manufacturers with the needed flexibility to plan investments and manage product costs, while at the same time meeting stringent GHG standards. Heavy-duty commercial fleets are incredibly diverse. Navistar's customers have an enormous variety of applications and we essentially produce custom vehicles for their use in large quantities. This means the engineering task of creating the right zero emissions vehicle for a particular application is an achievable, but still very significant task. Many fleets are confronted with the challenge of upgrading their charging infrastructure while at the same time considering investments in new diesel vehicles. The proposed rule's ABT provisions provide manufacturers a degree of flexibility necessary to meet the diverse range of heavy-duty applications and customer needs. [EPA-HQ-OAR-2022-0985-1527-A1, p. 4]

Navistar agrees with EPA's statements on the importance of providing manufacturers with compliance flexibilities through the inclusion of ABT provisions. Specifically, EPA stated that the 'proposed performance-based standards with ABT provisions give manufacturers a degree of flexibility in the design of specific vehicles and their fleet offerings, while allowing industry overall to meet the standards and thus achieve the health and environmental benefits projected for this rulemaking.' 88 Fed. Reg. at 26002. EPA noted further that it has considered:

- [T]he averaging portion of the ABT program in the feasibility assessments for previous rulemakings and continues that practice here. We also continue to acknowledge that the other provisions in ABT that provide manufacturers additional flexibility also support the feasibility of the proposed standards. By averaging across vehicles in the vehicle averaging sets and by allowing for credit banking across years, manufacturers have the flexibility to adopt emissions-reducing technologies in the manner that best suits their particular market and business circumstances. … It is clear that manufacturers are widely utilizing several of the credit programs available, and we expect that manufacturers will continue to take advantage of the compliance flexibilities and crediting programs to their fullest extent, thereby providing them with additional tools in finding the lowest cost compliance solutions in light of the proposed standards. [EPA-HQ-OAR-2022-0985-1527-A1, p. 4]

88 Fed. Reg. at 26002 (emphasis added). Flexibility is particularly important in the early years of this rule. In Navistar's view, that is the period most likely to be impacted by infrastructure shortfalls. Flexibility is needed to allow infrastructure to reach a certain scale, such as the availability of public charging on key transportation routes or concentrations of key depot charging availability. Public charging infrastructure is particularly significant and must come first to give fleets that operate over long-distance routes the confidence to electrify their fleets. Maximum flexibility is necessary, both in time and across vehicle categories. We strongly encourage EPA to expand the flexibilities in the proposed rule to allow manufacturers and, crucially, customers who will need to develop the necessary infrastructure to be able to manage through balancing across averaging sets and model years with enough flexibility to mitigate potential issues outside of the control of the manufacturer and customer, particularly infrastructure development. [EPA-HQ-OAR-2022-0985-1527-A1, pp. 4-5]

Organization: Truck and Engine Manufacturers Association (EMA)

CARB Advanced Clean Trucks (ACT) Rule – The EPA GHG Phase 3 regulation, like the current Phase 2 rule, is a national requirement on vehicle OEMs to sell vehicles across all 50

States that comply, in the aggregate, with a set of stringent GHG standards. The regulations require OEMs to track all sales and to "score" each vehicle type for its GHG performance. The aggregated scores are submitted annually to EPA to demonstrate compliance with the regulation. [EPA-HQ-OAR-2022-0985-2668-A1, p. 49]

California will be implementing a ZEV-truck sales mandate, the Advanced Clean Trucks (ACT) Rule, starting in 2024. Other states are adopting that regulation as well. The ACT regulation will mandate a yearly increase in the percentage of trucks sold that must be ZEVs. [EPA-HQ-OAR-2022-0985-2668-A1, p. 50]

EPA has requested comment on the interaction between the two regulations when it comes to the tracking and reporting of vehicle sales and the associated credits and debits that are earned by each. EMA sees the regulations as being distinct. Both regulations require the tracking of vehicles and reporting of all vehicles sold, either at a national or state level (for California and all other states that adopted the ACT regulation). There is no necessary interaction between the regulations. The sales at a state level, regardless of the state, contribute to the total sold within the U.S. based on the structure of these regulations. EMA believes there is no need for any regulatory ties between them. [EPA-HQ-OAR-2022-0985-2668-A1, p. 50]

EPA Summary and Response:

Summary:

ACEEE requested that EPA provide information regarding the credit balances it projects will be carried over from Phase 2 to Phase 3 and that EPA adjust the stringency of the standards in the final rule to account for those credits.

Allergy & Asthma Network et al. also expressed concern with ICE emission controls tampering and states that a "nationwide transition" to ZEVs lowers the possibility of tampering.

CARB noted that the proposed interim provision (40 CFR 1037.150(c)(2)) allowing small business manufacturers to continue to be subject to the Phase 2 MY 2027 and later standards did not include a limitation on the use of ABT if those small business manufacturers certified to custom chassis standards. CARB pointed out that the custom chassis provisions for vocational vehicles in 40 CFR 1037.105(h) disallows banking and trading of credits from vehicles certified to the custom chassis standards and they requested the same limitation apply to small business manufacturers certifying custom chassis vehicles.

Clean Air Task Force et al. agreed with EPA's decision not to reopen the general ABT in this proposal and agreed that EPA adequately justified its use of the ABT approach for the proposed standards. Clean Air Task Force et al. also provided a history of EPA's use of ABT in previous rules and suggested EPA could further note the existing regulations that already provide a more detailed description of how ABT relates to the CAA testing, certification, warranty, in-use compliance, and penalty provisions.

Colorado Department of Transportation et al. commented that aligning with the credit program of the ACT rule can "ensure consistency, and avoid weakening the effectiveness of the rule".

EDF noted EPA's long history of using ABT in its rulemakings and commented that EPA's decision not to reopen the availability of ABT was "reasonable".

Navistar commented in support of EPA's continued use of ABT, noting that the ABT provisions are a necessary flexibility for manufacturers to plan investments, manage costs, and meet the "diverse range of heavy-duty applications and customer needs". Navistar noted that ABT will be particularly important in the early years of the rule when infrastructure is growing and fleets are gaining confidence in the new vehicles. Navistar encouraged EPA to expand the flexibilities to across averaging sets and model years.

AESI, Eaton, and MECA expressed support for existing off-cycle credit provisions.

EMA commented that there is no need for a regulatory tie between the ACT regulation and a future federal regulation in terms of sales and credit reporting. They also state: "The sales at a state level, regardless of the state, contribute to the total sold within the U.S. based on the structure of these regulations."

Response:

We note that some of the general comments in this Section 10.1 referred to credit multipliers and averaging sets, which we respond to in more detail in Section 10.3 of this Response to Comment document.

Without reopening the general issue of necessity for ABT programs, we appreciate the comments from Clean Air Task Force et al., Eaton, EDF, and Navistar in acknowledging the continued value of our ABT provisions. , We share Allergy & Asthma Network et al.'s concern over tampering and agree that reducing the number of HD ICE vehicles in use would reduce the number of HD vehicles available for conventional tampering methods; however, we remind the commenter that we are finalizing performance-based standards and manufacturers can choose to comply with a mix of technologies that may continue to include HD ICE vehicles.

ACEEE requested that EPA share a projection of credits that manufacturers will have available in MY 2027 and that the agency consider available credits when setting the stringency of MY 2027 and later standards. While we do have record of manufacturers' credit balances for the current model year, we do not have sufficient information to make an accurate projection of how manufacturers will apply those credits moving forward. We have considered the potential for large credit balances to be carried over from Phase 2 into Phase 3 as a result of the Phase 2 credit multipliers, which informed some of the restrictions we are applying for credits from multipliers in Section 10.3 of this Response to Comment document. As described in Section II.G of the Preamble to this final rule, and Section 10.2.1 of this RTC document, we considered averaging in setting the emission standards for previous rulemakings and continue that practice in this rule. While we also considered the existence of other aspects of the ABT program (e.g., banking, trading) as supportive of the feasibility of the Phase 3 GHG standards, we did not rely on those other aspects in justifying the feasibility of the standards.

Regarding the Colorado DOT et al. comment about aligning with CARB's ACT credit provisions, the commenter did not provide enough specificity for the aspects of the CARB program with which they wish EPA to align. See Section 2 of this RTC document for comments and responses relating to other considerations of CARB ACT provisions and other incentive programs and see Section 10.3.2 for comments and our response relating to CARB's weight class modifiers for the ACT program.

CARB's request to restrict small manufacturers from banking and trading credits generated from certifying custom chassis vehicles is outside the scope of this rulemaking. CARB correctly noted that the broader custom chassis provisions (specifically 40 CFR 1037.105(h)(2)) disallow banking and trading of custom chassis credits. However, in Phase 2, we explicitly provided qualifying small manufacturers the flexibility to bank and trade from any averaging set (See 81 FR 73688 and 74061, October 25, 2016). In this rulemaking, we did not reopen these existing provisions for qualifying small manufacturers in this rulemaking and thus the existing Phase 2 provisions' flexibilities for qualifying small manufacturers continue to apply. We may consider new or revised small business provisions and flexibilities in a future rulemaking.

We appreciate AESI's, Eaton's, and MECA's support for the off-cycle credit provisions. We did not reopen the existing off-cycle credit provisions in the proposed rule and manufacturers will continue to have the option to pursue off-cycle credits for future advanced technologies.

10.2 ABT in Setting Standards

10.2.1 Fleet averaging methodology

Comments by Organizations

Organization: American Free Enterprise Chamber of Commerce (AmFree) et al.

BACKGROUND

A. Clean Air Act Section 202 And EPA's Fleetwide-Averaging Approach

Section 202(a) of the Clean Air Act authorizes EPA to promulgate "standards applicable to the emission of any air pollutant from any class or classes of new motor vehicles or new motor vehicle engines, which in [EPA's] judgment cause, or contribute to, air pollution which may reasonably be anticipated to endanger public health or welfare." 42 U.S.C. § 7521(a)(1). Those standards must apply to "such vehicles and engines for their useful life." Id. The standards cannot take effect until "after such period as [EPA] finds necessary to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such period," id. § 7521(a)(2)— commonly known as the "feasibility" requirement. [EPA-HQ-OAR-2022-0985-1660-A1, pp. 6 - 7]

EPA has previously invoked its Section 202(a) authority to set maximum motor-vehicle emission levels for criteria pollutants (i.e., pollutants for which minimum acceptable standards have been established, such as particulate matter, ozone, and nitrogen oxides)—and, more recently, for greenhouse gases ("GHGs"). See Massachusetts v. EPA, 549 U.S. 497, 532 (2007). But instead of prescribing maximum levels of particular pollutants that each vehicle within a covered "class" may emit, in prior regulations EPA has set maximum fleetwide-average emission levels, which consider a manufacturer's fleet collectively. 40 C.F.R. §§ 1037.701(a), 1037.710(a)–(b). EPA annually determines each manufacturer's compliance with those fleetwide-average standards, issuing "deficits" (resulting in civil penalties) to manufacturers whose fleets fail these average standards and "credits" to those whose fleets emit less than EPA allows. Id. §§ 1037.241(a), 1037.710(c); see id. § 1068.101(a)(1). Credits can be used immediately to offset deficits in a manufacturer's other fleets, "banked" to offset deficits in future years, or “trad[ed] . . . between manufacturers.” Id. §§ 1037.710(a), 1037.715(a), 1037.720(a). EPA refers to this approach as its “averaging, banking, and trading (ABT) program.” 88 Fed. Reg. at 25,929. This regulatory creation largely mirrors the system Congress enacted in the Corporate Average Fuel Economy provisions of the Energy Policy and Conservation Act. [EPA-HQ-OAR-2022-0985-1660-A1, p. 7]

B. The Proposed Heavy-Duty Rule

That fleetwide-averaging approach is at the heart of EPA’s proposed rule at issue—which sets stringent new GHG-emission standards for heavy-duty vehicles (such as delivery trucks, refuse haulers, and buses) for model years 2027 and beyond, Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles—Phase 3, 88 Fed. Reg. 25,926 (Apr. 27, 2023)—and its parallel proposed rule for light and medium-duty motor vehicles, Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles, 88 Fed. Reg. 29,184 (May 5, 2023). Although prior EPA rules issued under Section 202 have employed fleetwide averaging—including a light-duty motor-vehicle rule for earlier model years, currently being litigated, see Texas v. EPA, No. 22-1031 (D.C. Cir.)—EPA’s proposed Heavy-Duty and Light- and Medium-Duty rules do so in a fundamentally different way to achieve a different end. Previously, averaging was presented as merely a flexibility. Now, prompted by an Executive Order calling for a massive shift to “zero-emission vehicles” by 2030 and directing EPA to undertake rulemakings on these issues with that goal in mind, Exec. Order 14,037, 86 Fed. Reg. 43,583 (Aug. 5, 2021); see 88 Fed. Reg. at 25,929 & n.12, EPA openly seeks in both rules to shift a substantial portion of motor-vehicle production toward vehicles that produce zero GHG emissions in operation. Fleetwide averaging is the linchpin of that ambition—it is this that allows EPA to reverse engineer its preferred outcomes. [EPA-HQ-OAR-2022-0985-1660-A1, pp. 7 - 8]

To that end, the proposed Heavy-Duty rule would revise the existing GHG standards for model year 2027 and introduce new standards for heavy-duty vehicles (varying by type and use) for model years 2028 through 2032, which become more stringent each year. 88 Fed. Reg. at 25,929, 25,932. Although the proposed rule portrays those emission standards as “performance-based” and as allowing manufacturers to choose which emissions-control technologies to adopt, id. at 25,972, EPA has stated openly that it expects manufacturers to shift from internal-combustion engines toward battery-electric or fuel-cell vehicles, id. at 25,932. By 2032, EPA projects that 50 percent of vocational vehicles and 35 percent of day-cab tractors will be battery-electric or fuel-cell vehicles, and that 25 percent of sleeper-cab tractors will be fuel-cell vehicles. See id. at 25,933. In a break from its historic practice, EPA now overtly proposes to wield its Section 202 authority over emission levels to mandate the adoption of alternatives to internal-combustion engines—replacing pollutant-emitting motor vehicles that Section 202 governs with other, non-emitting vehicles that the statute does not cover. The proposed Heavy-Duty rule seeks to accomplish that unprecedented transformation on a highly compressed timeline, remaking the heavy-duty sector within less than a decade. [EPA-HQ-OAR-2022-0985-1660-A1, p. 8]

EPA cannot justify the proposed rule’s attempted transformation of the heavy-duty-vehicle sector as an application of its fleetwide-averaging approach to emissions. Fleetwide averaging itself contravenes the Clean Air Act. At a minimum, it is not clearly and unmistakably authorized as a back-door means of remaking the auto industry, as the major-questions doctrine requires. [EPA-HQ-OAR-2022-0985-1660-A1, p. 9]

B. EPA May Not Mandate Electrification Through Fleetwide Averaging

EPA has no clear congressional authorization for the proposed rule's electrification mandate. Under Section 202 of the Clean Air Act, EPA may "prescribe . . . standards" applicable to GHG emissions "from any class or classes of new motor vehicles or new motor vehicle engines" that EPA determines "cause, or contribute to, air pollution." 42 U.S.C. § 7521(a)(1); see also Massachusetts v. EPA, 549 U.S. 497, 532 (2007); 74 Fed. Reg. 66,496 (Dec. 15, 2009). Section 202 specifies that "[s]uch standards shall be applicable to such vehicles and engines for their useful life . . . whether such vehicles and engines are designed as complete systems or incorporate devices to prevent or control such pollution." 42 U.S.C. § 7521(a)(1). Nothing in the statutory text clearly authorizes EPA to mandate a compulsory shift toward zero-emission vehicles. [EPA-HQ-OAR-2022-0985-1660-A1, pp. 12 - 13]

EPA has attempted to ground its electrification mandate in its standard-setting authority under Section 202 through fleetwide averaging. Averaging and its corollaries in EPA's ABT program—crediting (whereby manufacturers can use "credits" generated for one fleet that surpassed the emissions level to offset a deficit in another fleet), banking (saving credits earned one year to offset deficits in future years), and trading (selling credits to competitors for money)— are crucial to EPA's effort to mandate electrification. The proposed rule specifies emissions standards that would operate not as maximum-emission thresholds for particular pollutants that any individual vehicle must meet, but rather as fleetwide-average emission levels that manufacturers' fleets must collectively satisfy. See 88 Fed. Reg. at 25,956 ("In this proposal, we continue to expect averaging would play an important role in manufacturer strategies to meet the proposed standards."). That averaging approach is essential to EPA's electrification mandate because it plainly would not be feasible for EPA to set maximum permissible GHG emissions at zero for individual vehicles: the "cost of compliance" with a zero-emissions mandate for every heavy-duty vehicle would doom such a requirement. 42 U.S.C. § 7521(a)(2). Instead, by allowing lower-emitting vehicles in a manufacturer's fleet to offset higher-emitting vehicles (in its own fleet or that of another manufacturer, through trading of credits), and by setting very stringent fleetwide-average GHG-emission standards that no conventional motor vehicle could satisfy, EPA's proposed rule forces manufacturers to produce a significant number of zero-emission (i.e., electric) vehicles. See 88 Fed. Reg. at 26,002; see also id. at 26,015 ("BEVs and PHEVs generate credits that can be traded among manufacturers and used to offset debits generated by vehicles using other technologies that do not themselves meet the proposed standards."). [EPA-HQ-OAR-2022-0985-1660-A1, p. 13]

The Clean Air Act, however, does not authorize EPA to employ that fleetwide- averaging approach at all—much less with the unmistakable clarity the major-questions doctrine demands. EPA's contrary interpretation has no foundation in the statutory text and would make a hash of the statutory structure, which repeatedly uses language that makes sense only in the context of emissions standards applicable to individual vehicles. Even if fleetwide averaging were permissible as a general matter, it cannot be exploited to shoehorn zero-emission vehicles—i.e., vehicles that do not "cause, or contribute to, air pollution," 42 U.S.C. § 7521(a)(1), and thus fall outside Section 202 entirely—into the fleetwide-average calculation as a means of mandating electrification. [EPA-HQ-OAR-2022-0985-1660-A1, p. 14]

1. The Clean Air Act Does Not Permit Fleetwide Averaging

Nothing in the text of Section 202 authorizes a fleetwide-averaging approach. To the contrary, Section 202's relevant provision authorizes emissions standards for "any class or classes of new motor vehicles or new motor vehicle engines" that EPA determines "cause, or contribute to, air pollution." 42 U.S.C. § 7521(a)(1) (emphases added). Those standards must "be applicable to such vehicles and engines for their useful life." Id. The text thus permits EPA to adopt a standard applicable to all of the vehicles (or engines) in a particular class. Whatever discretion EPA may exercise in defining a "class" of vehicles, the text requires standards for the vehicles in that class, not for the class as a collective. [EPA-HQ-OAR-2022-0985-1660-A1, p. 14]

The absence of any affirmative authorization for fleetwide averaging should come as no surprise because, as EPA acknowledged four decades ago, "Congress did not specifically contemplate an averaging program when it enacted the Clean Air Act." 48 Fed. Reg. 33,456, 33,458 (July 21, 1983). EPA's entire averaging edifice is based on the purported fact that the Act "does not explicitly preclude standards" based on fleetwide averaging. 54 Fed. Reg. 22,652, 22,665 (May 25, 1989) (emphasis added). Under the major-questions doctrine, however, the absence of a statutory prohibition on the approach the agency seeks authority to pursue is categorically insufficient: EPA needs "'clear congressional authorization' for the power it claims," West Virginia, 142 S. Ct. at 2609 (citation omitted), not congressional silence on the subject. Even outside of major- questions cases, congressional silence is not an invitation to make things up. See Entergy Corp. v. Riverkeeper, Inc., 556 U.S. 208, 223 (2009) ("statutory silence, when viewed in context," often is "best interpreted as limiting agency discretion"); Marx v. Gen. Revenue Corp., 568 U.S. 371, 381 (2013) ("[I]t is fair to suppose that Congress considered the unnamed possibility and meant to say no to it[.]" (citation omitted)); Univ. of Tex. Sw. Med. Ctr. v. Nassar, 570 U.S. 338, 353 (2013). [EPA-HQ-OAR-2022-0985-1660-A1, pp. 14 - 15]

In any event, the Clean Air Act refutes EPA's view that Congress left the door open to fleetwide averaging. Other provisions in Section 202 itself and Title II as a whole make clear that fleetwide averaging is fundamentally incompatible with the statutory structure and design. [EPA-HQ-OAR-2022-0985-1660-A1, p. 15]

Other portions of Section 202 confirm Section 202(a)(1)'s focus on emission standards applicable to individual vehicles. For example:

- Under 42 U.S.C. § 7521(b)(1)(A), the standards for light-duty vehicles and engines in model years 1977–79 must provide that "emissions from such vehicles and engines may not exceed 1.5 grams per vehicle mile of hydrocarbons and 15.0 grams per vehicle mile of carbon monoxide." Id. (emphasis added). This provision contemplates that "such vehicles"—i.e., individual light-duty vehicles—will not exceed these limits. Under an averaging approach, however, individual vehicles would be permitted to exceed these statutorily mandated standards.
- Similarly, 42 U.S.C. § 7521(b)(3) authorizes EPA to grant waivers from certain nitrogen-oxide emission "standards," see id. § 7521(b)(1)(B), for no "more than 5 percent of [a] manufacturer's production or more than fifty thousand vehicles or engines, whichever is greater." Id. § 7521(b)(3). The provision thus provides a default rule under which every vehicle must meet a per-vehicle emissions standard, then permits a waiver from that default rule for up to 5 percent of the fleet. Averaging is inconsistent with this provision, which depends on a set number of individual vehicles meeting the standards.
- And under 42 U.S.C. § 7521(m)(1), EPA must require manufacturers to install "diagnostic systems" on "all" new light-duty vehicles and trucks that are capable of

identifying malfunctions that "could cause or result in failure of the vehicles to comply with emission standards established under this section." Requiring diagnostic equipment on "all" vehicles makes no sense on an averaging approach; each vehicle must have a diagnostic system that ensures that vehicle's "compl[iance] with emission standards established under [Section 202]," id., yet under EPA's averaging approach, no particular vehicle need be in compliance. [EPA-HQ-OAR-2022-0985-1660-A1, p. 15]

Beyond Section 202 itself, averaging is also deeply in tension with "the design and structure of [Title II] as a whole." Util. Air, 573 U.S. at 321 (citation omitted). Consider Title II's provisions addressing testing, warranties, and penalties:

- Testing. EPA must "test . . . any new motor vehicle or new motor vehicle engine" to determine whether "such vehicle or engine" conforms with Section 202 emissions standards. 42 U.S.C. § 7525(a)(1). If the "vehicle or engine conforms to such regulations," EPA must issue the manufacturer a "certificate of conformity." Id. And a manufacturer may not sell a vehicle or engine not "covered by a certificate of conformity." Id. § 7522(a)(1). These provisions are not compatible with fleetwide-averaging for at least two reasons: first, the use of singular terms "vehicle" and "engine"—along with "any" and "such"—indicates that testing individual vehicles is required; and second, EPA cannot determine compliance with Section 202 standards before issuing a certificate of conformity—as the statute contemplates— under a fleetwide-averaging approach. (Instead, conformity is determined at "the end of the model year," when the manufacturer knows the quantity of "vehicles . . . produced in each vehicle family during the model year." 40 C.F.R. §§ 1037.705(c), 1037.250(a))
- Warranties. Title II's warranty provisions require a manufacturer to "warrant to the ultimate purchaser and each subsequent purchaser" "at the time of sale" that each new vehicle complies with applicable Section 202 standards. 42 U.S.C. § 7541(a)(1). Under an averaging approach, however, a manufacturer cannot determine compliance "at the time of sale," because actual compliance with an average standard can be determined only at year's end. Manufacturers may be able to make a rough predictive judgment ex ante, but they would be effectively warranting an unknown.
- Penalties. Under 42 U.S.C. § 7524(a), any violation of applicable standards "shall constitute a separate offense with respect to each motor vehicle or motor vehicle engine," with each offense subject to a civil penalty of up to $25,000. But under a fleetwide-averaging approach, "each motor vehicle or motor vehicle engine" cannot violate applicable emissions standards—only the fleet as a whole. [EPA-HQ-OAR-2022-0985-1660-A1, p. 16]

EPA also finds no quarter for fleetwide averaging in the case law. The best it can muster is a single decision that found no "clear evidence that Congress meant to prohibit averaging." Thomas, 805 F.2d at 425 (emphasis added); see 88 Fed. Reg. at 25,929 & n.9. But as explained above, under the major-questions doctrine, the absence of a "clear" prohibition is irrelevant: on the contrary, Congress must have specifically and clearly authorized the action. See West Virginia, 142 S. Ct. at 2609. Moreover, the Thomas court recognized inconsistencies between averaging and other statutory provisions, including Title II's "testing and certification provision, 42 U.S.C. § 7525," discussed above. 805 F.2d at 425 n.24. The court reserved judgment on that issue only because "it was not raised by any party before the agency." Id. EPA's best (indeed, only cited) case thus provides no support for construing Section 202 to authorize averaging. [EPA-HQ-OAR-2022-0985-1660-A1, pp. 16 - 17]

2. EPA Cannot Use Fleetwide Averaging To Mandate Electrification

Even if Section 202 authorized fleetwide averaging in some circumstances, that approach cannot be used, as EPA proposes, to blend together the emissions levels of conventional, pollutant-emitting vehicles with vehicles that (according to EPA) emit zero pollutants. By its terms, Section 202(a)(1) authorizes EPA to promulgate “standards applicable to the emission of any air pollutant from any class or classes of new motor vehicles or new motor vehicle engines, which in [its] judgment cause, or contribute to, air pollution.” 42 U.S.C. § 7521(a)(1) (emphases added). The text’s focus on the “emission” of pollutants that “cause . . . air pollution” demonstrates that Congress intended to cover only vehicles that actually emit the relevant pollutant—and to authorize EPA to set standards for the quantity of pollutants those vehicles may acceptably emit. Nothing in the text authorizes EPA to dragoon heavy-duty vehicle manufacturers into producing a separate line of vehicles that do not themselves emit the regulated pollutant at all. [EPA-HQ-OAR-2022-0985-1660-A1, p. 17]

EPA has elsewhere contended that the statute’s reference to “classes” of vehicles or engines permits it to treat polluting and non-polluting vehicles on the same footing. See EPA Br. 76–78, Texas. v. EPA, No. 22-1031 (D.C. Cir. Feb. 24, 2023). But that term cannot rescue EPA’s flawed interpretation. The relevant feature of a “class” of “motor vehicles” that “cause, or contribute to, air pollution” is that the vehicles in the class all emit the relevant pollutant. 42 U.S.C. § 7521(a)(1). A vehicle that emits zero pollutants is necessarily not part of that class. Given EPA’s own assumption that electric vehicles do not emit pollutants, electric vehicles cannot be among the “class or classes of new motor vehicles or new motor vehicle engines” that EPA may consider in setting Section 202 standards and they therefore may not be factored into a fleetwide average. If EPA were right, the relevant “category” EPA purports to be regulating would vanish at the point when EPA reaches the President’s goal that 100 percent of the heavy-duty fleet be “zero-emissions vehicles.” [EPA-HQ-OAR-2022-0985-1660-A1, pp. 17 - 18]

Organization: American Petroleum Institute (API)

iii. EPA has no authority under CAA §§ 202(a)(1) and (2) to establish emissions standards based on the average performance of two emissions control technologies.

The Proposed Rule is fundamentally different from the Phase 1 and Phase 2 GHG standards for heavy-duty vehicles in the manner in which the emission standards are established. EPA explains that the prior Phase 2 GHG standards for HD vehicles were not premised on the application of hybrid powertrains or ZEV technology. 88 Fed. Reg. at 25957. In contrast, the HD 3 proposal “include[s] both ICE vehicle and ZEV technologies.” Id. at 25958. [EPA-HQ-OAR-2022-0985-1617-A1, p. 20]

In particular, averaging is incorporated into EPA’s standard setting analysis in the Proposed Rule. EPA for each model year and for each vehicle type conducts an analysis of what standards could be met by traditional ICE vehicles and whether ZEVs are available for that model year for that vehicle type and, if so, at what volume. EPA then proposes an emissions standard for each model year and vehicle type that is a blended rate of the ICE value and the ZEV value (which is presumed to be zero) that is based on EPA's projection of how much of the market could be met with ZEVs. Id. at 25991-2. [EPA-HQ-OAR-2022-0985-1617-A1, p. 21]

EPA asserts that it "has long included averaging provisions for complying with emission standards in the HD program and in upholding the first HD final rule that included such a provision the D.C. Circuit rejected petitioner's challenge in the absence of any clear evidence that Congress meant to prohibit averaging." 88 Fed. Reg. at 25950. That is the only legal justification EPA asserts for using averaging in standard setting. [EPA-HQ-OAR-2022-0985-1617-A1, p. 21]

The use of averaging in standard setting is legally flawed for two reasons. First, EPA's asserted legal justification is inadequate. It is true that EPA has long used emissions averaging as a compliance method under its vehicle emissions standards. But here EPA is doing more – EPA uses averaging in setting the standards themselves. EPA provides no explanation of its legal authority for this novel approach. [EPA-HQ-OAR-2022-0985-1617-A1, p. 21]

Second, and in any event, EPA does not have legal authority to consider emissions averaging in standard setting. CAA § 202(a)(1) authorizes EPA to establish emission standards for "classes" of motor vehicles. In this case, EPA has used emissions data from two distinctly different classes of vehicles (ICE-powered vehicles and BEVs) in setting a single standard. That exceeds EPA's authority under CAA § 202(a)(1). Moreover, using averaging is unreasonable because there is no identifiable vehicle configuration that corresponds to EPA's proposed standards. That means the industry as a whole would have to certify at least two fundamentally different types of vehicles to satisfy the proposed standards. As a result, EPA is effectively setting two different standards for the same pollutant for the same class of vehicles under the guise of establishing a unitary standard for a single class of vehicles. [EPA-HQ-OAR-2022-0985-1617-A1, p. 21]

Furthermore, CAA § 202(a)(3)(A)(i) requires that HD standards reflect the "greatest degree of emissions reduction achievable through the application of technology which the EPA determines will be available." 42 U.S.C. § 7521(a)(3)(A)(i). Congress specifically directed EPA to set emissions for vehicles, not fleets of vehicles. Congress further required EPA to test these "motor vehicles or motor vehicle engines" to ensure they "conform to the standards." 42 U.S.C. § 7525(a)(2); see also id. § 7525(a)(1) (requiring certificates of conformity for specific vehicles). And Congress authorized EPA to grant waivers from certain nitrogen-oxide emissions standards "of no more than 5 percent of [a] manufacturer's production or more than fifty thousand vehicles or engines, whichever is greater." The testing of specific vehicles or engines and the presence of the waiver provisions cannot be implemented as intended under an averaging structure in which a significant portion of the fleet can be above the emissions standard so long as other vehicles perform sufficiently well to create average compliance. [EPA-HQ-OAR-2022-0985-1617-A1, p. 21]

Organization: American Thoracic Society (ATS)

The ATS further recommends EPA use caution when adopting any fleet averaging approaches. The ATS is concerned that if heavy duty truck manufacturers are allowed to meet emission reductions requirements through averaging of emission over an entire fleet, it will create perverse incentives for sellers and purchasers alike leading to a reduction in zero-emission vehicle sales. [EPA-HQ-OAR-2022-0985-1517-A1, p. 4]

Organization: Clean Fuels Development Coalition et al.

B. EPA lacks clear authority to use fleetwide averaging.

The reality, moreover, is that Congress has expressly precluded EPA from using Section 202(a) to phase out internal-combustion vehicles. EPA achieves that result only by misconstruing the standard-setting tools at its disposal. The text and structure of Section 202, and of Title II more broadly, unambiguously require that emission standards under Section 202(a) apply to individual vehicles, not to manufacturers' fleets on average. EPA claims to find authority for fleetwide averaging in Section 202(a), which authorizes the agency to issue "standards applicable to the emission of any air pollutant from any class or classes of new motor vehicles ... which in [its] judgment cause, or contribute to, air pollution which may reasonably be anticipated to endanger public health or welfare." 42 U.S.C. § 7521(a)(1). This says nothing about averaging across fleets. [EPA-HQ-OAR-2022-0985-1585-A1, p. 8]

EPA has already conceded as much. When the agency first adopted fleetwide averaging, it recognized that "Congress did not specifically contemplate an averaging program when it enacted the Clean Air Act." 48 Fed. Reg. 33,456, 33,458 (July 21, 1983). And "[j]ust as the statute does not explicitly address EPA's authority to allow averaging, it does not address the Agency's authority to permit banking and trading." 54 Fed. Reg. 22,652, 22,665 (May 25, 1989); see also 55 Fed. Reg. 30,584, 30,593 (July 26, 1990) (same). That is the end of the analysis. The statute does not "explicitly" allow averaging and so EPA lacks "clear congressional authorization" to enact the proposal. [EPA-HQ-OAR-2022-0985-1585-A1, p. 9]

Indeed, even if the phasing out of the internal combustion engine were not a major question, EPA's claim to authority here is unlawful. As discussed below, the Clean Air Act's text and structure are incompatible with averaging (and banking and trading). But even on the terms EPA itself has articulated, its interpretation is impermissible. When a statute "says nothing about" a potential regulatory power, it "would be improper to conclude that what Congress omitted from the statute is nevertheless within its scope." Univ. of Texas Sw. Med. Ctr. v. Nassar, 570 U.S. 338, 353 (2013); see also Entergy Corp. v. Riverkeeper, Inc., 556 U.S. 208, 223 (2009) ("statutory silence, when viewed in context," is in many situations "best interpreted as limiting agency discretion," not creating it). After all, "[a]n agency … 'literally has no power to act' … unless and until Congress authorizes it to do so by statute." FEC v. Cruz, 142 S. Ct. 1638, 1649 (2022). And agencies no less than courts have a "duty to respect not only what Congress wrote but, as importantly, what it didn't write." Va. Uranium, Inc. v. Warren, 139 S. Ct. 1894, 1900 (2019) (plurality op.). "And supplying the extra words 'on average' would have a significant substantive effect: 'roller coaster riders must be 48 inches tall' means something very different from 'roller coaster riders must be 48 inches tall on average.'" Opening Brief of Private Petitioners at 41, Texas v. EPA (D.C. Cir. No. 22-1031). [EPA-HQ-OAR-2022-0985-1585-A1, p. 9]

The inference against EPA's claim to be able to write into its authority a fleetwide averaging power is especially strong because Congress knows full well how to create such a program—it did so not only in EPCA, but also in other provisions of Title II of the Clean Air Act. See 2

U.S.C. § 7545(k)(l)(B)(v)(II) (directing EPA to take certain actions if “the reduction of the average annual aggregate emissions of toxic air pollutants in a [designated district] fails to meet” certain standards). Simply put: “if Congress had wanted to adopt an [averaging] approach” for motor vehicle standards under Section 202(a), “it knew how to do so.” SAS Inst., Inc. v. lancu, 138 S. Ct. 1348, 1351 (2018). That Congress didn’t is dispositive. See Marx v. Gen. Revenue Corp., 568 U.S. 371, 381 (2013) (“[I]t is fair to suppose that Congress considered the unnamed possibility and meant to say no to it[.]”); Russello v. United States, 464 U.S. 16, 23 (1983); Rotkiske v. Klemm, 140 S. Ct. 355, 360-361 (2019) (“Atextual judicial supplementation is particularly inappropriate when, as here, Congress has shown that it knows how to adopt the omitted language or provision.”).6 To quote Justice Frankfurter: “It is quite impossible…when Congress did specifically address itself to a problem…to find secreted in the interstices of legislation the very grant of power which Congress consciously withheld.” Youngstown Sheet & Tube Co. v. Sawyer, 343 U.S. 579, 609 (1952) (Frankfurter, J., concurring) [EPA-HQ-OAR-2022-0985-1585-A1, pp. 9 - 10]

6 At the very least, EPA should await the Supreme Court’s decision in Loper Bright Enterprises v. Raimondo (22-451), which will consider “[w]hether the Court should overrule Chevron or at least clarify that statutory silence concerning controversial powers expressly but narrowly granted elsewhere in the statute does not constitute an ambiguity requiring deference to the agency.”

Add to this that the “silence” argument is simply not correct. That fleet-wide averaging is not permitted—and is in fact forbidden—is confirmed by multiple parallel provisions from the Clean Air Act. For example, the testing requirements that accompany the Section 202(b) standards confirm that those standards apply to all vehicles individually. EPA must “test any emission control system incorporated in a motor vehicle or motor vehicle engine . . . to determine whether such system enables such vehicle or engine to conform to the standards required to be prescribed under [Section 202(b)].” 42 U.S.C. § 7525(a)(2). If the system complies with the testing, then EPA must issue a “‘verification of compliance with emission standards for such system.” Id. These provisions plainly require standards that apply to individual vehicles.7 The fundamental premise of this testing regime is that a vehicle can meet individually applied emission standards. Thus “the broader context of the statute as a whole,” Robinson v. Shell Oil Co., 519 U.S. 337, 341 (1997), confirms that EPA is out over its skis here. [EPA-HQ-OAR-2022-0985-1585-A1, p. 10]

7 See also, Petitioners Brief, Texas et al. v. EPA et al., No. 22-1031 at 51–62 (D.C. Cir., Nov. 3, 2022) (detailing myriad ways in which statutory text, structure, and related provisions confirm that fleetwide averaging is not authorized).

C. Even if EPA could use fleetwide averaging, this cannot be used to force electrification.

Part of the reason EPA has traditionally been granted deference in its averaging schemes is because the agency has historically used averaging as an accommodation to regulated parties, allowing them flexibility that the statute does not in fact permit in exchange for setting standards that themselves go beyond what is permissible. Thus, while some commentors have pointed out the illegality of this scheme, vehicle manufacturers have not opposed EPA’s averaging approach because it provided them with the flexibility necessary to achieve otherwise unachievable standards. But in this new proposal EPA is not offering an extra statutory accommodation, but is instead taking an additional step away from the statutory text by using fleetwide averaging to mandate electrification. [EPA-HQ-OAR-2022-0985-1585-A1, pp. 10 - 11]

In prior rules, the use of fleet-wide averaging meant that a vehicle manufacturer could comply by making some vehicles that emitted more and others that emitted less. But the proposal is now setting emissions standards in such a way that no fleet of internal combustion engine vehicles can meet the standards. This means that averaging no longer provides flexibility, but instead amounts to a de facto mandate to incorporate electric vehicles to comply with its proposed standards. [EPA-HQ-OAR-2022-0985-1585-A1, p. 11]

When considering EPA's authority to use averaging, courts have consistently found important that the averaging was a flexibility. See NRDC v. Thomas, 805 F.2d 410, 425 (D.C. Cir. 1986) ("EPA's argument that averaging will allow manufacturers more flexibility in cost allocation while ensuring that a manufacturer's overall fleet still meets the emissions reduction standards makes sense.") (emphasis added); White Stallion Energy Ctr., LLC v. EPA, 748 F.3d 1222, 1253 (D.C. Cir. 2014) (permitting averaging across multiple utility units under 42 U.S.C. § 7412(d) because averaging is a "more flexible, and less costly alternative."). [EPA-HQ-OAR-2022-0985-1585-A1, p. 11]

But in the proposed rule averaging does not represent an "alternative" or "flexibility," rather—just as in the Clean Power Plan—it is deployed as a tool for reverse engineering a preferred outcome by setting targets that cannot be achieved by disfavored fuel sources. "The proposed CO2 emission standards for each model year are calculated" by "project[ing the] fraction of ZEVs that emit zero grams CO2/ton-mile at the tailpipe" and "by multiplying the [remaining] fraction of ICE-powered vehicles in each technology package by the applicable existing MY 2027 CO2 emission standards." DRIA at 247–48. In other words, either a manufacturer builds electric vehicles to comply with the standards or it goes out of business. Even with extreme deference to an agency interpretation, this result is impermissible. [EPA-HQ-OAR-2022-0985-1585-A1, p. 11]

II. EPA lacks the Statutory Authority to Ignore Upstream Emissions for Electric Vehicles.

EPA has statutory authority to prescribe "standards applicable to the emission of any air pollutant from any class or classes of new motor vehicles or new motor vehicle engines, which in [its] judgment cause, or contribute to, air pollution which may reasonably be anticipated to endanger public health or welfare." 42 U.S.C. § 7521(a)(1). This presents an interpretive dilemma. On the one hand, if electric vehicles are not "vehicles" "which cause, or contribute to" a given type of air pollution, then EPA may not set standards for them. Id. On the other, if electric vehicles are "vehicles" "which cause, or contribute to" a given type of air pollution, then EPA must set "standards applicable to the[ir] emissions." Id. [EPA-HQ-OAR-2022-0985-1585-A1, p. 12]

The proposal tries to solve this problem by splitting the baby.8 EPA reasons that electric vehicles are vehicles that "cause or contribute to air pollution," but EPA just chooses to set their contribution to zero. This cannot be right. Cf. C.S. Lewis, That Hideous Strength 291 (Samizdat ed., 2015) ("Just imagine a man who was too dainty to eat with his fingers and yet wouldn't use forks!"). If electric vehicles truly emit no emissions, then they are not the sort of vehicle EPA can regulate. [EPA-HQ-OAR-2022-0985-1585-A1, p. 12]

8 Of course, the point of the story about Solomon is that the baby wasn't split. See 1 Kings 3:16- 28 ("Give the living child to the first woman, and by no means put him to death; she is his mother.").

Organization: Valero Energy Corporation

a) The statutory structure confirms EPA lacks statutory authority to use fleetwide averaging to mandate ZEVs.

EPA's proposal would require electrification by setting average emission standards for manufacturers' nationwide fleets and "averaging" in more and more zeros to represent the electric vehicles it wants to see in future years. Manufacturers that exceed the standards may bank credits and trade them to other manufacturers that fall short. [EPA-HQ-OAR-2022-0985-1566-A2, p. 64]

EPA relies on NRDC v. Thomas, 805 F.2d 410 (D.C. Cir. 1986), for the proposition that it is authorized to average HDVs. That case found EPA could average a manufacturer's different engine families. Id. at 425. It did so, however, with some caveats. First, its reasoning was based on a deference to EPA's interpretation of the statute "in the absence of clear evidence Congress meant to prohibit averaging." This standard, of course, is directly contrary to the standard applicable in this case in which EPA is proposing regulations that affect a major question—clear Congressional authority to permit averaging to mandate electric vehicles. Second, the parties failed to raise a textual argument against averaging. Id. at n.24 ("Although it was not raised by any party before the agency, and accordingly cannot be dispositive here … there is an additional argument against emissions averaging. The Act's testing and certification provision, 42 U.S.C. § 7525, speaks of 'any,' 'a,' or 'such' motor vehicle or engine being tested and certified. With averaging, some vehicles or engines would not be required to comply with the standards and would not be subject to NCPs for failing to so comply. This practice appears inconsistent with the requirement that 'any,' 'a,' or 'such' vehicle or engine be tested and required to comply with emissions standards."). [EPA-HQ-OAR-2022-0985-1566-A2, p. 64]

On the other hand, EPA has previously acknowledged that the Act is silent on the mechanisms of averaging, banking, and trading (ABT). When EPA first adopted fleetwide averaging, it recognized that "Congress did not specifically contemplate an averaging program when it enacted the Clean Air Act." 48 Fed. Reg. 33,456, 33,458 (July 21, 1983). And "[j]ust as the statute does not explicitly address EPA's authority to allow averaging, it does not address the Agency's authority to permit banking and trading." 54 Fed. Reg. 22,652, 22,665 (May 25, 1989); see 55 Fed. Reg. 30,584, 30,593 (July 26, 1990) (same). By definition, then, the Act does not address—let alone clearly authorize—the use of averaging, banking, and trading to electrify the Nation's vehicle fleet. [EPA-HQ-OAR-2022-0985-1566-A2, p. 64]

That should be the end of the analysis. Section 202 of the Clean Air Act does not itself "direct [conventional vehicles] to effectively cease to exist." West Virginia, 142 S. Ct. at 2612 n.3. EPA has instead relied on mechanisms that are not themselves spelled out in the statute and that have never before been used to mandate HD electric vehicles. Just as in West Virginia, EPA has nothing "close to the sort of clear authorization" necessary for such a transformational policy shift. 142 S. Ct. at 2614. [EPA-HQ-OAR-2022-0985-1566-A2, p. 64]

But in truth, the problem is far worse for EPA than that. As explained below, the Act unambiguously precludes fleetwide-average emission standards under Section 202(a). And even if the statute permitted some fleetwide averaging, it does not allow EPA to take the additional step of incorporating non-emitting vehicles into emission averages and thus forcing the market toward electric vehicles. The proposal is not merely stretching vague statutory language. It is defying clear statutory text. [EPA-HQ-OAR-2022-0985-1566-A2, p. 65]

The text and structure of Section 202, and of Title II more broadly, unambiguously require that emission standards under Section 202(a) apply to individual vehicles, not manufacturers' fleets on average. EPA claims to find authority for fleetwide averaging in Section 202(a), which authorizes EPA to issue "standards applicable to the emission of any air pollutant from any class or classes of new motor vehicles ... which in [its] judgment cause, or contribute to, air pollution which may reasonably be anticipated to endanger public health or welfare." 42 U.S.C. § 7521(a). [EPA-HQ-OAR-2022-0985-1566-A2, p. 65]

On its face, that provision authorizes EPA to set standards for vehicles that emit harmful air pollutants. It says nothing about averaging across fleets. As noted, when EPA first adopted fleetwide averaging, it acknowledged that "Congress did not specifically contemplate an averaging program when it enacted the Clean Air Act." 48 Fed. Reg. at 33,458. EPA claimed to have the authority because the Act "does not explicitly preclude standards" based on averaging. 54 Fed. Reg. at 22,666 (emphasis added). EPA was wrong. "[T]he broader context of the statute as a whole," Robinson v. Shell Oil Co., 519 U.S. 337, 341 (1997), makes clear that Section 202(a) does not permit fleetwide averaging. And, even if EPA could somehow show that the statute tacitly or implicitly allows (or does not expressly preclude) averaging, that would still be insufficient to meet the necessary clear congressional authority to use fleetwide averaging as a means to force a transition from internal-combustion engines to ZEVs. [EPA-HQ-OAR-2022-0985-1566-A2, p. 65]

a. Other provisions in Section 202 demonstrate that emission standards may not be based on averaging.

Title II is replete with provisions that necessarily apply to vehicles individually, not to fleets on average. That is evident first in the emission standards prescribed by Section 202 itself. For example, in Section 202(b), the Act sets forth specific light-duty vehicle emission standards that EPA must promulgate in "regulations under" Section 202(a). 42 U.S.C. § 7521(b). For vehicles in model years 1977 to 1979, the standards must provide that "emissions from such vehicles and engines may not exceed 1.5 grams per vehicle mile of hydrocarbons and 15.0 grams per vehicle mile of carbon monoxide." Id. § 7521(b)(l)(A). [EPA-HQ-OAR-2022-0985-1566-A2, p. 65]

Those provisions require that the "regulations under [Section 202(a)]" apply to "vehicles and engines," not "vehicles and engines on an average basis across a fleet." Construing those provisions to allow averaging would, in effect, add words to the statute that change its meaning. Neither courts nor agencies may "supply words ... that have been omitted." Antonin Scalia & Bryan Garner, Reading Law: The Interpretation of Legal Texts 93 (2012); accord Rotkiske.v. Klemm, 140 S. Ct. 355, 360-361 (2019). And supplying the extra words "on average" would have a significant substantive effect: "roller coaster riders must be 48 inches tall" means something very different from "roller coaster riders must be 48 inches tall on average." [EPA-HQ-OAR-2022-0985-1566-A2, p. 65]

The testing requirements accompanying the Section 202(b) standards confirm that those standards apply to all vehicles. In particular, EPA must "test any emission control system incorporated in a motor vehicle or motor vehicle engine ... to determine whether such system enables such vehicle or engine to conform to the standards required to be prescribed under [Section 202(b) of the Act].” 42 U.S.C. § 7525(a)(2). If the system complies, EPA must issue a “verification of compliance with emission standards for such system.” Id. Those requirements plainly contemplate standards that apply to individual vehicles and their emission-control systems. Not only does the statutory text frame the inquiry as whether an individual “vehicle” or “engine” conforms to the emission standards, but the provision’s foundational premise-that an emission-control system can enable a vehicle to meet emission standards depends on individually applied standards. [EPA-HQ-OAR-2022-0985-1566-A2, pp. 65 - 66]

Other parts of Section 202 further demonstrate that emission standards under Section 202(a) cannot rely on averaging. Section 202(b)(3), for example, authorizes EPA to grant waivers from certain nitrogen-oxide emission standards—which, again, are standards “under” Section 202(a), see 42 U.S.C. § 7521(b)(l)(B)—for no “more than 5 percent of [a] manufacturer’s production or more than fifty thousand vehicles or engines, whichever is greater.” Id. § 7521(b)(3). This provision would be nonsensical under a fleetwide-averaging regime. It contemplates a default under which every vehicle meets a standard, then gives manufacturers a waiver from that default for up to 5% of the fleet. But under fleetwide averaging, no waiver is needed. Instead, a vast proportion of a manufacturer’s fleet—perhaps 50% or more—effectively has a “waiver” so long as a sufficient number of vehicles outperform the standard. Likewise, Section 202(g), which specifies an increasing “percentage of each manufacturer’s sales volume” of each model year’s vehicles that must comply with specified emission standards, is fundamentally incompatible with averaging. Id. § 7521(g)(l). [EPA-HQ-OAR-2022-0985-1566-A2, p. 66]

Similarly, under Section 202(m), EPA must require manufacturers to install on “all” new light-duty vehicles and trucks “diagnostic systems” capable of identifying malfunctions that “could cause or result in failure of the vehicles to comply with emission standards established under this section.” Id. § 7521(m)(l). As this requirement makes clear, individual vehicles must “comply with emissions standards established under [Section 202].” Id. Otherwise, requiring diagnostic equipment on “all” vehicles makes no sense. In a fleetwide-averaging regime, this requirement would be pointless, as the deterioration or malfunction of an individual vehicle’s emission-related systems would provide virtually no information about whether the fleet as a whole is compliant. [EPA-HQ-OAR-2022-0985-1566-A2, p. 66]

b. Title II’s compliance and enforcement provisions for emission standards confirm that EPA cannot use fleetwide averaging.

Fleetwide averaging also clashes with “the design and structure of [Title II] as a whole.” Utility Air, 573 U.S. at 321 (citation omitted). Title II sets forth a comprehensive, interlocking scheme for enforcing emission standards through testing, certification, warranties, remediation, and penalties. Fleetwide-average standards are incompatible with these provisions, which are “designed to apply to” individual vehicles and “cannot rationally be extended” to fleets. Id. at 322. [EPA-HQ-OAR-2022-0985-1566-A2, p. 66]

Testing and Certification. Under Title II, EPA must “test, or require to be tested in such manner as [it] deems appropriate, any new motor vehicle or new motor vehicle engine submitted by a manufacturer to determine whether such vehicle or engine conforms with the regulations prescribed under [Section 202].” 42 U.S.C. § 7525(a)(l). If the ‘‘vehicle or engine conforms to such regulations,” EPA must issue the manufacturer a “certificate of conformity.” Id. EPA may later test a manufacturer’s vehicles and engines, and if “such vehicle or engine does not conform with such regulations and requirements, [EPA] may suspend or revoke such certificate insofar as it applies to such vehicle or engine." Id. § 7525(b)(2)(A)(ii). A manufacturer may not sell a vehicle or engine not "covered by a certificate of conformity." Id. § 7522(a)(l). [EPA-HQ-OAR-2022-0985-1566-A2, pp. 66 - 67]

Fleetwide averaging is incompatible with these requirements in at least two respects. First, by using the singular terms "vehicle" and "engine," along with "any" and "such," the statute contemplates that individual vehicles may be tested, determined to "not conform" with the standards, and have their certificates of conformity suspended or revoked. In a fleetwide-averaging regime, testing an individual vehicle or engine does not enable EPA to determine whether it "conforms with the regulations prescribed under [Section 202]," 42 U.S.C. § 7525(a)(l), because conformity turns not on an individual vehicle's emissions but on the fleet's average performance overall. Second, fleetwide averaging also makes it impossible to determine compliance with applicable emission standards before a vehicle is sold, as required to obtain the certificate of conformity needed for a sale. See 42 U.S.C. § 7522(a)(l). Under fleetwide-average standards, a vehicle's "conform[ity] with the regulations prescribed under [Section 202]" cannot be determined until the manufacturer calculates its production-weighted average at "the end of each model year," when the manufacturer knows the quantity and model of "vehicles produced and delivered for sale." 40 C.F.R. §§ 86.1818-12(c)(2)(2), 86.1865-12(i)(l), (j)(3). [EPA-HQ-OAR-2022-0985-1566-A2, p. 67]

For similar reasons, fleetwide averaging is inconsistent with the statutory definition of an "emission standard," which "limits the quantity, rate, or concentration of emissions of air pollutants on a continuous basis." 42 U.S.C. § 7602(k). It is impossible to know on a "continuous basis" whether a manufacturer's fleet complies with EPA's proposed average standards, because a manufacturer cannot calculate its production-weighted average until the end of the year. Simply put, an after-the-fact compliance regime is incompatible with the Act's testing and certification scheme. [EPA-HQ-OAR-2022-0985-1566-A2, p. 67]

Warranties and Remediation. Fleetwide-average standards similarly clash with Title II's warranty provisions. Under Section 207, a manufacturer must ‘‘warrant to the ultimate purchaser and each subsequent purchaser" "at the time of sale" that each new vehicle complies with applicable regulations under [Section 202]. 42 U.S.C. § 7541(a)(l) (emphasis added). Yet, as with certificates of conformity, manufacturers cannot warrant conformity with fleetwide-average emission standards at the time of sale, because compliance can be determined only at the end of the year. See 40 C.F.R. § 86.1865-12(i)(l) (requiring manufacturers to compute their "production weighted fleet average" by "using actual production [data]" for the year in question). [EPA-HQ-OAR-2022-0985-1566-A2, p. 67]

Fleetwide-average emission standards are also inconsistent with Title II's remediation and notification provisions. Those provisions state that if EPA "determines that a substantial number of any class or category of vehicles or engines ... do not conform to the regulations prescribed under [Section 202]," the manufacturer must remedy "the nonconformity of any such vehicles or engines." 42 U.S.C. § 7541(c)(l). If "a motor vehicle fails to conform," the manufacturer bears the cost. Id. § 7541(h)(l). Further, "dealers, ultimate purchasers, and subsequent purchasers" must be given notice of any nonconformity, id. § 7541(c)(2), which requires identification of specific nonconforming vehicles. None of this is possible where the nonconformity is tied to a fleet on average. [EPA-HQ-OAR-2022-0985-1566-A2, p. 67]

Penalties. Finally, EPA's fleetwide-averaging regime is inconsistent with the statute's penalty provision. Under Section 205, any violation "shall constitute a separate offense with respect to each motor vehicle or motor vehicle engine," with each offense subject to its own civil penalty of up to $25,000. 42 U.S.C. § 7524(a) (emphasis added). Under EPA's approach, however, no individual vehicle or engine violates the applicable standard, only the fleet as a whole. The statute provides no method for calculating penalties when a fleet fails to meet its fleetwide-average standard-because it does not authorize fleetwide-average standards. [EPA-HQ-OAR-2022-0985-1566-A2, pp. 67 - 68]

c. The broader text and history of Title II confirm that the rule exceeds EPA's authority through fleetwide averaging.

Other indicia of statutory meaning demonstrate that the proposed rule exceeds EPA's statutory authority under Section 202(a). Elsewhere in Title II, Congress showed that it knew how to legislate with respect to "average annual aggregate emissions." 42 U.S.C. § 7545(k)(l)(B)(v)(II) (directing EPA to take certain actions if "the reduction of the average annual aggregate emissions of toxic air pollutants in a [designated district] fails to meet" certain standards). [EPA-HQ-OAR-2022-0985-1566-A2, p. 68]

Thus, "if Congress had wanted to adopt an [averaging] approach" for motor vehicle standards under Section 202(a), "it knew how to do so." SAS Inst., Inc. v. Iancu, 138 S. Ct. 1348, 1351 (2018); see Rotkiske, 140 S. Ct. at 360-361 ("Atextual judicial supplementation is particularly inappropriate when, as here, Congress has shown that it knows how to adopt the omitted language or provision."). It did not choose that approach in Section 202(a). [EPA-HQ-OAR-2022-0985-1566-A2, p. 68]

The Energy Policy Conservation Act, enacted just two years before the 1977 Clean Air Act amendments, reinforces that conclusion. There, Congress directed the Secretary of Transportation to issue regulations setting "average fuel economy standards for automobiles manufactured by a manufacturer" in a given model year. 49 U.S.C. § 32902(a). That Congress has not used similar language in Section 202(a) of the Clean Air Act is a "telling clue" that the Act does not permit fleetwide averaging. Epic Sys. Corp. v. Lewis, 138 S. Ct. 1612, 1626 (2018). [EPA-HQ-OAR-2022-0985-1566-A2, p. 68]

The Clean Air Act's history also reflects Congress's understanding that emission standards would apply to all vehicles individually. Congress was so focused on reducing emissions at the level of the individual vehicle that, in the 1970 amendments, Congress permitted EPA to test any individual vehicle as it comes off the assembly line. See Pub. L. No. 91-601, § 8, 84 Stat. 1676, 1694-1696. Such a vehicle-by-vehicle test was meant to supplement the pre-1970 testing of prototypes. Congress explained that while testing of prototypes ''will continue," "tests should require each prototype rather than the average of prototypes to comply with regulations establishing emission standards." H.R. Rep. No. 91-1146, at 6 (1970). And if Congress forbade averaging across prototypes, it certainly did not permit averaging across entire fleets. [EPA-HQ-OAR-2022-0985-1566-A2, p. 68]

d. Related provisions confirm that Section 202(a) does not authorize averaging of non-emitting electric vehicles.

Other provisions of the Clean Air Act drive home the lack of statutory authorization to mandate electrification as well. In the Clean Air Act Amendments of 1990, Congress spoke directly to the phase-in of electric vehicles on America's roads. Congress instructed EPA to establish standards for "clean-fuel vehicles" operating on "clean alternative fuel," including "electricity." Pub. L. No. 101-549, § 229, 104 Stat. 2399, 2513 (codified at 42 U.S.C. §§ 7581(2), (7), 7582(a)). Congress required that certain areas of the country with the worst pollution would have to "phase-in" a "specified percentage" of "clean-fuel vehicles" using "clean alternative fuels" (defined to include "electricity") in certain fleets. 42 U.S.C. § 7586; see id. § 758l(a). The 1990 amendments highlight that Congress knows how to clearly establish standards that apply to electric vehicles, and to directly require that such vehicles be phased into a particular fleet. But Congress chose to do so only on a targeted, regional basis. The contrast between the 1990 amendments and Section 202(a) highlights the absence of any statutory authority for EPA's rule. [EPA-HQ-OAR-2022-0985-1566-A2, pp. 68 - 69]

Other related statutes also suggest the same. In the Energy Policy Act of 1992, Congress directed NHTSA to set fuel-economy standards based on averages, but prohibited NHTSA from setting fuel-economy standards that average in the fuel economy of electric vehicles. See Pub. L. No. 102-486 §§ 302, 403, 106 Stat. 2776, 2870-2871, 2876 (later codified at 49 U.S.C. § 32902(h)). This prohibition bars NHTSA from doing exactly what EPA is doing here: misusing its regulatory authority to force a transition from conventional vehicles to electric vehicles by artificially tightening the "average" standard a fleet must meet. Of course, when Congress finalized the language of Section 202(a)(l) in 1977, it had no need to explicitly block EPA from considering electric vehicles, because it did not contemplate that EPA would set emission standards using averaging in the first place (or that EPA would be setting standards for greenhouse gases). The prohibition on NHTSA nevertheless underscores just how far EPA is reaching here: it is straining statutory language to seize a power that Congress expressly denied to a sister agency that actually has authority to promulgate fleetwide-average standards. [EPA-HQ-OAR-2022-0985-1566-A2, p. 69]

e. EPA's lack of authority for a credit-trading scheme further confirms its lack of authority to set fleetwide averages.

The proposal's credit banking and trading program is critical to EPA's electrification mandate. But the agency also lacks authority under Title II to establish a credit scheme as part of its emission standards under Section 202(a). [EPA-HQ-OAR-2022-0985-1566-A2, p. 69.]

As with fleetwide averaging, EPA has previously acknowledged that Title II says nothing about banking and trading credits in connection with motor-vehicle emission standards. See 54 Fed. Reg. at 22,665. What EPA has ignored, however, is that Title II is not silent regarding banking and trading in other contexts. Indeed, in multiple other provisions under Title II, Congress expressly authorized the use of bankable and tradable credits. See, e.g., 42 U.S.C. § 7545(k)(7) (reformulated gasoline credits); § 7545(o)(2)(A)(ii)(II)(cc), (5)(A)(i) (renewable fuel credits); id. § 7545(o)(2)(A)(ii)(II)(cc), (5)(A)(ii) (biodiesel credits); id. § 7545(o)(2)(A)(ii)(II)(cc), (5)(A)(iii) (small refineries credits); id. § 7586(f) (clean-fuel fleet-operator credits); id. § 7589(d) (California pilot test program's clean-fuel vehicle manufacturer credit). [EPA-HQ-OAR-2022-0985-1566-A2, p. 69.]

Under EPA's proposed approach, those provisions would all be superfluous, because EPA already had the discretion to adopt a credit-trading regime for any program. If Congress had wanted to permit credits in connection with emission standards under Section 202(a), it knew how to and would have done so expressly. See SAS Inst., 138 S. Ct. at 1351. [EPA-HQ-OAR-2022-0985-1566-A2, p. 69.

For all these reasons, courts have cast substantial doubt on EPA's authority to set fleetwide-average emission standards. As the D.C. Circuit Court of Appeals explained in NRDC v. Thomas, 805 F.2d 410 (D.C. Cir. 1986), the "engine specific thrust" of Title II's "testing and compliance provisions" is evident both in Congress's choice to "spea[k] of 'any,' 'a,' or 'such' motor vehicle or engine" in the text of the statute and in the "troubling" legislative history recounted above. Id. at 425 n.24. The arguments were not dispositive in Thomas only because the parties there had failed to present them. Id. But the Court nevertheless recognized that the arguments were relevant to "future proceedings." Id.. [EPA-HQ-OAR-2022-0985-1566-A2, p. 69.]

f. At a minimum, EPA may not use fleetwide averaging to require electrification.

Despite the absence of statutory authorization for fleetwide averaging, EPA has long employed that mechanism without significant industry pushback. That is likely because fleetwide averaging has generally been offered as an accommodation to regulated parties, allowing them flexibility that the statute does not in fact permit. In its current proposal, however, EPA is not offering an extra-statutory accommodation. It is taking an additional step away from the statutory text by using fleetwide averaging to mandate electrification. [EPA-HQ-OAR-2022-0985-1566-A2, pp. 69 - 70.]

To be clear, in prior rules EPA set an average emission standard and allowed manufacturers to make some vehicles that emitted more and some that emitted less. Here, EPA has set tailpipe greenhouse-gas emission standards at a level so stringent that manufacturers must incorporate an increasing percentage of HD electric vehicles—which EPA treats as zero-emission vehicles—into their averages in order to comply with the "standards." See p. 13, supra. Put differently, the agency is proposing an emission standard that is artificially low because it incorporates electric vehicles, which EPA treats as emitting zero pollutants for averaging purposes. [EPA-HQ-OAR-2022-0985-1566-A2, p. 70.]

Whatever the permissibility of fleetwide averaging, the text and structure of Title II make plain that EPA cannot manipulate averaging as a means to force production of an increasing market share of electric vehicles. Section 202 does not grant EPA the power to make the internal-combustion engine go the way of the horse and carriage. At the very least, Section 202 is hardly clear in granting that awesome power—which is what matters under West Virginia. For automobiles as for power plants, EPA has purported to discover in the Clean Air Act the authority to "forc[e]" manufacturers to "cease making" a particular type of energy "altogether." 142 S. Ct. at 2612. We have seen that play recently before, and it should end the same way. [EPA-HQ-OAR-2022-0985-1566-A2, p. 70.]

<u>EPA Summary and Response:</u>

<u>Summary:</u>

AmFree et al. provided some background on EPA's use of fleetwide averaging in past regulations. AmFree et al. questions EPA's legal authority under the CAA for use of averaging in setting standards, suggests that non-emitting vehicles are not covered under the statute, and claims the rule constitutes a transformative change which implicates the Major Question Doctrine, and remakes the sector on a highly compressed timeline of less than a decade. AmFree et al. suggests the proposed standards are not "performance-based" when EPA states that it expects a shift from ICEs to EVs. AmFree et al. argues that fleetwide averaging is necessary (as no "conventional" individual vehicle could meet the Phase 3 standards) and not a flexibility in EPA's approach for this rule, unlike past rules' use of fleetwide averaging, and is used "in a fundamentally different way to achieve a different end" to mandate a shift of a substantial portion of production to certain preferred technologies (referencing one or more of the following in different parts of their comment: ZEVs, zero GHG emission vehicles, electrification, and/or alternatives to ICE). AmFree et al. further stated the following:

- Even if fleetwide averaging were permissible as a general matter, it cannot be exploited to shoehorn zero-emission vehicles—i.e., vehicles that do not "cause, or contribute to, air pollution,"[663] and thus fall outside Section 202 entirely—into the fleetwide-average calculation as a means of mandating electrification.
- "Congress did not specifically contemplate an averaging program when it enacted the Clean Air Act."[664]
- Under the Major Questions Doctrine, EPA needs "'clear congressional authorization' for the power it claims (to promulgate such a mandate, including through employing fleetwide averaging),"[665] not congressional silence on the subject, and it lacks such authorization.
- ... averaging is also deeply in tension with "the design and structure of [Title II] as a whole."[666] referencing provisions on testing, warranties, and penalties.

API, AFPM, Clean Fuels Development Coal., and Valero offered similar arguments challenging EPA's authority to implement any of the proposed provisions regarding fleetwide averaging and averaging in setting standards (and, to some extent, certain commenters (e.g. Valero also raise these arguments for banking and trading).

More specifically, first, the commenters acknowledge that EPA has included ABT in prior Title II emission standards rules for decades. The difference here, in their view, is that in prior rules, ABT has been offered as a flexibility, whereas here it is an integral part of the standard-setting mechanism. (AmFree et al., API, Clean Fuels Dvl. Coal.)

Second, these commenters all maintained that the ABT standard-setting feature of the rule was part and parcel of the transformational change to mandate electrification of the heavy duty sector, triggering the Major Question Doctrine. The commenters argued that since EPA concedes there is no explicit delegation in the statute regarding utilization of ABT, EPA lacks authority to use it here.

Third, the commenters argue that not only does the statute not explicitly authorize the use of ABT, but its text indicates that EPA lacks such authority. The commenters argue that section 202(a)(1) itself applies to "class" or "classes" of new motor vehicles. They argue that because BEVs and ICE vehicles are distinctly different types, they cannot be averaged together, and

[663] 42 U.S.C. § 7521(a)(1).
[664] 48 Fed. Reg. 33,456, 33,458 (July 21, 1983).
[665] *West Virginia*, 142 S. Ct. at 2609 (citation omitted).
[666] *Util. Air Regul. Group*, 573 U.S. at 321 (citation omitted).

moreover that “class” implies a singular standard, since a class cannot be treated as a collective (AmFree et al., AFPM). Commenters argue further that “the relevant feature of a “class” of “motor vehicles” that “cause, or contribute to, air pollution” is that the vehicles in the class all emit the relevant pollutant.[667] A vehicle that emits zero pollutants is necessarily not part of that class”. (AmFree et al., AFPM; to the same effect, API and Valero). The commenters suggest that no single vehicle configuration can meet the standards, so OEMs would have to certify two “fundamentally different vehicle types” to do so. (API). They indicate that EPA is essentially trying to add the words “on average” to the statute and that doing so would significantly change the meaning.

Looking beyond section 202(a)(1), these commenters point to other provisions which they claim are either fundamentally inconsistent with the standards including averaging, or, by alluding to or otherwise authorizing averaging, show that that Congress knew how to authorize averaging when it wished EPA to have that authority, so the absence of that authorization in section 202(a)(1) indicates EPA lacks the authority (invoking the so-called Russello canon of statutory construction). Provisions these commenters indicate are inconsistent with ABT are the following, as the commenters characterize the provisions:

- 42 U.S.C. § 7521(b)(l) requires that the “regulations under [Section 202(a)]” apply to “vehicles and engines,” not “vehicles and engines on an average basis across a fleet.” And supplying the extra words “on average” would have a significant substantive effect: “roller coaster riders must be 48 inches tall” means something very different from “roller coaster riders must be 48 inches tall on average.” The testing requirements accompanying the Section 202(b) standards confirm that those standards apply to all vehicles. In particular, EPA must “test any emission control system incorporated in a motor vehicle or motor vehicle engine ... to determine whether such system enables such vehicle or engine to conform to the standards required to be prescribed under [Section 202(b) of the Act].”[668] If the system complies, EPA must issue a “verification of compliance with emission standards for such system.”[669] Those requirements plainly contemplate standards that apply to individual vehicles and their emission-control systems. Not only does the statutory text frame the inquiry as whether an individual “vehicle” or “engine” conforms to the emission standards, but the provision’s foundational premise-that an emission-control system can enable a vehicle to meet emission standards depends on individually applied standards. (Chamber of Commerce, Valero). They also argue that 42 U.S.C. section 7521(b)(3) indicates that each individual vehicle or engine must meet a standard before EPA can grant a waiver based on use of innovative powertrain technologies (Chamber of Comm., API, Clean Fuels Dvl. Coal.). Valero argues more specifically that “Section 202(b)(3) authorizes EPA to grant waivers from certain nitrogen-oxide emission standards—which, again, are standards “under” Section 202(a), see 42 U.S.C. § 7521(b)(l)(B)—for no “more than 5 percent of [a] manufacturer’s production or more than fifty thousand vehicles or engines, whichever is greater’, but this provision makes no sense under a fleetwide-averaging regime: “It contemplates a default under which every vehicle meets a standard, then gives manufacturers a waiver from that default for up to 5% of the fleet. But under fleetwide averaging, no waiver is needed.

[667] 42 U.S.C. § 7521(a)(1).
[668] 42 U.S.C. § 7525(a)(2).
[669] *Id.*

Instead, a vast proportion of a manufacturer's fleet—perhaps 50% or more—effectively has a "waiver" so long as a sufficient number of vehicles outperform the standard."

- 42 U.S.C. § 7521(g)(l) indicates that specific percentages of vehicles must comply with the standards each model year, whereas they argue an averaging regime would allow higher percentages not to achieve if offset on a fleetwide basis. (Valero).
- 42 U.S.C. § 7521(m)(l) references diagnostic system requirements for light-duty vehicles and trucks applicable to "all" light duty vehicles, which system must be capable of identifying "failure of the vehicles to comply with emission standards under this section". The argument is that with a fleet average standard, the diagnostic results of any individual vehicle convey no useful information about compliance with an averaging-based standard. (AmFree et al., Valero, Chamber of Commerce).
- 42 U.S.C. § 7525(a)(l) and 7525(b)(2) direct EPA to test and certify individual motor vehicles or engines as meeting the applicable standards. They argue that since a manufacturer submits their ABT report at the end of the model year, a manufacturer doesn't truly know if its vehicles comply when they are sold. (AmFree et al., Chamber of Comm., API, Valero).
- 42 U.S.C. § 7541(a)(l) indicates that manufacturers must warrant that each new vehicle sold complies with the regulations "at the time of sale." They argue manufactures can't know a compliance from a fleet average perspective until they calculate their production-weighted averages at the end of the year. (AmFree et al., Chamber of Comm., Valero).
- 42 U.S.C. § 7541(c) states that manufacturers must remedy nonconforming vehicles and engines if EPA determines a "substantial number" of a class do not conform to the regulations. They argue it is not possible to do this when many vehicles are inherently not meeting the standard under an averaging program. (Valero).
- 42 U.S.C. § 7524(a) refers to civil penalties as separate offenses for each vehicle or engine. They argue the provision does not provide a method to calculate penalties for fleetwide-average standards where an entire fleet may fail to meet the standards. (AmFree et al., Chamber of Comm., Valero).
- 42 U.S.C. § 7602(k) defines an emission standard as a limit that applies on a continuous basis. They argue manufacturers don't know their compliance continuously under an averaging program, because they don't calculate the production-weighted average until the end of the model year. (Valero).
- They argue Congress directed EPA to test individual vehicles and explicitly forbade testing the average of prototypes in their 1970 amendments, which would have similarly applied to a broader averaging across fleets (citing H. Rep. No. 91-1146 at 6).

The commenters cite the following provisions (as characterized by the commenters) as evidence that Congress knew how to specify an averaging or ABT regime when it wished agencies to utilize one:

- 42 U.S.C. § 7545(k) explicitly directs EPA to consider "average annual aggregate emissions" for toxic air pollutants.
- Various Clean Air Act provisions specifically speak to averaging and credits. Commenters argue these are unnecessary provisions if such authority can be implied

absent an express delegation, and in any case, they are an indication that Congress knew how to specify use of ABT. [670]

- Relatedly, 42 U.S.C. §§ 7581 (7), 7582(a), 7586, 7589(d), which are among the clean-fuel vehicle provisions added as part of the 1990 CAA Amendments, direct EPA to establish standards that phased in a percentage of clean-fuel vehicles, including those fueled by clean alternative fuels such as electricity. Sections 7586(f) and 7589(d) refer to credit generation explicitly, which they argue indicates that Congress could authorize credit-based standards when it wished to. They argue Congress specifically chose to phase in electric vehicles "on a targeted, regional basis" which is in contrast to section 202(a). They also argue the definition of "clean alternative fuel" itself, in 42 U.S.C. section 7581(2) refers to "electricity", indicating that Congress knew how to specify use of electrification when it wished to.
- They argue that 49 U.S.C. § 32902(h) directs NHTSA to set fleet average fuel-economy standards, but "prohibited NHTSA from setting fuel-economy standards that average in the fuel economy of electric vehicles" and EPA was not given a similar restriction in 202(a) because Congress "did not contemplate that EPA would set emission standards using averaging in the first place." (Valero).

These commenters stated that they acknowledge that the D.C. Circuit has upheld EPA's use of ABT in Title II programs but distinguish these cases on several grounds. These commenters stated that if the rule triggers the Major Question Doctrine, then these cases indicate that ABT is not explicitly authorized. In addition, these commenters stated that these cases mistakenly consider Congressional silence as creating a gap which EPA has authorized discretion to fill. They also asserted that the dicta in *NRDC v. Thomas* footnote 24 cites to the CAA certification provisions[671] as contemplating a vehicle-by-vehicle certification regime and recognizes inconsistencies between averaging and other statutory provisions (noting the court "reserved judgment on that issue only because 'it was not raised by any party before the agency'").

ATS cautioned that a fleet averaging approach could "create perverse incentives" for sellers and purchases that could reduce zero-emission vehicle sales.

<u>Response:</u>

Many commenters maintained that both under the major questions doctrine and normal principles of statutory construction, standards using a fleet averaging form are impermissible under the Act. EPA disagrees with these comments for several reasons as explained in section I.C of the preamble and as further detailed below. First, EPA has employed fleetwide averaging in standard-setting and compliance since 1985. The final rule merely maintains and did not reopen the existing ABT programs, such that these comments are untimely and outside the scope of this final rule. Without reopening the ABT program, we respond to the comments raised substantively as well. Second, ABT is consistent with the standard-setting authority conferred by Congress in section 202(a)(1) and (2). Indeed, ABT furthers the goals of the statute in enabling manufacturers to achieve any given level of emissions reductions with lower costs and more flexibility. Third, ABT is consistent with the compliance and enforcement provisions of the Act. Commenters are simply wrong that ABT precludes compliance and enforcement vis-a-vis individual vehicles; rather, the regulatory program explicitly requires compliance by individual

[670] *See*, *e.g.*, CAA sections 211(k)(7), 211 (o)(2)(A)(ii)(II)(cc), 211(o)(5).
[671] CAA section 206.

vehicles, and EPA can and does enforce the program's requirements with respect to such individual vehicles. Fourth, the fact that Congress required EPA or other agencies to provide for tradable credits in some other programs outside of the motor vehicle emissions control context is not relevant in ascertaining the agency's authority to provide for ABT in our motor vehicle programs. Fifth, the statute does not preclude EPA regulating all HD vehicles—regardless of whether they emit or have an ICE powertrain—in the same class. Indeed, EPA previously defined the class as HD vehicles in the 2009 Endangerment Finding and did not reopen that finding in this proceeding. Moreover, the commenters' preferred classification is unreasonable as it would delay the adoption of effective and available pollution control technologies and forgo large benefits for the public health and welfare. EPA responds to comments about the major questions doctrine in RTC 2.1.[672]

Response 10.2.1.a: The Comments Are Untimely.

These comments are untimely and beyond the scope of this final rule. EPA did not reopen in this rulemaking whether it is permissible to use an averaging approach to setting standards under section 202(a)(1)-(2), or the general ABT program's flexibilities. EPA disagrees that EPA's approach in this rulemaking is novel from past rulemakings: EPA has not only repeatedly used averaging in setting standards under section 202(a)(1)-(2), including in setting the most recent HD GHG Phase 2 standards in 2016,[673] and noted the importance of ABT program flexibilities overall, but also repeatedly has explained that ABT is consistent with and gives full effect to the requirements of section 202 as well as the broader statutory scheme, including Title II's compliance and enforcement provisions applicable to such HD vehicles. Under such circumstances, it is eminently reasonable for EPA not to reconsider a question that has been settled for decades.[674] Additionally, as further discussed in this response and Section 2 of this RTC document, as well as in the final rule Preamble Sections I and II, the commenter's assertions of a change from EPA's historical approach rest on a false assertion that this rule mandates adoption of a specific compliance pathway; rather, the HD Phase 3 standards are performance-based standards with many potential compliance pathways, of which we provide several examples to further support that EPA is agnostic as to what technologies are ultimately applied in complying with the HD GHG Phase 3 standards.[675]

[672] Commenter AFPM attached its brief in *Texas v. EPA*, No. 22-1031 (D.C. Cir.) to its comments and referenced arguments therein. To the extent applicable, EPA also incorporates its responsive brief in that case by reference. EPA's Br., *Texas v. EPA*, No. 22-1031 (D.C. Cir.).

[673] *See, e.g.*, 81 FR 73715 ("[W]e have developed the final vocational vehicle standards using the same methodology as for all of the other Phase 2 standards, where we apply fleet average technology mixes to fleet average baseline vehicle configurations, and each average baseline and technology mix is unique for each vehicle subcategory.").

[674] *See Growth Energy v. EPA*, 5 F.4th 1, 13 (D.C. Cir. 2021).

[675] Commenters frame this assertion of a mandate in several different ways, all of which the rule's administrative record shows are false. Our additional example potential compliance pathways comprised of vehicles with ICE (relative to the reference case) that all emit criteria and GHG pollutants show that the Phase 3 standards are not a "ZEV" mandate, "Zero GHG vehicle" mandate, or "non-ICE" mandate, and also show that they are not an "electrification" mandate (even if one were to adopt this false premise of electrification as only applicable to PHEVs, BEVs, and FCEVs, which is incorrect as ICE vehicles also have electrified components, since at least one example potential compliance pathway is comprised of vehicles without those technologies relative to the reference case).

Commenters' claims that this rule is novel in treating ABT as integral to standard-setting, while prior rules viewed ABT only as a flexibility, are misplaced. As an initial matter, EPA considered only the availability of averaging, but not banking or trading, in identifying the level of the standards.[676] EPA has relied on the availability of averaging in countless standard-setting rulemakings since 1985. For example, the 1985 rule found that averaging was a key consideration in supporting the technological feasibility and lead-time of the standards. That rule stated:

> Particulate trap technology is heretofore untried on the fleet level. EPA believes that the … standard which, through averaging, effectively requires use of traps on 70 percent of all heavy-duty vehicles will significantly reduce the risk of widespread noncompliance while allowing manufacturers to gain valuable experience with this new technology. To promulgate this standard without allowing averaging … would increase the technological risk associated with the standard because traps would have to be used in even the most difficult design applications.[677]

Numerous subsequent rules have followed the same approach.[678] For example, the 1990 rule stated that "the standards were set with averaging in mind, making averaging integral to the standard."[679] Further, EPA has always viewed averaging as integral to standard-setting in the HD GHG program. For example, the HD Phase 2 GHG final rule stated that "ABT programs are more than just add-on provisions included to help reduce costs. They can be, as in EPA's Title II programs generally, an integral part of the standard setting itself.…Without ABT provisions (and other related flexibilities), standards would typically have to be adjusted to accommodate issues of feasibility and available lead time."[680]

Moreover, the legality of averaging under section 202(a) has already been litigated in *NRDC v. Thomas*, 805 F. 2d 410 (D.C. Cir. 1986), where the court of appeals ruled in favor of the agency. Commenters rely heavily on footnote dicta from that case to allege that the court identified potential statutory inconsistencies but did not reach them only because they were not raised in the litigation. We address the substance of these points later in our response. However, we note here that the footnote dicta were comprehensively addressed by EPA's 1989 proposal[681]

[676] While banking and trading provide manufacturers with additional flexibilities in meeting the standards, they are not necessary to EPA's judgment as to the feasibility of the standards. *See* preamble II.G. As such, they are also severable from the final standards.
[677] 50 FR 10634-35.
[678] *See also, e.g.*, 2010 LD GHG final rule, 75 FR 25412-13 (describing setting fleet average LD GHG standards, as EPA had previously set for Tier 2 NOx standards, and the integral role of ABT in standard setting itself for Title II engine and vehicle programs); 65 FR 6698, 6743-46 (Feb. 10, 2000) (Tier 2) ("An ABT program is an important factor that EPA takes into consideration in setting emission standards that are appropriate under section 202 of the Clean Air Act."); 64 FR 58471, 58481 (Oct. 29, 1999) (describing how EPA set the 2004 and later model year NOX+NMHC standards for HD diesel engines (62 FR 54694) in consideration of modified ABT provisions: "The final rule also contained modified ABT provisions for heavy-duty diesel engines … .").
[679] 55 FR 30594.
[680] 81 FR 73495/3 (Oct. 25, 2016); *see also* HD Phase 1 GHG Final Rule, 76 FR at 57127 (Sept. 15, 2011).
[681] 54 FR 22652, 22665-66 (May 25, 1989) ("EPA does not believe that the statutory text or legislative history cited by the court necessarily means that the CAA requires or that Congress intended that every vehicle or engine family emit at the same level. As the court itself noted, the Act gives EPA broad latitude in the testing of vehicles and, more fundamentally, in the formulation of standards. EPA promulgated the HDE NOx and PM emissions standards as

and 1990 final rule,[682] where we also received copious comments on this specific issue. Any party wishing to challenge EPA's authority for averaging in light of the Agency's interpretation of *NRDC v. Thomas* had ample opportunity to do so following EPA's promulgation of the 1989 and 1990 rulemakings, and yet, no party did so.

EPA also disagrees with commenters who claim this is the first time EPA has considered electrified technologies in establishing standards based on averaging. As we explain in Preamble I.B-C and our major questions doctrine response in RTC 2.1, all vehicles—including all ICE vehicles—today are electrified to some extent, and electrification exists on a large spectrum. The agency has considered powertrain electrification specifically since at least the 1998 NLEV rule and the 2000 Tier 2 standards. In the HD GHG program itself, EPA has previously adopted vehicle standards under 202(a)(1)-(2) where compliance pathways supporting the standards reflected inclusion of powertrain electrification technologies and included averaging with ICE vehicle technologies. For example, in promulgating the HD GHG Phase 2 standards in 2016, we explained that in the technology mix for the compliance pathway supporting the final standards for the full implementation year of MY 2027, we projected an overall vocational vehicle adoption rate of 12 percent mild hybrid electrified vehicles, which we estimated will be 14 percent of vehicles certified in the Multi-Purpose and Urban subcategories.[683] We also explained that the stringency of the HD GHG Phase 2 standards was derived on a fleet average technology mix basis and that the emission averaging provisions of ABT meant that the regulations did not require all vehicles to meet the standards. [684] No one challenged EPA's authority to adopt such standards relying on averaging or a technology mix that included electrified technologies in judicial challenges to the HD GHG Phase 2 rule.

EPA also notes that given the lengthy pedigree of the ABT program, manufacturers have come to rely on it for compliance with many of EPA's motor vehicle programs. As we explain in Preamble II.C.4, the majority of certified vehicle families (93%) and manufacturers (29 out of 40) rely on ABT to comply with the Phase 2 GHG rule.[685] Unsurprisingly, no directly regulated manufacturer is opposing the agency's authority for ABT or to establish standards with a fleet

averaged standards. It thus follows that in testing 'any' engine for compliance with those standards, EPA may hold particular engine families to different control levels as part of an averaged set of engine families so long as the engine families' average emission levels meet the applicable standard.").

[682] 55 FR 30584, 30593-94 (July 26, 1990) ("In [*NRDC v. Thomas*], the court upheld averaging, but expressed some reservations about averaging in light of a statutory provision and some legislative history not raised by the parties to the case. The court pointed out that under averaging some vehicles would not be required to comply with the standards and that this appeared inconsistent with the requirement that "any," a" or "such" vehicle or engine be tested and required to comply with emission standards. At the same time the court noted that the statutory language was ambiguous and that the testing and certification provisions empower the Agency to test vehicles and engines in the manner it 'deems appropriate' so as to conform to the prescribed standards. EPA fully discussed in the preamble to the proposed rule why the statute and its legislative history should be read to allow the Agency discretion to determine the manner of testing and certification of vehicles. EPA also found that the broad type of averaging represented by trading and banking would be consistent with the Congressional scheme. … EPA continues to believe that the statute provides the Agency discretion in this matter, and that trading and banking are consistent with the statutory aims.").

[683] 81 FR at 73708.

[684] 81 FR at 73715; *see also* 77 FR at 62854-55 and 62856-57 (October 15, 2012) (company by company projection of potential compliance pathways for MY 2021 and 2025 light duty vehicle GHG emission standards, indicating hybrid electrified vehicle penetrations of up to 15% for some companies).

[685] Most of the manufacturers that did not use ABT produced vehicles that were certified to the optional custom chassis standards where the banking and trading components of ABT are not allowed, and averaging is limited.

average form. Major manufacturers generally support ABT, and as we summarize in RTC 2.1, they specifically support EPA's decision to average ICE vehicles with ZEVs in establishing the standards. Indeed, many manufacturers affirmatively asked EPA to expand the ABT program in discrete ways to allow them additional flexibility, a topic which we address in RTC 10.3 and Preamble Section III.A. While the agency has authority to change its policies when warranted, commenters have advanced no persuasive justification for reopening ABT at this time, particularly in light of manufacturers' reliance interests and the ABT program's ability to effectuate greater emissions reductions at lower costs. Indeed, their comments do not appear to even recognize the considerable reliance interests of directly regulated entities, recycle legal arguments that the agency considered and rejected long ago in the 1990 rule,[686] and effectively concede that abandoning averaging would delay the application of pollution control technologies and forgo otherwise feasible emission reductions. The little that commenters do say about manufacturers' interests is fundamentally wrong. They erroneously claim that the reason manufacturers have not pushed back on ABT is because the manufacturers view it solely as an extra-statutory accommodation that allows them greater flexibility. In this rulemaking, EPA relied solely on averaging (and not banking or trading) in supporting the feasibility of the standards, and EPA thinks manufacturers understand very well how the agency has relied on averaging to establish countless standards since 1985. In sum, commenters have not adduced sufficient reasons to adopt a policy, much less revisit a longstanding, foundational part of the motor vehicle program with a forty-year pedigree.

We reiterate that EPA did not reopen this issue in this rulemaking and the comments are outside the scope of the rule. In responding, EPA notes that we are not here "undertak[ing] a serious, substantive reconsideration of the existing" position.[687] EPA's response is intended solely to clarify and correct the misstatements and misrepresentations made by commenters concerning EPA's historical approach to averaging in standard setting and ABT program flexibilities, how EPA's ABT program is implemented, and the corresponding statutory basis. In providing this response, EPA also notes the extraordinary nature of commenters' claims: given the widespread use of ABT across EPA's section 202(a) programs, commenters—none of whom are regulated entities under section 202(a)—are implying that the agency has continually violated countless Title II compliance provisions for nearly forty years. That is completely false, and the agency wants to set record straight.

Response 10.2.1.b: Section 202 (a) Delegates Authority to EPA to Adopt Standards With a Fleet Average Form.

[686] *See, e.g.*, 55 FR 30584, 30593-94.

[687] *Growth Energy v, EPA*, 5 F. 4th 1, 21 (D.C. Cir. 2021). *See also Pub. Emps. for Env't Resp. v. EPA*, 77 F.4th 899, 913 (D.C. Cir. 2023) ("PEER cites no cases, and we are aware of none, in which an agency reopened an issue by merely responding to a petition for rulemaking submitted by a third party" citing *Am. Rd.& Transp. Builders Ass'n v. EPA*, 705 F.3d 453, 457 (D.C. Cir. 2013) ('[A]n agency's response to a petitioner's comments cannot provide the sole basis for reopening'); *Banner Health v. Price*, 867 F.3d 1323, 1341 (D.C. Cir. 2017) (quoting *Kennecott Utah Copper Corp. v. U.S. Dep't of Interior*, 88 F.3d 1191, 1213 (D.C. Cir. 1996)) ("As here, when an 'agency merely responds to ... unsolicited comment[s] by reaffirming its prior position, that response does not' open the agency's position up to a challenge. Moreover, an agency does not 'reopen an issue by responding to a comment that addresses a settled aspect of some matter, even if the agency had solicited comments on unsettled aspects of the same matter.'").

Commenters maintained that section 202(a) does not mention averaging, banking, and trading. They assert that, whether under standard principles of statutory construction or under the major questions doctrine, Congressional silence is not tantamount to a delegation of authority.

The commenters are correct that section 202(a)(1) does not include the words "averaging, banking, and trading."[688] But the standard-setting framework in section 202(a)(1) readily encompasses performance-based standards that are based on consideration of averaging. We address the statutory text in this subsection 10.2.1.b. In later subsections, we explain how such standards fit well within the Act's implementation and enforcement mechanisms, and how other provisions in section 202 and elsewhere confirm EPA's authority under section 202(a)(1) to set such standards.

Section 202(a)(1) mandates that EPA "prescribe … standards applicable to the emission of any air pollutant from any class or classes of new motor vehicles…". The Supreme Court has made clear that fleet average and other requirements applicable at the fleet-wide (as opposed to individual vehicle) level are "standards" within the meaning of Title II of the Act. In *Engine Mfrs. Ass'n v. S. Coast Air Quality Mgmt. Dist.*, 541 U.S. 246 (2004),[689] the Court indicated that "standards" encompass "fleet average emission requirements," which "decrease over time, requiring manufacturers to sell progressively cleaner mixes of vehicles, and under which "[m]anufacturers retain flexibility to decide how many vehicles in each emission tier to sell in order to meet the fleet average."[690] The Court also found that "standards" include other types of fleet-wide requirements like mandates that fleet owners purchase vehicles of a given type,[691] and that a certain percentage of a manufacturer's new vehicle sales must consist of vehicles of a given type.[692]

Section 202(a)(1) also applies to "class or classes of new motor vehicles." "Class or classes" necessarily refers to groups of vehicles, as opposed to individual vehicles. So Section 202(a)(1) is naturally read to authorize EPA to set standards for groups of vehicles, which would include a manufacturer's fleet of vehicles that are in this group.

Regulation under Section 202(a)(1) is also conditioned on the Administrator finding that emissions from a class or classes of motor vehicles "cause, or contribute to, air pollution which

---

[688] EPA's response here focuses on averaging. However, "trading and banking are simply forms of averaging between manufacturers and over time. Thus, they pose similar legal issues." 54 FR 22665. With respect to the arguments raised by the adverse comments, EPA believes trading and banking are justified on similar bases as averaging. *See also generally* 54 FR 22665-67 (discussing the legal bases for trading and banking), 55 FR 30593-99 (same). In addition, EPA disagrees that banking and trading are necessary to standard-setting rather than being a flexibility for these Phase 3 standards. EPA did not rely on banking and trading to justify the feasibility of the standards. See preamble II.G.

[689] The Court in. *S. Coast Air Quality Mgmt. Dist* was construing CAA section 209(a), which refers to "any standard relating to control of emissions from new motor vehicles". This language is similar to the text of section 202(a). The *South Coast* Court made clear that there is no reason to read "standard" in section 202(a) differently than in section 209(a)): "A 'standard' is defined as that which 'is established by authority, custom, or general consent, as a model or example; criterion; test.' This interpretation is consistent with the use of 'standard' throughout Title II of the CAA (which governs emissions from moving sources) to denote requirements such as numerical emission levels with which vehicles or engines must comply, *e.g.*, [CAA section 202] (a)(3)(B)(ii), or emission-control technology with which they must be equipped, *e.g.*, [CAA section 206](a)(6)." *Id*. at 253.

[690] *Id*. at 250, n.3.

[691] *Id*. at 250, 258.

[692] *Id*. at 255.

may reasonably be anticipated to endanger public health or welfare." In enacting section 202(a)(1), Congress was concerned with classes of motor vehicles contributing to dangerous air pollution, not with individual vehicles doing so. Indeed, it is ordinarily only emissions from a group of vehicles (i.e., a class) not a single vehicle that could cause dangerous air pollution. As we explain further in Section 10.2.1.f, this is also how EPA has long interpreted the statute, including in making the 2009 GHG endangerment finding for motor vehicles. This further indicates that EPA may regulate the class of vehicles as a whole, including at the fleet-wide level, not just individual vehicles.

The statute explicitly subjects regulation under Section 202(a)(1) to the requirements of Section 202(a)(2), which states that "[a]ny regulation prescribed under paragraph (1) of this subsection (and any revision thereof) shall take effect after such period as the Administrator finds necessary to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such period." Fleet average standards relate directly to Section 202(a)(2)'s considerations of technical feasibility, cost, and lead time. As we explain in RTC 10.2.1.a above, EPA has found for decades that establishing fleet average standards allows the agency to set standards at a given stringency for lower cost. It also affords regulated entities more flexibility in determining how to meet those standards, accommodating practical realities of vehicle redesign cycles and market fluctuations, and allowing additional lead-time for a portion of the fleet to meet the standards if the regulated entity decides to have another portion of the fleet achieve the standards more rapidly.[693] Similarly, the ability to generate credits promotes earlier introduction of advanced technologies, furthering the Act's emission reduction and technology advancement goals.

The D.C. Circuit reviewed and upheld EPA's use of averaging in promulgating section 202(a) standards in *NRDC v. Thomas*, 805 F.2d 410 (D.C. Cir. 1986). Observing that there was no "clear congressional prohibition of averaging," the Court held that "the EPA's argument that averaging will allow manufacturers more flexibility in cost allocation while ensuring that a manufacturer's overall fleet still meets the emissions reduction standards makes sense."[694] While the Court noted in dicta that its analysis did not consider certain potential arguments not raised by the litigants—arguments which we addressed in a subsequently rulemaking[695] and which we discuss later in this response—its holding was unquestionably to uphold EPA's averaging program.

Congress subsequently ratified EPA's and the Court's interpretation in the 1990 Clean Air Act Amendments. "Congress is presumed to be aware of an administrative or judicial interpretation of a statute and to adopt that interpretation when it re-enacts a statute without change."[696] Ratification is particularly applicable here because there is explicit evidence in both the House and Senate legislative history indicating that Congress knew of EPA's and the Court's

[693] *See also White Stallion Energy Ctr., LLC v. EPA*, 748 F.3d 1222, 1253 (D.C. Cir. 2014) (allowing averaging across multiple utility units under CAA section 112(d), which "neither expressly allows nor disallows emissions averaging," where averaging is a "more flexible, and less costly alternative" than unit-by-unit compliance, even though "this may allow individual units to exceed the emissions limitation"), *rev'd on other grounds, Michigan v. EPA*, 576 U.S. 743 (2015).
[694] *NRDC v. Thomas*, 805 F.2d at 425.
[695] 55 FR 30584, 30593-94 (July 26, 1990); 54 FR 22652, 22665-66 (May 25, 1989).
[696] *See Lorillard v. Pons*, 434 U.S. 575, 580 (1978).

interpretation on this issue.[697] Legislative history from the House recognized that, under the Clean Air Act:

> EPA has promulgated regulations for averaging (50 Fed. Reg. 10606) and for banking and trading (55 Fed. Reg. 30584). Cognizant of these rules and the Court's decision in NRDC v. Thomas, 805 F.2d 410 (D.C. Cir. 1986) the House-Senate conferees chose not to amend the Clean Air Act to specifically prohibit averaging, banking and trading authority.
>
> Averaging, banking and trading programs, in fact, have very positive impacts on air quality. Such programs preserve the requirement that each family of engines must meet or exceed a preassigned standard. Furthermore, averaging programs create an incentive to produce engines lower than the applicable standard, and encourage the development and early use of improved emission control technologies, and the development and sale of alternative-fueled vehicles. Such programs also aid manufacturers in reducing the costs of controlling emissions.[698]

As such, "[t]he intention was to retain the status quo," that is, the agency's continued application of averaging in establishing the standards following *NRDC v. Thomas*.[699] Similar legislative history is found in the Senate.[700]

The text of the Act further corroborates Congress's ratification of EPA's use of averaging in setting section 202(a) standards. In section 219 of the Act, Congress directed EPA to establish standards for urban buses pursuant to section 202(a). Section 219(b)(1) provides:

> The standards under section 7521(a) of this title applicable to urban buses shall require that, effective for the model year 1994 and thereafter, emissions of particulate matter (PM) from urban buses shall not exceed 50 percent of the emissions of particulate matter (PM) allowed under the emission standard applicable under section 7521(a) of this title as of November 15, 1990, for particulate matter (PM) in the case of heavy-duty diesel vehicles and engines manufactured in the model year 1994.

The referenced 1994 HD PM standard (i.e., "the emission standard applicable under section 7521(a) of this title as of November 15, 1990, for particulate matter (PM) in the case of heavy-duty diesel vehicles and engines manufactured in the model year 1994") was a standard with a fleet average form. Indeed, it was one of the standards litigated in *NRDC v. Thomas* on the issue of averaging.[701] Thus, Congress expressly recognized an EPA standard with an averaging form and endorsed such a standard as the basis for further standard-setting under section 202(a).

[697] 136 Cong. Rec. 35,367 (1990), 1990 WL 1222469, at *1; 136 Cong. Rec. 36,713 (1990), 1990 WL 1222468, at *1.
[698] 136 Cong. Rec. 35,367, 1990 WL 1222469, at *1.
[699] *Id.*
[700] 136 Cong. Rec. 36,713, 1990 WL 1222468, at *1. (Congress, noting *NRDC v. Thomas*, instead opted to let the existing law "remain in effect.").
[701] *See NRDC v. Thomas*, 805 F.2d 410, 425 (D.C. Cir. 1986) ("The NRDC challenges the EPA's program of emissions averaging for the 1991 and 1994 PM standards and the 1991 NOx standard.").

Pursuant to this provision, EPA promulgated urban bus standards, and those standards provided for averaging, as well as banking and trading.[702]

Following the 1990 Amendments, EPA continued to establish many other motor vehicle standards based on averaging, and the use of ABT became a well-settled part of the regulatory landscape. Consistent with this, in enacting the Energy Independence and Security Act of 2007, Congress specifically recognized the possibility of fleet average GHG standards. The statute generally barred Federal agencies from acquiring "a light duty motor vehicle or medium duty passenger vehicle that is not a low greenhouse gas emitting vehicle."[703] It directed the Administrator to promulgate guidance on such "low greenhouse gas emitting vehicles," but explicitly prohibited vehicles from so qualifying "if the vehicle emits greenhouse gases at a higher rate than such standards allow for the *manufacturer's fleet average grams per mile of carbon dioxide-equivalent emissions for that class of vehicle*, taking into account any emissions allowances and adjustment factors such standards provide."[704] In other words, Congress explicitly contemplated the possibility of fleet-average GHG standards for motor vehicles.[705]

In light of the clear congressional authorization for averaging, EPA also does not agree with commenters who claim that averaging is precluded by the major questions doctrine. We further address the applicability of the major questions doctrine in RTC 2.1. We also disagree with commenters who claim that EPA is relying on silence as an implicit delegation of authority.[706] EPA is not asserting authority for ABT based on statutory silence; as explained above, the basis for ABT is the statutory text of section 202(a)(1)-(2), read in light of the context, purpose, and history.[707]

---

702 *See* 58 FR 15781, 15784, 15787.

703 42 USC 13212(f)(2)(A).

704 42 USC 13212(f)(3)(C) (emphasis added).

705 42 USC 13212 does not specifically refer back to section 202(a). However, we think it is plain that Congress intended for EPA to consider relevant section 202(a) standards in implementing section 13212. *See* 42 USC 13212(f)(3)(B) ("In identifying vehicles under subparagraph (A), the Administrator shall take into account the most stringent standards for vehicle greenhouse gas emissions applicable to and enforceable against motor vehicle manufacturers for vehicles sold anywhere in the United States.").

706 In addition, the commenters' selective quotation from *Entergy v. Riverkeeper*, 556 U.S. 208, 223 (2009), is inapposite. That case *upheld* EPA's determination that the delegation for EPA to issue standards reflecting "best technology available for minimizing adverse environmental impact" allowed standards based on cost-benefit analysis, notwithstanding that such an authorization appears nowhere in the statutory text. *Id*. at 218, 226. The commenters cite the following language from the opinion in support of their argument: "sometimes statutory silence, when viewed in context, is best interpreted as limiting agency discretion." Id. at 223. The following sentence of the opinion, however, states that "[f]or the reasons discussed earlier, § 1326(b)'s silence cannot bear that interpretation." *Id*. The Court thereupon concluded, "This extended consideration of the text of § 1326(b), and comparison of that with the text and statutory factors applicable to four parallel provisions of the Clean Water Act, lead us to the conclusion that it was well within the bounds of reasonable interpretation for the EPA to conclude that cost-benefit analysis is not categorically forbidden." *Id*. In any case, this case is not applicable because EPA is not relying on statutory silence here.

707 Notwithstanding commenters' selective citations of past preambles, the agency has never touted statutory silence as the basis for the ABT program. We have, as we do today, noted the fact that the statute does not explicitly specify an ABT program. But in promulgating such programs, we have also consistently justified them in light of the text and purpose of the Act. *See, e.g.,* 55 FR 30593-99 (describing in detail the legal bases for ABT and concluding on page 30599 that "EPA believes that trading, banking and expanded averaging are consistent with and support the goals and provisions of the Act. Compliance with the technology forcing 1991 and 1994 NOX and PM emissions

Response 10.2.1.c: Standards with a Fleet Average Form Are Consistent with the Statutory Context and Structure.

As explained above, in section 202(a)(1), Congress delegated to EPA the authority to adopt standards for new motor vehicles and to revise the standards as appropriate. Specifically, Congress entrusted to the Administrator the determination of the class or classes of vehicles subject to the standards, the form of the standard, the lead time provided, the consideration of the costs of compliance, and, taking these elements and other factors into account, the stringency of the standards. As we explain further in RTC 2.1, this delegation provides EPA the flexibility needed to appropriately address the widely varying circumstances that can arise under section 202, such as developments in the need for emissions control, technologies, and their costs. This provision's authority readily encompasses the kind of fleet averaging standards EPA has adopted over many years and covering many different types of vehicles and pollutants.

At various points, Congress directed EPA to exercise its section 202(a) authority to adopt certain specific standards.[708] These various provisions identify the specific group of vehicles to which they apply, as well as the specific model years, pollutants, and stringency of the standards. Although Congress limited EPA's discretion for those specific vehicles, model years, and pollutants, even in those cases Congress recognized and adopted provisions reflecting a variety of the flexibilities authorized in standard setting under section 202(a). For example, Congress directed that EPA provide for waivers; alternative standards for small volume manufacturers; phase-ins over time based on a percentage of a manufacturer's production; as well as standards that changed over the useful life of the vehicles.

In addition, Congress specifically addressed to what extent if any EPA's authority to revise these standards in the future, including under its general section 202(a)(1) authority, was limited. In general, Congress placed only a few limitations on EPA's future standard setting. Congress typically specified that EPA's future revisions of the standards for these vehicles and pollutants had to preserve a specified degree of stringency and in some cases, Congress specified the number of model years before revisions were allowed. But these provisions do not constrain EPA's general authority to set standards under section 202(a)(1) in other circumstances. Most importantly for purposes of this response, none of these provisions limit fleetwide averaging or otherwise limit EPA's authority to structure the form of future section 202(a)(1) standards in this rulemaking.

These provisions place no other limits on EPA's standard setting under section 202(a)(1). They did not limit EPA's ability to structure the form and level of future standards for these vehicles and pollutants, only the stringency and lead time. Through these provisions Congress placed no limits at all on EPA's authority to set standards under section 202(a)(1) for other vehicles and other pollutants. Congress directly addressed the specific limits it placed on EPA's future standard setting, and those are the only limits it imposed on the authority it provided EPA in setting standards under section 202(a).

standards will be enhanced, emissions will be reduced, not increased, and the important role of NCPs will not be supplanted. Furthermore, as indicated in the discussion above, EPA does not think that banking, trading or expanded averaging contradict the provisions of section 206 regarding certification and testing.").

[708] *See, e.g.*, CAA section 202(a)(3)(A)(i), 202(b), (g), (h).

EPA's past fleet averaging standards, as well as the standards at issue in this rulemaking, are fully consistent with the grant of authority in section 202(a)(1). In no case do these standards violate the limited conditions Congress placed on future standard setting in the provisions discussed in section 202.

We now discuss each of these provisions that commenters cite. Commenters refer to section 202(a)(3)(A)(i) as evincing Congressional intent not to include averaging as part of the standard setting process for heavy duty vehicles. But, this provision, like section 202(a)(1), refers to standards for emission from "classes" of heavy-duty vehicles (and from "categories" as well). This language is most naturally applicable to groups of vehicles like fleets.[709]

Commenters viewed sections 202(b)(1) and 206(a)(2) as showing incompatibility with standards predicated on averaging. The argument goes that section 202(b)(1) commands standards for "vehicles and engines," and that the testing of "any emission control system incorporated in a motor vehicle or engine" provisions in section 206(a)(2) only make sense on a per vehicle basis. They further point to the 5 percent waiver authority in section 202(b)(3) and the testing provision for section 202(b) standards found in section 206(a)(2). They maintain that the waiver provision is unnecessary in a fleet averaging regime since well over 5% of a manufacturer's vehicles could be above a fleet average limit without the need of a waiver, and note further that the testing provision is written in the singular ("vehicle or engine"), and so can only be read to mean vehicle-by-vehicle testing.

These arguments are misplaced. First, section 202(b)(1) is an explicit and narrow exception to EPA's general standard-setting authority under section 202(a)(1), which applies "[e]xcept as otherwise provided in subsection (b)." Section 202(b)(1) establishes standards for certain pollutants, model years, and classes of vehicles. It thus cannot derogate from the general scope of authority in section 202(a)(1). Specifically, it does not address HDV standards for GHGs and therefore has no applicability to the final standards at issue here. Moreover, on its face, section 202(b)(1) accords with fleet-average standards because it specifically refers to standards for certain classes of vehicles (e.g., light-duty vehicles for certain model years), as opposed to individual vehicles; the provision also uses the term "such vehicles and engines," which naturally refers back to the classes identified in the provision.

CAA section 206(a)(2) adds nothing to the commenters' argument. That provision requires EPA in some cases to test emission-control systems to determine whether they enable vehicles to conform with standards Congress prescribed in section 202(b). As such, section 206(a)(2) prescribes duties relating to standards under section 202(b), and as just discussed, that section has no bearing on the section 202(a) authority beyond the specific circumstances to which it applies, circumstances inapplicable here. Moreover, in section 206(a)(2), Congress had a specific reason to speak to individual vehicles. Added in 1970, it enabled a private party that developed a new "emission control system," such as a new catalyst, to submit a vehicle or engine incorporating that system for testing "to determine whether such system enables such vehicle or engine to conform to the [Subsection 202(b)] standards."[710] It was sensible for Congress to establish this mechanism for testing new technologies in the context of specific vehicles and individuals, rather than fleets. But there is no basis in section 206(a)(2) to think Congress meant

[709] *See also* Response 10.2.1.b and Response 10.2.1.f.
[710] CAA section 206(a)(2); *see* Environmental Policy Division of the Congressional Research Service, Volume 1, 93d Cong., 2d Sess., A Legislative History of the Clean Air Amendments of 1970, at 128, 200 (Comm. Print 1974).

to prohibit fleet averages even under section 202(b), let alone section 202(a). To the extent that it is relevant, section 206(a)(2) confirms that Congress intended EPA to consider all feasible emission-control technologies, even those that had not been developed as of 1970.

The commenters' reference to section 202(b)(3) is also mistaken. That provision allows EPA to impose standards less stringent than subsection (b)(1) standards for nitrogen-oxides emissions for up to 5% of production of model-years 1977-1979 light-duty vehicles, where an automaker "demonstrates that such waiver is necessary to permit the use of an innovative power train technology." Under subsection (b)(3), an automaker identifies its total production for the year and the specific emission standards to which each vehicle was certified. EPA would then assess whether at least 95% of the fleet met the subsection (b)(1)(B) standard and whether the rest met the subsection (b)(3) standard. But this would be true whether each of those standards was a vehicle specific standard, a fleet-average standard, or both. None of these approaches would be inconsistent with subsections (b)(1) and (b)(3). More basically, nothing in either subsection speaks to EPA's authority under section 202(a)(1). We reiterate that nothing in section 202(b), including the waiver provision in (b)(3), has any applicability beyond the specific circumstances to which it applies, which circumstances are inapplicable here.

Nor does anything in section 202(g) constrain standards with a fleet average form. This provision—as well as the parallel provision in section 202(h) —is another example of Congress directing EPA to use its section 202(a) authority in a specific manner, for specific vehicles (light-duty trucks and light-duty vehicles), pollutants (NMHC, CO, NOx, and PM), and model years. Under this provision for these specified pollutants and model years, such vehicles must meet one or the other of the specified phase-in standards. These provisions say nothing about EPA's authority to establish standards for different types of vehicles, pollutants, or model years. It is worth noting, however, that the phase-in of standards Congress specified in section 202(g) is an example of the range of forms available to EPA. As we explain further below in RTC 10.2.1.d.3, a phase-in form of a standard requiring specified percentages of a manufacturer's production of vehicles to meet a standard is similar to the fleet averaging-based form used in this rule.

Commenters also assert that compliance with a fleet average is inconsistent with the definition of "emission standard" in section 302(k): "a requirement … which limits the quantity, rate, or concentration of emissions of air pollutants on a continuous basis." The argument is that one cannot "know" "on a continuous basis" whether a manufacturer is meeting its fleet-average standard. It is not clear that the definitions in section 302 apply to Title II,[711] but even if they do, the emission standard definition requires standards to *apply* continuously, not that compliance be *measured* continuously. In general, fleet-average standards (including the vehicle specific numerical standards that apply both when the vehicle is new and when it is in use) control emissions from vehicles on a continuous basis. More specifically, as explained in Response 10.2.1.d., the Family Emission Limit for GHGs to which individual heavy-duty vehicles are certified are both applicable continuously and measurable at any time throughout the vehicle's useful life.

Finally, we note that the commenters' reliance on specific provisions in section 202 to limit EPA's more general authority under section 202(a)(1)-(2) is at odds with normal tenets of

[711] *Motor & Equip. Mfrs. Ass'n*, 627 F.2d at 1112 n.35. The commenters' arguments are also inconsistent with the Supreme Court's interpretation of "standard' in the context of Title II provisions on controlling emissions from motor vehicles in *South Coast*, as explained in Response 10.2.1.b. above.

statutory construction. Broad grants of discretionary authority like section 202(a)(1) are generally not limited by other narrower provisions focused on particular situations.[712] Moreover, Congress has expressly indicated what limitations the specific provisions impose on future EPA standard setting, but they do not impose any limitations which preclude fleet average standards, indicating that no such limitations should be implied. [713]

Response 10.2.1.d: Standards Using a Fleet Average Standard Form Fit the Act's Implementation and Enforcement Provisions

A number of commenters viewed fleet average standards as fundamentally incompatible with the certification of conformity provisions of section 206. They maintain that these provisions are written as vehicle specific: they refer to "engine" and "vehicle" in the singular, and they require a determination "whether such vehicle or engine" (referring back to the individual vehicle or engine) "conforms with the [section 202 emission standards]." They argue that testing of an individual vehicle, however, does not indicate whether or not a fleet average is achieved, since in their view conformity cannot be determined until the conclusion of a model year. For similar reasons, these commenters claim that fleet average standards are inconsistent with section 203(a)(1), which prohibits sale of a vehicle or engine not "covered by a certificate of conformity," and section 205(a), under which any violation of applicable standards "shall constitute a separate offense with respect to each motor vehicle or motor vehicle engine."

These commenters further maintain that fleetwide-average emission standards are inconsistent with Title II's remediation and notification provisions. Those provisions state that if EPA "determines that a substantial number of any class or category of vehicles or engines...do not conform to the regulations prescribed under [Section 202]," the manufacturer must remedy "the nonconformity of any such vehicles or engines."[714] If "a motor vehicle fails to conform," the

Cir. 2022) (standing for the proposition that one does not infer a limitation from a provision authorizing a different sort of activity: "[t]he section containing the "commensurate" language is a limitation on how much can be collected in fees from a particular user class. It is not a limitation on how those fees may be spent. Therefore, Appellants' argument that fees collected from multiple user classes cannot be comingled in a fund that pays for the inspections of fee-paying user classes fails because the FACT Act does not prohibit this form of cross-subsidization"); *GPA Midstream Ass'n v. United States Dep't of Transp.*, 67 F.4th 1188, 1196 (D.C. Cir. 2023) ("Section 4 creates neither a condition precedent nor a ban. As the petitioners themselves explain at length in their opening brief, § 4 does not apply to gathering pipelines. Section 4 by its plain terms applies only to "transmission pipeline facilities." We do not understand how § 4 could plausibly be read to create a condition precedent for a different type of pipeline facility.").

[714] CAA section 207(c)(l).

manufacturer bears the cost.[715] Further, "dealers, ultimate purchasers, and subsequent purchasers" must be given notice of any nonconformity,[716]which requires identification of specific nonconforming vehicles. These commenters maintain that none of this is possible where the nonconformity is tied to a fleet average.

EPA disagrees with these comments. The regulatory provisions for demonstrating compliance with emissions standards have been successfully implemented for decades, including provisions in our regulations for demonstrating compliance through our ABT program. Commenters who alleged inconsistency with the compliance and enforcement provisions fundamentally misapprehend the nature of EPA's HD GHG program and its ABT regulations, where compliance and enforcement do in fact apply to individual vehicles, consistent with the statute. Both the emission standard and FEL are specified in each vehicle's individual certificate of conformity, and apply both at certification and throughout that vehicle's useful life. As appropriate, EPA can suspend, revoke, or void certificates for individual vehicles. Manufacturers' warranties apply to individual vehicles. EPA and manufacturers perform testing on individual vehicles, and recalls can be implemented based on evidence of non-conformance by a substantial number of individual vehicles within the class. The details of the certification and enforcement process are set out in the remainder of this Response 10.2.1.d. The ultimate conclusion is that the regulatory scheme—including the use of FELs as the applicable in-use standard for all of the vehicles a manufacturer produces, combined with the pre-production testing, pre-production projection of production before certification, the required reporting of actual production and calculation of credits or deficits at the end of the model year, plus the ability to test in-use for compliance—fully satisfies the compliance and enforcement requirements of the statute.

Response 10.2.1.d.1: Overview of HD GHG Certification and Compliance

For the standards at issue in this rulemaking, as well as those adopted in many previous rulemakings for heavy duty vehicles, manufacturers may choose to demonstrate compliance with the applicable emission standard by using the regulatory provisions for averaging, banking, and trading.[717] They do so by dividing their vehicles into "families" or "subfamilies". For each family or subfamily, the manufacturer must designate a "Family Emission Limit", which is an "emission level…to serve in place of the otherwise applicable emission standard" for each family or subfamily.[718] The designated FEL applies to every vehicle within a family or sub-family and must be complied with throughout the vehicle's useful life. Manufacturers choosing to demonstrate compliance with the applicable emission standards using the ABT program must show compliance based on (among other things) production levels and emissions level of FELs.[719]

Each family or subfamily has a designated FEL, and credits are generated if the FEL is lower than the applicable standard, and debits are generated if the FEL is higher than the applicable

[715] CAA section 207(h)(l).
[716] CAA section 207(c)(2),
[717] 40 CFR 1037.241(a)(2).
[718] 40 CFR 1037.801 (definition of "Family emission limit").
[719] *See* 40 CFR 1037.705(b).

standard.[720] The manufacturer can use those credits to offset higher emission levels from vehicles in the same averaging set such that the averaging set meets the standards on "average", ''bank'' the credits for later use, or ''trade'' the credits to another manufacturer. In other words, under the existing ABT program, a manufacturer has two obligations – (1) all vehicles are certified to and must comply throughout their useful life with the FEL applicable to that vehicle's family or subfamily, and (2) the manufacturer's vehicles must comply with the applicable emission standard as a group, e.g., using a production-weighted average of the various FELs across the applicable averaging set.[721] Across an averaging set, all vehicle families must show a net zero or positive credit balance as detailed in the existing regulation.[722]

Before certification, manufacturers submit test results demonstrating projected compliance of their vehicles with the manufacturer's chosen FELs for each vehicle family and sub-family. Manufacturers also demonstrate that the projected production levels of each family and sub-family and the associated calculation of projected emission credits are in compliance with the applicable emission standard, averaged across the averaging set. If EPA determines that this initial demonstration is satisfactory, it issues a certification of conformity specifying the applicable vehicle standard and FEL for that vehicle family. The certificate is conditioned on a manufacturer's further demonstration of compliance based on its actual model year production, its demonstration of positive and negative credits for each vehicle family, and the ultimate demonstration that the net balance of emission credits across its vehicle families in each averaging set are either zero or positive.

The certificate of conformity itself contains the applicable emission standard for that category and subcategory of vehicle and the range of allowable FELs for vehicles in that family. See an example of an actual certificate of conformity appended at the end of this comment response.

In addition to the testing performed before production to obtain the certificate of conformity, in-use testing may be used by EPA to determine if vehicles comply with the FEL to which they are certified. If EPA determines that a substantial number of the vehicles in a family or subfamily do not meet their FEL in-use, EPA can, for example, issue a recall order under section 207(c)(1).

Response 10.2.1.d.2: Detailed Description of Existing General Part 1037 ABT Program

We now provide a more detailed description of the HD GHG ABT program. Prior to certification, manufacturers divide their vehicles into "families", which correspond to the categories and subcategories for vocational vehicles and for tractors.[723]For HD vocational vehicles, the subcategories are Urban, Rural, and Multi-purpose for each of the following: Light HDV, Medium HDV, and Heavy HDV. For HD tractors, day cabs and sleeper cabs are further

[720] "[F]or each family or subfamily…positive credits [are generated] for a family or subfamily that has an FEL below the standard." 40 CFR 1037.705(b).
[721] We explain later in Response 10.2.1.d.2 what averaging sets are, and further discuss their significance.
[722] Manufacturers must show "that [the manufacturer's] net balance of emission credits from all [the manufacturer's] participating vehicle families in each averaging set is not negative". 40 CFR 1037.730(c)(1), and 40 CFR 1037.241(a)(2) ("vehicle families within an averaging set are considered in compliance with the CO_2 emissions standards, if the sum of positive and negative credits for all vehicle configurations in those vehicles lead to a zero balance or a positive balance of credits").
[723] *See* 40 CFR 1037.230(a) ("divide your product line into families of vehicles based on regulatory subcategories").

subcategorized by roof height.[724] Manufacturers submit test results for ten (10) configurations from each vehicle family.[725] These ten test results are to be from vehicles representative of production vehicles[726] and are to include the highest and lowest results.[727] This range of test results establishes a range of "Family Emission Limits" (FEL), which is an "emission level…to serve in place of the otherwise applicable emission standard."[728] Families are then often further divided into sub-families – a sub-family being vehicles within a family that have identical emission levels.[729] The ten test results establish the "highest and lowest FELs to which [the manufacturer's] subfamilies will be certified."[730] The FELs which a manufacturer specifies "may not be less than the result" of the emission testing specified in 40 CFR 1037.520.[731] Based on the range of allowable FELs, manufacturers then identify the emission standards or FELs to which the vehicles in the vehicle family will be certified.[732]

There is one further refinement. Vehicle families are further grouped by "averaging sets": LHD, MHD, and HHD.[733] The manufacturer's application for certification must show that the individual families or subfamilies are projected to comply throughout their useful life with the FEL chosen by the manufacturer for that family or subfamily. The certification demonstration

---

[724] 40 CFR 1037.105 and 1037.106. Engine types are also subcategorized in 1037.105, although this is not relevant for purposes of the text discussion.
[725] 40 CFR 1037.205(o)(1). A "configuration" is "a unique combination of vehicle hardware and calibration … within a vehicle family." 1037.801.
[726] Since most heavy duty vehicles are built to order, testing of prototypes and estimating production are necessary whether or not a manufacturer is certifying on an averaging basis. *See* Comment of ATA in RTC 4.1 noting that HDVs are invariably highly customized.
[727] 40 CFR 1037.235(a) and 1037.205(o)(1).
[728] 40 CFR 1037.801.
[729] 40 CFR 1037.230(b).
[730] 40 CFR 1037.205(k).
[731] 40 CFR 1037.105(d) (vocational vehicles); 40 CFR 1037.106(d) (tractors).
[732] *See* 40 CFR 1037.205(k) ("[i]dentify the emission standards or FELs to which you are certifying vehicles in the vehicle family"); *see also* 40 CFR 1037.710 (b) ("You may certify one or more vehicle families…to an FEL above the applicable standard") and 1037.750 (b) (a manufacturer "may certify [its] vehicle family or subfamily to an FEL above an applicable standard based on a projection that [it] will have enough emission credits to offset the deficit for the vehicle family". As EPA explained more than three decades ago, "Within a given manufacturer's product line, averaging allows certification of one or more engine families at levels above the applicable emission standard, provided their increased emissions are offset by those from one or more families certified below the same emission standard, such that the average emissions from all the manufacturer's families (weighted by horsepower and production) are at or below the level of the emission standard. This allows a manufacturer to optimize its emission compliance strategies and minimize compliance costs. The specific mechanism by which this is accomplished is certification of the engine family to a family emission limit (FEL) set by the manufacturer. The FEL may be above or below the emission standard, but not higher than an emission ceiling set by EPA. The FEL essentially replaces the emission standard for certification, assembly-line testing (SEA) and recall purposes." 55 FR at 30585 (July 26, 1990). Similarly, *see* 54 FR at 22666 (May 25, 1989) ("EPA does not believe that the statutory text or legislative history cited by the court necessarily means that the CAA requires or that Congress intended that every vehicle or engine family emit at the same level. As the court itself noted, the Act gives EPA broad latitude, in the testing of vehicles and, more fundamentally, in the formulation of standards. EPA promulgated the HDE NOx and PM emissions standards as averaged standards. It thus follows that in testing "any" engine for compliance with those standards, EPA may hold particular engine families to different control levels as part of an averaged set of engine families so long as the engine families' average emission levels meet the applicable standard."). Although EPA was speaking in the context of standards for engines, the statements are equally applicable to vehicle standards.
[733] 40 CFR 1037.740 (via cross references in 40 CFR 1037.801 and 1037.701(a)(2)).).

must also show, based on projected production levels, that the manufacturer's vehicles will comply with the applicable standard across their vehicle families across the averaging set.[734]

The certificate itself is vehicle-specific, and identifies the vehicle family, emission standard applicable to the type of vehicle in that family (i.e., the subcategory-specific emission standard in 40 CFR 1037.105 and 1037.106), the applicable averaging set, the range of FELs for that vehicle family expressed as the range established from pre-certification testing, and conditions to which the certificate remains subject. Thus, in the certificate appended below, the vehicle is in the class 8 low-roof sleeper cab tractor subcategory with weight over 33,000 pounds; it is in the heavy heavy-duty averaging set; the CO_2 emission standard for this type of vehicle is 72.3 g CO_2/ton mile;[735] and the range of FELs for this family is 113.2 and 55.7 g/ton-mile. The certificate further specifies that it is subject to conditions, including all of the provisions in section 1037 subpart H specifying requirements for averaging.[736]

Manufacturers certifying using the ABT pathway must then submit an end-of-year report to EPA. The report shows the manufacturer's calculation of positive or negative credits for each family.[737] Credits are generated relative to the emissions standard: "for each family or subfamily…positive credits [are generated] for a family or subfamily that has an FEL below the standard."[738] Negative credits (i.e., debits) are the reverse: families or subfamilies with an FEL above the standard generated a deficit (a negative credit). Id. The report also must show "that [the manufacturer's] net balance of emission credits from all [the manufacturer's] participating vehicle families in each averaging set is not negative".[739]

If a manufacturer is not able to demonstrate that it meets the applicable standard through averaging across its families, it may use surplus credits from prior years (banking), or credits obtained from other manufacturers (trading) to offset its credit deficit and show compliance.[740] If that is not done, the manufacturer must designate which families or subfamilies are causing the deficit in credits compared to the standard.[741]

Putting this together, under the ABT certification pathway, prior to certification a manufacturer performs tests to show that the vehicles in that family will meet the FEL standard the manufacturer assigns for those vehicles. The manufacturer also makes a demonstration prior to certification that the levels of production for the various families will result in compliance

---

[734] *See* 40 CFR 1037.241(a)(2) ("your vehicle families within an averaging set are considered in compliance with the CO2 emissions standards…if the sum of positive and negative credits for all vehicle configurations in those vehicle families lead to a zero balance or a positive balance of credits"); *see also* 1037.725(a), (b) (application for certification must include, among other things, "the FELs you select for the vehicle family or subfamily", and "a statement that…you will not have a negative balance of emission credits for any averaging set when all emission credits are calculated at the end of the year").
[735] 40 CFR 1037.106(b), Table 1.
[736] *See also* 40 CFR 1037.255(a) ("[w]e may make the approval subject to additional conditions").
[737] 40 CFR 1037.730(b)(6).
[738] 40 CFR 1037.705(b).
[739] 40 CFR 1037.730(c)(1) and 1037.241(a)(2) ("vehicle families within an averaging set are considered in compliance with the CO_2 emissions standards, if the sum of positive and negative credits for all vehicle configurations in those vehicles lead to a zero balance or a positive balance of credits"). As explained in section III.A.3 of the preamble, and RTC 10.3.2 below, the Phase 3 rule contains a temporary flexibility whereby, among other things, credits generated by HDVs can be used across all of the HDV averaging sets in MYs 2027-2032.
[740] 40 CFR 1037.715, 1037.720.
[741] *See* example set out in 40 CFR 1037.730(b)(7).

with its projected fleet average for each vehicle family averaging set by averaging set. Vehicle families and subfamilies are then certified to the applicable standard and FEL. Conditions are placed on the certificates to ensure compliance with the fleet average after the year's production is completed. The production-weighted sum of the families and their FELs within each averaging set must be equal to or less than the applicable emission standard.

Should manufacturers run a credit deficit for the year for any vehicle family for any averaging set, and fail to utilize the various options in the rules for eliminating a credit deficit within a specified amount of time, EPA may void the certificate of the relevant vehicle family or subfamily. 40 CFR 1037.745. Conditions on certificates of conformity expressly provide that EPA can void certificates.[742] The vehicles whose certificates have been voided are then considered not covered by the certificates,[743] and the manufacturer is potentially subject to civil penalties for committing an act prohibited under CAA section 203 – introducing vehicles into commerce that are not covered by a certificate of conformity.

EPA may perform in-use testing "of any vehicle subject to the standards".[744] This in-use testing is compared to the FEL to which the vehicle is certified.[745]

Response 10.2.1.d.3: These Provisions Conform to All Requirements of the Act

The ABT program has been in place for decades and has worked admirably in practice. The elements of the program—including the certification of individual vehicles to an FEL, the requirement that vehicle families in an averaging set meet (or surpass) the emission standards across that averaging set, the system of pre-certification testing, the conditioning of certificates of conformity on end-of year demonstrations of compliance— are entirely consistent with the Act, including all the provisions cited by commenters.[746]

The argument that the regulatory approach is unlawful because conformity cannot be determined until the end of the model year is incorrect. Congress itself used this kind of approach when it mandated certain standards under section 202. For example, Congress mandated phase-ins over time of certain emission standards for certain vehicles and model years.[747] Each of these provisions requires that a specified percentage of a manufacturer's production has to meet a specified standard. This made the level of a manufacturer's production

742 *See* appended certificate ("It is also a term of this certificate that this certificate may be revoked or suspended or rendered void *ab initio* for other reasons specified in 40 CFR Part 1068").
743 *See, e.g.,* 40 CFR 1068.101(a)(1).
744 40 CFR 1037.401(a).
745 *See* 40 CFR 1037.241(a)(2) ("Note that the FEL is considered to be the applicable emissions standard for an individual configuration"). *See also* 40 CFR 1037.250(a) (which facilitates individual compliance by requiring manufacturers to report "by vehicle identification number and vehicle configuration and identify the subfamily identifier").
746 *See* CAA section 206(a)(1) (which leaves to EPA the means of determining "whether such vehicle…conforms with" the section 202 emissions standards and authorizes the Administrator to "test, or require to be tested in such manner as he deems appropriate" for purposes of vehicle certification); *see also EDF v. Thomas*, 805 F.2d 410, 425 n. 24 (D.C. Cir. 1986) (noting this discretion).
747 Sections 202(a)(6), (g)(1) (as noted earlier), (g)(2), and (j) (all of which require EPA to issue standards pursuant to section 202(a)).

over a model year a core element of the standard.[748] The form of the standard mandated by Congress recognized that pre-production certification would need to be based on a projection of production for the upcoming model year, with actual compliance with the required percentages not demonstrated until after the end of the model year.[749] EPA's ABT provisions use this same kind of approach, that also makes the level of a manufacturer's production a core element of the standard. In both forms, compliance is evaluated not only with respect to individual vehicles, but with respect to the fleet as a whole. The difference is that EPA's provisions provide manufacturers with greater flexibility in meeting the performance-based standards, allowing them the ability to achieve the required level of emission reductions even more cost-effectively.[750] That is, Congress' approach required a specific number of vehicles each year to meet more stringent standards, while EPA allows manufacturers to choose how many vehicles each year will meet the more stringent standards, subject to the overall constraint of a fleet average standard that gradually increases in stringency.

Vehicle manufacturers also warrant at the time of sale that each new vehicle is designed to comply with all applicable emission standards and will be free from defects that may cause noncompliance consistent with CAA section 207. Under 40 CFR 1037.120, manufacturers must warrant to the ultimate purchaser, and to subsequent purchasers, that the vehicle is "designed, built, and equipped" to conform at time of sale with all applicable standards, and is free of defects that will cause it to fail to conform in use during the applicable warranty period.[751] Components covered by the warranty include all emission-related components included in the manufacturer's application for a certificate of conformity, which are keyed to the FEL assigned to those vehicles. These provisions comport entirely with section 207 of the Act and are readily determinable at time of sale by reference to the certified FEL limit.

Consistent with section 205, civil penalties are prescribed in 40 CFR Part 1068 subpart B, which prohibits sale or offering into commerce any equipment not covered by a valid certificate of conformity, and authorizes assessment of civil penalties up to $44,539 per vehicle in violation.[752] As explained above, and illustrated in the appended Certificate of Conformity, individual certificates are conditioned on compliance with all regulatory requirements including all those pertaining to compliance demonstrations via averaging. A certificate can be voided "*ab initio*" in the event of a violation of averaging requirements. For example, if a manufacturer fails to meet the required standard using averaging, they can be required to identify the vehicle families or subfamilies that are causing the deficit.[753] The conditions in the certificates mean EPA may declare that the deficit causing vehicles are not covered by the certificate. If EPA exercises that authority, the vehicles causing the deficit would no longer be considered to be covered by the certificate and would be deemed to be introduced into commerce without a valid

[748] *See, e.g.*, CAA section 202(g)(1) (defining "standards which provide that emissions from a percentage of *each manufacturer's sales volume of such vehicles and trucks* shall comply with the levels specified in table G" (emphasis added)).
[749] *See* 56 FR 25724, 25733-34 (June 5, 1991).
[750] In any case, it is often a practical necessity that conformity be determined at end of year for heavy duty vehicles, whether or not they choose the ABT or individual certification path (the individual certification option is found in 1037.241(a)(1)). This is because so many heavy-duty vehicles are built to order, and precise specifications are not known by manufacturers at the model year's commencement.
[751] 40 CFR section 1037.120(a)(1) and (2).
[752] 40 CFR 1068.101(a)(1).
[753] 40 CFR 1037.730(b)(7).

certificate of conformity. This could lead to enforcement action and civil penalties for each of the vehicles not covered by a certificate, consistent with sections 203 and 205 of the Act. Contrary to commenters' assertions, the regulations thus establish a straightforward means of calculating per vehicle violations of the HDV standards if the applicable standard is not achieved on average across the manufacturer's families in each averaging set.[754] In addition, manufacturers can be penalized for prohibited acts like selling uncertified vehicles or failing to honor the emissions warranty, all of which apply under a fleet-average standard in the same way as they do under vehicle-specific standards.

Failure of vehicles to achieve their FEL in-use could lead to a recall under section 207(c)(1) if EPA determines that a substantial number of vehicles fail to achieve their FEL. Commenters' arguments that there is no way to assess if a substantial number of heavy-duty vehicles are non-conforming is incorrect. The certified FEL limit and in-use testing provide a ready means of determining if and how many vehicles fail to meet their applicable standard in-use.

Similarly incorrect is the commenters' argument that the standards do not allow for section 202(m) emission control diagnostic systems that accurately identify emission control-related deterioration that could result in failure of vehicles to comply with emission standards. Once again, every vehicle is certified to an FEL that is immediately determinable, as are means of diagnosing potential deterioration of the vehicle's emission control system relative to this FEL.[755]

Further, commenters reliance on the *NRDC v. Thomas* dicta is misplaced. First, the Court noted that Section 206(a)'s testing and certification provisions refer to vehicles, not to classes of vehicles.[756] As explained above, however, the certification is conditioned not only on compliance with the fleet-average standards, but also on each vehicle complying with its FEL.[757]

Second, the *NRDC* Court noted that in legislative history to the 1970 amendments, Congress indicated that each prototype, rather than the average of prototypes, should meet emission standards.[758] EPA addressed this concern in the preamble to a 1990 rule. Congress's concern was that "we did not have an adequate testing program" to "get to this problem of cleaning up the auto emissions,"[759] and that the testing of a small number of prototypes and averaging of those prototypes did not provide an accurate assessment of vehicle compliance with standards. But EPA's current certification and in-use standards are vehicle-specific and "ensure that each engine meets the [applicable] limit."[760] Averaging as used in the current program does not create any uncertainty as to whether manufacturers are in compliance with the standards because every

[754] *See* 1037.730(b)(7). We note again that the Phase 3 rule contains a temporary flexibility whereby compliance in MYs 2027-2032 can be demonstrated across all of the HDV averaging sets.
[755] Cf. 40 CFR Part 1037.201(l) (requirement for certification application to identify vehicle family's deterioration history) and 1037.241(c) (EPA may require certification applicant to provide analysis "showing that the performance of your emission controls will not deteriorate during the useful life" and potentially requiring applicant to develop deterioration factors for the vehicle and its emission control components).
[756] *NRDC v. Thomas*, 805 F.2d at 425 n.24.
[757] The *NRDC* Court also noted the "counterargument" to its concern, that "the manner of testing deemed appropriate or the content of the standards themselves is within the discretion of the agency." *NRDC v. Thomas*, 805 F.2d at 425 n.24.

vehicle must achieve its certified emission performance as part of the fleetwide compliance framework.

Response 10.2.1.d.4: Illustrative Certificate of Conformity

	UNITED STATES ENVIRONMENTAL PROTECTION AGENCY **2023 MODEL YEAR** **CERTIFICATE OF CONFORMITY** **WITH THE CLEAN AIR ACT**	**OFFICE OF TRANSPORTATION** **AND AIR QUALITY** **ANN ARBOR, MICHIGAN 48105**

Certificate Issued To: Volvo Group Trucks Technology, Powertrain Engineering, a Division of Mack Trucks (U.S. Manufacturer or Importer) **Certificate Number:** PVPT2TRACS00-019-R03	**Effective Date:** 07/18/2022 **Expiration Date:** 12/31/2023	Byron J. Bunker, Division Director Compliance Division	**Issue Date:** 07/18/2022 **Revision Date:** 10/17/2023

Model Year: 2023 **Vehicle Family:** PVPT2TRACS00 **Vehicle Regulatory Sub-category:** Class 8 low-roof sleeper cab tractors above 33,000 pounds GVWR **Averaging Set:** Heavy Heavy-Duty Vehicles (8)	**CO2 Emission Standard (g CO2/ton-mile):** 72.3 **Highest Projected CO2 Family Emission Limit (g/ton-mile):** 113.2 **Lowest Projected CO2 Family Emission Limit (g/ton-mile):** 55.7

Pursuant to Section 206 of the Clean Air Act (42 U.S.C. section 7525), 40 CFR Part 1037 and subject to the terms and conditions prescribed in those provisions, this certificate of conformity is hereby issued with respect to the test vehicle which represents the vehicle family, and is subject to the terms and conditions prescribed in those provisions. This certificate of conformity covers only those new motor vehicles which conform in all material respects to the design specifications that applied to those vehicles described in the documentation required by 40 CFR Part 1037 and which are produced during the model year stated on this certificate of the said manufacturer, as defined in 40 CFR Part 1037.

This certificate of conformity is conditional upon compliance of said manufacturer with the averaging, banking and trading provisions of 40 CFR Part 1037, Subpart H. Failure to comply with these provisions may render this certificate void *ab initio*.

It is a term of this certificate that the manufacturer shall consent to all inspections described in 40 CFR 1068 and authorized in a warrant or court order. Failure to comply with the requirements of such a warrant or court order may lead to revocation or suspension of this certificate for reasons specified in 40 CFR Part 1068. It is also a term of this certificate that this certificate may be revoked or suspended or rendered void *ab initio* for other reasons specified in 40 CFR Part 1068.

This certificate does not cover vehicles sold, offered for sale, or introduced, or delivered for introduction, into commerce in the U.S. prior to the effective date of the certificate.

Response 10.2.1.e. The Russello Canon Is Inapplicable

Commenters invoked the Russello and *expressio unius* canons of statutory construction, claiming that various provisions of both the CAA and other statutes indicate that Congress knew how to specify ABT-based standards when it wished, and therefore that the absence of such an explicit delegation in section 202(a)(1) is an indication that no such delegation is intended. We disagree with the relevance of these canons here, which we refer to collectively as the Russello canon. To begin with, the "canon does not apply unless it is fair to suppose that Congress considered the unnamed possibility and meant to say no to it, and that the canon can be overcome by contrary indications that adopting a particular rule or statute was probably not meant to signal any exclusion."[761] As explained above, a more direct and explicit indication of Congressional intent vis-a-vis ABT is available, as Congress ratified EPA's use of ABT as upheld by the D.C. Circuit's decision in *NRDC v. Thomas*, 805 F. 2d 410, 425 (D.C. Cir. 1986).[762] For this reason alone, the Russello canon does not apply.

Moreover, the Russello canon has limited if any utility where wording is not identical or otherwise substantially similar.[763] That is the case with respect to the provisions cited by the

[761] *Marx v. Gen. Revenue Corp*., 133 S. Ct. 1166, 1175 (2013).
[762] *See* 88 FR at 25950.
[763] *See Nat'l Postal Pol'y Council v. Postal Regul. Comm'n*, 17 F.4th 1184, 1191 (D.C. Cir. 2021), cert. denied, 142 S. Ct. 2868 (2022) ("The Mailers also invoke the presumption in *Russello v. United States* — that the inclusion of a phrase in one provision and its absence in another is deliberate, 464 U.S. 16, 23, 104 S.Ct. 296, 78 L.Ed.2d 17 (1983) — to argue that the exception to the price cap for emergencies in § 3622(d)(1)(E) demonstrates that Congress decided not to grant the Commission the authority to override the price cap in § 3622(d)(3). Mailers Br. 20–21. That canon has limited force here, however, because the two provisions use different words and are not otherwise

commenters. Commenters cite the Clean Fuels Vehicle provisions in Part C of Title II for the proposition that Congress knew how to specify an ABT program.[764] This program is found in a separate Part of the statute, uses different language than section 202, and is not otherwise parallel to section 202. Namely, the Part C provisions direct EPA to set standards for clean-fuel vehicles operating on clean alternative fuel including electricity, but only on a targeted regional basis. This was a specific project to advance alternative fuels and technologies,[765] not a limit on EPA's general Section 202(a)(1) authority. Moreover, the credit provisions are highly detailed, and in some cases, mandatory. For example, the credit provisions in section 246(f) are mandatory, specific to certain State Implementation Plan (SIP) revisions, and subject to limits on how the credits can be used, such as "to demonstrate compliance with other requirements applicable under this section in the same nonattainment area."[766] By contrast, section 202(a)(1) does not explicitly mandate or specify a credit program, and it also provides for nationally applicable standards. EPA's decision to implement ABT and fleet-average standards falls within Congress's delegation to the agency to establish the standards. Thus, sections 246 and 249 are quite different from section 202(a)(1), and the Russello canon is inapplicable.

Commenters cited the Reformulated Gasoline and Renewable Fuel Standards provisions of the Act as further examples of Congress knowing how to specify averaging or credit programs when it wished to adopt them.[767] These provisions involve fuels, not emission from motor vehicles, and so are not the same or parallel to section 202(a). Moreover, the credit programs in those provisions are also mandatory.[768] Further, Congress explicitly specified that the RFS program does not limit the agency's authority to promulgate other GHG programs.[769]

EPA notes that the ABT program for section 202(a) standards is not unique in lacking an explicit statutory ABT provision. Over the decades, EPA has also promulgated ABT programs in other similar instances. For instance, EPA has also implemented a highly successful ABT program for fuels standards under section 211(c).[770] Indeed, many fuels companies, such as members of commenters API and AFPM, have historically supported and benefited from these ABT programs. Like the section 202(a) ABT programs, fuels programs containing ABT provisions that are promulgated under section 211(c) also lack an explicit statutory ABT provision. Such absence is also in marked contrast to the section 211(k) ABT program.

More broadly, in light of the history of Federal environmental law, it is not surprising that the later-enacted clean fuel vehicles, reformulated gasoline, and RFS programs have explicit

---

parallel. *See City of Columbus v. Ours Garage & Wrecker Serv., Inc.*, 536 U.S. 424, 435–36, 122 S.Ct. 2226, 153 L.Ed.2d 430 (2002).").

[764] Commenters also cite to the Clean Fuel Vehicles program as evidence that Congress knew how to explicitly specify a program for electric vehicles. We respond to these comments in RTC 2.1.

[765] *See* H. REP. NO. 101-490, pt. 1, at 283 (1990), 1990 WL 1222133, at *65-66 (Congress wanted "to encourage a broad range of vehicles," including those using electricity, and break the "chicken and the egg" supply-and-demand problem among automakers, consumers, and fuel producers).

[766] CAA section 246(f)(2)(A).

[767] *See* CAA section 211(k)(7) (credits relating to reformulated gasoline), section 211(o)(5) (credit program for RFS).

[768] *See* CAA section 211(k)(7) (regulations "shall provide" for credits for certain reformulated gasoline), section 211(o)(5) (RFS regulations "shall provide" for credits).

[769] CAA section 211(o)(12).

[770] *See, e.g.*, 65 FR 6698 (Feb. 10, 2010); 79 FR 23416 (Apr. 28, 2014); 66 FR 5002 (Jan. 18, 2001); 72 FR 8428 (Feb. 26, 2007).

provisions relating to credits, while earlier-enacted the sections 211(c) fuels and 202(a) motor vehicle programs do not. Credit programs generally and ABT programs specifically were not widely used in the early days of federal air pollution control, and the lawmakers likely had limited knowledge of such programs.[771] For instance, at the time of the Motor Vehicle Air Pollution Control Act of 1965, there was no ABT program for any federal air pollution regulatory program. Congress, recognizing the need for regulatory flexibility so as to avoid obsolescence, declined to specify the details of how the standards should be implemented, entrusting those technical judgments to the expertise of the administrative agency.

Even further afield is Valero's assertion that the Energy Policy Conservation Act provision directing NHTSA to issue regulations setting "average fuel economy standards for automobiles manufactured by a manufacturer"[772] constrains EPA's section 202(a) authority. EPCA is a different statute from the CAA, and it is also concerned with entirely different purposes. Section 202(a) is concerned with preventing or controlling emissions of air pollutants from motor vehicles which contribute to endangerment, not with vehicular fuel economy.[773] The Russello canon has no applicability here.

Response 10.2.1.f: EPA May Include ZEV and ICE Heavy Duty Vehicles Within a Single Regulatory Class.

Several of the commenters argue that even if section 202(a)(1) authorizes fleet average standards, ICE and non-ICE vehicles' performance cannot be averaged together because they are not of the same "class" as required by section 202(a)(1). There are two versions of this argument: that all members of the class being averaged must emit the pollutant(s) which are contributing to endangerment, or that they have fundamentally different powertrains and so cannot be reasonably grouped together.

EPA disagrees. As discussed in Section I.A of the preamble, section 202(a) requires EPA to prescribe standards applicable to the emission of any air pollutant from any class or classes of new motor vehicles, which in the Administrator's judgment cause, or contribute to, air pollution which endangers public health and welfare. Congress defined "motor vehicles" by their function: "any self-propelled vehicle designed for transporting persons or property on a street or highway."[774] Likewise, with regard to classes, Congress explicitly contemplated functional categories: "the Administrator may base such classes or categories on gross vehicle weight, horsepower, type of fuel used, or other appropriate factors."[775] It is indisputable that ZEVs are

[771] *See* Ellerman, P.L. Joskow & D. Harrison, Jr., Emissions Trading in the U.S.: Experience, Lessons and Considerations for Greenhouse Gases (2003), *available at* https://globalchange.mit.edu/publication/13922 (discussing the history of ABT and other credit programs in US environmental law, summarized on p. 7 tab. 1).
[772]49 U.S.C. § 32902(a).
[773] *See Massachusetts v. EPA,* 549 U.S. 497, 532 (2007) ("that DOT sets mileage standards in no way licenses EPA to shirk its environmental responsibilities. EPA has been charged with protecting the public's "health" and "welfare," 42 U.S.C. § 7521(a)(1), a statutory obligation wholly independent of DOT's mandate to promote energy efficiency. See Energy Policy and Conservation Act, § 2(5), 89 Stat. 874, 42 U.S.C. § 6201(5). The two obligations may overlap, but there is no reason to think the two agencies cannot both administer their obligations and yet avoid inconsistency").
[774] CAA section 216(2).
[775] CAA section 202(a)(3)(A)(ii). This section applies to standards established under section 202(a)(3), not to standards otherwise established under section 202(a)(1). But it nonetheless provides guidance on what kinds of classifications and categorizations Congress thought were appropriate.

"new motor vehicles" as defined by the statute and that they fall into the weight-based "classes" that EPA established with Congress's explicit support.

Under section 202(a), regulation of motor vehicle emissions has two distinct aspects: (1) if the Administrator finds that "any class or classes of new motor vehicles or new motor vehicle engines, … in his judgment cause, or contribute to, air pollution which may reasonably be anticipated to endanger public health or welfare," then (2) "[t]he Administrator shall by regulation prescribe (and from time to time revise) in accordance with the provisions of this section, standards applicable to the emission of any air pollutant from" such class or classes. The first step of this inquiry is the endangerment finding, while the second step is setting the standards.[776] As the Supreme Court held in *Massachusetts* and the D.C. Circuit reaffirmed in *Coalition for Responsible Regulation*, the Endangerment Finding is a matter of "scientific judgment"—whether air pollution endangers and whether the class of motor vehicles contributes to such pollution.[777] By contrast, the decision on what standards to set is a policy decision subsequent to the endangerment finding based on technical determinations of technology availability, cost of compliance, and lead-time.[778]

In making the GHG Endangerment Finding in 2009, EPA defined the "classes" of motor vehicles and engines for GHG regulation as "Passenger cars, light-duty trucks, motorcycles, buses, and medium and heavy-duty trucks."[779] Heavy-duty ZEVs fall within the class of heavy-duty trucks. In making the Endangerment Finding, EPA satisfied the statutory prerequisite for establishing GHG standards for the entire class of HD vehicles, which includes zero-emitting HD vehicles that do not emit pollutants.[780] That is, the Administrator's judgment as to endangerment applied to the above-stated classes as wholes, with no qualification as to the level of emissions, powertrain, or any other characteristic. The Endangerment Finding was upheld after extensive litigation.[781] EPA did not reopen the 2009 Endangerment Finding in this rulemaking, and comments collaterally challenging it are beyond the scope of this rulemaking. Once EPA made

---

[776] See 74 FR 66544 ("the decisions on cause or contribute and endangerment are separate and distinct from the decisions on what emissions standards to set under CAA section 202(a)."); *see also id.* at 66501-02; Endangerment and Cause or Contribute Findings for Greenhouse Gases Under Section 202(a) of the Clean Air Act: EPA's Response to Public Comments, Volume 11: Miscellaneous Legal, Procedural, and Other Comments, 11.3.
[777] *Massachusetts v. EPA*, 549 U.S. 497, 534 (2007); *Coal. for Responsible Regul., Inc. v. EPA*. 684 F.3d 102, 117-19 (D.C. Cir. 2012).
[778] *See Coal. for Responsible Regul., Inc. v. EPA*, 684 F.3d 102, 118 (Policy inquiries "muddle the rather straightforward scientific judgment about whether there may be endangerment by throwing the potential impact of responding to the danger into the initial question. To be sure, the subsection following § 202(a)(1), § 202(a)(2), requires that EPA address limited questions about the cost of compliance with new emission standards and the availability of technology for meeting those standards, but these judgments are not part of the § 202(a)(1) endangerment inquiry. The Supreme Court made clear in Massachusetts v. EPA that … policy concerns were not part of the calculus for the determination of the endangerment finding in the first instance."); *see generally id.* at 117-19.
[779] 74 FR 66496, 66537 (Dec. 15, 2009).
[780] We note that this is not special to GHGs. For example, EPA has also made endangerment findings and established criteria pollutant standards for an entire class or classes of vehicles (e.g., for light-duty vehicles and heavy-duty vehicles), with includes ICE only vehicles, hybrid vehicles, and ZEV vehicles. Of course the nature of compliance demonstration may differ by vehicle. For example, it would be a waste of resources to test BEVs for tailpipe emissions, and thus EPA allows BEVs to certify to certain standards without testing.
[781] *Coal. for Responsible Regul., Inc. v. EPA*, 684 F.3d 102, 117 (D.C. Cir. 2012) ("We ultimately conclude that the Endangerment Finding is consistent with *Massachusetts v. EPA* and the text and structure of the CAA, and is adequately supported by the administrative record.").

the endangerment finding for the class, EPA was required to set emission standards for vehicles in that class to address the contribution to endangerment. In the final rule, as in prior GHG rules, EPA acts consistently with the endangerment finding in promulgating GHG regulations for the class of HD vehicles.

Some commenters nonetheless contend that ZEVs fall outside of EPA's regulatory reach under this provision because they do not cause, or contribute to, air pollution which endangers human health and welfare. That misreads the statutory text. Section 202(a)(1)'s focus on regulating emissions from "class or classes" indicates that Congress was concerned with the air pollution generated by a class of vehicles, as opposed to from individual vehicles. Accordingly, Congress authorized EPA to regulate *classes* of vehicles, and EPA has concluded that the *class* of heavy-duty vehicles as a whole causes or contributes to dangerous pollution. As noted, the *class* of heavy-duty vehicles includes ZEVs, along with ICE and hybrid vehicles. EPA has consistently viewed heavy-duty motor vehicles as a class of motor vehicles for regulatory purposes, including in the HD GHG Phase 1 and Phase 2 rules.

Commenters do not seriously question that HD vehicles as defined by EPA are a "class," which they clearly are. A "class" is a "set, group, collection…containing members having…at least one attribute in common."[782] Heavy duty motor vehicles are a "set" or "group" of vehicles "containing members" having two key attributes in common. They are all motor vehicles as defined in section 216(2) of the Act, and they also share the further common attribute of gross vehicle weight of 8,500 pounds or greater.[783] These HD vehicles, along with certain other vehicles (regulated by EPA under a separate rulemaking), are a subset of the statutory definition of "heavy duty vehicles," which refer to motor vehicles with "a gross vehicle weight … in excess of six thousand pounds."[784] The statute plainly permits such a classification as it often speaks of "classes" of "heavy duty vehicles."[785]

The class of HD vehicles, then, includes all HD vehicles without regard to whether or not they emit or have a specific propulsion system. This is consistent with EPA's historical approach to defining vehicle classes. Congress ratified this historical approach in the 1990 amendments to the CAA. Congress added definitions in section 216 that incorporated into the statute EPA's prior inclusive definitions of "light duty vehicle" and "light duty truck" which "have the meaning provided in regulations promulgated by the Administrator and in effect as of November 15, 1990." Congress then mandated certain standards for light duty vehicles and light duty trucks that incorporated those inclusive definitions,[786] which do not include any distinction based on whether a vehicle emits pollutants or has a certain powertrain. CAA sections 202(g), (h)(1), and (j)(1).

[784] CAA section 202(b)(3)(C).
[785] *See*, *e.g*., CAA section 202(a)(3)(A)(i).
[786] *See* 40 CFR 86.082-2 ("Light-duty truck means any motor vehicle rated at 8,500 pounds GVWR or less which as a vehicle curb weight of 6,000 pounds or less and which has a basic vehicle frontal area of 45 square feet or less, which is: (1) Designed primarily for purposes of transportation of property or is a derivation of such a vehicle, or (2) Designed primarily for transportation of persons and has a capacity of more than 12 persons, or (3) Available with special features enabling off-street or off-highway operation and use. * * * Light-duty vehicle means a passenger car or passenger car derivative capable of seating 12 passenger) or less."); 46 FR 50464-01, 50476-77 (Oct. 13, 1981).

Commenters fail to seriously grapple with these arguments, but nonetheless claim that the prerequisite for EPA regulation is the agency finding that *individual* regulated vehicles must themselves emit air pollutants. This claim is completely unmoored from the statutory text and purpose, which speaks in terms of "classes" of vehicles that emit pollutants. Section 202(a)(1) does not speak to emissions from individual vehicles at all. For that view to be right, Section 202(a) would have to be rewritten to say the emission of air pollutants "*from any new motor vehicle*."

Furthermore, while an individual vehicle could possibly "contribute" to dangerous air pollution warranting regulation, it would not typically "cause" such pollution. Instead, the more common "cause" would be a group of vehicles aggregated as a class. This confirms that "cause, or contribute to" clause as a whole modifies emissions from a "class or classes" of vehicles, rather than emissions from individual vehicles.[787]

These commenters also misunderstand the broader statutory scheme. Congress directed EPA to apply the standards to vehicles whether they are designed as complete systems or incorporate devices to prevent or control pollution. Thus, Congress understood that the standards may be premised on and lead to technologies that prevent pollution in the first place. It would be perverse to conclude that in a scheme intended to control the emissions of dangerous pollution, Congress would have prohibited EPA from premising its standards on controls that completely prevent pollution, while also permitting the agency to premise them on a technology that reduces 99 percent of pollution. Such a nonsensical reading of the statute would mean that the availability of technology that can reduce 99 percent of pollution could serve as the basis for highly protective standards, while the availability of a technology that completely prevents the pollution could not be relied on to set emission standards at all. Such a reading would also create a perverse safe harbor allowing polluting vehicles to be perpetually produced, resulting in harmful emissions and adverse impacts on public health, even where available technology permits the complete prevention of such emissions and adverse impacts at a reasonable cost. That result cannot be squared with section 202(a)(1)'s purpose to reduce emissions that "cause or contribute to air pollution which may reasonably be anticipated to endanger public health or welfare,"[788] or with the statutory directive to not only "control" but also "prevent" pollution.

Commenters' suggestion that EPA define the class to exclude ZEVs would also be unreasonable and unworkable. *Ex ante*, EPA does not know which vehicles a manufacturer may produce and, without technological controls including add-on devices and complete systems, *all* of the vehicles have the potential to emit dangerous pollution.[789] Therefore, EPA establishes standards for the entire class of vehicles, based upon its consideration of all available technologies. It is only after the manufacturers have applied those technologies to vehicles in actual production that the pollution is prevented or controlled. To put it differently, even

[787] The rule of last antecedent does not alter that conclusion. That rule is sometimes used to interpret "a list of terms or phrases followed by a limiting clause." *Lockhart v. United States*, 577 U.S. 347, 351 (2016). But Section 202(a)(1) presents no such list, and thus no conundrum of whether the final modifier applies to everything in a preceding list or just the last item.

[788] *See also Coal. for Responsible Regul.*, 684 F. 3d at 122 (explaining that the statutory purpose is to "prevent reasonably anticipated endangerment from maturing into concrete harm").

[789] As noted above, manufacturers in some cases choose to offer different models of the same vehicle with different levels of electrification. And it is the manufacturer who decides whether a given vehicle will be manufactured to produce no emissions, low emissions, or higher emissions controlled by add-on technology.

hypothetically assuming EPA could not set standards for vehicles that manufacturers intend to build as electric vehicles—a proposition which we do not agree with—EPA could still regulate vehicles manufacturers intend *not* to build as electric vehicles and that would emit dangerous pollution in the absence of EPA regulation.[790] When regulating those vehicles, Congress explicitly authorized EPA to premise its standards for those vehicles on a "complete system" technology that prevents pollution entirely, like ZEV technologies.

Commenters' claim that EPA must classify or categorize vehicles by powertrain is also misplaced. For any given class of vehicles, the Administrator may make appropriate subcategorizations in establishing the standards.[791] Section 202(a)(1) does not explicitly delineate how EPA should categorize, indicating that Congress entrusted this subsidiary technical determination to the Administrator's judgment.[792] EPA routinely makes categorizations based on characteristics like vehicle weight and functionality, and establishes different standards for each category where that is warranted, for instance, often establishing less stringent standards for heavier vehicles as compared to lighter vehicles of the same functionality in light of differences in technological feasibility and costs. This rulemaking proposed to generally maintain the pre-existing regulatory categories of vocational vehicles and tractors, as well as further subcategorizations within each of those categories, e.g., by weight (light heavy duty, medium heavy duty, and heavy heavy-duty vocational vehicles) and functionality (rural, urban, and multi-purpose vocational vehicles; day cabs and sleeper cab tractors, plus custom chassis subcategories).

Commenters do not identify anything in the statute that mandates categorization based on whether a vehicle emits or whether it has a certain powertrain. And in fact, Section 202(a)(1) does not require categorization (or classification) on these bases. Moreover, the intention underlying the commenters' preferred categorization is to delay the introduction of effective pollution control technologies like ZEVs, with the result of perpetuating dangerous air pollution. That is not a reasonable way to implement section 202(a)(1).

Although it does not directly apply to section 202(a)(1) standards, Section 202(a)(3)(A)(ii) provides guidance on what kinds of classifications and categorizations Congress thought were appropriate. [793] That section states "[i]n establishing classes or categories of vehicles or engines for purposes of regulations under this paragraph, the Administrator may base such classes or

---

[790] In other words, the additional ZEVs EPA projects in the modeled potential compliance pathway exist in the baseline case as pollutant-emitting vehicles with ICE. We further note that it would be odd for EPA to have authority to regulate a given class of motor vehicles—in this case heavy-duty motor vehicles—so long as those vehicles emit air pollution at the tailpipe, but to lose its authority to regulate those very same vehicles should they install emission control devices to limit such pollution or be designed to prevent the endangering pollution in the first place.

[791] We acknowledge that we have not always clearly delineated between the terms "class" versus "category." But the key point here is not the semantics of these two words, but rather a substantive distinction: the "classes" of vehicles that contribute to dangerous pollution for which EPA makes the endangerment finding and are thereby subject to the regulation for the relevant pollutant, and the "categories" or "subcategories" of vehicles within a class for which the agency may in its discretion establish different standards based on the characteristics of those subcategories.

[792] Congress, however, did provide indicia as to what appropriate categorizations could be in section 202(a)(3)(A)(ii), which we discuss further below. This section does not apply directly to this rulemaking but is nonetheless instructive as to potential means of categorizing (as well as classifying) heavy duty vehicles.

[793] Section 202(a)(3)(A)(ii) applies to standards established under section 202(a)(3), not to standards otherwise established under section 202(a)(1). Nonetheless, we think it provides guidance more generally on what classifications and categorizations Congress thought appropriate.

categories on gross vehicle weight, horsepower, type of fuel used, or other appropriate factors." The class of HD vehicles is distinguished from other motor vehicles by its members having a "gross vehicle weight" exceeding 8,500 pounds. The categories within HD vehicles are also distinguished by weight (e.g., light HD versus heavy HD vocational vehicles) as well as by function (e.g., vocational vehicles versus tractors), which the Administrator views as an "other appropriate factor."[794]

Moreover, we note that other parts of the statute do actually *require* distinctions based on powertrain or based on fuel type (which corresponds to powertrain). Even within section 202 itself, Congress specified certain standards applicable only to some "gasoline and diesel-fueled" vehicles.[795] In section 216(1), Congress also limited the definition of a nonroad engine to mean only certain kinds of "internal combustion engine."[796] This treatment shows that when Congress wants to require distinctions related to powertrain, it knew how to do so. The conspicuous absence of any such limitation in section 202(a)(1) suggests that no such limitation should be inferred.

Commenters' suggestion that ZEVs are somehow so fundamentally different from ICE vehicles as to require different classification or categorization is also misplaced. EPA has conducted comprehensive analysis in this rule demonstrating that, during the timeframe for this rule, ZEVs are generally capable of performing the same functions as ICE vehicles of their respective types and established the standards accordingly. Indeed, manufacturers will sometimes produce the same vehicle model with varying levels of electrification.[797] We also determined that ZEVs would not be reasonably available in certain applications—for example, those involving some custom chassis types, or operation in extreme weather conditions or at extreme daily VMT—and we accordingly assumed solely ICE vehicles would continue to be used for those applications.

Relatedly, a commenter claims that because there is no identifiable vehicle configuration that corresponds to the standards, industry as a whole would have to certify at least two fundamentally different types of vehicles to satisfy them. It is not entirely clear what this comment means. HD vehicles are a highly diverse class of vehicles, and different manufacturers produce different subsets of such vehicles, with diverse vehicle configurations. We expect manufacturers to continue to produce the kinds of vehicles they have traditionally produced as

---

[794] *See White Stallion Energy Center v. EPA*, 748 F. 3d 1222, 1249 ("[N]othing in the Clean Air Act 'requires' EPA to create a CFB subcategory. Rather, the statute gives EPA substantial discretion in determining whether subcategorization is appropriate. *See also* CAA § 112(d)(1), 42 U.S.C. § 7412(d)(1) (EPA "may distinguish among classes, types, and sizes of sources"); *Nat'l Ass'n of Clean Water Agencies v. EPA*, 734 F.3d 1115, 1159 (D.C.Cir.2013) ("EPA's subcategorization authority under § 112 involves an expert determination, placing a heavy burden on a challenger to overcome deference to EPA's articulated rational connection between the facts found and the choice made."); *NRDC v. EPA*, 489 F. 3d 1364, 1375 (D.C. Cir. 2007) ("Because Congress has vested EPA with subcategorization authority under Section 112(c)(1), and its exercise of that authority involves an expert determination, L–P carries a heavy burden to overcome deference to the agency's articulated rational connection between the facts found and the choices made.").

[795] CAA section 202(a)(3)(B)(ii), (h) tab. H, (i)(1); *see also* CAA section 202(a)(5)(A) ("gasoline vapor recovery"), (g) tab. G ("diesel-fueled LDTs"), (k) ("gasoline-fueled motor vehicles").

[796] CAA section 216(10).

[797] For example, the Freightliner Cascadia and eCascadia are ICE and BEV versions of Freightliner's HD semi truck. Or for example, the Ford F-150 has been offered in ICE and EV versions, while the Hyundai Ioniq and Kia Niro has been offered in HEV, PHEV, and EV versions. Jaguar Land Rover has also indicated that every model will be available with a fully electric version by the end of the decade.

the standards do not limit manufacturers to only producing a single vehicle configuration or applying only a single type of pollution control technology. Moreover, it is up to manufacturers to decide how to comply with EPA's standards, and we expect each manufacturer to choose the compliance pathway that best suits its business.

Commenters suggest that calculating a fleetwide average that includes both ZEVs and other vehicles creates an illogical or false average, but EPA rejects that suggestion. It is entirely consistent with the history of motor vehicle regulation under the CAA for pollution control technologies to be phased in across the fleet, and there is nothing false about the tailpipe emissions compliance figures being averaged together under this rule. After all, ZEVs do indeed produce no tailpipe emissions, so it is accurate to account for them as such. Indeed, it would be more inaccurate to exclude ZEVs in calculating fleetwide compliance. And there is nothing false about regulatory averages that include electric vehicles. Emission standards generally apply to all motor vehicles in the relevant class. Manufacturers count the emissions of every vehicle in their fleet when calculating fleet-average emissions. Electric vehicles are thus treated just like any other vehicle with emission-control technology. For that reason, averaging is technology neutral. The impact a particular technology has on a fleet's performance depends on its effectiveness. And electric vehicles are very effective at reducing greenhouse-gas emissions. But that effectiveness does not mean EPA must categorize electric vehicles separately or that such vehicles are beyond EPA's regulatory authority.

Some commenters latch onto the fact that EPA has historically established separate categories for spark ignition and compression ignition vocational vehicles for purposes of HD GHG regulation.[798] EPA is retaining this categorization scheme in this rule. We expect manufacturers to continue producing both spark and compression ignition ICE vocational vehicles during the timeframe of this rule; that is, manufacturers will likely comply with the Phase 3 standards, as with their Phase 2 predecessors, in whole or in part based on the GHG performance of both types of vocational vehicle engines. Given technological differences, spark and compression ignition ICE emit different amounts of pollutants, including GHGs, and including when using the same pollution control technologies.[799] As such, EPA's standards and categorization scheme appropriately reflect the different feasible emissions performance of these two types of internal combustion engines and vehicles. In principle, this is no different than having different GHG standards for, say, an ICE long-haul tractor and an ICE light HD vocational vehicle: they emit different amounts of pollutants, even when using the same pollution control technologies, and the standards appropriately reflect this difference.

We note the key difference between this scheme and the one that commenters say is compelled. Under Phase 3, vocational vehicles with all engine types must meet GHG standards whose stringency is supported by the feasible emission reductions under the modeled potential compliance pathway, which includes both ZEVs and vehicles with ICE technologies.[800] Under the commenters' approach, EPA is precluded from requiring any emission reductions associated with ZEV technologies that are available at a reasonable cost, and the nation has to forgo large public health and welfare benefits. We do not think such a result is reasonable.

---

[798] *See* 40 CFR section 1037.105 (b)(1).

[799] *See, e.g.,* 81 FR at 73562, 73679, 73703 (Phase 2 rule discussions of engine technologies considered in vehicle standard-setting).

[800] The standard can of course be met by any means a manufacturer chooses.

Finally, many of commenters' arguments rest on a false premise that ZEVs cannot emit any air pollutants. But ZEVs can in fact emit GHGs through their HVAC systems.[801] They can also emit GHGs and criteria pollutants when using fuel operated heaters.[802] And of course, ZEVs like any other motor vehicle emit PM through brake and tire wear.[803]

10.2.2 U.S.-Directed Production Volume

Comments by Organizations

Organization: California Air Resources Board (CARB)

I. Definition

1. U.S.-Directed Production Volume

Affected pages: 26019-26020

The NPRM requests comments on changing the definition of U.S.-directed production volume used in calculating credits beginning in the MY 2024. This proposed definition would include vehicles certified to a state's emission standard that is different from U.S. EPA's. [EPA-HQ-OAR-2022-0985-1591-A1, pp.67-68]

The U.S.-directed production volume definition should continue to exclude vehicles certified to a state's emission standard that is different from U.S. EPA's. Because California and a number of Section 177 states have adopted the ACT regulation, the inclusion of these vehicles in the production volume for the Phase 3 rulemaking could be appropriate only if the Phase 3 final rules will produce similar emission reductions— e.g., by encouraging similar ZEV penetration rates as those of the ACT regulation. In addition, California recently adopted the ACF regulation which establishes ZEV purchase requirements greater than required in the ACT regulation and a 100 percent manufacturer ZEV sales requirement in 2036, both of which exceed the stringency of U.S. EPA's NPRM. As such, CARB staff does not support the change in the definition of U.S.-directed production volume. The current definition of U.S.-directed production volume, which excludes vehicles certified to California and Section 177 state standards, should be maintained so that Phase 3 GHG achieves benefits beyond what the standards in California and the Section 177 states will already achieve. [EPA-HQ-OAR-2022-0985-1591-A1, p.68]

Eroding the effective Phase 3 GHG stringency in the U.S. EPA-only regulated states by averaging the California and Section 177 ACT states into the national average would work counter to the CAA purpose of state actions being additive beyond national actions. The flow of the vehicles sold subject to the effectively eroded standards back into California and Section 177 states on the used market and in the course of interstate commerce would result in emission increases and exacerbate our air pollution, public health, and climate challenges. [EPA-HQ-OAR-2022-0985-1591-A1, p.68]

---

[801] *See* 40 CFR sections 86.1819-14 (h) and 1037.115 (e) prescribing standards to control those emissions.
[802] *See* RTC section 4.10 responding to comments of CARB and Roush regarding fuel operated heaters in ZEVs.
[803] *See* RIA Chapter 4.1 discussing EPA's modelling of these emissions in calculating emission inventories associated with the Phase 3 rule. EPA has not to date adopted standards for such PM emissions; such standards would present a number of complex and novel issues.

In fact, if the U.S.-directed production volume definition is changed as proposed, CARB staff expects that manufacturers would be able to comply with the proposed Phase 3 2027 standards (preferred alternative) without taking any compliance actions (such as selling HD ZEVs or other lower emitting vehicles) outside California and Section 177 states. This is due to the early credit bank manufacturers can generate due to expected action by California and other Section 177 states. Per data in the DRIA, U.S. EPA expects nationwide vocational ZEV sales to increase from 1.1 percent in 2024 to 2.4 percent in 2026, and nationwide tractor ZEV sales to increase from 0.3 percent in 2024 to 1.0 percent in 2026. Assuming these vehicles are sold as BEVs eligible for a 4.5 ATC multiplier, these ZEV sales would provide manufacturers with a credit bank sufficient to offset a nationwide 25 percent ZEV sales requirement for vocational vehicles and nationwide 9 percent ZEV sales requirement for tractors. Given the 2027 standards for vocational vehicles and tractors are 20 percent and 10 percent respectively, these banked credits would almost completely offset the entire MY 2027 requirements under the NPRM. Given that U.S. EPA's reference case does not include the impacts of the ACF regulation, potential early action by manufacturers in California or other Section 177 states, nor the impacts of Vermont, Colorado, and Maryland or future states adopting the ACT regulation, the actual size of the credit bank will be greater than assumed in the reference case, and CARB staff expects that manufacturers would be able to comply with the proposed Phase 3 2027 standards without making any HD ZEVS or otherwise improving their average, nationwide emissions. This sizable bank will hinder U.S. EPA's overall program and reduce the number of ZEVs other states receive. Overall, maintaining separate programs by continuing to exclude vehicles certified to a state's emission standard that is different from U.S. EPA's in the definition of U.S.-directed production volume is critical to avoid these negative effects. [EPA-HQ-OAR-2022-0985-1591-A1, pp.68-69]

If U.S. EPA does finalize this change in definition, U.S. EPA should not make the change effective until MY 2027 (or later if U.S. EPA does not finalize more stringent standards for MY 2027). U.S. EPA argues that the expanded definition is appropriate because U.S. EPA is considering nationwide production volumes when setting these standards. But U.S. EPA is only doing so beginning with MY 2027. U.S. EPA has not proposed to (re)set its standards that way for MYs 2024 through 2026, and it should not, therefore, make any related definitional change for those years. Indeed, doing so would effectively change those standards without any determination (or basis for one) that those standards should be changed. And the same is true for U.S. EPA's other justification for this change. There cannot be any "potential difficulties surrounding manufacturers' long-term compliance planning" for MYs 2024 through 2026 of U.S. EPA's existing Phase 2 regulation, as those standards have been in place for a decade. Whatever justification U.S. EPA may have offered for this definitional change to accompany its revised standards for MY 2027 or its new standards for MY 2028 and later, there does not appear to be any justification for making this definitional change before any revised or new federal standards take effect. [EPA-HQ-OAR-2022-0985-1591-A1, p.69]

As an additional note, for clarity and consistency, CARB staff suggests that U.S. EPA ensure that the regulatory language concerning U.S.-directed production volume for vehicles generating and using emission credits in 40 CFR 1037.705 is consistent with that for engines in 40 CFR 1036.705(c)(4). It appears U.S. EPA has proposed changing 40 CFR 1036.705(c)(4) for engines but not proposed the adoption of consistent language in 40 CFR 1037.705. [EPA-HQ-OAR-2022-0985-1591-A1, p.69]

Organization: Clean Air Task Force et al.

G. EPA should not adopt the proposed definition of "U.S.-directed production volume" without strengthening its standards, and any change to the definition should take effect no earlier than 2027.

EPA's proposal would include vehicles certified to the ACT in California and other states within the "U.S.-directed production volume" eligible for credits. 88 Fed. Reg. at 26009-10 (proposing new definition of term). EPA proposes this change because "the ZEV production volumes destined for California and other states would correspond to a large portion of the nationwide production on which the proposed EPA standards are based," such that "it would be challenging for vehicle manufacturers to comply with the proposed standards if they could not account for those ZEVs." Id. at 26010. [EPA-HQ-OAR-2022-0985-1640-A1, pp. 78 - 79]

For the reasons set forth above, a standard that includes vehicles produced pursuant to the ACT (both in California and in states that have already adopted ACT) should be much more stringent than the standards that EPA proposes. The proposed change to the definition of "U.S.-directed production volume" should therefore be accompanied by a significantly more stringent final rule—one at least as protective of public health and welfare as the ACT implemented nationwide. Otherwise, there is no reason to conclude that it would be "challenging" for manufacturers to comply without accounting for vehicles in California and states adopting California's standards. Id. [EPA-HQ-OAR-2022-0985-1640-A1, p. 79]

Additionally, EPA offers no basis to implement the definitional change in 2024, well before the proposed standards take effect. Id. at 26009 (proposing that revision take effect in 2024). EPA's Phase 2 standards are not premised on ACT-certified vehicles, and there is no reasonable basis to believe that those standards will be difficult to meet without including ACT vehicles. EPA's desire for "consistent treatment of any production volumes certified to ACT" does not allow it to unmoor its regulatory change from its rationale: the need to match its definition to "the production on which the [Phase 3] standards are based," Id. at 26009-10, which does not apply to EPA's Phase 2 standards. And especially for those years in which EPA's final rule allows credit multipliers, including ACT-certified vehicles will deeply undermine the effectiveness of EPA's standards. Therefore if EPA finalizes its proposed change to the definition of "U.S.-directed production volume," that change should take effect no earlier than 2027. [EPA-HQ-OAR-2022-0985-1640-A1, p. 79]

Organization: Colorado Department of Transportation et al

- EPA proposes changes to the definition of 'U.S. directed production volume' a term that defines the geographic boundaries in which sales count toward manufacturers' compliance with EPA's heavy-duty GHG standards. Under the current Phase 2 regulations, this term excludes 'production volumes that are certified to different state emission standards,' meaning that sales in California and the Section 177 States that have adopted the ACT Rule do not count toward compliance with EPA's Phase 2 standards. Under EPA's proposed redefinition, 'total nationwide production volumes' would count toward compliance with its standards, 'including vehicles certified to state emission standards that are different than EPA's'. If EPA moves forward with a proposal that is less stringent than the ACT regulation, our state would not support this change, which would reduce the emission reduction impact of the rule in states that have not adopted the ACT rule. [EPA-HQ-OAR-2022-0985-1530-A1, pp. 2-3]

Organization: Cummins

11. Cummins proposes improved wording for 40 CFR §1036.705(c)(4).

40 CFR §1036.705(c)(4) should be reworded to align and be more consistent with 40 CFR §1036.801. Cummins proposes the following wording:

"Engines produced by a manufacturer for which the manufacturer has a reasonable assurance that sale was or will be made to ultimate purchasers in a state that has implemented emissions standards that are different than the emissions standards in this part." [EPA-HQ-OAR-2022-0985-1598-A1, p. 10]

Organization: Daimler Truck North America LLC (DTNA)

Inclusion of Nationwide Production Volumes in ABT. DTNA agrees with EPA's proposal to allow vehicles produced and certified to meet ACT sales volume requirements in California and other states to generate credits under the federal ABT program starting in MY 2024. Inclusion of nationwide production volumes—including those vehicles that are certified to state-specific emission standards—in credit calculations is in fact necessary to ensure that the Phase 3 standards, which are based on nationwide adoption rates, are feasible and appropriate. As EPA notes, HD ZEV production volumes destined for California and other states correspond to a large portion of the nationwide production on which EPA's proposed standards are based, and it would be extremely challenging for vehicle manufacturers to comply with the proposed standards if they could not account for those ZEVs.21 Including nationwide production volumes in ABT credit calculations is thus necessary to encourage nationwide HD ZEV proliferation, one of the main objectives of the Proposed Rule. [EPA-HQ-OAR-2022-0985-1555-A1, pp. 16-17]

21 See Proposed Rule, 88 Fed. Reg. at 26,010.

Applicable Engine Production Volume for Calculating ABT Credits.

EPA proposes a new 40 C.F.R. 1036.705(c)(4) to maintain the current exclusion of engines that are certified to state-specific engine standards from the engine production volumes used as the basis for ABT credit calculations under Part 1036.144 This modification is needed in light of EPA's proposal to broaden the definition of 'U.S.-directed production volume' (in both Parts 1036 and 1037) to allow GHG ABT credit calculations to encompass nationwide production volumes, as discussed in Section II.A. of these comments. [EPA-HQ-OAR-2022-0985-1555-A1, p. 75]

144 See Proposed Rule, 88 Fed. Reg. at 26,019.

DTNA requests that EPA take this opportunity to make a needed clarification that engines are excluded from credit calculations based upon the states in which they are sold, rather than the standards to which they were certified. [EPA-HQ-OAR-2022-0985-1555-A1, p. 75]

As EPA is likely aware, it is common practice for manufacturers to seek dual CARB and EPA certifications for their engines, including engines that are not ultimately sold in California or a CAA Section 177 opt-in state, so that they can be sold anywhere in the country. Because engines that are sold outside of California or Section 177 states would not be credit-eligible under these states' credit programs,145 it stands to reason that they should not be excluded from the federal ABT credit program just because of their CARB certification. [EPA-HQ-OAR-2022-0985-1555-A1, p. 75]

145 As such, these engines do not present the 'double-counting' problem that originally motivated EPA to exclude products certified to state-specific emission standards from the production volumes used as the basis for federal ABT credit calculations. In enacting this exclusion, EPA sought to ensure that engines already required to be certified under the California program (for sale there or in other states that require CARB certification) could not generate credits under the federal ABT program. This concern is not presented in the case of engines for which federal certification is required but CARB certification is optional because the engines are produced for sale outside of California/opt-in states. We understand that EPA concurs with this interpretation, as evidenced in its statements in the recently finalized Low-NOx Rule preamble. See 81 Fed. Reg. at 4,395, n. 413 (observing that while the 'final ABT program does not allow manufacturers to generate emissions credits from engines certified to state emission standards that are different than the federal standards,' this does not preclude manufacturers from generating emission credits 'if they produce larger volumes of engines to sell outside of those states that have adopted emission standards that are different than the federal standards') (emphasis added).

The requested clarification to Section 1036.705(c)(4) would make plain in the regulations that an engine with dual certification (i.e., one that is certified to both EPA and CARB emission standards) would not be excluded from a manufacturer's credit calculation where it is sold in a state where only EPA is certification is required. To effectuate this change, the Company proposes the following revision to the proposed new Section 1036.705(c)(4):

(c) Compliance with the requirements of this subpart is determined at the end of the model year by calculating emission credits based on actual production volumes, excluding the following engines:

(4) Engines ~~certified to state emission~~ produced by a manufacturer for sale in a state that has adopted emissions standards that are different than the emission standards in this part. [EPA-HQ-OAR-2022-0985-1555-A1, pp. 75-76]

Organization: Ford Motor Company

EPA has proposed a revision to the definition of "U.S.-directed production volume" as defined in 40 CFR §§ 1036.801 and 1037.801 in order to include vehicles sold in California or Section 177 states that have adopted the Advanced Clean Trucks (ACT) regulation, to take effect in 2024MY. Ford supports this proposed change and 2024MY timing. We agree with EPA that the revised definition is appropriate, and so is EPA's rationale in considering the impact of ACT on this HD GHG regulation. The revised definition will align with EPA's goal of increasing heavy-duty ZEV sales nationwide and will help avoid the need to predict or account for any distortionary impact that ACT may have on non-Section 177 state ZEV sales. We believe it is appropriate for EPA to consider nationwide ZEV sales as a whole in this rule. [EPA-HQ-OAR-2022-0985-1565-A1, p. 7]

At the same time, we also support the proposed revision to 40 CFR § 1036.705(c) to continue separate emission credit averaging, banking, and trading for engines certified to different state emission standards when those state standards are materially different than EPA's standards. As articulated by EPA, such a case will continue to exist between California's (and adopting Section 177 states') Heavy-Duty Omnibus rule and EPA's Clean Trucks Plan HD2027 rule, both of which regulate criteria emissions from heavy-duty engines but at different standards, useful lives, and in-use requirements. Engine emission standards for 2027MY and beyond do not include EVs in their averaging sets, for EPA or California, so the overlap in balancing Section 177 and non-Section 177 state ZEV sales does not exist as it does for EPA's proposed HD GHG rule and ACT. [EPA-HQ-OAR-2022-0985-1565-A1, p. 7-8]

Organization: International Council on Clean Transportation (ICCT)

TREATMENT OF ACT COMPLIANCE TOWARDS COMPLIANCE WITH PHASE 2 This section responds to EPA's request for comment on how to account for ZEV adoption rates that would arise from compliance with the California ACT program in setting the proposed Phase 2 GHG standards. We are concerned that EPA's decision to revise the definition of 'U.S.-directed production volume' will allow manufacturers to comply with the proposed CO2 standards through the sale of zero-emission trucks they are already required to sell under state law. This flexibility dilutes the stringency of the proposed standards, reinforces investments in fleet deployment and charging infrastructure in ACT states at the expense of non-ACT states, and limits the benefits of the rule in non-ACT states. [EPA-HQ-OAR-2022-0985-1553-A1, p. 14]

In our view the simplest solution would be to retain the existing definition of 'U.S.' directed production volumes that has been in effect since the adoption of the Phase 2 standards. This would ensure manufacturers are investing in more efficient and zero-emission vehicles in non-ACT states. This would also ensure utility companies and charging infrastructure providers are investing in non-ACT states. And this would provide greater certainty that the rule would deliver its intended benefits in non-ACT states. [EPA-HQ-OAR-2022-0985-1553-A1, p. 14]

If EPA chooses to adopt its proposed revision to the definition of 'U.S. directed production volume,' we suggest the agency determine the stringency of its standards based on a weighted average of ZEV sales required in ACT states and the additional forecasted ZEV sales in non-ACT states. In this way, EPA is aligning the stringency of its standards with the benefits of ZEV sales required under state laws, and it is reinforcing and securing the additional market potential for ZEV deployments in non-ACT states. [EPA-HQ-OAR-2022-0985-1553-A1, p. 14]

A hypothetical example of a sales-weighted average can be illustrated for Class 7-8 short haul tractors. The EPA proposal assumes a 35% ZEV sales share in MY 2032 in this segment. We assume nine states that have adopted the ACT account for 24% of national Class 7-8 short-haul tractor sales. We also assume the ACT requires 74% of MY 2032 sales of these vehicles to be zero-emission. The weighted national average ZEV sales share for Class 7-8 short-haul tractor trucks is 44.4%. This weighted average would be the basis for setting the stringency of the standard for this vehicle category. [EPA-HQ-OAR-2022-0985-1553-A1, pp. 14-15]

Averaging, Banking and Trading

U.S. Directed Production

EPA's analysis supporting this proposed rule is based on a 50-state approach which provides greater flexibility to address the complexities and fluid nature of heavy-duty vehicle purchases, licensing and operation. For these reasons, MECA believes that it is appropriate that U.S. directed production should include all 50 states. [EPA-HQ-OAR-2022-0985-1521-A1, p. 9]

Organization: Northeast States for Coordinated Air Use Management (NESCAUM) and the Ozone Transport Commission (OTC)

Definition of U.S.-Directed Production Volume

EPA asks for comment on its proposal to change the definition of the U.S.-Directed Production Volume in 40 CFR 1037.801 such that it represents the total nationwide production volumes, including vehicles certified to state emission standards that are different than the emission standards of 40 CFR part 1037. We request that EPA retain the definition of U.S.-Directed Production Volume as it currently is defined in 40 CFR 1037.801 so that Phase 3 GHG standards achieve benefits beyond what the standards in California and the Section 177 states achieve. [EPA-HQ-OAR-2022-0985-1562-A1, p. 14]

The current definition excludes vehicles certified to a state emission standard that is different from U.S. EPA's, in this case, vehicles certified to California and Section 177 state standards. The change in definition would allow inclusion of the Section 177 states' and California's MHD ZEV production volumes in the national average. Information in EPA's Draft RIA shows the agency expects nationwide vocational ZEV sales to increase from 1.1 percent in 2024 to 2.4 percent in 2026, and nationwide tractor ZEV sales to increase from 0.3 percent in 2024 to 1.0 percent in 2026. Assuming these vehicles are sold as BEVs eligible for a 4.5 advanced technology credit multiplier, these ZEV sales would provide manufacturers with a credit bank sufficient to offset a nationwide 25 percent ZEV sales requirement for vocational vehicles and nationwide 9 percent ZEV sales requirement for tractors. Given the 2027 standards for vocational vehicles and tractors are 20 percent and 10 percent respectively, these banked credits would almost completely offset the entire 2027 MY requirements under the proposed rule. As stated previously, EPA's reference case does not include the impacts of Vermont, Colorado, or future states adopting the ACT regulation, the ACF regulation, or potential early action by manufacturers. Because of this, the amount of banked ZEV credits will likely be greater than assumed in the reference case. This sizable bank will reduce the number of ZEVs other states receive. Thus, continuing to exclude vehicles certified to a state's emission standard different from EPA's in the definition of the U.S.-Directed Production Volume is critical to avoid these negative effects. [EPA-HQ-OAR-2022-0985-1562-A1, p. 14-15]

Organization: ROUSH CleanTech

We do not agree with EPA's proposed approach to combine all US sales into a single GHG credit pool, even if they are certified to alternate state standards. We recognize that by including California certified vehicles in the EPA credit pool it will give the appearance of higher BEV/FCEV adoption rates than if the EPA pool was federal only, but we do not believe this is a reasonable justification for a combined pool. States which adopt the ACT are forcing manufacturers to sell BEV/FCEV's, and in California and states which adopt the ACF, are forcing fleets to buy them. This behavior would totally distort the credit pool and market for the Phase 3 program, and almost certainly will result in little or no incentive for manufacturers to sell BEV's in federal states as BEV's sold in ACT states would receive valuable ACT credits in addition to valuable EPA GHG credits. We recommend that EPA follow current practice (and past precedent) and continue to maintain a separate credit pool that applies only to federal states and allow the ACT states to maintain their own pools (as they will otherwise have to under the ACT program). [EPA-HQ-OAR-2022-0985-1655-A1, p.3]

Organization: State of California et al. (2)

IV. EPA SHOULD NOT CHANGE THE DEFINITION OF "U.S.-DIRECTED PRODUCTION VOLUME," AND CERTAINLY SHOULD DO SO NO EARLIER THAN MODEL YEAR 2027

EPA has proposed to change its definition of "U.S.-directed production volume."241 This term defines the geographic boundaries in which sales count toward manufacturers' compliance with EPA's heavy-duty GHG standards.242 Under the current Phase 2 regulations, this term excludes "production volumes that are certified to different state emission standards," meaning that sales in California and the Section 177 States that have adopted California's ACT Rule would not currently count toward compliance with EPA's Phase 2 standards. EPA seeks comment on whether it should change this definition so that EPA would count "total nationwide production volumes" toward compliance with its standards, "including vehicles certified to state emission standards that are different than" EPA's.243 [EPA-HQ-OAR-2022-0985-1588-A1, pp. 35-36]

241 40 C.F.R. §§ 1036.801, 1037.801.

242 88 Fed. Reg. at 26,009.

243 Id. at 26,010.

Our States and Cities oppose this change. Congress intended EPA's standards to reduce harmful vehicular emissions, thereby protecting public health and welfare, through new vehicle sales in States that have not adopted California's standards. EPA's standards should be based on an assessment of technological development and applications manufacturers can make in those other States, and compliance should be determined accordingly. Certainly, EPA must consider the vehicles being produced for, and anticipated to be produced for, California and Section 177 States pursuant to those States' standards. That information is directly relevant to questions of technological feasibility and cost-effectiveness. This is so not because those vehicles facilitate compliance with EPA's standards, but because the ability to produce and use cleaner vehicles anywhere is one part of the picture of what may be feasible elsewhere. Thus, simply because EPA is "considering such production volumes in setting the stringency of the Phase 3 standards in this rulemaking," it does not logically follow that EPA should "allow[] inclusion of such production volumes in demonstrating compliance with" EPA's standards.244 [EPA-HQ-OAR-2022-0985-1588-A1, p.36]

244 Id.

Moreover, if EPA follows the path it has proposed here—changing the definition of "U.S.-directed production volume" beginning with MY2024, preserving the multiplier credits through MY2026, and finalizing its preferred alternative standards beginning in MY2027—EPA's standards will not protect the public health and welfare as the CAA requires. First, the timing of EPA's proposed definitional change would allow manufacturers to get credit for any ZEVs they sell to comply with state ACT regulations under EPA's existing Phase 2 standards for MY2024-

2026 which are not changing here. In other words, EPA would make compliance significantly easier (perhaps even effortless) in States outside California and the Section 177 States in MY2024-2026, even though EPA has made no finding that manufacturers face challenges with the federal Phase 2 standards in those years (nor could EPA do so). [EPA-HQ-OAR-2022-0985-1588-A1, p.36]

Second, and even worse, EPA would allow manufacturers to receive between 3.5 and 5.5 times the credit for any ZEVs they sell in ACT States for those three model years (2024-2026).245 So, even by simply meeting their compliance obligations in ACT States, manufacturers will rack up enormous credit banks under EPA's program. Manufacturers could then use banked credits, rather than emissions reductions, to comply in later years, which would slow, rather than advance, progress. [EPA-HQ-OAR-2022-0985-1588-A1, p.36]

245 Our States and Cities support the comments of others (including the California Air Resources Board) in urging EPA to end the multipliers earlier than MY2026.

Third, EPA's preferred alternative for MY2027 and beyond is not projected to provide the emissions benefits or to encourage technology-deployment levels equivalent to ACT. If EPA counts ACT compliance toward those weaker standards, it means the non-ACT States (including some joining this comment) can see technology deployment and public health protections at lower-than-average levels. If EPA sets a nationwide standard that it forecasts might result in 30 percent ZEVs nationally for vocational vehicle sales in MY2029, but ACT requires 40 percent in that same year,246 the actual ZEV sales in the non-ACT States can clearly fall well below the 30 percent nationwide forecast. EPA's approach clouds how much protection EPA anticipates its standards will provide in non-ACT States (where those standards are the only protection) and fails to adequately serve the markets EPA's standards are intended to cover. [EPA-HQ-OAR-2022-0985-1588-A1, p.37]

246 88 Fed. Reg. at 25,933.

If EPA intends to finalize the proposed change to the definition of "U.S.-directed production volume," it should, at a minimum, mitigate these adverse outcomes by:

- Making the definitional change effective no sooner than the model year for which EPA revises its Phase 2 standards or promulgates new ones—i.e., MY2027, if EPA revises those standards through this rulemaking; and
- Finalizing standards that produce protections equivalent to ACT. [EPA-HQ-OAR-2022-0985-1588-A1, p.37]

The first of these requests—delaying the effective date of the definitional change—comports with EPA's rationale for making the change at all. EPA says it is proposing this "revision [as] consistent with our intended approach of considering [national] production volumes in setting the stringency of the Phase 3 standards."247 That rationale ties the revision of the definition to EPA's standard-setting in this rulemaking, meaning the definition should be revised, if at all, when standards are newly set—in other words, in MY2027 (at the earliest), not MY2024. EPA also points to what it describes as "potential difficulties surrounding manufacturers' long-term compliance planning (due to the uncertainty surrounding whether additional states may adopt the California ACT program in the future)."248 EPA does not explain why any such "difficulties" are appropriate for EPA to address in advance, rather than for the State considering adoption of ACT in the future to address pursuant to its state law authority and the authority and requirements established in Section 177. EPA likewise does not explain how additional state adoptions would cause “difficulties” for manufacturer compliance with EPA’s standards if EPA’s standards remained as they are—based on, and complied with through, what can be achieved in non-ACT States. In any event, if EPA’s concern is about long-term planning for EPA’s standards, there is no reason for this change to take effect in MY2024-2026, as EPA’s standards for those years have been in place since 2016 and the current definition of “U.S.-directed production volume” has been in place even longer. [EPA-HQ-OAR-2022-0985-1588-A1, p.37]

247 Id. at 26,010.

248 Id.

The second request—finalizing standards more stringent than the preferred alternative—would ensure that EPA is not overstating the protectiveness of its own standards by effectively taking credit for protectiveness actually provided by States’ adoption of ACT. As shown above, standards that produce benefits and technological-deployment levels at least equivalent to ACT are both feasible and needed nationwide. If EPA finalizes standards that stringent, it would obviate both the lack of transparency and the lack of sufficient public protection that otherwise results from EPA disclosing only nationwide technology levels, all the while aware that those levels need not be achieved in the areas for which EPA itself has regulatory responsibility. [EPA-HQ-OAR-2022-0985-1588-A1, p.38]

In sum, our States and Cities do not see a need for EPA’s proposed definitional change and urge EPA to leave the existing definition in place. In any event, manufacturers should get no credit—and certainly not multiplied credit—for vehicles sold in ACT States in model years for which EPA is making no change to its standards. Any such credits would only undermine the existing Phase 2 standards about which EPA has made no findings of infeasibility. And, if EPA proceeds with its definitional change (in MY2027 or later), it should do so only if it also makes its own standards stringent enough to provide transparent and sufficient benefits to the non-ACT States—i.e., by recognizing that ACT-like levels of technological deployment and protection are feasible nationwide. [EPA-HQ-OAR-2022-0985-1588-A1, p.38]

Organization: Tesla, Inc. (Tesla)

Tesla Supports the Definition Change in ‘U.S. Directed Production Volume

‘As proposed, Tesla supports the agency’s revision of the definition of ‘U.S. directed production volumes’ to ensure nationwide production is included within the Phase 3 program starting in MY 2024.184 Compliance with ACT is based upon, inter alia, credits for ZEV sales in a set geographic market and not nation-wide fleet level emission standards. 185 Given these dramatically different compliance regimes, there is no ‘double counting’ in allowing vehicles sold in ACT states to be included in the national emissions standards. Ensuring inclusion of all nationwide sales in the compliance regime will be consistent with the EPA light-duty regime and provide manufacturers with a consistent context for long-term compliance planning. [EPA-HQ-OAR-2022-0985-1505-A1, p. 25]

Organization: Volvo Group

Definition of U.S.-directed Production Volume

Volvo Group agrees that the agency must codify new language as noted in Section III.A.1 of the NPRM revising the current definition of “U.S.-directed production volume” to include all vehicles produced for sales and delivery in the U.S., regardless of whether the vehicles are certified to federal, or state emissions standards. [EPA-HQ-OAR-2022-0985-1606-A1, p. 22]

EPA Summary and Response:

Summary:

A number of commenters supported all aspects of the proposed revision to the definition of U.S.-directed production volume (DTNA, Ford, MECA, Tesla, Volvo.) Tesla indicated that there would be no double-counting of credits given the significantly different compliance regimes under ACT (a sales mandate), and a federal fleet-average standard. DTNA maintains that since standards are based on a nationwide adoption rate, the revised definition is the only way standards might be ‘feasible and appropriate’. Ford added a cautionary note not to adjust the current approach for the Phase 2 engine standards.

Other commenters opposed the revised definition asserting that, combined with the multipliers available for advanced technology credits in that period, the new definition would erode the Phase 3 standard stringency as to result in no improvements beyond what would occur in the absence of the rule (CARB, CATF et al, Colorado DOT et al, ICCT, NESCAUM, State of California et al). The commenters argue that any emission reductions would be attributable to ZEV sales compelled by ACT and so would occur only in California and the section 177 states. The State of California et al. characterized any such credits as “windfall” since they would occur in the absence of federal regulatory standards. ICCT maintained further that the provision would create a disincentive for utilities, as well as for OEMs, to direct resources for ZEVs to non-ACT states. In addition to ACT, CARB also noted that they recently adopted the ACF regulation requiring fleets to purchase ZEVs at levels beyond what is reflected by the proposed Phase 3 standards and that “eroding the effective Phase 3 GHG stringency” by revising the U.S.-directed production volume definition would also erode the effectiveness of ACT and ACF by allowing vehicles subject to “eroded standards” to flow back into the state through interstate commerce or the used vehicle market.

CARB, ICCT, and NESCAUM quantified their concern of offsetting the Phase 3 standards. CARB and NESCAUM highlighted their concern over the BEV multiplier by projecting BEV sales volumes mandated by ACT in California and the section 177 states, and multiplying by 4.5 from MYs 2024-2026. In their calculation, they show that credits would be available to offset BEV penetration levels of 25% for vocational vehicles, and 9% for tractors (either exceeding or roughly the same as the potential compliance pathways projected at proposal for MY 2027).

Some of the commenters further suggested that these credits could even dilute the stringency of the Phase 2 standards, without justification, by making the revised definition effective in MY 2024 (CARB, CATF et al, Colorado DOT et al., State of California et al). CATF commented that “EPA’s desire for “consistent treatment of any production volumes certified to ACT” does not allow it to unmoor its regulatory change from its rationale: the need to match its definition to “the production on which the [Phase 3] standards are based,” Id. at 26009-10, which does not apply to EPA’s Phase 2 standards.

These commenters consequently urged that if EPA amends the U.S. Directed Production Volume definition as proposed, it either commence the change in MY 2027 rather than MY 2024 or that EPA must make a corresponding adjustment in stringency of the national standard. (CATF et al., ICCT, State of California et al. (2).) CATF et al. commented that the Phase 3 final rule should be as protective as ACT implemented nationwide, or EPA should not “conclude that it would be ‘challenging’ for manufacturers to comply without accounting for vehicles in California and states adopting California’s standards.” ICCT offered a second alternative to avoid diluting standard stringency: “If EPA chooses to adopt its proposed revision to the definition of ‘U.S. directed production volume,’ we suggest the agency determine the stringency of its standards based on a weighted average of ZEV sales required in ACT states and the additional forecasted ZEV sales in non-ACT states. In this way, EPA is aligning the stringency of its standards with the benefits of ZEV sales required under state laws, and it is reinforcing and securing the additional market potential for ZEV deployments in non-ACT states.”

In addition to reflecting these concerns regarding dilution of standard stringency, a number of these commenters challenged EPA’s rationale for the proposed changes. One of these commenters stated that if that rationale is to be consistent with the approach of setting standards considering national sales volumes of ZEVs (referring to 88 FR 26009/2), then the amended definition should commence in MY 2027 (State of California). Roush commented that including ACT-based sales in the national credit pool would give the misleading appearance of higher ZEV adoption rates, but that this was not an adequate justification for the amendment. Roush recommended that EPA “continue to maintain a separate credit pool that applies only to federal states and allow the ACT states to maintain their own pools”.

Several organizations commented with specific suggestions relating to the proposed regulatory language.

CARB suggested that EPA ensure that the regulatory language concerning U.S.-directed production volume for vehicles generating and using emission credits in 40 CFR 1037.705 is consistent with that for engines in 40 CFR 1036.705(c)(4). CARB stated that it appears U.S. EPA has proposed changing 40 CFR 1036.705(c)(4) for engines but not proposed the adoption of consistent language in 40 CFR 1037.705.

Cummins states that 40 CFR 1036.705(c)(4) should be reworded to align with 40 CFR 1036.801 and proposes the following: “Engines produced by a manufacturer for which the manufacturer has a reasonable assurance that sale was or will be made to ultimate purchasers in a state that has implemented emissions standards that are different than the emissions standards in this part.”

DTNA states that EPA’s proposed new 40 CFR 1036.705(c)(4) is needed in light of EPA’s proposal to broaden the definition of ‘U.S.-directed production volume’ (in both Parts 1036 and 1037) to allow GHG ABT credit calculations to encompass nationwide production volumes, as discussed in Section II.A. of these comments. DTNA requests that EPA make a needed clarification that engines are excluded from credit calculations based upon the states in which they are sold, rather than the standards to which they were certified. DTNA stated that since engines that are sold outside of California or Section 177 states would not be credit-eligible under these states' credit programs, they should not be excluded from the federal ABT credit program just because of their CARB certification.

DTNA proposes the following revision to the proposed new Section 1036.705(c)(4):

(c)(4) Engines ~~certified to state emission~~ produced by a manufacturer for sale in a state that has adopted emissions standards that are different than the emission standards in this part.

Ford expressed support for the proposed revision to 40 CFR 1037.705(c) and EPA's approach to continue separate credit ABT from engines certified to different state emission standards. Ford notes that both EPA and California do not include EVs in the MY 2027 and later engine CO_2 standards, so "the overlap in balancing Section 177 and non-Section 177 state ZEV sales does not exist as it does for EPA's proposed HD GHG rule and ACT."

Response:

As described in Section III.A.1 of the final rule preamble, we are finalizing a revised definition such that U.S.-directed production volume represents nationwide production, including any production in states that have adopted different standards. After considering comments, we are also finalizing the proposed effective date of MY 2024. In the final rule preamble, we include responses to comments expressing concerns that the new definition would erode the Phase 3 standard stringency and result in no improvements beyond what would occur in the absence of the rule (CARB, ICCT, NESCAUM). We also address comments urging that any definition change not occur until MY 2027 for concern over diluting the Phase 2 program (CARB, CATF et al, Colorado DOT et al., State of California et al).

We have considered ICCT's suggested alternative approach for setting the stringency of the Phase 3 standards. While we did not determine the stringency of the standards exactly as ICCT suggested, we did update our baseline in the FRM to model ZEV adoption in ACT states and non-ACT states separately as described in preamble Section V and RIA Chapter 4. This updated baseline was used in the analyses for the impacts of the final rule standards; for discussion of EPA's basis for concluding the final standards are feasible and appropriate, see preamble Section II.G. We note that our technology assessment in preamble Section II and RIA Chapter 2 is a national assessment of emission-reducing technologies and, as shown in preamble Section V, RIA Chapter 4, and RTC Section 2.4, we anticipate that the Phase 3 standards will lead to greater adoption of emission-reducing technologies (principally ZEVs) in non-ACT states. In Section III.A.1 of the final rule preamble, we note additional concerns with complexity and uncertainty in commenters' suggestions for different approaches to setting the Phase 3 standards while using the previous definition of U.S-directed production volume.

We disagree with Roush's recommendation that EPA maintain a federal credit pool and ACT states maintain their own pools, to the extent Roush is implying these pools should be maintained without any overlap in production volumes between the two pools. As we stated in final rule preamble III.A.1, even under the previous definition of US-directed production volume, manufacturers should be eligible to generate credits under the federal program for production and sales in excess of those required by ACT in states where ACT is applicable[804], as otherwise

[804] We note that commenter CATF appears to accept a similar principle, since it suggests that federal credits in states which have adopted ACT should be available once ACT requirements are surpassed. See the comment summary in the following Section 10.3.

the federal program could create a disincentive for such excess production and sales in such states. Indeed, as commenter Tesla suggests in a similar context, not recognizing such credits federally could also discourage states from adopting the ACT program. See section 10.3 below. It is also unclear how EPA could appropriately distinguish which credits should be treated as excess and part of compliance with the Phase 3 program, and the complexity involved in such a scheme raises verification concerns. These concerns are compounded given that the national standards reflect national production volumes, and the Roush comment would exclude not only ACT sales, but credit-generating sales as well, compounding the disconnect between federal standard setting and federal compliance.

We note further that, unlike a number of commenters, we do not regard an amended definition as a sharp change of approach. It in fact preserves the status quo that existed from the beginning of the HD GHG program through March 2023. That is, up until California enacted its ACT program and EPA granted a preemption waiver for that program, the regulatory definition of U.S. Directed Production Volume had no practical effect because the federal and California programs were identical. All credits were consequently generated nationwide. The change in definition thus preserves that status quo for the existing Phase 2 program, now that the federal and California programs differ, and carries that approach forward in promulgating the Phase 3 program (with corresponding consideration of the ACT program, as explained in final rule Preamble Sections II and V). Regarding the existing Phase 2 program in particular, we recognize that OEMs have brought existing compliance plans to our attention in public comments on this rule reflecting that status and, given the timing of the divergence of the federal and California programs and the proximity with existing compliance plans, EPA views preserving the status quo, whereby all credits are national, as appropriate.

We therefore proposed and are adopting the new definition of U.S.-directed production volume, in part, to avoid the risk that manufacturers may not be able to account for vehicle sales to Section 177 states in their credit calculations under a definition that excludes production volumes meeting different standards. See Section III.A.1 of the final rule preamble for additional reasons that further motivated our decision to revise the definition.

As described in Section III.C.2 of this final rule preamble, we proposed a new 40 CFR 1036.705(c)(4) as the location where we exclude engines certified to different state emission standards from being used to calculate emission credits in the HD engine program. After considering the comments from Cummins and DTNA, and noting that we never intended to discourage manufacturers from certifying a complete engine family to California-level standards, we are further revising the proposed provision to exclude engines if they are certified to different state standards and intended for sale in a state that adopted those different emission standards..[805] In comment, CARB suggested EPA use consistent regulatory language for vehicles and engines in 40 CFR 1037.705 and 1036.705, respectively. We decline CARB's request, noting that the vehicle and engine ABT programs intentionally differ under Phase 3 and we did not reopen the substance of the engine provisions in this rulemaking. The recently promulgated NOx standards for HD engines were developed excluding production volumes certified to different state NOx

[805] We are finalizing as proposed revisions that replace several instances of "U.S.-directed production volume" with a more general "production volume" where the text clearly is connected to ABT or add a more specific reference to the production volume specified in 40 CFR 1036.705(c). See revisions in 40 CFR 1036.150(d) and (k), 1036.725(b), and 1036.730(b).

standards and we are not revising the CO_2 standards for HD engines in the Phase 3 rule, and we also did not reopen any of these engine standards in this rulemaking. Thus, the final regulatory text retains the existing approach of excluding HD engine production volumes certified to different state standards for the credit calculations of 40 CFR 1036.705 to maintain the substance of the existing regulatory provisions. We note that we appreciate Ford's support of EPA continuing to exclude HD engines certified to different state standards from engine ABT calculations, and for recognizing that there is not the same need to account for the ACT regulation with respect to engines in the Phase 3 program.

10.3 ABT as a Compliance Flexibility

10.3.1 Credit Multipliers

Comments by Organizations

Organization: Advanced Engine Systems Institute (AESI)

AESI favors the termination of multipliers for PHEV and BEVs. These technologies are sufficiently incentivized, and the continued use of these multipliers may delay deployment of zero emission trucks. Multiplier incentives should continue for hydrogen fuel cell vehicles, which remain in the early deployment stage of that technology. EPA should also consider appropriate incentives for hydrogen combustion trucks; this would accelerate hydrogen infrastructure capacity and the deployment of fuel cell powered trucks. [EPA-HQ-OAR-2022-0985-1600-A1, p. 2]

Organization: American Council for an Energy-Efficient Economy (ACEEE)

EPA should ensure that credits from Phase 2 do not undermine the Phase 3 standards

Manufacturers' credits carried over from the Phase 2 program could substantially affect the efficacy of Phase 3. The proposal states: "In considering feasibility of the proposed standards, EPA also considers the impact of available compliance flexibilities on manufacturers' compliance options" (FR 26002). Yet EPA has not offered any projection of the credit balances to be carried over from Phase 2 to Phase 3, much less indicated how these credits might affect the levels of electrification achieved or the potential for backsliding on ICEV emissions under the proposed standards. [EPA-HQ-OAR-2022-0985-1560-A1, p. 17]

This concern is heightened by the proposal to leave in place the advanced technology multipliers for BEVs through 2026 (FR 26013). As discussed in ACEEE's comments on the 2022 heavy-duty NPRM, these very high multipliers together with sales mandates at the state level and market forces will generate sufficient credits to allow stagnation of average truck emissions levels in the early years of Phase 3, exactly when momentum must build toward rapid decarbonization of the commercial fleet.32 [EPA-HQ-OAR-2022-0985-1560-A1, p. 10]

32 https://www.aceee.org/sites/default/files/pdfs/aceee_hd_phase_2_ghg_comments.pdf

As an example of the ability of carryover credits to undermine the standards, consider the effects of maintaining the advanced technology multipliers in MY 2024-2026. Based on EPA's estimates of ZEV penetration in MY 2024-2026 in the DRIA (Tables 4-6), carryover of advanced technology multiplier credits would more than nullify EPA's proposed increase in stringency in the MY 2027 standards, which therefore would no longer serve to prompt the industry to start meaningful production of BEVs by MY 2027.33 [EPA-HQ-OAR-2022-0985-1560-A1, p. 17]

33 https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P10178RN.pdf

Organization: American Trucking Associations (ATA)

Drawing upon past experiences, fleets are concerned that manufacturers will limit diesel product availability to ensure they can comply with their GHG 3 target, which requires a certain percentage of ZEVs to be sold as part of the OEM's fleet mix. Under the GHG 2 regulation, fleets were obligated to purchase aero packages, specific tire configurations, and start-stop technology to ensure compliance with the EPA's technology package. This resulted in a restricted range of options when fleets placed vehicle orders. EPA's elimination of the Advanced Technology Credit for MY 2027, which provides a steeper incline for manufacturers to hit their new GHG 2027 proposed targets with ZEVs, will likely limit fleet technology choices. [EPA-HQ-OAR-2022-0985-1535-A1, p. 9]

E. Credits

1. Advanced Technology Credit (ATC) Multipliers for CO2 Emissions

Affected pages: 25934 and 26010-26013

The NPRM requests comment on the proposed elimination of the ATC multipliers for PHEVs and BEVs in MY 2027, one year earlier than provided in the existing Phase 2 GHG regulation. U.S. EPA is proposing to retain the existing ATC multiplier for FCEVs due to this technology still being in the early stage of development. [EPA-HQ-OAR-2022-0985-1591-A1, p.52]

During the development of federal Phase 2 GHG regulation in 2015, CARB staff advocated for larger credit multipliers compared to Phase 1 to encourage early development of technologies that were not yet commercially available, and to provide incentives to manufacturers who would like to produce HD ZEVs. U.S. EPA agreed and included ATC multipliers in the final Phase 2 GHG regulation. Federal Phase 2 GHG regulation offers credit multipliers for three types of advanced technologies: PHEVs with a multiplier of 3.5, BEVs with a multiplier of 4.5, and FCEVs with a multiplier of 5.5. While CARB staff appreciates that U.S. EPA took CARB's 2015 comments seriously and added the ATC multipliers, with the commercialization of HD ZEVs, CARB staff now believes the time has come to phase out these multipliers. [EPA-HQ-OAR-2022-0985-1591-A1, p.52]

CARB submitted more up-to-date comments in this regard to the U.S. EPA's March 2022 NPRM ''Control of Air Pollution from New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards"(HD2027 NPRM).185 CARB staff is now urging U.S. EPA to reduce and phase out the magnitude of the ATC multipliers over time as recommended in their third proposed HD2027 NPRM approach. Furthermore, CARB staff recommends the elimination of ATC multipliers for HD ZEVs that are certified under CARB's ACT regulation. CARB staff continues to urge U.S. EPA to reduce the magnitude of the ATC multipliers in MYs 2024 through 2026, as described in

U.S. EPA's third proposed HD2027 NPRM approach.186 [EPA-HQ-OAR-2022-0985-1591-A1, p.52]

185 Comment submitted by California Air Resources Board (CARB) Posted by the U.S. Environmental Protection Agency on May 15, 2022. https://www.regulations.gov/comment/EPA-HQ-OAR-2019-0055-1186

186 Fed. Reg. 17606-17607. March 28, 2022.

In addition to supporting U.S. EPA's proposal to eliminate ATC multipliers for PHEVs and BEVs for the MY 2027, CARB staff would also like to recommend elimination of ATC multipliers for FCEVs due to the HD ZEV sales mandate in California and Section 177 states.187 As a result of these states' sales mandates, there is no need for ATC multipliers for any HD ZEVs including FCEVs, and removing the multipliers would avoid the double counting of benefits from complying with a regulation while using the ATC multiplier. [EPA-HQ-OAR-2022-0985-1591-A1, pp.52-53]

187 States that have Adopted California's ACT regulation under Section 177 of the Federal CAA

4. It is suggested to clarify the basis for terminating the credit coefficient of electric vehicles on page 9 of Regulation 88 Federal Register (FR) 25926. [EPA-HQ-OAR-2022-0985-1658-A2, p.4]

88 Federal Register (FR) 25926 regulation proposes on page 9 to terminate the credit rating for electric vehicles one year in advance, while retaining the FCEV credit rating. It is recommended to treat all models equally and either terminate them all or postpone the cancellation for one year simultaneously. The current modifications are not conducive to encouraging relevant enterprises to continuously invest in and improve new technology research and development. [EPA-HQ-OAR-2022-0985-1658-A2, p.4]

Organization: Clean Air Task Force et al.

F. EPA Should Eliminate or Restrict the Availability of Advanced Credit Multipliers in 2025.

We support EPA's proposal to phase out advanced technology multipliers, which provide additional credits for PHEVs, BEVs, and FCEVs. 88 Fed. Reg. at 26010-13. We further request that EPA consider phasing those multipliers out in 2025 rather than 2026, or otherwise restricting their availability and use (e.g., by only providing them for long-haul sleeper cabs and other vehicles for which those technologies currently remain genuinely advanced, or eliminating them for vehicles necessary to satisfy ACT standards in California and states that have adopted those standards). [EPA-HQ-OAR-2022-0985-1640-A1, p. 76]

EPA adopted the credit multipliers as part of the Phase 2 program, "to create a meaningful incentive for those manufacturers considering developing and applying [the] qualifying advanced technologies into their vehicles." 88 Fed. Reg. 26010. They were based on a 2016 "cost analysis that compared the costs of these advanced technologies to the costs of other GHG-reducing technologies," and set at a level that, according to then-available data, "would make these advanced technologies more competitive" and "allow manufacturers to more easily generate a viable business case to develop these advanced technologies and bring them to market." Id. at

26,010-11. EPA recognized when it adopted them that the multipliers were appropriate only for "very advanced technology," and that "because they are so large" they should not "continue indefinitely." Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles–Phase 2, 81 Fed. Reg. 73478, 73497-98 (Oct. 25, 2016). [EPA-HQ-OAR-2022-0985-1640-A1, pp. 76 - 77]

EPA's current proposal recognizes that the circumstances that justified the multipliers have changed dramatically since the Phase 2 program was finalized. 88 Fed. Reg. at 26012 ("[W]e did not expect the level of innovation since observed, the IRA or BIL incentives, or that California would adopt the ACT rule at the same time these advanced technology multipliers were in effect."). Consequently "the multiplier credits could allow for backsliding of emission reductions expected from combustion vehicles for some manufacturers in the near term." Id. (describing "the generation of excess credits which could delay the introduction of technology in the near or mid-term"). EPA's modeling and standard-setting does not account for the use of those credits, 88 Fed. Reg. 26012, and EPA has proposed altering the ABT program (by redefining "U.S.-directed production volume") from MY 2024 onwards to make production volumes certified to ACT standards eligible for credits, id. at 26009. Those provisions, taken together, effectively and substantially dilute the nominal stringency of EPA's proposed standards—the effects of which are already overstated by virtue of EPA's underestimate of ZEV penetration in its baseline scenario. See Section III.B, above. [EPA-HQ-OAR-2022-0985-1640-A1, p. 77]

In response, EPA proposes to phase out the credit multipliers for BEVs and PHEVs one year early, in MY 2026. Id. That one-year change fails to respond adequately to the speed with which BEVs and PHEVs are reaching cost parity and entering the heavy-duty market. The ACT rule, and its adoption by other section 177 states, will result in significant BEV manufacture in 2025. Those programs require between 7 and 11 percent of heavy-duty vehicles (depending on class) certified and offered for sale to be ZEVs and have been adopted in California and seven other states. As EPA acknowledges, the multipliers generated in those states threaten to "create a large bank of credits with the potential to delay the real world benefits of [EPA's] proposed program." 88 Fed. Reg. at 26012. [EPA-HQ-OAR-2022-0985-1640-A1, p. 77]

The market analyses cited in EPA's proposal suggest that rapid technological development together with state rules and the IRA will render BEVs in many sectors cost-competitive and widely available before 2026. ERM determined that a variety of Class 5 and 6 ZEVs would reach purchase price parity with combustion vehicles by 2025, with many Class 8 vehicles at parity by 2026.347 ERM's analysis projects average Class 4-8 ZEV sales in 2025 between 8.8 percent (44,110 vehicles) and 20 percent (102,700 vehicles).348 ICCT's projections similarly indicate steep growth in BEV sales in the heavy-duty sector before 2025, especially buses and class 4 and 5 vehicles, with some sectors nearing 30 percent BEV penetration in 2025.349 Those projections sharply contrast with the projections that served as the basis for EPA's adoption of the multipliers. See Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium-and Heavy-Duty Engines and Vehicles – Phase 2; Regulatory Impact Analysis 2-194 (August 2016) (concluding that "fully electric vocational vehicles" will not "be widely commercially available" before 2027). They suggest that allowing BEVs and PHEVs to accrue credits through the proposed multipliers would significantly and unnecessarily reduce the effectiveness of EPA's standards. [EPA-HQ-OAR-2022-0985-1640-A1, pp. 77 - 78]

347 Robo & Seamonds, Technical Memo, at 4.

348 Id. at 9-11. ERM's analysis excludes PHEVs. Id. at 2.

349 Slowik et al., at 14-15, 24 (projecting that in some heavy-duty sectors ZEV shares near 30 percent, dominated by BEV).

The countervailing reason EPA offers for retaining the multipliers is an ostensible need to "continue to incentivize the development of BEVs," and concern regarding "impact on current manufacturer product plans." 88 Fed. Reg. at 26012. The IRA, however, provides more than adequate new incentives to secure any product plans that were premised on the availability of multipliers. The IRA provides substantial tax credits for battery manufacturers, and additional credits for heavy-duty vehicles. DRIA p.18-19 (Section 1.3.2.2). Indeed, the overall effect of the IRA is to eliminate "incremental cost (with the tax credit) of a BEV compared to a [combustion] vehicle," aside from supply equipment (which is itself subject to additional incentives under the IRA). Id. at 19-21. Manufacturers can, consequently, be safely expected to continue and expand their BEV-related product plans even without credits generated by the multipliers; the benefits those credits would have provided are more than offset by the addition of the IRA's tax credits. [EPA-HQ-OAR-2022-0985-1640-A1, p. 78]

By MY 2025, consequently, there will be little need for advanced technology multipliers, while retention of the multipliers risks major reductions in the real-world benefits of the standards in subsequent years. We therefore urge EPA to further reduce the availability and use of credit multipliers for BEVs and PHEVs. It should consider, for example: phasing out multipliers for BEVs and PHEVs in MY 2025; preventing vehicles certified in California and other states that have adopted ACT from receiving the credit multipliers ("Approach 1," described at 88 Fed. Reg. at 26011) unless they exceed the ACT sales requirements in those states; imposing a two-year limit on the use of any credits generated through advanced technology multipliers; allowing credits only for certain vehicles (e.g., long-haul sleeper cabs, see id. at 26013 (inviting comment on differentiating between weight classes)); or reducing the multipliers available for BEVs and PHEVs (e.g., from 4.5 and 3.5 to 2.5 and 1.5, respectively) in 2025. At a minimum, EPA should account for the use of the credits generated by the multipliers in setting its standards; their effects are likely to be too significant for EPA to reasonably ignore. [EPA-HQ-OAR-2022-0985-1640-A1, p. 78]

Organization: Clean Fuels Development Coalition et al.

Adding insult to regulatory injury, EPA has decided to remove its flexibilities all in one go. The agency previously doled out unlawful credit "multipliers" to electric vehicle manufacturers and that practice continues today under the rules currently in force. 88 Fed. Reg. 25,972 ("instead of including ZEV technologies in the technology packages for setting the Phase 2 standards, we provided advanced technology credit multipliers to help incentivize the development of ZEV technologies."). In other words, EPA's Phase II heavy-duty standards unilaterally created a regulatory cross subsidy program for electric vehicles by giving them double-credit for meeting the standards. This program results in higher prices for gasoline and diesel vehicles because manufacturers must generate or purchase the credits that EPA has created to meet standards. EPA has no authority to create such a subsidy program. It gets to set standards; it has no power to set standards beyond where it thinks they should be and then agree to relax those standards if a manufacturer gives money to the cause of electrification. "Pay our friends if you want more favorable standards" is, to put it mildly, not consistent with the rule of law. Nor is there any logical stopping point to which "friends" might be eligible for such cross-subsidies. [EPA-HQ-OAR-2022-0985-1585-A1, pp. 11 - 12]

The proposal does not acknowledge this lack of authority to create these subsidy programs, but, thankfully, it does propose to end the multiplier program. EPA must do so for both this rule and with respect to the rule currently in place— ideally through an interim final rule addressing that specific issue. [EPA-HQ-OAR-2022-0985-1585-A1, p. 12]

Organization: Daimler Truck North America LLC (DTNA)

EPA should not eliminate the Advanced Technology Credit multiplier for BEVs starting in MY 2026.

As discussed in Section I.B.2 of these comments, regulatory stability and adequate lead-time are key considerations in establishing and implementing new vehicle emission standards. These considerations are embedded in CAA Section 202 because they are necessary for manufacturers to be able to adequately plan their product portfolios, make wise investment decisions in new technology, and develop and validate successful, robust products. This is especially true as new regulatory requirements for certification and useful life have driven more onerous testing requirements and longer validation periods. [EPA-HQ-OAR-2022-0985-1555-A1, p. 74]

DTNA has supported EPA's GHG Phase 2 rules both during the original rulemaking process and during implementation. That support was conditioned on the totality of the Phase 2 program that EPA proposed, including compliance provisions like the Advanced Technology Credit multipliers. During the previous administration, DTNA, and the commercial vehicle industry as a whole, continued to support EPA's GHG Phase 2 rule—again, based upon belief in the importance of regulatory stability and that Agency rulemakings should be respected and not subject to a see-saw effect based on political considerations. [EPA-HQ-OAR-2022-0985-1555-A1, p. 74]

The purpose of Advanced Technology Credit multiplier is to incentivize manufacturers to develop commercial ZEVs to facilitate compliance with EPA's increasingly stringent emission standards. Now that many manufacturers have relied upon the availability of credit multipliers to plan their compliance strategies, exactly as EPA intended, the Agency is considering eliminating them out of concern that the incentives they provided to develop clean technologies may have led to the introduction of more ZEVs than EPA intended. [EPA-HQ-OAR-2022-0985-1555-A1, p. 74]

DTNA has invested considerable time in developing a product portfolio to meet GHG Phase 2 standards under the rules as originally promulgated, which include Advanced Technology Credit multipliers. The Company does not support removing these credits, especially now that we have defended preservation of the Phase 2 program and built compliance plans in reliance on the rules as written. [EPA-HQ-OAR-2022-0985-1555-A1, p. 74]

This is especially true for the alternate approaches EPA discusses in the Proposed Rule, which would phase out the Advanced Technology Credit multipliers even earlier—potentially as early as MY 2024. Changing these rules now would undermine manufacturer reliance interests on the availability of these credits in planning their compliance strategies, as well as the regulatory stability on which capital-intensive long lead-cycle businesses like DTNA depend. [EPA-HQ-OAR-2022-0985-1555-A1, p. 74]

EPA Request for Comment, Request #7: We are proposing in this action to eliminate the advanced technology vehicle credit multipliers for BEVs and PHEVs for MY 2027, one year before these credit multipliers were set to end under the existing HD GHG Phase 2 program. We propose retaining the existing FCEV credit multipliers, because the HD market for this technology continues to be in the early stage of development. We request comment on this approach.

DTNA Response: DTNA does not support the elimination of advanced technology vehicle credit multipliers for BEVs and PHEVs for MY 2027. The availability of these credit multipliers are an integral part of the Phase 2 greenhouse gas (GHG) regulatory program, and manufacturers have relied upon them to build their product and compliance strategies. DTNA addresses this issue in Section III.B.1 of these comments.[EPA-HQ-OAR-2022-0985-1555-A1, p. 159]

EPA Request for Comment, Request #65: We request comment on our proposed MY 2026 phaseout date or whether we should consider other approaches to account for ACT or incentive programs.

- DTNA Response: DTNA discusses this issue in detail in Section III.B.1. of these comments. EPA should not eliminate the Advanced Technology Credit multiplier for BEVs starting in MY 2026, as this would undermine manufacturer reliance interests on the availability of these credits in planning their compliance strategies, as well as the regulatory stability on which capital-intensive long lead-cycle businesses depend. [EPA-HQ-OAR-2022-0985-1555-A1, p. 170]

Organization: Eaton

While no ZEV penetration was assumed in Phase 2, the reality is that the market demands and provides ZEV solutions. Furthermore, the financial incentives of the bipartisan Inflation Reduction Act and many state programs like California HVIP, do provide additional support to these technologies. In fact, the most likely barrier to ZEV adoption is the lack of charging and Hydrogen infrastructure that is not within the purview of this NPRM. In the current situation, ZEV and PHEV multipliers are no longer a driving force for new technology, and with increasing ZEV adoption, they risk distorting the market and thus reduce the technology-neutral character of the regulations. We support the EPA position in sun-setting multipliers as outlined in the recent low NOx rule and recommend the same approach for Phase 3. [EPA-HQ-OAR-2022-0985-1556-A1, p. 6]

Organization: Environmental Defense Fund (EDF)

b) EPA should adopt a protective framework that helps to minimize any potentially adverse climate and health impacts associated with hydrogen usage.

Under the proposal's current framework, hydrogen powered vehicles are incentivized both through credit multipliers and their treatment as having zero-emissions for compliance with the standards. These incentives are misguided given that, as shown above, hydrogen powered vehicles' emissions impacts are worse than diesel vehicles using current, dominant forms of hydrogen production and, in many certain scenarios, using projected future grid electricity. We encourage EPA to strengthen its standards by removing blanket incentives and adopting protections that do not credit or incentivize hydrogen fueled vehicles as having zero-emissions when that is not the case. Instead, EPA should tailor its standards to encourage use of low-GHG hydrogen.218 We offer a few two specific suggestions related to these issues below. [EPA-HQ-OAR-2022-0985-1644-A1, 83]

218 In their assessment of low-GHG hydrogen, EPA should be consistent with standards set in the IRA production tax credit for clean hydrogen as well as other EPA standards such as the recently proposed Greenhouse Gas Standards and Guidelines for Fossil Fuel-Fired Power Plants.

Removing credit multipliers. EPA should remove credit multipliers for hydrogen fueled vehicles — which, as proposed, provide greater incentives for the production of FCEVs than for lower-emitting BEVs. EPA proposes to retain its existing Advanced Technology Credit Multipliers for FCEVs (which are higher than the multipliers for BEVs) through 2027, even though it will remove these same incentives for BEVs in 2026.219 Given that the emissions benefits of hydrogen powered vehicles vary widely — and are, in all cases, worse than that of BEVs — these incentives are counterproductive. EPA should phase out these credit multipliers for FCEVs by 2026, just as they have for BEVs. If EPA is going to maintain these incentives, it should do so only for manufacturers that can demonstrate their vehicles are producing real world emissions benefits by certifying they are running on green hydrogen.220 As the above analysis demonstrates, EPA must not allow any credits for vehicles fueled with hydrogen produced using SMR or grid electrolysis – both of which produce emissions outcomes worse than diesel vehicles in the 2027 timeframe. [EPA-HQ-OAR-2022-0985-1644-A1, 83-84]

219 88 Fed. Reg. 26012.

220 In passing the IRA, Congress recently recognized the importance of an approach to hydrogen powered vehicles that incentivizes clean hydrogen production through its tax credits for clean hydrogen production, which increase with lower lifecycle emissions. 26 U.S.C. §45V.

Apply a Utility / Correction Factor to Vehicles Fueled with Hydrogen. We also urge EPA to account for the wide variation in hydrogen fueled vehicles' emissions benefits in measuring their emissions for compliance with the standards. EPA proposes to count hydrogen powered vehicles as having zero emissions, similar to how it has treated BEVs in the past. However, EPA's prior justifications for treating BEVs this way do not apply to hydrogen powered vehicles.221 Not only do hydrogen powered vehicles not provide clear emissions benefits absent further controls on where the hydrogen they operate on comes from, but due to potential leakage of hydrogen from the vehicles and criteria pollutant emissions from H2ICEVs, they do have vehicle and tailpipe emissions that must be accounted for. Additionally, EPA has previously noted the existence of other emissions reduction programs or controls related to upstream emissions as justifying its focus on tailpipe emissions.222 However, emissions from hydrogen production are currently unregulated, making it especially important that EPA adopt an approach that considers and reflects how hydrogen fueled vehicles are powered and operated. [EPA-HQ-OAR-2022-0985-1644-A1, 84-85]

221 EPA's decision to treat BEVs as having zero-emissions was based on a careful consideration of the emissions benefits associated with BEVs because the original purpose of this approach was to "recognize the benefits of . . . dedicated alternative-fueled vehicles." 76 Fed. Reg. 57123. Because of the emissions issues associated with hydrogen powered vehicles, including the fact that they likely do have tailpipe emission through hydrogen leakage, this same justification cannot justify their parallel treatment.

Additionally, EPA has previously considered it important to its focus on tailpipe emissions that the upstream emissions are regulated by other rules.

222 76 Fed. Reg. 51705 (Aug. 27, 2012) ("There is no good reason to consider [the lifecycle emission of different types of fuels] here, especially where there already is a separate fuel based program, the RFS program, that is directly aimed at achieving the result POP Diesel seeks--a fuel program that achieves a reduction in lifecycle GHG emissions associated with the diesel fuel used by motor vehicles, through a mandate to use certain renewable diesel fuels.).

In this regard, EPA should not treat hydrogen fueled vehicles like BEVs but instead similarly to how the agency treats PHEVs,223 where EPA recognizes that sometimes PHEVs operate on battery power with real emissions benefits and other times the vehicle is powered by its ICE engine with emissions profiles more similar to fossil-powered vehicles. 224 For hydrogen fueled vehicles, EPA could adopt an approach to calculating their GHG emissions that includes a conservative low- GHG utility factor representing emissions attributable to hydrogen fueled vehicles assuming those vehicles are fueled using average, current forms of hydrogen production. For instance, a current factor would need to reflect the fact that most hydrogen is produced using SMR and does not result in real-world emission benefits when compared to diesel vehicles.225 [EPA-HQ-OAR-2022-0985-1644-A1, 85]

223 See 40 CFR § 600.116-12.

224 88 Fed. Reg. 29253 (May 5, 2023) ("Because the tailpipe CO2 produced from PHEVs varies significantly between [charge depleting] and [charge sustaining] operation, both the charge depleting range and the utility factor curves play an important role in determining the magnitude of CO2 that is calculated for compliance.").

225 This utility factor should also differ for H2ICEs, and FCEVS, which have differing emissions benefits.

EPA could, of course, update this factor over time as the relative mix of hydrogen production sources changes. Moreover, as with the credit multipliers, EPA should incentivize manufacturers who can demonstrate their hydrogen fueled vehicles are driving actual emissions benefits. It can do so by allowing manufacturers to adjust the low-GHG utility factor applied to their vehicles where they can show they are resulting in real world emissions benefits through emissions testing or certifying the vehicles run exclusively on low-GHG hydrogen. [EPA-HQ-OAR-2022-0985-1644-A1, 85]

We emphasize the importance of EPA adopting these protections and guardrails now, given the potential near term proliferation of hydrogen fuels and the absence of regulatory structures to ensure any hydrogen produced is done so in a way that minimize climate and health harming pollution. At the same time, we urge EPA to adopt future leakage standards related hydrogen fueled vehicles and explore and pursue all other regulatory authorities to reduce and eliminate harmful pollution associated with hydrogen production and use. [EPA-HQ-OAR-2022-0985-1644-A1, 86]

Organization: Fermata Energy

EPA should add in the final regulation a small multiplier credit for vehicles that have on-board AC bidirectional chargers or are integrated with multiple DC off-board chargers. [EPA-HQ-OAR-2022-0985-1662-A2, p.8]

The promise of bidirectional charging (AC or DC) to address air pollution, GHG emissions, and challenges to the electric grid is very significant with BEVs and PHEVS in medium- and heavy-duty vehicles. While we understand the desire by the EPA to simplify the regulation and reduce the use of bonus multiplier credits, we believe a small bonus credit in this regulation is justified and needed to unlock this technology because of the large emissions reduction benefits and other grid services enabled by bidirectional charging as described in Section II above. The EPA has a long history of providing multiplier credits to emerging technology and we strongly encourage the EPA to adopt in the final regulation a modest multiplier credit for class 2b-8 vehicles that appropriately phases out over time. This approach will not only will help enable the emerging V2G industry, but will also help consumers achieve lower operating costs,16 reduce GHG and traditional pollutants from fossil fueled power plants by shifting electricity use to renewable energy in the cleanest hours of the day, and reduce the need for high-emitting peaker plants. V2G also provides a zero-emission, lower cost alternative to high-emitting portable back-up generators, and saves utility ratepayers money with a low-cost resource compared to battery stationary storage. [EPA-HQ-OAR-2022-0985-1662-A2, p.8]

16 See footnote 11

Organization: International Council on Clean Transportation (ICCT)

ICCT supports the proposal to eliminate advanced technology credit multipliers. Historically, these multipliers were appropriate to provide manufacturers an incentive to invest in the research and development of battery electric and fuel-cell electric vehicles that had yet to be commercialized. Since the adoption of the Phase 2 standards, these technologies have entered the commercial market on a broad scale and, beginning in model year 2024, nine states will require manufacturers to sell them. We do not think multipliers have any further role to play in this rule. [EPA-HQ-OAR-2022-0985-1553-A1, p. 5]

Organization: International Union, United Automobile, Aerospace and Agricultural Implement Workers of America (UAW)

We are also concerned that the proposal plans to end the HD GHG Phase II credit multipliers for BEVs and PHEVs. Electrification is still in its infancy in the medium- and heavy-duty sectors. Credit multipliers are an important tool to provide industry with a pathway to compliance while rewarding the introduction of advanced technologies. There is no one-size-fits-all approach to improved efficiency and each manufacturer faces a unique set of challenges due to differences in fleet make-up. Overcompliance and credit multipliers give the industry the ability to deploy cleaner vehicles in segments and applications where it is technically and economically feasible, while continuing to meet customer demands. Where credits are phased down, EPA should consider options for the credit system that incentive domestic manufacturing on advanced technology vehicles and guard against manufacturers importing their way to compliance, particularly where vehicles, batteries, and other key components are built without robust environmental regulations. [EPA-HQ-OAR-2022-0985-1596-A1, p. 5]

Organization: Manufacturers of Emission Controls Association (MECA)

Analyses by ICCT and researchers at Carnegie Mellon have shown that extended use of super credits in the light-duty sector has resulted in the unintended consequence of increased emissions from the non-ZEV fleet as it is allowed to emit more under a fleet average regulatory structure that includes averaging, banking and trading provisions [17, 18]. [EPA-HQ-OAR-2022-0985-1521-A1, p. 9]

> [17]. A. Jenn, I. L. Azevedo and J. J. Michalek, “Alternative-fuel-vehicle policy interactions increase U.S. greenhouse gas emissions,” Transportation Research Part A: Policy and Practice, vol. 124, pp. 396-407, 2019.
>
> [18]. R. Minjares and J. Hannon, “Adapting US heavy-duty vehicle emission standards to support a zero-emission commercial truck and bus fleet,” 2022.

Given the considerable incentives created by the Inflation Reduction Act (IRA) and Bipartisan Infrastructure Law (BIL) and other federal and state programs supporting the production, sale and operation of heavy-duty zero tailpipe emitting vehicles, MECA agrees that Advanced Technology Multipliers for PHEVs, BEVs and FCEVs are no longer needed beyond MY 2027. Similar to the light-duty sector, an over-incentivized credit scheme for heavy-duty ZEVs is likely to result in market distortions that will reduce the broader deployment of electric and other advanced efficient powertrains and thus decrease the benefits anticipated by the standards. [EPA-HQ-OAR-2022-0985-1521-A1, p. 10]

MECA also supports the need for the inclusion of lifecycle analysis under the Phase 3 program to determine appropriate levels of crediting for zero emissions vehicles. To date, the assigning of zero CO2 emissions results in an arbitrarily large number of credits which impedes the adoption of all advanced CO2 reduction technologies. For this reason, MECA supports the accelerated retirement of advanced technology multiplier credits generated under the Phase 2 program by reducing their five-year lifetime. [EPA-HQ-OAR-2022-0985-1521-A1, p. 10]

Organization: MEMA

Advanced Technology Multipliers

Considering advanced technology multipliers, the agency has proposed to retain the technology multiplier for FCEV “because it has been slower to develop in the HD market.” [EPA-HQ-OAR-2022-0985-1570-A1, p. 14]

MEMA urges that the same consideration be made for H2ICE technology and that it be included along with FCEV in the credit multiplier calculation. [EPA-HQ-OAR-2022-0985-1570-A1, p. 15]

Organization: National Association of Clean Air Agencies (NACAA)

Eliminate Advanced Technology Multipliers After MY 2026

In its Phase 2 heavy-duty GHG rule, adopted in 2016, EPA provided Advanced Technology Multipliers through MY 2027 for battery electric vehicles (BEVs), plug-in hybrid electric vehicles (PHEVs) and fuel cell electric vehicles (FCEVs) to incentivize development and sales of these technologies. Since that time, the feasibility, availability and cost-competitiveness of the technologies EPA intended to incubate have far outpaced EPA’s expectations. Accordingly, the agency proposes to eliminate the Advanced Technology Multipliers for BEVs and PHEVs after MY 2026 and to retain the 5.5 multiplier for FCEVs through MY 2027. NACAA supports EPA’s proposal to end the BEV and PHEV Advanced Technology Multipliers with MY 2026 and, further, recommends that the agency also end the multiplier for FCEVs with MY 2026. Given the multiple commercialized heavy-duty fuel cell vehicles an Advanced Technology Multiplier beyond MY 2026 is not necessary and retaining one through MY 2027 could result in the significant generation of credits and an erosion of the CO2 emission standards. [EPA-HQ-OAR-2022-0985-1499-A1, p. 9]

Organization: National Parks Conservation Association (NPCA)

Lastly, NPCA wishes to express support for EPA's proposal to phase out advanced technology multipliers for various hybrid or ZEV models, and request that EPA expedite such a phase out to occur in 2025 instead of the proposed 2026 date. [EPA-HQ-OAR-2022-0985-1613-A1, p. 4]

Organization: Navistar, Inc.

Navistar is opposed to EPA's proposal to eliminate the credit multipliers under the Phase 2 program for MY 2027. In the proposed rule, EPA seeks to end credit multipliers for vehicles incorporating battery-electric technologies (BEVs) one year earlier than provided in the existing heavy-duty vehicle GHG Phase 2 program (i.e., no credit multipliers for BEVs in MY 2027 and later). Changes to the Phase 2 credit multiplier are unwarranted. As discussed above, multipliers are still very much necessary for the development and integration of new and higher-cost technologies into existing and new markets. Navistar has relied on the certainty of the GHG standards in engineering and manufacturing ZEV trucks. A transition of the trucking industry to ZEVs requires regulatory consistency and certainty, and well-designed incentives. EPA's proposal to change the Phase 2 GHG standards at this time undermine these important considerations. [EPA-HQ-OAR-2022-0985-1527-A1, p. 6]

Organization: Northeast States for Coordinated Air Use Management (NESCAUM) and the Ozone Transport Commission (OTC)

Advanced Technology Multipliers

We agree with EPA's proposal to remove the BEV advanced technology multiplier in MY 2026. The multiplier, if left in place, could result in significant production of credits and a dilution of the stringency of the GHG standards. We encourage EPA to remove the FCEV multiplier in 2026 as well. [EPA-HQ-OAR-2022-0985-1562-A1, p. 14]

Organization: Odyne Systems LLC

Extend or do not change the date for the PHEV credit multiplier rather than reduce it.

The EPA is considering reducing the credit multiplier timeframe for PHEVs and BEVs to 2027 rather than 2028. Odyne recommends extending the time frame or keeping it the same because, while there is much discussion about PHEVs and BEVs, very few are built. Credit multipliers will provide needed incentives for manufacturers to quickly sell PHEVs and BEVs and benefit from their investments. [EPA-HQ-OAR-2022-0985-1623-A1, p. 4]

Organization: PACCAR, Inc.

A. EPA Should Reconsider Its Proposed Credit Multiplier Changes

EPA's proposed changes to the battery electric and hybrid credit multipliers undermine the regulatory certainty on which OEMs have reasonably relied. EPA's HD GHG Phase 2 rulemaking included MY2027 advanced technology credit multipliers and successfully led OEMs to develop zero emissions powertrains earlier than they likely would have without the credit multipliers. Since then, OEMs have designed their product portfolios and compliance plans accordingly, including by increasing ZEVs because of the credit multipliers. The NPRM proposes to eliminate the battery electric and hybrid credit multipliers for MY2027 with less than four years lead-time for manufacturers to adjust their compliance plans. PACCAR therefore respectfully requests that EPA not eliminate the battery electric and hybrid credit multipliers for MY2027. [EPA-HQ-OAR-2022-0985-1607-A1, p. 9]

PACCAR also urges EPA to revise § 1037.150(p) to extend the fuel cell multiplier through at least MY2030. Doing so would incentivize further fuel cell technology investment, which remains immature. [EPA-HQ-OAR-2022-0985-1607-A1, p. 9]

EPA should also modify the advanced technology credit to add a hydrogen internal compression engine (ICE) credit multiplier through MY2030, which would incentivize hydrogen ICE technology investment. Increased use of hydrogen ICE powertrains would spur hydrogen refueling infrastructure development, which would benefit hydrogen ICE and fuel cell trucks because both vehicles rely on the same refueling infrastructure. The current lack of hydrogen refueling infrastructure is a significant impediment to both hydrogen ICE and fuel cell electric vehicle adoption and the credit multipliers would encourage growth. [EPA-HQ-OAR-2022-0985-1607-A1, p. 9]

Organization: Southern Environmental Law Center (SELC)

We therefore support EPA's proposal for stronger GHG emission standards for model year 2027 heavy-duty vehicles and the discontinuance of credit multipliers for BEVs and PHEVs after model year 2026. Any compliance flexibilities included in the standards must not unnecessarily dilute the stringency of the standards. BEVs and PHEVs are no longer "new advanced technologies" that need to be incentivized—especially considering the level of innovation and deployment of ZEV technology that has occurred since the Phase 2 rulemaking. As EPA notes, "the multiplier credits could allow for backsliding of emissions reductions expected from [internal combustion engine] vehicles for some manufacturers in the near term . . . as sales of advanced technology vehicles which can generate the incentive credit continue to increase."48 Getting ZEVs on the road should be a priority, but efforts to incentivize their deployment cannot erode improvements in internal combustion engine vehicles. [EPA-HQ-OAR-2022-0985-1554-A1, p. 6]

48 Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles—Phase 3, 88 Fed. Reg. 25926, 26012 (Apr. 27, 2023).

Organization: Strong Plug-in Hybrid Electric Vehicle (PHEV) Coalition

EPA should add a small bonus credit (multiplier) for vehicles that have on-board AC bidirectional chargers or are integrated with multiple DC off-board chargers, as this will bring overall cost savings, help the grid and send a strong signal to accelerate this needed technology. [EPA-HQ-OAR-2022-0985-1647-A2, p. 2]

EPA should consider providing small bonus credits (multipliers) in 2027 to 2030 for several advanced technologies including PHEVs with a long all-electric range and not just for fuel cell EVs as these technologies need extra lead time to develop given offerings for the heavy-duty market. As we describe below, having multiple technologies helps in reaching many hard-to-reach customer segments. [EPA-HQ-OAR-2022-0985-1647-A2, p. 2]

2) EPA should consider adding a small bonus for vehicles that have on-board AC bidirectional chargers or are integrated with multiple DC off-board chargers. Alternatively, at minimum, EPA should conduct an analysis on how EPA can advance bi-directional charging in the future. Justification: The promise of bi-directional charging (AC or DC) to address air pollution, GHG and electric grid issues is very significant with BEVs and PHEVS in light-, medium- and heavy-duty vehicles, or off-road equipment. For example, a recent May 2022 presentation by the World Resources Institute using Bloomberg NEF and Energy Information Administration data found the power capacity in 2030 for EVs to be 10 to 20 times more than the 2030 power capacity of stationary storage.6 While these numbers are for light-duty EVs, electrified trucks can also contribute and some fleets (e.g., school buses, municipal trucks, trucks in one-shift operations) are expected to be early adopters. EPA can and should play a role in helping to unlock this potential.

a. For example, the internal combustion engine in a PHEV has a much lower emission signature than a stand-alone, backup generator.

b. Bidirectional charging, like battery stationary energy storage, can reduce GHG and traditional pollutants from fossil fueled power plants by shifting electricity use to renewable energy in the cleanest hours of the day and reducing the need for high-emitting plants (such as traditional peaker power plants).

c. Bidirectional charging can also provide many types of grid services including ancillary services, providing resource adequacy, and helping with the evening transition from renewables to other generation resources. Because the batteries are already paid for by the truck owners, utilities can gain a low-cost resource compared to battery stationary storage.

d. The potential value is significant and can contribute to lower operating costs for BEVs and PHEVs.7 [EPA-HQ-OAR-2022-0985-1647-A2, p. 5]

6 See slide 5 at https://www.slideshare.net/emmaline742/building-resiliency-with-v2g-in-residential-homes-bycamron-gorguinpour

7 California Energy Commission, March 2019, Distribution System Constrained Vehicle-to-Grid Services for Improved Grid Stability and Reliability, Figure 42

While we understand the desire by EPA to simplify the regulation and reduce the use of bonus multiplier credits, we believe a small bonus credit in this regulation is justified and needed to unlock this technology because of the large emission reduction benefits and other benefits enabled by bidirectional charging. [EPA-HQ-OAR-2022-0985-1647-A2, p. 6]

8) However, the above incentive is not enough. Regarding EPA's question of whether to provide a longer period of credit multipliers (bonus credits) for fuel cell EVs, our coalition recommends a modest multiplier be provided in the final rule not just for FCEVs but also for PHEVs with a long all-electric range and for MY 2027 to 2030. These technologies need extra lead time to develop given offerings for the heavy-duty market, and it is in EPA's interest to have multiple technologies that provide customer choice and help EPA in reaching many hard-to- reach customer segments. [EPA-HQ-OAR-2022-0985-1647-A2, p. 7]

Organization: Tesla, Inc. (Tesla)

Tesla Supports Elimination and Rapid Phasedown of All GHG Credit Multipliers

Even though it is a scaling heavy-duty BEV manufacturer, Tesla supports eliminating advanced technology multipliers to ensure overall program integrity and supports firmly establishing a one-for-one credit ratio that is a more rational and transparent compliance mechanism and creates actual BEV vehicle deployment, thereby enabling deeper emission reduction targets. [EPA-HQ-OAR-2022-0985-1505-A1, p. 24]

Tesla also agrees with the agency that providing credit multipliers can unnecessarily dampen actual deployment of BEVs and lead to backsliding of emission reductions.178 This is true regardless of the technology to which a multiplier may be attached and is not applicable just to BEVs. Accordingly, Tesla supports an elimination on credit multipliers for all heavy-duty ZEVs and encourages EPA to tailor Approach 3 to reflect a rapid phasedown of multiplier credits, including eliminating the credit multipliers after MY 2026.[EPA-HQ-OAR-2022-0985-1505-A1, p. 24]

178 88 Fed. Reg. at 26012.

Furthermore, each of the other proposed options for reforming the existing credit multipliers presented by EPA all have substantial weaknesses. Approach 1 would provide multipliers only to those BEV sales in non-ACT states.179 This creates a disincentive for states to adopt ACT and will reduce adoption of a regulatory framework that would yield greater GHG reductions from the heavy-duty sector. [EPA-HQ-OAR-2022-0985-1505-A1, p. 24]

179 88 Fed. Reg. at26011-12.

Similarly, Approach 2 allowing for the use of multipliers and then capping the credit use, is equally flawed. Under this architecture, manufacturers will likely deploy ZEVs to maximize generation of multiplier credits up to the cap limit but move no further.180 In the E.U, a similar 'Super Credit' multiplier exists for light-duty vehicles which emit <50g CO_2/km, which can be earned from 2020-2022 inclusive. In the first year of the Super Credit eligibility, eight out of ten manufacturers reached the cap.181 This was achieved by aggressive sales practices (pricing and pre-registrations) to capture the maximum value of the credits up to the cap, and then halting further sales once the cap was reached. [EPA-HQ-OAR-2022-0985-1505-A1, pp. 24-25]

180 Id.

181 ICCT, CO2 emissions from new passenger cars in Europe: Car manufacturers' performance in 2020 (August 2021) at 4, Table 1. available at https://theicct.org/sites/default/files/publications/eu-co2-pvs-performance-2020-aug21_0.pdf

Finally, as a general matter of policy development, in setting an emissions performance standard the regulation should be agnostic with respect to what technology is used to meet, and ideally outperform, the standard. Allowing the continuation of credit multipliers for FCEVs in the proposed regulation's crediting provisions will promote the inefficient investment into a technology with little near-term ability to address the critical GHG emissions problem. As one recent study concluded, hydrogen fuel cell trucks are unlikely to be commercially viable and the urgency of the climate crises should compel a focus on BEV deployment.182 EPA should ensure this focus and eliminate the credit multipliers for all ZEVs. [EPA-HQ-OAR-2022-0985-1505-A1, p. 25]

182 Plotz, Nature Electronics, Hydrogen technology is unlikely to play a major role in sustainable road transport (Jan. 31, 2022) available at https://www.nature.com/articles/s41928-021-00706-6

Organization: Truck and Engine Manufacturers Association (EMA)

FCEV Credit Multiplier – The Phase 2 regulation provides credit multipliers for vehicles incorporating BEV and FCEV technologies. For Phase 3, EPA proposes to eliminate the credit multiplier for BEVs because the technology is now in production for most OEMs, so the extra incentive is no longer critical to bring the technology to market more quickly. EPA is proposing to maintain the credit multiplier for FCEVs. EMA supports EPA's proposal to continue to provide incentives for fuel-cell technology vehicles to encourage the quicker development and deployment of this still-nascent zero-emission technology. [EPA-HQ-OAR-2022-0985-2668-A1, p. 49]

Organization: Truck Renting and Leasing Association (TRALA)

Carbon Offset Credit Periods Should be Extended

TRALA recommends OEM multiplier credits for BEV sales remain in effect through 2030 for Classes 2-7 and for Class 8 vehicles through 2035. If ZEV technologies accelerate at the levels envisioned by the agency, multiplier credits will not be utilized or needed by OEMs. But if lack of capable infrastructure delays mainstream adoption of ZEV technologies, credit multipliers will offer a needed path for OEMs to maintain compliance while also incentivizing further private investment in infrastructure. With respect to Class 8 vehicles, FCEVs will likely continue to lag years behind their BEV counterparts, so applying the FCEV multiplier to hydrogen ICE vehicles (H2-ICE) will enable ready H2-ICE technology to develop infrastructure necessary to deploy FCEVs. [EPA-HQ-OAR-2022-0985-1577-A1, p. 22]

Organization: Volvo Group

Expiring BEV and Plug-in Hybrid Electric Vehicle (PHEV) Advanced Technology credit multiplier in 2026

The Volvo Group is still concerned that the conditions and enablers within the market will not be available at levels allowing any finalized standards to be achieved across all averaging sets. Thus, we suggest the agency set specific MY2026 total industry EV sales penetration thresholds within an averaging set as a criterion for reducing or removing the multiplier at the end of the 2026 Model Year. For example, the EPA could set a threshold ratio comparing actual model year 2026 EV sales percentages within an averaging set to the MY 2027 adoption rate used to set stringency. If the decided ratio were met, the multiplier would expire as proposed. [EPA-HQ-OAR-2022-0985-1606-A1, p. 22]

The agency could also set a range for this ratio. If the minimum level were met, the multiplier would be reduced, ramping down until meeting the maximum threshold, where it would expire as proposed. A method such as this would help to minimize potential risk in the early years of the transition, while also minimizing, or potentially eliminating concern over credit windfalls, as any credit multiplier would be dependent on the market readiness for EVs within a specific averaging set, and not applied to all equally. [EPA-HQ-OAR-2022-0985-1606-A1, p. 22]

Organization: Zero Emission Transportation Association (ZETA)

ZETA supports the proposed accelerated phaseout of HDEV credit multipliers by MY 2027. HDEV technology has progressed rapidly since the Phase 2 GHG emissions standards finalized in 2016. HDEVs will soon penetrate the market to a much greater degree than was previously anticipated. EPA has recognized that multipliers present a tradeoff between driving emissions reductions and incentivizing new technology. Based on the technology available today, multipliers are no longer required to incentivize HDEV technology investments, and a more stringent GHG standard would most effectively drive HDEV adoption and, in turn, emissions reductions. While we believe it is appropriate to phase out credit multipliers for HDEVs, we recognize that other zero-emission technologies, such as hydrogen fuel cell vehicles, are in a different stage of development and deployment. While we are not recommending phasing out credit multipliers for these technologies, we request EPA articulate clear guidelines for when it would be appropriate to do so. [EPA-HQ-OAR-2022-0985-2429-A1, p. 16]

EPA Summary and Response:

Summary:

Commenters' support for EPA's proposed approach for phasing out advanced technology credit multipliers ("multipliers") varied. As noted in this summary, some commenters supported EPA's proposal to phase out PHEV and BEV multipliers after MY 2026 and retain the FCEV multiplier through MY 2027. Others commented that EPA should retain the multipliers through MY 2027 as finalized in the Phase 2 program. Some commenters requested EPA eliminate some or all multipliers before 2026, while others recommended EPA extend the availability of some or all multipliers beyond MY 2027. A few commenters offered other suggestions for credit multipliers.

Commenters supporting EPA's proposed phase out of multipliers

AESI commented in support for eliminating PHEV and BEV multipliers and continuing fuel cell multipliers. Additionally, AESI recommended EPA consider incentives for H2 combustion to accelerate H2 infrastructure capacity which they suggest would further benefit fuel cell trucks.

ACEEE commented that multipliers had the potential to "more than nullify EPA's proposed increase in stringency", which could reduce industry's motivation to produce BEVs. ACEEE expressed concern that credits might potentially lead to backsliding on internal combustion engine vehicles, with emphasis that that advanced technology multipliers could lead to "stagnation of average truck emission levels in the early years of Phase 3".

Eaton supported sunsetting the BEV and PHEV multipliers as proposed, noting that the multipliers are no longer the driving force in light of market demands and financial incentives of the IRA.

MECA supported EPA's proposed phase-out of the BEV and PHEV multipliers, noting available incentives, including the BIL and IRA, and state programs to support production in lieu of multipliers and the risk of market distortions, reduced deployment of advanced technology, and decreased benefits of the standards if multipliers continue to be available. MECA also recommended EPA reduce the five-year lifetime of advanced technology multiplier credits and suggests the agency should include a lifecycle analysis "to determine appropriate levels of crediting for zero emissions vehicles".

ICCT expressed support for "the proposal to eliminate adv tech multipliers".

SELC supported the proposal to end BEV and PHEV credit multipliers in MY 2026, noting that it "should be a priority" to incentivize those vehicles, but that multipliers can "erode improvements" in ICE-based vehicles, suggesting a concern with potential dilution of the Phase 2 standards.

ZETA supported the proposed phase-out of multipliers for HDEVs (i.e., heavy-duty electric vehicles). ZETA indicated that they are "not recommending phasing out credit multipliers" for FCEV, but requested that EPA present clear guidelines for phasing them out.

<u>Commenters requesting EPA phase out multipliers earlier than proposed</u>

A number of commenters urged earlier phase out of the multipliers because the BIL and IRA are now providing all the incentive for adoption needed. Certain of these commenters also noted that the ACT program likewise provides sufficient incentive. (CATF, Eaton, MECA.)

NACAA and NESCAUM and OTC supported the proposal to phase out the BEV and PHEV multipliers and recommended EPA also phase out the FCEV multiplier in MY 2026 as well.

EDF recommended removing credit multipliers for all hydrogen-fueled vehicles (including FCEVs) or, at minimum, phasing out the FCEV multipliers with BEVs by MY 2026. EDF referred to the upstream emissions associated with hydrogen production as justification for removing the FCEV multipliers, which they suggest is "worse than diesel vehicles" in some cases.

Specific to hydrogen, EDF pointed out that EPA's original reasons in phases 1 and 2 for not accounting for upstream emissions – that upstream emissions are regulated (under stationary source standards, or, for biofuels, under the RFS program), and that not-yet commercialized technologies need regulatory encouragement – either do not apply for hydrogen since hydrogen emissions are not regulated or have been overtaken by events such as the introduction of HD BEVs. EDF thus sees no need for the credit multiplier for hydrogen-fueled vehicles of any type. EDF further recommends that EPA apply a correction factor or utility factor to any vehicle fueled with hydrogen, so a manufacturer's compliance accounts for the unregulated emissions from hydrogen production, pointing to a similar approach in the current rules for PHEVs. EDF suggests those factors could be adjusted over time if a manufacturer can demonstrate lower emissions through testing. Lastly, EDF encouraged EPA to adopt leakage standards for hydrogen-fueled vehicles and to work with other agencies to address pollution from hydrogen production.

CARB recommended EPA adopt the third approach that was proposed in the HD2027 NPRM for advanced technology credit multiplier. Specifically, they would like EPA to incrementally reduce the magnitude of all of the advanced technology credit multipliers over the period of MYs 2024 through 2026. CARB also requested that EPA remove multipliers for any HD ZEVs certified to CARB's ACT regulation, including those sold in California or Section 177 states, suggesting that retaining the multiplier would be double-counting of benefits.

Similar to CARB, Tesla supported eliminating multipliers according to Approach 3 from EPA's HD2027 NPRM. Tesla noted that the HD2027 Approach 1 (limit BEV multipliers to non-ACT states) disincentivizes ACT adoption and the HD2027 Approach 2 (cap use of multipliers) would give manufacturers little incentive to produce beyond the cap limit. Finally, Tesla requested that EPA eliminate the FCEV and BEV multipliers in the same model year to ensure the regulation is agnostic to technology.

NPCA supported the proposal to phase our advanced technology multipliers and requested that EPA "expedite" it to occur in 2025.

CATF et al. also recommended EPA accelerate the phase out multipliers for all BEV, PHEV, and FCEV by 2025 or restrict their availability. CATF et al suggested the market and IRA will lead to BEVs being widely available by MY 2026 and keeping the multipliers could risk reducing the benefits of the standards. They maintain that ICCT's analysis and EPA's own analysis show that substantial percentages of HDVs are likely candidates for early BEV adoption. Therefore, allowing these credits with the 4.5 multiplier creates a large bank of credits which may be windfalls if generated in California or section 177 states. Thus, EPA's original justification for the credit multipliers – to encourage nascent, promising technology not yet in commercial use – has been superseded.

CATF et al. suggested phasing out by MY 2025 would prevent manufacturers from getting credit multipliers for vehicles certified to ACT. Some example restrictions CATF et al. suggested include: eliminating them for vehicles that would be used to meet the ACT standards in California or other states that adopted ACT; impose a 2-year limit on using credits generated with multipliers; limiting the multipliers to long-haul sleeper cabs or other vehicles categories where those technologies are still "genuinely advanced"; or reducing the value of the multipliers in 2025. CATF et al. further suggested that EPA should account for credit multipliers in setting the standards noting the proposed change to the definition of U.S.-directed production volume.

Commenters requesting EPA retain Phase 2 multipliers or extend their availability

Odyne Systems requested EPA extend or keep the same timeframe for PHEV or BEV credit multipliers, because very few are built.

EMA expressed support for the proposal to retain the FCEV multiplier through MY 2027.

DTNA requested EPA retain the multipliers as finalized in Phase 2, noting their continued support for Phase 2 program and manufacturers' reliance on those multipliers in implementing their compliance strategies for which the company "invested considerable time in developing".

UAW expressed concern over phasing-out the BEV and PHEV multipliers, noting that multipliers are “an important tool” for compliance that manufacturers can use to introduce advance technologies in vehicle segments and applications “where it is technically and economically feasible, while continuing to meet customer demands”. UAW requested that EPA “guard against” the potential for vehicles and components to be imported from areas “without robust environmental regulations”.

Navistar opposed the proposal to phase out the BEV and PHEV multipliers noting manufacturers’ reliance on these multipliers in devising their multi-year compliance strategy for the Phase 2 rule, and manufacturers’ continued need for regulatory consistency and certainty.

PACCAR requested EPA reconsider phasing out the BEV and PHEV multipliers, indicating that OEMs built credit multipliers into their product portfolios and compliance plans. PACCAR also requested EPA extend the FCEV multiplier through at least MY 2030, suggesting fuel cell technology is still “immature”. PACCAR also requested EPA add a multiplier for H2ICE through MY 2030 as well to “spur hydrogen refueling infrastructure development”.

Strong PHEV requested the current multiplier for FCEV and a new multiplier for PHEVs with “a long all-electric range” be extended to MY 2030.

TRALA requested EPA extend the BEV multiplier through 2030 for Classes 2-7 and through 2035 for Class 8, noting credit multipliers will help if infrastructure lags. TRALA also requested the FCEV credit multiplier apply for H2ICE.

Other comments relating to multipliers

ATA cautioned that phasing out the advanced technology multiplier in MY 2027 will make it more challenging for manufacturers to meet the standards and “likely limit fleet technology choices” because the rule “requires a certain percentage of ZEVs to be sold”. ATA pointed to past fleet experiences under the Phase 2 program where the association stated that “fleets were obligated” to purchase technology packages with their new vehicles so manufacturers could comply with EPA’s regulation.

China/WTO recommended treating BEVs, PHEVs, and FCEVs the same, ending the “credit rating” (i.e., multipliers) at the same time.

Clean Fuels Development Coalition et al. commented that EPA must end current multiplier program. Furthermore, they argue EPA had no authority to create multipliers in the first place and that EPA does not have the authority to set standards “beyond where it thinks they should be” and then “relax those standards of a manufacturer gives money to the cause of electrification”. They suggest multipliers are essentially a ZEV subsidy program and manufacturers would charge more for gas/diesel vehicles because they have to buy emission credits from EPA’s “friends”.

Fermata Energy and Strong PHEV recommended EPA add a multiplier option for vehicles with onboard AC bidirectional chargers or multiple DC off-board chargers. Strong PHEV recommended EPA conduct an analysis on bidirectional charging for the future.

Volvo expressed concern about meeting the proposed standards across all averaging sets and suggested EPA set specific EV sales penetration thresholds for MY 2026 to use as criteria for evaluating the need to discontinue multipliers on an individual averaging set-basis.

Response:

As described in section III of the Preamble to this rule, we are not taking final action on the proposal to revise the Phase 2 rule to provide for an earlier phase out (one year early) of multipliers for PHEVs and BEVs. As such, manufacturers may continue to generate credits that include credit multipliers for PHEV, BEV, and FCEV technologies through MY 2027 as was adopted in Phase 2. Retaining the existing Phase 2 ABT provisions on credit multipliers should address potential concerns or uncertainties raised by manufacturers regarding their compliance plans relying on the credits generated under the existing Phase 2 credit multiplier provisions.

Also described in section III of the Preamble to this rule, we disagree with those commenters that assert manufacturers will necessarily comply with the Phase 3 standards by virtue of complying with ACT. These comments assume a given volume of Phase 2 credits will be generated and carried over into Phase 3, and thus presuppose manufacturers' compliance strategies with both the federal performance-based Phase 2 and 3 standards and the California ACT program. However, after balancing the concerns raised in comments and related uncertainties we identified, we are finalizing a provision that will limit when manufacturers may use credits generated from credit multipliers in MY 2027 through 2029 and eliminate the availability of those multiplier credits for use in MY 2030 and later.

In response to PACCAR's comment on lead time, we note that we did consider timing for production plans in developing both the standards and the credit provisions of the Phase 3 final rule; however, the four-year lead time referred to in PACCAR's comment does not apply (see section II.F.2 of the final rule preamble).

We acknowledge comments requesting that EPA also phase out the FCEV credit multiplier before MY 2027. CARB indicated the FCEV credits would be double-counted due to the ACT sales mandates. As discussed in section 10.2.1 of this response to comment document and section III.A.1 of the final rule preamble, our revised definition of U.S.-directed production volume, effective in MY 2024, will ensure credits from all vehicles are not double-counted as a result of ACT or other state programs.

In response to EDF's request that EPA provide restrictions on which type of H2-powered vehicles qualify for incentives, we refer to sections 9.3 of this RTC document for more discussion of our consideration of H2 technology. Furthermore, EDF's suggestion to adopt a utility factor for hydrogen-fueled vehicles, analogous to that applied for PHEVs, is less impactful for a standard based on tailpipe emissions. CO_2 tailpipe emissions of GHGs are zero and near-zero for FCEVs and H2ICE vehicles regardless of the hydrogen source, whereas the utility factor for PHEVs reflects the drastically different pollutant emissions when the vehicle operates on battery or on internal combustion engine. EDF's suggestion would only make sense if the vehicle emission standards were based on some type of lifecycle approach. We explain in section 17.2 of this document the many reasons that we decline to implement CAA Title II in that manner. EDF also requested a hydrogen leakage standard for vehicles powered by hydrogen. We did not propose any such requirement and do not have sufficient data on hydrogen leakage to do so.

In response to Tesla's comment that FCEV are "unlikely to be commercially viable," we refer to our discussions of fuel cell technology in Section II.D of the final rule preamble and Chapter 2.5 of the final RIA for this rule. In response to EDF and MECA suggesting that EPA base standards on some type of lifecycle analysis rather than on tailpipe, we refer to section 17.2 of this response to comment document where we discuss our reasons for not doing so.

To address the concern of reduced Phase 3 stringency raised in comments (ACEEE, CATF et al., EDF, MECA, SELC), we are finalizing provisions to limit the potential use of this flexibility, as mentioned earlier in this response, which will allow use of multiplier credits to address Phase 2 compliance and use in specified circumstances to smooth the transition in the Phase 3 program's initial model years only. We are also phasing out the multiplier portion of any advanced technology credits that remain after MY 2029. In Section III of the Preamble to this rule, we describe these provisions we are finalizing to minimize the impact on the projected stringency of Phase 3.

We appreciate ATA's comment sharing the experience of their member fleets that manufacturers have previously restricted the range of options available to fleets as part of their compliance plans. However, we note that none of EPA's GHG programs *require* manufacturers to sell a certain percentage of any technology, as claimed in ATA's comment. As reiterated here and throughout the final rule preamble, EPA's Phase 3 standards are supported by multiple potential compliance pathways and manufacturers have a range of other options for meeting the standards.

Volvo's comment reflects a similar misapprehension. Volvo suggests tying multipliers to ZEV adoption rates, such that "EPA could set a threshold ratio comparing actual model year 2026 EV sales percentages within an averaging set to the MY 2027 adoption rate used to set stringency." But the standard is performance-based, and there are many ways to achieve the standards other than the potential compliance pathway which EPA costed. So, deviation from that EPA's potential pathway in practice is not an alarm bell, but rather an indication that an OEM has chosen to comply in a different matter. That choice should not trigger some type of automatic consequence, including an automatic adjustment to multiplier level, or retention of multipliers.

Clean Fuels Development Coalition et al. maintains that advanced technology multipliers are "a regulatory cross subsidy program for electric vehicles" and that "EPA has no authority to create such a subsidy program." In the same vein, CFDC et al. states that EPA "gets to set standards; it has no power to set standards beyond where it thinks they should be and then agree to relax those standards if a manufacturer gives money to the cause of electrification." First, the advanced technology multipliers at issue are part of the existing regulations that were established in Phase 2 and we did not generally reopen those provisions in this rulemaking; rather, we specifically only proposed to revise the sunset date one year earlier. Second, the commenter significantly mischaracterizes EPA's previous action. As EPA stated in first adopting the advanced technology multipliers and as repeated in the Phase 3 proposal in language quoted by the commenter, the advanced technology multipliers are not reflected in the stringency of the standard. They are a compliance flexibility. See 88 FR at 25972/2 ("instead of including ZEV technologies in the technology packages for setting the Phase 2 standards, we provided advanced technology credit multipliers to help incentivize the development of ZEV technologies."). Thus, the commenter's rhetoric notwithstanding, EPA did not set standards "beyond what it thinks they should be" and then selectively relax the standards. The advanced multiplier provision is a compliance flexibility, not part of the basis that supports the feasibility of the Phase 2 standards. As to commenter's argument that EPA did not have the authority to create such a flexibility in the Phase 2 final rule, it was within EPA's authority as well as reasonable for EPA to develop a mechanism which modestly encourages utilization of these advanced but nascent technologies that had the potential to lead to large reductions in GHG emissions in determining compliance with emission standards.

The commenter's assertion that "[t]his program results in higher prices for gasoline and diesel vehicles because manufacturers must generate or purchase the credits that EPA has created to meet standards" is difficult to understand. The premise appears to be that the Phase 2 standards can only be met be OEMs producing vehicles which get the benefit of the credit multipliers, or by buying credits from manufacturers who do. This is simply not the case. First, the Phase 2 standards were premised on a mix of improvements to ICE engine efficiency and vehicle improvements, not on adoption of zero emission or plug-in hybrid technologies. Second, in practice, although there has been some penetration of these technologies into the HD fleet, that penetration is minimal, meaning that of the hundreds of thousands of successful certifications under Phase 2, the overwhelming majority reflect the types of improvements on which EPA predicated the Phase 2 standards. A choice to comply by buying credits is just that, a choice, and nothing forced upon a manufacturer by the rule.

In this Phase 3 final rule, we are acting to limit the impact of the existing credit multiplier incentives while balancing concerns of timing regarding near-term OEM production plans for compliance. See Section III.A.2 of the final rule preamble for a description of our considerations. Furthermore, we note that credits from both advanced technologies and other vehicles are generated relative to established standards and not relative to credits generated from other vehicles. Nor does our cost analysis, which shows that the standards' costs are reasonable, consider credit purchase. Consequently, overcompliance using one set of vehicle technologies does not negate another vehicle's ability to meet the standard. Finally, as with the Phase 2 standards, in this Phase 3 final rule, EPA did not rely upon potential credits generated through the advanced technology credit multiplier flexibility when developing the stringency of the Phase 3 standards; rather, the Phase 3 standards are supported by potential compliance pathway(s) as described in Section II of the final rule preamble and can be met using a range of technologies without utilizing such credits resulting from the multipliers.

We are not finalizing new multipliers to apply for technologies other than PHEV, BEV, and FCEV. As noted in Section III.A.2 of the final rule preamble, the proposal regarding Phase 2's credit multipliers was limited to evaluating approaches to phase out their availability for use. We did not propose or request comment on extending credit multipliers to apply for other technologies and comments requesting new multipliers are out of scope for this final rule.

AESI recommended EPA provide an incentive for H2 combustion trucks. Others (MEMA, PACCAR, TRALA) suggested that a multiplier for H2 ICE technologies would further incentivize hydrogen-based vehicle technologies and encourage hydrogen infrastructure investment and development. We are not finalizing an additional multiplier for credits generated from H2 ICE technology, but we are finalizing our proposed approach to deem CO_2 emissions to be zero from H2 ICE vehicles powered by neat hydrogen, which reduces some of the testing required to certify these vehicles.[806]

[806] We also note that, in Section III.C.2 of the preamble to this final rule, we describe additional relief from CO_2 testing that we are finalizing for engines, by exempting H2 ICE fueled with neat hydrogen from CO_2 testing by deeming their CO_2 emissions as 3 grams CO_2/ton-mile.

Fermata Energy and Strong PHEV suggested "vehicle to grid" (V2G) bidirectional chargers can address air pollution, GHG emissions, and electric grid challenges, but provided no data to show a reduction in *tailpipe* CO_2 from the technology. As described in section 17.1 of this RTC document, we are not taking a lifecycle approach to setting standards in this rule and without a clear reduction in tailpipe emissions, we would have no basis for considering whether a compliance flexibility predicated on use of this technology is warranted. At this time, while we retain our approach of only considering tailpipe emissions from heavy-duty vehicles, we do not expect to initiate any analyses relating to bidirectional charging, as requested by Strong PHEV.

10.3.2 Averaging Set

Comments by Organizations

Organization: Allergy & Asthma Network et al.

EPA Should Ensure Real-World Benefits

As in many of our organizations' previous comments to EPA on other proposals to reduce emissions from the heavy-duty vehicles sector, we note that the potential for banking, averaging and trading can allow for gaming of the system that reduces real-world emissions cleanup. We urge EPA to ensure that engine families are not allowed to generate excess emissions above the final limits by balancing benefits of zero-emission or hybrid vehicles against them. [EPA-HQ-OAR-2022-0985-1532-A1, p. 4]

Organization: American Council for an Energy-Efficient Economy (ACEEE)

EPA also raises the possibility of allowing advanced technology credits to be used across averaging sets (FR 26013), even though the ZEV adoption targets in the proposal are tailored to the opportunities and constraints for electrification for each specific vehicle type. As EPA and NHTSA observed in the Preamble to the final Phase 2 rule, "combined with the very large multipliers being adopted, there could be too large a risk of market distortions if we allowed the use of these credits across averaging sets" (Phase 2 FR 73498). That risk remains. [EPA-HQ-OAR-2022-0985-1560-A1, p. 17]

Advanced technology credits should remain applicable within averaging sets only. [EPA-HQ-OAR-2022-0985-1560-A1, p. 17]

Organization: California Air Resources Board (CARB)

2. Other Potential HD CO2 Emission Credit Flexibilities

Affected page: 26013

The NPRM requests comments on allowing ATCs to be transferred across averaging sets and on setting restrictions on such credit usage. CARB regulations do not support the use of credit transfer across averaging sets. CARB staff specifically required class 7 and 8 tractor deficits under ACT to be settled using class 7 and 8 tractor ZEV credits to assure sufficient production of HD ZEV semi tractors to reduce emissions and meet pressing needs around ports, railyards, freight facilities, and other directly community impacting truck activities. U.S. EPA should consider whether the credit structure finalized would allow manufacturers to effectively ignore entire categories of vehicles. As discussed further in the EJ-related comments in Part I. Section H. below, CARB staff encourages U.S. EPA to adopt sector specific ZEV sales requirements for the heaviest tractor class to ensure progress in environmental justice communities. [EPA-HQ-OAR-2022-0985-1591-A1, p.54]

5. Weight Class Modifiers (WCM)

Affected page: 26013

In response to U.S. EPA's request for comment, CARB staff does not believe the inclusion of WCM is necessary for the Phase 3 standards. The WCM values were designed based on the structure of the ACT regulation which bases credit balances on vehicles and was designed to allow manufacturers significant flexibility given the diversity of vehicle operations from class 2b to 8. The WCMs are designed to give manufacturers flexibility to focus sales on specific segments while maintaining emission benefits. Given that U.S. EPA's NPRM uses an emissions basis for calculating credits rather than vehicles, and is structured more narrowly, the inclusion of WCMs in U.S. EPA's NPRM would not provide any additional benefit. [EPA-HQ-OAR-2022-0985-1591-A1, p.58]

Organization: Clean Air Task Force et al.

EPA should also not adopt any of the proposed additional flexibilities in the use of advanced technology credits. Id. at 26013 (inviting comments on use of credits across averaging sets). Those flexibilities promise to unnecessarily exacerbate the above-described distortions. [EPA-HQ-OAR-2022-0985-1640-A1, p. 78]

Organization: Daimler Truck North America LLC (DTNA)

Manufacturers should be allowed to transfer credits generated by ZEVs among all available vehicle categories.

The flexibility to transfer ZEV credits among available vehicles categories would enable manufacturers to determine the classes and vehicle categories that they believe are best suited to ZEV adoption. Under this approach, manufacturers could focus their ZEV product and market development efforts on certain vehicle categories, using credits to offset CO2 emissions from vehicle categories that are less suitable for ZEV adoption. EPA could effectuate such flexibility by amending its regulations to provide that the averaging set limitations in 40 CFR 1037.740 do not apply to ABT credits generated by ZEVs. [EPA-HQ-OAR-2022-0985-1555-A1, pp. 74-75]

This compliance flexibility should be allowed without a credit discount and should apply to all credits generated by ZEVs (including BEV, H2-FCEV, and H2-ICE) throughout the life of the GHG Phase 3 program. This flexibility should also apply to credits which are traded between manufacturers to enable a vibrant credit market and to incentivize manufacturers large and small to develop ZEVs. [EPA-HQ-OAR-2022-0985-1555-A1, p. 75]

EPA Request for Comment, Request #66: We request comment on the potential need for additional flexibilities to assist manufacturers in the implementation of Phase 3. Specifically, we request comment on providing the flexibility for manufacturers to use advanced technology credits across averaging sets, subject to a cap.

- DTNA Response: EPA should allow manufacturers to transfer credits generated by ZEVs among all available vehicle classes, as discussed in Section III. B. 1 of these comments. [EPA-HQ-OAR-2022-0985-1555-A1, p. 171]

EPA Request for Comment, Request #67: During this proposed Phase 3 standards transition, we are considering whether additional flexibilities in the Phase 3 program emissions credit ABT program design may be warranted, similar to the Phase 1 provision which allowed credits generated from advanced technologies to be transferred across averaging sets. We request comment on including a similar flexibility for the Phase 3 program.

- DTNA Response: See DTNA Response to Request # 66, above. [EPA-HQ-OAR-2022-0985-1555-A1, p. 171]

Organization: Ford Motor Company

To achieve the 2032 goals EPA has proposed and Ford supports, the final regulation must include two key elements. First, as EPA outlined and requested comment on, EPA must allow manufacturers to trade credits generated by heavy-duty ZEVs across averaging sets, including from class 2b and class 3 ZEVs to light-heavy-duty and medium-heavy-duty vocational vehicles. If the EPA limits a manufacturer's ability to make such trades, credit trading caps should be in the range of multiple megatons. This will be a necessary flexibility because decarbonizing heavy-duty transportation will be stepwise – manufacturers will introduce ZEVs more quickly in vehicle segments where ZEVs are able to more quickly meet customer needs, with remaining segments switching to zero emission technologies as charging infrastructure and consumer enthusiasm for ZEVs improves. [EPA-HQ-OAR-2022-0985-1565-A1, p. 2-3]

GHG Credit Flexibilities

EPA has requested comment on several possible mechanisms by which manufacturers might generate GHG credits based on ZEVs and transfer those credits across averaging sets. First, EPA suggested a provision similar to that used in the Phase 1 heavy-duty GHG standards, which "would allow vehicle CO_2 credits generated by PHEVs, BEVs, and FCEVs to be used across vehicle averaging sets or possibly across engine averaging sets as specified in 40 CFR part 1036," as an interim measure to begin in 2027MY and to end after 2032MY (88 Fed. Reg. at 26,013). Ford strongly supports this proposed credit trading provision. [EPA-HQ-OAR-2022-0985-1565-A1, p. 6]

Ford and other heavy-duty vehicle manufacturers often produce a relatively smaller number of engines and powertrains in the heavy-duty space (40 CFR Part 1036 and 1037 certification) as compared to the light-duty space (40 CFR Part 86 certification). This will make transitioning to heavy-duty ZEVs more of a stepwise process compared to the light-duty fleet, where multiple vehicles, platforms, engines, and powertrains all contribute to the same averaging set, and changing one platform or powertrain to a ZEV replacement can accomplish relatively smooth year-over-year fleet ZEV percentage increase. In the heavy-duty space, a manufacturer may, for example, devote available engineering resources to developing and launching a light heavy-duty ZEV and not have resources to develop and launch a medium heavy-duty ZEV until two years later. If a manufacturer generates positive CO_2 credits and complies with vocational vehicle fleet electrification targets (overall, cumulative across all averaging sets), then it is reasonable to allow that manufacturer to transfer credits from averaging sets with early ZEV adoption to averaging sets that will add ZEV options later during the program. [EPA-HQ-OAR-2022-0985-1565-A1, p. 6]

Regarding heavy-duty engines certified under 40 CFR Part 1036, Ford also supports the ability for manufacturers to generate CO_2 credits from heavy-duty ZEVs and transfer those credits to heavy-duty engine averaging sets. Current regulations do not include ZEVs in these averaging sets, leaving relatively less flexibility to comply than for heavy-duty vocational vehicle averaging sets but also providing no particular incentive to adopt ZEVs. Allowing transfer of ZEV-generated CO_2 credits would provide manufacturers increased flexibility in their compliance plans and also provide environmental benefits by encouraging overcompliance with vocational vehicle GHG standards and ZEV sales percentages. Overall, credit transfers into heavy-duty engine averaging sets would help keep heavy-duty engine and heavy-duty vocational vehicle GHG compliance more closely aligned and not at risk of diverging to the point that robust compliance in one space is not at all reflected in the other. [EPA-HQ-OAR-2022-0985-1565-A1, p. 6-7]

EPA has also requested comment on appropriate restrictions on number of credits that could be transferred from one averaging set to another. In the Phase 1 heavy-duty GHG program, the advanced credits that could be brought into any service class in any model year were capped at 60,000 Mg. This credit cap is far too low for larger, higher-volume manufacturers like Ford to provide useful flexibility. As an example, suppose a manufacturer sells 150,000 light heavy-duty vehicles per year. If these vehicles were all certified at the existing Phase 2 2027MY light heavy-duty multipurpose compression-ignition standard of 330 g CO_2/ton-mile, the manufacturer would generate a 4.68 Mt CO_2 (4,680,000 Mg CO_2) deficit against the proposed 2027MY light heavy-duty multipurpose compression-ignition standard of 257 g CO_2/ton-mi: [EPA-HQ-OAR-2022-0985-1565-A1, p. 7]

((257g CO_2/ton - mile)-(330 g CO_2/ton-mile)) x (2.85 tons payload) x (150,000 units) x (150,000 mile UL) x 10^{-6}= 4,681,125 Mg CO_2

Large year-over-year stringency increases have the potential to create credit deficits in the megaton CO_2 range for manufacturers with sufficient volume, especially in the first year of the program transitioning from the 2026MY standards to the proposed 2027MY standards when manufacturers would have previously been planning to the phase 2 2027MY standards. Accordingly, Ford proposes not less than a five megaton (5,000,000 Mg) CO_2 credit transfer cap into any averaging set in any model year. This cap would allow a useful amount of flexibility given the rate of change of the standards and possible manufacturer fleet volumes for these vehicle classes. [EPA-HQ-OAR-2022-0985-1565-A1, p. 7]

Organization: Manufacturers of Emission Controls Association (MECA)

Furthermore, the Phase 2 regulation did not allow for the transfer of credits across averaging sets, and we believe this provision should be extended into the Phase 3 final rule. This is particularly important as the increasing number of electric trucks sold will afford EPA an opportunity to assess durability, FUL and LCA for different vehicle classes and averaging sets. [EPA-HQ-OAR-2022-0985-1521-A1, p. 10]

For similar reasons, MECA does not support the use of weight class modifiers which we believe can have the same effect of reducing or delaying the broader deployment of advanced

GHG reducing technologies across all commercial vehicle sectors. [EPA-HQ-OAR-2022-0985-1521-A1, p. 10]

Organization: National Association of Clean Air Agencies (NACAA)

End the Phase 2 Credit Exchange Between Vocational Vehicles and Tractors

The averaging, banking and trading program under EPA's current Phase 2 heavy-duty GHG program allows CO2 emission credits to be exchanged between vocational vehicles and tractors within a weight class. With the final Phase 3 rule, EPA should end the Phase 2 credit exchange program to ensure that manufacturers produce heavy-duty ZEVs across the range of vehicle configurations they produce. [EPA-HQ-OAR-2022-0985-1499-A1, p. 9]

Organization: Northeast States for Coordinated Air Use Management (NESCAUM) and the Ozone Transport Commission (OTC)

Averaging Banking and Trading (ABT)

EPA requests comment on the consideration of the use of credits across averaging sets and specifically requests comment on consideration of a program similar to ARB's ACT credit program. EPA proposed to allow the transfer of CO2 credits between class 4-6 vocational vehicles and class 7 and 8 tractors. In the ACT regulation, tractor ZEV sales cannot be offset by sales of class 4-6 vehicles. In the final rule, we encourage EPA to disallow the transfer of credits across classes 4-6 to class 7 and 8 tractors. We encourage EPA to only allow ZEV tractor sales credits to be used to offset tractor sales deficits. As stated earlier, tractor emissions make up the lion's share of heavy-duty vehicle emissions and fuel consumption. Allowing the use of credits across averaging sets could reduce the effectiveness of the regulation. [EPA-HQ-OAR-2022-0985-1562-A1, p. 14]

Organization: Strong Plug-in Hybrid Electric Vehicle (PHEV) Coalition

EPA in finalizing the regulation, should make sure that averaging, banking and trading provisions are open to all propulsion technologies including PHEVs, BEVs and FCEVs (technology neutral and performance based) and provide increased flexibility to trade the CO2 reduction benefits of PHEVs, BEVs and FCEVs between different sizes and types of vehicles until at least MY 2032. [EPA-HQ-OAR-2022-0985-1647-A2, p. 2]

7) Our coalition is supportive of continuing averaging, banking and trading provisions as long as it is technology neutral, and performance based and does not favor engine-based technology. Regarding EPA's question on flexibility in the averaging, banking, and trading system, we support including the ability to trade the CO2 reduction benefits of PHEVs, BEVs and FCEVs between different sizes and types of vehicles until at least MY 2032. We believe this is a modest way to help encourage the most advanced clean technologies in this regulation. [EPA-HQ-OAR-2022-0985-1647-A2, p. 7]

Organization: Tesla, Inc. (Tesla)

No Trading Should Be Allowed Across Averaging Sets

The final rules should not allow crediting trading across averaging sets.183 As the agency suggests, allowing such trading will distort the marketplace, decrease the predictability and integrity of the rule's benefits, and may unnecessarily result in focusing on electrification of only certain heavy-duty segments. Given the difference in carbon emission impacts between the averaging sets, credits generated from lower weight class ZEVs should not be allowed to offset heavier weight class vehicle credits deficits. In short, EPA should maintain a credit trading policy that ensures manufacturers seek GHG reductions and electrification in all heavy-duty segments. [EPA-HQ-OAR-2022-0985-1505-A1, p. 25]

183 88 Fed. Reg. at 26013.

Organization: Volvo Group

Flexibilities

Full credit fungibility across vehicle averaging sets

In NPRM Section III.A.3 "Other Potential HD CO2 Emission Credit Flexibilities" the agency requested "comment on the potential need for additional flexibilities to assist manufacturers in the implementation of Phase 3." [EPA-HQ-OAR-2022-0985-1606-A1, p. 20]

First and foremost, Volvo Group no longer sees the need to restrict vehicle credits to use within an averaging set. Since the Phase 1 program development began in 2009, and continuing through the development of the Phase 2 program finalized in late 2016, the Volvo Group has been the sole voice of opposition among the major vehicle OEMs to movement of vehicle credits across averaging sets. Since Volvo Group did not have a significant North American offer outside of the Heavy-Heavy Duty (HHD) vehicle averaging set during this time, we opposed this flexibility due to the unlevel playing field and resultant competitive disadvantage it would create. With the 2020 launch of the well-received Mack MD Class 6/7 medium duty trucks, Volvo Group no longer sees a competitive disadvantage to movement of credits across vehicle weight classes, nor does it see a competitive advantage provided to any one OEM by expanding credit fungibility. An expanded allowance would, however, allow manufacturers to focus development resources and budgets on the most cost-effective improvements for customers, further easing the transition to ZEV technologies. Thus, Volvo Group requests the agency finalize an allowance for full credit fungibility across vehicle sub-categories without restriction. Since credits in each averaging set are calculated in Mg of CO2 reduction, and already account for the payload and useful life mileage within the averaging set in which they were earned, Volvo Group sees no reason that these credits should be subjected to discounting, or any other method of reduction in value of transferred credits. [EPA-HQ-OAR-2022-0985-1606-A1, p. 20-21]

Vehicle Advanced Technology (AT) credit fungibility to engine averaging sets

The agency also went on to further specifically "request comment on providing the flexibility for manufacturers to use advanced technology credits across averaging sets, subject to a cap" (emphasis is the agency's own). Volvo Group sees no reason why one-way movement of any vehicle credit, regardless of the technology from which it is derived, should not be allowed to offset engine deficits. Nor do we see the need for a cap on the number of credits that could be moved from the vehicle averaging sets into the engine averaging sets. Since, as noted previously in these comments, the benefits of the current Phase 2 regulation and the proposed Phase 3 rule are derived solely from complete vehicle improvements that incorporate the actual fuel map of the installed engine, the greenhouse gas reductions from the regulation are not decreased by offsetting engine deficits with vehicle credits. Additionally, a cap does nothing to increase the calculated benefit of the regulation but is rather an arbitrary and capricious method of driving additional engine improvements above and beyond the engine efficiency reductions manufacturers will need to claw back due to the discussed impacts of the EPA's model year 2027 NOx reductions finalized in the Clean Trucks Plan NOx regulation. Since, the expected engine level of improvements from the model year 2024 to the model year 2027 compression ignition engine standards range only from ~0.5% to ~0.9% (see table below for specific values and averaging sets), the expected improvements are negligible compared to the actual benefit derived from a Phase 3 regulation predicated on any level of zero-emission vehicle penetrations. Lastly, in a scheme where only one-way movement of vehicle credits into engine averaging sets is allowed, any amount of credits moved from the vehicle to engine averaging sets are effectively retired, reducing the OEMs available credit balance to be carried forward. (Refer to Table 2 on page 21 of docket number EPA-HQ-OAR-2022-0985-1606-A1). [EPA-HQ-OAR-2022-0985-1606-A1, p. 21]

As such, Volvo Group urges the agency to finalize an allowance for unrestricted one-way movement of any category or class of vehicle credits into engine averaging sets throughout the Phase 3 regulatory period from model year 2027 through 2032 with no cap on the number of credits that can be moved. [EPA-HQ-OAR-2022-0985-1606-A1, p. 21]

Providing a Weight Class Modifier on Credits to Incentivize Adoption in Heavier Weight Classes

Volvo Group agrees that this approach would be valuable to incentivize development of EVs in heavier weight categories. [EPA-HQ-OAR-2022-0985-1606-A1, p. 22]

EPA Summary and Response:

Summary:

EPA requested comment on providing a flexibility for manufacturers to use advanced technology credits across averaging sets, with the potential for caps or other limitations, as an interim allowance from model years 2027 through 2032 (see 88 FR at 26013). Commenters expressing support for using credits across averaging sets generally noted that the flexibility would help manufacturers implement advanced technologies in the vehicle segments with the greatest demand or cost effectiveness, and some of those commenters suggested EPA expand the flexibility beyond the examples provided in the requests for comment. Commenters opposed to allowing credit transfers across averaging sets generally expressed concern over market distortions and reduced effectiveness of the rule.

Among the commenters supporting credit transfers across averaging sets, DTNA requested that all credits generated by ZEVs, including BEV, H2-FCEV, and H2-ICE, should be available to all vehicle categories, indicating that it would allow manufacturers to "determine the classes and vehicle categories that they believe are best suited to ZEV adoption" and offset CO_2 emissions from other categories they determine are less suitable for ZEVs. DTNA further suggested that these ZEV credits should not be discounted and the allowance should apply for all credits generated by ZEVs "throughout the life of the GHG Phase 3 program".

Ford requested that EPA allow credit transfers across averaging sets, including "Class 2b and 3 ZEVs to light-heavy-duty and medium-heavy-duty vocational vehicles", indicating that a stepwise approach will be needed for the heavy-duty sector and manufacturers would benefit from introducing ZEVs to vehicle categories where ZEVs would "more quickly meet customer needs". Specifically, they emphasized that a manufacturer may have more engineering resources dedicated to light-duty ZEV development and medium-duty ZEVs may have a two year delay. Ford also requested the ability to generate CO2 credits from heavy-duty ZEVs that could be used in heavy-duty *engine* averaging sets to maintain consistent compliance between engine and vocational vehicles. Regarding a credit trading cap, Ford, suggested a cap should be "in the range of multiple megatons" as opposed to the 60,000 Mg value indicated by EPA. Ford suggested that manufacturers with large production volumes can have megaton credit deficits and suggests "not less than a five megaton (5,000,000 Mg) CO2 credit transfer cap into any averaging set in any model year".

Strong PHEV Coalition suggested ABT should be open to PHEVs, BEVs, and FCEVs and that those vehicles should have the flexibility to trade credits "between different sizes and types of vehicles until at least MY 2032".

Volvo noted their previous opposition to transferring credits across averaging sets, citing a competitive disadvantage during the Phase 1 and Phase 2 programs. Since then, Volvo has released a Class 6/7 truck and no longer sees a competitive disadvantage to that potential credit allowance. Volvo suggested the expanded credit fungibility would allow manufacturers to "focus development resources and budgets on the most cost-effective improvements for customers, further easing the transition to ZEV technologies". Volvo requested no restrictions (e.g., discounting) on the credit transfers, because the payload and useful life mileage in the credit calculation account for differences between averaging sets. Like Ford, Volvo also requested one-way transfer of vehicle credits to offset engine deficits, but unlike Ford, maintained that there should not be a cap, stating "a cap does nothing to increase the calculated benefit of the regulation but is rather an arbitrary and capricious method of driving additional engine improvements above and beyond the engine efficiency reductions manufacturers will need to claw back" due to the recent EPA heavy-duty NOx regulation. Volvo noted that the relatively small change in engine standards from MY 2024 to 2027 would have a "negligible" improvement compared to Phase 3 and that any manufacturer who opted to use this one-way credit would then lose the ability to apply those credits to a vehicle.

Other commenters cautioned against allowing credit transfers across averaging sets. ACEEE commented that "advanced technology credits should remain applicable within averaging sets only". ACEEE expressed concern over the risk of market distortions if EPA were to allow credits, especially those generated with multipliers, to be used across averaging sets.

Allergy & Asthma Network et al. noted the potential for "gaming" through use of ABT, and specifically urged EPA not to allow engine families "to generate excess emissions above the final limits by balancing benefits of zero-emission or hybrid vehicles against them".

CARB noted that the ACT program specifically requires tractor deficits to be settled using tractor ZEV credits to "assure sufficient production of HD ZEV semi tractors" and CARB suggested EPA should consider whether manufacturers could "effectively ignore entire categories of vehicles" when evaluating possible credit approaches to finalize. CARB encouraged EPA to adopted ZEV sales requirements specifically for the Heavy HDV tractors indicating that it would "ensure progress" in EJ communities.

CATF cautioned that allowing use of credits across averaging sets would "exacerbate" the concerns they expressed in section 10.3.1 of this response to comment document over credit multipliers distorting the stringency of the Phase 3 program.

MECA supported extending the Phase 2 restriction on transferring credits across averaging sets into Phase 3, noting that EPA could better assess the durability, FUL, and LCA for vehicles within the averaging sets.

Tesla did not support allowing credit trading across averaging sets, indicating that the allowance would "distort the marketplace, decrease the predictability and integrity of the rule's benefits, and may unnecessarily result in focusing on electrification of only certain heavy-duty segments".

Several commenters requested that EPA further limit the current averaging sets to reduce the risk that ZEV vocational vehicles could reduce incentive for manufacturers to produce ZEV tractors.

NACAA requested EPA revise the current ABT program to disallow credits exchanges between vocational vehicles and tractors within the same weight class. NACAA suggested that continuing the current approach would not "ensure that manufacturers produce heavy-duty ZEVs across the range of vehicle configurations".

NESCAUM and OTC noted that CARB's ACT regulation disallows transferring credits between vocational vehicles and tractors. NESCAUM and OTC commented that EPA should also disallow transferring credits between Class 4-6 vehicles and Class 7 and 8 tractors and only allow credits from ZEV tractor sales to offset tractor deficits. They noted that tractor emissions "make up the lion's share of heavy-duty vehicle emissions" and transferring credits across averaging sets "could reduce the effectiveness of the regulation".

Regarding EPA's request for comment on weight class multipliers, CARB and MECA recommended EPA not apply weight class modifiers. CARB indicated that the weight class multipliers they applied in their ACT rule were specific to that rule and should not apply to a federal program. Volvo stated that weight class modifiers would "incentivize development of EVs in heavier weight categories".

Response:

We are retaining our current GVWR-based averaging set definitions and the flexibility that allows credits to be averaged, banked, or traded within an averaging set. After considering comments and further evaluation of the example flexibilities included as requests for comment in the proposal, the final provision, available as an interim, transitional flexibility during model years 2027 through 2032, will allow manufacturers to use credits generated from heavy-duty vehicles across averaging sets. In Section III.A.3 of the final rule preamble, we describe how the allowance applies for heavy-duty vehicles under 40 CFR 1037 and heavy-duty vehicles under 40 CFR part 86, subpart S. While some commenters expressed general support for our request for comment on allowing one-way transfer of CO_2 credits from heavy-duty vehicle averaging sets to heavy-duty engine averaging sets, we are not finalizing that option in this final rule. We expect we would need to apply restrictions on the engine averaging sets where vehicle credits can be applied to limit potential disproportionate adverse emission impact on certain engine categories and also set FEL caps to avoid backsliding on the engine standards. At this time, we believe the complexity of this flexibility would limit its use relative to the other flexibilities we are finalizing in this rule.[807]

ACEEE commented that the risk of market distortions is greater considering the availability of credits generated with multipliers. In response, as described in preamble Section III and our response in RTC section 10.3.1, we note that we are separately taking steps to reduce the impact of credits from multipliers by restricting their use toward Phase 3 compliance and removing any remaining multipliers in model year 2030.

We disagree with Volvo's statement that a cap is a "rather an arbitrary and capricious method" of achieving more emissions reductions from engines. Rather, caps are important in cases where credits have the potential to lead to a disproportionate negative emissions impact on one or more vehicle or engine categories. As noted previously, we are not finalizing the option for manufacturers to use heavy-duty vehicle credits in heavy-duty engine averaging sets, in part to avoid the potential for disproportionate negative emissions impact on one or more engine categories. However, we are not including a cap on credits transferred between heavy-duty vehicle averaging sets in the final interim flexibility. A cap would be justified in cases where vehicles with zero or near-zero tailpipe CO_2 emissions are able to offset a significant number of vehicles in any given averaging set under this flexibility. Our assessment of the effect of those vehicles does not indicate a such an offset.

We requested comment on the possibility of allowing credits generated by Class 2b and 3 PHEV, BEV, and FCEV pickup trucks and vans[808] to transfer to the heavy-duty vehicle averaging sets (see 88 FR at 26013). Ford commented in support of that potential allowance, indicating there is a two-year delay in adapting light-duty vehicle technology for the heavy-duty vehicle market. After considering comments, we are extending our model year 2027 through 2032 allowance for transferring credits across averaging sets to include credits from Class 2b and 3 PHEV, BEV, and FCEV pickup trucks and vans. Specifically, we are finalizing an interim allowance for one-way credit transfers from averaging sets for heavy-duty vehicles certified to 40 CFR part 86, subpart S, to averaging sets for heavy-duty vehicles certified to 40 CFR part 1037. We are limiting this aspect of the flexibility to transferring credits generated during MYs 2027-2029 from to 40 CFR part 86, subpart S, to 40 CFR part 1037 in recognition that there is greater availability of PHEV, BEV, and FCEV in pickup trucks and vans and less need to offer a flexibility for vehicles in that market. We note that it would take multiple pickup trucks or vans to offset any single heavy-duty vehicle, and any credits transferred under this flexibility would no longer be available for the part 86 ABT program to aid in manufacturers meeting the requirements for those vehicles.

We did not propose and are not revising the current ABT provisions to disallow credit exchanges between vocational vehicles and tractors within a given averaging set, as requested by NACAA and NESCAUM/OTC. NACAA correctly pointed out that EPA's current rules for heavy-duty vehicle averaging sets allows credits to be exchanged between all vehicles within an

[807] See also revised 40 CFR 86.1819-14, new 40 CFR 1036.150(bb), and new 40 CFR 1037.150(z) that specify how manufacturers can exchange credits across averaging sets in 40 CFR parts 86, 1036, and 1037 during model years 2027 through 2032.
[808] These vehicles are certified to 40 CFR part 86, subpart S.

averaging set. As defined in 40 CRR 1037.740, averaging sets mirror the vehicle weight classes, which are largely based on vehicles' GVWR (see 40 CFR 1037.140 and the definition of "class" in 40 CFR 1037.801). As such, the Medium HDV and Heavy HDV classes, and their corresponding averaging sets, may contain both vocational vehicles and tractors if they have a similar GVWR. As CARB noted in their comment, they designed the ACT regulation to limit how credits can be used to offset tractor deficits. We understand the concerns from CARB, NACAA, and NESCAUM/OTC that manufacturers may generate Phase 3 credits from certain vehicles within a weight class in order to avoid producing ZEV for others. We note that the possibility of offsetting some applications is inherent in the design of the ABT provisions, which allows manufacturers to decide which vehicle applications to apply technologies for their specific company's product line. The structure of the ABT program, including the current GVWR-based averaging sets, have been in place since Phase 1 (see 76 FR 27239) and, as noted in section 10.2 of this RTC document, we are not reopening issues relating to the structure of the ABT program. We are repeating these points here to respond to this comment, not to indicate any reconsideration of this established position.

We further note, in response to NACAA and NESCAUM/OTC, that subcategory-specific emission standards continue to apply for heavy-duty vehicles and that emission credits generated within a given averaging sets must balance to zero (or a zero balance is achieved in the following three model years). Consequently, vehicle families across each averaging set are meeting their emission targets, with the associated environmental and health benefits, *on average* and individual vehicles are certified as well to the FEL for that vehicle family or subfamily. See section 10.2 of this RTC document. We do not have data to suggest a clear advantage of separate averaging sets for vocational vehicles and tractors, since manufacturers may produce more ZEV tractors, but they may also opt to produce fewer ZEV vocational vehicles in the vocational averaging set.

11 Battery Durability and Warranty

11.1 Battery Durability

Comments by Organizations

Organization: American Fuel and Petrochemical Manufacturers (AFPM)

3. EPA's Approach Fails to Address Important Issues That Will Affect Consumers' Best Interest.

EPA's proposal may impose additional costs of economic risk to small business owners who will be asked to depend upon increasingly expensive, lesser-proven HDVs for their livelihood. HD engine standards and the standards for MY 2021 and later light-HD engines apply over a useful life of 15 years or 150,000 miles, whichever comes first. 150,000 miles is well below the period of use for a comparable ICE powertrain. In the Proposed Rule, EPA asserts that it "concurs with the emerging consensus that battery durability is an important issue. The ability of a zero-emission vehicle to achieve the expected emission reductions during its lifetime depends in part on the ability of the battery to maintain sufficient driving range, capacity, power, and general operability for a period of use comparable to that expected of a comparable ICEVs. Durable and reliable electrified vehicles are therefore critical to ensuring that projected emissions reductions are achieved by this proposed program."93 EPA further states that it "proposed a specific durability testing requirement in the Proposed Rule and received comment on that proposal, including comment stating that the requirements could result in increases in the battery capacity beyond what was needed to meet the job of the customer. Due to these concerns and because we are still evaluating the range of durability metrics that could be used for quantifying HD BEV performance, EPA is not proposing specific durability testing requirements in this rule."94 EPA should consider inclusion of durability requirements in this proposal as 150,000 miles is well below the period of use for a comparable ICE powertrain and will impact consumers as there is not enough data regarding these technologies due to their very small market penetration. [EPA-HQ-OAR-2022-0985-1659-A2, pp. 25 - 26]

93 Proposed Rule at 26,014–15.

94 Id. at 26,015.

EV batteries are high-cycle batteries and are made to function for approximately 10 years for a light-duty vehicle, and a shorter time for medium- and heavy-duty vehicles. [EPA-HQ-OAR-2022-0985-1659-A2, p. 29]

EV batteries lose approximately 3 percent of their charging capacity and associated range per year of operation. These percentages likely are higher for higher mileage utilization for typical heavy-duty vehicles. EPA has not made any effort to account for battery degradation, and associated reductions in charging efficiency, charging capacity, customer impacts and accelerated battery replacement and costs. [EPA-HQ-OAR-2022-0985-1659-A2, p. 29]

Many 'spent' EV batteries still have 70-80 percent of their capacity left, which is more than enough to be repurposed into other uses such as energy storage and other lower-cycle applications.108 This will extend the time that batteries and raw materials remain in use and therefore increase the demand for virgin critical minerals. [EPA-HQ-OAR-2022-0985-1659-A2, p. 29]

Organization: California Air Resources Board (CARB)

c. Battery durability monitor

Affected pages: 26016, 26127, and 26124 (1037.115(f))

In response to U.S. EPA's request for comment, CARB staff suggests that requirements for entire system monitoring to be added instead of requirements for battery monitoring only. The requirements could include monitoring of the energy storage system, the thermal management system, the regenerative braking system, the charging system, the motor/generator, and fuel-cell stack, if present. [EPA-HQ-OAR-2022-0985-1591-A1, p.37]

CARB staff suggests requiring manufacturers to provide a description of a method for monitoring and calculating the battery state of health. CARB staff suggests that manufacturers of BEVs should provide the rated energy capacity for their batteries and the SAE J1798 procedure should be followed for testing the battery rated energy capacity. "Battery durability subfamily" needs to be defined. [EPA-HQ-OAR-2022-0985-1591-A1, p.37]

California's Zero Emission Powertrain (ZEP) Test Procedure sets requirements for battery monitoring. CARB staff suggests that NPRM could be aligned with the ZEP procedure.114 [EPA-HQ-OAR-2022-0985-1591-A1, p.37]

114 California Standards and Test Procedures for New 2021 and Subsequent Model Heavy-Duty Zero-Emission Powertrains, June 27, 2019. https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2019/zepcert/froattc.pdf

Organization: Clean Air Task Force et al.

V. EPA Should Adopt the Proposed Warranty and Durability Requirements.

A. EPA should adopt the proposed durability provisions but should also require state-of-certified-range monitors.

We urge EPA to adopt the proposed durability and warranty requirements. 88 Fed. Reg. at 26013-16. As EPA explains, the calculation of emission credits for ZEVs is based on attributed mileage over their useful life. 88 Fed. Reg. at 26013. In addition to helping ensure that ZEVs will in fact achieve the projected emission reductions throughout their useful lives, the warranty and durability requirements will enhance consumer confidence in ZEVs and promote their faster adoption among purchasers, leading to greater air quality benefits. [EPA-HQ-OAR-2022-0985-1640-A1, p. 81]

EPA's authority to adopt the proposed durability requirements is grounded in section 206 of the Clean Air Act, which (read in conjunction with section 203) provides that before introducing a new motor vehicle into commerce, a manufacturer must obtain an EPA "certificate of conformity" indicating that the vehicle complies with applicable emission standards promulgated under section 202. 42 U.S.C. § 7525(a)(1); 42 U.S.C. § 7522(a)(1). Section 202(a)(1), in turn, requires vehicles to achieve compliance with standards throughout their "useful life," "whether such vehicles and engines are designed as complete systems or incorporate devices to prevent or control such pollution." 42 U.S.C. § 7521(a)(1). Section 206 also provides that EPA may condition the certificate of conformity "upon such terms…as [it] may prescribe." 42 U.S.C. § 7525(a)(1). The statute thus confers broad authority on EPA to ensure that ZEVs (like any other motor vehicle) in fact achieve the level of emission reductions attributed to them for purposes of compliance calculations throughout their useful lives. [EPA-HQ-OAR-2022-0985-1640-A1, pp. 81 - 82]

As part of the durability requirements, we urge EPA to require heavy-duty BEVs and PHEVs to have a state-of-certified-range (SOCR)355 monitor that can be accessed by consumers. 88 Fed. Reg. at 26015. Compared to usable battery energy (the metric EPA has proposed), SOCR monitors provide important information on range and battery performance that drivers and consumers can easily understand. Requiring manufacturers to provide SOCR monitors, in addition to the other battery durability measures EPA has proposed, would also enhance consumer confidence in used heavy-duty ZEVs. [EPA-HQ-OAR-2022-0985-1640-A1, p. 82]

355 SOCR is "the measured or on-board electric range at a specific point in its lifetime, expressed as a percentage of the certified range." UN Global Technical Regulation No. 22 (In-vehicle Battery Durability for Electrified Vehicles), ECE/TRANS/180/Add.22, at II.3.10., Apr. 14, 2022, https://unece.org/sites/default/files/2023-01/ECE_TRANS_180a22e.pdf; see also 88 Fed. Reg. at 26015 (referring to Global Technical Regulation No. 22).

Finally, while EPA proposes that the new battery durability monitoring requirements take effect "beginning with MY 2027," the proposed regulatory text (40 C.F.R. § 1037.115(f)) states that they "apply starting in model year 2030." Compare 88 Fed. Reg. at 26014, with id. at 26124. In the final rule, EPA should update the regulatory text to clarify that the requirements apply starting in MY 2027. [EPA-HQ-OAR-2022-0985-1640-A1, p. 82]

Organization: Cummins Inc.

V. Battery Durability Requirements

12. An on-board state-of-certified-energy (SOCE) monitor accuracy requirement is needed.

Cummins supports having a customer facing SOCE monitor that includes an accuracy requirement. We propose aligning this requirement with the proposed accuracy requirements in EPA's Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles proposal which states that in-use vehicles must display SOCE values that are accurate within 5 percent of measured values as calculated in GTR No. 22. [EPA-HQ-OAR-2022-0985-1598-A1, p. 10]

13. Cummins supports common sense battery durability requirements.

Cummins supports common sense battery durability requirements to ensure a level playing field across all zero emissions vehicle manufacturers and to ensure vehicle owners receive robust new technology which will spur broader adoption. Battery durability is important to the future of battery electric vehicles (BEV). Many fleets are purchasing BEV for the first time and directly comparing them to the existing ICE vehicles in their fleets. If fleets experience a sub-par product that does not meet their expectations, they will hesitate to continue to invest in this product which could result in ICE vehicles remaining in their fleets for longer periods of time. Heavy-duty durability requirements must deviate from the proposed Light-Duty and Medium-Duty Rule and protect for miles, years, and weight, with a focus on the throughput of the battery with regards to the machine. Cummins commits to working with EPA and other stakeholders to develop recommended durability requirements. [EPA-HQ-OAR-2022-0985-1598-A1, p. 10]

14. A test procedure for determining Useable Battery Energy (UBE) is needed for BEV.

Having a standard test procedure for determining UBE in BEV is needed to ensure a level playing field for battery durability. Just as there is a proposed test procedure for hybrids, a standard test procedure should be developed for HD BEVs. Cummins commits to working with EPA to develop a standard test procedure for determining UBE that is appropriate for heavy-duty BEV. [EPA-HQ-OAR-2022-0985-1598-A1, p. 10]

Organization: Daimler Truck North America LLC (DTNA)

DTNA supports the proposed battery durability monitoring and ZEV warranty requirements but requests revisions to proposed Section 1037.115(f) to clarify the Agency's intent. [EPA-HQ-OAR-2022-0985-1555-A1, p. 66]

DTNA agrees with EPA that customer adoption of new vehicle technologies, especially ZEVs, relies on certainty that the products can do the jobs that customers need them to do over a predictable period of time. DTNA is focused on providing our customers with durable products that have predictable maintenance and repair costs. To this end, we spend considerable development and validation resources to test vehicles for hundreds of thousands of miles before production, working hand-in-hand with customers to ensure they have the best possible experience with our products. Manufacturers are well-motivated by market forces to develop robust, durable, and maintainable products, thus EPA regulations are not needed to ensure quality. Simply put, manufacturers must develop economical, reliable, and durable products, or customers will not buy them. [EPA-HQ-OAR-2022-0985-1555-A1, p. 66]

Nonetheless, DTNA requests that EPA revise the language proposed for 40 C.F.R. 1037.115(f) to specify the State-of-Certified-Energy (SOCE) monitoring requirements that will apply rather than incorporating a general reference to the 'monitoring requirements' GTR No. 22, which could be imprecise and open to interpretation. The regulatory language proposed for Section 1037.115(f) states that 'Monitoring requirements related to State of Certified Range (SOCR)', 'Accuracy requirements for SOCE in GTR No. 22,' and 'Minimum Performance requirements for battery durability' from GTR No. 22 'do not apply,' but the Agency does not specify exactly which clauses of GTR No. 22 are intended to apply. EPA also does not clearly state that the requirements for 'In-Use Verification' in GTR No. 22 do not apply. [EPA-HQ-OAR-2022-0985-1555-A1, p. 67]

DTNA recommends that EPA clarify its intent by incorporating and modifying the language from GTR No. 22 that the Agency intends to adopt. Specifically, the Company recommends that Section 1037.115(f) read as follows:

(f) State-of-Certified-Energy (SOCE) monitors.

(1) The requirements of this section apply starting in model year 2030.

(2) The manufacturer shall install an SOCE monitor that operates during the life of the vehicle. The SOCE monitor shall maintain an estimate of the state of certified energy (on-board SOCE).

The manufacturer shall determine the algorithms by which on-board SOCE is determined for the vehicles they produce. The manufacturer shall update the on-board SOCE with sufficient frequency as to maintain the necessary degree of accuracy during all normal vehicle operation. The on-board SOCE shall have a resolution of 1 part in 100 and be reported as the nearest whole number from 0 to 100.

(3) The manufacturer shall make available the most recently determined values of the on-board SOCR and on-board SOCE via the OBD port or otherwise make the SOCE available to the operator.

(4) For battery electric vehicles, use good engineering judgment to develop a test procedure for determining useable battery energy (UBE).

(5) For plug-in hybrid electric vehicles, determine UBE as described in 40 C.F.R. 1036.545 [EPA-HQ-OAR-2022-0985-1555-A1, pp. 67-68] The warranty and battery durability monitoring requirements in the Proposed Rule strike an adequate balance between ensuring this baseline level of product performance and not adding undue burden and expense to ZEVs. [EPA-HQ-OAR-2022-0985-1555-A1, p. 67]

EPA should not set additional product requirements for ZEVs that could increase cost or limit manufacturers' ability to provide customers with adequate choice in the market. [EPA-HQ-OAR-2022-0985-1555-A1, p. 68]

While DTNA supports EPA's proposed durability monitoring and warranty requirements, as discussed above, the Company does not support additional ZEV requirements that could add costs and disincentivize ZEV adoption. Related to this key point, DTNA offers the following responses to EPA's requests for comment on potential additional requirements related to battery health. [EPA-HQ-OAR-2022-0985-1555-A1, p. 68]

EPA should not set durability standards, including a minimum State-of-Certified-Energy (SOCE) or State-of-Certified-Range (SOCR).

The ZEV market is still developing, and factors will emerge bearing on battery and fuel cell durability that cannot be adequately considered during this rulemaking. For example, high-speed charging (megawatt charging or more) will almost certainly become a market necessity, which will enable further penetration of ZEVs but will likely have an effect on battery life that manufacturers cannot predict at the time of certification. Similarly, the state of hydrogen infrastructure and the quality and purity of the supplied hydrogen could affect fuel cells in ways that are not well understood today. [EPA-HQ-OAR-2022-0985-1555-A1, p. 68]

Additionally, widespread adoption of Vehicle-to-Grid operations or for auxiliary power draws in the form of so-called Electric Power Takeoff (ePTO) applications are not well understood and could impact battery durability. Both of these technologies could draw as much or more power from the vehicle as driving and must be accounted for in any standard regulating the lifetime operation of the vehicle. [EPA-HQ-OAR-2022-0985-1555-A1, p. 68]

Manufacturers can develop ZEVs to meet any reasonable useful life or durability periods that EPA requires, but it is important to recognize the impact that these requirements would have on vehicle costs and adoption rates. In the Low-NOx Proposed Rule, where EPA last considered promulgating ZEV durability requirements, the Agency proposed to require ZEVs to meet durability timeframes of the longest-lived, highest mileage diesels in order to generate NOx emission credits. As EPA acknowledged in the Low-NOx Proposed Rule, compliance with these requirements would necessarily require manufacturers to make choices that add to vehicle costs and/or diminish functionality:

- '[M]anufacturers could choose to design the battery or fuel cell in their product to have a larger capacity at the start of the vehicle life and limit the extent to which the initial capacity is available for use […] Alternatively, a manufacturer could choose to include battery or fuel cell maintenance or replacement as part of critical emission-scheduled maintenance.'138 [EPA-HQ-OAR-2022-0985-1555-A1, pp. 68-69]

138 See Low-NOx Proposed Rule, 87 Fed. Reg. at 17,559

In other words, a sufficiently long durability or range requirement would require manufacturers to: (1) install a larger battery or fuel cell; (2) limit the capability of the vehicle by restricting its available energy; and/or (3) replace the battery or fuel cell during its useful life. Each of these actions would necessarily add significant cost or reduce the effectiveness of the vehicle at a given cost point, ultimately reducing vehicle versatility and negatively impacting ZEV adoption rates. To avoid this result, manufacturers should be free to develop the products that customers need, and market forces should determine the adequate mix of durability, cost, warranty, and other operational considerations. [EPA-HQ-OAR-2022-0985-1555-A1, p. 69]

Lastly, if EPA were to adopt durability requirements premised upon use of a SOCE or SOCR monitor, these requirements would increase vehicle costs and create regulatory burdens that would put ZEVs at a competitive disadvantage relative to their ICE vehicle counterparts. Such requirements would amount to an 'OBD monitor for range,' which existing conventional vehicles are not required to have. OEMs receive certification based on the GHG emissions performance of their conventional vehicles for the regulatory useful life of the vehicle but are not required to provide a means for monitoring vehicle range over time. For ZEVs, degradation of energy capacity or range is, to some degree, expected and in any case will not cause a ZEV to emit any pollutant. DTNA supports providing SOCE information to the customer but, for the reasons stated herein, would not support durability requirements based on SOCE or SOCR. [EPA-HQ-OAR-2022-0985-1555-A1, p. 69]

EPA should not set any requirements related to a Certified Range, including an initial Certified Range value, or a monitor or other requirement for SOCR. DTNA understands that EPA is considering whether or not it should require vehicles to have a SOCR, including an initial certification for range, a health monitor in terms of certified range, or potentially a durability requirement related to certified range. A range requirement would be incompatible with the unique product and operational realities of commercial vehicles, would not be feasible due to technical considerations, and would not be protective of the environment. [EPA-HQ-OAR-2022-0985-1555-A1, p. 69]

Commercial vehicle ranges are extremely variable and are based to a great degree on the load the vehicle is carrying; its operational characteristics, including terrain and drive profile, and whether it is conducting auxiliary work operations that require a large accessory load; and the specifics of the vehicle equipment. While this is also true for light-duty vehicles to some extent, the variability in range for commercial vehicles is much greater for a given battery capacity, making any certified range value effectively meaningless. Before proposing any requirements regarding certified range, EPA should study this issue to understand the wide variability of ranges in a properly-operating commercial ZEV. [EPA-HQ-OAR-2022-0985-1555-A1, p. 69]

In addition to the considerations above, DTNA believes commercial vehicles have such wide-ranging equipment types that it would be highly impractical to certify a range (or variety of ranges) for a vehicle family. Under existing regulations, there can be a wide range of vehicles within a given family. These vehicles may have widely varying powertrain types and capacities, aerodynamics, transmissions, drive axle ratios, and more, all of which can have dramatic impacts on range. While ZEV vehicle types are limited today, future families including ZEVs are likely to have similarly wide-ranging configurations, and it is quite possible that a vehicle family with one zero-emission powertrain configuration could cover hundreds or thousands of different vehicle specifications, each with widely varying ranges. Moreover, it would be practically impossible for a vehicle manufacturer to determine and certify the range for each configuration. [EPA-HQ-OAR-2022-0985-1555-A1, p. 70]

DTNA supports EPA's proposal to allow BEV manufacturers to develop their own procedures for determining Certified Energy at the time of certification and for SOCE on each vehicle. [EPA-HQ-OAR-2022-0985-1555-A1, p. 70]

Manufacturers are best positioned to determine the appropriate method for calculating the SOCE at the time of certification and for developing appropriate algorithms for onboard SOCE. EPA has previously proposed specific test procedures, such as the proposed Multicycle Test (MCT) in the Low-NOx Proposed Rule. Such proposals are needlessly prescriptive and do not adequately consider the wide range of vehicle applications and impracticality of testing such configurations, as detailed in DTNA's comments on the Low-NOx Proposed Rule.139 [EPA-HQ-OAR-2022-0985-1555-A1, p. 70]

139 See Comments of DTNA North America LLC, Control of Air Pollution from New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards; Proposed Rule (May 13, 2022) at 121-123, https://www.regulations.gov/comment/EPA-HQ-OAR-2019-0055-1168.

Ultimately, the purpose of a battery health test is to measure how much capacity is available in the battery pack. EPA requests comment on whether a vehicle-level test is appropriate for these purposes. It is unclear why components besides the battery should be part of the test. While the drive motor, accessories, control strategies, etc. might change the rate at which power is consumed from the battery, they have no effect on the total amount of energy stored in the battery pack. With many vehicle configurations that could affect the outcome of the test, any vehicle-level test will need to be repeated many times—one for each configuration that affects the test—with no significant additional information to be gained about the capacity of the battery pack. [EPA-HQ-OAR-2022-0985-1555-A1, p. 70]

DTNA supports EPA's proposal to let manufacturers determine the most appropriate test procedures, but if the Agency believes a prescribed test is necessary, it should consider a test that measures battery energy directly using a standardized charge-discharge cycle to determine battery capacity. Such a test reduces the number of configurations a manufacturer must test and provides detailed information about the capacity of the battery in a useable, repeatable manner. The industry already uses such a test for this purpose—the 'Static Capacity Test (Constant Current Method)' set forth in Society of Automotive Engineers (SAE) J1798, 'Recommended Practice for Performance Rating of Electric Vehicle Battery Modules,' which is incorporated by reference in CARB's standards and test procedures for HD zero-emission powertrains.140 [EPA-HQ-OAR-2022-0985-1555-A1, p. 70]

> 140 See CARB, 'California Standards and Test Procedures for New 2021 and Subsequent Model Heavy-Duty Zero Emission Powertrains' (June 27, 2019) at C-11, https://ww2.arb.ca.gov/sites/default/files/2020-05/ADA__California%20Standards%20And%20Test%20Procedures%20For%20New%202021%20And%20Subsequent%20Model%20Heavy-Duty%20Zero-Emission%20Powertrains.pdf.

Any battery health test procedure, for BEVs or for FCEVs, must be developed in concert with truck, battery, and fuel cell manufacturers to adequately capture the wide range of applications and equipment, technology types, and degradation modes of these vehicles, as well as recognize the practical constraints on executing these tests. This is especially important if EPA, in the future, proposes to require a battery durability or in-use verification aspect of their regulation. Such procedures must be developed with manufacturers and account for the challenges of testing in commercial vehicles. [EPA-HQ-OAR-2022-0985-1555-A1, p. 71]

EPA Request for Comment, Request #68: EPA requests comment both on this rule's proposed approach and on an alternative approach of EPA defining a test procedure to determine UBE, such as the test procedure EPA proposed in the HD2027 NPRM, CARB zero-emission powertrain certification, and the test procedures being considered by the UN ECE EVE IWG.

- DTNA Response: DTNA supports EPA's proposal to allow manufacturers to determine UBE, but would not support EPA setting a specific test procedure to determine UBE. If a regulatory test procedure for demonstrating UBE is deemed necessary, however, EPA should adopt battery-only test for UBE, like that incorporated into CARB's zero-emission powertrain certification standards and procedures, rather than any test performed at the chassis or vehicle level. UBE certification at the vehicle or chassis level would be impractical for the HD market, due to the wide variety of vehicles and applications in this sector, and the irrelevance of chassis components to battery energy. DTNA discusses these issues in detail in Section III.A. of these comments. [EPA-HQ-OAR-2022-0985-1555-A1, p. 171]

EPA Request for Comment, Request #69: While we are not proposing to require that heavy-duty BEVs and PHEVs implement a state-of-certified-range (SOCR) monitor, we are requesting comment on whether we should require the SOCR monitor defined in GTR No. 22.

- DTNA Response: EPA should not finalize any requirements regarding SOCR, due in part, to the wide variety of vehicles and applications in the HD market that would make certification impractical, and because electric vehicle range does not affect the CO2 emissions of the vehicles. DTNA discusses these issues in Section III.A. of these comments. [EPA-HQ-OAR-2022-0985-1555-A1, p. 171]

Organization: Fermata Energy

III. Recommendations regarding V2G in EPA rules and EPA's Proposed Battery Durability Monitoring and Warranty Requirements for Heavy Duty Electric Vehicles

Any eventual battery durability requirements set by EPA should account for frequent bidirectional charging (e.g. such as vehicle-to-grid) activities [EPA-HQ-OAR-2022-0985-1662-A2, p.6]

We recognize that the EPA is not setting a battery durability requirement at this time, and is instead proposing to require battery state of health and durability monitoring. The EPA specifically mentioned the need for larger batteries that may not be used as a reason for proposing monitoring. However, the EPA made no mention of the need for vehicle-to-grid technology in heavy duty BEVs and PHEVs in the proposed rule. [EPA-HQ-OAR-2022-0985-1662-A2, p.6]

Battery degradation is an inherently complex topic; battery chemistry, temperature, use cases, the EV duty cycle, and other factors all impact battery degradation. Some V2X activities, especially those utilizing bidirectional charging capabilities, will require additional battery cycling that will impact long-term battery durability. While the exact level of cycling will depend on the specific V2X use case and could vary based on customer behavior, it is reasonable to expect that in the future most EVs could experience some incremental level of degradation due to V2X activities. [EPA-HQ-OAR-2022-0985-1662-A2, p.6]

Given the extensive public and private benefits that V2X can offer, as detailed above, it is paramount that any battery durability requirements EPA establishes for EVs not inadvertently foreclose V2X, and especially V2G opportunities. Setting overly-stringent durability requirements that limit V2X activities – whether intentionally or not – conflicts with EPA's larger mission of reducing emissions and accelerating EV adoption. [EPA-HQ-OAR-2022-0985-1662-A2, p.6]

Furthermore, we note there are ongoing efforts by the Informal Working Group on Electric Vehicles and the Environment under the United Nations Economic Commission for Europe (UN ECE) to develop minimum performance requirements for EV batteries that include V2X considerations. This Working Group is chaired by the US Environmental Protection Agency (EPA) and includes the European Commission, individual European and Asian countries, as well as industry stakeholders from around the world. In order to account for VGI activities, the Working Group is also considering a "virtual km" mechanism, in which the energy discharged by the EV battery in bidirectional mode is converted to a km-equivalent via a predetermined formula.14 The total mileage used for confirming the compliance with the performance requirements would consist of the sum of the km driven and the virtual km. While Fermata Energy is not necessarily endorsing this specific approach or methodology, we believe that the EPA should seriously consider an agreed upon method to account for V2G battery degradation such as the UN Global Technical Regulation "virtual miles" before adopting a final regulation with durability or warranty requirements. [EPA-HQ-OAR-2022-0985-1662-A2, p.7]

14 For example, see the following presentation on V2X virtual mileage at the 50th EVE IWG meeting: https://wiki.unece.org/download/attachments/128420289/Input%20on%20V2X%20virtual%20mileage.pptx?api=v2

In the absence of an agreed upon method to account for V2G battery degradation, OEMs may choose to reach battery warranty agreements with V2X services providers to approve specific equipment for use with their bidirectionally-enabled vehicles. In September 2022, Nissan approved the Fermata Energy bidirectional charger as the first bidirectional charging system for use with its all-electric LEAF vehicle in the US.15 While these sorts of battery warranty approvals are a very important development for the bidirectional charging industry, OEM approval processes can be slow. It may take years for other OEMs to negotiate these sorts of agreements with V2X charger manufacturers and service providers. An agreed-upon methodology for accounting for V2G battery degradation would be the more expedient approach to ensuring battery durability, instead of relying on OEM to EVSE agreements, which could take years. [EPA-HQ-OAR-2022-0985-1662-A2, pp.7-8]

15 https://usa.nissannews.com/en-US/releases/release-5078281d19ed36853371357c4a1a8244-nissan-approves-first-bi-directional-charger-for-use-with-nissan-leaf-in-the-us

Organization: International Council on Clean Transportation (ICCT)

ICCT supports the proposal to establish durability monitoring and warranty requirements for batteries. The battery is the most significant new cost component of a zero-emission vehicle. The used vehicle market will rely to a significant extent on access to objective information on the state of health of the battery to inform residual value calculations. Durability monitoring and warranty requirements will provide greater certainty to fleet customers that their batteries are reliable. These requirements will create a level playing field for the industry to meet minimum reporting and warranty expectations. [EPA-HQ-OAR-2022-0985-1553-A1, p. 5]

Organization: Manufacturers of Emission Controls Association (MECA)

Battery State of Health (SOH) Monitors as per UNECE GTR No. 22b & Labeling

MECA supports the inclusion of SOH monitors and usable battery energy (UBE) measurement requirements as per UN ECE GTR No. 22b that include vehicle miles traveled and power take-off (PTO) equivalent miles traveled. This information will serve to generate durability data to support future EPA programs, as well as industry and consumer needs. The UN-ECE is expected to finalize GTR No.22b in the next year and once completed EPA should assess and align with this global regulation. MECA believes that mandated battery labeling requirements will facilitate in-use vehicle service and end-of-life vehicle recycling. Towards this goal, EPA should align battery labeling requirements with those required under California’s ACC II light-duty regulation. [EPA-HQ-OAR-2022-0985-1521-A1, p. 11]

Organization: Tesla, Inc. (Tesla)

The Proposed Battery State of Health Monitor/State of Certified Energy Provisions for Monitoring Battery Durability Are Reasonable

Building consumer assurance is a key factor towards achieving significantly higher levels of BEV penetration, especially in the heavy-duty markets. Tesla agrees with EPA that consumers should have access to information regarding the state of battery health (SOH), especially those considering the purchase of a used BEV or when filing a warranty claim. As further noted, durability monitoring can ensure emission reduction benefits are met and provide integrity to credit trading. [EPA-HQ-OAR-2022-0985-1505-A1, p. 25]

Tesla has favored a SOH monitor based upon battery capacity because it is directly proportional to vehicle range, depends on the least test conditions, can easily be run with an onboard diagnostic procedure, and can be verified with simple measurement equipment. Nonetheless, Tesla recognizes and participated in proceedings developing the UN GTR 22 and agrees with EPA's adoption of the GTR 22 and a SOH monitor communicating the battery's state of certified energy (SOCE) based upon usable battery energy (UBE).186 [EPA-HQ-OAR-2022-0985-1505-A1, p. 25]

186 88 Fed. Reg. at 26015.

In the heavy-duty NOX NPRM Tesla provided detailed responses to many aspects of the proposed test procedures.187 Given the diversity of heavy-duty platforms, requiring a one size fits all SOCE test procedure will lead to inaccurate and distorted results. Therefore, Tesla supports the agency's proposal to allow BEV manufacturers to develop their own SOCE test procedures.188 The agency is correct that a customer-accessible SOH monitor needs to be accurate, transparent, verifiable and, importantly, easy for a consumer to understand. As such, customers will be best served by allowing manufacturers to develop test procedures that are adapted to their unique vehicle design. Tesla supports the agency's decision to not implement a durability requirement.189 Imposing specific durability testing requirements on BEVs provides no emissions reduction benefit. BEVs do not emit tailpipe (or evaporative) criteria pollutants and changes in battery durability and retained range do not alter this fact. Unlike emission controls in ICE vehicles, BEVs are also not vulnerable to defeat devices and tampering.190 Requiring durability standards can cause greater tailpipe emissions by harming the rate of BEV uptake through imposition of substantial new costs and designs with reserved battery capacity. Tesla respectfully submits that any speculative benefit from consumer assurance provisions such as durability requirements must be balanced against increase up-front costs on BEVs, which are likely to slow consumer uptake and thereby increase emissions. Moreover, as the DOE has documented, BEV range continues to accelerate as the technology is deployed.191 As BEV range increases, the loss of incremental battery capacity over time (due to expected degradation) will matter less to consumers. Similarly, the agency should allow manufacturers to address range monitoring as each sees fit to do, and Tesla does not support imposition of a state of certified range (SOCR) monitor.192 [EPA-HQ-OAR-2022-0985-1505-A1, p. 26]

ii. Authority to adopt requirements for ZEV powertrain components

In the NPRM, EPA claims it has the authority to adopt durability, useful life, and warranty requirements for the various components of ZEV powertrains, including batteries, fuel cells, and electric motors. More specifically, EPA is proposing to set specific mileage and years-based warranty requirements for BEV and FCEV batteries, as well as certain other associated electric powertrain components (e.g., fuel-cell stack, electric motors, and inverters). The proposed warranty periods would be five years or 50,000 miles for light heavy-duty ZEVs, and five years or 100,000 miles for medium-duty and heavy-duty ZEVs. EPA also is proposing to adopt new battery durability monitoring requirements for HD BEVs and plug-in hybrid electric vehicles (PHEVs) beginning with the 2027 model year. EPA is further proposing to mandate that OEMs provide a customer-facing battery state-of-health (SOH) monitor for all heavy-duty BEVs and PHEVs. The SOH monitor would need to monitor and communicate the vehicle's state of certified energy (SOCE), including the state of the usable battery energy (UBE) expressed as a percentage of the original UBE when the BEV was new. [EPA-HQ-OAR-2022-0985-2668-A1, p. 17]

Notwithstanding its claims, EPA does not have the delegated authority under the CAA to adopt the proposed requirements for ZEV batteries and associated electric powertrain components, which have no capability of producing emissions of any air pollutants. EPA's authority to adopt warranty, durability and useful life requirements for motor vehicles is delineated in CAA sections 202(d), and 207(a) and (b). Those provisions constrain EPA's authority to ensuring vehicles' and engines' compliance for prescribed periods of time with "standards applicable to the emission of any air pollutant from any class or classes of new motor vehicles or new motor vehicle engines." (CAA section 202(a)(1); 42, U.S.C. §7521(a)(i).) [EPA-HQ-OAR-2022-0985-2668-A1, pp. 17 - 18]

For example, CAA section 202(d) states that EPA "shall prescribe regulations, under which the useful life of vehicles and engines shall be determined for the purpose of subsection (a)(1) of section 7541 [CAA section 202(a)(1)]." As noted, that statutory purpose is to authorize EPA to establish standards to limit "the emission of any air pollutant from any class or classes of new motor vehicles or new motor vehicle engines." The CAA defines "air pollutant" to mean "any air pollution agent or combination of such agents...substance or matter which is emitted into or otherwise enters the ambient air." (CAA, section 302(g); 42 U.S.C. §7602(g).) The CAA further defines "emission standard" to mean a requirement "which limits the quantity, rate or concentration of emissions of air pollutants on a continuous basis." (42 U.S.C. §7602(k).) Thus, EPA's authority to prescribe useful life requirements under CAA section 202(d) is directly tied to the purpose of extending the time span of emission standards that limit the rate, quantity or concentration of emissions of air pollutants from new motor vehicles or new motor vehicle engines. Since ZEV powertrains, including ZEV batteries, do not and cannot emit any air pollutants in any quantity into the ambient air (and so, in effect, are outside of the practical scope of emission standards), EPA does not have the authority to set emissions-related useful life requirements for BEV and FCEV powertrains or their various non-emitting components. [EPA-HQ-OAR-2022-0985-2668-A1, p. 18]

Similarly with respect to the proposed warranty and durability requirements, EPA's authority to adopt those types of requirements is set forth in CAA section 207. In particular, CAA section 207(a)(1) makes it clear that the scope of authorized warranties is to ensure that vehicles and engines "are designed, built and equipped so as to conform at the time of sale with the applicable regulations [i.e. emission standards] established under section 7521 [section 202(a)(1)]." (42 U.S.C. §7541(1).) Here again, ZEV powertrains and associated components do not and cannot emit any air pollutants, and so are not among the types of combustion sources that can be subject to emission standards. Consequently, they are not among the types of mobile sources that can be covered by the emissions-related warranties authorized under the CAA. [EPA-HQ-OAR-2022-0985-2668-A1, p. 18]

While it is certainly true that EPA has the authority to set lower emission standards as advancements in technology allow, even down to zero, the scope of EPA's related authority to establish emissions warranty and durability periods is fundamentally different. More specifically, EPA does not retain the authority to establish "emissions-related" warranty and durability requirements for mobile source powertrains that are inherently incapable of generating any emissions of any air pollutants, including when those ZEV powertrains deteriorate, malfunction, or completely breakdown. [EPA-HQ-OAR-2022-0985-2668-A1, p. 18]

It is axiomatic that ZEV powertrains do not have the capacity to emit air pollutants. That holds true when those powertrains are new, when they are deteriorated, and even when they cease working altogether. Thus, ascribing "emissions-related" warranty and durability requirements to those ZEV powertrains and their components is, in effect, a non sequitur. [EPA-HQ-OAR-2022-0985-2668-A1, p. 18]

EPA's authority to prescribe emissions-related warranty and durability regulations is premised on the concept that mobile sources subject to the regulations need to rely on emissions-reducing components, such as exhaust aftertreatment systems, that can deteriorate over time in a manner that can increase emissions in-use to levels above the applicable underlying emission standards. EPA clearly has the authority to guard against those adverse results by adopting emissions-related warranty and useful life provisions that promote both the manufacture of more durable emissions-related components, and the prompt repair of malfunctioning emissions-related components. [EPA-HQ-OAR-2022-0985-2668-A1, p. 19]

But none of the above pertains to ZEV powertrain components that are inherently incapable of generating any air pollutants whatsoever. As a consequence, EPA's authority to adopt emissions-related warranties and durability periods also does not apply. It is the same reason that EPA is not authorized to adopt emissions-related warranty and durability regulations for steering wheels, brake pedals, windshields, or even current-technology car and truck batteries. [EPA-HQ-OAR-2022-0985-2668-A1, p. 19]

In the end, EPA's proposed warranties and durability requirements for ZEV batteries and other ZEV powertrain components amount to attempted forays into the regulatory realm of consumer protection – an attempt to ensure that ZEV powertrains meet consumer expectations and needs for range and reliability. EPA's jurisdiction does not extend that far. [EPA-HQ-OAR-2022-0985-2668-A1, p. 19]

In sum, the useful life, warranty and durability requirements EPA is authorized to adopt under the CAA are all directly tied to ensuring compliance over time with the air pollutant emission standards that EPA sets for new motor vehicles and new motor vehicle engines. Since ZEV powertrains and their associated components do not and cannot emit any air pollutants, and so are not within the scope of any specific emission standards, they are, by definition, also not within the scope of EPA's regulatory authority as it pertains to useful life, warranty and durability requirements. Consequently, those types of proposals must not be included in any final Phase 3 rule. [EPA-HQ-OAR-2022-0985-2668-A1, p. 19]

Battery Durability Monitor – Notwithstanding our comments above on EPA's lack of delegated authority under the CAA to adopt the proposed battery durability monitor requirements, we offer several provisional comments on those proposed provisions. [EPA-HQ-OAR-2022-0985-2668-A1, p. 54]

The NPRM includes proposed regulatory language for the battery durability requirements in 40 C.F.R. § 1037.115(f), stating that "[t]he requirements of this section apply starting in model year 2030. See, 88 Fed. Reg. 26124 (emphasis added). We agree that the proposed effective date of MY 2030 would be earliest reasonable timing within which to implement battery durability monitors. Developing battery durability monitors will require significant and time-consuming development work by manufacturers. It will take time and resources for manufacturers to design the monitor systems, develop test procedures for measuring battery energy, and to ensure that the procedures accurately and repeatably measure the battery energy. That task is made significantly more challenging by the large number of battery configurations that manufacturers must develop to meet the needs of the highly diverse commercial vehicle market. Additionally, manufactures must redesign many unique vehicle dashboards to incorporate the required state-of-energy displays; and changing dashboards requires notoriously long lead-times due to the necessary tooling changes, and their complex interactions with multiple vehicle systems. [EPA-HQ-OAR-2022-0985-2668-A1, pp. 54 - 55]

The preamble contains an apparent typographical where it states that "EPA is proposing new battery durability monitoring for HD BEVs and PHEVs … beginning with MY 2027." See, Id. at 26014 (emphasis added). That early implementation is not consistent with the proposed regulatory language, and, more importantly, is not feasible. [EPA-HQ-OAR-2022-0985-2668-A1, p. 55]

The NPRM would require that manufacturers "use good engineering judgement to develop a test procedure for determining useable battery energy (UBE)." See, Id. at 26124. There is no doubt that manufacturers are in the best position to develop the most effective and efficient test procedures for measuring UBE. Measuring UBE for the many different battery configurations needed for the commercial vehicle market may necessitate bench-testing to avoid the costs and complexity associated with vehicle-level testing. One effective method for conducing that bench-testing is the SAE International standard J1798_200807 – Recommended Practice for Performance Rating of Eclectic Vehicle Battery Models, which is incorporated by reference in CARB's Heavy-Duty Zero-Emission Powertrain Certification Requirements. See, 13 CCR § 1956.8, D. [EPA-HQ-OAR-2022-0985-2668-A1, p. 55]

The NPRM also includes in the battery durability monitor requirements in 40 C.F.R. § 1037.115(f) several references to the United Nations Economic Commission for Europe (UNECE) Global Technical Regulation (GTR) No. 22 on In-Vehicle Battery Durability for Electrified Vehicles:

Battery durability monitor. Battery electric vehicles and plug-in hybrid electric vehicles must meet monitoring requirements related to batteries serving as a Rechargeable Energy Storage System from GTR No. 22 (incorporated by reference, see § 1037.810). The requirements of this section apply starting in model year 2030. The following clarifications and adjustments to GTR No. 22 apply for vehicles subject to this section:

(1) Install a customer-accessible display that monitors, estimates, and communicates the vehicle's State of Certified Energy (SOCE) include information in the application for certification as described in § 1037.205. Monitoring requirements related to State of Certified Range (SOCR) do not apply.

(2) Accuracy requirements for SOCE in GTR No. 22 do not apply. Minimum Performance Requirements for battery durability also do not apply. (See, 88 Fed. Reg. 26124 (emphasis added).) [EPA-HQ-OAR-2022-0985-2668-A1, p. 55]

The proposed battery durability monitor requirements in 40 C.F.R. § 1037.115(f) that reference GTR No. 22 are imprecise and unclear. GTR No. 22 is a comprehensive standard with numerous detailed requirements. While the proposed regulatory language identifies several sections of GTR No. 22 that do not apply, the language does not specify which clauses of GTR No. 22 do apply. Additionally, the UNECE is currently developing revisions to GTR No. 22, and will soon approve an amended version. A general reference to a GTR, which may soon be out-of-date, is not appropriate or implementable. Instead, we recommend that § 1037.115(f) include the following straightforward and implementable requirements:

- The manufacturer shall install a State of Certified Engine (SOCE) monitor that operates during the life of the vehicle. The SOCE monitor shall maintain an estimate of the state of certified energy (on-board SOCE).
- The manufacturer shall determine the algorithms by which on-board SOCE is determined for the vehicles they produce. The manufacturer shall update the on-board SOCE with sufficient frequency as to maintain the necessary degree of accuracy during all normal vehicle operation.
- The on-board SOCE shall have a resolution of 1 part in 100 and be reported as the nearest whole number from 0 to 100.
- The manufacturer shall make available the most recently determined values of the on-board SOCR and on-board SOCE via the OBD port or otherwise make the SOCE available to the operator.
- For BEVs, use good engineering judgment to develop a test procedure for determining UBE.
- For PHEVs, determine UBE as described in 40 C.F.R. § 1036.545. [EPA-HQ-OAR-2022-0985-2668-A1, pp. 55 - 56]

Organization: Zero Emission Transportation Association (ZETA)

iv. Range and durability

In the LDV segment, a recent study found that a majority of EVs retain at least 90 percent of their original range capacity left even after driving more than 100,000 miles—a testament to battery durability.122 While HDVs operate under different duty cycles and applications, there is good reason to believe advances in LDV battery technologies and durabilities will extend into other vehicle classes. CATL—recently announced a new "condensed" battery with 500 Wh/kg. CATL expects to start mass production of the model in 2023,123 and such an increase in battery capacity will benefit HDEVs in an outsized way. Bloomberg recently reported that the average range for a U.S. EV in the U.S. has quadrupled since 2011. In 2022, it stood at 291 miles and today is a third higher than the global average.124 Policies such as EPA's emissions standards are critical to helping maintain the U.S.'s position as a global leader. [EPA-HQ-OAR-2022-0985-2429-A1, p. 29. This comment can also be found in section 4 of this comment summary.]

EPA Summary and Response:

Summary:

Multiple commenters including the American Fuel and Petrochemical Manufacturers, Allergy & Asthma Network et al., ICCT, CARB, MECA, … commented that EPA should finalize durability requirements for ZEV, to ensure ZEV durability is comparable to the comparable HD ICE powertrain.

CARB commented that EPA should finalize entire system monitoring requirements instead of requirements just for the battery. CARB suggested that SAE J1798 should be used for determining battery energy capacity and stated that EPA should include battery durability subfamily definitions. CARB further maintained that EPA should adopt California's Zero Emission Powertrain (ZEP) Test Procedure for the battery monitor.

Clean Air Task Force et al. commented that EPA should finalize the proposed durability requirements and make them effective for MY2027 and later vehicles. They also commented that EPA should require state-of-certified-range monitors.

Cummins commented that they support common sense battery durability requirements to ensure a level playing field across all zero emissions vehicle manufacturers and to ensure that vehicle owners receive robust new technology which will spur broader adoption. Cummins commented that having a standard test procedure for determining usable battery energy (UBE) is needed to ensure a level playing field.

DTNA supports the proposed battery durability monitoring requirements, but also stated that EPA should not set durability standards. DTNA doesn't support a state-of-health (SOH) monitor based on state-of-certified range (SOCR). DTNA supports allowing manufacturers to define the test procedure for determining UBE. DTNA commented that EPA should allow manufacturers to develop their own test procedure for determining UBE, and that if EPA must define a test procedure, it should align with CARB's zero-emission powertrain certification standards and procedures. DTNA commented that EPA should include all the durability monitoring requirements in 40 CFR 1037, rather than reference the GTR No. 22. DTNA commented that impacts from vehicle-to-grid and electric power takeoff applications are not well understood and could impact battery durability. DTNA also commented that it is not clear why components other than the battery should be included in the test.

EMA agreed with the proposal (including proposed regulatory text) stating that battery durability requirements commence in MY 2030. In their view, MY 2030 would be the earliest reasonable timing within which to implement battery durability monitors. In this regard, EMA notes an inconsistency between the proposed regulatory text (giving MY 2030 as the commence date) and the Preamble, which gave MY 2027 as the starting date.

EMA supports the NPRM requiring that manufacturers "use good engineering judgement to develop a test procedure for determining useable battery energy (UBE)."

EMA comments that battery electric vehicles and plug-in hybrid electric vehicles must meet monitoring requirements related to batteries serving as a Rechargeable Energy Storage System from GTR No. 22. The requirements of this section apply starting in model year 2030. EMA requests that the following clarifications and adjustments to GTR No. 22 be made for vehicles subject to this section:

(1) Install a customer-accessible display that monitors, estimates, and communicates the vehicle's State of Certified Energy (SOCE) include information in the application for certification as described in 40 CFR 1037.205. Monitoring requirements related to State of Certified Range (SOCR) do not apply.

(2) Accuracy requirements for SOCE in GTR No. 22 do not apply. Minimum Performance Requirements for battery durability also do not apply.

EMA comments that the proposed battery durability monitor requirements in proposed 40 C.F.R. § 1037.115(f) that reference GTR No. 22 are imprecise and unclear. GTR No. 22 is a comprehensive standard with numerous detailed requirements. While the proposed regulatory language identifies several sections of GTR No. 22 that do not apply, the language does not specify which clauses of GTR No. 22 do apply. They recommend that § 1037.115(f) include the following language, which they characterize as providing straightforward and implementable requirements:

The manufacturer shall install a State of Certified Engine (SOCE) monitor that operates during the life of the vehicle. The SOCE monitor shall maintain an estimate of the state of certified energy (on-board SOCE).

The manufacturer shall determine the algorithms by which on-board SOCE is determined for the vehicles they produce. The manufacturer shall update the on-board SOCE with sufficient frequency as to maintain the necessary degree of accuracy during all normal vehicle operation.

The on-board SOCE shall have a resolution of 1 part in 100 and be reported as the nearest whole number from 0 to 100.

The manufacturer shall make available the most recently determined values of the on-board SOCR and on-board SOCE via the OBD port or otherwise make the SOCE available to the operator.

For BEVs, use good engineering judgment to develop a test procedure for determining UBE.

For PHEVs, determine UBE as described in 40 C.F.R. § 1036.545.

EMA and Volvo commented that EPA doesn't have the legal authority to require a battery durability monitor for ZEVs, the argument being that CAA section 202(d), 207 (a), and 207 (b) do not apply to vehicles with no tailpipe emissions. They make the same argument with respect to warranty and useful life requirements for ZEV powertrains and related components. EMA agrees that EPA may issue emission standards, including standards of zero, for new motor vehicles. However, EMA asserts that, thereafter " EPA does not retain the authority to establish "emissions-related" warranty and durability requirements for mobile source powertrains that are inherently incapable of generating any emissions of any air pollutants, including when those ZEV powertrains deteriorate, malfunction, or completely breakdown." EMA states that this is because "[i]t is axiomatic that ZEV powertrains do not have the capacity to emit air pollutants." EMA likens warranty and durability requirements issued under such circumstances to issuing warranty and durability standards for floor mats or steering wheels. We address these arguments together in the response following these summaries.

MECA commented that they support inclusion of SOH monitors and usable battery energy (UBE) measurement requirements that include vehicle miles traveled and power take-off (PTO) equivalent miles traveled. MECA also commented that EPA should require battery labeling requirements.

Fermata Energy commented that EPA should not set durability requirements that would discourage the use of V2X. The durability monitoring requirements and minimum performance requirements should consider V2X.

Tesla supported the proposed durability monitoring requirements, including the proposal to not define the test procedure for determining UBE.

Response Concerning Legal Authority:

EPA does not accept the argument that it lacks legal authority to adopt durability, warranty, and useful life requirements for ZEV powertrains and components. EPA's response is set out in full in Preamble Section III.B. As explained there, we reject EMA's suggestion that EPA does not have authority to set durability or warranty requirements because ZEV batteries are not emission-related for several reasons. First, EMA argues that because ZEVs do not themselves emit, they and their powertrain components are "not within the scope of any specific emission standards," and therefore they cannot be subject to "emissions-related" durability and warranty requirements. But EPA does have the authority to set standards for ZEVs as they are part of the "class" of regulated vehicles. Congress authorized EPA to regulate *classes* of vehicles, and EPA has concluded that emission of air pollutants from the *class* of heavy-duty vehicles as a whole causes, or contributes to, air pollution emissions which endangers public health and welfare. See Preamble Section I.C and RTC Section 10.2.1.f. Thus, the class of new motor vehicles for which EPA must establish emission standards are those whose emissions contribute to endangerment, CAA section 202(a)(1), namely "Passenger cars, light-duty trucks, motorcycles, buses, and medium and heavy-duty trucks."[809] The *class* of heavy-duty vehicles includes heavy-duty electric vehicles.

In addition, all vehicles, including ZEVs, are subject to an applicable Family Emission Limit (FEL) throughout their useful life to demonstrate compliance with EPA's GHG emissions standards.[810] EMA is thus incorrect in suggesting that useful life, warranty, and durability standards are unimplementable for ZEV powertrains and components. EPA accounts for durability at certification by requiring, as part of the compliance demonstration for meeting GHG emission standards, a demonstration that emission controls will not deteriorate during useful life, a battery in a hybrid electric vehicle being the given example. 40 CFR 1037.241(c); see generally RTC section 10.2.1.d . Durability of a BEV battery is covered by this same provision and principle Vehicle manufacturers also warrant at the time of sale that each new vehicle is designed to comply with all applicable emission standards and will be free from defects that may cause noncompliance. CAA section 207. Thus, under 40 CFR 1037.120, manufacturers must warrant to the ultimate purchaser, and to subsequent purchasers, that the vehicle is "designed, built, and equipped" to conform at time of sale with all applicable standards, and is free of defects that will cause it to fail to conform in use during the applicable warranty period. 40 CFR section 1037.120(a)(1) and (2). Components covered by the warranty include all emission-related components included in the manufacturer's application for a certificate of conformity, which are keyed to the FEL assigned to those vehicles. These provisions comport entirely with section 207 of the Act and are readily determinable at time of sale by reference to the certified FEL limit. See generally Preamble Section III.B and RTC 10.2.1.d.3.

EMA argues secondly that a component only counts as emission-related if its failure would allow the vehicle to continue operating, but with higher emissions. But nothing in the statute imposes such a limitation. Moreover, while it is true that the failure of a battery would cause the vehicle to stop operating, the same is true for some other vehicle components that have also historically been subject to durability requirements. For instance, EPA has set durability requirements for diesel engines (see 40 CFR 86.1823-08(c)), failure of which could cause the vehicle to stop operating. Similarly, Congress explicitly provided that electronic control modules (ECMs) (described in the statute as "electronic emissions control units") are "specified major emissions control component[s]" for warranty purposes per section 207(i)(2); failure of ECMs can also cause the vehicle to stop operating, and not necessarily increase the emissions of the vehicle.

EMA is similarly incorrect in asserting that by applying durability and warranty requirements to vehicular components which do not emit, EPA is engaging impermissibly in a type of consumer protection. In fact, such provisions are routine. The Phase 2 rule, for example, includes "emission-related warranty requirements" for a series of ICE vehicle components which themselves do not emit but whose performance is necessary to assure that a vehicle complies with the standards throughout its useful life, among them vehicle speed limiters, tire pressure monitoring systems, idle-reduction systems, aerodynamic components, and hybrid system

[809] 74 FR 66496, 66537 (Dec. 15, 2009).
[810] See Preamble section I.C and Response to Comments Section 10.2.1 for further description of EPA's authority to set standards under section 202(a) using an averaging form, and to include ZEVs and PHEVs within a fleet average-based standard. For a more detailed description of the ABT process for HDVs, see section III.A above and section 10.2.1.d of the Response to Comments. EPA replies to the commenter's assertions regarding authority to establish standards for a vehicle's useful life as part of that same response to comments as well as in Preamble section III.B. .

components. 40 CFR section 1037.120(c). ZEV powertrains and components are exactly comparable: they are, in the words of the regulation, all “emission-related components,” id., and in the words of the statute, “devices to prevent or control pollution.” CAA section 202(a)(1).

EPA's authority to set and enforce durability requirements for emission-related components like batteries is an integral part of its title II authority. Durability requirements ensure that vehicle manufacturers and the vehicles they produce will continue to comply with emissions standards set under 202(a) over the course of those vehicles' useful lives. EPA has separate authority to set warranty requirements for batteries in ZEVs and PHEVs. CAA section 207(a)(1). Providing a warranty for emission-related components like batteries precisely accomplishes the Congressional purpose of assuring purchasers that vehicles will conform to applicable emission standards at time of sale and in use. For standards to be meaningfully applicable across a vehicle’s useful life, EPA’s assessment of compliance with such standards necessarily includes an evaluation of the performance of the emissions control systems, which for BEVs, FCEVs, and PHEVs includes the battery system both when the vehicle is new and across its useful life. This is particularly true given the averaging form of standards that EPA uses for GHG emissions (and which EMA continues to support), and with which most manufacturers choose for demonstrating compliance. For EPA to determine the level at which to set fleet average standards, the Agency needs to have confidence that the emissions reductions—and thus credits generated —by each ZEV and PHEV introduced into the fleet are reflective of the real world. This is particularly important because one of the elements of the credit generating formula is useful life of the vehicle in miles travelled. See 40 CFR 1037.705(a). Although the standards exist independently from durability, ensuring that ZEVs contain durable batteries is thus linked to the integrity of the averaging process: assuring that vehicles will perform in fact for the useful life mileage reflected in any credits they may generate. Put another way, durable batteries are a factor ensuring the real-world performance of the averaging form of the standard: that the standard is met per vehicle, and on average, per fleet throughout the vehicles’ useful life. The battery warranty provisions finalized in this rulemaking in turn allow for confidence that the batteries installed by vehicle manufacturers are durable and thus support the standard.

See Section III.B of the preamble for a complete response.

Responses to Remaining Comments

We do not agree with CARB’s comment that EPA should adopt an entire system monitoring requirement as Part of the Phase 3 rule (and CARB appears to advocate that such a program commence in the initial model year of the program as well). We didn’t propose such a requirement, and such a requirement would merit full public process including an opportunity for comment. In addition, CARB didn’t provide sufficient detail on what an “entire system monitoring requirement” would be, so we lack the necessary detail to finalize an entire system monitoring requirement at this time. Regarding the comment from CARB that SAE J1798 should be required for determining usable battery energy (UBE), we don’t agree. See Preamble Section III.B for details on why we are finalizing as proposed that manufacturers will seek approval for the procedure to determine UBE, and the criteria manufacturers would have to consider in making that determination. In addition, we disagree that now is the right time to finalize a subfamily definition, as we are still learning what parameters are important for dividing ZEV families. For example, we have not determined whether a ZEV family be divided into subfamilies if the ZEV family includes multiple battery families, or whether ZEV only be divided into subfamilies if the ZEV family includes multiple battery chemistries. We believe that these decisions are best made once there is more real-world data on these ZEV.

We disagree with the comment from Clean Air Task Force that the durability monitoring requirement should start with MY 2027, as this would only provide manufacturers a few years to develop and get approval for the test procedure to determine UBE. The final rule provides necessary lead time, with this requirement commencing in MY 2030.

We disagree with the comment from Cummins that the Phase 3 rule should include a standard test procedure for determining UBE. As discussed in Section III.B of the preamble, the final rule instead provides for individual approvals of UBE test procedures, based on criteria set in the regulations.

We agree with the comments that now is not the right time to finalize durability standards for ZEV. As we discussed in Section III.B of the preamble, we are instead finalizing durability monitoring requirements for ZEV. We also agree with DTNA's comment that all the durability monitoring requirements should be included in 40 CFR 1037 and, consistent with DTNA's comment that confusion might result from incorporating GTR No. 22 by reference without further specification as to what parts apply, have not included a reference to GTR No. 22 for any of the durability monitoring requirements. DTNA requested clarification or definitions as to which components would be included in a test procedure, but this comment is moot since, as noted, the final rule provides for individual applications for test procedures to determine UBE. Determination of which components are included consequently will be determined case-by-case as part of that application process.

Regarding the comments from DTNA, Fermata, and MECA that the durability requirements should consider impacts on the use of V2X or the use of PTO, we are finalizing a durability *monitoring* requirement, without setting minimum performance requirement of maintaining a certain SOCE value for a defined period of time. Because of this, the finalized requirements do not directly impact V2X or PTO considerations. If the use of V2X or PTO had significant impacts on the durability of the battery, the monitor should detect those impacts. The finalized requirements leave it to the user to decide how to respond. However, in a future action, EPA may decide to set minimum performance requirements for SOCE and if so, EPA may consider how the use of V2X and PTO will impact the durability of the battery.

Regarding EMA's comment on the implementation date of the durability monitoring requirements, we have clarified that the requirements start with MY 2030, as consistently stated throughout this rule and in the regulatory text.

Regarding the comments on the proposed revisions to 40 CFR 1037.115(f), we have considered them along with the other comments on this section in the text of the final regulation. As noted above, we agree that the rule text should contain all the requirements instead of incorporating by reference the requirements in GTR No. 22. We agree with the comments that the SOCR monitor and the Minimum Performance Requirements should not be required at this time. As discussed further in the Section III.B of the preamble, we are however finalizing accuracy requirements for the SOCE monitor.

Regarding MECA's comments on finalizing requirements for battery labeling, we disagree that this is the right time to do so. We believe that requirements like this would be better considered when there are more HD ZEV in the market to make an informed decision on what labeling information would be needed, such that we don't add requirements that result in unnecessary barriers to the development of the technology.

11.2 Warranty

Comments by Organizations

Organization: Allergy & Asthma Network et al.

We also continue to urge EPA to reflect the full useful life of heavy-duty vehicles in their testing and warranty requirements. Warranty provisions must match the full useful life of the vehicle, and we encourage EPA to consider this as one million miles. [EPA-HQ-OAR-2022-0985-1532-A1, p. 4]

Organization: American Fuel and Petrochemical Manufacturers (AFPM)

Clear guidance on repackaging, certification, standardization, and warranty liability of spent EV batteries would be needed to overcome safety and regulatory challenges reuse poses at scale.109 [EPA-HQ-OAR-2022-0985-1659-A2, p. 29]

109 IEA Report 2022.

Organization: American Thoracic Society (ATS)

ATS encourages EPA to ensure required reductions are achieved in the real world. Reductions in vehicle tailpipe emissions has largely been a success story, with the automobile industry ushering in significant technology advances to reduce overall emissions. Unfortunately, we have seen many cases of car and heavy-duty truck companies trying to 'beat' emissions standards through deceit and evasion rather than 'meeting' standards through innovation. The ATS encourages EPA to ensure that it has appropriate post purchase surveillance capacity to ensure promised emissions reductions are achieved in real world use. [EPA-HQ-OAR-2022-0985-1517-A1, p. 4]

ATS recommends that EPA requires heavy-duty manufacturers to warranty the functionality of vehicle tailpipe GHG and criteria pollutant control technology through the expected useful lifetime of the heavy-duty vehicle. Allowing industry to warranty emissions control systems for a short time will likely encourage cheating and likely prevent achieving the anticipated emissions reductions. [EPA-HQ-OAR-2022-0985-1517-A1, p. 4]

Organization: California Air Resources Board (CARB)

2. Warranty Requirements

a. BEV and FCEV Component Warranty

Affected Page: 26016

The NPRM is proposing that manufacturers identify HD BEV and FCEV batteries and associated electric powertrain components as components covered under the emission-related warranty in the vehicle's application for certification. These components would be covered under the existing regulations' emissions warranty periods of five years or 50,000 miles (whichever is greater) for light HDVs or five years or 100,000 miles (whichever is greater) for medium HDVs and heavy HDVs. [EPA-HQ-OAR-2022-0985-1591-A1, p.56]

CARB staff recommends that U.S. EPA consider providing additional guidance for manufacturers to determine which components would be covered under warranty, how failures would be defined, and what types of failures would be covered under warranty. Without further guidance, manufacturers may not properly identify all components that should be covered under warranty. Perhaps certain components and systems (inverters, motors, thermal management systems, etc.) can be required to be included as parts identified to be covered under warranty for all vehicles. This would give potential purchasers confidence that common major components would be covered under warranty. [EPA-HQ-OAR-2022-0985-1591-A1, p.56]

Additionally, providing specific parameters for when the failure of a battery or other component used with HD BEVs or FCEVs should be covered under warranty would be valuable for potential purchasers. For example, the battery warranty does not specify what amount of deterioration would be considered a failure that would be covered under warranty. This could lead to manufacturers having different levels of what they consider a failure causing confusion and uncertainty amongst potential purchasers. [EPA-HQ-OAR-2022-0985-1591-A1, p.56]

Not having certainty of the level of deterioration that would be covered could be problematic for potential purchasers as battery repairs/replacements would be very costly. Also, if a battery deteriorates too much, it could render a vehicle useless as it may no longer be able to perform the tasks that it was designed for due to the limited amount of usable energy it could store. If the warranty specifically stated how much the state of health of a battery could deteriorate over the warranty period, and there were clearer guidelines that could better inform potential purchasers about what types of failures would be covered under warranty, it could lead to increased consumer confidence and support for HD ZEV adoption. [EPA-HQ-OAR-2022-0985-1591-A1, p.57]

Organization: Clean Air Task Force et al.

V. EPA Should Adopt the Proposed Warranty and Durability Requirements.

B. EPA should adopt the proposed warranty requirements.

We support the proposed warranty provisions, which fall well within EPA's authority under the Clean Air Act. Section 207 provides that manufacturers of motor vehicles must warrant that the vehicle is "free from defects in materials and workmanship which cause such vehicle . . . to fail to conform with applicable regulations" for the warranty period specified by EPA through regulation. 42 U.S.C. § 7541(a)(1). Using this authority, EPA has historically required manufacturers to provide warranties for a broad array of "emission-related" vehicle components, including tires, tire pressure monitoring systems, speed limiters, and aerodynamic performance devices, 40 C.F.R. § 1037.120(c), all of which play a role in reducing vehicle emissions. BEV and FCEV batteries, fuel-cell stacks, electric motors, and inverters are no different—they are "emission-related" components because they enable the elimination of tailpipe emissions from motor vehicles. We agree with EPA's rationale for applying warranty requirements to BEV and FCEV batteries and associated emission-related electric powertrain components, 88 Fed. Reg. at

26016-17, and we urge EPA to finalize this aspect of the proposal. [EPA-HQ-OAR-2022-0985-1640-A1, p. 82]

Organization: Daimler Truck North America LLC (DTNA)

While DTNA recognizes the benefit of an emissions warranty for conventional vehicles, these benefits are not the same for ZEVs. Emissions-related warranties for conventional vehicles help ensure that customers are motivated to repair failures of emissions control equipment throughout the vehicle's life. Since a manufacturer must account for potential warranty outlays and pass that cost to the customer at the time of initial purchase, customers have 'already paid for' the eventual repairs to their emissions control systems and do not face a substantial disbenefit (the added cost of the repair) when considering whether or not to repair the system. If the customer elects not to repair emissions control equipment that is under warranty, the vehicle continues to operate while potentially emitting higher levels of controlled pollutants. [EPA-HQ-OAR-2022-0985-1555-A1, p. 66]

The same logic does not apply for ZEVs, as they do not have failure modes that can cause increased emission levels of controlled pollutants. The only failures that EPA aims to warrant against for a ZEV are failures that have direct operational impacts on the customer, which is motivation enough to drive a repair. DTNA believes that ZEV warranty coverage and length should be an area of competition between OEMs, where manufacturers seek to best optimize for their customers' demands and thereby drive the highest ZEV penetration rates possible. [EPA-HQ-OAR-2022-0985-1555-A1, p. 66]

DTNA supports well-informed and carefully crafted regulations, which can serve as a check to make sure that all manufacturers entering the commercial ZEV market provide a baseline level of assurance for product durability, protecting against market distortion by manufacturers offering low-cost, low-quality products that they will not stand behind. However, overly onerous product requirements can serve to increase product cost, drive additional manufacturer burden, and reduce the number of choices manufacturers are able to provide to customers, thereby slowing ZEV adoption rates and undermining EPA's aims in this rulemaking. [EPA-HQ-OAR-2022-0985-1555-A1, p. 67]

EPA's proposed ZEV warranty requirement and the current useful life mileages, which are based on the existing GHG Phase 2 values, represent an adequate compromise such that manufacturers will not be required to offer costly warranties that customers may not want. [EPA-HQ-OAR-2022-0985-1555-A1, p. 69]

EPA should make a number of clarifications to its warranty proposal regarding covered components and failures.

EPA proposes to require manufacturers to identify BEV and FCEV batteries and 'associated electric powertrain components' in their certification applications as components covered under the existing emission-related warranty.141 To eliminate any confusion over this requirement, EPA should specify the 'associated components' that must be covered by warranty. While it is clear in the Proposed Rule that high-voltage battery and fuel cell stacks must be covered, the ambiguous phrase 'associated electric powertrain components' used in the preamble and the proposed use of the phrase 'other components' in 40 CFR 1037.120(c) could include any combination of components, from motors and inverters to power distribution modules, cabling, control surfaces, cooling systems, and more. To increase regulatory certainty, and to ensure that manufacturers are on a level playing field with respect to warranty costs, EPA should revise 40 CFR 1037.120(c) to specify which ZEV components are covered by the emission-related warranty. DTNA recommends that EPA clarify that only the high-voltage battery or fuel-cell stack should be covered by the emissions warranty. Alternately, EPA could consider the list of components defined by CARB's definition of 'Zero Emissions Powertrain.' [EPA-HQ-OAR-2022-0985-1555-A1, p. 71]

141 Proposed Rule, 88 Fed. Reg. at 26,016.

EPA should also clarify its warranty requirement to specify that a covered failure is one that results in a complete lack of motive capability. Mere degradation of the battery and/or associated ZEV powertrain components, which could result in a reduction of range but not a complete lack of motive capability, should not be considered a warrantable failure under the emission-related warranty requirements. ZEV range degradation does not impact the vehicle's emissions of CO2 or other criteria pollutants. It would be impossible for EPA to determine an adequate reduction in range that could be described as a failure in all circumstances, and that could not rightly be described as a properly operating vehicle in other contexts. For example, if an OEM were to sell one configuration with an estimated range of 250 miles, which, over its life, experienced degradation that reduced its nominal range to 125 miles, this could be described as a 'failure' in some contexts. However, that same OEM would be able to sell a similar vehicle with a smaller vehicle which started life with a nominal range of 125 miles. That vehicle would not be considered 'failed' at the start of its life, and in fact, both vehicles would qualify for the same amount of CO2 credit under EPA's rules—since they both emit zero CO2 over their useful lives. Such comparisons illustrate why EPA should clarify that an emissions-related warranty only covers component failures that result in a complete lack of motive capability. Manufacturers are free to warrant the range of the vehicle over a period of time as the market demands and the technology supports. [EPA-HQ-OAR-2022-0985-1555-A1, p. 71]

Lastly, DTNA disagrees with EPA's proposed revision to 40 C.F.R. 1037.120(c) to remove the sentence stating that the emission-related warranty does not need to cover components whose failure would not increase a vehicle's emissions of any regulated pollutant. This could be read to extend the emissions-related warranty for ZEVs to include components that have no effect on GHG emissions, including aerodynamics, tires, and other components. While it is true that such a component, if failed, may slightly reduce the range of the ZEV, such failure would not increase vehicle emissions, and a vehicle without such failures, but even shorter range, could be sold as new and generate the same amount of CO2 credit. Additionally, EPA adds 'to the extent such emission-related components are included in your application for certification.' It is not clear why a manufacturer would include these components in its application for certification; these components are not required to be included specifically, and a manufacturer gains no emissions credit by including them as emissions-reduction technology. A ZEV with no aerodynamic fairings is still a ZEV and generates the same amount of CO2 credit as a vehicle with significant aerodynamic technology. By potentially requiring these components to be covered by emission-control warranty, EPA disincentivizes their use, and treats some ZEVs as 'better' than others using inconsistent logic. [EPA-HQ-OAR-2022-0985-1555-A1, p. 72]

To refine its warranty proposal, DTNA recommends that EPA (1) specifically enumerate the ZEV components that must be covered by warranty and (2) clarify that only failures resulting in a complete lack of operation of the vehicle must be covered by the emission control warranty. [EPA-HQ-OAR-2022-0985-1555-A1, p. 72]

Organization: Dana Incorporated

Vehicle Basic and ePowertrain Warranty

EPA is proposing that manufacturers identify ePowertrain components as components covered under their vehicles' emissions-related warranty. Warranty requirements in the heavy-vehicle class 6 through 8 segments are wide-ranging, complex, and highly dependent on vehicle application. In addition to vehicle basic warranties, it is common for component providers to offer additional coverage on engines, motors, invertors, e-axles, and drive axles. The variation and complexity in the vehicle duty-cycle merits a tailored warranty plan. Given this dynamic, EPA should consider ePowertrain warranties for BEVs for linehaul applications that extend to a 5-year duration and should be valid for minimum of 300,000 miles. For class 6, 7 and 8 vocational (or non-linehaul applications), the ePowertrain warranty term should be reduced to 3 years / 100,000 miles to better represent the warranties currently applied in the heavy-vehicle segment. [EPA-HQ-OAR-2022-0985-1610-A1, p. 3]

Organization: Fermata Energy

Final battery warranty requirements should include a thorough understanding of the impact on V2G in heavy duty vehicles so as to not discourage V2G. [EPA-HQ-OAR-2022-0985-1662-A2, p.6]

EPA is proposing a battery warranty of 5 years or 50,000 miles for Light HDV and 5 years or 100,000 miles for Medium HDV and Heavy HDV. However, we do not see any consideration of frequent use of V2G in this proposal. V2G technology is emerging in heavy-duty vehicles, such as school buses and other use cases such as fleets with only an eight-hour work day and sixteen hours to be connected to a charger. The concern is that overly restrictive warranty or durability requirements by EPA could place arbitrary restrictions on V2X activities. Fermata Energy appreciates EPA's intent to ensure consumer protection and customer satisfaction with EV ownership through robust standards and to meet the useful life requirements in the Clean Air Act. However, overly stringent requirements that constrain battery cycling could also constrain the novel set of value propositions that V2X offers and that would otherwise spur EV adoption (e.g., home backup power, payment for grid services, etc.). Overly stringent battery durability requirements could drive OEMs to limit the range, performance, and/or state of charge of EV batteries, or take other measures to provide for sufficient degradation margin in later years. As such, Fermata Energy believes that EPA should consider an approach to durability requirements that balances competing factors and specifically consider the GHG benefits of V2G as a storage technology which unlocks and enables a faster, more cost-effective transition to renewable energy. [EPA-HQ-OAR-2022-0985-1662-A2, pp.6-7]

Organization: Manufacturers of Emission Controls Association (MECA)

Durability and Warranty Requirements

MECA believes that durability and warranty requirements instill confidence in the reliability of all technologies to fleet and truck owners. Therefore, based on their given weight class and application, diverse heavy-duty powertrains should be required to meet similar durability and warranty requirements. MECA recognizes that EPA's currently proposed warranty periods of 50,000 miles / 5 years for light-heavy-duty and 100,000 miles / 5 years for medium and heavy-heavy duty zero emissions vehicles reflect the low market penetration and lack of experience with this new technology. However, EPA should set a phase-in schedule to collect real-world data from electric trucks with the goal to align the durability, warranty and full useful life of the heavy-duty zero emission vehicles to more closely match the recently adopted durability and warranty requirements outlined under the EPA Heavy-Duty Engine and Vehicle Standards for MY 2027 and beyond which are shown in Table 1 below. [EPA-HQ-OAR-2022-0985-1521-A1, pp. 10 - 11.] [See Docket Number EPA-HQ-OAR-2022-0985-1521-A1, page 11 for Table 1.]

MECA believes that equivalent warranty periods and durability for zero emissions vehicles are essential to ensure confidence in the technology for truck and fleet owners as well as ensure longer term emissions reductions. [EPA-HQ-OAR-2022-0985-1521-A1, p. 11]

Organization: MEMA

Warranty Provisions Must Not Harm Aftermarket or Preclude Choice in Repair

MEMA urges the EPA to clarify that warranty repairs can be completed at dealer or authorized repair locations, at independent aftermarket repair locations, or at the fleet owner's own shops. The repair and maintenance of in-service vehicles is critical to ensuring that they operate as designed and continue to meet safety and emissions standards. A properly operating vehicle is critical for consumers who rely on light-duty passenger vehicles for daily transportation. This importance is increased when considering the regular repair, maintenance, and service of heavy-duty commercial vehicles. For these commercial vehicles, vehicle downtime costs the vehicle owner's business money, leads to shipment delays, and negatively impacts supply chains. In many locations throughout the country, the nearest dealer or authorized repair facility is, at best inconvenient or, at worst, hundreds of miles away. [EPA-HQ-OAR-2022-0985-1570-A1, pp. 13 - 14]

MEMA urges EPA to clarify and specify the specific vehicle parts intended to be covered by the proposed warranty, namely the vehicle high-voltage battery and propulsion motors. Heavy-duty vehicles include thousands of individual parts and components. Many of these parts are regularly replaced because they experience wear over time. As currently written in the NPRM, the boundaries of which parts are covered by the warranty, and which are not covered are unclear. This uncertainty could lead to vehicle owner misunderstandings, unintended legal exposure for OEMs and technology providers, and significantly increased new vehicle costs that counter the goal of targeted market adoption. [EPA-HQ-OAR-2022-0985-1570-A1, p. 14]

Taken further, MEMA urges EPA to not require warranty coverage on parts that have a shorter life and are a routinely replaced due to wear, or are adjacent to the warrantied parts through physical, electrical, or software connections but not the targeted component; such as sensors, filters, monitoring systems, cooling systems, HVAC, braking systems, control systems, inverters, converters, charging systems, structural systems, other drivetrain components, electrical motors not part of the forward propulsion system, and filters. We urge EPA to work with industry stakeholders, including suppliers, to develop a list of wear and non-applicable parts and components with these criteria in mind. [EPA-HQ-OAR-2022-0985-1570-A1, p. 14]

Organization: Northeast States for Coordinated Air Use Management (NESCAUM) and the Ozone Transport Commission (OTC)

Battery warranty

EPA's proposal includes battery durability monitoring requirements applicable to heavy-duty battery electric vehicles. The proposal, however, appears to lack similar provisions applicable to heavy-duty FCEVs. We encourage EPA to establish warranty provisions for heavy-duty FCEVs. [EPA-HQ-OAR-2022-0985-1562-A1, p. 14]

Organization: ROUSH CleanTech

We are concerned with the proposed revision to 40CFR1037.120(c) ("The emission-related warranty also covers other added emission-related components to the extent they are included in your application for certification, and any other components whose failure would increase a vehicle's CO2 emissions.") We believe the "any other components" language is needlessly broad, and would likely incorporate non-emissions components such as wheel bearings, parking brakes, brake pads, etc. into the GHG warranty because they have failure modes that can cause drag. We hope this was not the intent of the authors, but if so then we suggest that this concept should receive significantly more review and discussion in industry. Moreover, we believe that the proposed "any other component" clause will result in a warranty increase that is meant only for ICE vehicles, since the same failing component on a BEV/FCEV does not increase CO2 emissions under EPA's definition, even though it would unquestionably result in a reduction in vehicle efficiency and harm the environment. We recommend that EPA remove the bolded portion from the proposed rule, since that is more elegant than somehow incorporating regulations that consider the CO2 emissions associated with energy production. [EPA-HQ-OAR-2022-0985-1655-A1, p.4]

Organization: Strong Plug-in Hybrid Electric Vehicle (PHEV) Coalition

Regarding battery warranties and battery durability, we are concerned that bi-directional charging was not considered and request a more reasonable proposal in the final rule that assumes frequent bi-directional charging and does not unintentionally discourage vehicle-to-grid technology. [EPA-HQ-OAR-2022-0985-1647-A2, p. 2]

5) Regarding battery warranties, we are concerned that bi-directional charging was not considered and request a more reasonable proposal in the final rule that assumes frequent bidirectional charging. As described in our recommendation 2 above, vehicle-to-grid and vehicle to building provide substantial benefits to society and to consumers. Therefore, EPA in its final rulemaking should carefully avoid unintentionally discouraging the development of this market with warranty requirements for PHEVs (and BEVs) that are too stringent. We understand that there are many factors to consider including consumer protection, useful life requirements in the Clean Air Act, but the benefits to consumers, utility ratepayers and the environmental benefits of V2G and vehicle to building should also be considered. Regarding battery durability, we appreciate that EPA proposes only monitoring requirements and request EPA, in developing any durability requirements, to thoughtfully consider V2G and not discourage its development. [EPA-HQ-OAR-2022-0985-1647-A2, pp. 6 - 7]

Organization: Tesla, Inc. (Tesla)

Warranty Provisions Are Consistent with the Industry

Tesla supports the agency clarifying that the application of the existing warranty provisions found at 40 C.F.R. 1037.120 includes BEV components.193 Since deployment of the Semi, Tesla has provided warranties to purchasers that are consistent with (and even exceed) the proposed requirements. [EPA-HQ-OAR-2022-0985-1505-A1, p. 26]

193 88 Fed. Reg. at 26015-16.

Organization: Truck and Engine Manufacturers Association (EMA)

Emission-Related Warranty Requirements – Notwithstanding our comments above on EPA's lack of delegated authority under the CAA to adopt the proposed emission-related warranty requirements, we offer several provisional comments on those proposed provisions. [EPA-HQ-OAR-2022-0985-2668-A1, p. 56]

The NPRM includes a proposed revisions to 40 C.F.R. § 1037.120(c) to add the following bolded language to identify the components required to be covered under an emission-related warranty:

Components covered. The emission-related warranty covers … fuel cell stacks, and RESS [rechargeable energy storage system] and other components used with hybrid systems, battery electric vehicles, and fuel cell electric vehicles to the extent such emission-related components are included in your application for certification. See, 88 Fed. Reg. 26125 (emphasis added). [EPA-HQ-OAR-2022-0985-2668-A1, p. 56]

The NPRM does not provide any clear direction on what is included in the phrase "other components," or even if includes anything beyond fuel cell stacks, RESS (i.e., battery systems), and "emission-related components that are included in [the manufacturer's] application for certification." EPA should clarify that the emission-related warranty provisions only apply to RESS and fuel cell stacks, and possibly other components in the manufacturer's certification application. [EPA-HQ-OAR-2022-0985-2668-A1, p. 56]

Traditional emission-related warranty requirements serve the useful purpose of motivating a trucking company to keep the emissions control systems functioning properly throughout each vehicle's useful life. Since a failure of a traditional emissions-related component may not negatively affect the ability of a commercial vehicle to perform its intended function, the fleet owner may not otherwise be motivated to remedy the failure. In the commercial vehicle market, other warranties are negotiated between the buyer and seller, and each one represents the result of a calculated shifting of financial risk between upfront expenditures and ongoing maintenance costs. [EPA-HQ-OAR-2022-0985-2668-A1, pp. 56 - 57]

Warranting the RESS and fuel cell stacks for the terms proposed in the NPRM may be appropriate while EPA and the industry gather data on how HDOH batteries and fuel calls age in the field. Adding other components to those warranties will only serve to add unnecessary upfront cost to the acquisition price of a ZEV, since manufacturers must add to the price of the vehicle the expected costs through the life of the warranty. Those additional warranty requirements also could interfere with the traditional negotiations between commercial vehicle buyers and the selling manufacturers and/or dealer, forcing higher upfront costs on trucking fleets that may be able to manage maintenance costs more efficiently. [EPA-HQ-OAR-2022-0985-2668-A1, p. 57]

In addition to clarifying that the proposed emission-related warranty provisions only apply to RESS and fuel cell stacks, EPA should clarify that the warranties only cover failures that result in a lack of motive capability. Mere degradation of the RESS or fuel cell, which may result in reduced range but not a complete lack of motive capability, should not be considered a warrantable failure. It would be impossible to determine an adequate reduction in range that could be a "failure" in all circumstances, especially considering the diversity of operations and vehicle configurations in the commercial vehicle industry. [EPA-HQ-OAR-2022-0985-2668-A1, p. 57]

Considering the broad variety of operations and vehicle configurations in the commercial vehicle industry, warranty periods in terms of miles and years may not capture all the RESS loads of an HDOH vehicle. Accordingly, we recommend that EPA add a third parameter for the warranty terms that accounts for total energy throughput. EPA should allow manufacturers to account for truck refrigeration units, sleeper-cab heating and air conditioning, power take-offs, and other auxiliary loads on the RESS. One way to account for those loads is by determining the "virtual distance" the vehicle travels, such as by using the following formula developed by the UNECE working group that is developing the amendments to GTR No. 22: [EPA-HQ-OAR-2022-0985-2668-A1, p. 57] [See the Formula on page 57 of docket number EPA-HQ-OAR-2022-0985-2668-A1.]

Using the above formula, the warranty miles would be equal to the actual vehicle odometer miles plus the virtual distance. Using such a calculation would increase transparency to the customer, further enable auxiliary load technologies, and avoid requiring warranties that are not appropriate for how the vehicle operates. [EPA-HQ-OAR-2022-0985-2668-A1, p. 57]

Organization: Valero Energy Corporation

EPA goes on to explain that "typical battery warranties being offered by HD BEV manufacturers range between 8 and 15 years today. A BEV battery replacement may be practically necessary over the life of a vehicle if the battery deteriorates to a point where the vehicle range no longer meets the vehicle's operational needs. We believe that proper vehicle and battery maintenance and management can extend battery life."43 [EPA-HQ-OAR-2022-0985-1566-A2, p. 9]

43 DRIA at 185.

EPA cites no authority for the basis of this opinion, and fails to acknowledge that battery degradation is not necessarily a matter of improper maintenance and management – weather, vehicle use (duty cycles), charging behavior, battery chemistry, and even bi-directional charging are known to influence battery life.44 [EPA-HQ-OAR-2022-0985-1566-A2, p. 9]

44 Further, for purposes of EPA's analysis, it should not matter whether or not the battery or fuel cell stack replacement were to occur under warranty. Coverage under a warranty does not make the replacement free – it is still a cost that must be accounted for.

Organization: Volvo Group

We do not believe that EPA has the authority to mandate useful life and warranty requirements for zero-emission vehicles, since there is no situation in which the failure of any system on a ZEV would cause that ZEV to produce increased emissions. [EPA-HQ-OAR-2022-0985-1606-A1, p. 3]

Organization: Zero Emission Transportation Association (ZETA)

ZETA's member companies stand by the durability of their products and many of them have their own warranties. While we support EPA's proposed warranty requirements, we note that designating the electric battery and powertrain as "emissions control equipment" under the Clean Air Act could subject these components to additional regulatory requirements and rules. Specifically, we are concerned about the uncertainty in how EPA's anti-tampering rules may apply to these components and request EPA clarification on how enforcement would be applied. [EPA-HQ-OAR-2022-0985-2429-A1, p. 16]

EPA Summary and Response:

Summary:

ATS recommends that EPA finalize warranty requirements through the useful life of the vehicle to ensure emission reduction in the real world and discourage cheating.

CARB commented that EPA should provide additional guidance on which components and what types of failures are covered under the warranty, and in addition how the failures would be defined. CARB commented that this should be done so that manufacturers properly identify all components and to give potential purchasers confidence that major components would be covered under warranty.

DTNA supports the proposed ZEV warranty requirements and commented that EPA's proposed ZEV warranty requirement represents an adequate compromise such that manufacturers will not be required to offer costly warranties that customers may not want. DTNA requests that EPA specify which ZEV components are covered by the emission-related warrant, and that EPA should clarify its warranty requirement to specify that a covered failure is one that results in a complete lack of motive capability. DTNA disagrees with EPA's proposed revision to 40 CFR 1037.120(c) to remove the sentence stating that the emission-related warranty does not need to cover components whose failure would not increase a vehicle's emissions of any regulated pollutant and adds 'to the extent such emission-related components are included in your application for certification.' This could be read to extend the emissions-related warranty for ZEVs to include components that have no effect on a ZEV's GHG emissions (zero, by definition), including aerodynamics, tires, and other components. DTNA recommends that EPA (1) specifically enumerate the ZEV components that must be covered by warranty and (2) clarify that only failures resulting in a complete lack of operation of the vehicle must be covered by the ZEV emission control warranty. DTNA commented that EPA should leave ZEV warranty to the market.

Dana commented that EPA should finalize longer warranty periods than proposed.

EMA commented that the NPRM includes a proposed revisions to 40 CFR 1037.120(c) to add the following language to identify the components required to be covered under an emission-related warranty: “Components covered. The emission-related warranty covers … fuel cell stacks, and RESS [rechargeable energy storage system] and other components used with hybrid systems, battery electric vehicles, and fuel cell electric vehicles to the extent such emission-related components are included in your application for certification.” EMA comments that EPA should clarify that the emission-related warranty provisions only apply to RESS and fuel cell stacks, and possibly other components in the manufacturer’s certification application. EMA comments that including RESS and fuel cell stacks for the terms proposed in the NPRM may be appropriate while EPA and the industry gather data on how HDOH batteries and fuel calls age in the field, but adding other components to those warranties will only serve to add unnecessary upfront cost to the acquisition price of a ZEV.

EMA comments that EPA should clarify that the warranties only cover failures that result in a lack of motive capability and not a reduction in range as it would be impossible to determine an adequate reduction in range that could be considered a failure.

EMA recommends that EPA add a third parameter for the warranty terms that accounts for total energy throughput. EPA should allow manufacturers to account for truck refrigeration units, sleeper-cab heating and air conditioning, power take-offs, and other auxiliary loads on the RESS. This could be done by determining the “virtual distance” the vehicle travels, such as by using a formula developed by the UNECE working group that is developing the amendments to GTR No. 22: [See the Formula on page 57 of docket number EPA-HQ-OAR-2022-0985-2668-A1.] Using this formula, the warranty miles would be equal to the actual vehicle odometer miles plus the virtual distance.

EMA and Volvo commented that EPA doesn’t have the authority to require emissions warranty for ZEV. Fermata Energy and Strong Plug-in Hybrid Electric Vehicle (PHEV) Coalition commented that EPA should finalize warranty periods that consider V2G and V2X.

MEMA commented that EPA specify which vehicle parts are covered by the warranty. MEMA urges EPA to not require warranty coverage on parts that have a shorter life and are a routinely replaced. MEMA commented that EPA should clarify that warranty repairs can be completed by authorized repair locations, at independent aftermarket repair locations, or at the fleet owner’s own shops.

MECA commented that EPA should phase in Warranty requirements for ZEV with the goal to align with the MY 2027 and later warranty requirements finalized in the EPA Heavy-Duty Engine and Vehicle Standards rule.

NESCAUM and OTC commented that EPA should establish warranty provisions for FCEVs.

ROUSH CleanTech is concerned with the proposed revision to 40 CFR 1037.120(c) They believe the “any other components” language is needlessly broad, and would likely incorporate non-emissions components such as wheel bearings, parking brakes, brake pads, etc., into the GHG warranty because they have failure modes that can cause drag. They recommend that EPA remove the portion of the text that incorporates regulation that consider the CO2 emissions associated with energy production.

Valero Energy commented replacement of the battery and/or fuel must be accounted for even if they are covered by warranty.

ZETA support proposed warranty requirement but is concerned about the uncertainty in how EPA's anti-tampering rules may apply to these components and request EPA clarification on how enforcement would be applied.

Response:

In response to the comments on the length of the warranty requirements, as discussed in Section III.B of the preamble, we believe that aligning the warranty requirements for ZEV with the existing warranty requirements in 40 CFR 1037 for conventional vehicles is an appropriate suggestion which we are adopting.

Regarding the comments from CARB, DTNA, EMA, and MEMA on which components and what failures are subject to the warranty requirements, see our response in Section III.B of the preamble.

Regarding the comment from EMA on adding a total energy throughput term, we are not finalizing this since we are not defining a specific percentage of new UBE that must be maintained during the warranty period.

Regarding the comments from EMA and Volvo on EPA lacking the authority to set warranty requirements for ZEV, see our response in Section 11.1 of the response to comments document and in Section III.B of the preamble.

In response to Fermata Energy and Strong Plug-in Hybrid Electric Vehicle (PHEV) Coalition comment that EPA should finalize warranty periods that consider V2G and V2X, we are not finalizing requirements that are defining a specific percentage of new UBE that must be maintained during the warranty period. Due to this and since the final warranty periods are consistent with warranties already being provided by ZEV manufacturers, there are not any specific changes to the warranty requirements due to considerations of V2G or V2X.

In regard to MEMA's comment that EPA should clarify that warranty repairs can be completed by authorized repair locations, at independent aftermarket repair locations, or at the fleet owner's own shops, MEMA's concern is addressed in existing 40 CFR 1037.125(f).

In response to NESCAUM and OTC comments that EPA should establish warranty provisions for FCEVs, the final requirements apply to all ZEV including FCEV. See Section III.B of the preamble on what FCEV components are subject to the warranty requirements.

Roush's comment regarding the scope of the "any other components" clause in proposed (and now final) section 1037.120(c) is fully addressed in the Section III.C of the preamble. Regarding Valero Energy's comment in accounting for the replacement of the battery and/or fuel, our analysis shows that the battery and fuel cell can be designed to last at 10 years and for the vehicles where we determined a battery replacement may be needed, we have accounted for the costs in the BCA. See RIA Chapter 2.4.1.1.4, RIA Chapter 3.4.6.5, and RTC Section 3.8.3.

In response to ZETA's comment on clarifying the implications of designating the electric battery and powertrain as "emissions control equipment," and how anti-tampering requirements would apply, more information is needed to provide a complete response. The anti-tampering requirements are generally in place to prevent modifications to engines and vehicles that would increase emissions. ZEV have zero tailpipe emissions, so unless the changes to the ZEV decrease the operational life of the vehicle, the emissions of the vehicle wouldn't go up. With this said, more information/specifics are needed to respond to this comment.

12 Program Costs

12.1 Vehicle costs

Comments by Organizations

Organization: Clean Fuels Development Coalition et al.

And, as will be discussed later in this comment, the proposal's listed costs grossly underestimate the rule's true costs. The proper metric is aggregate cost because the major-questions doctrine asks about the rule's significance to the "national economy." West Virginia v. EPA, 142 S. Ct. at 2609 (2022). These aggregate costs include: [EPA-HQ-OAR-2022-0985-1585-A1, p. 4]

Direct compliance costs: Not only the increased vehicle costs, but also the costs to build out factories, and the cross-subsidies from every diesel truck purchaser to every battery electric truck purchaser in the country. [EPA-HQ-OAR-2022-0985-1585-A1, p. 5]

EPA Summary and Response:

Summary:
The Clean Fuels Development Coalition commented that we are underestimating costs of the rule in that we are only accounting for direct compliance costs.

Response:
In our analysis, for compliance costs we accounted for both direct and indirect costs for manufacturers (the regulated entities under the final rule's Phase 3 standards). Indirect manufacturing costs accounts for costs associated with producing the unit of output that are not direct manufacturing costs such as research and development (R&D), warranty, corporate operations (such as salaries, pensions, health care costs, dealer support, and marketing) and profits. This methodology is meant to address all compliance costs associated. See RIA Chapters 3.2.1 (direct costs for manufacturers) and 3.2.2 (indirect costs to manufacturers). As detailed in Sections II and IV of the preamble and Chapters 2 and 3 of the RIA, in addition to compliance costs for manufacturers, our cost analyses also appropriately assessed purchaser costs and social costs of the final rule. See, for example, RIA Chapters 3.4 (purchaser costs) and 3.5 (social costs). See also RTC Sections 2 and 3 for responses to comments on major questions doctrine and additional responses on costs.

12.2 RPE

Comments by Organizations

Organization: American Free Enterprise Chamber of Commerce (AmFree) et al.

Second, EPA's estimates of indirect costs are further flawed. They are calculated by multiplying the direct costs (already defective for the reasons stated) by so-called "retail price equivalent" ("RPE") multipliers. Draft RIA at 279. The multipliers EPA uses that are substantially out of date and inappropriate for complex electric vehicles. EPA's multipliers are derived from a 2010 report relying on 2008 data that did not even involve electric vehicles. See id. at 279 n.8 (citing Alex Rogozhin et al., Heavy Duty Truck Retail Price Equivalent and Indirect Cost Multipliers, Draft Report, RTI Int'l, at 3-2, 5-1 (July 2010) ("Heavy Duty Truck RPE")). The report's most aggressive technological scenario accounted for only "hybrid-electric powertrains." Heavy Duty Truck RPE at 5-1. And EPA did not even apply the multipliers associated with that scenario—it instead applied the multipliers from the "industry average" scenario, id. at 3-9; see Draft RIA at 279, resulting in a significant underestimate of indirect costs. [EPA-HQ-OAR-2022-0985-1660-A1, p. 54]

Organization: Daimler Truck North America LLC (DTNA)

Based upon currently available data, it appears that EPA significantly under-projects the incremental cost of ZEVs due to a stack-up of discrepancies in direct manufacturing costs and indirect manufacturing costs. For example, EPA's derived Retail Price Equivalent Factors derived from SEC filings60 may not accurately capture manufacturers' indirect Research and Development (R&D) expenditures, which will be required for ongoing ZEV product development. Never before have manufacturers invested in so many propulsion technologies simultaneously, including new diesel technologies for CARB24 and EPA27 NOx standards, BEVs, FCEVs, and hydrogen combustion technologies. In the HD TRUCS model, EPA projects battery density and fuel cell efficiency to increase throughout the Phase 3 program, indicative of additional R&D investments. EPA is also projecting increased customer adoption by MY 2032, citing technology improvements. However, DTNA is observing slow uptake of these products and increased uncertainty in macroeconomic conditions that may impact the trucking industry and recovery of R&D costs. [EPA-HQ-OAR-2022-0985-1555-A1, p. 33]

60 See id. at 279.

EPA Request for Comment, Request #20: We request comment on our approach, including other data we should consider in our assessment of energy consumption.

- DTNA Response: EPA should consider all available data including that which can be provided by manufacturers in confidential settings; however, given that the HD ZEV market is currently in a nascent state, any data available today is necessarily limited. EPA should thus re-evaluate its assumptions on this issue on a regular basis, using the best available data. See Section II.C.2 of DTNA's comments. [EPA-HQ-OAR-2022-0985-1555-A1, p. 161]

EPA Request for Comment, Request #74: We request data to inform RPE factors for the heavy-duty industry.

- DTNA Response: See DTNA Response to Request # 20, above. [EPA-HQ-OAR-2022-0985-1555-A1, p. 172] [Refer to section 2 of this comment summary]

<u>EPA Summary and Response:</u>

<u>Summary:</u>

Both AmFree and DTNA maintain that EPA's estimate of manufacturers' indirect costs, using Retail Price Equivalent (RPE) multipliers, are underestimated. AmFree maintains that the source of EPA's estimate is a 2010 study which is out-of-date in that it does not consider any indirect costs associated with fully electrified powertrains, and considers hybrid powertrains only. Further, AmFree claims that EPA did not even use the multipliers associated with that degree of electrification, and instead used an averaged multiplier. DTNA also maintains that EPA's multipliers reflect out of date information, in that companies are now engaged in "unprecedented" research and development (R&D) associated with different types of powertrains not reflected in the companies' SEC filings which form the basis for EPA's RPE estimate.

Response:

AmFree and DTNA commented on the retail price equivalent (RPE) markup factor used to estimate indirect costs. Both argued that the factor used by EPA was improperly low and based on dated information given that it was derived in an era when battery electric heavy-duty vehicles did not exist. AmFree further argued that EPA had failed to consider the most aggressive technology scenario considered in the RPE source study –hybridization – and instead considered only the "industry average" scenario. This latter argument suggests a misunderstanding or mischaracterization of the RPE source study. The study was meant to estimate indirect cost impacts of lower complexity versus higher complexity technologies, not necessarily higher technology. In other words, a battery electric powertrain may be higher technology, in that it is newer relative to internal combustion technologies to which it might be compared, but it may not necessarily be more complex. In fact, battery electric powertrains tend to have far fewer parts and could be considered less complex. But that approach, termed indirect cost multipliers (ICMs) to differentiate them from the RPE, is not even relevant in this situation because EPA is not using the ICM approach. Somewhat ironically, the RTI (2010) RPE source study (cited fully in DRIA p. 309 reference 8) argued that, in the short-term, a higher complexity technology, which AmFree argues electrification represents, would have ICM markups of 1.52, which is higher than the 1.42 RPE markup used in the NPRM, and long-term ICM markups of 1.31, lower than the NPRM's 1.42 RPE markup.

The real point of the RPE source study was that some elements of the RPE should not be considered as a rule's compliance costs for manufacturers . For example, part of the RPE is meant to reflect costs associated with running and maintaining production facilities. If EPA requires an emission reduction that results in widget 1 being replaced by widget 2 at a cost of $100 per widget but there is no impact on the cost of running and maintaining the production facility, why should those facility-related indirect costs change at all? Under the RPE approach, any direct cost incurred by an entity is assumed to share in the burden of covering indirect costs, and indirect costs simply scale in concert with direct costs. The intent behind the ICM markup approach developed by EPA was to more appropriately weigh a single technology (e.g., cooled exhaust gas recirculation), that might be added to an engine or vehicle, against another technology (e.g., direct injection) when determining compliance pathways. If one technology reasonably incurred lower indirect costs than another, it might represent a more attractive compliance pathway. However, the analysis behind the proposal and final rule does not weigh single technologies against one another and instead weighs entirely different powertrains against one another. Whichever powertrain is considered, it would be expected to carry its full weight in recovering costs which makes the RPE approach more appropriate. In the NPRM, we did not adopt the ICM approach and did not adopt the ICM's use of near-term vs. long-term indirect costs and have instead reasonably chosen to rely on RPE markups themselves. While it is true that the source study dates from 2010, we note that commenter did not submit information upon which to base any changes.

Regarding the accuracy of SEC filings capturing R&D expenditures, we assume that the commenter is speaking of recent expenditures relative to the expenditures at the time of the RPE report being completed. We maintain that it is appropriate to use an approach based on indirect costs historically scaling with direct costs, and we apply that through the RPE approach. This historical trend was discussed at length in the 2020 light-duty CAFE and GHG rulemaking (see 87 FR at 25770 to 25773 (May 2, 2022)). While it is perhaps true that a higher percentage of R&D budgets are being directed toward BEV and FCEV development than toward ICE development, or that the electrification share of R&D expenditures are increasing as the ICE share decreases, we estimate that the R&D budgets of industry members are, on average, scaling with direct costs and revenues in a manner consistent with historical trends. To assess this estimate, we looked at recent financial statements for Cummins, PACCAR and Tesla, three of the prominent regulated entities subject to this rule and for which financial data is readily available (see table below). We looked at their income statements and found the ratios of R&D to total revenues (our proxy for direct plus indirect costs), the ratios of R&D to the cost of revenues, and the ratios of total revenues to cost of revenues to be very consistent for the past three years. While R&D is in fact increasing year-over-year, as argued by commenters, the ratio of R&D to revenues and cost of revenues is relatively constant. We acknowledge this is a simplifiedlook and includes only three companies; however, it is not meant to replace our 2010 RPE study. The point we are making with these data is simply that financials within companies tend to scale in relatively consistent ways. Absent better, more recent, or additional data from commenters, we conclude that our approach remains reasonable and we continue with this approach.

Income Statement data from Yahoo! Finance, accessed January 19, 2024

Income Statement	12 months ending	Cummins (stock symbol CMI)	PACCAR (stock symbol PCAR)	Tesla (stock symbol TSLA)
Total Revenues (thousands of dollars)	12/31/2022	28,074,000	28,819,800	81,462,000
	12/31/2021	24,021,000	23,522,300	53,823,000

12.3 Learning curve

Comments by Organizations

Organization: American Free Enterprise Chamber of Commerce (AmFree) et al.

e. EPA's Estimate Of The Cost Of Compliance Is Defective

EPA's estimate of the cost to manufacturers of complying with the proposed standards also has significant flaws. First, as to direct manufacturing costs, EPA applied a "learning curve" to the cost of manufacturing new electric vehicles that predicts that costs will dramatically decrease over time. Draft RIA at 277–78. And, in particular, it chose to apply a "steeper learning algorithm" for zero-emission technologies. Id. at 277. That algorithm assumes that by 2033, manufacturing costs will be about 75 percent of what they will be in 2027, and that by 2055, costs will be about 54 percent of the 2027 amount. Id. at 278. But EPA appears to have pulled the figures for this learning curve out of thin air—it nowhere identifies how they were calculated or why they are reasonable. Id. at 277–78. Given that this learning curve has a direct and significant effect on EPA's direct-costs calculation, as well as its indirect-costs estimate, any final rule must explain how it was generated and why it is appropriate under the circumstances.

Organization: Daimler Truck North America LLC (DTNA)

Learning Curve Reductions in Unit Production Costs

The learning curve that EPA factors into its unit production cost estimates may not be accurate for BEV or FCEV products. EPA states the learning curve represents a 'learning by doing' approach for manufacturers, including simplified machining and assembly operations, use of lower cost materials, and a reduction in the complexity and number of parts over time.59 DTNA agrees that production efficiencies typically improve over time, leading to some direct manufacturing cost savings, but BEVs and FCEVs already use fewer mechanical parts compared to conventional vehicles, and it is possible they will not experience as sharp of a learning curve. The HD ZEV market cannot take advantage of synergies with the passenger car market, due to the more extreme use cases and longer lifetimes of components required for HDVs. Further, a number of components will need to undergo additional refinement to achieve EPA's projected efficiencies and will not be able to take advantage of economies of scale. [EPA-HQ-OAR-2022-0985-1555-A1, p. 33]

59 See DRIA a 277.

Finally, a larger fraction of ZEV production costs come from raw materials as compared to conventional vehicle manufacturing, suggesting that production efficiencies over time are likely to lead to fewer cost reductions compared to the conventional vehicle space. Further, HD ZEV production costs will be impacted by raw material pricing, which is subject to significant market volatility, as DTNA experienced in 2022 due to a surge in lithium prices, which increased battery costs that were in turn passed on to consumers in the form of increased product prices. To account for these considerations, EPA should adjust the ZEV learning curve assumptions in the HD TRUCS tool as new data becomes available. [EPA-HQ-OAR-2022-0985-1555-A1, p. 33]

EPA Request for Comment, Request #20: We request comment on our approach, including other data we should consider in our assessment of energy consumption.

- DTNA Response: EPA should consider all available data including that which can be provided by manufacturers in confidential settings; however, given that the HD ZEV market is currently in a nascent state, any data available today is necessarily limited. EPA should thus re-evaluate its assumptions on this issue on a regular basis, using the best available data. See Section II.C.2 of DTNA's comments. [EPA-HQ-OAR-2022-0985-1555-A1, p. 161]

EPA Request for Comment, Request #73: We request comment on [EPA's] approach [to estimate the extent to which learning effects will reduce incremental costs of ZEV technologies], including methods for accounting for the projected future ICE costs.

- DTNA Response: [See DTNA Response to Request # 20, above. [EPA-HQ-OAR-2022-0985-1555-A1, p. 172] [Refer to section 2 of this comment summary]

Organization: Energy Innovation

D. Factors Affecting Learning Curves for HDV Electrification

We appreciate the EPA's attention to learning curves in the proposed rule, for they affect the rate of deployment of newer technologies, which leads to learning-by-doing advances in performance and production, and economies of scale, which lower the cost of production. Learning curves affect how quickly BEVs can outcompete ICE vehicles on purchase price, which is a primary factor in market adoption and consumer acceptance. From our research, we have identified the following factors that warrant further consideration by the EPA as it develops the final rule. Combined, these factors suggest faster learning curves compared to levels modeled:

7. Novel battery chemistries
8. Faster-than-expected moderation of pandemic-induced supply chain disruption
9. Battery pack economies of scale
10. Tendency of battery outlooks to underestimate future learning curves [EPA-HQ-OAR-2022-0985-1604-A1, pp. 12 - 13]

1. Novel battery chemistries

Novel battery chemistries nearing commercial availability will open new avenues for innovation, and their effects will not be limited to technological change. Novel battery chemistries will also have economic benefits by spreading EV battery demand across a greater array of raw inputs. More diverse mineral input supplies will disperse demand instead of concentrating it, reducing supply-side price pressure. New battery chemistries will also increase competition between battery technologies, reducing producer profit margins and improving consumer economics. [EPA-HQ-OAR-2022-0985-1604-A1, p. 13.] [See Figure 7, Demand for Colbalt, on page 13 of docket number EPA-HQ-OAR-2022-0985-1604-A1.]

Evidence of how new battery technologies can quickly disrupt markets has recently been provided by cobalt-free lithium-ion-phosphate batteries, growing to 40 percent of global battery market demand in the first half of 2023.22 BloombergNEF analysis finds that global demand for cobalt would be 52 percent higher if lithium-ionphosphate batteries had not grown as they have.23 [EPA-HQ-OAR-2022-0985-1604-A1, p. 13]

22 Heejin Kim, “Korea’s Battery Makers Embrace LFP Cells as China Strides Ahead,” Bloomberg, May 15, 2023, https://www.bloomberg.com/news/articles/2023-05-15/korea-s-battery-makers-embrace-lfp-cells-as-china-strides-ahead#xj4y7vzkg.

Two new battery chemistries entering commercial use this year in EV battery packs are sodium-ion batteries24 and lithium-sulfur batteries.25 BloombergNEF estimates sodium-ion uptake, substituting for lithium-based chemistries, could lower lithium demand by 40 percent in 2035.26 Lastly, one of China’s major battery makers announced it boosted the energy density of lithium-ion-phosphate batteries by adding manganese, producing a battery able to travel 621 miles (1,000 km) on a single charge.27 [EPA-HQ-OAR-2022-0985-1604-A1, p. 14.] [See Figure 8, Impact of Sodium-Ion Battery Update on Lithium Demand, on page 14 of docket number EPA-HQ-OAR-2022-0985-1604-A1.]

2. Faster-than-expected moderation of pandemic-induced supply chain disruption

Key mineral inputs to battery production have dropped in price over the last six months more quickly than had been anticipated. Lithium prices have also fallen, dropping by half from a November 2022 peak.28 The downward trend in cobalt has been even more severe, partly because of the reduction in global cobalt demand due to lithium-ion phosphate batteries' growing market share. In June, the cobalt price had dropped to $14 per pound, down 65 percent from its 2022 peak.29 [EPA-HQ-OAR-2022-0985-1604-A1, p. 14]

28 Annie Lee, "Lithium Prices in China Halve in Just Four Months," Bloomberg, March 21, 2023, https://www.bloomberg.com/news/articles/2023-03-21/china-lithium-prices-halve-since-november-as-supply-woes-ease#xj4y7vzkg.

29 Lee.

Trends in cobalt and lithium prices are part of a broader trend in moderation of supply-chain pressures on EV batteries. Goldman Sachs Group Inc. is forecasting "softness for battery metals including cobalt, lithium and nickel in the second half of 2023 amid an oversupply."30 [EPA-HQ-OAR-2022-0985-1604-A1, p. 14]

30 "Cobalt Price Has Fallen Nearly 30% This Year," Mining.Com (blog), June 12, 2023, https://www.mining.com/cobalt-price-has-fallennearly-30-this-year/.

Another factor creating downward price pressure in the near term is record inventories. On May 11, 2023, Bloomberg reported that "[b]attery inventory is at an all-time high."31 [EPA-HQ-OAR-2022-0985-1604-A1, p. 14.] [See Figure 9, Global Cobalt Metal Price, on page 15 of docket number EPA-HQ-OAR-2022-0985-1604-A1.]

31 Shall Ren, "Banks Are Roaring Back in Xi's New China," Bloomberg, May 23, 2023.

3. Battery pack economies of scale

As battery size increases, the added cost of the pack needed to contain battery cells falls, reducing cost ($/kWh), keeping other factors constant. The larger the battery size, the more the costs associated with the packaging and management system can be distributed among more cells. These fixed costs remain largely the same whether the battery is small or large, so increasing the size of the battery allows for a lower cost per cell. A larger battery pack generally allows for more efficient design and packaging of the battery cells. For example, in a larger pack, cells can be arranged more closely together, reducing the amount of wasted space and materials. This again reduces the ratio of battery pack to cell. [EPA-HQ-OAR-2022-0985-1604-A1, p. 15]

A recent study by ICCT shows that larger batteries offer lower costs.32 Comparing the 2030 cost outlook for a car battery providing 300 miles vs. 150 miles of range, the larger battery costs $68 per kWh vs. $79 per kWh, offering a 14 percent advantage. [EPA-HQ-OAR-2022-0985-1604-A1, p. 15]

32 Peter Slowik et al., "Assessment of Light-Duty Electric Vehicle Costs and Consumer Benefits in the United States in the 2022-2035 Time Frame," International Council on Clean Transportation, October 2022, https://theicct.org/wp-content/uploads/2022/10/ev-cost-benefits-2035-oct22.pdf. Table 5 at 10.

As the EPA notes in the proposed rule, design aspects of commercial vehicle battery packs can create challenges. It is particularly important to recognize pack-level scale economies will be an advantage for battery packs for commercial vehicles compared to personal passenger vehicles. [EPA-HQ-OAR-2022-0985-1604-A1, p. 15]

4. Tendency of battery outlooks to underestimate future learning curves

Historic forecasts of battery prices have largely underestimated the impact of future learning curve effects. Recent, open-source, peer-reviewed research by the Institute for New Economic

Thinking (INET) at Oxford University33 shows the persistent underestimation of future innovation for batteries and develops an empirical forecasting approach that performs better.34 [EPA-HQ-OAR-2022-0985-1604-A1, p. 15]

33 “Institute for New Economic Thinking, University of Oxford,” n.d., https://www.inet.ox.ac.uk.

34 Rupert Way et al., “Empirically Grounded Technology Forecasts and the Energy Transition,” Joule 6, no. 9 (September 21, 2022): 2057–82, https://doi.org/10.1016/j.joule.2022.08.009 and https://www.cell.com/joule/fulltext/S2542-4351(22)00410-X.

Figure 10 is reproduced from the INET article to help illustrate this point. The figure denotes historical prices for lithium-ion (Li-ion) consumer battery cell prices and Li-ion EV battery packs with black and red data points, respectively, while red line segments trace historical forecasts for the most optimistic scenarios by leading energy-economy modelers such as the International Energy Agency. [EPA-HQ-OAR-2022-0985-1604-A1, pp. 15 - 16]

The figure’s graphing of historical data alongside past forecasts of battery cell and EV battery pack prices reveals the persistent gap between actual and forecasted innovation for batteries. [EPA-HQ-OAR-2022-0985-1604-A1, p. 16]

Even the most optimistic projections for each past forecast lowball future learning curves, since empirical price reductions trace a steeper trajectory, with cost dropping faster, compared to the forecast’s shallower slope. The result is even more compelling considering the comparison to the most optimistic of each battery forecast sampled. [EPA-HQ-OAR-2022-0985-1604-A1, p. 16]

These four factors impacting learning curves will very likely affect the BEV market over the next decade, which should inform the EPA’s analysis and its final proposed rule for HDVs. [EPA-HQ-OAR-2022-0985-1604-A1, p. 16.] [See Figure 10, Technology Forecasts and Energy Transition, on page 16 of docket number EPA-HQ-OAR-2022-0985-1604-A1, p. 16]

Organization: POET

The Trinity report also identified the following additional overly optimistic assumptions:

- ‘Application of an aggressive ‘learning curve’ for HD ZEV powertrains (Table 3-2 of the DRIA) which lowers the main element of HD ZEV cost by about 25% over the period from 2027 to 2032 and by 46% by 2055 while assuming no virtually no reductions (2% by 2032 and 8% by 2055) in the cost of conventional powertrains. These cost reductions are claimed despite that fact that substantial learning related to the production of batteries, fuel cells, and other ZEV componentry has already occurred in the light-duty sector and further learning curve benefits are expected to be much smaller than those forecast by U.S. EPA.’72 [EPA-HQ-OAR-2022-0985-1528-A1, pp. 17-18]

72 Id.

Organization: Truck and Engine Manufacturers Association (EMA)

The HD TRUCS tool also assumes aggregate cost reductions for each year of the Phase 3 regulation, model years 2027 through 2032. Those assumed cost reductions are premised on the experience that suppliers and OEMs can gain year-over-year from manufacturing ZEV components and vehicles, starting with the year that the technology is introduced into production. Those experience-based reductions are reflected in a "learning curve," which is documented in EPA's draft RIA. The learning curve yields a year-by-year reduction in costs, starting with a higher percentage reduction for the 2027 to 2028 model year, and then lower percent cost reductions for each subsequent year of learning. EPA has developed one learning curve for BEVs and FCEVs, and another for ICEs. The ICE curve reflects lower percent changes each year compared to the BEV/FCEV curve, since ICE technologies have been in production for many years. [EPA-HQ-OAR-2022-0985-2668-A1, p. 21]

Learning Curve – The Draft RIA documents EPA's approach to accounting for anticipated improvements in cost as a result of manufacturing experience. It is reflected in HD TRUCS through the "learning curve" concept. Table 3-2 of the Draft RIA (reproduced below) contains the values of the learning curve that EPA used in HD TRUCS. The Table shows the learning curve values for 2027 through 2051, with unique values for BEV and FCEV powertrains versus ICE-powered vehicles. The greater the difference between years, the greater the reduction that is applied. [EPA-HQ-OAR-2022-0985-2668-A1, p. 26]

For its version of HD TRUCS, EPA begins to apply the learning curve impacts on costs starting in 2027. Presumably, that correlates with EPA's expectation of the introduction of new technologies, based on the values in the BEV/FCEV portion of the table. For the first step, between 2027 and 2028, the EPA learning curve applies a 7.9% cost reduction factor. For the second step, between 2028 and 2029, EPA uses a 6% reduction, followed by reductions of 4.8%, 4.0% and 3.4% out to 2032. ICE powertrains have a much gentler slope of learning-curve cost reductions between 2027 and 2032, starting at 1% for the first two years, as can be seen in the table below. [EPA-HQ-OAR-2022-0985-2668-A1, p. 26] [See Table 3-2 on page 27 of docket number EPA-HQ-OAR-2022-0985-2668-A1]

EMA agrees with EPA that cost reductions can and do come down over time. The major point of difference, however, relates to when the learning curve should be deemed to start. EMA believes that the learning curve, should start when the ZEV technology initially goes into production, not when a given technology-forcing regulation might take effect. In that regard, the steep portion of the learning curve, when the greatest reductions can occur, is happening now for BEVs (not four years hence), since the actual start of production of BEV technologies began in 2022. It is incorrect and inappropriate, therefore, for EPA to assign 2027 as the start of the learning curve and the start of significant cost reductions for OEMs when, in actuality, those reductions are already included in today's projections of 2027 BEV costs. Accordingly, the values in the NPRM table are only reasonable if the starting year of the learning curve discounts is pulled back to 2022. [EPA-HQ-OAR-2022-0985-2668-A1, p.27]

In sum, it is more appropriate to start the learning curve cost discounts for BEV technologies in 2022, and then to use EPA's table to calculate the reductions that will occur in 2028 through 2032 based on the later-year values in the table. Applying those adjustments, the first years of the learning curve table become the Early Learning Year, as shown in the table below. It should be noted that the Learning Scalars are identical between the NPRM learning table and the Early Learning Years table below. [EPA-HQ-OAR-2022-0985-2668-A1, p.27] [See the Learning Curve table on page 28 of docket number EPA-HQ-OAR-2022-0985-2668-A1]

Specifically then, for the regulatory years of 2027-2032, EMA recommends that the following Learning Scalars along with the associated percentage cost reductions should be used in the final revised HD TRUCS tool: [EPA-HQ-OAR-2022-0985-2668-A1, p.28] [See the Proposed Learning Curve table on page 28 of docket number EPA-HQ-OAR-2022-0985-2668-A1.]

Learning Curve Start Year – As discussed above, EMA has changed the learning-curve start year for BEVs from 2027 to 2022 in this run. The revised values for the learning curve inputs are show in the table below. The ensuing table shows the revised projected ZEV adoption rates for 2027 and 2032 that result from using the revised learning curve inputs. [EPA-HQ-OAR-2022-0985-2668-A1, p. 35.] pSee the Proposed Learning Curve Table on page 35 of docket number EPA-HQ-OAR-2022-0985-2668-A1.]

Organization: Valero Energy Corporation

9. EPA provides no basis or explanation for the learning curves applied to BEV, FCEV, and ICE powertrains.

EPA assumes that the costs for EV batteries, fuel cell stacks, hydrogen fuel tanks, on-board chargers, power electronics, final drive, and fuel cell stack tractors will be reduced each year of the rulemaking period, according to a "learning curve" defined in Table 3-2 of the Draft RIA. EPA provides no basis, reference, or explanation for the learning scalar factors. EPA also fails to acknowledge the impact of variable commodity prices on the cost to produce these components. [EPA-HQ-OAR-2022-0985-1566-A2, p. 18]

In Table 3-2, EPA also defines a learning curve to ICEVs, similarly with no basis, reference, or explanation. However, in the HD TRUCS model, EPA fails to apply the learning-based cost reductions that it defines in Table 3-2 to ICEVs, just one more intentional or unintentional tipping of the scales towards ZEVs. [EPA-HQ-OAR-2022-0985-1566-A2, p. 18]

EPA Summary and Response:

Summary:

Commenters agreed that some degree of savings reflecting learning was appropriate. Commenters asserted different positions regarding the amount to allocate to learning and the time when a learning curve should be assessed. DTNA agrees that learning will result in improved production efficiencies and lower costs of production; however, DTNA asserted that this learning might not have the same rates as ICE since BEVs have fewer moving parts. DTNA also asserted that the use case of HDVs – more extreme operating conditions and longer lifetimes – means that learning synergies with the passenger vehicle market will not occur. Both DTNA and Valero questioned the appropriateness of the learning scalar factors EPA used at proposal in light of the effect of critical commodity prices on component costs, which costs are independent of learning. AmFree et al. and Valero commented that EPA does not identify how learning factors were calculated or justify why they are reasonable. Valero commented that HD TRUCS did not apply learning to ICE vehicles.

Energy Innovation suggests that faster learning curves may be appropriate for BEVs due to novel battery chemistries that can disrupt markets and increase competition; faster-than-expected moderation of pandemic-induced supply chain disruption; battery pack economies of scale; and the tendency of battery outlooks to underestimate future learning curves.

EMA did not disagree with the rate of learning over time included in the NPRM; however, they asserted learning should start in 2022 rather than 2027 (the date included in the NPRM) because OEMs began producing HD BEVs in 2022. EMA explained that this would mean at the start of the rule, the learning would be in the "flatter part" of the curve. POET separately asserted that EPA's NPRM learning curve was overly optimistic/aggressive because of experience from LDVs in the production of batteries and other ZEV components (thus similarly implying that learning began earlier and should not commence in 2027).

Response:

Regarding comments related to battery costs, we respond to those in Section 3.4.1 of this document. Regarding critical materials and prices, we respond to such comments in Section 17.2 of this document. EPA agrees that we should use the best available data for learning curves and we have done so. Also, as discussed in Section II of the preamble, we are committing to monitor the industry's compliance with the standards.

Cost reduction via learning-by-doing is a well established phenomenon having been studied for over 50 years with some of the earliest works dating to World War II.[811] Therefore, we know that learning-by-doing occurs and will continue to occur in the HD industry given the level of competition and the ingenuity of its employees and, we suspect, regardless of the number of parts in a given system. Some commenters referred to our learning-by-doing as a means of addressing economies of scale. This is not a correct representation since our learning-by-doing is exactly that, learning-by-doing and is not meant to reflect cost changes associated with economies of scale.

Regarding comments that learning in the light-duty sector may not translate to the heavy-duty sector, we do not agree with assertions that such learning transfer would not occur. The learning we are estimating is primarily at the cell level and not so much at the pack level. While packs may differ, cells should be similar.

We note that several of the commenters concur with the general point that learning-by-doing occurs and will continue to occur in the HD industry (and that EMA concurs with EPA's NPRM learning curve, but disagrees at what point in the learning we will be at in 2027 and later). One key point is estimating at what speed that learning will occur. Traditionally, cost-reductions on the order of 80 percent to 90 percent are expected to occur with each doubling of cumulative production. In other words, if a widget costs $100 to make in year one with production of 100 units, then the cost could be expected to reduce to $80 to $90 by the time 200 units have been produced.[812]

Due to modeling constraints and the difficulty in applying learning effects as a function of sales within a model that adjusts sales based on learning effects, we have traditionally applied learning impacts using static learning factors applied to a given cost estimate as a means of reflecting learning-by-doing effects on future costs. [813] Further, we have traditionally applied

[811] See "Cost Reduction through Learning in Manufacturing Industries and in the Manufacture of Mobile Sources, Final Report and Peer Review Report," EPA-420-R-16-018.
[812] *ibid*.
[813] See the 2010 light-duty greenhouse gas rule (75 FR 25324, May 7, 2010); the 2012 light-duty greenhouse gas rule (77 FR 62624, October 15, 2012); the 2011 heavy-duty greenhouse gas rule (76 FR 57106, September 15,

those static learning factors across regulatory scenarios even though, as in the NPRM, a higher sales penetration of BEV and FCEV—i.e., advanced—technology in the action scenarios would arguably result in more rapid learning relative to the no-action scenario where less penetration of those technologies is projected. Because the learning effects are static, the next key point becomes a matter of estimating where on the learning curve a technology is considered to be. In other words, is a technology on the early steeper portion of the learning curve or on the later, flatter portion of the learning curve. In the NPRM, we estimated that ICE technology was on the flatter portion of the curve, given that most ICE technologies have been in production for many years, and that advanced technologies like BEV and FCEV technologies were on the steeper portion. We continue with that approach in the FRM analysis, although we have shifted the learning effects for advanced technology in a manner consistent with some of the comments. More specifically, we apply the same learning curve in the final rule for BEVs and FCEVs but on a portion of the curve that is less steep (flatter) in MY 2027 and later than we used in the NPRM.

We note that beyond suggesting that a learning curve commence coincident with HD BEV production, commenters did not provide any different learning factors and did not assert that learning impacts should be fully removed. Commenters also did not question that the learning factors applied to electrification technologies appropriately includes more learning year-over-year than the learning factors applied to ICE vehicle technologies. We reiterate that such an approach is warranted given that ICE vehicle technologies have been implemented for over 100 years while the newer technologies (e.g., HD BEV technology) is relatively new and is undergoing rapid development around the world. Lastly, we note that, while our learning factors for BEV and FCEV technologies were more aggressive than those for ICE vehicle technologies, in the proposal they resulted in only a 26 percent cost reduction by model year 2033, a full 7 years from MY 2027. In the final analysis, the cost reduction between MY 2027 and MY 2033 is just 22 percent from learning. Such a set of learning factors does not seem overly aggressive given the pace of change in the BEV and FCEV vehicle space.

EPA acknowledges the uncertainties with forecasting the rate of learning. It is possible that manufacturers will learn more quickly than we anticipate, causing costs to be lower than we projected; for example, as noted above, a higher sales penetration of BEV and FCEV technology in the action scenarios would arguably result in more rapid learning relative to the no-action scenario where less penetration of those technologies is projected, and in turn more rapid learning than EPA accounted for. It is also possible that manufacturers will learn more slowly than anticipated, for instance, in the event DTNA is correct that BEV learning is slower due to BEVs having fewer parts. Considering all these uncertainties, the historical data on learning in the HD and motor vehicle markets over time, as well as the significant forces driving increased producing of HD BEV and FCEV and thus their learning in the future, EPA's technical judgment is that the learning factors we have applied are reasonable.

Regarding the comments from Energy Innovation, while we acknowledge the points raised, these do not pertain to the concept of learning-by-doing which our learning factors are meant to capture. Novel battery chemistries that might have lower costs would represent a new technology, not cost reductions via learning-by-doing to our estimated technologies. Similarly,

2011); the 2016 heavy-duty greenhouse gas rule (81 FR 73478, October 25, 2016); the 2014 light-duty Tier 3 rule (79 FR 23414, April 28, 2014); the heavy-duty NOx rule (88 FR 4296, January 24, 2023).

supply chain issues returning to historical norms is not an effect meant to be captured via our learning-by-doing cost reduction estimates.

For the FRM, we are applying ICEV learning both in HD TRUCS as well the cost calculations in RIA 3 and preamble Section IV.

13 Emission Impacts

Comments by Organizations

Organization: American Council for an Energy-Efficient Economy (ACEEE)

We note that, in contrast to the energy efficiency ratios implied by Table 2 showing that the H2-FCEV truck uses 57% more energy per mile than the BEV, EPA adopts an assumption that a H2-FCEV uses only 25% more energy than a BEV (DRIA p.313). ACEEE looked at the sources referenced in the DRIA, which include the GREET and MOVES models, and was unable to find the basis for this claim. In fact, the MOVES document cited by the DRIA states the following:

In addition, heavy-duty fuel cell vehicles (FCEVs) have a lower efficiency ratio than their BEV counterparts. However, an identical EER is implicitly applied to both BEVs and FCEVSs in MOVES, since BEV and FCEV vehicles have been aggregated within the electricity fuel type by the time the EERs are applied. To account for this, the energy consumption rates for FCEVs in EmissionRate are scaled up by a ratio of 1.6, based on values in GREET 202164 as explained in Appendix D…27 (emphasis added). [EPA-HQ-OAR-2022-0985-1560-A1, p. 13.]]This comment can also be found in section 7 of this comment summary.]

Appendix D states (p.51):

The 1.6 multiplier for the FCEV emission rates was derived from the relative miles per gallon diesel equivalent estimated in GREET 2021. While the GREET model anticipates that the relative miles per gallon will vary with vehicle class, as show in Table D-5, we currently expect most FCEVs will be used in long-haul applications. Thus, we selected the values for Combination Long-Haul Vans to represent all heavy-duty FCEVs. Consistent with GREET and with the MOVES adjustment report, the listed value for EVs was also decreased by 15 percent to account for battery and charging losses that are not relevant for FCEVs. This results in a ratio of 1.61 which we rounded to 1.6. [EPA-HQ-OAR-2022-0985-1560-A1, p. 13.]

Hence the cited MOVES document does not appear to support the DRIA claim that an FCEV uses only 25% more energy to operate than a BEV, but instead supports the values shown in Table 2 above. [EPA-HQ-OAR-2022-0985-1560-A1, p. 13.]

EPA notes that most hydrogen is produced today via steam methane reforming (SMR) but cites provisions in IIJA and IRA promoting green hydrogen production in support of its “simplifying assumption”, for purposes of the rule impacts analysis, that any hydrogen used to fuel heavy-duty FCEVs will be produced through grid electrolysis (FR 26042, footnote 664). Based on this assumption, EPA calculates declining carbon intensity of hydrogen fuel as a result of anticipated grid decarbonization. However, it is not clear that the hydrogen for use as a transportation fuel will generally be produced through grid electrolysis in the coming years or will have carbon emissions similar to hydrogen from grid electrolysis. [EPA-HQ-OAR-2022-0985-1560-A1, p. 14.]

EPA points to incentives for clean hydrogen production in IIJA and IRA, as well as “new transportation and other demand drivers and potential future regulation” (DRIA p.321) to support this assumption. However, potential dramatic increases in the coming years in the volume of both clean hydrogen and hydrogen produced through electrolysis are insufficient to ensure that hydrogen production through SMR will decline or that hydrogen used to fuel heavy-duty vehicles will become cleaner in tandem with grid decarbonization. This is especially true given the many uses to which a growing hydrogen supply could be put. [EPA-HQ-OAR-2022-0985-1560-A1, p. 14.]

It should be noted that EPA's analysis of the upstream impacts of BEVs, as well as those of hydrogen-fueled vehicles, relies on assumptions regarding the decarbonization of the electricity (FR 26044). However, those assumptions, unlike the hydrogen assumptions, are based on a quantitative analysis of IIJA and IRA incentives, resulting in a much more convincing case for low-carbon electricity generation. [EPA-HQ-OAR-2022-0985-1560-A1, p. 14.]

EPA should not incentivize hydrogen-fueled vehicles without strong evidence that hydrogen fuel for transportation will be clean in the foreseeable future. For H2-ICEVs in particular, for which intrinsic efficiency advantages are modest, actual GHG benefits may be negative, and potential future benefits are based largely on changes to the fuel rather than to the vehicle, the zero-upstream incentive is inappropriate. It would offer manufacturers the same compliance benefit for an H2-ICEV as for a BEV or FCEV but require only relatively small changes to the engine, as described At FR 25960. The fact that H2-ICEVs produce NOx makes conferring ZEV benefits on them all the more inappropriate. Low-carbon hydrogen-fueled vehicles are best incentivized through performance-based standards. [EPA-HQ-OAR-2022-0985-1560-A1, pp. 14 - 15.]

Organization: American Free Enterprise Chamber of Commerce (AmFree) et al.

B. EPA's Analysis Of Net Emissions Is Flawed

EPA estimates that the proposed rule will result in a net reduction of emissions from 2027 to 2055. See 88 Fed. Reg. at 26,045. That estimate is dubious. EPA's modeling omits critical sources of emissions and rests on several significant, unwarranted assumptions. [EPA-HQ-OAR-2022-0985-1660-A1, p. 54]

Downstream Emissions. EPA's projection of reduced net emissions from the proposed rule rests primarily on a predicted reduction in "downstream" emissions— i.e., emissions generated by operating motor vehicles. 88 Fed. Reg. at 26,039, 26,045. But in estimating the proposed rule's effect on downstream emissions, the agency omits the particulate emissions caused by brake and tire wear. Id. at 26,039; Draft RIA at 328 n.A, 342. That omission has no analytical justification, departs from prior agency practice, and improperly skews the calculation in favor of electric vehicles. [EPA-HQ-OAR-2022-0985-1660-A1, p. 54]

Particulate emissions from brake and tire wear fit comfortably within the downstream category, which includes anything "emitted directly by a vehicle." Draft RIA at 310. The draft regulatory impact analysis at times acknowledges this fact—for instance, EPA includes "particulate emissions from brake wear and tire wear" within a list of examples of downstream sources of pollution. Id. But the agency does not account for these emissions when modeling the proposed standards' ultimate emissions impact. EPA instead simply states—with no further explanation—that "primary exhaust PM2.5 [particulate matter] does not include brake wear and tire wear"; EPA includes a footnote mentioning that, if it did factor those sources into the analysis, the estimated reductions would be lower. Id. at 328 n.A; see also id. at 342. [EPA-HQ-OAR-2022-0985-1660-A1, pp. 54 - 55]

The agency's decision to ignore brake and tire wear is not only inconsistent with its own definition of downstream emissions but also marks a change from settled agency practice. In earlier GHG rules for heavy-duty vehicles, EPA considered brake and tire emissions when analyzing the impact of the proposed standards. See Greenhouse Gas Emissions Standards and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles, 76 Fed. Reg. 57,106, 57,301 n.a (Sept. 15, 2011) ("HD GHG I") ("PM2.5 from tire wear and brake wear is included."); Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles—Phase 2, 81 Fed. Reg. 73,478, 73,578 n.b (Oct. 25, 2016) ("HD GHG II") ("The impacts shown include all PM2.5 impacts from the rule including impacts from increased tire wear and brake wear that results from the slight increase in VMT projected as a result of this rule."). And in one of those rules, EPA even decided to adopt "[f]urther PM [c]ontrols" after concluding that the standards would increase particulate emissions by 464 tons in 2040 and 534 tons in 2050. HD GHG II, 81 Fed. Reg. at 73,579. The agency has not acknowledged its change in position here, let alone explained "why the new approach" of ignoring emissions from brake and tire wear "better comports with . . . the provisions that Congress enacted." Am. Fed'n of Gov't Emps. v. FLRA, 25 F.4th 1, 12 (D.C. Cir. 2022). That is reason enough to conclude that "the [agency] has not, in fact, engaged in reasoned decision-making." Id. (internal quotation marks and brackets omitted). [EPA-HQ-OAR-2022-0985-1660-A1, p. 55]

Nor could EPA contend that this omission is insignificant. The draft regulatory impact analysis describes brake and tire wear as "a significant source of particulate emissions" and estimates that, if they were included, the expected reduction in particulate emissions would decrease by half or more in every year the agency considered. Draft RIA at 328 & n.A (emphasis added). For model year 2035, particulate-emissions reductions would fall from 6 percent to 3 percent. Id. By model year 2045, they would decline from 30 percent to 10 percent. Id. And by 2055, they would plummet from 39 percent to 13 percent. Id. [EPA-HQ-OAR-2022-0985-1660-A1, p. 55]

This substantial decrease is not surprising. Emissions from tire wear, for example, rise as vehicles (1) get heavier and (2) apply higher torques at lower speeds—two traits prominent in electric vehicles, especially relative to internal-combustion-engine vehicles. See e.g., Raheb Mirzanamadi & Mats Gustafsson, Users' Experience of Tyre Wear on Electric Vehicles, Swedish Nat'l Road & Transp. Rsch. Inst., at 10 (June 2022) ("[E]lectric vehicles . . . have higher acceleration and are heavier than equivalent internal combustion engine vehicles . . . which can lead to higher non-exhaust emissions from tyre and road wear as well as higher resuspension of road dust."); Ye Liu et al., Exhaust and Non-Exhaust Emissions from Conventional and Electric Vehicles: A Comparison of Monetary Impact Values, J. Cleaner Prod., Vol. 331 (Jan. 2022) ("[I]t can be observed that compared [to] ICEVs, EVs emit more non-exhaust PM2.5 and PM10 emissions. Such an increase in non-exhaust emissions is associated with the equivalent EVs possessing heavier weight relative to [ICEVs]."); Gunda Obereigner at al., Active Limitation of Tire Wear and Emissions for Electrified Vehicles, SAE Techn. Paper (Apr. 6, 2021) ("[A]s electrified vehicles weigh more and typically exhibit higher torques at low speeds, their non-exhaust emissions tend to be higher than for comparable conventional vehicles, especially those generated by tires."). [EPA-HQ-OAR-2022-0985-1660-A1, pp. 55 - 56]

At various other points in the proposed rule, the agency asserts without explanation that the per-mile rate of brake wear is "expected to be lower" for electric vehicles "due to regenerative braking systems." 88 Fed. Reg. at 25,987; see also id. at 26,035; Draft RIA at 185, 194. EPA cites nothing to support that expectation. But even if true, that has nothing to do with tire wear—an independent source of particulate emissions and, by some accounts, "the most important one." OECD, Non-Exhaust Particulate Emissions from Road Transport (Dec. 7, 2020); see also Kris Vanherle et al., Transport Non-Exhaust PM-Emissions, European Envt'l Agency (Mar. 2021) ("[R]egardless of the potential of regenerative braking to reduce brake wear, on motorways, EVs have higher PM emissions compared to ICEVs due to higher tyre wear associated with higher weight."). Other studies note that regenerative braking is one of "the most commonly answered reasons" for accelerated tire wear, further demonstrating that the existence of regenerative braking does not justify EPA's omission. Mirzanamadi, Users' Experience of Tyre Wear, supra, at 11, 51. [EPA-HQ-OAR-2022-0985-1660-A1, p. 56]

The proposed rule, requiring a widespread shift to electric vehicles, would therefore affect particulate emissions much differently than prior rules that focused solely on adaptations for internal-combustion-engine vehicles. Indeed, according to a recent study, particulate emissions from tire wear are "around 1,850 times greater" than those that come from a tailpipe. Emission Analytics, Graining Traction, Losing Tread Pollution from Tire Wear Now 1,850 Times Worse than Exhaust Emissions (May 10, 2022). And the Organisation for Economic Cooperation and Development reports that "[w]ear and tear from brakes, tyres and road surfaces will soon overtake car exhaust fumes as the leading source of fine particles released into the air by road traffic, . . . and heavy electric vehicles with long-distance batteries could compound the problem even as they slash emissions from engine exhaust." Measures Needed to Curb Particulate Matter Emitted by Wear of Car Parts and Road Surfaces, OECD (July 12, 2020). By excluding this category of emissions from its analysis, EPA elides one of the key ways its proposal will cause more harm than good. [EPA-HQ-OAR-2022-0985-1660-A1, pp. 56 - 57]

Upstream Emissions. In addition to overstating reductions in downstream emissions, the proposed rule fails to account properly for increases in "upstream" emissions—those that "are not emitted by the vehicle itself but can still be attributed to its operation." Draft RIA at 310. In evaluating this category, EPA improperly cabins its analysis to only those emissions caused by electric-generating units ("EGUs") and refineries—i.e., emissions generated to provide power to operate vehicles. See 88 Fed. Reg. at 26,039–40; Draft RIA at 310. This marks another unexplained shift in agency policy. And even when examining this limited set of upstream sources, the agency makes unfounded assumptions and methodological choices that are (once again) skewed in favor of the proposed rule. [EPA-HQ-OAR-2022-0985-1660-A1, p. 57]

First, the emissions associated with powering a vehicle—whether by electricity from an EGU or fuel from a refinery—are far from the only ones reasonably "attributed" to its operation. Draft RIA at 310. Depending on the vehicle, there are also emissions associated with producing, recycling, and disposing of batteries; operating charging infrastructure; and extracting, refining, transporting, and storing petroleum fuels. These emissions can be substantial and, when considered together, may undermine EPA's assumption that swapping internal- combustion-engine vehicles for electric ones will necessarily result in an environmental good. [EPA-HQ-OAR-2022-0985-1660-A1, p. 57]

The International Energy Agency's discussion of emissions from mining illustrates this point. According to the IEA, "the production and processing of energy transition minerals are energy-intensive" and involve "relatively high emission[s]." Role of Critical Minerals at 15, 130; see also Charging Infrastructure Challenges for the U.S. Electric Vehicle Fleet, Am. Transp. Rsch. Inst., https://tinyurl.com/3ktjd85v ("Mining and processing produce considerable CO2 and pollution issues."). For this reason, producing an electric vehicle is a more carbon- intensive process than producing a conventional one. Role of Critical Minerals at 194. [EPA-HQ-OAR-2022-0985-1660-A1, pp. 57 - 58]

EPA never explains why emissions from EGUs and refineries are the only ones relevant to the analysis. Nor does it acknowledge that its current position departs from earlier GHG rulemakings, where it did consider additional upstream sources. See HD GHG I, 76 Fed. Reg. at 57,301 ("To project these impacts, EPA estimated the impact of reduced petroleum volumes on the extraction and transportation of crude oil as well as the production and distribution of finished gasoline and diesel."); HD GHG II, 81 Fed. Reg. at 73,852 ("To project these impacts, Model B estimated the impact of reduced petroleum volumes on the extraction and transportation of crude oil as well as the production and distribution of finished gasoline and diesel."). EPA has an obligation to explain why a more cabined view of upstream emissions is appropriate here. See Am. Fed'n of Gov't Emps, 25 F.4th at 12. [EPA-HQ-OAR-2022-0985-1660-A1, p. 58]

Second, EPA's assessment of EGU emissions is flawed. EPA assumes that the amount of emissions associated with increased demand for electricity will "decrease[] over time because of projected changes in the future power generation mix, including cleaner combustion technologies and increases in renewables." 88 Fed. Reg. at 25,935. That expectation is entirely speculative and, in large part, based on the availability of three tax credits that Congress recently approved as part of the IRA to incentivize manufacturing, production, and investment in low-carbon initiatives. See id. at 25,935 n.63, 26,040 n.654, 26,044; Draft RIA at 321 n.vi, 325, 345, 347, 349. The agency does not explain the applicability of these tax credits or provide any data or evidence showing, or even suggesting, that they will have such a material impact on the power-generation mix. See Appalachian Power Co. v. EPA, 249 F.3d 1032, 1053 (D.C. Cir. 2001) (per curiam) (explaining that "model assumptions must have a 'rational relationship' to the real world"). Before modeling EGU emissions based on them, EPA must make an earnest effort to assess the number of EGUs that will receive the credits and whether the savings will be enough to incentivize such a major shift in their operations. If the agency is unable or unwilling to provide that analysis, it must project EGU emissions based on the power-generation mix that is now available. And if EPA concludes that the power-generation mix will change even without the widespread availability of the IRA tax credits, it must explain the basis for that belief. [EPA-HQ-OAR-2022-0985-1660-A1, p. 58]

In addition, whether the power-generation mix stays the same or changes in the way EPA speculates, it is necessary to assess whether EGUs will use the same sources to power their base loads and the peak loads that will inevitably occur if the proposed rule is adopted. According to a recent study, changes in the electricity sector have caused EGUs to increasingly rely on coal to meet demand that exceeds their typical capacity. See Stephen P. Holland et al., Why Marginal CO2 Emissions Are Not Decreasing for US Electricity: Estimates and Implications for Climate Policy, Nat'l Acad. of Scis., at 1 (2022) ("More recently, however, changes in the electricity sector have pushed coal, which has the greatest CO2 intensity, to more frequently be used as the marginal fuel for generation, thereby increasing marginal emissions."). Providing electricity to meet peak loads can therefore have a disproportionately high impact on emissions, which cannot be adequately captured by looking at "average emissions" (i.e., carbon intensity) across the electricity sector. Id. Instead, "estimates of marginal emissions . . . are needed to accurately evaluate the impacts of policies or behaviors that cause changes in the demand or supply of electricity." Id. at 2. [EPA-HQ-OAR-2022-0985-1660-A1, p. 59]

The authors of the study demonstrated the importance of this point in the context of electric vehicles. They analyzed the Biden Administration's goal to make half of new vehicle purchases electric by 2030 and concluded that, when taking marginal emissions into account, "the increase in electricity sector CO2 emissions . . . would undo more than half of the reductions from reducing the number of gasoline-fueled, light-duty vehicles." Holland et al., Why marginal CO2 emissions are not decreasing, supra, at 2. By contrast, if they had instead looked only at average emissions, "the emissions reductions would [have been] overestimated by somewhere between 27% and 114%." Id. [EPA-HQ-OAR-2022-0985-1660-A1, p. 59]

EPA does not explain whether or how it takes marginal emissions into account when estimating EGU emissions. Neither the notice of proposed rulemaking nor the draft regulatory impact analysis discusses this concept, and stakeholders were denied an opportunity to study the agency's complicated modeling given the exceedingly short window for public comment. Given the importance of this issue, EPA should clearly explain whether it considered marginal emissions as the study discussed above advises, and if not, the basis for its alternative approach.8 [EPA-HQ-OAR-2022-0985-1660-A1, p. 59]

8 EPA's underestimation of EGU emissions also affects its evaluation of fuel-cell vehicles. Although the vast majority of hydrogen used for fuel-cell vehicles is made through "steam methane reforming," "largely as part of petroleum refining and ammonia production," the agency makes the "simplifying assumption" that "all hydrogen used for FCEVs is produced via grid electrolysis of water and can therefore be entirely represented as additional demand to EGUs." 88 Fed. Reg. at 26,042 & n.664; Draft RIA at 321–22. Even assuming that "simplifying assumption" is warranted, EPA must accurately predict EGU emissions to measure the effect of shifting from internal-combustion-engine to fuel-cell vehicles. For the reasons described above, it has not done so.

Finally, EPA may be substantially overestimating the decrease in refinery emissions. The agency "assumed refinery activity decreases with decreased demand for liquid fuel from heavy-duty vehicles." 88 Fed. Reg. at 26,040. But at the same time, EPA "recognize[d] that there is significant uncertainty in the impact reduced fuel demand has on refinery emissions." Draft RIA at 327. "If refineries do not decrease production in response to lower domestic demand" and "increase exports instead," then the agency "would project no emission reductions from refineries" rather than the ones they include in their analysis. Id. (emphasis added); see also id. at 345, 350. EPA must explain the basis for its assumption that refineries will decrease production before it factors these sizeable reductions into the calculation. See Int'l Harvester Co., 478 F.2d at 645 (explaining that EPA must "support its methodology as reliable" with more than "speculation"). [EPA-HQ-OAR-2022-0985-1660-A1, p. 60]

Organization: American Fuel and Petrochemical Manufacturers (AFPM)

1. EPA Cannot Adequately Substantiate the Need for Regulatory Action

The structure of the Clean Air Act and its regulatory provisions for standard setting also are premised on EPA identifying sources of emissions that cause or contribute to non-attainment with the National Ambient Air Quality Standards ("NAAQS"). However, EPA makes no attempt to outline a baseline scenario whereby all stationary and mobile sources in the country achieve current EPA standards. Such a baseline is necessary because it is the only means by which the agency and the public can compare the marginal costs and benefits of further tightening emission standards and deploying different technologies and alternatives. EPA's failure to conduct either a baseline or marginal analysis (while also failing to account for billions of dollars in costs) is inconsistent with the structure of the Clean Air Act, and good regulatory practice, and makes it impossible to conduct an alternatives analysis, as required under Executive Order 12866 (Regulatory Planning and Review) and OMB Circular A-4; as such, the proposed rule, if finalized, is arbitrary and capricious. [EPA-HQ-OAR-2022-0985-1659-A2, p. 24]

In addition to the above, EPA did not fully consider that the higher purchase price of new ZEVs will keep older, more polluting trucks on the road longer whereas new and heavier ZEVs will increase particulate matter ("PM") emissions through increased brake, tire, and road wear. Data from EPA's 2020 National Emissions Inventory97 shows that direct PM2.5 emissions from roadways can be due to roadway dust vs. on-road mobile vehicle engine emissions. Roadway dust emissions which include particles from tire wear are correlated with vehicle weight, so increases in fleet average vehicle weight would be expected to increase roadway dust PM2.5 emissions.98 In addition, a study by the American Transportation Research Institute found that the weight of a BEV Class 8 Sleeper Cab tractor is nearly double that of a comparable ICEV, weighing 32,016 pounds (lbs) versus 18,216 lbs.99 Therefore, converting ICEs to ZEVs under the proposed regulation would significantly increase the average vehicle weight on U.S. roadways, which in turn would increase the entrained road dust emissions. There also exist overall truck weight restrictions, which could require a greater number of ZEVs to move the same tonnage of cargo, thus increasing vehicle miles traveled and potentially PM emissions. EPA also ignores the GHG emissions associated with manufacturing more, less dense, remotely located intermittent generation sources and battery back-up, plus the need for more natural gas peaking capacity and massive transmission, substation, and transformer investment to integrate these technologies into the power grid. Those emissions are significant and may offset or eliminate the benefits that EPA calculates. [EPA-HQ-OAR-2022-0985-1659-A2, pp. 26 - 27]

Organization: American Petroleum Institute (API)

1. Decrease in non-GHG refinery emissions

We question the agency's projections of refinery emissions decreases due to reduced fuel demand (Draft RIA, Table 4/18). The analysis assumes that there will be less domestic fuel demand due to a marked uptick in the use of HD ZEVs. However, as we have noted throughout these comments, there is significant concern that the market may not reach the levels of HD ZEV penetration suggested by the proposal. If fleets continue to use ICEVs in significant numbers, which could reasonably be expected based on various factors (e.g., the life of HD vehicles, costs of purchasing new vehicles, etc.), even with an increased use in biofuels, there will continue to be a demand for conventional fuels. There could also be increased demand for refined products in other countries that the U.S. could supply. [EPA-HQ-OAR-2022-0985-1617-A1, pp. 13 - 14]

Furthermore, EPA's analysis assumes that lower domestic fuel demand, due to increased usage of HD ZEVs, will result in reduced refinery throughput. However, this assumption may not hold true as the U.S. has emerged as a major player in the global market for refined products, actively exporting significant quantities. While the EPA assumes that a gallon of reduced domestic demand would reduce net crude and product imports by 0.864 (Draft RIA Section 6.5), their assumption fails to consider the possibility that refinery throughput could remain steady while the U.S. simultaneously increases its exportation of refined products. [EPA-HQ-OAR-2022-0985-1617-A1, p. 14]

EPA justifies its assumption that imports will fall 86.4 percent by comparing the AEO 2022 Reference case with the AEO 2022 Low Economic Growth case. This comparison is not suitable for drawing these conclusions because in the Low Economic Growth case, U.S. refined product exports are lower compared to the Reference Case, suggesting a decline in global demand for refined products. Regardless of the assumption's merits, the EPA doesn't explicitly state, in its regulatory impact analysis, that the reduced global demand for refined products is, in part, an assumption based on the forecasts EPA uses for its analysis and not attributable to its regulation. [EPA-HQ-OAR-2022-0985-1617-A1, p. 14]

Organization: Clean Air Task Force

A. EPA underestimated the net benefits of the proposed rule by undercounting refinery emissions.

EPA attempts to account for the climate benefits and the criteria pollutant health benefits of the proposed rule in its quantitative cost-benefit analysis. See 88 Fed. Reg. 26074-26078. For both of these analyses, EPA includes emissions from onroad heavy-duty vehicles (i.e., tailpipe emissions) and upstream emissions from electric generating units (EGUs) that produce the fuel (e.g., electricity, hydrogen) that powers ZEVs. However, EPA does not include in this analysis upstream emissions from refineries that produce the fuel (i.e., gasoline or diesel) that powers combustion vehicles. In order to calculate the full net benefits of the proposed rule, and to provide parallel treatment of fuel production for ZEVs and combustion vehicles, EPA should account for refinery emissions in its cost-benefit analysis. [EPA-HQ-OAR-2022-0985-1640-A1, pp. 79 - 80]

EPA defines upstream emissions sources as "those that occur before tailpipe emissions from vehicles, such as from electricity generation for charging BEVs, the production of hydrogen used to fuel FCEVs, and emissions generated during petroleum-based fuel production and distribution." 88 Fed. Reg. at 26039-26040. However, while EPA quantified emissions changes associated with upstream EGUs, it did not quantify emissions changes associated with producing or extracting crude or transporting crude or refined fuels. See 88 Fed. Reg. at 26044. Instead, EPA provided a limited analysis of refinery emissions in only "one analysis year (2055) and only certain non-GHG pollutants (NOx, PM2.5, VOC, and SO2)." DRIA at 344. [EPA-HQ-OAR-2022-0985-1640-A1, p. 80]

This disparate treatment of upstream emissions sources underestimates the benefits of the proposed rule. Indeed, EPA acknowledges that its methodology "likely underestimates the net emissions reductions that may result from the proposal." 88 Fed. Reg. at 26044. In the limited analysis that EPA did conduct for 2055, refinery criteria emissions decreases are of a similar order of magnitude to EGU emissions increases, the latter of which are included in the net benefit calculations. In the case of SO2, including reductions in refinery emissions resulting from the standards in net emissions calculations would shift the impact of the proposed standards from a net increase in emissions to a net decrease in emissions. [EPA-HQ-OAR-2022-0985-1640-A1, p. 80]

EPA recognizes that were it to "estimate impacts on refinery GHG emissions, [EPA would] expect that the decrease in liquid fuel consumption associated with this rule would lead to a reduction in those emissions." 88 Fed. Reg. at 25935 n.62. Refinery emissions can increase the lifecycle GHG emissions of petroleum-based fuels over downstream tailpipe emissions significantly, depending on the source and type of oil. For example, accounting for refinery (midstream) emissions from oil produced from South Belridge in California's San Joaquin Valley would increase total emissions by 20 percent compared to just accounting for combustion (downstream) emissions.350 [EPA-HQ-OAR-2022-0985-1640-A1, p. 80]

350 Carnegie Endowment for Int'l Peace, Profiling Emissions in the Supply Chain, Oil-Climate Index, http://oci.carnegieendowment.org/#supply-chain (last visited June 9, 2023).

In finalizing the standards, EPA should ensure that it has a complete accounting of these upstream refinery emissions to properly measure the net benefits of the options under consideration. Failing to do so would undercount the benefits associated with more stringent standards. [EPA-HQ-OAR-2022-0985-1640-A1, p. 80]

Organization: Clean Fuels Development Coalition et al.

And, as will be discussed later in this comment, the proposal's listed costs grossly underestimate the rule's true costs. The proper metric is aggregate cost because the major-questions doctrine asks about the rule's significance to the "national economy." West Virginia v. EPA, 142 S. Ct. at 2609 (2022). These aggregate costs include: [EPA-HQ-OAR-2022-0985-1585-A1, p. 4]

Air quality effects: This includes the air quality and health impacts from significant increases in tire wear from heavy-duty vehicles, as well as the increases in CO2 emissions that will result from manufacturing more electric generation infrastructure, transmission, distribution, charging equipment, the manufacturing of batteries, etc.5 Most egregious is the omission of the cost of increased brake and tire wear, which the proposal describes as "a significant source of particulate emissions" and estimates that, if they were included, the expected reduction in particulate emissions would decrease by half or more in every year the agency considered. DRIA at 328. These added emissions are so high that they offset most of the benefits from eliminating tailpipe emissions. [EPA-HQ-OAR-2022-0985-1585-A1, pp. 5 - 6]

5 As will be discussed later in the comment, EPA's current assessment of emissions impacts, listed in Table ES-5, are "downstream" only, meaning the "emissions processes … that come directly from a vehicle, such as tailpipe exhaust, crankcase exhaust, evaporative emissions, and refueling emissions." 88 Fed. Reg. 25,935. This unreasonably ignores all the "upstream" emissions the rule would produce and does so only by footnote. This appears to be intentionally misleading.

D. The proposed rule misstates emissions benefits because it neglects upstream electric generating unit emissions, among others.

In addition to underestimating costs, the proposal also overstates benefits. The most egregious of these comes from the way EPA accounts for upstream emissions for electric generating units. To realize substantial reductions in GHG emissions—and thus benefits from said emissions—the rule relies on the decrease in emissions from petroleum-fueled heavy-duty vehicles replaced by electric heavy-duty vehicles. But these vehicles are themselves still responsible for emissions from the electricity that powers them. Current electricity GHG emissions factors are approximately 442,000 U.S. Tons of CO2 / Terawatt-Hour. How much carbon dioxide is produced per kilowatt-hour of U.S. electricity generation, Energy Information Administration, https://www.eia.gov/tools/faqs/faq.php?id=74&t=11. The proposal estimates that this will fall to 136,686 U.S. Tons of CO2 / Terawatt-Hour in 2035 and 30,130 U.S. Tons of CO2 / Terawatt-Hour in 2050. DRIA at 325. [EPA-HQ-OAR-2022-0985-1585-A1, p. 34]

This is unrealistic. Emissions reduction on the U.S. electric grid have thus far come primarily from natural gas replacing coal. To continue to lower CO2 emissions in this manner would require an almost complete conversion to low carbon sources. But barriers to wind, solar, and nuclear adoption will not enable these changes. Furthermore, researchers estimate that the 350 million EVs required to decarbonize the fleet in 2050 could use as much as half of US national electricity demand. Thea Riofrancos et al., Achieving Zero Emissions with More Mobility and Less Mining, U.C. Davis Climate + Community Project (Jan. 2023), https://subscriber.politicopro.com/eenews/f/eenews/?id=00000185-e562-de44-a7bfed7751a00000. [EPA-HQ-OAR-2022-0985-1585-A1, p. 34]

These costs also ignore that realizing these reductions requires the installation of new solar and wind generation, which itself has a cost. Without additional wind and solar generation, upstream emissions from electricity generating units will not decrease as much as EPA expects, diminishing those benefits. In addition to the direct costs of this generation, the proposal also ignores the greenhouse gas emission associated with manufacturing more, less dense, remotely located intermittent generation sources, and the battery back-up; transmission, substation, and transformer investment to integrate these technologies into the power grid; and natural gas peaking capacity necessary to sustain their intermittency. These emissions are significant and must be accounted for in the calculation of any benefits of the proposed rule. [EPA-HQ-OAR-2022-0985-1585-A1, pp. 34 - 35]

Organization: Cummins Inc.

We also appreciate EPA's assumption that emissions generated from creating hydrogen are the same as grid emissions. [EPA-HQ-OAR-2022-0985-1598-A1, p. 9]

Organization: Delek US Holdings, Inc.

EPA compounds this flaw by making unsupported assumptions regarding total emissions impacts of its proposal. While it claims that the overall analysis for combined downstream and upstream emissions "likely underestimates the net emissions reductions that may result" from the Proposed Rule, EPA failed to offer a data-based substantiation. The Proposed Rule did not quantify emissions changes associated with producing or extracting crude or manufacturing refined fuels.18 It failed to assess emissions from battery manufacturing or electricity production. EPA should provide a more comprehensive analysis to comply with its directive under the Clean Air Act and better assess the resulting impact of the Proposed Rule. [EPA-HQ-OAR-2022-0985-1561-A1, p. 5]

18 Proposed Rule at 26,044. Although EPA stated it "expects the increased adoption of HD ZEVs to increase emissions from EGUs and decrease emissions from refineries," EPA quantified only the criteria pollutant emission reductions it anticipated from Refineries for the year 2055. Proposed Rule at 25,936, 26,042–44 (Table V–9).

The Proposed Rule predicts net emissions reductions but does not adequately evaluate local ambient air quality impacts from increased power generation spurred by the mass adoption of electric vehicles. Although EPA modeled changes to power generation anticipated by the Proposed Rule as part of its upstream analysis, EPA does not consider the potential degradation of air quality in areas in the direct vicinity of existing or new power plants, especially as the need for baseload generation at times when the sun is not shining and the wind is not blowing rises exponentially with rapid electrification.38 [EPA-HQ-OAR-2022-0985-1561-A1, p. 8]

38 Proposed Rule at 25,983.

Organization: Environmental Defense Fund (EDF)

VI. EPA should ensure rigorous accenting and protective safeguards are in place related to the production and use of hydrogen

a) EPA should ensure its assessment of hydrogen is rigorous, comprehensive, and fully accounts for potential adverse climate and health impacts associated with hydrogen production and use

i. The method of hydrogen production impacts whether hydrogen fueled vehicles decrease the vehicle's associated emissions when compared to diesel vehicles or increases them.

In the proposal, EPA assumes all of the hydrogen used to fuel FCEVs will be produced through grid electrolysis. Currently, 95% of hydrogen is produced from natural gas in a process called steam methane reformation (SMR).206 SMR emits CO2 as a byproduct of the hydrogen production resulting in a carbon intensity of between 8 and 12 kg of CO2/kg H2. Hydrogen produced using electricity from the current U.S. average grid has a carbon intensity of 21 kg of CO2/kg H2.207 [EPA-HQ-OAR-2022-0985-1644-A1, 78]

206 DRIA page 80

EDF assessed the emissions associated with vehicles using different sources of hydrogen, calculating the difference in CO2 emissions of BEVs, FCEVs, and H2ICE vehicles, and conventional diesel ICE vehicles with the carbon intensities of the fuels along with the powertrain efficiencies taken into consideration. We used the vehicle efficiencies from ICCT's report on decarbonizing tractors. The efficiencies used in that study are similar to those assumed by EPA in HD TRUCS with the exception that ICCT also includes H2 ICE vehicles allowing for an equal comparison.208 We included the combustion emissions from diesel, the production emissions from electricity and SMR hydrogen, and the electricity production emissions for grid electrolysis hydrogen. We included hydrogen produced using the current grid, EPA's modeled incremental 2035 grid, and linearly extrapolated to calculate the grid emissions in 2027.209 210 The results of this analysis are plotted below in Figure 12, which importantly does not include any additional upstream emissions (i.e. methane emissions from natural gas production). [EPA-HQ-OAR-2022-0985-1644-A1, 79] [See Figure 12 on p. 80 of Docket Number EPA-HQ-OAR-2022-0985-1644-A1]

209 Frequently Asked Questions: How much carbon dioxide is produced per kilowatt-hour of U.S. electricity generation? 2022. U.S. Energy Information Administration, https://www.eia.gov/tools/faqs/faq.php?id=74&t=11

210 Section 4.3.3.2 EGU Emissions Modeling Methodology from Draft RIA

Regardless of the grid, the emissions from the electricity needed to power BEVs is lower than the combustion emissions from a diesel vehicle. Using the current grid, BEVs represent a decrease of roughly a third and by 2035, they reduce emissions by almost 80%. This analysis shows that the emission reductions from FCEVs and H2ICE vehicles are highly dependent on the production method of the hydrogen and increase emissions relative to diesel vehicles when the hydrogen is produced by SMR, the current grid, and even the projected 2027 grid. Additionally, assuming EPA's 2035 grid mix, the emission benefits of BEVs are roughly twice those of FCEVs and four times those of H2ICE vehicles. [EPA-HQ-OAR-2022-0985-1644-A1, 80]

Moreover, FCEVs and ICE vehicles are much less efficient than BEVs. Additionally, 40% of the energy from the electricity used to make hydrogen using electrolysis is lost in the process. When the inefficiencies of both processes are combined, it takes 2.6 times as much electricity to power a FCEV as a BEV. When considerations like compression and transportation of the hydrogen are included, three to four times more energy is needed for hydrogen road transportation.211When considerations like compression and transportation of the hydrogen are included, three to four times more energy is needed for hydrogen road transportation compared to battery electric vehicles.212 213 [EPA-HQ-OAR-2022-0985-1644-A1, 80-81]

211 Eriko Shrestha and Tianyi Sun. Rule #1 of deploying hydrogen: Electrify first. 2023. 212 Eriko Shrestha and Tianyi Sun. Rule #1 of deploying hydrogen: Electrify first. 2023. EDF Blog Energy Exchange, https://blogs.edf.org/energyexchange/2023/01/30/rule-1-of-deploying-hydrogen-electrify-first/

213 Hydrogen vehicles fueled with low-GHG hydrogen would provide substantial climate benefits relative to diesel vehicles. They would also require substantially more low carbon electricity than a BEV.

Unless hydrogen fueled vehicles use low-GHG hydrogen, they do not substantially reduce climate emissions. While switching to BEVs reduces emissions relative to diesel vehicles using today's grid, the same cannot be said for FCEVs or H2ICE vehicles using hydrogen produced from SMR or grid electrolysis – both of which increase emissions relative to diesel vehicles. Indeed, even in 2030, emissions associated with grid electrolysis hydrogen fueled vehicles are higher than diesel vehicles. [EPA-HQ-OAR-2022-0985-1644-A1, 81]

ii. EPA should consider the impacts of hydrogen leakage given recent science demonstrating climate impacts.

While EPA accounts for the EGU emissions associated with hydrogen production from grid electrolysis in the assessments of costs and benefits, the impact of hydrogen leakage is not accounted for in the proposal. A recent but growing body of evidence clearly shows that hydrogen gas in the atmosphere causes global warming and EPA must consider these impacts when setting standards. [EPA-HQ-OAR-2022-0985-1644-A1, p. 81]

Hydrogen is a short-lived, indirect GHG that causes warming by increasing the concentration of other GHGs in the atmosphere. It is a small and slippery molecule that can easily escape from all parts of the value chain. Recent studies have found hydrogen's warming power is over 30 times larger than CO2 pound for pound over the 20 year period after it is emitted, and about 10 times larger over 100 years – values that are 2-6 times higher than previously thought.214 EDF research shows that if the hydrogen emissions rate is high across the value chain, it can severely undermine the intended benefits of clean hydrogen.215 [EPA-HQ-OAR-2022-0985-1644-A1, p. 81-82]

Department for Business, Energy & Industrial Strategy. https://www.gov.uk/government/publications/atmospheric-implications-of-increased-hydrogen-use (Attachment DD).

215 Id.

Currently, estimates of hydrogen leakage rates range considerably, due to a lack of empirical data on leakage from specific infrastructure such as electrolyzers, pipelines, and storage. Hydrogen emissions associated with production include both unintended leakage and intentional purging/venting (which can be controlled by incorporating technology that recombines purged and vented hydrogen back into the production process). Overall, estimates of emissions associated with electrolytic hydrogen production currently range from 0.1% to 9.2%. Blue hydrogen production is estimated to have less than 1.5% hydrogen emissions, since waste gas is likely to be flared or used for process heat. Hydrogen also has the potential to leak from various delivery segments of the value chain, including compression, liquefaction, storage, and transportation via pipelines or trucks. Overall, current estimates of leakage rates for the full hydrogen value chain, including production, processing, storage and delivery, range up to 20%.216 [EPA-HQ-OAR-2022-0985-1644-A1, p. 82]

216 Estimates include Cooper et al., (2022). "Hydrogen emissions from the hydrogen value chain-emissions profile and impact to global warming". Science of the Total Environment. Vol. 830. https://linkinghub.elsevier.com/retrieve/pii/S004896972201717X; Frazer-Nash Consultancy (2022). "Fugitive Hydrogen Emissions in a Future Hydrogen Economy". https://www.gov.uk/government/publications/fugitive-hydrogen-emissions-in-a-future-hydrogen-economy; Arrigoni, A. and Bravo Diaz, L. (2022). "Hydrogen emissions from a hydrogen economy and their potential global warming impact". Publications Office of the European Union, Luxembourg. doi:10.2760/065589, JRC130362; and Schultz et al., (2003). "Air Pollution and Climate-Forcing Impacts of a Global Hydrogen Economy". Science, Vol. 302. https://www.science.org/doi/10.1126/science.1089527

Studies on hydrogen leakage often rely on natural gas supply chain leakage as a proxy, and there is a high degree of uncertainty in existing methane emission estimates. Moreover, the patterns of hydrogen leakage can be different from that of methane, with fluid dynamics theory suggesting that hydrogen can leak 1.3 to 3 times faster than methane, and experimental studies suggest different leak rates for different leak regimes.217 However, development of appropriate sensor technologies is currently underway which would enable such measurement. [EPA-HQ-OAR-2022-0985-1644-A1, p. 82-83]

217 Ibid.

No estimates currently exist of the potential for leakage that would result from FCEVs or H2ICE vehicles fueling or the potential leakage that could result from vehicles while they are in use. Given the nature of hydrogen (small and as a result leak prone) and the necessary widespread infrastructure needed to enable vehicle refueling, the potential for leakage is a large source of concern for EDF. Accordingly, we urge EPA to consider the impact of hydrogen leakage in impacting the greenhouse gas emissions profile of H2 ICE vehicles and fuel cell vehicles. [EPA-HQ-OAR-2022-0985-1644-A1, p. 83]

b) EPA significantly underestimated upstream emissions from the production, transportation and distribution of gasoline and diesel fuel

EPA underestimates upstream emissions from the production, transportation and distribution of gasoline and diesel fuel. Using more reasonable assumptions to characterize these emissions would increase the benefits of EPA's heavy-duty standards. In particular, there are several areas we encourage EPA to more fully consider, to provide a more comprehensive assessment of the final rule's benefits. [EPA-HQ-OAR-2022-0985-1644-A1, p. 91]

1) Production of raw materials used in the production of gasoline and diesel fuel. EPA has not, but should, consider upstream emissions impacts associated with changing crude oil production and in doing so, should consider differences in pollution profiles associated with specific types and source of crude oil no longer being used by U.S. refineries as well as emissions associated with other potential refinery inputs (for instance natural gas or natural gas liquids.) These emissions are included in GREET and we encourage EPA to likewise include them in its analysis. [EPA-HQ-OAR-2022-0985-1644-A1, p. 91]

2) Transportation of gasoline and diesel fuel to the refinery. EPA likewise did not consider emissions associated with transportation of gasoline and diesel fuels to refineries. GREET addresses the emissions from transporting the other raw materials used by refineries, such as natural gas and natural gas liquids and EPA should include their reduction (including both greenhouse gases and other air pollutants) in its benefit analyses of the Final Rule. [EPA-HQ-OAR-2022-0985-1644-A1, p. 91]

3) Refinery Emissions. EPA does consider refinery emissions but consideration appears limited to 2055 and is not reflected in the agency's cost-benefit analysis. We encourage EPA to remedy both of these issues, extending the analysis and ensuring the pollution reduction benefits are part of EPA's cost-benefit analysis. EDF estimated the health benefits of reductions in upstream fossil fuel emissions using EPA's projections of the reduction in gasoline and diesel fuel use for this proposal.241 We applied the upstream emission factors that EPA used in its recent light-duty GHG rule for MYs 2023-2026 to these emission reductions.242 EDF then applied the benefit per ton estimates for a 3% discount rate for refinery emissions for the year 2040 to these emission reductions.243 [EPA-HQ-OAR-2022-0985-1644-A1, p. 91-92]

241 Table 6-2 of the Draft RIA

242 Row 29 of the UE_Gasoline and Row 29 of the UE_Diesel worksheets of the "parameters_FW-OEMs_YearShift.xlsx" file used to estimate emission impacts of the final standards. Changes in CNG use (in terms of gasoline equivalent gallons) were added to those of gasoline.

243 Table 14, Technical Support Document, Estimating the Benefit per Ton of Reducing Directly-Emitted PM2.5, PM2.5 Precursors and Ozone Precursors from 21 Sectors, U.S. Environmental Protection Agency Office of Air and Radiation Office of Air Quality Planning and Standards Research Triangle Park, NC 27711, April 2023

This "benefit per ton" analysis was the most recent we could readily find. It only presents a point estimate for each pollutant, while past studies, including EPA's analysis of emissions from vehicles and electricity generating units in this Proposal typically present a range. We found a net present value in 2027 (discounted at 3% per year) for upstream fossil fuel health benefits of $29 billion. Comparing these point estimates of the benefits per ton of refinery emissions to those developed by EPA in 2018 implies that they represent a mid-point of the typical range.244 This $29 billion estimate of the health benefits of reduced upstream fossil fuel emissions exceeds the mid-point of EPA's total estimate of health benefits of the proposal of $15-$29 billion.245 Though this estimate is approximate, it underscores the magnitude of these benefits and the importance of EPA considering them in its final rule. [EPA-HQ-OAR-2022-0985-1644-A1, p. 92]

244 Technical Support Document, Estimating the Benefit per Ton of Reducing PM2.5 Precursors from 17 Sectors U.S. Environmental Protection Agency Office of Air and Radiation, Office of Air Quality Planning and Standards Research Triangle Park, NC 27711, February 2018

245 Table 7-18 of the Draft RIA.

4) Finished fuel distribution and production and transportation of ethanol to retail fuel stations. EPA likewise failed to consider these impacts and doing so is possible using existing tools, including GREET. [EPA-HQ-OAR-2022-0985-1644-A1, p. 92]

5) Emissions from the production and transportation of ethanol used in U.S. gasoline should also be considered. EPA makes no mention of these emissions. [EPA-HQ-OAR-2022-0985-1644-A1, p. 92]

In each of these areas, EPA has either failed to consider or underestimated emissions associated with production and distribution of gasoline and diesel fuel. A more comprehensive assessment of these impacts would only further strengthen the benefits of final heavy-duty vehicle standards. [EPA-HQ-OAR-2022-0985-1644-A1, p. 93]

Organization: MCS Referral & Resources

Comment 1

In Tables V-6 and IX-9 (reprinted below), the estimated reductions are not credible because they are based on not credible estimates of total emissions before reductions. [EPA-HQ-OAR-2022-0985-1629-A1, p. 1]

The tables show downstream HDE reductions in both criteria and toxic air pollutants under EPA's proposal and an alternative, expressed in tons and as a % of estimated emissions before any reductions for 2035, 2045 and 2055. [EPA-HQ-OAR-2022-0985-1629-A1, p. 1] [[See Docket Number EPA-HQ-OAR-2022-0985-1629-A1, page 1, for referenced tables]]

From these tables (and from the data on reductions in downstream carbon dioxide given in Tables V-4 and IX-7), I calculated the estimates used by EPA of the total emissions for CO2 and several of the criteria pollutants before downstream reductions in 2035, 2045, and 2055. The total emissions BEFORE reductions should be the same under both proposals. [EPA-HQ-OAR-2022-0985-1629-A1, p. 2]

As shown in DD Table 1 below, they are within 5% of each other in all cases except the PM estimates for 2035, which are inexplicably 11.9% higher for the EPA proposal than the alternative. [EPA-HQ-OAR-2022-0985-1629-A1, p. 2]

Critically, all these downstream pollutant estimates (pre-reduction) also should rise or fall together in 2045 and 2055, relative to the prior decade, given that they are all coming from the same group of non-electric vehicles. But as shown in the columns at right labeled % Change…, this is not the case. [EPA-HQ-OAR-2022-0985-1629-A1, p. 2]

Implausibly and inconsistently, the pre-reduction pollutant estimates for CO2, CO, PM, and NOx all showed no change or declined from 2035 to 2045 (as shown in red below), while only NOx also declined from 2045-55. The most extreme declines are seen in the pre-reduction emissions for PM in 2045, which EPA is estimating will decrease by 49% from 2035 to 2045 in its favored proposal, and by 43% in the alternative, while CO emissions declined less than 3% and CO2 emissions less than 4%. This is not credible. [EPA-HQ-OAR-2022-0985-1629-A1, p. 2]

Over 2 decades (from 2035-55), EPA's pre-reduction emissions of both NOx and PM2.5 declined by exactly 1/3 or more, while both CO2 and CO increased. These also are not plausible or consistent estimates. [EPA-HQ-OAR-2022-0985-1629-A1, p. 2]

We recommend that EPA recalculate all the rows in these tables using estimates for downstream emissions (pre-reductions) that are the same in both its favored proposal and the alternative. [EPA-HQ-OAR-2022-0985-1629-A1, p. 2] [[See Docket Number EPA-HQ-OAR-2022-0985-1629-A1, page 2, for referenced tables]]

Carbon monoxide should be included in all tables that estimate GHG emissions because it is a greenhouse gas. According to the IPCC, the indirect Global Warming Potential for CO over 20 years is 2.8 to 10, which is in addition to CO's direct GWG potential of approximately 1.3. See: https://archive.ipcc.ch/ipccreports/tar/wg1/249.htm#tab69 [EPA-HQ-OAR-2022-0985-1629-A1, p. 2]

Comment 10

Rows should be added for estimates of CO contributions to GHG emissions in Tables IX-7, 8, 12,13,16, and 17. [EPA-HQ-OAR-2022-0985-1629-A1, p. 5]

Organization: POET

Current hydrogen production also leads to significant upstream emissions because it is produced via steam methane reforming ('SMR') using fossil fuels as process energy.36 EPA hopes to rely on hydrogen produced via electrolysis using renewable grid electricity.37 Yet today, hydrogen produced using grid electricity, renewable or otherwise, accounts for less than 1 percent of all hydrogen produced.38 Most hydrogen—about 95 percent—is produced using SMR without carbon capture.39 The IRA and BIL incentives are meant to address this by pushing hydrogen production toward electrolysis using renewable energy or SMR with carbon capture, but that shift is in its infancy and assumptions about the rapid conversion of hydrogen production to zero-carbon sources seem highly optimistic. The IRS, for instance, has yet to release critical guidance on how it will implement the production tax credit for low-carbon hydrogen.40 Yet EPA essentially assumes that carbon-intensive hydrogen is equivalent to hydrogen produced via electrolysis using renewable or nuclear energy in terms of emissions.41 That assumption is deeply flawed, as shown by the graph below: [EPA-HQ-OAR-2022-0985-1528-A1, pp. 11-12] [Refer to Figure 1-12, DOE Comparison of Domestic Hydrogen Production Pathways, on p. 12 of docket number EPA-HQ-OAR-2022-0985-1528-A1]

36 See U.S. Dep't of Energy, Hydrogen Production: Natural Gas Reforming, available at https://www.energy.gov/eere/fuelcells/hydrogen-production-natural-gas-reforming (last visited June 16, 2023) ('95% of the hydrogen produced in the United States is made by natural gas reforming in large central plants.').

Review of U.S. EPA's Assessment of Reductions in GHG Emissions Due to HD ZEVs

At a high level, the U.S. EPA's assessment of the reductions in GHG emissions due to the deployment of HD ZEVs, presented in Chapter 4 of the DRIA, is straightforward. The agency uses its MOVES emissions inventory model to estimate GHG emissions from conventional HD vehicles and then subtracts the GHG emissions associated with the electricity used to power BEVs and the hydrogen used to power FCEVs. In estimating GHG emissions associated with electricity and hydrogen production for use in HD vehicles, U.S. EPA assumes that all BEVs will be charged using grid electricity and that all FCEVs will be fueled with hydrogen produced by electrolysis using grid electricity (DRIA Chapter 4.3.3.1.). Unfortunately, while the basic approach used in the assessment is straightforward there are a number of concerns resulting from the way it was implemented by U.S. EPA. [EPA-HQ-OAR-2022-0985-1528-A1, p. 29]

The first concern is associated with the emission factors used for electricity generation for future years that reflect U.S. EPA's assumptions of the impact of the IRA. These are presented in Table 4-8 of the DRIA. Focusing on the CO2 emission factors, the 136,686 ton per Terawatt value for 2035 is 72% lower than the 2021 value published by EIA7 for gas fired generation and 88% lower than that for coal generation. The 2050 emission factor assumed to apply by U.S. EPA is 94 and 97% lower than the EIA 2021 gas and coal emission factor, respectively. For comparison, a summary published by EIA8 suggests that the IRA will reduce electric sector CO2 emissions by about 50% in 2035 relative to 2021 with that value remaining relatively constant thereafter. Obviously, the assumption of optimistically low electricity generation emission rates by U.S. EPA leads to higher estimates for the CO2 reductions predicted to result from the Proposed Rule. [EPA-HQ-OAR-2022-0985-1528-A1, p. 29]

7
https://www.eia.gov/tools/faqs/faq.php?id=74&t=11#:~:text=In%202021%2C%20total%20annual%20U.S.%20electricity%20net%20generation,billion%20short%20tons%20%E2%80%94of%20carbon%20dioxide%20%28CO%202%29.

8 https://www.eia.gov/outlooks/aeo/IIF_IRA/

A related concern is U.S. EPA's assumption that the hydrogen used by HD FCEVs and H2-ICE vehicles will be generated from very low carbon grid electricity rather than steam methane reforming or higher carbon grid electricity. The import of this issue can be seen from Figure 1-12 of the DRIA which is reproduced below. The current carbon intensity of hydrogen produced from several different pathways are shown by the green bars. As shown, electrolysis to produce hydrogen from grid electricity is currently a high carbon intensity pathway accounting for less than 1% of hydrogen production. Reforming of natural gas without carbon capture and sequestration which accounts for about 95% of production is also a high carbon intensity pathway. However, instead of making the reasonable assumption that the carbon intensity of a substantial amount of the hydrogen used to fuel HD FCEVs will be at these levels, U.S. EPA is essentially assuming that the carbon intensity will be at the same level as that shown for production from electrolysis using electricity from renewable or nuclear generation sources. Again, if U.S. EPA's optimistic assumptions are not realized in practice, effective GHG emissions from HD FCEVs will be much higher than forecast and the GHG reductions from the Proposed Rule will be similarly reduced. [EPA-HQ-OAR-2022-0985-1528-A1, pp. 29-30] [Refer to Figure 1-12 (DOE), Comparison of Domestic Hydrogen Production Pathways, on p. 30 of docket number EPA-HQ-OAR-0222-0985-1528-A1]

Another concern with U.S. EPA's estimates of the GHG emission reductions associated with the Proposed Rule is the agency's inconsistent treatment of the methane (CH4) and nitrous oxide (N2O). These compounds are potent GHGs as shown by their 100 year global warming potential relative to CO2 in Table 4-11 of the DRIA. Also shown in Table 4-11 are the estimated reductions of these pollutants from HD vehicles from the proposed rule. However, despite the fact that electricity generation from combustion sources also results in emissions of methane and nitrous oxide, U.S. EPA fails to quantify or even mention the fact that there will be offsetting increases in emissions of these pollutants due to increased demand for electricity in Chapter 4 of the DRIA. For example, no emission factors for these compounds are presented in Table 4-8 and they are not included in any of the comparisons of increased emissions from electricity generation versus decreased emissions from HD vehicles shown in Chapter 4. This failure to properly address the overall impact of the Proposed Rule on methane and nitrous oxide emissions overstates the actual GHG emissions reduction which are shown in Table 4-15 of the DRIA. [EPA-HQ-OAR-2022-0985-1528-A1, p. 30]

The U.S. EPA Emission Inventory analysis in Chapter 4 also overstates the GHG reductions associated with the Proposed Rule by failing to account for the fact that conventional vehicles operate on fuels that are a mixture of fossil and low-carbon renewable fuels – including ethanol, renewable diesel fuel and biodiesel fuel. Based on data from EIA,9 the average ethanol content of gasoline sold in the U.S. is expected to increase from about 10% to 12% between now and 2050 while the average content of the combination of renewable and biodiesel is expected to increase from about 7% to 10% over the same range. Although the actual impact of proper accounting for renewable fuels on CO2 emissions from the Proposed Rule will be slightly smaller than the percentages listed above, they should clearly be accounted for by U.S. EPA. It is also important to note that use of ethanol and other renewable fuels capable of reducing GHG emissions from both new and in-use HD vehicles could be increased through incentives like those that have been provided to electricity and hydrogen through the IRA and the structure of the Proposed Rule. In addition, the magnitude of GHG reductions due to the use of ethanol and other renewable fuels could be increased by greater use of carbon capture and storage during their production, which would further lower their carbon intensity. [EPA-HQ-OAR-2022-0985-1528-A1, pp. 30-31]

9 https://www.eia.gov/outlooks/aeo/data/browser/#/?id=11-AEO2023&cases=ref2023&sourcekey=0

Taken together, all of the concerns discussed above suggest that GHG emission benefits of the Proposed Rule are likely to be substantially less than claimed by U.S. EPA. [EPA-HQ-OAR-2022-0985-1528-A1, p. 31]

EPA Summary and Response:

Summary:

EPA received several comments regarding emission inventories and emissions impacts of the rule, with most comments containing criticism or recommendations regarding the modeling methodologies and tools EPA used. Many commenters argued that EPA's analysis overstated the rule's emission impacts, while others argued that EPA's analysis understated the emission impacts of the rule. For the most part, these arguments related specifically to EPA's upstream emissions modeling, including emissions sources such as electricity power generation, hydrogen production, and the refining of fossil fuels for gasoline and diesel fuel.

Response:

EPA has grouped comments and their responses by subject matter. The subject matter sections include: emissions from brake wear, tire wear, and road dust; IPM and power sector modeling; refinery emissions modeling; upstream emission sources EPA estimated; hydrogen production for fuel cell electric vehicles; suggested improvements in analysis; and points needing clarification. Remaining comments and their responses are grouped together in the final section labeled "Other comments."

Emissions from brake wear, tire wear, and road dust

EPA received comments stating that even though ZEVs have zero tailpipe emissions, other emission sources from their operation are important to consider. The comments stated that the biggest source of particulate emissions from their operation come from the wearing of tires, brakes, and the fugitive emissions of road dust while driving, collectively referred to here as non-exhaust emissions. Several commenters provided comment on EPA's modeling of these emissions.

> *AmFree et al.: But in estimating the proposed rule's effect on downstream emissions, the agency omits the particulate emissions caused by brake and tire wear.*

Later in the comment, AmFree et al. repeats:

> *AmFree et al.: The agency has not acknowledged its change in position here, let alone explained "why the new approach" of ignoring emissions from brake and tire wear "better comports with . . . the provisions that Congress enacted."*

AmFree et al.: EPA instead simply states—with no further explanation—that "primary exhaust PM2.5 does not include brake wear and tire wear"; EPA includes a footnote mentioning that, if it did factor those sources into the analysis, the estimated reductions would be lower. That omission has no analytical justification, departs from prior agency practice, and improperly skews the calculation in favor of electric vehicles.

This is incorrect. EPA did model emissions from brake and tire wear for all vehicles, including ZEVs, in the proposed rulemaking. However, for the reasons described below, we assumed HD ZEVs emit brake and tire wear emissions at the same level as their ICE counterparts. The assumption of equal brake and tire wear in MOVES is the reason that emissions from these sources are only mentioned in a footnote to DRIA Table 4-12, which states in full:

"Note that primary exhaust PM2.5 does not include brake wear and tire wear which are a significant source of particulate emissions. After accounting for brake wear and tire wear, the total primary PM2.5 emission reductions would be 3 percent in 2035, 10 percent in 2045, and 13 percent in 2055." DRIA p. 328 note A to Table 4-12.

This footnote may have resulted in confusion because it refers to a reduction in the relative impact (i.e., percentage) when considering all sources of PM together instead of just exhaust. The estimated reductions in particulate matter, in absolute tons, are not impacted whether we consider total PM or just exhaust PM. Therefore, the emission estimates are not skewed. To minimize confusion, in the final rulemaking we present the impact on total particulate matter emissions.

AmFree et al., AFPM, and Clean Fuels Development Coalition et al. then describe the expected relationship between tire wear emissions and characteristics of HD ZEVs. Particulate emissions from tire wear are generated from friction at the interface of a tire and the road. The commenters stated that rates of tire wear are positively correlated with vehicle torque, acceleration, and mass because these factors cause the tires to exert a greater force against the road. The commenters also stated that HD ZEVs tend to be heavier than comparable ICE vehicles and have greater torque and acceleration across a motor's RPM range, so it is reasonable to expect EVs to have higher rates of particulate emissions from tire wear.

AmFree et al.: Emissions from tire wear, for example, rise as vehicles (1) get heavier and (2) apply higher torques at lower speeds—two traits prominent in electric vehicles, especially relative to internal-combustion-engine vehicles.

AFPM: new and heavier ZEVs will increase particulate matter ("PM") emissions through increased brake, tire, and road wear. Roadway dust emissions which include particles from tire wear are correlated with vehicle weight, so increases in fleet average vehicle weight would be expected to increase roadway dust PM2.5 emissions.

AFPM: converting ICEs to ZEVs under the proposed regulation would significantly increase the average vehicle weight on U.S. roadways, which in turn would increase the entrained road dust emissions.

Clean Fuels Development Coalition et al.: Most egregious is the omission of the cost of increased brake and tire wear, which the proposal describes as "a significant source of particulate emissions" and estimates that, if they were included, the expected reduction *in particulate emissions would decrease by half or more in every year the agency considered. These added emissions are so high that they offset most of the benefits from eliminating tailpipe emissions.*

The comments cite several sources between them. One source is a 2022 survey of BEV drivers by the Swedish National Road and Transport Research Institute (Mirzanamadi and Gustafsson, 2022).[814] This report surveyed more than 300 EV operators and found that "[t]he results showed that approximately 33% of private users and 12.5% of professional users experienced faster tyre wear in their EVs/HEVs/PHEVs, compared with tyre wear in ICEVs. Generally, for all electric vehicle types, most professional users experience similar tyre wear as for ICEVs." This study's evidence is, at best, suggestive of increased tire wear emissions, given that fewer than half of the drivers surveyed experienced increased tire wear in the real world.

Another source cited is a study published in 2022 by Ye Liu et al.[815] which estimates the relative brake and tire wear emissions of ZEVs based on mathematical modeling. In it, they demonstrate that, relative to comparable ICE vehicles, we may expect ZEVs to have increased particulate emissions from tire wear and road dust, by roughly 10% and 15%, respectively (see Table 3 in the study).

Three more sources cited by the commenters (a 2020 OECD report,[816] a 2022 report by the private company Emission Analytics,[817] and an SAE technical paper by Obereigner et al.[818]) discuss ZEV tire wear and road dust suspension relative to ICE vehicles but do not make the direct comparison between the technologies as characterized by the commenters. In discussing ZEV versus ICE non-exhaust emissions, the OECD report cited specifically acknowledges the uncertainty in the balance of ZEV and ICE non-exhaust emissions, saying, "There is no scientific consensus as to what the net effect is." The Emission Analytics report suggests that ZEVs may have greater tire wear emissions but does not directly claim this. And the cited SAE technical paper specifically discusses engineering approaches which could be used to ensure that ZEVs do not have greater tire wear PM emissions than comparable ICE vehicles.

Overall, the sources cited by the commenters do not fully support the claim that "new and heavier ZEVs will increase particulate matter emissions." We discuss further below how we considered whether it may be reasonable to project an increase in particulate emissions from tire

wear and road dust from ZEVs relative to comparable ICE vehicles, but at this time our assessment is that this relationship is uncertain and subject to change as EV engineering evolves.

AmFree et al. did not mention brake wear as a source of particulate emissions from HD ZEVs in addition to tire wear, and AFPM made only a passing mention. Unlike tire wear, it is reasonable to expect HD ZEVs to have lower brake wear emissions than comparable ICE vehicles. Most ZEVs are equipped with regenerative braking systems. Particulate emissions from brakes are generated by the force of friction used to dissipate vehicle energy at the brake surface. Heavier vehicles require more energy to be dissipated, and therefore brake wear emissions when using friction brakes will be higher. However, when a vehicle is using regenerative brakes, some of the kinetic energy from slowing the vehicle is directed towards recharging the battery instead of relying on friction brakes for deceleration. Thus, there is less material wear via friction and emissions from friction brakes and regenerative braking systems reduce particulate emissions.[819] This effect is discussed by all the non-exhaust emission studies cited by the commenters. In fact, the modeling study by Liu et al., cited by AmFree et al., found in a literature review that regenerative braking decreases brake wear emissions from ZEVs by 68 percent. In their modeling, the reduced brake wear emissions often exceed the increased tire wear and road dust emissions such that ZEVs have lower non-exhaust emission impacts, when monetized, than comparable diesel vehicles. This can be calculated using Table 6 of the paper.

EPA investigated the possibility of updating our modeling assumptions on brake wear and tire wear emissions from electric vehicles. Updating these non-exhaust PM emission rates specific to HD ZEVs would require having detailed emissions data in which brake wear and tire wear emissions can be calculated in various operating conditions. None of the sources cited by commenters support this level of detailed analysis, nor could EPA find any sources of data or studies that allow this level of detailed analysis. Many sources attempt to compare non-exhaust PM emissions from ZEVs directly to ICE vehicles, but they are often modeling studies like Liu et al. or studies done under conditions that may not be representative of real-world operation.

EPA also could not find a single study which evaluated either brake wear or tire wear of heavy-duty ZEVs specifically. All sources we found, including those cited by commenters, focus on light-duty ZEVs because they already have higher volumes of adoption. Even if studies or data focused on light-duty vehicles were at the necessary level of detail, using them to extrapolate to heavy-duty vehicles would be unreasonable because of the large number of confounding factors. The most significant factor is the fact that many heavy-duty vehicles have more axles, and therefore a greater number of non-traction tires, and many HDVs pull trailers. The impact of greater torque from the driving axle on the wear of these non-traction axle tires is not clear, nor is the impact of regenerative braking on the brake wear from these additional axles. An additional confounding factor is the fact that estimating brake and tire wear of ZEVs in a high-torque setting is not straightforward because it depends, in part, on the engineering of the vehicle's motor, brake systems, and tires. This is discussed as part of the SAE technical paper cited by AmFree et al., for example. Finally, the relationship between propulsion technology (an EV versus an ICE vehicle) and vehicle weight is less clear for heavy-duty vehicles than for light-duty vehicles because many heavy-duty vehicles are designed to pull large payloads. If heavy-duty ZEVs have comparable weight to ICE vehicles when considering a vehicle's payload, then

[819] U.S. Department of Energy. "How Regenerative Brakes Work". Energy Saver. Available online: https://www.energy.gov/energysaver/how-regenerative-brakes-work.

it would be unreasonable to expect greater rates of non-exhaust PM emissions due to differences in weight.

Overall, EPA is receptive and appreciates the comments from stakeholders regarding the modeling of tire wear, brake wear, and road dust emissions. We accounted for both brake and tire wear emissions in the proposal and do so in the final rulemaking. To estimate increased tire wear emissions from HD ZEVs relative to ICE vehicles, as suggested by the commenters, without a corresponding decrease in brake wear emissions would improperly bias the total downstream PM inventory impacts. After consideration of the current data sources and literature, we have found that, at this time, there is no study or source of data with sufficient information to improve upon this modeling approach for the FRM.

Despite the overall level of uncertainty in the data and the literature, based on engineering principles, it would be reasonable to expect a HD ZEV that is heavier than a comparable HD ICE vehicle to have increased tire wear emissions but expect HD ZEVs to have decreased brake wear emissions relative to ICE vehicles. Should this prove to be true, these trends are in offsetting directions. Thus, EPA feels that our current modeling approach will not significantly mispresent the PM inventory. In other words, we expect the overall impact of updating brake and tire wear emission rates for HD ZEVs in MOVES on the rule's projected benefits would be small.

<u>IPM & power sector modeling</u>

Many commenters characterized EPA's analysis of EGU emissions as being insufficiently detailed, including EPA's modeling of the impact of the Inflation Reduction Act on the power sector, independent of the impact of the final standards.

> *POET: The first concern is associated with the emission factors used for electricity generation for future years that reflect U.S. EPA's assumptions of the impact of the IRA. … Obviously, the assumption of optimistically low electricity generation emission rates by U.S. EPA leads to higher estimates for the CO2 reductions predicted to result from the Proposed Rule.*

> *AmFree et al.: That expectation is entirely speculative and, in large part, based on the availability of three tax credits that Congress recently approved as part of the IRA to incentivize manufacturing, production, and investment in low-carbon initiatives. The agency does not explain the applicability of these tax credits or provide any data or evidence showing, or even suggesting, that they will have such a material impact on the power-generation mix. Before modeling EGU emissions based on them, EPA must make an earnest effort to assess the number of EGUs that will receive the credits and whether the savings will be enough to incentivize such a major shift in their operations.*

These comments misunderstand EPA's power sector modeling with IPM. The modeling done in IPM is neither an "assumption of optimistically low electricity generation emission rates" nor "entirely speculative."

IPM's documentation, which is publicly available online[820] and in the docket, clearly explains how it models the power sector, including the relevant provisions of the Inflation Reduction Act.

[820] U.S. EPA. "Post-IRA 2022 Reference Case". Power Sector Modeling. April 5, 2023. Available online: https://www.epa.gov/power-sector-modeling/post-ira-2022-reference-case

IPM “represents economic activities in key components of energy markets – fuel markets, emission markets, and electricity markets.” It “determines the least-cost method of meeting energy and peak demand requirements over a specific period. In its solution, the model considers a number of key operating or regulatory constraints that are placed on the power, emissions, and fuel markets.” (Chapter 2.1 of IPM’s documentation.) In summary, IPM models future emissions by modeling how future energy needs can be met in the most economically advantageous way. A key economic input of the IPM modeling for the final rule’s analysis were provisions of the IRA which incentivize the manufacturing, production, and investment in low-carbon initiatives.

Therefore, by using IPM, EPA did make a reasoned effort to assess the impact of the IRA on the power generation mix. Moreover, IPM modeling includes inputs specific to the existing electric system infrastructure, including representations of specific EGUs via the National Electric Energy Data System (NEEDS)[821] which contains the generation unit records used to construct IPM’s model plants. More specific documentation on the IRA’s impact on the buildout of new EGUs can be found in Chapter 4.5 of IPM’s documentation (Inflation Reduction Impacts on New Units).

AmFree et al. asked that EPA also address many aspects of electricity generation which are also included in IPM modeling.

> *AmFree et al.: According to a recent study, changes in the electricity sector have caused EGUs to increasingly rely on coal to meet demand that exceeds their typical capacity … it is necessary to assess whether EGUs will use the same sources to power their base loads and the peak loads that will inevitably occur if the proposed rule is adopted.*

> *AmFree et al.: EPA does not explain whether or how it takes marginal emissions into account when estimating EGU emissions. Neither the notice of proposed rulemaking nor the draft regulatory impact analysis discusses this concept.*

IPM accounts for these peak-load and marginal emissions via its operating reserve requirements, as discussed in Chapter 3.7 of IPM’s documentation. At a high level, IPM models that peak loads are met plus a reserve margin determined by reliability standards. Reserve margins are generally met via electricity generation fuels that provide more flexibility, such as natural gas. With the addition of greater renewable generation driven in part by the IRA, a greater need for flexible fuels is included in IPM, with the documentation stating, “As variable renewable generation increases, it is likely that operating reserve requirements will increase due to the variability of the renewable resources.” Therefore, marginal emissions are accounted for in EPA’s EGU emissions analysis, though separating emissions between regular and marginal activity is not possible.

Furthermore, the total electricity demand at any given time attributable to heavy-duty vehicles is small relative to the total grid demand (see section 7.1 of this RTC document, noting among other things that the Edison Electric Institute concurs with this finding), so EPA expects the additional electricity demand represented by heavy-duty electric vehicles to have a minimal impact on the fuel chosen to meet operating reserve requirements.

---

[821] U.S. EPA. “National Electric Energy Data System (NEEDS)”. Power Sector Modeling. October 31, 2023. Available online: https://www.epa.gov/power-sector-modeling/national-electric-energy-data-system-needs

Delek US Holdings, Inc. stated that EPA did not adequately address air quality concerns for communities near existing or new power plants (this is addressed in section 16 of this Response to Comments document), and stated that this issue is especially important during downtimes for renewable sources:

> *Delek US Holdings, Inc.: EPA does not consider the potential degradation of air quality in areas in the direct vicinity of existing or new power plants, especially as the need for baseload generation at times when the sun is not shining and the wind is not blowing rises exponentially with rapid electrification.*

Electricity generation during downtimes for renewable sources is accounted for in IPM. First, IPM modeling includes estimates of the availability of each energy source, including renewables (see Chapter 3.5.1 of IPM's documentation). Thus, IPM's modeling considers that renewable energy sources do not have 100% availability, as mentioned by Delek US Holdings, Inc., and the IPM emissions modeling quantitatively reflects this fact.

Second, energy storage (when energy is stored for later use when renewable generation exceeds demand, typically using batteries or pump storage) is a key technology for clean power generation during downtimes for renewable sources. IRA includes incentives for the buildout of energy storage capacity, which is included in the 2022 post-IRA version of IPM. Therefore, our power sector modeling also quantitatively reflects ways that clean power can be generated during downtimes for renewables.

Refinery emissions

EPA's refinery emission impacts were modeled based on the key assumption that, as domestic demand for refined diesel and gasoline falls, so too does refining activity. API and AmFree et al. comment on this assumption.

> *API: EPA's analysis assumes that lower domestic fuel demand, due to increased usage of HD ZEVs, will result in reduced refinery throughput. However, this assumption may not hold true as the U.S. has emerged as a major player in the global market for refined products, actively exporting significant quantities…. their assumption fails to consider the possibility that refinery throughput could remain steady while the U.S. simultaneously increases its exportation of refined products.*

> *AmFree et al.: EPA may be substantially overestimating the decrease in refinery emissions. The agency "assumed refinery activity decreases with decreased demand for liquid fuel from heavy-duty vehicles … EPA must explain the basis for its assumption that refineries will decrease production before it factors these sizeable reductions into the calculation.*

EPA is receptive to comments from stakeholders that U.S. refineries may increase exports to offset a reduction in domestic fuel demand. Historically, U.S. net exports of crude oil and refined products have shifted in response to changes in policy at the federal level and there are good economic reasons why U.S. refineries might continue to operate at similar levels despite reduced U.S. product demand. Therefore, we have updated our approach to refinery modeling, specifically addressing the comments we received on exports.

We performed a new analysis to determine the extent to which we should expect U.S. refineries to change activity in response to decreased domestic demand in Chapter 4.2.5 of the

RIA. Based on this work and in response to the comments we received, we updated our modeling in the FRM to assume that 50 percent of the drop in domestic demand will be reflected by reduced refinery activity. This is much lower than the 93 percent we assumed in the NPRM. We also performed a sensitivity analysis should only 20 percent of the drop in domestic demand be reflected by reduced U.S. refinery activity. This is presented in Chapter 4.9 of the RIA.

Our updated refinery emissions modeling methodology discussed in RIA Chapter 4.2.5 is also responsive to comments from EDF and Clean Air Task Force requesting that our refinery emissions modeling be more expansive.

> *EDF: EPA does consider refinery emissions but consideration appears limited to 2055 and is not reflected in the agency's cost-benefit analysis. We encourage EPA to remedy both of these issues, extending the analysis and ensuring the pollution reduction benefits are part of EPA's cost-benefit analysis.*

> *Clean Air Task Force: EPA includes emissions from onroad heavy-duty vehicles (i.e., tailpipe emissions) and upstream emissions from electric generating units (EGUs) that produce the fuel (e.g., electricity, hydrogen) that powers ZEVs. However, EPA does not include in this analysis upstream emissions from refineries that produce the fuel (i.e., gasoline or diesel) that powers combustion vehicles. In order to calculate the full net benefits of the proposed rule, and to provide parallel treatment of fuel production for ZEVs and combustion vehicles, EPA should account for refinery emissions in its cost-benefit analysis.*

> *Clean Air Task Force: In finalizing the standards, EPA should ensure that it has a complete accounting of these upstream refinery emissions to properly measure the net benefits of the options under consideration. Failing to do so would undercount the benefits associated with more stringent standards.*

The commenters' understanding of our modeling of refinery emissions for the proposed standards is correct. We improved the analysis for refinery emissions for the FRM by calculating year-over-year refinery emissions inventory impacts that can be compared with downstream and EGU emissions and assessed in our net GHG emissions impacts of the final rule. We discuss this updated methodology in RIA Chapter 4.2.5. Additionally, emissions of CO_2 and other GHGs from refineries were included in the cost-benefit analysis of the final standards.

API comments on the methodology EPA used to estimate the reduction in refinery activity given a reduction in domestic fuel demand.

> *API: While the EPA assumes that a gallon of reduced domestic demand would reduce net crude and product imports by 0.864, their assumption fails to consider the possibility that refinery throughput could remain steady while the U.S. simultaneously increases its exportation of refined products. EPA justifies its assumption that imports will fall 86.4 percent by comparing the AEO 2022 Reference case with the AEO 2022 Low Economic Growth case. This comparison is not suitable for drawing these conclusions because in the Low Economic Growth case, U.S. refined product exports are lower compared to the Reference Case, suggesting a decline in global demand for refined products. Regardless of the assumption's merits, the EPA doesn't explicitly state, in its regulatory impact*

analysis, that the reduced global demand for refined products is, in part, an assumption based on the forecasts EPA uses for its analysis and not attributable to its regulation.

This comment is based on an incorrect interpretation of the methodology EPA used to estimate refinery emission reductions.

First, the 0.864 import factor is not an indication that imports will fall 86.4%, an amount that far exceeds the estimated total domestic demand reduction that could be attributed to the standards. Instead, it represents the extent to which EPA estimated imports would decrease relative to a domestic decrease in petroleum consumption. In other words, for every gallon of reduced petroleum consumption, we estimated imports would be reduced by 0.864 gallons.

Second, the use of the AEO 2021 (we did not use AEO2022 as the comment states) Low Economic Growth Case is not indicative of an EPA assumption that the future drop in domestic demand or imports will be in part due to economic conditions. EPA used the Low Economic Growth Case as a proxy to quantitatively estimate, given a drop in domestic demand, how U.S. oil imports will be affected. However, all drop in domestic demand associated with the refinery modeling is attributed to the final standards in our analysis.

API expresses concern with the refinery emissions modeling methodology should the final standards be met by increased adoption of cleaner ICE technologies rather than ZEV adoption.

API: The analysis assumes that there will be less domestic fuel demand due to a marked uptick in the use of HD ZEVs. However, as we have noted throughout these comments, there is significant concern that the market may not reach the levels of HD ZEV penetration suggested by the proposal. If fleets continue to use ICEVs in significant numbers, which could reasonably be expected based on various factors (e.g., the life of HD vehicles, costs of purchasing new vehicles, etc.), even with an increased use in biofuels, there will continue to be a demand for conventional fuels.

Because the final CO_2 emission standards are technology neutral and are evaluated at the fleet level, it will be up to the industry to choose the manner in which they comply. As noted in sections 2.1 and 9.2 of the RTC, there are many potential compliance pathways and EPA assessed additional example potential compliance pathways in the final rule that do not include ZEV technologies in their technology mix. EPA modeled the emission impacts of the final standards consistent with the modeled potential compliance pathway, which includes ZEV technologies as well as ICE vehicle technologies that meet the MY 2027 Phase 2 emission standards. If the standards are met via improved ICE efficiency (which our analysis indicates is possible), then there will still be substantial fuel consumption reductions attributable to the final standards, since there would still be the same reductions in GHG emissions. That is, because there is a consistent CO_2 emission rate per gallon of fuel burned, we expect to see a similar decrease in total fuel demand attributable to the standards regardless of the compliance pathway chosen by the industry. This means the compliance pathway chosen by manufacturers will also have little effect on the monetized GHG emission benefits.

Upstream emission sources estimated

Several commenters provided feedback to EPA on which upstream emissions sources were modeled and how that affects the modeled net emission impacts of the final standards. AmFree et al. asserted a limitation on EPA's approach in the proposal:

AmFree et al.: First, the emissions associated with powering a vehicle—whether by electricity from an EGU or fuel from a refinery—are far from the only ones reasonably "attributed" to its operation. Depending on the vehicle, there are also emissions associated with producing, recycling, and disposing of batteries; operating charging infrastructure; and extracting, refining, transporting, and storing petroleum fuels. These emissions can be substantial and, when considered together, may undermine EPA's assumption that swapping internal- combustion-engine vehicles for electric ones will necessarily result in an environmental good.

EPA acknowledges that there are other potential emissions further upstream than those EPA included in our analysis for both ICE and ZEV technologies. It is true that, as discussed in RIA Chapter 4, our analysis of upstream emissions is limited to EGUs and refineries. This approach represents a reasonable balance between considering effects of the rule on upstream emissions and limiting that consideration to reasonably proximate and predictable effects. Because we lack the data and capacity to predict every upstream effect of the rule throughout the supply chain and the broader economy, we judge that by examining the upstream emissions of the reasonably proximate and significant aspects of certain upstream emissions sectors, EGUs and refineries, we have taken into consideration significant upstream effects of the rule on air quality, such that our analysis is sufficiently complete for consideration in the rulemaking. We expect some of the emissions sources listed by AmFree et al. (for example, the operation of charging infrastructure and the transportation of petroleum fuels) to have only marginal impacts on the magnitude of the net emission impacts. This is discussed throughout this RTC section 13, and more discussion of the consideration of lifecycle emissions in setting standards and EPA's response can be found in section 17.1 of this RTC document.

AmFree et al. also commented that this represents a change in how EPA has modeled upstream emissions for previous heavy-duty GHG rules. In this comment, they are referring to EPA's modeling for the HD GHG Phase 1 and HD GHG Phase 2 rules, which included the extraction and transportation of crude oil and distribution of finished gasoline and diesel. Similarly, Delek US Holdings, Inc. and EDF comments that EPA should consider many upstream emission sources, including those that EPA considered in the previous rules.

AmFree et al.: EPA never explains why emissions from EGUs and refineries are the only ones relevant to the analysis. Nor does it acknowledge that its current position departs from earlier GHG rulemakings, where it did consider additional upstream sources. EPA has an obligation to explain why a more cabined view of upstream emissions is appropriate here.

Delek US Holdings, Inc.: The Proposed Rule did not quantify emissions changes associated with producing or extracting crude or manufacturing refined fuels.18 It failed to assess emissions from battery manufacturing or electricity production. EPA should provide a more comprehensive analysis to comply with its directive under the Clean Air Act and better assess the resulting impact of the Proposed Rule.

EDF: EPA has not, but should, consider upstream emissions impacts associated with changing crude oil production.

EDF: EPA likewise did not consider emissions associated with transportation of gasoline and diesel fuels to refineries.

EDF: Finished fuel distribution and production and transportation of ethanol to retail fuel stations. EPA likewise failed to consider these impacts.

EDF: Emissions from the production and transportation of ethanol used in U.S. gasoline should also be considered. EPA makes no mention of these emissions.

We acknowledge that EPA's Phase 3 analysis differs from our approach in Phase 1 and Phase 2. However, EPA's upstream modeling reasonably includes the three most significant sectors in terms of understanding the impact of the standards on overall GHG and CAP/HAP emissions (downstream, EGUs, and refineries). EPA took this approach in our Phase 3 analysis for several reasons. In the illustrative AQM analysis for our most recent LMDV NPRM,[822] we did consider impacts on crude production wells and pipeline pumps, and natural gas production wells and pipeline pumps. That analysis suggested that emission reductions from crude production wells and pipeline pumps were being partially offset by increases from natural gas production well and pipeline pumps. The net oil and gas sector emissions changes are therefore small relative to those of the onroad and power sectors.

In addition, modeling EGU and refinery emissions is balanced in considering the operation of ZEV versus ICE vehicles. For both vehicle types, our analysis considers the emissions and energy consumption of the vehicle itself plus the production of the fuel it uses, be it refined liquid fuels for ICE vehicles or electricity for ZEVs. It would skew the emission results if EPA calculated reduced transport of fuels caused by a reduction in ICE vehicle usage but no corresponding increase in the transport of fueling sources, such as natural gas, used to power the increased EV usage. Similarly, EPA does not assess comparable emissions associated with refinery waste generation and management (many of those wastes are listed as hazardous under the RCRA subtitle hazardous waste program, 40 CFR Part 261 hazardous wastes K 048-052).

There were also practical reasons for EPA to model upstream emissions only from EGUs and refineries. EPA has available tools that are well suited to modeling the impacts of the standards on these two sources (i.e., IPM and a combination of the emissions modeling platform and EIA's Annual Energy Outlook). EPA determined that other modeling tools, in particular GREET and EPA's previous upstream modeling tool for emissions from previous HD GHG rules, did not have the same advantages as our chosen methodology for the purposes of modeling quantitative and detailed upstream emission impacts from the final standards.

Specifically, EPA's upstream analysis for the previous HD GHG rules was based on a spreadsheet modeling tool which incorporated upstream emission factors from GREET. These emission factors from GREET were process-level emission factors and often encompassed several upstream emissions sources together, such as both crude extraction and transport. This spreadsheet-based approach was not designed, and is not adequate, to capture the complexities associated with major shifts in transportation fuels. Furthermore, matching GREET's emission factors to more specific emissions and activities estimates from EPA's detailed models, including IPM and MOVES, would introduce additional uncertainty.

[822] U.S. EPA. "Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles: Draft Regulatory Impact Analysis". April 2023. Available online: https://nepis.epa.gov/Exe/ZyPDF.cgi/P10175J2.PDF?Dockey=P10175J2.PDF

While EPA included fewer upstream emission sources for this rule than previous HD GHG rules, it's important to note that this modeling is more detailed and rigorous, for the purposes of this rulemaking, than if we had used the same approach as we did for previous rules. Neither EPA's spreadsheet tool nor GREET are dynamic models, in which projections of future time periods depend on the simulation of prior time periods. IPM, however, is a dynamic model. Because of its dynamic nature, the inclusion of rule-specific IPM runs allows for a better understanding of how the standards (especially possible HD ZEV adoption driven by the standards) impact the full U.S. energy system.

Nevertheless, EPA does not dispute the utility of other upstream emissions modeling tools, especially GREET, for other purposes. For example, we used GREET in a comparative analysis of different hydrogen production pathways to meet the fueling needs of additional FCEVs (as we modeled in our potential compliance scenario of the final standards) in RIA Chapter 4.8. There is ongoing work to develop the capability to capture upstream and cross-sector impacts in more detail, including the use of multi-sector modeling tools such as EPA's GLIMPSE framework.[823]

Clean Fuels Development Coalition et al. also noted that there are emissions associated with the buildout of a more renewable power grid.

> *Clean Fuels Development Coalition et al.: EPA also ignores the GHG emissions associated with manufacturing more, less dense, remotely located intermittent generation sources and battery back-up, plus the need for more natural gas peaking capacity and massive transmission, substation, and transformer investment to integrate these technologies into the power grid.*

IPM modeling predicts that most of the actions taken that make the power grid cleaner are driven by economic conditions and the Inflation Reduction Act and occur regardless of the promulgation of the final standards. Therefore, most of the emissions associated with infrastructure updates for the power sector are not attributable to the final standards.

However, some infrastructure updates, especially those related to the charging of heavy-duty BEVs and hydrogen production would, at least in part, be attributable to electrification driven by the final standards. The magnitude of these emissions depends on how manufacturers choose to comply with the final standards. EPA has no tooling available to quantify these emissions directly. Given that we expect the final standards to have a small impact on electricity transmission, generation, and cost (see section 7 of this RTC document), we also expect the emissions impact of possible grid infrastructure updates to be small.

Hydrogen production for fuel cell electric vehicles

To estimate emissions from hydrogen production for fuel cell electric vehicles in the proposed rule analysis, EPA assumed that all hydrogen would be produced onsite via grid electrolysis and could therefore be represented as such in IPM. DRIA pp. 321-22. This was a simplifying assumption, and we received many comments regarding that assumption.

[823] U.S. EPA. "GLIMPSE – A computational framework for supporting state-level environmental and energy planning". February 1, 2024. Available online: https://www.epa.gov/air-research/glimpse-computational-framework-supporting-state-level-environmental-and-energy

Cummins Inc.: We also appreciate EPA's assumption that emissions generated from creating hydrogen are the same as grid emissions.

POET: A related concern is U.S. EPA's assumption that the hydrogen used by HD FCEVs and H2-ICE vehicles will be generated from very low carbon grid electricity rather than steam methane reforming or higher carbon grid electricity … U.S. EPA is essentially assuming that the carbon intensity will be at the same level as that shown for production from electrolysis using electricity from renewable or nuclear generation sources. Again, if U.S. EPA's optimistic assumptions are not realized in practice, effective GHG emissions from HD FCEVs will be much higher than forecast and the GHG reductions from the Proposed Rule will be similarly reduced.

POET: *Current hydrogen production also leads to significant upstream emissions because it is produced via steam methane reforming ('SMR') using fossil fuels as process energy. EPA hopes to rely on hydrogen produced via electrolysis using renewable grid electricity. Yet today, hydrogen produced using grid electricity, renewable or otherwise, accounts for less than 1 percent of all hydrogen produced. Most hydrogen—about 95 percent—is produced using SMR without carbon capture. The IRA and BIL incentives are meant to address this by pushing hydrogen production toward electrolysis using renewable energy or SMR with carbon capture, but that shift is in its infancy and assumptions about the rapid conversion of hydrogen production to zero-carbon sources seem highly optimistic. The IRS, for instance, has yet to release critical guidance on how it will implement the production tax credit for low-carbon hydrogen. Yet EPA essentially assumes that carbon-intensive hydrogen is equivalent to hydrogen produced via electrolysis using renewable or nuclear energy in terms of emissions. That assumption is deeply flawed,*

AmFree et al.: Although the vast majority of hydrogen used for fuel-cell vehicles is made through "steam methane reforming," "largely as part of petroleum refining and ammonia production," the agency makes the "simplifying assumption" that "all hydrogen used for FCEVs is produced via grid electrolysis of water and can therefore be entirely represented as additional demand to EGUs." Even assuming that "simplifying assumption" is warranted, EPA must accurately predict EGU emissions to measure the effect of shifting from internal-combustion-engine to fuel-cell vehicles. For the reasons described above, it has not done so.

EDF: The method of hydrogen production impacts whether hydrogen fueled vehicles decrease the vehicle's associated emissions when compared to diesel vehicles or increases them … SMR emits CO2 as a byproduct of the hydrogen production resulting in a carbon intensity of between 8 and 12 kg of CO2/kg H2. Hydrogen produced using electricity from the current U.S. average grid has a carbon intensity of 21 kg of CO2/kg H2 … the emission reductions from FCEVs and H2ICE vehicles are highly dependent on the production method of the hydrogen.

EDF: EPA should ensure its assessment of hydrogen is rigorous, comprehensive, and fully accounts for potential adverse climate and health impacts associated with hydrogen production.

ACEEE: [I]t is not clear that the hydrogen for use as a transportation fuel will generally be produced through grid electrolysis in the coming years or will have carbon emissions similar to hydrogen from grid electrolysis. EPA points to incentives for clean hydrogen production in IIJA and IRA, as well as "new transportation and other demand drivers and potential future regulation" to support this assumption. However, potential dramatic increases in the coming years in the volume of both clean hydrogen and hydrogen produced through electrolysis are insufficient to ensure that hydrogen production through SMR will decline or that hydrogen used to fuel heavy-duty vehicles will become cleaner in tandem with grid decarbonization. This is especially true given the many uses to which a growing hydrogen supply could be put.

EPA's modeling assumption that 100 percent of the hydrogen needed to fuel FCEVs would be produced by grid electrolysis is not, despite POET's characterization, an assertion that the emissions from various hydrogen production methods are the same. Indeed, we acknowledge that they are different in DRIA Chapter 4.3.3, stating ,

"[w]e recognize that the relative emissions impact of hydrogen production via SMR versus grid electrolysis depends on how electricity is produced, which varies significantly by region across the country. We also recognize that electrolysis powered by electricity from the grid on average in the U.S. may overestimate the upstream emissions impacts that are attributable to HD FCEVs in our analysis."

We used IPM to evaluate emissions from the U.S. electricity grid for the analysis. More details regarding comments on IPM modeling and EGU emissions can be found earlier in this response to comments section. EPA is reviewing a petition to regulate some methods of hydrogen production given anticipated growth in the sector spurred by IRA incentives,[824] but emissions from hydrogen production facilities are not regulated at this time. Thus, our capabilities to evaluate impacts associated with hydrogen production are currently limited.

We acknowledge there is uncertainty in how hydrogen needed for FCEVs will be produced in the future, bringing uncertainty into upstream emissions estimates for hydrogen-fueled vehicles. As described in RIA Chapter 1.8 and RTC Section 8, BIL and IRA both include provisions that incentivize reducing the emissions and carbon intensity of hydrogen production. For example, in June 2023, DOE updated Clean Hydrogen Production Standard (CHPS) guidance that establishes a target for lifecycle (defined as "well-to-gate") GHG emissions associated with hydrogen production, accounting for multiple requirements within the BIL provisions.[825] In December 2023, the Treasury Department and Internal Revenue Service proposed regulations to offer

[824] On September 15, 2023, EPA received a petition from the EDF and 13 other health, environmental, and community groups to regulate fossil and other thermochemical methods of hydrogen production, given the current emissions from these facilities and the anticipated growth in the sector spurred by IRA incentives. Petitioners advocate for regulatory safeguards to help ensure that the anticipated growth in this sector does not result in an unbounded increase in emissions of GHGs, criteria, and hazardous air pollutants (HAP). The petition requests that EPA list hydrogen production facilities as significant sources of pollution under CAA sections 111 and 112, and that EPA develop standards of performance for new and modified hydrogen production facilities plus emission guidelines for existing facilities.

[825] U.S. Department of Energy, Hydrogen Program. "Clean Hydrogen Production Standard Guidance". June 2023. Available online: https://www.hydrogen.energy.gov/library/policies-acts/clean-hydrogen-production-standard.

income tax credit for the production of clean hydrogen (45V), as established in the IRA.[826] Several programs initiated by BIL and IRA investments that could heavily influence the character of the emerging hydrogen production market are under ongoing development.

In light of the uncertainties in this area, and based on the comments received, EPA performed a comparative analysis for upstream emissions from FCEVs for the FRM. We compare emissions from grid electrolysis with other hydrogen production methods (see RIA Chapter 4.8). The analysis covers the bounds of a 100 percent grid electrolysis scenario with a 100 percent SMR sensitivity, but also evaluates other clean options such as SMR and auto-thermal reforming (ATR) with carbon capture and sequestration (CCS) technologies. We did this to acknowledge comments that noted that hydrogen today in the U.S. is predominantly produced using SMR, while demonstrating potential impacts of additional pathways expected to be possible with commercialized technologies in the timeframe of the rule.

The analysis has additional rigor and shows that the relative emissions of producing hydrogen via steam methane reforming versus electrolysis change over time. Compared to grid-based electrolysis, we estimate SMR to have lower emissions in earlier years and higher emissions in later years. This conclusion is in line with EDF comments, for example, that cite current emission factors for each process which show that SMR is lower emitting than electrolysis based on today's grid. The analysis also shows that grid-based electrolysis, especially when a large share of electricity is generated via renewable sources, is a viable pathway to achieve reductions in emissions from producing hydrogen. EPA's IPM modeling shows grid electrolysis is modeled to become lower emitting over time. Thus, over the full 2027-2055 modeling domain for the emission impacts analysis, our hydrogen production assumptions do not significantly overestimate or underestimate the cumulative upstream emission impact estimates we present in the RIA.

EDF submitted additional detail in their comment regarding hydrogen production:

> *EDF: Additionally, 40% of the energy from the electricity used to make hydrogen using electrolysis is lost in the process. When the inefficiencies of both processes are combined, it takes 2.6 times as much electricity to power a FCEV as a BEV. When considerations like compression and transportation of the hydrogen are included, three to four times more energy is needed for hydrogen road transportation compared to battery electric vehicles.*

EPA's modeling of FCEV and BEV efficiencies is in general agreement with the values estimated by EDF. EPA's analysis of hydrogen production emissions resulting from grid electrolysis included the energy needed to compress the hydrogen but assumed on-site generation instead of transporting significant amounts of hydrogen. This difference in assumptions has a small impact on the total upstream emissions estimated for HD FCEVs in our analysis.

Some commenters suggested that EPA is optimistic about the future of hydrogen and should not incentivize hydrogen without strong evidence that hydrogen will be clean.

---

[826] 88 FR 89220. Section 45V Credit for Production of Clean Hydrogen; Section 48(a)(15) Election To Treat Clean Hydrogen Production Facilities as Energy Property. Available online: https://www.federalregister.gov/documents/2023/12/26/2023-28359/section-45v-credit-for-production-of-clean-hydrogen-section-48a15-election-to-treat-clean-hydrogen.

ACEEE: EPA should not incentivize hydrogen-fueled vehicles without strong evidence that hydrogen fuel for transportation will be clean in the foreseeable future.

EDF: Emission reductions from FCEVs and H2ICE vehicles are highly dependent on the production method of the hydrogen and increase emissions relative to diesel vehicles when the hydrogen is produced by SMR, the current grid, and even the projected 2027 grid.

EDF: EPA should ensure rigorous accenting and protective safeguards are in place related to the production and use of hydrogen.

POET: Again, if U.S. EPA's optimistic assumptions are not realized in practice, effective GHG emissions from HD FCEVs will be much higher than forecast and the GHG reductions from the Proposed Rule will be similarly reduced.

As described in Preamble Section 2 and in RTC sections 2, 9, and 17.1, EPA's final Phase 3 standards are performance-based vehicle exhaust standards. We included HD FCEV technology in our modeled potential compliance pathway used for inventory modeling (and H2 ICE in some of our additional example compliance pathways) due to the large potential to reduce GHG emissions from vehicles, as well as existing manufacturer and market developments for these technologies. The final rule considers lower levels of early market FCEV adoption and infrastructure development compared to the proposed rule. The associated hydrogen consumption due to the final rule by 2032 is less than two percent of the amount of hydrogen currently produced in the U.S. annually (see RIA Chapter 1.8.3.4). Thus, the emissions impact of hydrogen consumption based on the modeled potential compliance pathway in the final standards is relatively small.

Meanwhile, given the opportunity for hydrogen to contribute to national decarbonization goals across sectors over the coming decades, EPA is engaged in whole-of-government efforts to continue to expand and implement a U.S. National Clean Hydrogen Strategy and Roadmap,[827] which aims to reduce emissions associated with the production, transport, storage, and use of hydrogen. The larger global interest in hydrogen is driven by the technology's emissions reduction potential,[828] and pressures to achieve GHG reductions is likely to increase over time.

<u>Suggested improvements in analysis</u>

Some commenters made suggestions for how EPA should improve the emission impacts analysis for the final rulemaking.

MCS Referral & Resources recommended that EPA model carbon monoxide as a greenhouse gas and quantify the benefits similarly to methane and nitrous oxide.

[827] U.S. Department of Energy. "U.S. National Clean Hydrogen Strategy and Roadmap Interagency Collaboration". Available online: https://www.hydrogen.energy.gov/docs/hydrogenprogramlibraries/pdfs/national-hydrogen-strategy-interagency-collaboration.pdf

[828] IEA (2019), The Future of Hydrogen, IEA, Paris https://www.iea.org/reports/the-future-of-hydrogen, Licence: CC BY 4.0

MCS Referral & Resources: Carbon monoxide should be included in all tables that estimate GHG emissions because it is a greenhouse gas. According to the IPCC, the indirect Global Warming Potential for CO over 20 years is 2.8 to 10, which is in addition to CO's direct GWG potential of approximately 1.3. Rows should be added for estimates of CO contributions to GHG emissions in Tables IX-7, 8, 12,13,16, and 17.

CO is not considered to be a GHG of significance in the IPCC's AR5 report,[829] is not included in EPA's annual GHG Sources and Sinks report,[830] and is also not included in EPA's 2009 endangerment finding for six well-mixed greenhouse gases constituting the air pollution which endangers public health or welfare.[831] Therefore, EPA did not quantify CO as a greenhouse gas for the final rulemaking analysis.

EDF makes a similar assertion about hydrogen that is leaked to the atmosphere:

EDF: A recent but growing body of evidence clearly shows that hydrogen gas in the atmosphere causes global warming and EPA must consider these impacts when setting standards. Hydrogen is a short-lived, indirect GHG that causes warming by increasing the concentration of other GHGs in the atmosphere. It is a small and slippery molecule that can easily escape from all parts of the value chain. Recent studies have found hydrogen's warming power is over 30 times larger than CO2 pound for pound over the 20-year period after it is emitted, and about 10 times larger over 100 years – values that are 2-6 times higher than previously thought.

EDF: EPA should ensure its assessment of hydrogen is rigorous, comprehensive, and fully accounts for potential adverse climate and health impacts associated with hydrogen production and use.

EDF: Accordingly, we urge EPA to consider the impact of hydrogen leakage in impacting the greenhouse gas emissions profile of H2 ICE vehicles and fuel cell vehicles.

Please see RIA Section 1.8.4 for discussion of emerging science on the global warming potential of hydrogen at scale. We are not aware of extensive literature on the health impacts of hydrogen production, but anticipate research to scale on topics such as this with development of the market over the next decade.

We did not quantify H_2 as a greenhouse gas for the final rulemaking analysis for the same reasons we did not quantify CO. EDF's comment went on to discuss various data sources and methodologies for estimating hydrogen leakage rates, which could serve as a basis for future work estimating the climate warming impacts of hydrogen gas. These comments, however, are out of scope for the final rulemaking analysis because we are not estimating hydrogen emissions as a GHG.

[831] 74 FR 66496

POET suggests that EPA should quantify the emission impacts of methane and nitrous oxide in the power sector:

> *POET: However, despite the fact that electricity generation from combustion sources also results in emissions of methane and nitrous oxide, U.S. EPA fails to quantify or even mention the fact that there will be offsetting increases in emissions of these pollutants due to increased demand for electricity in Chapter 4 of the DRIA.*

We updated our power sector modeling to include estimates of methane and nitrous oxide from EGUs for the final rulemaking analysis. We also updated our refinery modeling to include year-over-year impacts of refinery methane and nitrous oxide emissions. Chapters 4.5 and 4.6 of the RIA present net impacts for CO_2, CH_4, and N_2O emissions, as well as total GHG (CO_2e) emissions.

EDF and Clean Air Task Force recommended improvements to our refinery emissions methodology, which we implemented. This is discussed more in the refinery emissions portion of this RTC section.

Points needing clarification

Several comments included incorrect assertions or points needing clarification regarding EPA's emissions modeling results.

Delek US Holdings, Inc. suggest that EPA made unfounded assumption in its modeling of the proposed standards.

> *Delek US Holdings, Inc.: EPA compounds this flaw by making unsupported assumptions regarding total emissions impacts of its proposal. While it claims that the overall analysis for combined downstream and upstream emissions "likely underestimates the net emissions reductions that may result" from the Proposed Rule, EPA failed to offer a data-based substantiation.*

This assertion is incorrect. While our statement that the modeling of the proposed standards "likely underestimates the net emissions reductions that may result" from the proposed standards is not supported by direct modeling, the statement is not unsupported. Specifically, we cite our lack of modeling of fuel extraction and transport, incomplete modeling of refinery emissions (DRIA page 349), and assumption that 100% of hydrogen for fuel cell electric vehicles will be produced by grid electrolysis (DRIA page 322) as reasons to believe our net emissions analysis may underestimate total downstream and upstream emission reductions.

In part as a response to this comment and others like it, we have made several improvements to our modeling of upstream emissions for the FRM, including evaluating more pollutants from both EGUs and refineries, calculating year-over-year refinery emissions impacts, and evaluating two sensitivity cases in our emissions modeling related to refinery emissions and emissions from hydrogen production.

While there are other upstream emission sources that we did not estimate which would decrease our net emission reduction estimates (for example, the transport of fuels for electricity generation), we evaluated the scope of those emissions and concluded that their impact on our overall emissions estimates would be small – we discuss this in more detail in the portion of this RTC on upstream emissions sources we estimated. Therefore, we support our statement in the

DRIA that our NPRM emissions inventory analysis likely underestimated total downstream and upstream emission reductions.

MCS Referral & Resources comment includes discussion about whether EPA used the same reference inventory for both the proposal and alternative scenarios. To determine this, they calculate a "pre-reduction" based on the emission reduction in absolute and percentage terms for each pollutant and scenario.

> *MCS Referral and Resources: As shown in DD Table 1 below, they are within 5% of each other in all cases except the PM estimates for 2035, which are inexplicably 11.9% higher for the EPA proposal than the alternative.*

While this is true based on their arithmetic (using 6% estimate for the proposal and 5% estimate for the alternative does result in the 11.9% difference MCS states), this error is simply introduced by rounding. The percent change for the proposal is presented as 6%, rounded down from 6.49%, while the alternative reduction is 5%, rounded up from 4.76%. Applying the "pre-reduction" calculation using these more precise percentages yields a consistent inventory within 5%.

> *MCS Referral & Resources: Critically, all these downstream pollutant estimates (pre-reduction) also should rise or fall together in 2045 and 2055, relative to the prior decade, given that they are all coming from the same group of non-electric vehicles. But as shown in the columns at right labeled % Change, this is not the case. Implausibly and inconsistently, the pre-reduction pollutant estimates for CO2, CO, PM, and NOx all showed no change or declined from 2035 to 2045 (as shown in red below), while only NOx also declined from 2045-55. The most extreme declines are seen in the pre-reduction emissions for PM in 2045, which EPA is estimating will decrease by 49% from 2035 to 2045 in its favored proposal, and by 43% in the alternative, while CO emissions declined less than 3% and CO2 emissions less than 4%. This is not credible. Over 2 decades (from 2035-55), EPA's pre-reduction emissions of both NOx and PM2.5 declined by exactly 1/3 or more, while both CO2 and CO increased. These also are not plausible or consistent estimates.*

EPA finds the reference emission inventory estimates credible, and disagrees with the assertion that the inventories, or "pre-reductions," for all pollutants should move together. The reason for this is simple – while the group of vehicles being displaced in the analysis by ZEVs is the same for all pollutants, the impact each type of vehicle has on the inventory of each pollutant is not the same. This is discussed at length in Chapter 4.3 of the RIA. See DRIA Chapters 4.3.2 (Year-over-year Impacts) and 4.3.3 (Detailed Emission Impacts).

Importantly, DRIA Chapter 4.3.3 includes a discussion of how and why different pollutants have different inventory trends over time based on the heavy-duty vehicles that are displaced by ZEVs. For example, in the proposal's DRIA, EPA says,

> *"In summary, we expect the displacement of HD ICE vehicles of all fuel types with HD ZEVs would drive broad emission reductions—we expect the displacement of diesel HD vehicles will be the primary source of NOX reductions; we project the displacement of gasoline light HD trucks will be the primary source of PM2.5 and VOC reductions; and*

we anticipate the displacement of HD CNG vehicles will be the primary source of methane reductions." DRIA p. 344.

As is discussed elsewhere in this response to comment section, POET comments that EPA failed to account for emissions of methane and nitrous oxide, both greenhouse gases, in the upstream emissions analysis. Specifically, they argue that this skews the net impacts presented in Chapter 4:

POET: This failure to properly address the overall impact of the Proposed Rule on methane and nitrous oxide emissions overstates the actual GHG emissions reduction which are shown in Table 4-15 of the DRIA.

Table 4-15 of the DRIA does not present net GHG emission reductions, but total downstream emission reductions. This is made clear by the caption "Cumulative 2027–2055 downstream GHG emission reductions from the proposed CO_2 emission standards." For the proposal analysis, EPA's downstream emissions modeling included methane and nitrous oxide, but the upstream emissions modeling did not. Therefore, EPA did not present net GHG emission reductions at all in Chapter 4 of the DRIA. Instead, EPA only presented net CO_2 emission impacts, which are modeled for all downstream and upstream emission sources considered. Thus, the proposal's GHG emission reductions are not misrepresented as POET's comment argues.

The FRM analysis includes full GHG emissions modeling (including CO_2, CH_4, and N_2O) for all sectors. Therefore, RIA Chapter 4 presents net GHG impact of the final standards considering all three modeled greenhouse gases.

POET also comments that EPA's modeling of downstream GHG emissions is skewed by failing to account for renewable fuels:

POET: The U.S. EPA Emission Inventory analysis in Chapter 4 also overstates the GHG reductions associated with the Proposed Rule by failing to account for the fact that conventional vehicles operate on fuels that are a mixture of fossil and low-carbon renewable fuels – including ethanol, renewable diesel fuel and biodiesel fuel. Based on data from EIA,9 the average ethanol content of gasoline sold in the U.S. is expected to increase from about 10% to 12% between now and 2050 while the average content of the combination of renewable and biodiesel is expected to increase from about 7% to 10% over the same range. Although the actual impact of proper accounting for renewable fuels on CO2 emissions from the Proposed Rule will be slightly smaller than the percentages listed above, they should clearly be accounted for by U.S. EPA.

Ethanol blends and biodiesel are included in the MOVES model. This is discussed in the MOVES Fuel Supply Technical Report.[832] By using fuel properties consistent with real-world blending of biofuels with fossil fuels, EPA accounts for their CO_2 emission impacts contrary to POET's assertion that we failed to account for biofuel blending in our inventory analysis.

Delek US Holdings, et al. state that, among other factors, EPA failed to assess the emissions impact from electricity production.

---

[832] U.S. EPA. "Fuel Supply Defaults: Regional Fuels and the Fuel Wizard in MOVES4". August 2023. Available online: https://nepis.epa.gov/Exe/ZyPDF.cgi/P10186PT.PDF?Dockey=P10186PT.PDF

Delek US Holdings, Inc.: It failed to assess emissions from battery manufacturing or electricity production.

EPA evaluated the power sector impacts of the rule, including emissions estimates from electricity production, using IPM. However, the comment is correct that EPA did not model battery manufacturing emissions because they are out of scope for this rulemaking. We discuss upstream emissions in an earlier portion of this RTC section and life cycle analysis, in RTC section 17.

Clean Fuels Development Coalition et al. comment that EPA's power sector modeling does not include the infrastructure costs of transitioning from traditional fossil power sources to renewables:

Clean Fuels Development Coalition et al.: These costs also ignore that realizing these reductions requires the installation of new solar and wind generation, which itself has a cost.

These costs are specifically modeled by IPM and factored into the modeled decisions of the power sector organizations. More discussion on this topic can be found in the IPM & power sector modeling portion of this RTC section and in the upstream emissions sources estimated portion of this RTC section. More generally, we also discuss electricity generation infrastructure impacts in section 7 of this RTC document and discuss our estimation of program costs from the rule in RIA Chapter 3.

We reiterate that IPM modeling predicts that actions taken to make the power grid cleaner, including the installation of new solar and wind generation, are driven by economic conditions and the Inflation Reduction Act and occur regardless of the promulgation of the final standards. This means that renewable installation costs were accounted for in our power sector modeling, and that it is not appropriate to attribute those costs to the rule itself. However, we model that the final standards will increase electricity demand, and that such demand will be met by all EGU fuel types, including coal, natural gas, and renewables. The emissions associated with the increased use of fossil fuels relative to the reference case is included in our emissions modeling in RIA Chapter 4. Costs related to buildout of additional electricity infrastructure (including generation, transmission, and distribution) attributable to the HD interim standards and LD final standards, are included in the IPM and RPM analysis. The distribution costs are informed by the TEIS while generation and transmission are informed by IPM. We also discuss such electricity costs, including their impact on vehicle operator costs, in RIA 2 and RTC sections 6 and 7.

Clean Fuels Development Coalition et al.: Furthermore, researchers estimate that the 350 million EVs required to decarbonize the fleet in 2050 could use as much as half of US national electricity demand.

In MOVES, we project that there will be about 350 million vehicles on the road in 2050. However, that includes all vehicles (light-duty plus heavy-duty) and we do not project the entire fleet to be ZEVs in 2055. The total population of HD vehicles impacted by the proposed standards is less than 25 million in 2050 and our projected HD ZEV sales percentage is far lower than 100 percent. The impact the electrification from these vehicle segments will have on the total electricity demand in the United States will therefore be much smaller than the comment asserts, on the order of less than 5% (in 2050) according to our modeling. This is also discussed in section 7.1 of the RTC, which notes among other things that the Edison Electric Institute, the trade association for all the nation's investor-owned utilities, concurs with EPA's finding.

AFPM asserts that EPA did not adequately account for, or model, existing EPA standards in evaluating the emissions impact of the proposed standards.

> *AFPM: EPA makes no attempt to outline a baseline scenario whereby all stationary and mobile sources in the country achieve current EPA standards. Such a baseline is necessary because it is the only means by which the agency and the public can compare the marginal costs and benefits of further tightening emission standards and deploying different technologies and alternatives.*

In order to calculate the emissions impact of the final standards, EPA first modeled the emissions inventory without the final standards, which is referred to in our documentation as the reference case. The reference case assumes full compliance with all finalized EPA standards for both mobile and stationary sources, among other finalized federal actions such as the Inflation Reduction Act. To be clear, the reference case does not assume compliance with proposed federal actions which are not yet promulgated and hence have no immediate impact.

We did not ignore these potential actions and their impacts. We show in RTC section 7.2, and sources there cited, that there is no reasonable scenario where grid capacity is inadequate to meet demand after considering a series of EPA potential actions (under the CAA, RCRA, and the Clean Water Act) which could affect the power generating sector. Therefore, the assertion that EPA did not "attempt to outline a baseline scenario whereby all stationary and mobile sources in the country achieve current EPA standards" is incorrect.

ACEEE asserts that there in an inconsistency between the MOVES documentation and the DRIA in terms of the ratio applied to BEV energy consumption to estimate FCEV energy consumption:

> *ACEEE: We note that, in contrast to the energy efficiency ratios implied by Table 2 showing that the H2-FCEV truck uses 57% more energy per mile than the BEV, EPA adopts an assumption that a H2-FCEV uses only 25% more energy than a BEV. ACEEE looked at the sources referenced in the DRIA, which include the GREET and MOVES models, and was unable to find the basis for this claim. In fact, the MOVES document cited by the DRIA … does not appear to support the DRIA claim that an FCEV uses only 25% more energy to operate than a BEV, but instead supports the values shown in Table 2 above.*

This is a misunderstanding on the part of ACEEE. The MOVES technical report they quote is the "Greenhouse Gas and Energy Consumption Rates for Onroad Vehicles in MOVES3.R1" technical report. MOVES3.R1 was not used in the modeling of the proposed standards. Instead, we used MOVES3.R3, so the correct citation for the FCEV:BEV ratio is "Greenhouse Gas and Energy Consumption Rates for Onroad Vehicles in MOVES3.R3," in which Appendix D contains documentation regarding the ratio of 1.25:

> *The multiplier for the FCEV emission rates was derived from the relative energy consumption for heavy-duty fuel cell and battery electric vehicles as published by Islam, et al. in 2022. The authors used Autonomie to estimate the fuel savings of various alternative fuels for heavy-duty vehicles and show that FCEVs consume, on average, 1.6*

times more energy than comparable BEVs. This is consistent with values estimated in GREET 2022.

We adjusted this value down to account for the fact that MOVES calculates an energy consumption for charging and battery losses and for HVAC usage as documented in the MOVES adjustment report. FCEVs do not have batteries chargeable by grid energy, so we removed that effect by a typical charging and battery efficiency value of 15%. We found two sources regarding the relationship between FCEV energy consumption and temperature. The first, an ICCT study on FCEV tractor-trailer fuel economy, showed that FCEV energy consumption does not change with ambient temperature, while the second, a real-world study of BEV and FCEV bus energy demand, showed that FCEV energy demand changes with temperature but to a lesser extent than BEVs. Therefore, we also applied an 8% correction to the FCEV multiplier to remove the national average temperature adjustment applied in MOVES. The final result is an FCEV energy demand multiplier of 1.25.

Other comments

Some comments related to the VMT projections we used to determine emission impacts.

AmFree et al.: In earlier GHG rules for heavy-duty vehicles, EPA considered brake and tire emissions when analyzing the impact of the proposed standards. See Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles—Phase 2, 81 Fed. Reg. 73,478, 73,578 n.b (Oct. 25, 2016) ("HD GHG II") ("The impacts shown include all PM2.5 impacts from the rule including impacts from increased tire wear and brake wear that results from the slight increase in VMT projected as a result of this rule.").

AFPM: There also exist overall truck weight restrictions, which could require a greater number of ZEVs to move the same tonnage of cargo, thus increasing vehicle miles traveled and potentially PM emissions.

To clarify, the increase in brake and tire wear PM emissions modeled as part of the HD GHG Phase 2 rule was, as the comment cited by AmFree et al. states, caused by EPA modeling a VMT rebound effect. EPA did not model or expect a similar effect with the Phase 3 rule. See 88 FR at 26072 and RIA Chapter 6.1.

EPA does not expect VMT to be meaningfully impacted by the standards, even accounting for greater vehicle weights. This is because most heavy-duty vehicles have a GVWR that is well below legal road limits (Class 4-6 single-unit trucks, for example). Of the vehicles which can plausibly hit weight limits, MOVES has an average vehicle mass of 24.6484 metric tonnes, or roughly 54,000 pounds. This means that most heavy-duty freight vehicles can gain the added battery weight and still not hit road limits. For additional discussion on the impact to payload see RTC 3.10.1 and RIA Chapter 2.9.1.

POET: It is also important to note that use of ethanol and other renewable fuels capable of reducing GHG emissions from both new and in-use HD vehicles could be increased through incentives like those that have been provided to electricity and hydrogen through the IRA and the structure of the Proposed Rule.

This comment is out of scope of this rulemaking. Please see also section 9 of this RTC document.

> *AFPM: EPA did not fully consider that the higher purchase price of new ZEVs will keep older, more polluting trucks on the road longer.*

EPA did not model pre-buy and its environmental effects in our emission inventory modeling, but the ZEV purchaser costs were modeled in HD TRUCS and evaluated as part of our assessment of program costs. These costs are discussed in Chapter 2.10.6 of the RIA and Section 4 of the response to comment document. In addition, possible emissions effects under different fleet turnover scenarios are discussed in RIA Chapter 6.1.

ACEEE comments that some hydrogen-powered vehicles have non-zero emissions of both GHGs and criteria pollutants (such as NO_X).

> *ACEEE: EPA should not incentivize hydrogen-fueled vehicles without strong evidence that hydrogen fuel for transportation will be clean in the foreseeable future. For H2-ICEVs in particular, for which intrinsic efficiency advantages are modest, actual GHG benefits may be negative, and potential future benefits are based largely on changes to the fuel rather than to the vehicle, the zero-upstream incentive is inappropriate. It would offer manufacturers the same compliance benefit for an H2-ICEV as for a BEV or FCEV but require only relatively small changes to the engine, as described At FR 25960. The fact that H2-ICEVs produce NOx makes conferring ZEV benefits on them all the more inappropriate. Low-carbon hydrogen-fueled vehicles are best incentivized through performance-based standards.*

For clarity, EPA did not explicitly model or project adoption of HD-ICE vehicles in our modeled potential compliance pathway used for emission inventory modeling. More discussion of H2-ICE vehicles themselves, including a response to this comment’s statements about achieving compliance using H2-ICE vehicles, can be found in section 9.3 of this RTC document.

14 Climate Change Impacts

Comments by Organizations

Organization: Allergy & Asthma Network et al.

Heavy-duty vehicles are also a major source of carbon pollution. Transportation is the single biggest source of greenhouse gas emissions in the U.S., making cleaning up trucks and buses a critical part of addressing climate change. Climate change is a health emergency, leading to more frequent and intense extreme weather events like flooding, excessive heat, drought, and wildfires; longer and more intense allergy seasons; increased risks from water-borne and vector-borne diseases like Lyme Disease; and worsening air quality. [EPA-HQ-OAR-2022-0985-1532-A1, p. 2]

Organization: American Thoracic Society (ATS)

Heavy-duty vehicles are significant contributors to greenhouse gas and criteria pollutant emissions. [EPA-HQ-OAR-2022-0985-1517-A1, p. 1]

Heavy-duty vehicles constitute an important aspect of transportation in the United States. In 2021, trucks and buses accounted for only 5% of all registered vehicles but were responsible for 11% of vehicle miles traveled.1 These vehicles also play a substantial role in the United States (US) GHG emissions profile. Specifically, the transportation sector is responsible for 29% of the nation's GHG emissions, with nearly one-quarter of that originating from medium- and heavy-duty trucks.2 The emissions from heavy-duty vehicles are also at risk of increasing, with steady increases in freight movement expected through at least 2050.3 As such, EPA's proposed rule to address heavy-duty vehicle emissions presents an important opportunity to curtail this durable driver of GHG emissions. [EPA-HQ-OAR-2022-0985-1517-A1, pp. 1-2]

In addition to the immediate health effects, the reduction in GHGs and mitigation of rising global temperatures will reduce the frequency and severity of future health risks such as wildfires.25 GHGs contribute to the increased frequency and severity of wildfire events.26,27 Without abatement, GHGs will continue to fuel more frequent and more intense wildfires, leading to more frequent poor air quality days during which millions of vulnerable Americans are at risk of worsening underlying respiratory and cardiovascular disease.28,29 Indeed, the blanket of smoke over much of the continent from Canadian wildfires in June 2023 resulted in millions of people in the Northeast not being able to leave their homes or exercise outdoors due to health concerns related to wildfire smoke exposure. This was sighted as an unprecedented event, but unfortunately, such events are becoming more and more frequent because of climate change. [EPA-HQ-OAR-2022-0985-1517-A1, p. 3]

Organization: Arizona State Legislature

To justify the proposed rule, EPA repeatedly claims that transportation represents 27% of U.S. greenhouse gas emissions, and heavy-duty vehicles contribute one-fourth of those emissions. See, e.g., 88 Fed. Reg. 25,928, 25,952, 26,047. EPA worries about reported changes in global average temperature increase and sea level rise. Id. at 26,046. 'Tens of billions of dollars of U.S. real estate could be below sea level by 2050 under some scenarios,' EPA warns. Id. at 26,047. [EPA-HQ-OAR-2022-0985-1621-A1, p. 9]

But EPA does not know if the proposed rule will avoid any of these possible disasters. EPA admits that it did not even try to find out: 'EPA did not conduct modeling to specifically quantify changes in climate impacts resulting from this rule in terms of avoided temperature change or sea-level rise . . .' Id. Perhaps this is because 'China's annual emissions are more than double those of the United States.'15 Thus, cutting emissions from a portion of one sector that comprises one-fourth of American emissions, which are less than half the emissions of China, may not make any noticeable difference to avoiding the possible climate disasters of which EPA is concerned. [EPA-HQ-OAR-2022-0985-1621-A1, p. 9]

15 Michael Birnbaum and Christian Shepherd, How the U.S. wants to pressure China to help avert climate catastrophe, THE WASHINGTON POST, May 30, 2023, available at https://www.washingtonpost.com/climateenvironment/2023/05/30/biden-us-china-climate-emissions/.

The actual climate benefits of the proposed rule must be calculated in order to weigh those benefits against the costs and transformative nature of the proposed rule. EPA's summary conclusion that implementing the proposed standards 'would contribute toward the goal of holding the increase in the global average temperature to well below 2°C above pre-industrial levels' is not good enough. Id. at 26,047 (emphasis added). [EPA-HQ-OAR-2022-0985-1621-A1, p. 9]

Organization: Clean Air Task Force et al.

2. Greenhouse gas emissions from heavy-duty vehicles endanger public health and welfare by intensifying the climate crisis.

Over thirteen years ago, based upon a massive scientific record, EPA found that new motor vehicles and engines contribute to emissions of GHGs that drive climate change and endanger the health and welfare of current and future generations. 74 Fed. Reg. at 66496. Specifically, EPA found that the intensifying climate crisis increased the frequency of warmer temperatures, heat waves, and other extreme weather, worsened air quality by increasing regional ozone pollution, increased the spread of food and waterborne illnesses, increased the frequency and severity of seasonal allergies, and increased the severity of coastal storm events due to rising sea levels. 74 Fed. Reg. at 66525–26. [EPA-HQ-OAR-2022-0985-1640-A1, p. 10]

Since EPA issued the Endangerment Finding in 2009, dire evidence of the current and future impacts of climate change has continued to accumulate. Recent studies demonstrate that climate change continues to cause heat waves and extreme weather events across the United States.6 Between May and mid-September in 2022, "nearly 10,000 daily maximum temperature records were broken."7 Additionally, 2022 was "one of the top 10 hottest years on record for daily maximum temperatures" in 13 states, as well as one of the top 10 hottest for daily minimum (nighttime low) temperatures for 31 states.8 Warmer temperatures endanger public health by increasing the risk of heart disease, worsening asthma and chronic obstructive pulmonary disease from increases of ground-level ozone, and causing dehydration and many other ailments.9 Studies have also found that heat waves and extreme weather events cause severe psychiatric and mental health impacts.10 Climate change continues to lead to higher than normal pollen concentrations and earlier and longer pollen seasons, causing worse allergies and asthma.11 The intensifying climate crisis also increases the risk of drought across the U.S, which impacts water supply, agriculture, transportation, and energy, and increases the risk and magnitude of wildfires.12 And recent projections show that sea level rise is anticipated to be on the high end of model projections.13 Studies have found that many of the dangers wrought by climate change exact a higher toll on people with low incomes and people of color.14 [EPA-HQ-OAR-2022-0985-1640-A1, pp. 10 - 11]

The transportation sector has been responsible for an increasing percentage of GHG emissions in the U.S. since 2009, thereby playing an outsized role in intensifying the climate crisis. When EPA made its Endangerment Finding for GHGs, the transportation sector was responsible for 23 percent of total annual U.S. GHG emissions. 74 Fed. Reg. at 66499. Since then, transportation sector GHG emissions have only increased as a share of U.S. emissions, surpassing the electric power sector as the largest U.S. source of GHG emissions and contributing 27.2 percent of total GHG emissions in 202015 and 28.5 percent in 2021.16 After dipping in 2020 due to the COVID-19 pandemic, CO2 emissions from the transportation sector increased by 11.5 percent between 2020 and 2021.17 Transportation as an end use sector "account[ed] for 1,757.4 [million metric tons] CO2 in 2021 or 37.9 percent of total CO2 emissions from fossil fuel combustion."18 [EPA-HQ-OAR-2022-0985-1640-A1, pp. 11 - 12]

17 Id. at 2-13

18 Id. at 2-17

HDVs are the second-largest domestic contributor of GHGs in the transportation sector. Medium- and heavy-duty vehicles represent only 5 percent of vehicles on the road.19 Yet in 2021, they accounted for 25 percent of CO2 emissions from the transportation sector.20 CO2 emissions from medium- and heavy-duty trucks increased by 75 percent from 1990 to 2021.21 This increase was driven, in part, by substantial growth in medium- and heavy-duty truck vehicle miles traveled, which increased by 66 percent between 1990 and 2021.22 Vehicle miles traveled are expected to rise in the heavy-duty vehicle sector over the coming decades.23 As a result, GHG emissions from heavy-duty vehicles represent a large portion of overall GHG emissions in the United States and contribute heavily to the intensifying climate crisis. Adopting stringent GHG emission standards for HDVs will lead to massive public health benefits by limiting these pollutants.24 [EPA-HQ-OAR-2022-0985-1640-A1, p. 12]

Lung Ass'n, Delivering Clean Air: Health Benefits of Zero-Emission Trucks and Electricity 5 (2022), https://www.lung.org/clean-air/electric-vehicle-report/delivering-clean-air ("Pollution from heavy-duty vehicles is harmful even if it occurs from lower volumes of traffic, and combustion vehicles and trucks still contribute to the acceleration of climate change and the health impacts stemming from it.")

The most recent synthesis of the United Nations Intergovernmental Panel on Climate Change (IPCC) Sixth Assessment Report confirms the danger to public health and welfare posed by GHG emissions from the transportation sector. The report found that global surface temperature was around 1.1ºC higher in 2011-2020 than it was in 1850-1900.25 While average annual GHG emissions growth has slowed in certain sectors such as energy supply and industry, growth in GHG emissions from the transportation sector has remained relatively constant at about 2 percent per year.26 The latest IPCC report warned that "[d]eep, rapid and sustained GHG emissions reductions, reaching net zero CO2 emissions and including strong emissions reductions of other GHGs . . . are necessary to limit warming to 1.5°C . . . or less than 2°C . . . by the end of the century."27 To have a chance at limiting global temperature increase to 1.5ºC and avoid the worst impacts of climate change, current GHG emissions from the transportation sector must drop by 59 percent by 2050 compared to 2020 emissions.28 The IPCC concluded in its 2022 report that "[l]and-based, long-range, heavy-duty trucks can be decarbonised through battery-electric haulage... complemented by hydrogen[-based]... fuels in some contexts."29 [EPA-HQ-OAR-2022-0985-1640-A1, p. 12]

Organization: Electrification Coalition (EC)

In addition to our national security challenges, the U.S. also faces the rapidly growing threat of climate change. The latest National Climate Assessment3, which Congress mandated in 1990 under the Global Change Research Act, shows that the U.S. has been observing the impacts of climate change for decades and that more frequent and extreme weather and climate-related events are creating new and increasing risks across U.S. communities – which we have recently seen with wildfires that have ravaged the country, more powerful hurricanes causing loss of lives and immense destruction, more intense tornadoes destroying communities, and extreme weather events in areas that we should not expect to see these weather events in. [EPA-HQ-OAR-2022-0985-1558-A1, p. 3]

3 https://nca2018.globalchange.gov/

To overcome these national security concerns from climate change, the U.S. must reduce carbon emissions. The EPA notes that the transportation sector is the largest source of greenhouse gas emissions, representing 27% of total greenhouse gas emissions; narrowing into the transportation sector, heavy-duty vehicles are the second largest contributor to greenhouse gas emissions, at 25%.4 [EPA-HQ-OAR-2022-0985-1558-A1, p. 3]

4 See page 25928 of the Environmental Protection Agency's (EPA) proposed rule for Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles-Phase 3 in the Federal Register: https://www.govinfo.gov/content/pkg/FR-2023-04-27/pdf/2023-07955.pdf

Organization: Environmental Protection Network (EPN)

The Need for and Benefits of the Proposal

As noted in the proposal, transportation is the single largest U.S. source of greenhouse gas emissions, making up 27% of the total. Within the transportation sector, all HDV (Class 2b-8) are the second largest contributor, at 25% of all transportation sources. Further, a recent Rhodium Group report revealed that greenhouse gas emissions for the transportation sector and national economy grew 1.3% in 2022.4 This upward trend is pushing the country off course from President Biden's stated goal. [EPA-HQ-OAR-2022-0985-1523-A1, pp. 1-2]

Organization: National Parks Conservation Association (NPCA)

Pollution from Heavy-Duty Vehicles Furthers Climate Change and Harms our Parks and Communities. [EPA-HQ-OAR-2022-0985-1613-A1, p. 2]

The irrefutable consensus among leading scientists has demonstrated time and again that climate change poses an increasing existential threat to America's national parks and the world around them. According to the Intergovernmental Panel on Climate Change (IPCC) in their recently released Synthesis for the 6th Assessment Report (AR6),

- [h]uman activities, principally through emissions of greenhouse gases, have unequivocally caused global warming, with global surface temperature reaching 1.1°C above 1850–1900 in 2011–2020. Global greenhouse gas emissions have continued to increase, with unequal historical and ongoing contributions arising from unsustainable energy use, land use and land-use change, lifestyles and patterns of consumption and production across regions, between and within countries, and among individuals.7 [EPA-HQ-OAR-2022-0985-1613-A1, p. 2]

7 IPCC, Synthesis Report of the IPCC Sixth Assessment Report (AR6): Summary for Policymakers, Doc. 4,

The IPCC further states that current policies and laws ‘fall short of the levels needed to meet climate goals across all sectors and regions,’ and will likely result in warming that ‘will exceed 1.5°C during the 21st century and make it harder to limit warming below 2°C.’8 [EPA-HQ-OAR-2022-0985-1613-A1, p. 2]

8 Id. at 10.

Our national park system hosts some of America’s most beloved natural and cultural resources, yet our parks are uniquely vulnerable to the changing climate.9 The burning of fossil fuels has resulted in national park mean annual temperatures increasing ‘at double the rate of the U.S. as a whole’ between 1895 and 2010.10 The ecological turmoil caused by this warming and the resulting extreme weather conditions is disastrous for nearly all national park units and is expected to only get worse. As temperatures increase, climate effects are felt across all park geographic regions and locations, from coastal areas to mountain ranges.11 These climate effects include: (1) rising sea levels; (2) increasingly intense wildfires; (3) threat and harm to wildlife habitats and lifestyles; (4) the rapid growth of disruptive, invasive species; (5) extreme weather damage; (6) drier conditions leading to difficult droughts; (7) loss of snow and ice; (8) changing landscapes and disrupted ecosystems; (9) destruction of irreplaceable park structures and artifacts; and (10) altered visitation patterns and significant losses to valuable tourism revenue.12 [EPA-HQ-OAR-2022-0985-1613-A1, pp. 2-3]

RES. LETTERS 1 (2018), https://perma.cc/99FL-CA3S.

Due to the propensity of such extreme events to damage national parks, our findings indicate that climate change is a very real and significant concern for 80 percent of the nation’s parks.13 If climate change continues at this rate, park wildlife and plant species’ populations will plummet, and additional extinctions are likely to occur. In the decades to come, destruction from climate change could very well cause the near total loss of numerous namesake natural features across the park system, including, but not limited to, glaciers in Glacier National Park, everglade forests in Everglades National Park, saguaro cacti in Saguaro National Park, Joshua trees in Joshua Tree National Park, and giant sequoias in Sequoia National Park. Moreover, threats such as sea-level rise and storm related flooding and erosion put a long list of cultural park resources at risk, including historic structures from the National Mall in Washington, DC to the Golden Gate National Recreation Area in San Francisco. [EPA-HQ-OAR-2022-0985-1613-A1, p. 3]

13 NPCA, Air and Climate Report: Polluted Parks, NPCA.org (2019), https://www.npca.org/reports/air-climate-report.

The transportation sector is now the largest source of GHG emissions in the United States, and HD vehicles are the second-largest contributor of domestic GHG emissions despite representing only 5 percent of vehicles on the road.14 EPA’s proposed Phase III GHG standards for heavy-duty vehicles will help address this top source of climate altering pollution, and, in so doing, protect our parks from the worst of this devastation. Taking strong action to reduce greenhouse gas emissions from heavy-duty vehicles will be a massively helpful step to limit warming below 2°C and protect our treasured national parks. [EPA-HQ-OAR-2022-0985-1613-A1, p. 3]

Organization: Our Children's Trust

2. EPA continues a long-standing practice of discounting the lives of children and unborn future generations when it analyzes and considers the formulation of proposed regulations to carry out its delegated authority to protect the air and human health and welfare. That charge, to protect air quality in order to protect human health and welfare, is a charge not to merely protect one living generation of adults' air quality, but to protect babies, children, and "our Posterity"—for the U.S. Constitution is clear that all sovereign authority vested in our federal government, and here as delegated to EPA, cannot be used to destroy the nation and thereby its sovereignty, precluding children of today and tomorrow from inheriting the air and water and land in sound condition and having the ability to govern themselves to also protect the lifegiving air and all generations to come. What is at stake in this proposed rule are lives of children—their health and safety. [EPA-HQ-OAR-2022-0985-1633-A1, p. 2]

The Earth's Energy Is Imbalanced and thus the EPA Must Cease Infringing the Constitutional Rights of Youth. EPA has Public Trust and Constitutional Obligations to use its Authority to Protect the Atmosphere. [EPA-HQ-OAR-2022-0985-1633-A1, p. 2]

5. Excess accumulation of greenhouse gases in our atmosphere results in an Earth energy imbalance and thus an accumulation of heat in our climate system.4 The best available science informs that Earth's energy balance can only be restored by returning the atmospheric CO2 concentration to below 350 ppm by 2100.5 Experts have opined that it is economically and technically feasible to achieve the science-based greenhouse gas emission reduction target of close to 100% by 2050, while simultaneously enhancing sequestration capacity of sinks to draw down historical cumulative CO2 emissions, placing the U.S. on an emissions trajectory consistent with returning atmospheric CO2 to below 350 ppm by 2100, which would bring long-term heating of the Earth back down to approximately 1.0°C above preindustrial temperatures, stabilizing the climate.6 Please explain how the proposed rule aligns with restoring Earth's Energy Imbalance. [EPA-HQ-OAR-2022-0985-1633-A1, pp. 2 - 3]

Env't L.J. 102 (2022).

6. Current increased average temperatures of 1°C and greater (now at ~1.2°C) are already dangerous according to the IPCC.7 Basing policies and decisions that align with temperature targets of 1.5°C is catastrophic for our children and posterity.8 The IPCC special report on Global Warming of 1.5°C (2018) stated that allowing a temperature rise of 1.5°C "is not considered 'safe' for most nations, communities, ecosystems and sectors and poses significant risks to natural and human systems as compared to the current warming of 1°C (high confidence)."9 The 2023 IPCC Summary for Policymakers for the Synthesis Report (AR6) stated: "Risks and projected adverse impacts and related losses and damages from climate change will escalate with every increment of global warming (very high confidence). They are higher for global warming of 1.5°C than at present, and even higher at 2°C (high confidence)."10 Medical experts have recently recognized that "[t]he science is unequivocal; a global increase of 1.5°C above the pre-industrial average and the continued loss of biodiversity risk catastrophic harm to health that will be impossible to reverse."11 As such, 1.5°C should not be used to guide U.S. policy that is required to be based on best available science. The EPA should not be advancing policies that knowingly make the climate crisis worse, and potentially unsolvable. [EPA-HQ-OAR-2022-0985-1633-A1, pp. 3 - 4]

7 IPCC, Summary for Policymakers, in Synthesis Report of the IPCC Sixth Assessment Report (AR6) (2023), https://report.ipcc.ch/ar6syr/pdf/IPCC_AR6_SYR_SPM.pdf.

8 See IPCC, Overarching Frequently Asked Questions: FAQ 3: How will climate change affect the lives of today's children tomorrow, if no immediate action is taken? in Climate Change 2022: Impacts, Adaptation and Vulnerability (2022) ("[T]oday's children and future generations are more likely to be exposed and vulnerable to climate change and related risks such as flooding, heat stress, water scarcity, poverty, and hunger. Children are amongst those suffering the most . . . [C]hildren aged ten or younger in the year 2020 are projected to experience a nearly four-fold increase in extreme events under 1.5°C of global warming by 2100[.]")

9 M.R. Allen et al., Technical Summary, in Global Warming of 1.5°C, at 44 (2018); see also Assessing "Dangerous Climate Change". This was similarly noted in the IPCC, Summary for Policymakers, in Climate Change 2022: Impacts, Adaptation and Vulnerability, at 13 (2022): "Global warming, reaching

1.5°C in the near-term, would cause unavoidable increases in multiple climate hazards and present multiple risks to ecosystems and humans (very high confidence).” Note that global warming was at ~1.0°C when this report was finalized; it has now risen to 1.2°C.

11 Lukoye Atwoli et al., Call for Emergency Action to Limit Global Temperature Increases, Restore Biodiversity, and Protect Health, 398 The Lancet 939 (2021) (emphasis added), https://doi.org/10.1016/S0140-6736(21)01915-2.

7. Climate change is causing a public health emergency that is already adversely impacting the physical and mental health of American children through, among other impacts, extreme weather events, rising temperatures and increased heat exposure, decreased air quality, altered infectious disease patterns, and food and water insecurity.12 Children are uniquely vulnerable to climate change impacts because of their developing bodies, higher exposure to air, food, and water per unit body weight, unique behavior patterns, dependence on caregivers, political powerlessness, and longevity on the planet.13 The protection of constitutional rights of children, by following the science, is of the utmost importance and must be incorporated in all relevant EPA rulemaking and policies. [EPA-HQ-OAR-2022-0985-1633-A1, p. 4]

12 IPCC, Summary for Policymakers, in Climate Change 2022: Impacts, Adaptation and Vulnerability, at 11, 17 (2022). This summary found that the current level of global warming is already driving heat waves that cause human morbidity, heavy rains, flooding, extreme fires and drought, coral bleaching and demise, massive shifts in species habitats, loss of glaciers, snow and permafrost, as well as more destructive hurricanes. Id. at 11.

8. Our Children’s Trust represents twenty-one youth plaintiffs, including eleven Black, Brown, and Indigenous youth, in the constitutional climate lawsuit, Juliana v. United States, in which the Administrator, in his official capacity, and EPA are defendants. This case asserts, and courts have found, that, through the government’s past and ongoing affirmative actions that cause climate change, it has violated the youngest generation’s constitutional rights to life, liberty, property, and equal protection of the law, as well as failed to protect essential public trust resources. In this litigation, federal courts have affirmed “that the federal government has long promoted fossil fuel use despite knowing that it can cause catastrophic climate change”14 and “has long understood the risks of fossil fuel use and increasing carbon dioxide emissions”.15 The Ninth Circuit Court of Appeals found that there was evidence showing that the federal government was a substantial factor in causing the youth’s constitutional injuries because “[a] significant portion of [GHG] emissions occur in this country; the United States accounted for over 25% of worldwide emissions from 1850 to 2012, and currently accounts for about 15%.”16 Without immediate effective action, our children and future generations will continue to suffer injury with long-lasting and potentially irreversible consequences.17 These judicially-recognized facts should guide EPA’s

policies and practices so they can identify, and alter, those policies that exacerbate American youth's existing climate change injuries. [EPA-HQ-OAR-2022-0985-1633-A1, pp. 4 - 5]

Chem. & Phys. 3761 (2016); U.S. Global Change Research Program, Fourth National Climate Assessment, Vol. II (2018); David I. Armstrong McKay et al., Exceeding 1.5°C Global Warming Could Trigger Multiple Climate Tipping Points, 377 Science eabn7950 (2022); Nico Wunderling et al., Global Warming Overshoots Increase Risks of Climate Tipping Cascades in a Network Model, 13 Nature Climate Change 75 (2023). Note that many researchers use the temperature targets set during the Paris Accord as a point of reference, not as a sanctioning of those levels of average planetary heating.

9. Under the 5th Amendment to the U.S. Constitution, the government is restrained from engaging in conduct that infringes upon fundamental rights to life, liberty, and property, and equal protection of the law, all of which includes a climate system that sustains human life and liberty. Under the Public Trust Doctrine, embedded in our Constitution and other founding documents, and in the very sovereignty of our Nation, U.S. residents (both present and future, i.e., Posterity) have a right to access and use crucial natural resources, like air and water. The U.S. government, and its executive agencies, have fiduciary duties as trustees to manage, protect, and prevent substantial impairment to our country's vital natural resources which the government holds in trust for present and future generations.18 [EPA-HQ-OAR-2022-0985-1633-A1, p. 5]

Organization: Southern Environmental Law Center (SELC)

I. GHG emissions and other harmful pollutants from heavy-duty vehicles cause significant environmental, public health, and economic harms.

The transportation sector is the largest source of GHG emissions in the United States,3 and this is also true for most states in the South. In fact, transportation is the primary source of carbon dioxide (CO_2)—the most prevalent GHG in our atmosphere—in every state in SELC's region except for Alabama, where it is the second largest source.4 In Georgia, Tennessee, North Carolina, South Carolina, and Virginia, emissions from transportation sources account for nearly half of all CO_2 emissions.5 Within the transportation sector, heavy-duty vehicles are responsible for a disproportionate share of the GHG pollution. Nationwide, trucks account for 25 percent of all climate change-inducing pollution from the transportation sector despite comprising less than 10 percent of vehicles on the road.6 The disproportionate harm caused by trucks is also evident in the South. In North Carolina, heavy-duty vehicles make up only 6 percent of the total fleet, but they contribute significantly to heat-trapping GHG emissions from the state's transportation sector;7 in Virginia, heavy-duty vehicles make up only about 5 percent of the state's fleet, yet they contribute 26 percent of all GHG emissions from transportation sources.8 In the coming years, heavy-duty vehicle traffic is expected to increase,9 and higher regional growth rates are projected in the South.10 [EPA-HQ-OAR-2022-0985-1554-A1, p. 1-2]

3 The transportation sector generates 27 percent of all GHG annual emissions in the United States. See id. at 25928.

GHG emissions are the primary driver of climate change,11 and the United States is already experiencing the environmental, public health, and economic impacts of a changing climate.12 While the effects of climate change are well-documented nationwide, the geography and demographics of the South make the region particularly vulnerable to climate change. A 2023 analysis of climate vulnerabilities across the United States found that the 100 census tracts with the highest overall climate vulnerability are located in 28 counties in nine southern states, including Alabama, Georgia, Tennessee, North Carolina, and South Carolina.13 Climate vulnerability, or the predisposition to climate change-related hazards due to "greater exposure to climate risks and lower ability to prepare, adapt, and recover from their effects," often correlates with race, income, and other socioeconomic factors.14 The two counties with the highest number of census tracts among the 100 most vulnerable are located within SELC's region: Shelby County, Tennessee has 21 of the top 100 most vulnerable tracts, and Mobile County, Alabama has 14.15 [EPA-HQ-OAR-2022-0985-1554-A1, p. 2-3]

11 See INTERGOVERNMENTAL PANEL ON CLIMATE CHANGE, SYNTHESIS REPORT OF THE IPCC SIXTH ASSESSMENT REPORT (AR6): SUMMARY FOR POLICYMAKERS 4 (2023) ("Human activities, principally through emissions of greenhouse gases, have unequivocally caused global warming, with global surface temperature reaching 1.1°C above 1850-1900 in 2011-2020.").

15 Id. at 6.

Rising temperatures are one of the many effects of climate change. The decade from 2010 to 2020 was the warmest on record in the South, and the region is already experiencing a higher percentage of intensifying heat waves than other parts of the country.16 Longer and more intense heat waves reduce air quality and cause heat-related illnesses like heat cramps, heatstroke, heat exhaustion, kidney-associated diseases, and asthma.17 These health effects are especially likely in vulnerable populations such as children, outdoor workers, and the elderly.18 In addition, the South is home to some of the fastest-growing metropolitan areas in the country.19 Auto-oriented development often increases impervious surfaces and reduces tree canopy cover, which combined with climate change can create and exacerbate heat island effects, resulting in more emergency room visits, reduced life expectancy, and worsened mental health outcomes in impacted communities.20 These impacts are often most acute in communities of color that have suffered a history of environmental injustice.21 [EPA-HQ-OAR-2022-0985-1554-A1, p. 3]

With over 12,000 miles of coastline,22 the South is also experiencing frequent flooding due to increased extreme storm events and sea level rise. Sea level has been rising at a rate about three times the global pace along the mid-Atlantic coast.23 In the Hampton Roads region of Virginia—which has the highest rate of sea level rise on the East Coast24—the sea level has risen by more than a foot over the last 80 years,25 and scientists predict an additional rise of 1.5

to 2 feet by 2050.26 As warmer ocean temperatures result in heavier, more frequent rainfalls and slower-moving hurricanes, inland flooding is also increasing.27 The number of Category 4 and 5 hurricanes in the mid-Atlantic basin—such as Hurricanes Ian, Irma, Michael, Mathew, and Florence—has grown substantially since the 1980s.28 These weather events cause serious injuries and fatalities,29 property damage, respiratory effects from mold exposure, and may lead to public emergencies and infrastructure disruptions, stressing health services and communities.30 [EPA-HQ-OAR-2022-0985-1554-A1, p. 3-4]

There are also massive economic costs to climate change, and studies have found that the future costs will be unequally distributed across the United States.31 Relative to the rest of the nation, the South will face the largest economic losses from climate change, with low-income and minority communities particularly affected.32 Lower income counties in the South may lose between 5 and 20 percent of gross domestic product per year—compared to an average yearly loss of 1.2 percent nationally—for every additional degree of warming by the 2080s.33 [EPA-HQ-OAR-2022-0985-1554-A1, p. 4]

A. Reducing GHG Emissions from Heavy-Duty Vehicles Is A Necessary Part of Tackling the Growing Climate Emergency

The Sixth Assessment Report of the Intergovernmental Panel on Climate Change ("IPCC Report") confirms the widespread and irreversible impacts caused by anthropogenic climate change.2 Annual mean temperatures across North America have trended upward since 1960.3 Nine of the United States' ten warmest years on record have occurred since 1998, while worldwide, all ten of the warmest years on record have occurred since 2005.4 Indeed, April 2023 was the fourth-warmest April on record, with the second-highest ocean temperatures of any month on record.5 There is a "virtually certain" chance that 2023 will rank among the ten warmest years on record, with a 93 percent chance it will rank among the top five.6 [EPA-HQ-OAR-2022-0985-1588-A1, pp.2-3]

2 IPCC, 2022: Summary for Policymakers [H.-O. Pörtner, D.C. Roberts, M. Tignor, E.S. Poloczanska, K. Mintenbeck, A. Alegría, M. Craig, S. Langsdorf, S. Löschke, V. Möller, A. Okem, B. Rama (eds.)] ("Summary for Policymakers"). In: Climate Change 2022: Impacts, Adaptation and Vulnerability. Contribution of Working Group II to the Sixth Assessment Report of the Intergovernmental Panel on Climate Change [H.-O. Pörtner, D.C. Roberts, M. Tignor, E.S. Poloczanska, K. Mintenbeck, A. 6 NOAA, supra note 5.

As temperatures rise, threats to public health and the environment in our States and Cities continue to mount. The IPCC Report emphasizes the importance of limiting warming, ideally to 1.5 degrees Celsius,7 although even this level of warming would pose unavoidable risks to humans and ecosystems.8 The transportation sector is the largest source of GHG emissions in the United States, with heavy-duty vehicles being the second-largest contributor within that sector. Reducing GHG emissions from heavy-duty vehicles is thus an essential element of addressing the growing climate emergency already impacting our residents. Our comments focus on the following climate impacts with economic, health, and societal damage in our States and Cities: wildfire damage, flooding and drought, melting of snowpack and diminishing water supply, and sea-level rise. [EPA-HQ-OAR-2022-0985-1588-A1, p.3]

8 Id. at 13–17 (Summary for Policymakers).

1. Increased Risk of Wildfire Damage

Rising temperatures combined with drier conditions are increasing the risk of wildfires.9 By engendering warm and dry conditions,10 climate change has contributed to more extreme wildfires in North America.11 Consistent with this projection, the 2020 wildfire season was unprecedented—wildfires in Colorado burned more than 665,000 acres,12 and historic wildfires burned 10.2 million acres across California, Oregon, and Washington.13 California is uniquely vulnerable to wildfires because it has a short rainy season with significant plant growth in the winter followed by dry periods that turn the plant growth into potential fuel sources, making these areas highly fire-prone.14 Indeed, a major commercial insurer cited wildfire risk as the reason it recently stopped accepting applications for homeowners insurance in California.15 The places at greatest risk of wildfire damages are in the "Wildland-Urban Interface," "where houses and wildland vegetation meet or intermingle,"16 and California has more homes in this Interface than any other state.17 Increasing wildfires also endanger electrical transmission and distribution assets in Northern California, where critical power lines cross highly fire-prone areas.18 Warming has also led to longer fire seasons.19 Since the 1970s, wildfire season in the Western U.S. has extended from five months to over seven months long.20 In the coming decades, climate change is projected to further increase fire activity across North America.21 [EPA-HQ-OAR-2022-0985-1588-A1, pp.3-4]

21 Sixth Assessment, supra note 2, at 1948 (Ch. 14).

These massive wildfires have broad impacts across our States and Cities. The 2020 wildfires—which conservatively cost an estimated $16.5 billion22—put half a million Oregonians under evacuation warnings or orders,23 led to the displacement of about 100,000 people in California,24 and killed 46 people in California, Oregon, and Washington.25 The particulate matter produced by wildfires is hazardous to human health and disruptive to daily activities,26 disrupting education in California due to cancelled classes for 1.1 million students27 and reducing test scores, leading to reduced long-term future earnings.28 This public health concern grows as the frequency and intensity of wildfires increase and is not limited to States where the wildfires are burning. The rising heat from the wildfires takes particulate matter and toxic gases in the smoke into the jet stream, which can carry those hazardous substances thousands of miles and cause harmful air pollution across the country. During the 2020 wildfire season and again in July of 2021, smoke from wildfires burning on the West Coast caused New York City to experience some of the worst air quality in the world.29 And in June 2023, New York City was once again blanketed in smoke, resulting in the highest measurements of 2.5 micron particles since recording began in 1999.30 The combination of fierce wildfires in Canada and airflow patterns prompted the U.S. National Weather Service to issue air quality alerts for most of the Atlantic seaboard.31 [EPA-HQ-OAR-2022-0985-1588-A1, pp.4-5]

2. Increased Risk of Severe Flooding and Severe Drought

Warmer temperatures also contribute to the severity of flooding experienced by our States and Cities. High-intensity rainfall (and other extreme weather events) create flooding risks32 and heavy precipitation can overwhelm water control infrastructure.33 In three events in summer 2022 alone, streets and homes in Dallas Fort-Worth were flooded after 18 hours of heavy precipitation, causing hundreds of car crashes and other water-related emergencies;34 Death Valley, California received nearly a year's worth of rain in three hours,35 causing the loss of a critical portion of a water system, the Emergency Operations Building, and over 600 feet of the water main;36 and the St. Louis metropolitan area experienced its most intense rainfall since 1874, causing catastrophic flash flooding.37 California also experiences intense floods from "atmospheric rivers"—narrow, intense bands of moist air that transport large amounts of water vapor towards Earth's poles.38 California's mountain ranges force this warm moist air upwards, causing the water vapor to fall as rain.39 These particular California topographic features render the atmospheric rivers devastating to local communities in the state.40 [EPA-HQ-OAR-2022-0985-1588-A1, pp.5-6]

Warmer temperatures also contribute to the severity of drought experienced by our States and Cities. In 2022, Massachusetts experienced significant or critical drought conditions across the entire state, leading to drought-induced fires, water restrictions, and water quality and availability impacts on private wells and water-dependent habitats across the state.41 Since early 2020, the southwestern United States has experienced one of the most severe long-term droughts of the past 1,200 years, triggered by multiple seasons of record low precipitation and near-record temperatures.42 Drought also afflicted the Pacific Northwest in 2020, caused by the mountain snowpack melting quickly rather than gradually into the foothills and plateau.43 Droughts in the western United States have caused substantial economic and environmental damage.44 California is particularly vulnerable to the increased risk of drought as warming temperatures "lead[] to more precipitation falling as rain rather than snow, faster melting of winter snowpack, greater rates of evaporation, and drier soils."45 Between September 2019 and August 2022, California experienced the driest three-year stretch on record.46 [EPA-HQ-OAR-2022-0985-1588-A1, p.6]

Both droughts and floods will become more intense as the Earth warms, which may result in, among other impacts, the degradation of water supply security,47 ecological vulnerabilities,48 and water quality impairment.49 This threat is becoming increasingly dramatic on the Colorado River, where key reservoirs have been pushed to their limits.50 Indeed, Arizona recently announced that it would not approve new housing construction in the Phoenix metropolitan area due to a limited supply of groundwater.51 If reservoir levels continue to fall, the water supply of 25 million Americans in Arizona and California faces increasing risk.52 [EPA-HQ-OAR-2022-0985-1588-A1, pp.6-7]

Most of California's precipitation occurs as snow, so water availability depends on the mountain snowpack,53 which supplies approximately 30 percent of California's annual water demand.54 Rising atmospheric temperatures decrease that snowpack, regardless of precipitation changes.55 Indeed, California's water management systems have been built around the natural reservoir of the snowpack, which will melt earlier and faster in higher temperatures. Projections show that carry over storage—the volume of water in reservoirs before the start of the wet season in late fall—in California's two largest reservoirs, Shasta and Oroville, will decline by about one-third by the end of the century.56 Reductions in snowpack and river flow may require the state to invest in expensive new water resources such as water desalination or other alternative solutions.57 [EPA-HQ-OAR-2022-0985-1588-A1, p.7]

3. Sea Level Rise

Climate change causes sea level rise in two primary ways: 1) by melting ice sheets and glaciers, and 2) by warming seawater, which consequently expands.58 In the past three decades, rates of sea level rise have accelerated along most North American coasts.59 Sea level rise has caused flooding, erosion, and infrastructure damage along the western Gulf of Mexico and the southeast US coasts,60 and is even more dangerous in combination with dynamic processes like storm surge flooding and ocean acidification.61 California's 3,500-mile coastline is particularly susceptible to the dangers of sea-level rise, with even typical tides and storms producing extreme high-water events. Projected sea level rise will likely cause severe economic disruption and damage to the nearly 27 million Californians—more than any other State in the nation—who live in a coastal county.62 Projections show that somewhere between 31 to 67 percent of Southern California beaches may be lost by 2100.63 By the middle of the century, flooding from rising sea levels and storms is likely to make billions of dollars of coastal property unusable.64 In a worst case scenario of 6.6 feet of sea level rise combined with a 100-year storm, the resultant flooding in Southern California could affect a quarter of a million people, $50 billion worth of property, and $39 billion worth of buildings.65 A projected sea level rise of 0.9 meters by 2100 would place 4.2 million people at risk of inundation in US coastal cities.66 [EPA-HQ-OAR-2022-0985-1588-A1, pp.7-8]

For all these reasons, reducing GHG emissions from heavy-duty vehicles—the second largest source of GHGs within the transportation sector in the United States—is a critical step in tackling the climate emergency. [EPA-HQ-OAR-2022-0985-1588-A1, p.8]

Organization: World Resources Institute (WRI)

EPA studies show that medium- and heavy-duty vehicles generate 23 percent of the transportation sector's greenhouse gas emissions (GHG), contributing to the severity of climate change impacts, including heat waves, drought, sea level rise, extreme climate and weather events, coastal flooding, and wildfires. Some populations may be especially vulnerable to these and other climate change impacts, including low-income communities, people with disabilities, people of color, and Indigenous populations. Furthermore, studies (such as the recent 'Zeroing in on Healthy Air' from the American Lung Association) show that regulations and policies designed to reduce GHG emissions, such as through accelerating electric transportation, will have the added benefit of reducing other forms of pollution, such as air toxics and particular matter, that impact public health and disproportionately impact overburdened communities. [EPA-HQ-OAR-2022-0985-1601-A1, pp. 3 - 4]

Organization: Zero Emission Transportation Association (ZETA)

b. Reducing HDV Emissions Protects the Environment and the Climate

Emissions from diesel engines have detrimental impacts not only on human health, but on natural ecosystems as well. A study from the University of Southampton demonstrated that exposure to diesel exhaust has negative impacts on pollinators and that NOx emissions altered the smell of five out of the eleven most common single compound floral odors.13 In areas where diesel exhaust is present, a 2022 study found that there were 70% fewer pollinators and 90% fewer flower visits.14 A separate study from the Journal of Environmental Health Science and Engineering suggests that prolonged exposure to internal combustion engine exhaust has potentially significant impacts on agro-ecosystems and plant germination.15 [EPA-HQ-OAR-2022-0985-2429-A1, p. 6]

13 "Diesel fumes alter half the flower smells bees need," University of Southampton, (October 19, 2015) https://www.southampton.ac.uk/news/2015/10/diesel-fumes-alter-flower-smell-for-bees.page

While HDVs make up just 10 percent of vehicles on the road, they generate more than 25 percent of the total GHG emissions from the transportation sector.16 As the nature of anthropogenic climate change is becoming increasingly evident,17 the urgency needed in addressing its causes is becoming greater.18 Electrification is the best path forward for reducing transportation emissions, and HDV electrification in particular presents an outsized opportunity for emissions reductions. In addition to emitting higher volumes of pollutants compared to other classes of vehicles, commercial HDVs also spend more time on roads.19 The average Class 8 semi travels 63,000 miles every year—more than four times the vehicle miles traveled (VMT) of a single passenger vehicle.20 All this additional time spent on the road means more GHG emissions over the life of a HDV meaning it is even more urgent to decarbonize this segment of the transportation sector. [EPA-HQ-OAR-2022-0985-2429-A1, pp. 6 - 7]

EPA Summary and Response:

Summary:

Many commenters (Allergy & Asthma Network et al, American Thoracic Society (ATS), Clean Air Task Force et al., Environmental Protection Network (EPN), National Parks Conservation Association (NPCA), Southern Environmental Law Center (SELC), State of California et al., World Resources Institute (WRI), Zero Emission Transportation Association (ZETA)) stressed that climate change is a top public health priority and a public health emergency. These commenters stated that climate change is endangering the public health and welfare of all populations, including children, by increasing risks of heart disease, mental health, pollen seasons, allergies, drought, frequent flooding, and other listed impacts. One of these commenters stated that climate change also poses an increasing threat to America’s national parks (National Parks Conservation Association). These commenters stated that massive economic costs to climate change and studies have found that the future costs will be unequally distributed across the US. where, the geography and demographics of the South make the region particularly vulnerable to climate change.

Many of the commenters identified a litany of harms associated with the on-going climate crisis, and the heavy-duty sector's contribution to the GHG emissions which are driving that crisis. Harms identified in the comments included:

- Worsening air quality, especially ozone levels (Allergy and Asthma network, Clean Air Task Force);
- -- rise in vector borne disease (Allergy and Asthma Network)
- -- flooding (e.g. Southern Env. Law Center, State of Cal.)
- -- drought (e.g. State of Cal.)
- Excessive heat (CATF, State of Cal.)
- Wildfires (American Thoracic Society, Electrification Coal., National Parks Conservation Ass/n,)
- Adverse mental health implications (CATF, Our Children's Trust)
- -- sea level rise (CATF, St. of Cal.)
- -- disproportionate impact on disadvantaged communities, both domestic and worldwide (Southern Env Law Ctr., CATF, World Resources inst.)
- --national security implications (Electrification Coal.)
- Disastrous impacts on parks from invasive species (National Parks Conservation Ass'n)
- -- loss of needed snowpack (National Parks Conservation Ass'n, State of Cal.)
- -- termination of property insurance due to wildfire and other climate-related risks (State of Cal.)
- Enormous financial losses, already in the billions of dollars annually from wildfires alone (Southern Env. Law Center, State of Cal.)

This group of commenters stated that although heavy duty vehicles comprise only about 5% of on-road vehicles, they account for nearly one third of VMT – hence their substantial contribution to this on-going endangerment.

Arizona State Legislature stated that the proposed rule is arbitrary and capricious because it fails to model and calculate the climate change impacts in order to weigh the benefits against the costs and the transformative nature of the proposed rule. Without a showing that the rule will result in some type of quantifiable effect to prevent climate harms, this commenter questions its legality, and asserted that EPA's summary conclusion that the standards would contribute towards the goal is not good enough.

Our Children's Trust suggested that EPA is not appropriately discounting the lives of children and unborn future generations when it analyzes and considers the formulation of proposed regulations to carry out its delegated authority to protect the air and human health and welfare, and that children are uniquely vulnerable to climate change. The commenter asserts that failure to manage, protect, and prevent substantial impairment to the earth, air, and climate would violate the federal government's fiduciary obligations under the Fifth Amendment of the Constitution and the Public Trust Doctrine. The commenter also asserted that in this rule the Ninth Circuit's findings in *Juliana v. United States*, 947 F.3d 1159, 1164 (9th Cir. 2020), on the federal government's role should guide EPA's policies and practices so that EPA can identify, and alter, those policies that exacerbate American youth's existing climate change injuries. Finally, the commenter argued that 1.5°C presents significant risks to the planet when compared to 1°C, and that therefore the EPA should not use a 1.5°C target to guide policy.

Response:

The EPA appreciates that many commenters are concerned about past, present, and future climate change and the many impacts on human health and welfare that result from climate change. The GHG reductions resulting from this rule will be a meaningful contribution to slowing the rate of future climate change. Importantly, EPA has found in the record for this rulemaking that the standards will significantly reduce GHG emissions - approximately one billion metric tons in net CO_2 cumulative emission reductions between 2027 and 2055. See preamble section V and RIA chapter 4, which provide more detail on these emissions estimates and how they were calculated. Because this reduction is due to one action, for one sector, for one nation, it is a meaningful contribution. *See Coalition for Responsible Regulation*, 684 F. 3d at 332 ("EPA found that the emission standard would result in meaningful mitigation of greenhouse gas emissions. For example, EPA estimated that the Rule would result in a reduction of about 960 million metric tons of CO2e emission over the lifetime of the model year 2012-2016 vehicles affected by the new standards.") Climate change is not expected to be solved by any single action, but rather by a large number of them. As the Supreme Court recognized, "Agencies, like legislatures, do not generally resolve massive problems in one fell regulatory swoop. ... And reducing domestic automobile emissions is hardly a tentative step." Massachusetts v. E.P.A., 549 U.S. 497, 524 (2007); . Thus, EPA disagrees with the commenters that EPA has not provided a basis for this action consistent with the requirements of CAA section 202(a)(1)-(2). See section 2.4 of this RTC for response to comments regarding the stringency of the final rule relative to the proposal.

While EPA did not conduct additional climate modeling in support of this rulemaking, EPA is not required to do so in setting the Phase 3 standards under CAA section 202(a)(1)-(2). See *Coal. For Resp. Regulation*, 684 F. 3d at 128 (noting that EPA section 202(a)(1) authority is not "conditioned on evidence of a particular level of mitigation" but rather that that authority is triggered by a showing of significant contribution, which was made in EPA's Endangerment Finding; plus, , as just quoted above, the record under review in that case showed estimated "meaningful" emission reductions some millions of tons less than projected under the Phase 3 rule). Indeed, CAA section 202(a)(1)-(2) does not require the agency to calculate the benefits of its rulemaking at all, and the commenter failed to adduce any statutory authority or other legal basis for the proposition that EPA must calculate benefits generally or specifically must model avoided temperature change or sea level rise.

We also note that, for purposes of E.O. 12866, EPA has estimated the value of the benefits of these reductions by applying the SC-GHG, which is a sufficient means of calculating benefits and so makes it unnecessary to conduct any further climate modelling for that purpose. The development of the SC-GHG involves the use of climate models in order to estimate the damages of an additional ton of emissions and is therefore a reasonable approach that uses the appropriate tool in benefit-cost analysis. When considering those monetized climate benefits, the monetized benefits of the rule far exceed its costs. EPA's reliance on SC-GHG to assess the climate benefits of this rulemaking is clearly reasonable. As we explain in preamble section VII.A and RIA Chapter 7, the SC-GHG is based on a voluminous record, significant public process, and the well-considered judgment of experts.

In response to Our Children's Trust, EPA follows applicable guidance and best practices when conducting its benefit-cost analyses, including OMB Circular A-4 and EPA's Guidelines for Preparing Economic Analyses. With respect to the application of discount rates, EPA notes that we "use constant discount rates (1.5-percent, 2-percent, and 2.5-percent) similar to the near-term Ramsey discount rates to calculate the present and annualized value of SC-GHGs for internal consistency" (from the notes on Table VII-2). That approach to discounting follows the same approach that the February 2021 TSD recommends "to ensure internal consistency—i.e., future damages from climate change using the SC-GHG at 2.5 percent should be discounted to the base year of the analysis using the same 2.5 percent rate." EPA has also consulted the National Academies' 2017 recommendations on how SC-GHG estimates can "be combined in RIAs with other cost and benefits estimates that may use different discount rates." The National Academies reviewed "several options," including "presenting all discount rate combinations of other costs and benefits with [SC-GHG] estimates." With regards to Our Children's Trust criticism and assertions regarding a 1.5°C target, the EPA is setting standards under Clean Air Act section 202(a)(1)-(2) as described in preamble sections I and II. With regards to Our Children's Trust discussion of the unique vulnerability of children to climate change, the EPA does recognize these vulnerabilities (see, e.g., the EPA report *Climate Change Impacts on Children's Health and Well-Being in the U.S.*), and the emissions reductions resulting from this rule will make an important contribution to efforts to limit climate change and its anticipated impacts to children relative to a future without this rule.

With respect to comments raising Public Trust legal theories, the Agency does not dispute that climate change poses a serious threat, nor that addressing climate change requires the active involvement of the federal government. Commenters espouse novel Constitutional and Public Trust legal theories not relevant to this rulemaking and cite *Juliana v. United States,* 947 F.3d. 1159 (9th Cir.), *Juliana v. United States*, 217 F. Supp. 3d 1224, 1254 (D. Or. 2016) and *Held v. Montana,* No. CDV-2020-307 (1st Dist. Ct. Mont., 2023). The Agency notes that the referenced district court decision in Juliana was overruled for lack of jurisdiction, and further notes that the referenced 9th Circuit decision did not reach the merits of the Constitutional and public trust theories at issue in that case. Juliana v. United States, 947 F.3d 1159, 1175 (9th Cir. 2020), reh'g en banc denied, 986 F.3d 1295 (9th Cir. 2021). Further, *Held v. Montana* (currently subject to appeal) is a case decided by a Montana state court judge interpreting Montana's constitution.

EPA follows applicable guidance and best practices when conducting its benefit-cost analyses, including OMB Circular A-4 and EPA's Guidelines for Preparing Economic Analyses. With respect to the application of discount rates, EPA notes that it used the same discount rate as the rate used to discount the value of damages from future GHG emissions, for internal consistency. That approach to discounting follows the same approach that the February 2021 TSD recommends "to ensure internal consistency—i.e., future damages from climate change using the SC-GHG at 2.5 percent should be discounted to the base year of the analysis using the same 2.5 percent rate." EPA has also consulted the National Academies' 2017 recommendations on how SC-GHG estimates can "be combined in RIAs with other cost and benefits estimates that may use different discount rates." The National Academies reviewed "several options," including "presenting all discount rate combinations of other costs and benefits with [SC-GHG] estimates."

15 Health and Environmental Effects of Non-GHG Pollutants

Comments by Organizations

Organization: Allergy & Asthma Network et al.

Reducing greenhouse gas emissions that drive climate change from the transportation sector is a top public health priority, and maximizing the benefits to cleaning up conventional pollution from the heavy-duty vehicle sector at the same time is a health equity imperative. We urge EPA to finalize the strongest possible heavy-duty greenhouse gas standards by the end of 2023, at least as strong as those in the Advanced Clean Trucks program (ACT). These standards should ensure real-world pollution reductions and spur the transition to zero-emission trucking. [EPA-HQ-OAR-2022-0985-1532-A1, p. 1]

Health Impacts of Heavy-Duty Vehicle Emissions

Emissions from traffic are a complex mixture of pollutants that make people sick and shorten lives. In 2022, the Health Effects Institute (HEI) released the largest systematic review of its type to date that looked at hundreds of studies on traffic pollution and related health effects between1980 and 2019. The review concluded with a high level of confidence that long-term exposure to traffic pollution is linked with all-cause, circulatory and ischemic heart disease mortality; with a moderate to high level of confidence that it is linked to lung cancer mortality, asthma onset in children and adults and acute lower respiratory infections; and with a moderate level of confidence that it is linked to term low birth weight and small for gestational age in fetuses, active asthma in children and respiratory mortality, ischemic heart disease events and diabetes in adults.1 The review also found that the evidence for health impacts of traffic related air pollution has grown since the last HEI study in 2010. [EPA-HQ-OAR-2022-0985-1532-A1, pp. 1 - 2]

1 Health Effects Institute. Special Report 23. A Special Report of the HEI Panel on the Health Effects of Long-Term Exposure to Traffic-Related Air Pollution June 2022, updated April 2023. https://www.healtheffects.org/publication/systematic-review-and-meta-analysis-selected-health-effects-long-term-exposure-traffic

The heavy-duty vehicle sector is a driver of these health impacts. Despite making up less than 10 percent of all vehicles on the road, medium- and heavy-duty vehicles produce the majority of harmful on-road emissions, including conventional air pollutants like fine particulate matter (PM2.5), and nitrogen oxides (NOx). NOx is a precursor of another air pollutant, ozone, which in addition to causing health harm is also a greenhouse gas. [EPA-HQ-OAR-2022-0985-1532-A1, p. 2]

Organization: American Thoracic Society (ATS)

Heavy-duty vehicles are significant contributors to greenhouse gas and criteria pollutant emissions. [EPA-HQ-OAR-2022-0985-1517-A1, p. 1]

In addition to GHG generation, heavy-duty vehicles are a major source of criteria air pollutants in the US.4 As outlined in the proposed rule, implementing stricter CO2 emission standards will also reduce primary criteria air pollutants levels. Heavy-duty vehicles directly contribute to criteria air pollutant generation via engine combustion, engine crankcase exhaust, vehicle evaporative emissions, and vehicle refueling emissions. They also indirectly increase criteria air pollution from electrical generating units and refinery emissions. [EPA-HQ-OAR-2022-0985-1517-A1, p. 2]

4. Anenberg, S. C. et al. Impacts and mitigation of excess diesel-related NOx emissions in 11 major vehicle markets. Nature 545, 467–471 (2017).

Generation of criteria air pollutants is dependent on GHG emissions. Global temperature elevations from GHG emissions directly increase criteria pollutant levels, such as ozone and particulate matter with a diameter <=2.5μm (PM2.5), by accelerating photochemical reactions in the atmosphere and increasing the frequency of wildfires.5 Based on estimates of net effects from the proposed rule, EPA projects reductions in nitrogen oxides (NOx), PM2.5, volatile organic compounds (VOCs), and sulfur dioxide (SO2) by 70,838 (28%), 967 (39%), 20,775 (37%), & 518 U.S. tons, respectively, by calendar year 2055. As ozone is a secondary criteria air pollutant that forms from the reaction of NOx and VOCs,6 as NOx and VOC emissions reduce, so will ozone levels. Thus, limiting GHG emissions through the regulation of heavy-duty trucks reflects a primary prevention tool to mitigate excessive criteria air pollutant levels as well as reducing harmful exposure to those living in closest proximity to busy roads. This is critically important given the numerous adverse human health effects of excess exposures to these pollutants. [EPA-HQ-OAR-2022-0985-1517-A1, p. 2]

Organization: Clean Air Now

Most heavy-duty trucks on the road today are powered by diesel engines, the exhaust from which poses a direct threat to human health and the environment. Diesel engines emit a mixture of pollutants, including NOx, VOCs, and $PM_{2.5}$, all of which have been directly linked to severe health consequences, including neurological, cardiovascular, respiratory, reproductive, and immune system damage. [EPA-HQ-OAR-2022-0985-1579-A1, p. 2]

Organization: Environmental Defense Fund (EDF)

Despite making up less than 10 percent of vehicles on the road, the buses, trucks, and tractor trailers that distribute our goods are the largest contributor to ozone-forming oxides of nitrogen (NOx) emissions from all highway vehicles.2 They are also responsible for a significant amount of health-harming fine particulate matter (PM2.5) and more than 430 million tons of climate pollution3 – nearly a quarter of all transportation sector emissions and more than the entire country of Australia.4 [EPA-HQ-OAR-2022-0985-1644-A1, p. 7]

3 EPA, Inventory of U.S. Greenhouse Gas Emissions and Sinks: 1990 – 2021, https://www.epa.gov/ghgemissions/inventory-us-greenhouse-gas-emissions-and-sinks-1990-2021.

4 International Energy Agency, Atlas of Energy (2020), http://energyatlas.iea.org/#!/tellmap/1378539487.

The health burden from truck and bus pollution is substantial, causing adverse health impacts in utero, in infants and children, and in adults and the elderly – with those who live closest to our nation's roads and highways, ports, distribution centers, freight depots, and other well-known sources of truck pollution facing the greatest harms. EPA has estimated that 72 million people live within 200 meters of a truck freight route, and relative to the rest of the population, people of color and those with lower incomes are more likely to live near truck routes.5 Please see EDF's comments on the Proposed Rule, Control of Air Pollution from New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards, 87 Fed. Reg. 17414 (Mar. 28, 2022) dated May 16, 2022 and resubmitted to this docket for a more thorough discussion of the substantial health and environmental harms associated with the diesel and GHG emissions from medium- and heavy-duty vehicles.6 [EPA-HQ-OAR-2022-0985-1644-A1, p. 7]

6 EDF's comments on the Proposed Rule, Control of Air Pollution from New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards, 87 Fed. Reg. 17414 (Mar. 28, 2022) dated May 16, 2022 (Attachment A).

1. Impacts of diesel fumes on children

Nationally, about 26 million children take 480,000 buses to and from school each day. School buses travel about 12,000 miles per year per bus or almost 6 billion cumulative miles per year and over 90 percent of these school buses run on diesel.102103 Diesel exhaust is composed of very fine particles of carbon and a mixture of toxic gases and has been named a human carcinogen by the World Health Organization. There is no known safe level of exposure to diesel exhaust for children, especially those with respiratory illness. Evidence shows that school aged children are especially vulnerable to the health harming impacts of diesel pollution and that it can have long term consequences.104 105 And as diesel school buses drive their routes, toxic air pollutants remain in the cabin of the vehicle – exposing children for extended periods of time.106 Research conducted by Environment & Human Health Inc. has shown that harmful PM2.5 pollution levels on school buses can exceed surrounding areas by five to 10 times.107 [EPA-HQ-OAR-2022-0985-1644-A1, p. 47-48]

Organization: Evergreen Action

Heavy duty vehicles are responsible for 25 percent of greenhouse gas emissions within the transportation sector, while also accounting for significant amounts of soot and smog that disproportionately impacts low-income populations and communities of color. Meaningfully addressing public health burdens and meeting this administration's climate targets of 50-52% emissions reduction by 2030 will require strong standards to significantly cut vehicle pollution within this decade. [EPA-HQ-OAR-2022-0985-1595-A1, p. 1]

Organization: Lion Electric, Co. USA

Additionally, heavy-duty vehicles, such as delivery vans, garbage trucks, and 18- wheelers, are prolific polluters; accounting for 10% of on-road vehicles, they are responsible for nearly 30% of transportation-related GHG, 45% of on-road nitrogen oxides and 57% of particulate matter emissions. This truck tailpipe pollution contributes to asthma, bronchitis, cardiovascular diseases, and premature death. EPA, Do the Right Thing on Truck Pollution (nrdc.org). [EPA-HQ-OAR-2022-0985-1506-A1, p. 2]

Organization: MCS Referral & Resources

Comment 5

At https://www.federalregister.gov/d/2023-07955/p-1503

In a discussion of carbon monoxide health effects, EPA claims: "Controlled human exposure studies of subjects with coronary artery disease show a decrease in the time to onset of exercise-induced angina (chest pain) and electrocardiogram changes following CO exposure. " [EPA-HQ-OAR-2022-0985-1629-A1, p. 3]

EPA gives no reference for this claim, which is not true. While a few studies commissioned by EPA from Aronow et al in the 1970s and Allred et al in the 1980s claimed to find this result, both were undermined by falsifying their methods and results. See: https://www.dropbox.com/s/fmwp8bmke2e8zfo/Donnay%202015%20SOT%20poster%20on%20EPA%20CO%20NAAQS%20Fraud.pdf?dl=0 [EPA-HQ-OAR-2022-0985-1629-A1, p. 3]

Not surprisingly, subsequent efforts to reproduce these findings have been unsuccessful. See these 14 studies that found contradictory results: https://pubmed.ncbi.nlm.nih.gov/?term=29343136,24923364,21933352,17321552,16937915,11696871,10492650,8210613,8441830,6695663,6750056,7304396,7389699,4640286&format=abstract [EPA-HQ-OAR-2022-0985-1629-A1, p. 3]

Given these facts, we recommend that EPA stop claiming that people with coronary artery disease show a decrease in time to exercise-induced angina or ECG changes after CO exposure. They do not. [EPA-HQ-OAR-2022-0985-1629-A1, p. 3]

Comment 8

EPA should acknowledge the literature that identifies CO as a carcinogen, which the 2010 ISA did not review. Over 100 studies show that relatively low levels of CO in the endogenous range act as a carcinogen, boosting the growth of cancers, including all types of leukemias and almost all types of solid tumors. See for example:

Ambient air pollution is associated with the increased incidence of breast cancer in US. Wei Y, Davis J, Bina WF. Int J Environ Health Res. 2012;22(1):12-21. doi: 10.1080/09603123.2011.588321.

Ambient carbon monoxide exposure and elevated risk of mortality in the glioblastoma patients: A double-cohort retrospective observational study. Yoon SJ, Noh J, Son HY, Moon JH, Kim EH, Park SW, Kim SH, Chang JH, Huh YM, Kang SG. Cancer Med. 2020 Dec;9(23):9018-9026. doi: 10.1002/cam4.3572. Epub 2020 Nov 7

Heme Oxygenase-1 and Carbon Monoxide Regulate Growth and Progression in Glioblastoma Cells. Castruccio Castracani C, Longhitano L, Distefano A, Di Rosa M, Pittalà V, Lupo G, Caruso M, Corona D, Tibullo D, Li Volti G. Mol Neurobiol. 2020 May;57(5):2436-2446. doi: 10.1007/s12035-020-01869-7. Epub 2020 Feb 27.

Carbon monoxide (CO)/heme oxygenase (HO)-1 in gastrointestinal tumors pathophysiology and pharmacology - possible anti- and pro-cancer activities. Krukowska K, Magierowski M.Biochem Pharmacol. 2022 Jul;201:115058. doi: 10.1016/j.bcp.2022.115058. Epub 2022 Apr 28. [EPA-HQ-OAR-2022-0985-1629-A1, p. 4]

Organization: Southern Environmental Law Center (SELC)

In addition to GHG emissions, heavy-duty vehicles are significant sources of other harmful pollutants such as particulate matter (PM), sulfur oxides (SOX), carbon monoxide (CO), and nitrogen oxides (NOX).34 These “criteria pollutants” have damaging effects on our environment and air quality—NOX is a central precursor to photochemical smog;35 acid rain results from sulfur dioxide (SO2) and NOX emissions;36 and PM is the primary cause of reduced visibility and regional haze in the United States.37 Additionally, exposure to criteria pollutants has been linked to respiratory and cardiovascular problems such as an increased incidence of asthma and heart disease, reduced lung function, and a greater number of overall hospitalizations,38 and all of these pollutants have a health-based National Ambient Air Quality Standard (NAAQS) established by EPA.39 As with GHG emissions, heavy-duty vehicles are also responsible for an outsized portion of criteria pollutants—heavy-duty diesel vehicles alone account for 20 percent of all NOX and 25 percent of PM2.5 pollution emitted by vehicles in the United States.40 As noted in the Federal Register notice, “72 million people live within 200 meters of a truck freight route,”41 and over 10 million students attend schools within 200 meters of major roads,42 making exposure to heavy-duty vehicle tailpipe pollution a serious public health issue nationwide. B. Tighter GHG Standards Will Also Help Reduce Non-GHG Emissions and Help States to Attain and Maintain Federal Air Quality Standards

Heavy-duty vehicles are also a significant source of air pollutants that contribute to ambient concentrations of ozone, inhalable particulate matter (PM2.5), and air toxics.67 Exposure to ozone and PM2.5 has serious health effects and is associated with increased risk of premature deaths, emergency room visits, and hospital stays.68 A range of adverse respiratory effects are linked to these pollutants such as asthma, respiratory inflammation, and decreased lung function and growth.69 [EPA-HQ-OAR-2022-0985-1588-A1, p.8]

67 88 Fed. Reg. at 26,047.

68 Id. at 26,049-51.

69 Id.

In particular, PM2.5 poses serious health risks as the fine particles can lodge deep into the lungs and possibly enter into the bloodstream, causing irregular heartbeat, heart attacks, as well as increased risk of lung cancer.70 Recent evidence also suggests a causal relationship between PM2.5 exposure and a host of other negative health impacts, including male and female reproductive and developmental effects from long-term exposure (i.e., fertility, pregnancy, and birth outcomes), metabolic effects from long-term and short-term exposure, and nervous system effects from short-term exposure.

71 Heavy-duty engine emissions also contribute to ambient levels of air toxics, 72 such as benzene, formaldehyde, acetaldehyde, and naphthalene, which are known or suspected to cause cancer and other serious health effects.73 [EPA-HQ-OAR-2022-0985-1588-A1, pp.8-9]

73 88 Fed. Reg. at 26,054-58.

The Clean Air Act ("CAA") requires EPA to set and regularly review and revise federal health-based ambient air quality standards for "criteria pollutants," including PM2.5, NOx, and ground-level ozone.74 These National Ambient Air Quality Standards ("NAAQS") aim to protect the health of their residents from air pollution resulting from emissions of criteria air pollutants. The NAAQS for ozone, established in 2015 and retained in 2020, is an 8-hour standard with a level of 70 parts per billion, although EPA recently announced that it may reconsider the previous administration's decision to retain the ozone NAAQS.75 EPA is also implementing the previous 8-hour ozone standard, set in 2008 at a level of 75 parts per billion. For PM2.5, there are two NAAQS that were set in 1997, revised in 2006 and 2012, and retained in 202076: an annual standard (12.0 micrograms per cubic meter) and a 24-hour standard (35 micrograms per cubic meter). [EPA-HQ-OAR-2022-0985-1588-A1, p.9]

74 42 U.S.C §§ 7408-7409.

75 See U.S. Environmental Protection Agency, Ozone National Ambient Air Quality Standards (NAAQS), https://www.epa.gov/ground-level-ozone-pollution/ozone-national-ambient-air-quality-standards-naaqs (last accessed June 16, 2023); U.S. Environmental Protection Agency, EPA to Reconsider Previous Administration's Decision to Retain 2015 Ozone Standards, https://www.epa.gov/ground-level-ozone-pollution/epa-reconsider-previous-administrations-decision-retain-2015-ozone (last accessed June 16, 2023).

76 On June 10, 2021, EPA announced that it will reconsider the previous administration's decision to retain the PM NAAQS. See Press Release, EPA, EPA to Reexamine Health Standards for Harmful Soot that Previous Administration Left Unchanged (June 10, 2021), https://www.epa.gov/newsreleases/epa-reexamine-health-standards-harmful-soot-previous-administration-left-unchanged.

Depending on whether the air quality in an area meets the NAAQS for a particular pollutant, EPA designates the area as being in "attainment" or "nonattainment." EPA further classifies areas that are in nonattainment according to the severity of their air pollution problem, and areas with more severe pollution levels are given more time to meet the standard while being subject to more stringent control requirements under State Implementation Plans. [EPA-HQ-OAR-2022-0985-1588-A1, p.9]

As of May 31, 2023, there were 34 ozone nonattainment areas for the 2008 ozone NAAQS77 and 47 ozone nonattainment areas for the 2015 ozone NAAQS.78 Sixteen of the 8-hour ozone nonattainment areas are located in California and the only two extreme nonattainment areas in the nation are located in the South Coast Air Basin and San Joaquin Valley of California.79 Indeed, for the South Coast Air Basin to meet the federal ozone standards, overall NOx emissions need to be reduced by 70 percent from today's levels by 2023, and approximately 80 percent by 2031.80 The New York Metropolitan area (CT-NJ-NY) ozone nonattainment area failed to reach attainment by the deadline for serious nonattainment of the 2008 ozone NAAQS and was re-classified to severe nonattainment status for that NAAQS.81 And Wisconsin has three remaining nonattainment areas for the 2015 ozone NAAQS, all located downwind of some of the largest intermodal operations in the country.82 Many areas of the country are also currently in nonattainment for the PM2.5 NAAQS standards, and as of May 31, 2023, more than 31 million people live in PM2.5 (2006) nonattainment areas.83 [EPA-HQ-OAR-2022-0985-1588-A1, pp.9-10]

Substantial emission reductions are critically necessary given the extraordinary challenges that California faces to attain and maintain ozone and PM2.5 NAAQS and, thereby, protect public health. And, as noted, other States need to reduce these emissions in order to protect their residents. Reducing emissions from heavy-duty vehicles sold nationwide will help all states attain and maintain NAAQS for these pollutants, particularly since vehicles sold in one State can, and are, driven in or through others. According to California's Emission FACtors ("EMFAC") 2017 emissions inventory model, almost a million heavy-duty vehicles operate on California roads each year and contribute 31 percent of all statewide NOx emissions.84 Heavy-duty vehicles are responsible for 32 percent of mobile source NOx emissions in the South Coast Air Basin.85 Medium and heavy-duty vehicles are responsible for 52 percent of the NOx and 45 percent of the PM2.5 emitted by on-road vehicles in New York. Heavy-duty vehicles play an important role in the transport of goods for interstate commerce and frequently cross state borders.86 Therefore, stringent federal standards would assist states—including those with state regulatory programs applicable to in-state sales—attain and maintain the NAAQS. Organization: World Resources Institute (WRI)

There are 20 million children that rely on the nation's fleet of over 480,000 school buses to transport them safely to school every day. More than 90 percent of the school buses on the road today are diesel-powered, a known carcinogen linked to a range of negative health outcomes and cognitive development impacts. [EPA-HQ-OAR-2022-0985-1601-A1, p. 1]

Pollution Impacts Children's Health
Enacting the strongest emissions standards is essential for children's health. Currently, diesel school buses represent more than 90 percent of the 480,000 school buses on the road today, transporting over 20 million students daily and driving 3.3 billion miles annually. Children are particularly susceptible to the negative health effects of diesel exhaust from school buses, a known carcinogen linked to reduced lung development and increased risk for asthma and pneumonia in children, among other risks. In addition, there is evidence that reducing diesel exhaust exposure can improve not only students' respiratory health, but also their academic outcomes. [EPA-HQ-OAR-2022-0985-1601-A1, p. 3]

Organization: Zero Emission Transportation Association (ZETA)

a. Reducing HDV Emissions Protects Public Health

Diesel fumes, in particular, pose a substantial risk to human health8—and an overwhelming majority of ICE-powered HDVs run on diesel.9 On-road diesel emissions are responsible for poor air quality, impaired respiratory systems, and cardiovascular issues. Exposure to these toxins has both cancerous and noncancerous health risks, including potential neurological, cardiovascular, respiratory, reproductive, and immune system damage.10 [EPA-HQ-OAR-2022-0985-2429-A1, p. 5]

A large portion of the U.S. population remains vulnerable to these dangers. 45 million people in the United States live within 300 feet of a major traffic facility or corridor.11 Proximity to these roadways exposes residents to needless health risks and replacing older truck and bus fleets with electrified alternatives has the potential to yield significant public health benefits. According to the American Lung Association, the widespread transition to zero-emission transportation by 2050 can produce up to $72 billion in avoided health costs, save approximately

6,300 lives, and prevent more than 93,000 asthma attacks and 416,000 lost workdays each year.12 [EPA-HQ-OAR-2022-0985-2429-A1, pp. 5 - 6]

EPA Summary and Response:

Summary:

Commenters noted the needed reductions in emissions of non-GHG air pollutants, in particular $PM_{2.5}$ and ozone precursors, that are associated with the proposed heavy-duty GHG standards. The commenters mentioned that the non-GHG emission reductions would impact air quality and health and cited health effects associated with these pollutants. Several commenters pointed to findings specifically related to exposure to diesel PM from school buses and the need to reduce emissions from school buses. One commenter particularly noted that states need the emission reductions to attain and maintain the ozone and $PM_{2.5}$ NAAQS. In addition, a commenter stated that EPA was relying on long-since discredited studies for its finding that people with coronary artery disease show a decrease in time to exercise-induced angina or ECG changes after CO exposure, and that EPA needs to acknowledge studies identifying CO as carcinogenic. Another commenter noted that maximizing the benefits to cleaning up conventional pollution from the heavy-duty vehicle sector is a health equity imperative.

Response:

Section VI.B of the preamble describes the health and environmental effects caused by emissions of criteria and toxic pollutants. EPA agrees that emissions from heavy-duty trucks and upstream sectors contribute to concentrations of ozone, $PM_{2.5}$, NO_2, SO_2, CO, and air toxics, which are all associated with impacting human health. Heavy-duty trucks and buses continue to contribute significantly to air pollution at the local, regional, and national level, often disproportionally affecting communities of color and low-income populations, see Section 18 of this document for responses related specifically to environmental justice. EPA also agrees that protecting children’s health is a high priority, and that children can have increased vulnerability and susceptibility for adverse health effects from air pollution exposures. For responses to comments on maximizing the stringency of the standards please see Section 2.4 of this document.

Some commenters agree with or reiterate scientific information that the EPA had included in the proposal, and some commenters provide additional scientific or technical information regarding criteria and air toxic pollutant impacts from diesel trucks, including school buses, and upstream sources, or offer their views or opinions regarding such information. The EPA does not interpret these supportive comments as indicating disagreement with the evidence on health or welfare effects information that was presented in the proposal, but rather understands these comments to suggest that the additional information they provide should also be considered as support for finalizing the standards.

In response to commenters who identify potential health or welfare effects of criteria and air toxic pollutants through scientific information, views, or analyses, that were not addressed in the proposed or final action, the EPA notes that the health and welfare evidence presented in Section VI.B of the preamble sufficiently summarizes the potential health and welfare impacts of all pollutants that would be reduced or increased by the proposal. After consideration of comments, we did not alter our discussion and consideration of non-GHG pollutant impacts from the proposal. As explained in preamble Section II and V, while the final standards do not directly address non-GHG pollutants and EPA did not consider any potential non-GHG pollutant impacts of vehicle emissions in selecting the proposed CO_2 emission standards, EPA's assessment is that the net non-GHG emission impacts are supportive of the final standards.

With respect to comments related to CO exposure and health effects, we note that the EPA's statement that "controlled human exposure studies of subjects with coronary artery disease show a decrease in the time to onset of exercise-induced angina (chest pain) and electrocardiogram changes following CO exposure," is based on findings of multiple studies reviewed in the 2010 CO Integrated Science Assessment (ISA).[833]

As the commenter notes, the underlying data for this claim is partially based on results from an HEI multicenter study that investigated the effects of CO exposure in individuals with coronary artery disease. This effort resulted in three peer-reviewed publications, which have been cited more than 250 times: Allred et al 1989a[834], Allred et al 1989b[835], and Allred et al 1991.[836] These studies found that exposures to CO decreased the time to onset of angina during exercise by 4.2% (low exposure group) or 7.1% (high exposure group) and decreased the time to development of ischemic ST-segment changes during exercise by 5.1% (low exposure group) or 12.1% (high exposure group). In addition, several other studies investigating individuals with stable angina also demonstrated that CO exposure during exercise decreases the time to onset of

angina, as well as reduces the duration of exercise and increases ventricular arrhythmias.[837,838,839,840,841]

All ISAs undergo review by an independent Clean Air Scientific Advisory Committee (CASAC), whose members have expertise in a variety of scientific fields relevant to air pollution and air quality issues. In their final Advisory Report for the 2010 CO ISA, CASAC referenced the importance of the above studies ("The most compelling CO-related cardiovascular results remain those from the controlled human exposure studies of Allred et al; Kleinman et al; and Sheps et al.") and expressed support for the related causality determination ("The Panel members concur with the ISA's conclusion that a causal relationship is likely to exist between relevant short-term CO exposure and CV morbidity.").[842]

We have also reviewed the fourteen studies recommended by the commenter. Out of the fourteen studies, none were directly comparable to those discussed above (i.e., controlled human exposure to CO in individuals with coronary artery disease). Three of the recommended studies were review articles,[843,844,845] three were experimental animal studies,[846,847,848] and eight studies

were conducted in humans.[849,850,851,852,853,854,855,856] Out of the eight human studies, two did not investigate a CO exposure (17-18), and one was an epidemiologic study evaluating the effects of acute CO exposures at non-ambient levels(19). The remaining five studies investigated potential cardiovascular effects of CO exposure in healthy individuals (20 - 24), a topic which was discussed in the previous ISA. In reference to effects on exercise-induced angina, the 2010 CO ISA stated that "no such effects have been observed in healthy adults following controlled exposures to CO." Furthermore, it states, "Although some studies have reported CO-induced hemodynamic changes among healthy adults at COHb concentrations as low as 5%, this effect has not been observed consistently across studies."[1] These statements are consistent with the provided studies and do not alter the conclusions of the 2010 CO ISA.

The 2010 CO ISA focused on publications from 1999 to May 2009, and no studies were identified which investigated potential carcinogenic effects of CO. The studies which the commenter provides, published from 2012 to 2020, will be considered for inclusion in the next ISA for CO.

16 Air Quality Impacts of Non-GHG Pollutants

Comments by Organizations

Organization: American Fuel and Petrochemical Manufacturers (AFPM)

4. EPA fails to properly evaluate the environmental costs and benefits of the Proposed Rule.

The Proposed Rule predicts net emissions reductions but does not adequately evaluate local ambient air quality impacts from increased power generation spurred by the mass adoption of electric vehicles. Although EPA modeled changes to power generation anticipated by the Proposed Rule as part of its upstream analysis, EPA does not consider the potential degradation of air quality in areas in the direct vicinity of existing or new power plants.95 [EPA-HQ-OAR-2022-0985-1659-A2, p. in areas in the direct vicinity of existing or new power plants.95 [EPA-HQ-OAR-2022-0985-1659-A2, p. 26]

95 Id. at 25,983.

Organization: Delek US Holdings, Inc.

c. BEVs increased demand for power generation will also result in greater emissions of criteria pollutant emissions.

The Proposed Rule predicts net emissions reductions but does not adequately evaluate local ambient air quality impacts from increased power generation spurred by the mass adoption of electric vehicles. Although EPA modeled changes to power generation anticipated by the Proposed Rule as part of its upstream analysis, EPA does not consider the potential degradation of air quality in areas in the direct vicinity of existing or new power plants, especially as the need for baseload generation at times when the sun is not shining and the wind is not blowing rises exponentially with rapid electrification.38 [EPA-HQ-OAR-2022-0985-1561-A1, p. 8]

38 Proposed Rule at 25,983.

Comment 3

At https://www.federalregister.gov/d/2023-07955/p-1440

EPA describes Carbon Monoxide as "a colorless, odorless gas emitted from combustion processes." This is a true statement as far as it goes but not a complete one. EPA should acknowledge that CO is emitted by rainwater, freshwater, saltwater, and most soils as well as by all mammals via their lungs, skin, and eyes. It also is produced in the atmosphere from the oxidation of methane, isoprene, terpene, and acetone.
See: https://www.ipcc.ch/site/assets/uploads/2018/03/TAR-04.pdf [EPA-HQ-OAR-2022-0985-1629-A1, p. 3]

Comment 4

At https://www.federalregister.gov/d/2023-07955/p-1443

EPA writes "The lifetimes of the components present in diesel exhaust range from seconds to days." This is not true of CO, whose lifetime in air is weeks to months [EPA-HQ-OAR-2022-0985-1629-A1, p. 3]

EPA Summary and Response:

Summary:

Two commenters, Delek U.S. Holdings, Inc. and AFPM, asserted that EPA has failed to assess localized air quality impacts due to increased criteria pollutant emissions in areas proximate to EGUs. One commenter also noted that vehicle electrification will increase energy demand and emissions from power plants, and that this increased demand will result in even more emissions from power plants when renewables (wind and solar) are unavailable.

A commenter, MCS Referral & Resources, pointed out an error in the description of the sources of CO and in the description of diesel exhaust component lifetimes.

Response:

As described in Section VI.C of the preamble, we did not conduct air quality modeling for this rule. Our consideration of statutory factors does not require air quality modeling, and for the purposes of this rule, which focuses on GHGs, we believe our assessment of non-GHG emissions (and the associated monetized benefits per ton reduced) is sufficient. As described in Section V of the preamble, we modeled and present projected changes in emissions, including from the EGU sector, due to this rule. Our modeling of projected emissions from the power sector was done using the Integrated Planning Model (IPM), which we note considers both the fact that renewables are not always available and ways clean power can be supplied when they are not. Please see Chapter 4.2.4 of the RIA and Section 13 of this Response to Comment document for more information on the IPM modeling done to project emissions from the power sector.

As further discussed in Section V of the preamble, Chapter 4.2.4 of the RIA, and Section 13 of this Response to Comment document, we project that emissions from EGUs will increase, and we expect that increased emissions from EGUs may increase ambient concentrations of some pollutants in areas downwind of EGUs. We also expect the power sector to become cleaner over time as a result of the IRA and future policies, which will reduce the air quality impacts of EGUs.

After consideration of comments by MCS, clarifying edits have been made to the CO background section to indicate that CO can also be formed by photochemical reactions, as well as being formed by incomplete combustion. In addition, clarifying edits have also been made to the diesel exhaust background section to indicate that lifetimes of components of diesel exhaust can range from seconds to months, rather than seconds to days.

Organization: Alliance for Vehicle Efficiency (AVE)

AVE asks EPA to fully account for upstream emissions for all technologies. [EPA-HQ-OAR-2022-0985-1571-A1, p. 6]

EPA's narrow focus on tailpipe emissions creates obvious contradictions. In the Proposal, EPA does not recognize H2-ICE platforms that use a pilot ignition for combustion as a ZEV technology irrespective of the significant CO_2 reductions compared to today's diesel trucks. Still, EPA acknowledges that the increased number of BEV trucks on the road (as a result of the Proposal) will significantly diminish the predicted 1.8 billion metric tons of CO_2 reductions from the new standard because of emissions from energy used to power the U.S. electrical grid. "We project a cumulative increase from calendar years 2027 through 2055 of approximately 0.4 billion metric tons of CO_2 emissions from EGUs as a result of the increased demand for electricity associated with the proposal…" 16 [EPA-HQ-OAR-2022-0985-1571-A1, p. 6]

16 Federal Register / Vol. 88, No. 81 / Thursday, April 27, 2023 / at 25935

Simply put, the production of electricity to power new BEVs will reduce the estimated CO_2 savings from these trucks by over 22%. EPA should seek to offset this reduction by strengthening the Proposal's support for renewable diesel, renewable natural gas, and vehicles that use lower carbon fuels. Only analyzing ZEVs at the tailpipe distorts environmental gains and will delay the air quality improvements the U.S. is striving to achieve. [EPA-HQ-OAR-2022-0985-1571-A1, p. 6]

Congress has repeatedly seen the need to employ lifecycle assessments for future compliance standards and has asked EPA to look beyond a vehicle's tailpipe when analyzing GHG emissions. [EPA-HQ-OAR-2022-0985-1571-A1, p. 7]

"Vehicle Emissions Lifecycle Analysis. -- The Committee encourages the Agency to build upon its efforts to develop standardized modeling to evaluate the full lifecycle of all vehicle technologies and transportation fuels by integrating full lifecycle analysis accounting into new vehicle standards aimed at reducing greenhouse gas emissions. The Agency is also encouraged to coordinate with other federal agencies that are conducting similar lifecycle models for vehicles to best understand the full impact of standards seeking to reduce greenhouse gas emissions." 17 [EPA-HQ-OAR-2022-0985-1571-A1, p. 7]

17 H. Rept. 117-400 - Department Of The Interior, Environment, & Related Agencies Appropriations Bill, 2023 at P.86

Continuing to focus solely on tailpipe emissions for future standards also ignores President Biden's January 25, 2021, Executive Order, in which he stressed the need for environmental standards to account for all greenhouse gas emissions. [EPA-HQ-OAR-2022-0985-1571-A1, p. 7]

"Sec. 5. Accounting for the Benefits of Reducing Climate Pollution. (a) It is essential that agencies capture the full costs of greenhouse gas emissions as accurately as possible, including by taking global damages into account. Doing so facilitates sound decision-making, recognizes the breadth of climate impacts, and supports the international leadership of the United States on climate issues." 18 [EPA-HQ-OAR-2022-0985-1571-A1, p. 7]

18 7040 Federal Register / Vol. 86, No. 14 / Monday, January 25, 2021 / Presidential Documents

We support a transition from a tailpipe-based standard to a more complete life-cycle assessment. This approach is consistent with technology neutrality and will allow the U.S. to truly reach its environmental goals by promoting cleaner more efficient technologies. [EPA-HQ-OAR-2022-0985-1571-A1, p. 7]

Organization: American Council for an Energy-Efficient Economy (ACEEE)

Failure to include upstream emissions accounting will undermine the standards

The proposed rule would prolong the policy of assigning zero emissions to ZEVs through Phase 3. In the Phase 2 heavy-duty rule, EPA justified its decision to extend its zero-upstream treatment of electric vehicles:

As we look to the future, we project limited adoption of all-electric vehicles into the market. Therefore, we believe that this provision [zero upstream] is still appropriate. Unlike the 2017–2025 light-duty rule, which included a cap whereby upstream emissions would be counted after a certain volume of sales (see 77 FR 62816–62822), we believe there is no need to establish a cap for heavy-duty vehicles because of the small likelihood of significant production of EV technologies in the Phase 2 timeframe.26 [EPA-HQ-OAR-2022-0985-1560-A1, p. 11]

26 https://www.govinfo.gov/content/pkg/FR-2016-10-25/pdf/2016-21203.pdf

As this rationale suggests, however, ignoring upstream emissions in vehicle compliance values could have serious adverse consequences at a time when the objective is to move ZEVs into the mainstream throughout the heavy-duty vehicle market. The timeframe of Phase 3 is just such a time. [EPA-HQ-OAR-2022-0985-1560-A1, p. 12]

Upstream emissions resulting from the fueling of ZEVs will remain significant throughout the Phase 3 time frame, and excluding them from vehicles' compliance certification values will prevent the standards from helping to reduce those emissions. In particular, the standards will not promote vehicle efficiency, one of the most important means of reducing emissions for ICEVs and ZEVs alike. [EPA-HQ-OAR-2022-0985-1560-A1, p. 12]

Another adverse effect of zero-upstream accounting is that it distorts the relative emissions of ICEVs and BEVs. ANL's GREET 2022 model projects that a MY 2030 BEV tractor emits 52% as much CO2 on a well-to-wheels basis as a comparable diesel tractor would. The nominal reduction from BEV adoption under the rule, by contrast, would be 100%. As a result, if a manufacturer were to exceed EPA's projected ZEV adoption—which is a distinct possibility under the proposed standards—emissions reductions under the program could fall well below the anticipated reductions. [EPA-HQ-OAR-2022-0985-1560-A1, p. 12]

Treating hydrogen-fueled vehicles as ZEVs adds to the risk of zero-upstream accounting

EPA expanded the definition of ZEVs to include hydrogen FCEVs (H2-FCEVs) in the heavy-duty 2027 final rule and now proposes to expand it further to include hydrogen ICEVs (H2-ICEVs) (FR 25994, footnote 517). Considering hydrogen-fueled vehicles to be ZEVs compounds the problems created by ignoring upstream emissions for BEVs, however. Both H2-FCEVs and H2-ICEVs currently have pump-to-wheels efficiencies closer to diesel vehicles than to battery electric vehicles, as illustrated by the numbers for long-haul combination trucks in Table 2. [EPA-HQ-OAR-2022-0985-1560-A1, p. 12.] [See Table 2, Energy usage and GHG emissions rates of MY 2030 long-haul combination trucks, on page 12 of docket number EPA-HQ-OAR-2022-0985-1560-A1.]

Including upstream emissions in vehicle certification emissions values based on national average GHG emissions associated with fuel production and distribution would achieve this outcome, both for electricity and for hydrogen. Refining this approach to better reflect the real-world benefits of ZEVs, for example by averaging upstream emissions over the life of the vehicle based on projected carbon reductions in electricity and hydrogen production and/or by weighting emissions geographically by vehicle sales distribution, would be appropriate ways to preserve the program's incentive for ZEV production while maintaining the performance basis of the standards. [EPA-HQ-OAR-2022-0985-1560-A1, p. 15.]

The longer EPA delays accounting for upstream emissions in ZEV compliance values, the more difficult it will be to introduce this feature when ZEV shares are high. The federal government has provided large subsidies for heavy-duty ZEV purchase and charging infrastructure, which is the best way to incentivize their adoption beyond the credits these vehicles could obtain through performance-based standards. EPA properly notes that advanced technology multipliers should be phased out as heavy-duty EV adoption ramps up rapidly and as monetary incentives are offered (FR 25931); similarly, zero-upstream accounting should cease in this phase of the standards. [EPA-HQ-OAR-2022-0985-1560-A1, p. 15.]

Distorting performance-based standards with unearned emissions reduction credits has undermined vehicle standards for decades and this practice should be avoided in future rules. Furthermore, the incentive upstream accounting provides to steadily increase the efficiency of BEV and hydrogen-fueled vehicles would improve the sustainability and affordability of these vehicles in the future. Absent upstream accounting, the EPA rule loses all oversight of the emissions caused by these vehicles, and the market is left to maximize their efficiency and maintain a downward emission trajectory. [EPA-HQ-OAR-2022-0985-1560-A1, p. 15.]

If EPA is not prepared to fully implement upstream accounting by MY 2027, it could phase in this treatment over the time frame of Phase 3. At the bare minimum, EPA should affirm in the final rule that, after MY 2032, the presumption is that upstream emissions will be accounted for in vehicle certification values. This will enable EPA to ensure that emissions reductions do in fact continue to progress as ZEVs achieve dominance in the market. [EPA-HQ-OAR-2022-0985-1560-A1, p. 15.]

Organization: American Free Enterprise Chamber of Commerce (AmFree) et al.

Upstream Emissions. In addition to overstating reductions in downstream emissions, the proposed rule fails to account properly for increases in "upstream" emissions—those that "are not emitted by the vehicle itself but can still be attributed to its operation." Draft RIA at 310. In evaluating this category, EPA improperly cabins its analysis to only those emissions caused by electric-generating units ("EGUs") and refineries—i.e., emissions generated to provide power to operate vehicles. See 88 Fed. Reg. at 26,039–40; Draft RIA at 310. This marks another unexplained shift in agency policy. And even when examining this limited set of upstream sources, the agency makes unfounded assumptions and methodological choices that are (once again) skewed in favor of the proposed rule. [EPA-HQ-OAR-2022-0985-1660-A1, p. 57]

First, the emissions associated with powering a vehicle—whether by electricity from an EGU or fuel from a refinery—are far from the only ones reasonably "attributed" to its operation. Draft RIA at 310. Depending on the vehicle, there are also emissions associated with producing, recycling, and disposing of batteries; operating charging infrastructure; and extracting, refining, transporting, and storing petroleum fuels. These emissions can be substantial and, when considered together, may undermine EPA's assumption that swapping internal- combustion-engine vehicles for electric ones will necessarily result in an environmental good. [EPA-HQ-OAR-2022-0985-1660-A1, p. 57]

The International Energy Agency's discussion of emissions from mining illustrates this point. According to the IEA, "the production and processing of energy transition minerals are energy-intensive" and involve "relatively high emission[s]." Role of Critical Minerals at 15, 130; see also Charging Infrastructure Challenges for the U.S. Electric Vehicle Fleet, Am. Transp. Rsch. Inst., https://tinyurl.com/3ktjd85v ("Mining and processing produce considerable CO2 and pollution issues."). For this reason, producing an electric vehicle is a more carbon- intensive process than producing a conventional one. Role of Critical Minerals at 194. [EPA-HQ-OAR-2022-0985-1660-A1, pp. 57 - 58]

EPA never explains why emissions from EGUs and refineries are the only ones relevant to the analysis. Nor does it acknowledge that its current position departs from earlier GHG rulemakings, where it did consider additional upstream sources. See HD GHG I, 76 Fed. Reg. at 57,301 ("To project these impacts, EPA estimated the impact of reduced petroleum volumes on the extraction and transportation of crude oil as well as the production and distribution of finished gasoline and diesel."); HD GHG II, 81 Fed. Reg. at 73,852 ("To project these impacts, Model B estimated the impact of reduced petroleum volumes on the extraction and transportation of crude oil as well as the production and distribution of finished gasoline and diesel."). EPA has an obligation to explain why a more cabined view of upstream emissions is appropriate here. See Am. Fed'n of Gov't Emps, 25 F.4th at 12. [EPA-HQ-OAR-2022-0985-1660-A1, p. 58]

C. The Method For Measuring Compliance Is Irrational

The proposed rule provides that EPA will test vehicle compliance with the new standards by considering solely the grams of pollutants emitted from the tailpipe. See 88 Fed. Reg. at 25,935 n.61 ("We are continuing and are not reopening the existing approach taken in both HD GHG Phase 1 and Phase 2, that compliance with the vehicle exhaust CO2 emission standards is based on CO2 emissions from the vehicle."). Although this method might have been appropriate to measure compliance with past regulations, it makes little sense here, given the agency's new focus on electric heavy-duty vehicles. Because the proposed rule effectively requires manufacturers to shift from internal-combustion engine vehicles (which cause emissions mostly from the tailpipe) to electric vehicles (which cause emissions mostly by other means), a granular focus on tailpipe emissions will not give EPA an accurate picture of the amount of emissions attributable to any manufacturer's fleet. [EPA-HQ-OAR-2022-0985-1660-A1, p. 60]

Indeed, EPA correctly recognized elsewhere in the proposed rule that upstream emissions are relevant to its overall effort to address the "human-induced buildup of GHGs in the atmosphere." 88 Fed. Reg. at 25,953. For instance, when estimating the proposed rule's impact on overall emissions, as well as the costs and benefits that it generates, EPA took into account at least some (though far from all relevant) upstream emissions. See id. at 26,039–40, 26,075–76. In doing so, EPA acknowledged that it would be irrational to adopt a rule that decreases downstream emissions but has the effect of increasing overall emissions. The same principle applies here: It would be irrational to find a manufacturer's fleet compliant if the vehicles within the fleet have lower tailpipe emissions but that cause emission of harmful pollutants in other ways (for example, through their production, or generation of the electricity used to power them) that exceeds the levels permitted for tailpipe emissions. EPA offered no explanation for this inconsistent approach to upstream emissions. [EPA-HQ-OAR-2022-0985-1660-A1, pp. 60 - 61]

Moreover, factoring a broader set of emissions into the compliance calculation will not be difficult or unduly burden EPA. The agency has already developed a method for attributing some of these emissions to manufacturers. In its proposed rule for light- and medium-duty vehicles, EPA explained that it initially planned to take emissions from electricity generation into account by "attribut[ing] a pro rata share of national CO2 emissions from electricity generation to each mile driven under electric power minus a pro rata share of upstream emissions associated with . . . gasoline production." Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles, 88 Fed. Reg. 29,184, 29,252 (May 5, 2023). That method remains available here. And EPA could develop similarly simple and administrable techniques to account for other key sources of upstream emissions like battery production. [EPA-HQ-OAR-2022-0985-1660-A1, p. 61]

For all of these reasons, EPA's proposed method of calculating compliance is irrational. Any final rule must comprehensively account for the emissions generated by electric vehicles to ensure that EPA's solution (a widespread shift to electric vehicles) bears a rational connection to its regulatory goal of reducing harmful emissions. Cf. Am. Fed'n of Gov't Emps., 25 F.4th at 9 (faulting agency for failing to explain why the standard it adopted will address "the principal problem the new standard is designed to fix"). [EPA-HQ-OAR-2022-0985-1660-A1, p. 61]

Organization: American Fuel and Petrochemical Manufacturers (AFPM)

2. EPA Fails to Adequately Account for the Lifecycle Emissions of ZEVs.

As discussed above, because EPA may only prescribe standards applicable to vehicles that "cause or contribute" to air pollution, its standards cannot account for ZEVs with no tailpipe emissions. However, if EPA is authorized to promulgate such standards, those standards must account for any upstream emissions from upstream electric generating units ("EGU"), and the mining of battery materials. The failure to do so ignores the policy objectives of the statute and creates an uneven playing field that substantially disadvantages ICEVs and fails to address a major aspect of GHG emission reduction. Indeed, Clean Air Act Section 202(a)(4)(B) requires that EPA calculate these lifecycle emissions impacts. [EPA-HQ-OAR-2022-0985-1659-A2, p. 24]

EPA's reference to electric vehicles as "zero emission vehicles" is misleading. For instance, the fuel source of a BEV—a battery composed of GHG emissions intensive minerals and the electricity generated to power the battery—produces emissions. The fact such emissions occur upstream of the vehicle's operation and therefore lack tailpipe emissions stacks the deck in favor of this technology, even though they do cause emissions. There is no logical basis for omission because, as EPA is aware, concerns about GHG emissions relate to their longer-term global concentrations. Consequently, all vehicle related emissions should be an important consideration regardless of where such emissions occur. Without comparing lifecycle ZEV emissions to lifecycle emissions from ICEVs, EPA cannot know if or how much its standards are actually decreasing emissions on a relevant scale. Thus, while EPA is not required to solve all emissions problems in one rulemaking, EPA cannot even claim to be solving part of the problem here without addressing upstream and downstream emissions. EPA's approach of mandating BEVs cannot possibly be reasonable if it is merely shifting emissions from one source to another at the cost of hundreds of billions of dollars—trillions when costs to upgrade EV infrastructure are factored in—or could do so more cost-effectively by choosing a different approach.92 [EPA-HQ-OAR-2022-0985-1659-A2, p. 25]

92 5 U.S.C. § 706(2)(A); cf, Antonin Scalia, "Regulatory Review and Management," Regulation Magazine 19 (Jan./Feb. 1982) ("Is it conceivable that a rule would not be arbitrary or capricious if it concluded with a statement to the effect that 'we are taking the foregoing action despite the fact that it probably does more harm than good, and even though there are other less onerous means of achieving precisely the same desirable results'?").

The flaw in EPA's approach is illustrated by the fact that emissions standards easily become meaningless by changing the engine's location. The Proposed Rule would treat a BEV charged by a diesel-powered generator as if it had zero tailpipe emissions, notwithstanding the fact that it remains "powered" by a diesel engine located outside the vehicle. A HDV directly powered by a diesel engine inside the vehicle, however, is credited with the emissions produced by that engine. Thus, the source of the "fuel" matters, the location should not. EPA arbitrarily ignores emissions from ZEVs. [EPA-HQ-OAR-2022-0985-1659-A2, p. 25]

EPA compounds this flaw by making unsupported assumptions regarding total emissions impacts of its proposal. While it claims that the overall analysis for combined downstream and upstream emissions "likely underestimates the net emissions reductions that may result" from the Proposed Rule, EPA failed to offer a data-based substantiation. The Proposed Rule failed to assess emissions from battery manufacturing or electricity production. EPA acknowledges that its standards will increase the demand for electricity and that demand will subsequently increase emissions from the electric generating sector, but it makes no real attempt to quantify those emissions or compare them to alternative options for reducing emissions from this sector. EPA should provide a more comprehensive analysis to comply with its directive under the Clean Air Act and better assess the resulting impact of the Proposed Rule. [EPA-HQ-OAR-2022-0985-1659-A2, p. 25]

Organization: American Petroleum Institute (API)

b. API supports the concepts of a lifecycle approach to GHG emissions reductions.

i. EPA should use a lifecycle assessment (LCA) approach vs. tailpipe only

To effectively achieve emissions reductions in the transportation sector, we believe that technology-neutral solutions are needed, utilizing an approach that addresses fuels, vehicles, and infrastructure systems. This is best accomplished through holistic policies that encompass the lifecycle emissions of both the fuel and the vehicle. This combination makes for the most effective reduction of transportation GHG emissions, as emissions occur at multiple stages of the lifecycle of internal combustion engine vehicles (ICEVs) and battery electric vehicles (BEVs) and the fuels used in them. Further, utilizing a lifecycle approach would enable quantification of the emissions associated with heavy-duty (HD) vehicles, and allow technologies to be identified that provide more expeditious and robust GHG emissions reductions. [EPA-HQ-OAR-2022-0985-1617-A1, pp. 4 - 5]

Use of a lifecycle approach would better achieve the goals of the proposed rule, as it would allow the agency and stakeholders alike to fully identify and reduce transportation sector carbon emissions and to identify and develop meaningful solutions. The reductions achieved by EPA's existing programs – including the Phase 1 and Phase 2 HD GHG rules, and criteria pollutant programs – are due in large part to addressing emissions holistically, and utilizing all available and emerging technology to do so.1 The myopic focus on tailpipe emissions in the proposed rule essentially means that the rule would only address certain transportation carbon emissions, while ignoring other sources of emissions and potential emissions reduction solutions. A lifecycle approach would allow EPA to quantify all of the emissions associated with HD vehicles, and to mitigate those emissions more effectively. [EPA-HQ-OAR-2022-0985-1617-A1, p. 5]

1 By EPA's own account, transportation pollution has been reduced significantly since the passage of the Clean Air Act – fuel sulfur levels are 90 percent lower and new heavy-duty vehicles are nearly 99 percent cleaner than 1970 models (https://www.epa.gov/transportation-air-pollution-and-climate-change/history-reducing-air-pollution-transportation), and new heavy-duty diesel engines being manufactured today achieve near-zero criteria pollutant emissions with increasing fuel efficiency and lower CO_2 emissions.

ii. Zero emission vehicles also have emissions impacts

As with ICEVs, ZEVs have carbon emissions impact associated both with their production and throughout their lifetime which EPA should incorporate in its analysis. While ZEVs can be an important part of a diverse transportation future to reduce GHG emissions, they do produce GHG emissions. Battery electric vehicle (BEV) and fuel cell electric vehicle (FCEV) production, use, and the disposal of BEV batteries, are not zero-emission activities. Further, all fuels – whether conventional fuels or electricity – have associated carbon emissions regardless of their source. As noted in the results of a report by the American Transportation Research Institute (ATRI), BEVs and FCEVs generate significant CO_2 emissions and will continue to have CO_2 emissions impacts in the future. Further, for certain HD truck classes, especially in the near term, BEVs may be more CO_2 emissions-intensive relative to comparable ICEVs in performing the same work (see Table 17, Figure 11).2 While meaningful reductions have historically been accomplished by focusing on tailpipe emissions from the vehicle, the growing market share of different technologies that include significant upstream emissions warrant inclusion of those emissions in the standard. [EPA-HQ-OAR-2022-0985-1617-A1, p. 5]

2 "Understanding the CO_2 Impacts of Zero-Emission Trucks", American Transportation Research Institute, May 2022.

The HD ZEV market is nascent, which has resulted in limited data on their emissions impacts and the proposal does not present or consider the actual GHG emissions associated with their production and use. We encourage the agency to not only acknowledge and address the CO_2 emissions of HD ZEVs, but to also continue to study the impacts. (As noted below in these comments, we strongly recommend that EPA include both a readiness assessment prior to program implementation as well as a program review once implementation begins.) The nascent HD ZEV market makes it hard to adequately assess the emissions impact due to the lack of available technology to actually evaluate. Yet, there will be CO2 emissions associated with the production and use of ZEVs, and it is important to address these emissions to provide a full picture of the emissions impacts and mitigation needs. [EPA-HQ-OAR-2022-0985-1617-A1, pp. 5 - 6]

Organization: Anonymous Public Comment

I am commenting on the EPA'S Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles proposal and its potential negligence towards the environment. I agree with parts of the proposal, specifically the impending restrictions on emissions standards. According to Phase 2 heavy duty vehicles produced in the model year 2028 and beyond will be held to stricter emissions standards. This would be greatly beneficial as it would not require a fleet overhaul. This would keep this stage from being economically taxing on current fleets. Additionally this would allow for gradual shifts that allow for current fleets to plan ahead and not get caught off guard by emissions restrictions. With this said I do disagree with the proposition of incentivizing electric heavy duty vehicles. At surface level this may seem like it benefits the environment however the other side of this coin is that it will incentivize fleet owners scraping their current vehicles in favor of electric vehicles. With the current quantity of semi trucks in America breaching 4 million (Zippia 2023), a massive shift towards new electric vehicles would cause hundreds of thousands of semi trucks to end up in the dump. Present in these scraped cars are many toxic chemicals like lead and mercury (EPA, 2023). Without proper disposal these chemicals could escape landfills and pollute water sources that you and I drink from through the contamination of toxic leachate. In addition to the initial environmental tax of scrapped vehicles, this plan would do very little to actually reduce emissions. According to Penn state 88% of U.S. energy comes from nonrenewable sources with 11% coming from coal, a fuel source that is half as efficient as oil. A switch to electric semi trucks would only remask the issue of increasing emissions and it would have the potential to cause an increase in emissions due to the use of coal to produce the energy for transportation instead of oil. The money that would be spent on incentives would be better spent elsewhere on technologies like carbon capture and storage. [EPA-HQ-OAR-2022-0985-1867]

Organization: Banks, Ben

The proposal for requiring 'ZEV' purchases on a percentage basis is too early, not attainable and cost restrictive. Let alone, our studies have shown that our net carbon footprint would be worse with a Battery Electric Vehicle (BEV) fleet, compared to our modern diesel fleet today. [EPA-HQ-OAR-2022-0985-1473-A1, p. 1]

'ZEV' is a misleading acronym. While electric vehicles may not have tailpipe emissions, approximately 60% of our electricity today is generated by fossil fuels. Cobalt, Lithium, etc., required to manufacture batteries for BEV's are primarily sourced overseas, with poor environmental standards, mined with equipment with no emission standards and/or with child and slave labor. [EPA-HQ-OAR-2022-0985-1473-A1, p. 1]

The current tunnel vision approach to ZEV's fails to consider the significant opportunities that are likely to come with hydrogen. Perhaps equally important is the recent use of R99, a renewable diesel fuel that is a direct replacement for petroleum based fuel. Studies have shown R99 emissions at 30-40% that of petroleum based fuel. When comparing the total lifecycle carbon footprint of a BEV (production, electricity generation, disposal), R99 has actually been shown to have less of a carbon footprint than BEV and does not rely on Russia, The Democratic Republic of Congo, or China to source materials for production. (Reference ATRI study at the link below) [EPA-HQ-OAR-2022-0985-1473-A1, p. 1]

> https://truckingresearch.org/2022/05/03/new-atri-research-quantifies-the-environmental-impacts-of-zero-emissiontrucks/

Yet another significant consideration is our nation's ability to provide enough electricity to charge commercial BEV's. While California is 'leading the way' on ZEV integration, the state doesn't generate enough power for their consumption needs today. [EPA-HQ-OAR-2022-0985-1473-A1, p. 1]

> https://truckingresearch.org/2022/12/06/new-atri-research-evaluates-charging-infrastructure-challenges-for-the-u-selectric- vehicle-fleet/

While admirable in nature, the goal of converting a significant portion or our new commercial truck production over to BEV in a decade is not cost effective, is not achievable and will likely have a worse environmental impact than focusing on realistic alternatives, such as R99 and hydrogen power. Interestingly enough, American Transportation Research Institute (ATRI) data was used in the calculation of maintenance expense on Internal Combustion Engine (ICE) commercial motor vehicles, but no reference of the valuable studies above was made in the subject NPRM. We believe strongly that the EPA needs to not only focus on greenhouse gas emissions (GHG), but the true, net carbon footprint involved with ZET/BEV commercial motor vehicles. Focusing solely on GHG and neglecting the overall global carbon impact fails to truly make the best decisions for our environment. [EPA-HQ-OAR-2022-0985-1473-A1, pp. 1-2]

Organization: BorgWarner Inc.

BorgWarner urges EPA to avoid tailpipe-specific ZEV definitions.

BorgWarner supports EPA moving beyond analyzing vehicle emissions only at the tailpipe and proposes that EPA incorporate accounting of upstream emissions for compliance purposes. As we are investing in advanced technologies, it is important to look at the overall environmental impact to determine broad pathways to achieve our emission reduction goals. This approach is consistent with technology neutrality, global carbon neutrality goals, and a holistic environmental impact assessment. [EPA-HQ-OAR-2022-0985-1578-A1, pp. 5 - 6]

Organization: Bradbury, Steven G.

Furthermore, EPA has deliberately left out of its cost-benefit equation entirely the upstream carbon dioxide emissions associated with EV production.49 The minerals and components used in EV batteries are mostly processed or manufactured in China using power generated from coal. While the U.S. has achieved huge reductions in carbon dioxide emissions by converting coal-fired power plants to natural gas, China's and other Asian nations' carbon emissions are growing rapidly because of their heavy reliance on coal, and EPA's rules will only accelerate that dynamic.50 An automotive engineering analysis published in 2022 estimated that the carbon dioxide emissions from producing the battery used in one small EV (the Nissan Leaf) were equivalent to driving an ICE vehicle 24,000 miles (two years of driving), and those from producing the battery used in a large EV (the Tesla Model S) were equivalent to driving an ICE vehicle 60,000 miles (five years of driving).51 In these rulemaking proposals, EPA has completely ignored the fact that EVs start out their lives on the road with such a huge head start (two to five years worth) in carbon dioxide emissions over their ICE counterparts. [EPA-HQ-OAR-2022-0985-2427-A2, pp. 17-18]

49 See id. at 29197, 29254.

50 See Robert Bryce, "The Iron Law of Electricity Strikes Again as Vietnam Boosts Coal Burn," June 17,

2023, https://robertbryce.substack.com/p/the-iron-law-of-electricity-strikes.

51 See Tristan Burton, et al., Convergent Science, Inc., "A Data-Driven Greenhouse Gas Emission Rate Analysis for Vehicle Comparisons," SAE Int'l Journal of Electrified Vehicles, April 13, 2022, https://doi.org/10.4271/14-12-01-0006 (also available at https://www.sae.org/publications/technicalpapers/content/14-12-01-0006/).

EPA's benefits analysis is flawed and arbitrary.

On the benefits side of the ledger, EPA claims sky-high monetized benefits from the asserted reductions in carbon dioxide emissions—to the tune of upwards of a trillion dollars.64 These estimates are based on predicted reductions in the amount of gasoline and diesel fuel that would be burned if the U.S. auto fleet converts to EVs at the rates projected by EPA. But they completely ignore the very large increase in carbon dioxide emissions that would necessarily occur from the projected expansion in the production of EV batteries. They also ignore the upstream emissions of carbon dioxide from the increased electricity generation that would be needed to charge the projected fleet of EVs. [EPA-HQ-OAR-2022-0985-2427-A2, p. 22]

64 See id. at 29200, 29344.

EPA's refusal to account for these huge offsetting emissions of carbon dioxide fundamentally distorts its analysis of net benefits in a manner that arbitrarily favors the Agency's preferred regulatory outcome. It is, in fact, false and misleading to label EVs "zero-emission vehicles" when the production of EV batteries and the charging of the batteries over the life of the vehicles both generate enormous amounts of carbon dioxide. [EPA-HQ-OAR-2022-0985-2427-A2, p. 22]

Organization: Chevron

1. Lifecycle GHG based standards

The proposals are focused on tailpipe GHG emissions rather than lifecycle emissions. Therefore, upstream GHG emissions for fuel and vehicle manufacturing are not included in the analysis, favoring "zero tailpipe emission" technologies like Battery Electric Vehicles (BEV) and Fuel Cell EVs (FCEV). [EPA-HQ-OAR-2022-0985-1552-A1, p.3]

We recommend EPA revise the proposed standards to incorporate a lifecycle GHG assessment of truck propulsion and fuel technologies, as outlined in recent research published by the American Transportation Research Institute (ATRI)1. This analysis uses recent research concerning lifecycle analysis included in the most recent Greenhouse Gases, Regulated Emissions, and Energy Use in Transportation (GREET) model. GREET accounts for the greenhouse gas emissions associated with: the production of truck chassis; propulsion and fuel technology including engines, batteries, fuel cells and liquid fuel production; the use of these vehicles over one million miles using different fuel and propulsion systems; and the emissions associated with the recycling of these vehicles at the end of their service lives. ATRI concludes that heavy-duty internal combustion engines powered by biomass-based diesel fuel offers greater lifecycle emission reductions than relying exclusively on either battery electric or fuel cell solutions. [EPA-HQ-OAR-2022-0985-1552-A1, p.3]

1 Understanding the CO2 Impacts of Zero-Emission Trucks, American Transportation Research Institute, May 2022

One study from the University of British Columbia2 compared the lifecycle GHG emissions from a variety of heavy-duty powertrain technologies coupled with different fuel sources. These technologies included battery electric, hydrogen fuel cell, and conventional diesel internal combustion engines. The study found that the lifecycle GHG emissions were dependent on the individual production pathways for the electricity, hydrogen, and renewable diesel fuels. Diesel engines fueled by renewable diesel can contribute lower overall GHG emissions than electric vehicles using electricity from high carbon intensity sources. The ultimate choice of fuel and vehicle technology for a particular application should consider multiple factors in addition to the carbon intensity value. These factors include customer preference, vehicle usage, fuel supply chain reliability, infrastructure development, economic drivers, and environmental impact. [EPA-HQ-OAR-2022-0985-1552-A1, p.3]

2 Comparative Life Cycle Analysis of Heavy-Duty Vehicles (Class 7/8) Fueled by Renewable Diesel, Electricity, and Hydrogen, University of British Columbia Sustainable Scholars, August 2022

Similar research commissioned by the Diesel Technology Forum 3 finds that trucks fueled using biomass-based diesel may offer lower lifecycle emissions compared to the operation of battery electric trucks, especially in regions of the country that may not experience fast adoption of renewables that reduce the carbon intensity of electricity. Refueling a fleet of Class 7 and 8 trucks with B20 (20 percent biodiesel and 80 percent ultra-low sulfur diesel) offers immediate GHG reductions that would not be met for several years by replacing the same fleet of trucks with all-electric solutions using the carbon intensity of the California grid. Repowering these same Class 7 and 8 trucks using 100 percent biomass-based diesel would outperform battery electric options using the California grid electricity past 2032. We understand that this research accompanies the comment submitted by the Diesel Technology Forum. [EPA-HQ-OAR-2022-0985-1552-A1, p.4]

3 Environmental Benefits of Medium- and Heavy- Duty Zero Emission Vehicles Compared with Clean Bio- & Renewable-Fueled Vehicles 2022-2032, Prepared for Diesel Technology Forum by Stillwater Associates LLC, July 19, 2022, https://dieselforum.egnyte.com/dl/MWHPcRW4e6

California's long-term climate policy has narrowly focused on exploration of electrification scenarios across the mobile source sectors. However, a study by Ramboll4 took a broader view and analyzed multi-technology pathways, which included a combination of lower-emission (75% to 100% lower) vehicle technologies and fuel mixes (including lower carbon intensity liquid and gaseous fuels). The Ramboll study demonstrated that there are faster paths to meeting near-term federal health requirements, making progress on climate goals, and achieving greater reductions per dollar spent. [EPA-HQ-OAR-2022-0985-1552-A1, p.4]

4 Ramboll "Multi-Technology Scenarios: Heavy-Heavy Duty Truck Sector". 2021. Available here: https://www.arb.ca.gov/lists/com-attach/78-sp22-kickoff-ws-B2oFdgBtUnUAbwAt.pdf

Organization: Clean Fuels Development Coalition et al.

II. EPA lacks the Statutory Authority to Ignore Upstream Emissions for Electric Vehicles.

EPA has statutory authority to prescribe "standards applicable to the emission of any air pollutant from any class or classes of new motor vehicles or new motor vehicle engines, which in [its] judgment cause, or contribute to, air pollution which may reasonably be anticipated to endanger public health or welfare." 42 U.S.C. § 7521(a)(1). This presents an interpretive dilemma. On the one hand, if electric vehicles are not "vehicles" "which cause, or contribute to" a given type of air pollution, then EPA may not set standards for them. Id. On the other, if electric vehicles are "vehicles" "which cause, or contribute to" a given type of air pollution, then EPA must set "standards applicable to the[ir] emissions." Id. [EPA-HQ-OAR-2022-0985-1585-A1, p. 12]

The proposal tries to solve this problem by splitting the baby.8 EPA reasons that electric vehicles are vehicles that "cause or contribute to air pollution," but EPA just chooses to set their contribution to zero. This cannot be right. Cf. C.S. Lewis, That Hideous Strength 291 (Samizdat ed., 2015) ("Just imagine a man who was too dainty to eat with his fingers and yet wouldn't use forks!"). If electric vehicles truly emit no emissions, then they are not the sort of vehicle EPA can regulate. [EPA-HQ-OAR-2022-0985-1585-A1, p. 12]

8 Of course, the point of the story about Solomon is that the baby wasn't split. See 1 Kings 3:16- 28 ("Give the living child to the first woman, and by no means put him to death; she is his mother.").

Of course, EPA freely admits that electric vehicles do produce upstream emissions, and that these upstream emissions matter. This is true and very important. And the proposal does consider upstream emissions when determining the rule's impact on total emissions. 88 Fed. Reg. 25,936. EPA's position is that this inconsistent approach to electric vehicles' upstream emissions is reasonable because it treats upstream emissions of all vehicles, electrified or not, the same way for compliance purposes. But that is precisely what makes the rule unreasonable. Electric vehicles produce many times the upstream carbon-dioxide emissions as conventional vehicles, and those upstream emissions account for 100% of an electric vehicle's carbon-dioxide emissions from use. In contrast, upstream emissions are only a small part of a conventional vehicles' total emissions. EPA's across-the-board failure to consider upstream emissions for purposes of compliance means that its rule considers most of gasoline-powered vehicles' carbon-dioxide emissions, but none from electric vehicles. Treating upstream emissions of all vehicles, electrified or not, the same way puts a thumb on the scale against conventional vehicles in favor of electric vehicles, and for no good reason the proposal gives. See FCC v. Prometheus Radio Project, 141 S. Ct. 1150, 1158 (2021) (An agency's bare preference for one technology cannot satisfy the requirement that it "reasonably consider[] the relevant issues and reasonably explain[] the decision."). At the very least, ignoring these emissions for compliance without cost-benefit analysis is arbitrary and capricious. [EPA-HQ-OAR-2022-0985-1585-A1, pp. 12 - 13]

EPA tries to work around this obvious inconsistency by refusing to address it: "We are continuing and are not reopening the existing approach taken in both HD GHG Phase 1 and Phase 2, that compliance with the vehicle exhaust CO2 emission standards is based on CO2 emissions from the vehicle." 88 Fed. Reg. 25,931, n.61. But it cannot so refuse. The proposal would constructively reopen the issues, making a fresh challenge timely. See Sierra Club v. EPA, 551 F.3d 1019, 1026 (D.C. Cir. 2008). Where prior rulemakings "did not give [petitioners] adequate … incentive to contest the agency's decision," the decision is "constructively reopened" by the new rule. National Ass'n of Mfrs. v. Department of Interior, 134 F.3d 1095, 1104 (D.C. Cir. 1998). Here, the proposal's novel use of its preexisting "framework" to mandate heavy-duty electric vehicles—rather than just providing flexibility—"significantly alters the stakes of judicial review" and thus constructively reopens the matter. Kennecott Utah Copper Corp. v. Department of Interior, 88 F.3d 1191, 1227 (D.C. Cir. 1996). [EPA-HQ-OAR-2022-0985-1585-A1, p. 13]

A. EPA has authority to consider the lifecycle emissions from different fuels in its standard setting.

Section 202(a)(3)(A)(ii) authorizes EPA to look beyond the basic engine to set its engine or vehicle emission standards. Specifically, it states that, "in establishing classes or categories of vehicles or engines for purposes of regulations under this paragraph, the Administrator may base such classes or categories on gross vehicle weight, horsepower, type of fuel used, or other appropriate factors." 42 U.S.C. § 7521(a)(3)(A)(ii) (emphasis added). To account for the "type of fuel used," EPA would need to engage in lifecycle emissions analysis. EPA has often eschewed lifecycle analysis because of the nature of the pollutants it regulates, but it is the obvious best fit for carbon regulation. Section 202(a)(1) gives EPA's authority to issue rules setting emissions standards for "air pollutants" that it finds may reasonably be anticipated to endanger public health or welfare. And while most air pollutants work on the local and regional level, which makes lifecycle analysis a poor fit, greenhouse gases' harms are all at the global level. Except in truly extreme concentrations, CO_2 emissions do not lead to adverse health effects if breathed in. [EPA-HQ-OAR-2022-0985-1585-A1, p. 15]

Clean Air Act Section 202(a)(4)(A) and (B) require that EPA consider whether its proposed standards "will cause or contribute to an unreasonable risk to public health, welfare or safety", including whether the proposed standard "causes, increases, reduces, or eliminates emissions of any unregulated pollutants" and to assess "the availability of other devices, systems, or elements of design which may be used to conform to requirements prescribed under this subchapter without causing or contributing to such unreasonable risk." EPA's proposal not only fails to consider unreasonable risks associated with lifecycle emissions (and safety) of forced electrification of the heavy-duty fleet, but also fails to calculate the lower lifecycle emissions impacts (and lower safety risks) for other regulatory constructs including increased reliance on alternative liquid fuels. [EPA-HQ-OAR-2022-0985-1585-A1, pp. 15 - 16]

V. The Proposed Rule Misleads Consumers by Using the Term "Zero-emissions Vehicle" to Refer to Vehicles that EPA Concedes Produce Emissions.

While it is true that all-electric vehicles have no tailpipe emissions, it is completely false to claim that they are "zero-emissions vehicles." EPA acknowledges that what it calls "ZEVs" have upstream emissions. 88 Fed. Reg. 25,936. Despite this, the proposal repeatedly describes these vehicles as having no emissions. This is per se unreasonable, and it also enables illegal marketing by auto-manufacturers. Seizing on EPA's label, dozens of auto-manufacturers have described their electric vehicles as "zero-emissions." See, for example:

- "…we have also built the broadest combination of zero-emissions technologies dedicated to the commercial vehicle industry like battery electric and fuel cell electric powertrain solutions and electrolyzers for green hydrogen production." Cummins Launches Accelera by Cummins to Advance the Transition to a Zero-Emissions Future, Cummins Newsroom (Mar. 8, 2023), https://www.cummins.com/news/releases/2023/03/08/cumminslaunches-accelera-cummins-advance-transition-zero-emissions-future (last accessed June 15, 2023).

- "…the Biden Administration rolled out an executive order to advance light-duty electrification and 'smart fuel efficiency and performance standards' for medium- and heavy-duty trucks. Walmart and PepsiCo are encouraged by this ambition and momentum and are ready to work with the Administration, Congress, and state and local officials in shaping effective solutions that will enable a zero emissions future for fleets." Luke McCollum, VP Supply Chain Sustainability, Walmart and Roberta Barbieri, VP Global Sustainability, PepsiCo, Here's How Policy Can Design a Reliable and Resilient Zero Emissions Future for Transportation Fleets, LinkedIn (Dec. 14, 2021), https://www.linkedin.com/pulse/heres-how-policy-can-design-reliableresilient-zero-emissions-cortes/?published=t (last accessed June 15, 2023).
- "Nikola Corporation (Nasdaq: NKLA), a global leader in zero-emission transportation and energy infrastructure solutions, and Proterra Inc (Nasdaq: PTRA), a leading innovator in commercial vehicle electrification technology, today announced a strategic, multi-year supply agreement to power Nikola zero-emission semi-trucks with Proterra¡¦s industry-leading battery technology." Nikola and Proterra Agree to Long-Term Battery Supply for Zero-Emission Class 8 Semi Trucks, Nikola (Jan. 18, 2022), https://www.nikolamotor.com/press_releases/nikola-and-proterraagree- to-long-term-battery-supply-for-zero-emission-class-8-semitrucks-150/ (last accessed June 15, 2023).

- "We are aggressively going after every aspect of what it takes to put everyone in an EV because we need millions of EVs on the road to make a meaningful impact toward building a zero-emissions future." Our Path to an All-Electric Future, General Motors, https://www.gm.com/electricvehicles (last accessed June 15, 2023).
- "Roadtripping in your EV is not only zero emissions, it's zero-limits." Going EV, Nissan, https://www.nissanusa.com/vehicles/electriccars.html (last accessed June 15, 2023).
- "Zero Emissions. Zero Worries. ...get into your emissions-free Fisker Ocean." Fisker Ocean, Fisker, https://www.fiskerinc.com/ocean (last accessed June 15, 2023).
- "The Golf Style eHybrid means you can drive with zero emissions." Way to Zero, Volkswagen, https://www.volkswagen.co.uk/en/electric-andhybrid/sustainability/way-to-zero.html (last accessed June 15, 2023). [EPA-HQ-OAR-2022-0985-1585-A1, pp. 17 - 19]

There is no point on the grid powered entirely by wind, solar, or hydro energy. Even in California, where renewable energy is a priority, daily evening peak load is still routinely supplied by approximately 70 percent fossil fuels. See e.g., Today's Outlook, California ISO, https://www.caiso.com/TodaysOutlook/Pages/supply.html#section-supply-trend (data from August 2022, showing more than 70 percent of energy from natural gas, coal, and imports). According to a report by the California Energy Commission, demand from residential and nonresidential EV chargers could amount to more than 1 GW by 2025, causing significant impacts at the local level. Gavin Bade, CEC: California EV Chargers Will Add 1 GW of Peak Demand by 2025, Utility Dive (Mar. 20, 2018), https://www.utilitydive.com/news/ceccaliforniaev-chargers-will-add-1-gw-of-peak-demand-by-2025/519517/. [EPA-HQ-OAR-2022-0985-1585-A1, p. 19]

Manufacturing an electric vehicle also produces a significant number of greenhouse-gas emissions, much more than is required to produce a conventional vehicle. As does the electricity production, transmission, and distribution supply chain associated with electric vehicles, including chargers and operation and maintenance, can be greenhouse-gas intensive. Key components of the electrical infrastructure, such as copper and grain-oriented electrical steel, require energy-intensive extraction and processing, which contribute to the overall carbon emissions. As electric vehicles become increasingly common, the necessary infrastructure will balloon. [EPA-HQ-OAR-2022-0985-1585-A1, p. 19]

Making false claims in the marketing of products is prohibited by the Federal Trade Commission Act, which prohibits "unfair or deceptive acts or practices in or affecting commerce" 15 U.S.C. § 45. Because it facilitates these deceptive acts and promotes innumerable other false "zero emission" statements, the proposal is arbitrary and capricious. [EPA-HQ-OAR-2022-0985-1585-A1, p. 19]

Organization: ClearFlame Engine Technologies

EPA Could Adopt a Lifecycle Approach to Dedicated Alternative Fuel Vehicles in the Final Rule [EPA-HQ-OAR-2022-0985-1654-A2, p. 9]

We agree with other commenters that EPA has the authority to set Phase 3 GHG emissions standards based on lifecycle GHG reductions, rather than limiting itself to reducing tailpipe emissions only. [EPA-HQ-OAR-2022-0985-1654-A2, p. 9]

Courts interpreting Section 202 have found that EPA has significant discretion in how it sets emissions reduction standards. This is necessary to address the many complicated scientific, design, and engineering concerns regarding how best to reduce air pollution. The D.C. Circuit has observed that '[m]anufacturers produce a wide variety of motor vehicles of different sizes, some using different engine technologies resulting in unusual emission characteristics.' Nat. Res. Def. Council, Inc. v. U. S. Envtl. Prot. Agency, 655 F.2d 318, 322 (1981). EPA's authority to set emissions reduction standards is flexible enough to create engine certification pathways that account for the lifecycle emissions reductions that result from the switch from fossil to biogenic carbon emissions.22 [EPA-HQ-OAR-2022-0985-1654-A2, p. 9]

> 22 We believe that incorporating E98 and other renewable SLFs will also make the Final Rule more defensible against a legal challenge. As EPA knows, courts may invalidate rules if the agency has 'entirely failed to consider an important aspect of the problem' or 'offered an explanation for [their] decision[s] that runs counter to the evidence before the agenc[ies].' Motor Vehicles Mfrs. Ass'n v. State Farm Mutual Automobile Ins. Co., 463 U.S. 29, 43 (1983). Further, West Virginia v. EPA faulted EPA for using its Clean Air Act authority to 'substantially restructure the American energy market' in a way that 'Congress had conspicuously and repeatedly declined to enact itself.' 142 S. Ct. 2587, 2610 (2022) (quotation omitted).

To be clear, ClearFlame strongly supports the use of electric and hydrogen vehicles to decarbonize transportation where they can provide a cost-effective solution at scale. We support the rapid deployment of all fuels and technologies that can help our nation hit its climate goals. However, by incentivizing two technologies in the Blueprint (i.e., electric and hydrogen vehicles) while ignoring the potential benefits of dedicated alternative fuel vehicles, we are concerned that the Proposal could be susceptible to legal critique. Adding certification pathways and other incentives for dedicated SLF vehicles to the Final Rule would make the program more defensible as a continuation of historical carbon-reducing policies repeatedly established by Congress to incentivize ethanol and other biofuels to reduce the use of carbon-emitting fossil fuels and increase the use of low-carbon, renewable biofuels produced on farms and in our rural communities across the nation.

Carbon dioxide is different from the criteria pollutants EPA has historically regulated. Its impacts are global, and its adverse effects are not limited to the places where they are emitted. To mitigate these effects as quickly as possible, a different approach to regulating carbon dioxide emissions is warranted that captures the full lifecycle benefits of ethanol and other biofuels and integrates it into EPA's certification pathways when they replace fossil diesel fuel in a dedicated engine system. [EPA-HQ-OAR-2022-0985-1654-A2, p. 10]

As noted above, when biofuels emit carbon dioxide when burned, that carbon dioxide is biogenic. In the context of a tailpipe-only rule, it is correct to state that this combustion does not add to climate change, because the natural carbon cycle has not been altered (in contrast to burning fossil fuels, which introduces extracted carbon into the atmosphere). In other words, a tailpipe-focused CO2 rule should treat biogenic carbon as 'zero emissions' for the same reason as hydrogen—because neither directly contains fossil-derived carbon. [EPA-HQ-OAR-2022-0985-1654-A2, p. 10]

If, instead, EPA chooses to develop a lifecycle-focused rule to align with climate impact in the strongest possible way, a different accounting is needed – but fortunately, science offers an equally rigorous way of determine total (i.e. lifecycle emissions). From a lifecycle perspective, a preponderance of research substantiates that ethanol is roughly 50 percent lower than diesel when taking into account the upstream impacts from the production and distribution of the two fuels.23 A lifecycle-based emissions rule would account for the fact that consumption of 1 MJ of ethanol has 50% the GHG impact as 1 MJ of diesel – and so, when comparing two identical engines consuming energy at the same rate, one running on ethanol would receive half the emissions certification calculation as one running on diesel. [EPA-HQ-OAR-2022-0985-1654-A2, p. 10]

23 Based on GREET calculation.

A lifecycle regulatory framework would best align with the real-world GHG reduction outcomes we want to drive. It would incentivize investment in (and adoption of) solutions that guarantee displacement of fossil-fuels with lower lifecycle carbon alternatives. The more we can convert the fleet of ICE vehicles to engines that can only operate on fuels with lower lifecycle carbon emissions, the less we will need to rely on fossil fuels that increase the atmosphere's net carbon load, i.e., that drive climate change. The lifecycle benefits of such technologies should be integrated into the Final Rule to encourage this transition, and we believe that EPA has the authority to take this step. [EPA-HQ-OAR-2022-0985-1654-A2, p. 10]

To do so, EPA can address lifecycle emissions reductions by integrating the significant data and experience EPA has obtained in administering in the Renewable Fuel Standard (RFS) program and other resources (such as GREET) to determine the full lifecycle emissions reductions of a dedicated alternative fuel vehicle, which would then be integrated into its certification pathways. [EPA-HQ-OAR-2022-0985-1654-A2, p.11]

Indeed, in pilot projects and in an independent Total Cost of Ownership, ClearFlame's engine results in a 42% lifecycle GHG emissions reduction, compared t (TCO) analysis,25 our dedicated E98 engine showed 22% lower lifecycle emissions than a BEV truck based on the average U.S. national grid mix.26 The same TCO study also found that based on national carbon intensity averageso traditional diesel.28 Forcing vehicles to switch to technologies that could instead increase lifecycle emissions cannot be what the Clean Air Act requires or incentivizes. 'Since the earliest days of the CAA, Congress has emphasized that the goal of section 202 is to address air quality hazards from motor vehicles, not to simply reduce emissions from internal combustion engines to the extent feasible.'29 While EPA is referring to electric vehicles here, the sentiment could apply to dedicated alternative fuel vehicles as well. By integrating lifecycle analysis into the certification of dedicated alternative fuel engines, the Final Rule can accelerate and increase the overall emissions benefits of the program. [EPA-HQ-OAR-2022-0985-1654-A2, p.11]

Sustainable Sourcing

Sustainable sourcing of materials is still a concern in the production of HD BEVs, and there is little consideration of the manufacturing side in the NPRM proposal. The proposal is mainly focused on in use CO2 reduction rates of HID vehicles. In assessing the impact of its proposals, EPA should consider the impact of manufacturing of the full propulsion system to ensure that the cross-over point combining CO2 emissions in manufacturing and in-use vehicle emissions is reasonable for the targeted adoption rate proposed. A cross-over point should be provided in addition to what is provided on break-even timing for HD BEV owners. [EPA-HQ-OAR-2022-0985-1610-A1, p. 3]

Organization: Delek US Holdings, Inc.

III. The Proposed Rule Underestimates the Lifecycle GHG Emissions of BEVs

Contrary to the naming convention, ZEVs—including BEVs—are not truly zero-emission vehicles. In fact, the lifecycle GHG emissions of BEVs exceed that of ICE-powered vehicles. If EPA is authorized to promulgate such standards, those standards must account for any upstream emissions from electric generating units. The failure to do so creates an uneven playing field that substantially disadvantages ICE engines. [EPA-HQ-OAR-2022-0985-1561-A1, p. 4]

EPA's reference to electric vehicles as "zero emission vehicles" is misleading. The fuel source of a BEV—a battery composed of carbon intensive minerals and the electricity generated to power the battery—produces emissions. The fact such emissions occur 100% upstream of the vehicle's operation and therefore fall outside of the tailpipe emissions calculation stacks the deck in favor of this technology. There is no logical basis for this omission because, as EPA is aware, GHG emissions have a global impact. Consequently, controlling air pollutant emissions should be important regardless of where such emissions occur. [EPA-HQ-OAR-2022-0985-1561-A1, p. 4]

The flaw in EPA's approach is illustrated by the fact that emissions standards easily become meaningless by changing the engine's location. A BEV charged by the owner through the use of a diesel-powered generator has zero emissions, notwithstanding the fact that it remains "powered" by a diesel engine located outside the vehicle. A HDV directly powered by a diesel engine inside the vehicle, however, is credited with the emissions produced by that engine. Thus, the source of the "fuel" matters. EPA's myopic approach fails to account for such impacts. [EPA-HQ-OAR-2022-0985-1561-A1, pp. 4 - 5]

Organization: Environmental Defense Fund (EDF)

Apply a Utility / Correction Factor to Vehicles Fueled with Hydrogen. We also urge EPA to account for the wide variation in hydrogen fueled vehicles' emissions benefits in measuring their emissions for compliance with the standards. EPA proposes to count hydrogen powered vehicles as having zero emissions, similar to how it has treated BEVs in the past. However, EPA's prior justifications for treating BEVs this way do not apply to hydrogen powered vehicles.221 Not only do hydrogen powered vehicles not provide clear emissions benefits absent further controls on where the hydrogen they operate on comes from, but due to potential leakage of hydrogen from the vehicles and criteria pollutant emissions from H2ICEVs, they do have vehicle and tailpipe emissions that must be accounted for. Additionally, EPA has previously noted the existence of other emissions reduction programs or controls related to upstream emissions as justifying its focus on tailpipe emissions.222 However, emissions from hydrogen production are currently unregulated, making it especially important that EPA adopt an approach that considers and reflects how hydrogen fueled vehicles are powered and operated. [EPA-HQ-OAR-2022-0985-1644-A1, 84-85]

221 EPA's decision to treat BEVs as having zero-emissions was based on a careful consideration of the emissions benefits associated with BEVs because the original purpose of this approach was to "recognize the benefits of . . . dedicated alternative-fueled vehicles." 76 Fed. Reg. 57123. Because of the emissions issues associated with hydrogen powered vehicles, including the fact that they likely do have tailpipe emission through hydrogen leakage, this same justification cannot justify their parallel treatment. Additionally, EPA has previously considered it important to its focus on tailpipe emissions that the upstream emissions are regulated by other rules.

222 76 Fed. Reg. 51705 (Aug. 27, 2012) ("There is no good reason to consider [the lifecycle emission of different types of fuels] here, especially where there already is a separate fuel based program, the RFS program, that is directly aimed at achieving the result POP Diesel seeks--a fuel program that achieves a reduction in lifecycle GHG emissions associated with the diesel fuel used by motor vehicles, through a mandate to use certain renewable diesel fuels.).

In this regard, EPA should not treat hydrogen fueled vehicles like BEVs but instead similarly to how the agency treats PHEVs,223 where EPA recognizes that sometimes PHEVs operate on battery power with real emissions benefits and other times the vehicle is powered by its ICE engine with emissions profiles more similar to fossil-powered vehicles. 224 For hydrogen fueled vehicles, EPA could adopt an approach to calculating their GHG emissions that includes a conservative low- GHG utility factor representing emissions attributable to hydrogen fueled vehicles assuming those vehicles are fueled using average, current forms of hydrogen production. For instance, a current factor would need to reflect the fact that most hydrogen is produced using SMR and does not result in real-world emission benefits when compared to diesel vehicles.225 [EPA-HQ-OAR-2022-0985-1644-A1, 85]

223 See 40 CFR § 600.116-12.

224 88 Fed. Reg. 29253 (May 5, 2023) ("Because the tailpipe CO2 produced from PHEVs varies significantly between [charge depleting] and [charge sustaining] operation, both the charge depleting range and the utility factor curves play an important role in determining the magnitude of CO2 that is calculated for compliance.").

225 This utility factor should also differ for H2ICEs, and FCEVS, which have differing emissions benefits.

Organization: Hexagon Agility Inc.

Hexagon Agility strongly encourages the U.S. Environmental Protection Agency ('EPA') to utilize a life cycle approach to emissions, taking into account the full well to wheel impact of heavy-duty vehicles. While the Proposed Rules suggests that EPA intends to take both a fuel and technology neutral approach to achieving emission reductions, in reality that cannot be achieved with a tailpipe only focus. This is because heavy duty vehicles running on renewable natural gas ('RNG') or other clean fuels such as hydrogen do not get any credit under the current Proposed Rule. Heavy duty vehicles running on RNG are available, scalable and cost effective, and provide for the fastest way to decarbonize the transport sector. Specifically, we request that EPA revise the Proposed Rule to include a mechanism to give emissions credit to heavy duty vehicles running on renewable or other clean fuels, including long haul, transit and refuse vehicles. [EPA-HQ-OAR-2022-0985-1507-A1, p. 1]

These comments are divided into several sections:

3. Objections to refusing to include "Upstream" GHG considerations when choosing regulatory definitions of actual and associated emissions for electrically recharged vehicles by using the excuse that upstream emissions are not considered for GHG calculations for petroleum-based liquid fuels when such calculations have been made by others and are easily verifiable by EPA. We argue that upstream emissions should and must be included in any calculations for GHG reductions while Criteria Pollutants should continue to be based on either individual vehicle tail-pipe emissions or corporate or manufacturer duty-type fleet averages. [EPA-HQ-OAR-2022-0985-2675-A2, p. 1]

Comment

3. The EPA appears to be using a very "special" consideration of emissions that are to be counted as regulated emission from Battery Electric Vehicles (BEV). In unbelievable statements of contorted logic, the EPA has set forth what we describe as a complete artifice designed to promote and "force" a major change to vehicle propulsion starting in model year 2027. While it is true that during operation BEVs produce no criteria pollutants and emit no GHG gasses, the same cannot be said for the probable sources of the electric power used to recharge the batteries of BEVs. We wish this were not so, but we must deal factually with emissions associated with BEV recharging. If the EPA is serious about GHG reductions, they MUST include and consider the GHG emissions of grid-connected Electric Generating Units (EGU). Much like the water that

comes from our faucets, several water sources could be being used to provide that water. So it is with electricity. No one can distinguish or filter out clean electrons coming from wind and solar sources and “dirty” electrons coming from GHG-intensive electric generation. [EPA-HQ-OAR-2022-0985-2675-A2, p. 8]

Power that comes into homes and businesses may well be a mix of so-called clean energy and emission-laden dirty energy produced by burning fossil fuels. In fact, the mix of electricity generation varies greatly by state or region, depending on what the “serving utility” chooses to use for generation. Some regions rely almost entirely on fossil fuel and nuclear generation methods, while others have added or switched to renewable energy production methods, such as wind and solar as part of their generation mix. There are few if any regions of the United States that are completely powered by renewable or GHG-free energy. There are GHG implications for most of the so-called renewable generation methods. Solar panels are often produced with high Global Warming Potential (GWP) chemicals being released and there are GHG emissions associated with the steel, carbon fibers, plastics and copper conductors used in wind turbines. All this is to say there are GHG emissions associated with virtually all forms of electric generation that cannot be ignored when considering whether or not the introduction of a new form of vehicle propulsion that relies on recharging batteries will have associated GHG emissions. The latest figures from the Energy Information Agency for 2022, show the mix of energy production for the US: [EPA-HQ-OAR-2022-0985-2675-A2, p. 9]

U.S. utility-scale electricity generation by source, amount, and share of total in 20221 Data as of February 2023 [See figure, EPA-HQ-OAR-2022-0985-2675-A2, p. 9]

As you can see, 60.2% of overall US electricity generation was still produced by burning fossil fuels with their associated GHG and other pollutant emissions. When we aggregate how much GHG emissions might be attributable to recharging Battery Electric Vehicles we normally do so on a nation-wide scale using the latest available information. Since regional electric power generation is so varied, we cannot say a BEV in Southern California will have lower associated GHG emissions than one recharging in St. Paul, Minnesota. [EPA-HQ-OAR-2022-0985-2675-A2, p. 9]

Therefore, as of 2022, we can say in aggregate, there is a 60% chance that the electrons used to recharge BEVs over the next few years will be from fossil CO2 emitting fossil fuel generating plants. That is why, any scientific calculations made for the GHG contributions that a BEV makes must consider how the recharging power delivered to the BEV was generated. A BEV may have zero operating emissions but they do NOT have zero GHG emissions associated with their use. It is our considered engineering opinion that much of the so-called “low-hanging fruit” for renewable generation in the US has already been implemented and is now on-line or soon will be. [EPA-HQ-OAR-2022-0985-2675-A2, p. 10]

Think about an Electric Utility company that has literally made billions of dollars of investments in coal and/or natural gas fired power plants. In their board room minds, they are doing just fine making electricity in the same old way as they did 50 years ago and feel no compunction at all about charging their customers more for electricity when the cost of the fossil fuels they burn go up. Why would such a business feel compelled to create “stranded assets” of their fossil-fired generating facilities long before their estimated useful life expires and switch over to renewable forms of electricity generation? Might it be because the board of directors and the management suddenly “feel” like it is the “right” thing to do for the planet. Really??

Seriously, businesses have built-in inertia when they have made large investments in what brings in revenue for the business and for their stock holders. They might agree that new generating capacity should be renewable, but there is great impetus to expand their existing fossil fuel-fired facilities with a new generator unit. [EPA-HQ-OAR-2022-0985-2675-A2, p. 10]

So, the 60% fossil fuel number may stubbornly stay close to that figure for some time. The EPA attempted to control both pollutant and GHG emissions from power plants when the “Clean Power Plan” was part of policy thrusts, but they were less than successful in courts and countering the Utility and Fossil Fuel lobbies in Congress. [EPA-HQ-OAR-2022-0985-2675-A2, p. 10]

https://www.nationofchange.org/2022/07/05/the-supreme-court-has-curtailed-epas-power-to-regulate- carbon-pollution-and-sent-a-warning-to-other-regulators/

Given that background, let us look at how EPA proposes to treat and count emissions from BEV vehicles from excerpts from the Federal Register publication:

From Section III. B. 7. “Treatment of PEVs and FCEVs in the Fleet Average: As originally envisioned in the 2012 rule, starting with MY 2022, the compliance value for BEVs, FCEVs, and the electric portion of PHEVs in excess of individual automaker cumulative production caps would be based on net upstream emissions accounting (i.e., EPA would attribute a pro rata share of national CO2 emissions from electricity generation to each mile driven under electric power…). The 2012 rule would have required net upstream emissions accounting for all MY 2022 and later electrified vehicles. However, in the 2020 rule, prior to upstream accounting taking effect, EPA revised its regulations to extend the use of 0 g/mile compliance value through MY 2026 with no production cap, effectively continuing the practice of basing compliance only on tailpipe emissions for all vehicle and fuel types.” [EPA-HQ-OAR-2022-0985-2675-A2, p. 10]

Let’s stop here and parse out this set of statements. Prior to the cited text, EPA gave some history on how they were thinking about applying regulations for BOTH criteria pollutants and GHG emissions. Ostensibly because the number of BEVs was so small, auto makers were given credit for emission reductions, particularly GHG reductions, up to a company-wide vehicle production cap (a maximum value over which the company would not receive any emission credits). That is why the “individual automaker cumulative production caps” is part of the cited statements above. EPA states that their original thinking on GHG emissions from BEVs would be “based on net upstream emissions accounting,” which they further explain would be a “pro-rata share of national CO2 emissions from electricity generation to each mile driven under electric power.” As we discussed above, a nation-wide aggregation of the share of recharging GHG emissions attributable to fossil fueled generation would be about 60% as of 2022. [EPA-HQ-OAR-2022-0985-2675-A2, p. 11]

However, for some reason the EPA made a decision prior to doing any actual “upstream” CO2 accounting in their 2020 rulemaking that they would NOT do any upstream (meaning emissions attributable to activities that produced either the fuel in a gas tank or electricity to recharge a battery) accounting specifically for GHG emissions AND for criteria pollutants. EPA seems to justify its astonishing position on not accounting for GHG emissions related to battery recharge by saying they are treating all vehicles the same by not trying to account for all upstream emissions for BOTH liquid petroleum fuels and recharge electricity. [EPA-HQ-OAR-2022-0985-2675-A2, p. 11]

Let us state for the record that we agree with EPA for regulatory treatment of criteria pollutants from BEVs as zero grams per mile. We don't see any other way of accounting for both upstream and operations-attributable emissions, even though there were emissions related to the production of the materials used in the BEV, those emissions are virtually the same as those for producing a conventional gasoline vehicle. The only emission exceptions would be for battery production and electric motor components that would have different emission profiles than gas engine parts. We think these are minor differences and the upstream emissions for both the gasoline and BEV vehicles themselves are a wash. [EPA-HQ-OAR-2022-0985-2675-A2, p. 11]

However, KALA, in the most strenuous way possible, disagrees that upstream GHG emissions for battery recharge should treated the same way as zero grams per mile. The justification that you are treating each vehicle type the same is simply not tenable in any stretch of the imagination. We think that the EPA may have been incorrectly influenced by electrification zealots within the agency who when discussing how BEV GHG emissions should be handled argued something like this: [EPA-HQ-OAR-2022-0985-2675-A2, p. 11]

Hey guys we all know that we want to electrify the fleet as much as possible, after all we know that electrification is the only way to truly get GHG emissions under control in a big way, don't we? So, hey, let's figure out a way to justify treating the emissions from BEVs as zero all the way around even though we know there are upstream GHG emissions for battery recharge. Maybe if we say that we will treat emissions the same as "tail pipe' emissions while operating the vehicles, we can get away with counting BEV emissions as zero and really push the auto makers away from gasoline into making predominantly BEVs. [EPA-HQ-OAR-2022-0985-2675-A2, p. 11]

Now, we don't know how the decision was made to treat BEV GHG emissions as zero without any regard for how different BEVs are. The method used for regulating tail pipe emissions from gasoline vehicles requires fuel to be stored in the gas tank and that fuel is used to power the internal combustion engine, which emits both GHG and other air pollutants. That is no different than filling a battery up with "electric fuel" and then accounting for the emissions that made the BEV go down the road. It just so happens that the emissions to fill up the BEV's "tank" occur before the stored energy is used, but that is because the mode of propulsion and the way in which energy is stored and "refilled" is so different in a BEV. [EPA-HQ-OAR-2022-0985-2675-A2, p. 12]

No matter how the EPA moved from the "correct" way to treat BEV emissions by accounting for net upstream GHG emissions as a pro-rata share of national CO2 emissions from electric generation to the "insane" way of completely ignoring them, the initial way of treating GHG emissions from BEVs was the correct first impulse. Otherwise we have no way of comparing GHG emissions from gasoline and diesel powered vehicles and BEVs. It could be that the EPA attempted to make calculations for that pro-rata share of national electric generation CO2 emissions (as an engineer that is what I would do) and found the results not to their liking. That could well be because of the abysmal final efficiency of converting the energy in fossil fuels into rolling motion of a BEV. We offer an info graphic way of showing that terrible efficiency below: [EPA-HQ-OAR-2022-0985-2675-A2, p. 12]

[See figures from EPA-HQ-OAR-2022-0985-2675-A2, pp. 12-13]

The science and engineering behind the GHG emission figures associated with BEVs has principally to do with efficiencies of conversion of fossil fuels (remember we still have 60.2% of all electricity being generated by fossil fuels) to electricity and the losses that are seen in transmission, recharge of batteries and conversion of electric charge stored in batteries to rolling motion of the vehicle. The GHG impact of this horrendously low final efficiency is that far more GHG is produced to propel a BEV one mile than a comparable gasoline-powered vehicle. We believe it is entirely possible that the EPA understood the implications of such poor efficiencies, decided that it was in the national interest of the country to electrify the US fleet anyway regardless of the true GHG emission aspects of BEVs and found a way to drive or "Steer" fleet change over by ignoring upstream GHG emissions associated with BEV battery recharge in the regulatory scheme. We hope that is not the case, but it sure looks and feels that way. [EPA-HQ-OAR-2022-0985-2675-A2, p. 13]

EPA further continues to justify the compliance treatment of BEVs in Section III. B. 7. "EPA is proposing to make the current treatment of PEVs and FCEVs through MY 2026 permanent. EPA proposes to include only emissions measured directly from the vehicle in the vehicle GHG program for MYs 2027 and later (or until EPA changes the regulations through future rulemaking) consistent with the treatment of all other vehicles. Electric vehicle operation would therefore continue to be counted as 0 g/ mile, based on tailpipe emissions only…. The program has now been in place for a decade, since MY 2012, with no upstream accounting and has functioned as intended, encouraging the continued development and introduction of electric vehicle technology." [EPA-HQ-OAR-2022-0985-2675-A2, p. 13]

What did the EPA just say? They brazenly state that no matter what, GHG emissions from BEVs would continue to be counted as zero grams per mile. The program that counts emissions that way has "functioned as intended" to encourage BEV development and introduction into the vehicle fleet. Did they really just say that? Yes, EPA seems to be saying that it doesn't matter how illogical their counting method is for BEVs for GHGs, they are going to continue to do it that way and their motives to encourage or even force BEV transition and displacement through regulation becomes clear. [EPA-HQ-OAR-2022-0985-2675-A2, p. 14]

EPA further tries to justify their zero GHG emissions policy by again stating in Section III.B. 7. the following: "This approach of looking only at tailpipe emissions and letting stationary source GHG emissions be addressed by separate stationary source programs is consistent with how every other light duty vehicle calculates its compliance value. If EPA deviated from this tailpipe emissions approach by including upstream accounting, it would appear appropriate to do so for all vehicles, including gasoline- fueled vehicles." [EPA-HQ-OAR-2022-0985-2675-A2, p. 14]

We applaud the EPA for attempting, once again, to reduce stationary source (Electric Generating Units are considered to be stationary emissions sources) emissions. But, we are questioning the motives of the EPA for counting emissions from BEVs. As explained above, the equivalence way of looking at attributable GHG emissions is the "Filled Tank" approach suggested in this comment. How it was filled and whether or not the tank has associated emissions either from burning the stored contents of the tank in the case of liquid fuels or consuming the energy stored in a battery should make no difference in attributing GHG emissions to either situation. The only difference is when the related emissions occurred, before the stored energy was used or after the stored energy was used. This minor temporal difference cannot be ignored unless the EPA has an ulterior motive of forcing the change over of vehicle types in the US fleet through regulation. [EPA-HQ-OAR-2022-0985-2675-A2, p. 14]

The excuse in the cited FedReg text above that if EPA somehow deviated from the tail pipe emissions approach by including upstream [emissions] accounting they might have to do so for gasoline-fueled vehicles. Our response to that "terrible burden" on the EPA to account for upstream petroleum emissions is that such an argument is specious at best and just another vacuous justification. So what if the EPA had to account for upstream petroleum emissions. That might give us a higher resolution picture of the entirety of the vehicle GHG problem in a larger context. If the EPA considers the issue of accounting for upstream petroleum emissions too great a burden, the good news is that others have actually done this accounting. The group that we believe had the best methodology for accounting GHG emissions at stages of petroleum production and refining is the Renewable and Appropriate Energy Laboratory (RAEL) at UC Berkeley In a paper by the late Alex Farrell, GHG emissions at production stages provided total upstream emissions leading up to gasoline burned in ICEs. That group had a uniquely legible way to portray those upstream emissions graphically as shown below. [EPA-HQ-OAR-2022-0985-2675-A2, p. 14]

http://rael.berkeley.edu/old_drupal/sites/default/files/EBAMM/FarrellEthanolScience012706.pdf [EPA-HQ-OAR-2022-0985-2675-A2, p. 14]

Fig. 2. Alternative metrics for evaluating ethanol based on the intensity of primary energy inputs (MJ) per MJ of fuel and of net greenhouse gas emissions (kg CO2-equivalent) per MJ of fuel. For gasoline, both petroleum feedstock and petroleum energy inputs are included. ‘‘Other’’ includes nuclear and hydrological electricity generation. Relative to gasoline, ethanol produced today is much less petroleum intensive but much more natural gas and coal-intensive. Production of ethanol from lignite fired biorefineries located far from where the corn is grown results in ethanol with a high coal intensity and a moderate petroleum intensity. Cellulosic ethanol is expected to have an extremely low intensity for all fossil fuels and a very slightly negative coal intensity due to electricity sales that would displace coal. [EPA-HQ-OAR-2022-0985-2675-A2, p. 15]

The caption explains the units for GHG emissions calculated, which should be easily converted to what ever units EPA would like to use for its purposes. So, please, EPA, don't tell us such calculations would be a huge burden since someone else has done them for you. [EPA-HQ-OAR-2022-0985-2675-A2, p. 15]

Overall Comment #3 Conclusions:

A. Despite EPA's published protestations that their new rulemaking will provide leeway for multiple methods of vehicle propulsion to continue and that they have no wish to direct which propulsion method is the one they prefer, the evidence from statements made in describing the unreasonable "regulatory trick" of counting ONLY BEV tail pipe emissions for GHGs, has and will "Steer" automakers decisions toward BEVs as THE compliance solution. When EPA essentially says: "BEVs would be counted as 0 g/ mile in compliance calculations. The program has now been in place for a decade with no upstream accounting and has functioned as intended, encouraging the continued development and introduction of electric vehicle technology.," there is no doubt left in our minds as to the intentions of the EPA to change out ICE vehicles for BEVs through regulatory fiat. [EPA-HQ-OAR-2022-0985-2675-A2, p. 15]

Now, back to the Most Probable Time-of-Day for Recharge (MPTODR) issue. If most BEV owners will choose to recharge overnight, this is the time when utility companies are generating what is called Base Load. Base Load is the minimum power output load that a utility company has for its daily load swings. This is the time when most people are asleep and not using a lot of electric power, as opposed to increased power needs when people are up and using more electricity. Most utility companies use the Base Load time period to do maintenance on their Intermediate and Peaking generators. With a massive increase in BEV recharging needs in the overnight Base Load time frame, utility companies may have to run their Intermediate generating units during that time, as well as for meeting daytime loads. [EPA-HQ-OAR-2022-0985-2675-A2, p. 34]

Many utility companies use coal-fired generation for Base Load power needs because they cannot switch coal-fired generators on and off like they could a natural gas-fired turbine generator. It can take days for a large coal generating station to come up to temperature from cold start and start making electricity. We believe that some utility companies will choose to add coal-fired or natural gas-fired generating capacity to meet increased Base Load demand, rather than adding renewables, which would need to be wind power because solar power is not available at night. Whatever generating mix utility companies decide to use to meet BEV recharging demand, the proportion of fossil-fueled generation will be larger because solar will not be available during the MPTODR. This is another aspect of making the upstream calculations for fossil-fired pro rata GHG accounting that we are urging EPA to do for attributable BEV GHG emissions. [EPA-HQ-OAR-2022-0985-2675-A2, p. 34]

Organization: Lubrizol Corporation (Lubrizol)

Each of the Blueprint's strategies can yield extremely low-carbon performance. However, the lifecycle emissions of each technology should be considered and integrated into the Final Rule. We are concerned about the unintended consequences of a "tailpipe-only" approach that neglects upstream emissions and other emissions impacts of future engines and vehicles. Our concern is equally valid, whether the technology is an ICE vehicle operating on petroleum diesel, an ICE vehicle operating on a SLF, an ICE vehicle operating on hydrogen, a battery-electric vehicle, or fuel cell vehicle. The end goal should be a heavy-duty vehicle market that emits as few GHGs as possible, on a lifecycle basis. [EPA-HQ-OAR-2022-0985-1651-A2, p. 2]

Organization: Lynden Incorporated

Overall Negative Environmental Impacts

'Zero Emission Vehicles' do not make sense economically or operationally, so to justify the transition to these vehicles there must be an overall environmental benefit. However, 'Zero-Emission Vehicles' are not carbon-neutral or emission-free, they are just 'emissions somewhere else'. [EPA-HQ-OAR-2022-0985-1470-A1, p. 3]

The emissions associated with fuel production and electric generation should be considered when ranking vehicles for the EPA's Greenhouse Gas Emissions Standards. [EPA-HQ-OAR-2022-0985-1470-A1, p. 3]

California's own Low-Carbon Fuel Standard shows that even with all the renewables in their electric grid, electric vehicles provide only a 6% advantage in greenhouse gas emissions compared to traditional diesel4. For most of the Country, where electricity is generated by coal and natural gas, running an electric vehicle produces substantially more greenhouse gas emissions compared to diesel. According to American Transportation Research Institute, any significant reduction in CO_2 is not realized until 2050 when it is predicted that the mix of power is transformed to more renewable options5. [EPA-HQ-OAR-2022-0985-1470-A1, p. 3]

4 Lookup table for gasoline and diesel and fuels that substitute for gasoline diesel https://ww2.arb.ca.gov/sites/default/files/classic/fuels/lcfs/ca-greet/lut.pdf

5 U.S. Energy Information Administration. (February 8, 2021). 'EIA projects renewable share of U.S. electricity generation mix will double by 2050.' EIA. Available online: https://www.eia.gov/todayinenergy/detail.php?id=46676

These metrics only consider the electricity needed to run the vehicle itself. It does not include the 5% line loss in transmitting the electricity through power lines to the charging stations nor the 8% of energy lost as heat when charging the vehicle. These losses alone negate any CO_2 emissions benefit of electric vehicles. [EPA-HQ-OAR-2022-0985-1470-A1, p. 3]

In addition, any thoughtful rule, with the goal of reducing emissions from the freight industry needs to consider the ability to move freight, not the empty truck. A battery electric truck that weighs 9,000 lbs more than its diesel counterpart will need to make 20% additional trips to move the same amount of freight, thereby increasing associated electric emissions by 20% plus line loss and charging inefficiency. [EPA-HQ-OAR-2022-0985-1470-A1, p. 4]

To electrify the trucking fleet in the U.S., the entire global production of these minerals would need to be commandeered for 6-30 years6. The environmental impact of mining and refinement of these minerals as well as the impact of battery waste and disposal should be considered as well as the ramifications to national security when we become dependent on other countries for those materials. [EPA-HQ-OAR-2022-0985-1470-A1, p. 4]

6 Charging Infrastructure Challenges for the U.S. Electric Vehicle Fleet (December 2022) American Transportation Research Institute (ATRI). https://truckingresearch.org/2022/12/06/charging-infrastructure-challenges-for-the-u-s-electric-vehicle-fleet/

Organization: Manufacturers of Emission Controls Association (MECA)

To drive future U.S. technology leadership, EPA should recognize the need to include life cycle analysis in future rulemaking. This is particularly relevant to heavy-duty vehicles because of the magnitude of their power demand, battery size and charging time. Efficiency regulations have historically driven vehicle manufacturers and technology suppliers to continue to innovate and develop better materials, components, and vehicle systems to reduce energy demand, operating costs and related emissions of vehicles. By assigning realistic "non-zero" emission values to EVs and FCEVs, EPA will provide a regulatory incentive to further improve the electric efficiency of components and powertrain technologies that will further reduce vehicle related environmental impacts. [EPA-HQ-OAR-2022-0985-1521-A1, p. 8]

Organization: Mille Lacs Band of Ojibwe (Band)

Conceptually, the Band fully supports the aggressive decarbonization of heavy-duty vehicles, and reductions in other greenhouse gas (GHG) emissions as put forth in both the proposed rule and in the alternative also offered in the rule. However, the Band is concerned that EPA has not taken into consideration the GHG emissions associated with mining and processing of critical metals, GHG emissions associated with the manufacturing of these heavy-duty vehicles, and then material management associated with disposal of these heavy-duty vehicles at the end of their use life. If the processes involved before these heavy-duty vehicles go to market, and the processes involved after these heavy-duty vehicles go off from use life, both have significantly more GHG emissions involved, then it doesn't matter what GHG standards for heavy-duty vehicles are, if the result is United States not actually accomplishing net GHG emissions reduction, this will be a serious threat to the health of the people and of the environment. Because of this, we encourage EPA to make provisions in this rule that set up for new rulemaking for GHG reductions in the processes leading up to the sales of these vehicles that comply with the new GHG emissions standards, to set up for new rulemaking for GHG reductions in the processes after these vehicles come off their use life, and to have the three rules working in tandem to ensure there is actual GHG emissions reductions across the United States. [EPA-HQ-OAR-2022-0985-1609-A1, p.2]

Organization: Moving Forward Network (MFN) et al.

Second, EPA should update the EJ analysis to thoroughly analyze the "cradle to grave" impacts of the proposal and the potential disproportionate and cumulative impacts that EJ communities may face as a consequence of the rule. For example, the EJ analysis acknowledges that electricity generating units disproportionately impact communities of color and may experience some disbenefits where fossil fuel is burned for electricity generation. 72 However, EPA failed to fully consider the upstream and downstream impacts associated with energy generation, especially the disproportionate impacts and potential harms to EJ communities. This is critical to analyze, and EPA should quantify and evaluate these impacts in detail and include measures to avoid and mitigate these effects. [EPA-HQ-OAR-2022-0985-1608-A1, p. 31-32]

72 U.S. EPA. Draft Regulatory Impact Analysis, Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles: Phase 3, EPA-420-D-23-004. (April 2023). p. 398. https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P10178RN.pdf.

The proposed rule fails to consider the full lifecycle impacts associated with technologies that will be used to comply with the rule. This includes a full life cycle analysis of the battery supply chain; a life cycle analysis of hydrogen (including grey, blue, green, and any other forms of hydrogen) that could fuel trucks and assessing the emissions associated with hydrogen combustion; and life cycle analysis of diesel and natural gas fuels that could comply with the rule. Conducting these "cradle to grave" analyses is necessary to consider the localized environmental justice harms that could result from technology choices. [EPA-HQ-OAR-2022-0985-1608-A1, p.32]

Organization: National Association of Convenience Stores (NACS), NATSO, and SIGMA

The Proposed Rule Fails to Account for the Lifecycle Emissions of Electric Trucks.

Under the Proposal, electric trucks effectively serve as the only means of compliance with the standards in part because the Agency focuses solely on tailpipe emissions rather than the full lifecycle emissions of heavy-duty vehicles. This is a flawed approach. EPA should incorporate lifecycle GHG emissions into its analysis to fairly consider multiple technologies and ensure an accurate accounting of the lifecycle carbon intensity associated with particular fuels and technologies. This will facilitate continued investment in non-electric decarbonization technologies alongside investments in EV HD trucks, while simultaneously anticipating and addressing regional differences applicable to such emissions. [EPA-HQ-OAR-2022-0985-1603-A1, p. 7]

This analysis should include everything from the acquisition of critical minerals, the use of natural resources for refining and processing, engine and battery manufacturing, tailpipe emissions, and other confounding variables like prolonged internal combustion engine ('ICE') turnover rates and vehicle end-of-life consequences. Importantly, a lifecycle analysis of EVs will better equip EPA to understand the varying costs and emissions reductions associated with all technologies and best inform manufacturers and consumers of their options. [EPA-HQ-OAR-2022-0985-1603-A1, p. 7]

Though HD EVs do not directly have tailpipe emissions, other segments along the lifecycle of the EV do. The fuel source of an EV—a battery composed of carbon intensive minerals and the electricity generated to power the battery—produces meaningful emissions to which the Proposal turns a blind eye. Addressing the impact of climate change, however, requires mitigating emissions irrespective of whether they originate from a tailpipe, a mining operation, a power plant, or a battery plant. Consequently, emissions standards should account for the entire lifecycle emissions [EPA-HQ-OAR-2022-0985-1603-A1, p. 7]

EPA makes flawed assumptions regarding the total emissions impacts of the Proposal. While it claims that the overall analysis for combined downstream and upstream emissions 'likely underestimates the net emissions reductions that may result' from the Proposed Rule, EPA fails to substantiate this claim with sufficient data or detailed analysis. The Proposed Rule did not quantify emissions changes associated with producing or extracting crude or manufacturing refined fuels.15 [EPA-HQ-OAR-2022-0985-1603-A1, p. 7]

15 Proposed Rule at 26,044.

While diesel-powered trucks generally emit more carbon dioxide during operation, the emissions associated with the manufacturing of diesel-powered trucks are significantly lower than those emitted from both battery-electric and fuel-cell electric trucks.16 A recent examination conducted by Volvo provides an analogous case study of emissions resulting from light-duty vehicle manufacturing. The impacts are exaggerated for HD trucks. Volvo concluded that the 'accumulated emissions from the [m]aterials production and refining, [Lithium-ion] battery modules and Volvo Cars manufacturing phases of C40 Recharge are nearly 70 percent higher than for XC40 ICE.'17 Volvo explains, '[e]lectrification of cars causes a shift of focus from the use phase to the materials production and refining phase.'18 HD electric trucks, which require substantially more manufacturing components, have an even greater emissions impact. [EPA-HQ-OAR-2022-0985-1603-A1, pp. 7-8]

The Proposed Rule similarly fails to adequately evaluate local ambient air quality impacts from increased power generation. Though EPA modeled changes to power generation anticipated by the Proposed Rule as part of its upstream analysis, the Agency does not consider the potential degradation of air quality in areas in the direct vicinity of existing or new power plants.19 This is further complicated by the fact that emissions associated with electricity generation are not consistent across the U.S. In contrast to EPA's generalized emissions benefits, the emissions advantages of EVs are much lower in states with relatively high carbon profiles for electricity generation than those states with relatively low carbon profiles. Indeed, the Fuels Institute analyzed these differences and concluded that in states with high-carbon intensity electric generation, such as West Virginia, ICE vehicles produced decidedly fewer carbon emissions relative to EVs over the entire 200,000 mile life of the vehicles.20 Of course, the Report recognizes emissions advantages to EVs in those low-carbon states as well, but these differences further illustrate the importance of considering a more heterogenous approach to the HD freight industry. [EPA-HQ-OAR-2022-0985-1603-A1, p. 8]

19 Proposed Rule at 25,983.

20 Ricardo Inc., TRANSPORTATION ENERGY INSTITUTE, 'Lifecycle Analysis Comparison' (Jan. 2022) available https://transportationenergy.org/wp-content/uploads/2022/10/FI_Report_Lifecycle_FINAL.pdf.

The Proposed Rule also overlooks the emissions impacts from the substantial expansion of the electrical grid. While EPA credits emissions reductions from assuming the power sector will become cleaner over time using renewable generation and electricity storage (i.e., batteries), it ignores the impacts of building out that infrastructure. New power generation, renewable power generation, and energy storage require the same critical minerals necessary for EV batteries. Increased electricity demand compounds the stress on critical minerals. Indeed, copper and aluminum—both needed for HD electric trucks—are also the two main materials in wires and cables. Battery storage equipment for solar and other renewable energy sources rely on similar battery chemistries as HD electric trucks.21 The simultaneous spike in demand for materials such as copper and aluminum for both the grid and EV manufacturing will increase extraction and refining efforts globally, potentially exacerbating consequences on a regional level.22 By failing to consider geographic electricity generation differences and the potential benefits of a non-homogenized truck population, the Proposal misses the opportunity to most effectively respond to emissions concerns and, more importantly, could indirectly lead to increased emissions in certain regions. A full accounting of the relative advantages and disadvantages of the different vehicle technologies is necessary to ensure the Proposal harnesses the benefits of competition among different current and potential future vehicle technologies. [EPA-HQ-OAR-2022-0985-1603-A1, pp. 8-9]

21 And, as described above, higher prices on these materials could have a major impact on future grid investments. International Energy Agency, The Role of Critical Minerals in Clean Energy Transitions

(March 2022), 77–80, available at https://iea.blob.core.windows.net/assets/ffd2a83b-8c30-4e9d-980a-52b6d9a86fdc/TheRoleofCriticalMineralsinCleanEnergyTransitions.pdf.

22 The U.S. is almost entirely dependent on other countries, especially China, for materials essential to manufacturing heavy-duty electric trucks, meaning the Proposal may potentially raise national security concerns.

Organization: Natural Gas Vehicles for America (NGVAmerica)

NGVAmerica supports EPA finalizing regulations that achieve needed emission reductions and incorporate a strong fuel- and technology-neutral performance standard. Future standards must incorporate realistic expectations about the pace, cost, and deployability of technology, and to ensure success must encourage engine makers and vehicle manufacturers to deploy a variety of available, scalable, and cost-effective technologies. To achieve these objectives and drive manufacturers toward zero-emission technology, EPA must incorporate well-to-wheel emission or life-cycle assessments into its regulations. We therefore request that EPA develop and approve a method of calculating and certifying emission reductions related to the use of low-carbon and carbon-negative biofuels. [EPA-HQ-OAR-2022-0985-1522-A1, p. 1]

The time has come for EPA to fully embrace all low-carbon technologies and provide a level playing field in its regulations. EPA staff previously stated to NGVAmerica in meetings that the Renewable Fuel Standard Program already incentivizes low-carbon fuels like RNG and that its vehicle regulations are not intended for that purpose. EPA staff also has acknowledged in meetings with NGVAmerica that when it comes to greenhouse gas emissions, moving to a life cycle analysis (LCA) or well-to-wheels (WTW) approach would be preferable, and previously indicated as part of the proceedings for the 2012 light-duty GHG regulations that it would move away from the tailpipe only approach once automakers surpass sales of 200,000 vehicles. EPA under the Biden Administration, however, has abandoned that prior commitment. [EPA-HQ-OAR-2022-0985-1522-A1, p. 2]

There are ample studies that support the importance of evaluating well-to-wheel emissions. A September 2022 study published in the Journal Sustainable Energy & Fuels included the following:

The results show that in both the U.S. and EU markets, waste-streams-to-energy technologies, such as CNG production via AD of wet waste resources, offer the biggest opportunities to reduce WTW GHG emissions. …Drop-in renewable diesel fuels, produced from forest residues or wood waste feedstock via thermochemical conversion technologies, including FT and pyrolysis technologies, could potentially reduce GHG emissions more than 75% in both the U.S. and the EU, despite the varying energy efficiency of the conversion routes and feedstocks used.3 [EPA-HQ-OAR-2022-0985-1522-A1, pp. 3 - 4]

3 Journal of Sustainable Energy & Fuels, Decarbonization potential of on-road fuels and powertrains in the European Union and the United States: a well-to-wheels assessment, (Published Sept. 1, 2022) (Decarbonization potential of on-road fuels and powertrains in the European Union and the United States: a well-to-wheels assessment - Sustainable Energy & Fuels (RSC Publishing).

This report looks at benefits in the U.S. and Europe, references numerous other studies, and its authors include several prominent experts on greenhouse gas emissions. A White Paper entitled Smart CO2 Standards for Negative Emissions Mobility published by the European Biogas Associations references nearly a dozen studies with similar findings regarding emission reduction benefits and cost-effectiveness of RNG reductions. A copy of that document is included in Appendix A. [EPA-HQ-OAR-2022-0985-1522-A1, p. 4.] [See Docket Number EPA-HQ-OAR-2022-0985-1522-A1, pages 14-28, for Appendix A.]

Another excellent report on the importance of accounting for well-to-wheel emissions and life-cycle emissions was prepared in 2021 by Frontier Economics for NGVA Europe. That report was specifically prepared with the intention of highlighting the need for regulatory standards that account for well-to-wheel emissions. The frontier economics evaluation included a comparison based on conventional natural gas, 100 percent biomethane, and a mixture of 40 percent conventional natural gas and 60 percent biomethane. This study supports the contention that a mixture of biomethane of 60 percent biomethane is cost-competitive from a purchase perspective with electric vehicle technology while also delivering greater emission CO2 equivalent emission reductions. A copy of this report is included in Appendix B. [EPA-HQ-OAR-2022-0985-1522-A1, p. 4.] [See Docket Number EPA-HQ-OAR-2022-0985-1522-A1, pages 29-102, for Appendix B.]

A report4 prepared by Ramboll US Consulting, Inc. for the Western States Petroleum Association provides additional evidence on the cost-effectiveness and well-to-wheel benefits of natural gas vehicles and other low-emission technologies. The report evaluated California's plans to focus almost exclusively on electrification as the solution to address transportation related emissions including NOx emissions and greenhouse gas emissions. [EPA-HQ-OAR-2022-0985-1522-A1, p. 4]

4 Ramboll Multi-Technology Pathways Study - Western States Petroleum Association (wspa.org)

The report's executive summary includes the following:

- Expanded implementation of zero-emission and Low-NOx vehicles, coupled with increased introduction of renewable liquid and gaseous fuels, can deliver (as shown in Figures ES-1) and more cost-effective benefits than a zero-emission vehicle (ZEV)-only approach.
- As advanced low-emitting trucks are commercially available (citation omitted) to deliver benefits to communities sooner, multi-technology pathways can help achieve emission reductions without reliance on infrastructure and technology upgrades that will take years to resolve.
- There is growing potential for renewable fuels, including those with negative carbon intensity, to [sic] achieve GHG reductions, which CARB has not acknowledged fully in the MSS nor assessed the potential for early and cost-effective GHG reductions through these multi-technology vehicle pathways.
- Low-emission heavy-duty trucks are cost-competitive with (or cheaper than) battery electric vehicles (BEVs). This is true even though battery technology promises (such as greater energy density/lower cost) have not been adequately demonstrated and related transmission/distribution infrastructure cost have not been included in the state's analyses. [EPA-HQ-OAR-2022-0985-1522-A1, pp. 4 - 5]

In addition to the greenhouse gas emission benefits, it is important to note that virtually all new natural gas engines already achieve emission reductions of nitrogen oxides that surpass the reductions required by EPA recently finalized low-NOx rule for medium and heavy-duty vehicles. All new natural gas trucks and buses regardless of whether they operate on conventional natural gas or RNG therefore provide meaningful reductions of this important pollutant. EPA's regulations provide averaging, banking, and trading credits to manufacturers that exceed emission requirements (i.e., deliver lower emitting engines). The new regulations are expected to further encourage the development and sale of natural gas engines. The incentive for lower polluting natural gas engines however could be offset by this rulemaking if EPA does not amend its proposal to incorporate well-to-wheel, greenhouse gas emission benefits of NGVs. [EPA-HQ-OAR-2022-0985-1522-A1, p. 17]

Organization: Neste US

I. A LIFE CYCLE ANALYSIS BETTER ACCOUNTS FOR A VEHICLE'S GHG EMISSIONS

While regulating emissions from vehicle tailpipes makes sense for relatively short-lived criteria pollutants like particulate matter and nitrogen oxides, a life cycle analysis is necessary to fully account for a vehicle's GHG emissions in two important ways. [EPA-HQ-OAR-2022-0985-1615-A1, p. 1]

First, while electric vehicles (EVs) and hydrogen fuel cell electric vehicles (FCEVs) have no tailpipes, their production and daily use both produce GHG emissions. Those emissions come both from the fossil-fueled power plants that charge EVs or produce hydrogen for FCEVs, as well as the substantial resources needed to produce their EV batteries. Unfortunately, the Agency does not consider those life cycle emissions in this proposed rule. Consequently, the proposal favors technologies that merely shift emissions upstream. [EPA-HQ-OAR-2022-0985-1615-A1, p. 1]

Second, while the combustion of fossil fuels and biofuels both emit CO2, their contribution (or lack thereof) to the concentration of CO2 in the atmosphere is quite different. As EPA noted in the development of an accounting framework for biogenic CO2 from stationary sources, "fossil and biogenic carbon interact with the overall carbon cycle on very different time scales."1

"CO2 emissions from the consumption of fossil fuels will inevitably increase the amount of carbon in the atmosphere on policy-relevant time scales, but such an outcome is not inevitable with the consumption of biologically based feedstocks. The amount of biologically based feedstocks consumed [...] during a year may be partially or completely balanced by the amount of feedstock that grows during the year.2 [EPA-HQ-OAR-2022-0985-1615-A1, pp. 1 - 2]

1 U.S. Environmental Protection Agency, Accounting Framework for Biogenic CO2 Emissions from Stationary Sources, September 2011 https://www.epa.gov/sites/default/files/2016-08/documents/biogenic-co2-accounting-framework-report-sept-2011.pdf

2 Ibid

For both of these reasons, the Agency should reconsider the methodology used to calculate GHG emissions from heavy-duty vehicles. Applying a life cycle analysis, instead of counting emissions solely from a vehicle's tailpipe, would more accurately reflect the relative climate impacts of each technology. [EPA-HQ-OAR-2022-0985-1615-A1, p. 2]

Organization: POET

EPA is not limited to considering only tailpipe emissions in developing its proposed standards. Indeed, the rule would arguably be arbitrary and capricious if it were only to address tailpipe emissions. EPA should also credit lifecycle GHG emissions reductions. The reason for this is straightforward. GHGs are not like other regulated air pollutants: they are a global contaminant. The endangerment finding that motivated EPA to issue the Proposed Rule recognized that GHGs are problematic wherever and whenever they are emitted, not just when they are released from a single point in their lifecycle such as at a tailpipe. Focusing only on tailpipe emissions ignores the significant lifecycle GHG emissions reductions that renewable fuels offer by displacing fossil fuels. It also ignores that tailpipe-focused solutions, such as electrification or hydrogen-based technologies—though they are becoming greener—still largely depend on fossil fuels and carbon-intensive processes that release significant upstream emissions. [EPA-HQ-OAR-2022-0985-1528-A1, p. 2]

It is also worth noting that, even if EPA does not adopt the lifecycle approach to assess GHG emissions from heavy-duty vehicles, it could still distinguish between biogenic and fossil carbon sources and credit the former as carbon neutral. This approach would at least recognize the carbon neutrality of combusting renewable fuels. [EPA-HQ-OAR-2022-0985-1528-A1, p. 2]

EPA Has the Authority to Set GHG Emissions Standards Based on Lifecycle GHG Emissions Reductions, Rather Than Standards Based Only on Reducing Tailpipe Emissions. [EPA-HQ-OAR-2022-0985-1528-A1, p. 7]

EPA has broad authority under Clean Air Action 202 to set vehicle emissions standards as it sees fit. That authority necessarily extends not only to tailpipe emissions reductions; it also includes other emissions in the fuel and vehicle manufacturing lifecycle. [EPA-HQ-OAR-2022-0985-1528-A1, p. 7]

Clean Air Act 202(a) allows EPA to set vehicle emissions standards for any air pollutant the Administrator determines may reasonably be anticipated to endanger public health or welfare. EPA may regulate emissions of such a pollutant ‘from any class or classes of new motor vehicles or new motor vehicle engines.’19 The statute does not expressly limit EPA to regulating emissions only from vehicle tailpipes or the engines themselves. Instead, it is broadly worded to include emissions of any air pollutant that ‘cause[s], or contribute[s] to, air pollution.’20 Lifecycle (upstream) emissions, especially for GHGs, fit that description,21 as EPA itself has recognized.22 [EPA-HQ-OAR-2022-0985-1528-A1, pp. 7-8]

19 42 U.S.C. 7521(a)(1).

20 Id.

21 Other constraints in 202(a) do not bar EPA from considering lifecycle emissions. The statute states that EPA’s standards must apply to vehicles and engines during their useful life, cannot take effect until after a time that the EPA Administrator determines is necessary for the development and application of the technologies needed to meet EPA’s standards, and must consider costs. Id. 7521(a). None of those provisions prohibit EPA from considering a vehicle’s lifecycle GHG emissions in regular a class or classes of motor vehicles.

22 Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles, 88 Fed. Reg. 29184 at 29197 (May 5, 2023).

Other provisions setting specific requirements for certain vehicles and pollutants do not apply. GHGs are not like 'hydrocarbons, carbon monoxide, oxides of nitrogen, and particulate matter.'23 EPA's general 202(a) authority controls. And in Massachusetts v. EPA, the Supreme Court confirmed that EPA has broad authority to regulate additional, non-specified pollutants, provided EPA determines they endanger the public health or welfare.24 [EPA-HQ-OAR-2022-0985-1528-A1, p. 8]

23 See 42 U.S.C. 7521(a)(3)(A)(i).

24 See Massachusetts v. EPA, 549 U.S. 497, 506-07 (2007).

Courts interpreting 202 have also found that EPA has significant discretion. That discretion is necessary to allow EPA to leverage its expertise to address the many complicated scientific, design, and engineering concerns regarding how best to reduce air pollution. The D.C. Circuit has observed that '[m]anufacturers produce a wide variety of motor vehicles of different sizes, some using different engine technologies resulting in unusual emission characteristics.'25 If EPA's authority to set emissions standards is flexible enough to address those varying vehicle characteristics, it should be similarly flexible to allow EPA to credit lifecycle emissions reductions. [EPA-HQ-OAR-2022-0985-1528-A1, p. 8]

25 Nat. Res. Def. Council, Inc. v. U. S. Envtl. Prot. Agency, 655 F.2d 318, 322 (1981).

EPA's approach in the Proposed Rule is consistent with this view. EPA observes that, '[s]ince the earliest days of the CAA, Congress has emphasized that the goal of section 202 is to address air quality hazards from motor vehicles, not to simply reduce emissions from internal combustion engines to the extent feasible.'26 While EPA is referring to electric vehicles, that sentiment applies to other technologies as well. The goal is not simply to reduce ICE emissions. It is to address air quality hazards from carbon dioxide emissions associated with classes of vehicles. One ton of GHG emissions causes the same harm whether resulting from tailpipe emissions or upstream emissions. And, in both cases, the emissions would not occur but for the production of a class or classes of vehicles. [EPA-HQ-OAR-2022-0985-1528-A1, pp. 8-9]

26 88 Fed. Reg. at 25950.

Therefore, GHG emissions from any phase of a vehicle's lifecycle should be equally subject to 202(a). Biofuels address those hazards caused by GHG emissions by reducing emissions on a lifecycle basis. At a minimum, the benefits generated by bioethanol in reducing lifecycle GHG emissions should be recognized through a crediting mechanism or other compliance flexibility benefits. [EPA-HQ-OAR-2022-0985-1528-A1, p. 9]

EPA's discussion of the legislative and regulatory history regarding automotive emissions under the Clean Air Act repeatedly refers to alternative power sources and fuels.27 Nothing in the record suggests that alternative power sources excluded other low-carbon alternatives, such as renewable fuels. Both the goals of the Clean Air Act and legislative and regulatory history support EPA's broad authority to address motor vehicle carbon emissions beyond just electrification. [EPA-HQ-OAR-2022-0985-1528-A1, p. 9]

27 Id.

EPA's proposed rule for light-duty and medium-duty vehicles, in fact, confirms that EPA believes it can regulate upstream emissions under 202. EPA notes that current regulations would require 'upstream emissions accounting for BEVs and PHEVs as part of a manufacturer's compliance calculation' to begin in MY 2027.28 EPA is proposing to eliminate that upstream emissions accounting.29 But the fact that the current regulations do account for upstream emissions demonstrates that EPA knows it has the power to account for upstream, i.e., lifecycle emissions. EPA clearly has this authority. EPA is not limited only to regulating tailpipe emissions. [EPA-HQ-OAR-2022-0985-1528-A1, p. 9]

28 88 Fed. Reg. at 29197.

29 Id.

Incorporating lifecycle emissions reductions into the Proposed Rule is the best reading of 202 for carbon dioxide as an air pollutant, because, unlike other regulated substances, carbon dioxide (as a GHG) is a global, rather than a local, pollutant, meaning that it does not necessarily cause adverse effects in the specific places where emitted. GHGs instead result in adverse effects at a global scale when they enter the atmosphere and linger, contributing to rising sea levels and eroding coastlines, flooding, more frequent and intense storms, melting polar icecaps, and droughts. The proposed standards that concentrate only on GHG tailpipe emissions could end up promoting technology pathways that would eliminate tailpipe emissions from the transportation sector while inadvertently increasing lifecycle GHG emissions. A GHG emissions rule that results in an increase in net GHG emissions is the very definition of arbitrary and capricious. [EPA-HQ-OAR-2022-0985-1528-A1, p. 9]

Failing to Account for Lifecycle Emissions Could Lead to Absurd Results. [EPA-HQ-OAR-2022-0985-1528-A1, p. 11]

EPA risks implementing a rule that leads to absurd results if it omits the lifecycle emissions benefits of biofuels. The rule could end up incentivizing transportation fuels that greatly increase upstream carbon emissions in the near- and medium-term. Today, electricity generation remains largely fossil-based. Increasing electricity demand in the near-term with ZEVs could drive up fossil fuel use while the country sorts through the many challenges associated with developing renewable electric generating facilities and the transmission capacity to support the clean power those facilities will produce.33 Additionally, EPA ignores that the higher demand for electricity will lead to increased emissions of both methane and nitrous oxide, potent GHGs that are released when electricity is generated using fossil fuels.34 BEVs will also require extracting certain metals at a far larger scale. That extraction can be energy-intensive and much of it occurs in countries where mining can severely degrade the environment, including by clear-cutting rainforests that store vast amounts of carbon.35 [EPA-HQ-OAR-2022-0985-1528-A1, p. 11]

33 See Attachment A, Trinity Consultants, Review of U.S. EPA's Proposed Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles—Phase 3, at 8-10 (June 16, 2023).

34 Id. at 9 (noting that the 'failure to properly address the overall impact of the Proposed Rule on methane and nitrous oxide emissions overstates the actual GHG emissions reduction which are shown in Table 4-15 of the DRIA').

35 J. Emont, EV Makers Confront the 'Nickel Pickle,' Wall Street Journal (June 4, 2023), https://www.wsj.com/articles/electric-vehicles-batteries-nickel-pickle-indonesia-9152b1f (describing the EV makers shift from cobalt mining in the Democratic Republic of Congo to nickel mining by clear-cutting Indonesian rainforests).

Incorporating renewable fuels could also shore up the rule against a challenge that it violates West Virginia v. EPA. That case overturned the Clean Power Plan because the Supreme Court determined that the Plan went too far toward requiring a shift from conventional sources of electricity generation to renewables, which in the Court's view, would have substantially restructured the American energy market.42 Crediting biofuels in the Proposed Rule would have the opposite effect. Biofuels are already a key component of the American transportation sector. This is not the case in which, as the Supreme Court stated in West Virginia v. EPA, the 'history and the breadth of the authority that [EPA] has asserted, and the economic and political significance of that assertion, provide a reason to hesitate before concluding that Congress meant to confer such authority.'43 Congress has given EPA plain authority to incentivize biofuels under the Clean Air Act and RFS. Those preexisting programs have encouraged producers to make billions of gallons of renewable fuels every year. Congress' mandate was clear. The RFS was meant to encourage the production of renewable fuels that are 'used to replace or reduce the quantity of fossil fuel present in a transportation fuel.'44 EPA must interpret its 202 authority in a manner that is consistent with the other directives that Congress has imposed on the transportation sector. [EPA-HQ-OAR-2022-0985-1528-A1, pp. 12-13]

Organization: Strong Plug-in Hybrid Electric Vehicle (PHEV) Coalition

In addition, CARB funded research by UC Davis,13 shows a PHEV 60 has the same life cycle GHG emissions as a Tesla model S because of the weight of the Tesla and it has fewer GHG life cycle emissions than a heavier BEV with 400- or 500-mile AER. Toyota's publicly available tool also correctly shows this result.14 Furthermore, the UC Davis analysis does not include battery manufacturing GHG emissions. Using data from the USDOE cradle to grave analysis,15we estimate that adding 350 miles more of AER adds about 10 grams per mile of GHG emissions to the above analysis for a light duty EV. Further, a flex fuel vehicle requirement to enable low carbon fuels for these stronger PHEVs would further lower their life cycle GHG. The figure below further illustrates the large emissions from battery manufacturing for light duty BEVs and PHEVs and helps illustrate the issue for heavy duty BEVs and PHEVs. [EPA-HQ-OAR-2022-0985-1647-A2, pp. 13 - 14.] [Refer to the graph on p. 14 of docket number EPA-HQ-OAR-2022-0985-1647-A2.]

15 See page 143 at https://greet.es.anl.gov/publication-c2g-2016-report. Extrapolate from 210 to 410-mile all electric range and divide by 150,000-mile vehicle life.

Organization: Transfer Flow, Inc.

A singular fixation focusing only on tailpipe emissions reduction does not consider important life-cycle emission analysis.3 Vehicular emissions should be considered from the cradle to the grave, from manufacturing and usage to end-of-life disposal of both the vehicle and the energy source used to power the vehicle or equipment. Requiring new vehicles sold to either be battery electric vehicles (BEVs), plug-in electric hybrids (PHEV), or fuel-cell battery electric vehicles crowds out and ignores other viable and proven near-zero technologies. [EPA-HQ-OAR-2022-0985-1534-A1, p. 3]

3 https://www.youtube.com/watch?v=S1E8SQde5rk

Implementation of any and all available near-zero technologies should be encouraged for a multitude of reasons. All near-zero technologies should be ramped up and implemented as quickly as feasible in order to help meet the EPA's pollution prevention goals. Encouraging the sales of all new vehicles or equipment to contain some sort of electric vehicle technology and, therefore, also contain a heavy-duty battery instead of encouraging the adoption of the plethora of currently available near-zero technologies is a disservice to the citizens of our great country. [EPA-HQ-OAR-2022-0985-1534-A1, p. 3]

Organization: Valero Energy Corporation

E. EPA has not adequately considered the consequences of the proposed rule with regard to byproducts and coproducts of petroleum refining.

In its consideration of demand destruction on domestic petroleum refining, EPA fails to consider the full breadth of products made from petroleum that are consumed every day in the United States. A partial list of more than 6,000 products made from oil and gas is provided in Table 1. [EPA-HQ-OAR-2022-0985-1566-A2, p. 44.] [See Table 1, Products Made from Oil and Gas, on page 45 of docket number EPA-HQ-OAR-2022-0985-1566-A2.]

EPA fails to consider how the U.S. will source asphalt to pave its roads, tires to support its electrified transportation sector, and a multitude of other consumer products and pharmaceuticals that are integral to day-to-day life of Americans if domestic petroleum refining is phased out or disrupted.212 For example, the amount of asphalt produced is in direct correlation to the amount of liquid transportation fuel refined. Asphalt is a co-product and cannot be independently manufactured.213 The loss of domestic asphalt production would force rail transport of higher volumes and from further distances, driving up costs and GHG emissions, and compounding the burden on communities already impacted by excessive train lengths that in some cases have resulted in fatalities.214 If the United States' asphalt needs were to exceed the potential for railed supplies, incremental asphalt would need to be imported by marine vessel, likely from Asia. EPA's proposal neither accounts for the GHG burdens being outsourced by EPA's policies nor the logistics-related increases in GHG emissions. [EPA-HQ-OAR-2022-0985-1566-A2, p. 44]

212 See Table 1, below.

213 https://www.wsj.com/articles/you-cant-build-roads-without-oil-fossil-fuel-refining-asphalt-renewables-synthetic-materials-consumer-products-biden-11664982934

214 https://www.washingtonpost.com/nation/interactive/2023/long-trains-block-intersections-paramedics/

Further, the proposed rule fails to account for how the amount of sulfur available in the United States will be adversely impacted. The chemical can be used in "construction materials, traditional batteries, rubber (vulcanization), pharmaceuticals, paper bleaching, water treatment, cosmetics/skin care, detergents,…and most importantly fertilizers."215 Most of the world's sulfur is now produced through the Claus Recovery Method, which is used at oil and natural gas refineries to keep sulfur dioxide from escaping into the atmosphere.216 On average, this process in the U.S. alone creates 8 million tons of sulfur every year.217 Without this product, there would be a sulfur deficiency in many crops throughout the U.S.218 It is a key ingredient in phosphate fertilizers with nearly 50% of sulfur supply worldwide being used in this manner.219 Total U.S. economic impact is about $130 billion with 487,330 fertilizer industry related jobs in the U.S. with wage earnings of $34.31 billion.220 [EPA-HQ-OAR-2022-0985-1566-A2, pp. 44 - 45]

Sulfur is also used in manufacturing copper and lithium for batteries. For copper smelting in the U.S., "approximately 1.4 million tons of [sulfur] is required."221 For the electric vehicle future that some agencies anticipate, an additional 85,000 tons of sulfur would be needed in only two years for copper production alone.222 For lithium, the "crushed ore is leached for several days with diluted [sulfuric] acid."223 With current projections for the lithium need, it is possible 21% of current sulfur will be used in the process.224 [EPA-HQ-OAR-2022-0985-1566-A2, p. 45]

This list above from the U.S. DOE makes clear that "car battery cases," "car enamel" and "automotive parts" are "products made from oil and natural gas." Petroleum products have been key components of EV innovation, making vehicles lighter and more efficient through the application of plastics, engineered polymers, and fiber-reinforced composites integral to EV design.226 EVs need petrochemicals, and petrochemicals will continue to play a critical role in further reducing the weight of EVs, which will help increase their range.227 The HD Phase 3 GHG Rule should not only account for leakage associated with the production of petrochemicals necessary to produce EVs, but also analyze the impact discontinued oil and refining production will have on the U.S.'s ability to encourage EV production to scale with its proposals. [EPA-HQ-OAR-2022-0985-1566-A2, p. 46]

III. Transportation decarbonization should embrace all technologies.

Exclusive reliance on ZEV technologies ignores both the full lifecycle GHG emissions of ZEVs and the benefits of low-carbon liquid fuels and other emerging technologies. EPA should evaluate the merits of all fuels and vehicle technologies on a full lifecycle basis. [EPA-HQ-OAR-2022-0985-1566-A2, p. 50]

Despite being treated by regulators as zero-emission vehicles, electric vehicles are not emissions free – in fact, when it comes to HDV, they are not even the most effective technology available today to reduce GHG emissions. Low carbon fuels have been and will continue to be essential to decarbonization of the transportation sector. Over the past few years, commenters and other entities have provided EPA information about other available and emerging technologies. EPA should consider information provided and seek out additional information in order to complete a robust analysis of available and emerging technologies that can include liquid fuels and will achieve similar emission reductions but involve less risk than a ZEV only approach. [EPA-HQ-OAR-2022-0985-1566-A2, p. 50]

For example, a lifecycle analyses conducted by Southwest Research Institute finds that GHG emissions from a heavy-duty internal combustion engine vehicle ("ICEV") that runs on renewable diesel with a carbon intensity of 25 gCO2e/MJ results in 60% fewer lifecycle GHG emissions when compared to a battery electric vehicle ("BEV"), as illustrated by Figure 9. [EPA-HQ-OAR-2022-0985-1566-A2, p. 50. See Figure 9, Heavy-Duty Long-Haul Vehicle Lifecycle Emissions, on page 51 of docket number EPA-HQ-OAR-2022-0985-1566-A2.]

California has felt the real-world implications of its climate policy with rolling blackouts and sky-high energy prices; it is now implementing a broader approach to GHG reductions that includes investment in carbon capture and fossil fuel infrastructure to ensure future system reliability. EPA's proposal need not focus on an arbitrary rejection of continued reliance on liquid fuels infrastructure; rather, it can and should present a transparent, technology-neutral approach that allows for innovation that would better serve America's most vulnerable communities. [EPA-HQ-OAR-2022-0985-1566-A2, p. 51]

EPA should include consideration of emerging innovative approaches and new technologies for reducing GHG emissions from ICEVs, such as on-board carbon dioxide (CO2) capture and subsequent sequestration. Analysis from a Northwestern University research team has shown that cost-effective diesel tractor trucks combined with well-developed on-board carbon capture technologies offer a practical way to make large freight vehicles carbon neutral when running on fossil fuels and even carbon negative when running on biofuels.235 Given existing liquid fuel infrastructure, "rapid adoption of such vehicles should be possible and CO2 emissions can be continuously decreased."236 Further, EPA should consider how to reconcile its efforts in the vehicles rules with the mandates of the RFS, and should reconsider how it evaluates ICE vehicles' GHG emissions so that appropriate recognition is given to lifecycle reductions achieved through the RFS, state carbon-intensity reduction measures such as the California Low

Carbon Fuel Standard, and emerging measures such as carbon sequestration. [EPA-HQ-OAR-2022-0985-1566-A2, pp. 51 - 52]

235 Schmauss, Travis A. & Barnett, Scott A, "Viability of Vehicles Utilizing On-Board CO2 Capture," ACS Energy Letters 2021, 6, 8, 3180-3184 (August 18, 2021) https://doi.org/10.1021/acsenergylett.1c01426.

236 Id.

EPA's asserted authority also implicates another key "consideration[] of national policy": national security. NHTSA has acknowledged that the United States "has very little capacity in mining and refining any of the key raw materials" for electric vehicles. 86 Fed. Reg. 49,602, 49,797 (Sept. 3, 2021). And unlike biofuels and petroleum, most of the supply of critical components of batteries and motors for electric vehicles is controlled by hostile or unstable foreign powers, in particular China. Shifting to electric vehicles would thus make the American automotive industry critically dependent on one of the Nation's primary geopolitical rivals.

Specifically, China is by far the largest source of graphite, which is used for lithium-ion batteries, and rare-earth elements like neodymium, which are used for permanent-magnet motors. By some estimates, a transition to electric vehicles would raise demand for graphite by 2500% and rare-earth elements by 1500%. International Energy Agency, *The Role of Critical Minerals in Clean Energy Transitions* 97 (March 2022). Another key component of lithium batteries, cobalt, is controlled by the Democratic Republic of the Congo, which is implicated in significant human-rights concerns (including child labor), and Chinese state-owned enterprises have a controlling interest in 70% of Congo's cobalt mines. [EPA-HQ-OAR-2022-0985-1566-A2, pp. 55 - 56]

Organization: Western States Trucking Association (WSTA)

We have been extensively involved in the efforts to change both California and federal emissions standards and request that USEPA conduct a full life-cycle assessment of battery electric vehicles ("BEV") before adopting the proposed rule. [EPA-HQ-OAR-2022-0985-1533-A1, p. 1]

Our request is motivated by our conclusion that BEVs are not "zero emissions" and have significant environmental and social impacts that USEPA should not ignore. The attached documents calculate that BEVs have a carbon intensity of 62 to 90 (gCO2e/MJ) in California when combining the energy required to produce electricity to charge the BEVs and the manufacturing process of the battery from the mining of the minerals though the battery and vehicle manufacturing. [Attachments "Western States Trucking Association Comments to California Air Resources Board" and "Comments to the California Air Resources Board regarding environmental justice and the technical report 'Lifecycle Greenhouse Gas Impacts of Electric Vehicle Manufacturing'" can be found on pages 3-40 of EPA-HQ-OAR-2022-0985-1533-A1.] This has implications for a national rule as USEPA proposes.

Organization: Westport Fuel Systems

Well To Wheels Emissions Compared to Tailpipe Only Measurements

We urge the EPA to consider the merits of well to wheels (WTW) emissions rather than tailpipe only emissions in the evaluation of technologies in the rule. For example, a vehicle equipped with an HPDI fuel system using RNG provides a CO2 reduction of approx. 20% tank to wheels (mode dependent) compared to a reference diesel vehicle. It also has low CH4 emissions (current European product: < 0.5g/kWh as per Euro VI). The EPA GHG Standards being a CO2 equivalent standard encompassing CH4, it accomplishes the over-arching objective of reducing GHG emissions. However, on a WTW basis, the GHG reductions – including CO2, CH4 and N2O measured on a CO2 equivalent (CO2e) basis – realized with an HPDI system fuelled by RNG are far greater and more accurately represent the actual vehicle emissions. Indeed, the large benefits of RNG are derived from the Well To Tank portion. In California, the RNG vehicle fuel portfolio has been carbon negative since 20201. In North America overall, 69% of all on-road fuel used in natural gas vehicles in 2022 was RNG2. According to NGVAmerica, RNG used as a transportation fuel offset a total of 5.63 million tons of CO2e in 2022. [EPA-HQ-OAR-2022-0985-1567-A1, p. 4]

1 Source: Fly in pg 1 (ngvamerica.org)

2 Source: NGV RNG Driving Down (ngvamerica.org)

The full impact of vehicle CO2 emissions is represented best by a full lifecycle analysis or WTW emissions rather than tailpipe only measurements. We encourage the EPA to consider how the Phase 3 Rule can reflect the value of using low carbon fuels, such as RNG and green hydrogen in the calculations of zero emissions vehicles. While a tailpipe measurement gives a particular result, the measurement cannot account for the full impacts of the fuel used, even for BEVs. [EPA-HQ-OAR-2022-0985-1567-A1, p. 4]

EPA Summary and Response:

Summary:

Notwithstanding EPA's explicit statements that it was "continuing and … not reopening the existing approach … that compliance with the vehicle exhaust CO2 standards is based on CO2 emissions from the vehicle," 88 FR at 25956/1, a number of commenters maintained that lifecycle GHG emissions should be reflected in the emission standards themselves as well as in the compliance regime for the standards (i.e., certification). These commenters included fuel suppliers, fuel producers, several fleets and dealers, and a few environmental groups. No entity regulated by this rulemaking raised this issue. In addition, no commenter questioned the appropriateness of EPA considering upstream emissions as part of its overall assessment of CO_2 emission impacts, non-CO_2 emission impacts, or use in cost-benefit calculations. Borg Warner explicitly endorsed EPA's approach to counting BEVs and FCEVs as zero emitting for standard setting and compliance purposes.

The remainder of this section addresses exclusively the issue of life cycle in the standard setting process and in determining compliance with standards. Comments relating to EPA's consideration of upstream emissions in calculating emission impacts are addressed in section 13 of this document and other sources there cited.

A threshold issue addressed by some of the commenters is whether EPA has the legal authority to predicate using some type of lifecycle approach in standard setting. Some of these commenters (Clear Flame, POET) cited the discretion afforded by CAA section 202 (a) (1).

Other commenters cited CAA sections 202 (a)(3)(A) and 202 (a)(4)(A) and (B) (Clean Fuels Development Coalition, AFPM).

Most of these commenters' arguments were based on considerations of policy. They point out that ZEVs in fact have greenhouse gas emissions associated with their production and their fuel source, i.e., emissions upstream of the vehicle tailpipe (and some commenters would consider downstream emissions as well, such as emissions attributable to battery disposal). Given these emissions, they maintain, it is more consistent with the Act's emission reduction goals, and the technology-neutral basis of the Phase 3 rule, to account for those emissions in the standards (e.g., comments of ACEEE, AmFree, Delek, Clear Flame). Certain proponents of alternative fuel use presented studies and other information which they characterized as showing that ICE vehicles powered by various types of biofuels would emit less than a comparable BEV vehicle, and, in any case, alleged that emission reductions from alternative fuel-powered vehicles would accrue immediately rather than after fleet turnover. (Comments of Alliance for Vehicle Efficiency, ACEEE, API, Valero.) Some commenters went further and argued that EPA would be acting arbitrarily by ignoring lifecycle impacts in the standards, since this would amount to just moving pollution around rather than reducing it, and would otherwise arbitrarily fail to solve the problem the rule is addressing. (Comments of American Fed. of Petroleum Mfr's, POET).

Commenters were divided as to how a lifecycle approach could be reflected in the standards. Indeed, it was not always clear if the commenters intend for the approach only to apply to standards for ZEVs, or for all vehicles. With respect to ZEVs, suggestions ranged from accounting only for GHG emissions from the electricity generating source (potentially including an accounting for electricity lost in transmission and distribution), to emissions from battery manufacture, battery disposal, electricity supply chains, and mining of materials critical to battery production (including from overseas mining venues). (e.g., Comments of AFPM, API, National Ass'n of Convenience Stores, Western Trucking, Lynden, Valero Energy Corporation.) Commenters were unclear as to whether their suggestions applied to GHG emissions only, or to other pollutants as well (although some pointed out that GHGs are exceptional, being global pollutants, such that a lifecycle accounting was justified). (Comments of Clear Flame, Delek.)

Some of these same types of comments addressed FCEVs and Hydrogen ICE vehicles:

- AVE noted that EPA's narrow focus on tailpipe emissions means that EPA does not recognize H2-ICE vehicles that use a pilot ignition for combustion as ZEVs, even though H2 ICEVs reduce CO2 emissions compared to today's diesel trucks. Though ACEEE observed that EPA proposed to expand the definition of ZEV to include H2 ICEVs.
- ACEEE described problems with considering H2-fueled vehicles as ZEVs, asserting that this strategy adds to the risk of zero-upstream accounting (i.e., not considering lifecycle emissions). They believe that upstream emissions should be accounted for in ZEV compliance values and, if EPA is not prepared to do so by MY 2027, then EPA could phase in a remedy during the timeframe of the Phase 3 rule.
- Ben Banks suggested there are possible benefits to focusing on hydrogen or other fuels like renewable diesel, when considering a total lifecycle carbon footprint. Hexagon Agility similarly asked for consideration of emissions credits for other clean fuels like renewable natural gas. ClearFlame believes the rule should not be limited to electric and hydrogen vehicles and should treat biogenic carbon emissions from biofuels as zero-emissions at tailpipe.

- Chevron cited a study that showed that lifecycle GHG emission from various HD powertrain technologies vary based on production pathway, suggesting that multiple factors should come into play when making vehicle choices.
- CFDC noted the term ZEV is misleading, given that ZEVs have upstream emissions. Lubrizol also called for lifecycle emissions accounting. MFN noted that a lifecycle analysis, including for all forms of hydrogen, is necessary to consider localized environmental justice harms. Neste, POET, and Westport stated that if emissions from hydrogen production are not accounted for, there is merely a shift in emissions from tailpipe to upstream.

These comments are summarized and responded to broadly throughout this section. Additional comments related to calculating emissions impacts associated with upstream hydrogen are in Section 13.

Several commenters noted that EPA also did not consider emissions from mining and resource extraction processes as well as from battery production:

> *AmFree et al.: The International Energy Agency's discussion of emissions from mining illustrates this point. According to the IEA, "the production and processing of energy transition minerals are energy-intensive" and involve "relatively high emissions." For this reason, producing an electric vehicle is a more carbon- intensive process than producing a conventional one.*

> *AFPM: The need for expanded grid capabilities simultaneous to expanded ZEV production places a more pressing demand on materials like copper and aluminum thereby increasing extraction and refining efforts throughout the global market.*

> *AFPM: The mining sector will also need to grow exponentially to meet ZEV demand as anticipated, and required, by the Proposed Rule. Mining is an energy- and environmental resource-intensive activity. … One study demonstrates that the steps for extracting, and processing critical minerals are responsible for approximately 20 percent of the lifecycle GHG emissions.*

> *Steven G. Bradbury: But they completely ignore the very large increase in carbon dioxide emissions that would necessarily occur from the projected expansion in the production of EV batteries.*

Response:

EPA reiterates, as it did at proposal, that it is not reopening the issue of a lifecycle approach to Phase 3 emission standards. At the same time, EPA has a legal obligation to respond to the comments it receives. In responding, EPA notes that we are not here "undertak[ing] a serious, substantive reconsideration of the existing" position. *Growth Energy v, EPA*, 5 F. 4th 1, 21 (D.C. Cir. 2021). The following responses reflect EPA's prior statements addressing this issue, not any type of substantive reassessment. See *Pub. Emps. for Env't Resp. v. EPA*, 77 F. 4th 899, 913 (2023) ("PEER cites no cases, and we are aware of none, in which an agency reopened an issue by merely responding to a petition for rulemaking submitted by a third party," citing *Am. Rd.& Transp. Builders Ass'nv. EPA,* 705 F. 3d 453, 457 (D.C. Cir. 2013) ("[A]n agency's response to a petitioner's comments cannot provide the sole basis for reopening").

EPA is adhering to the approach from Phase 1 and 2: the section 202(a)(1) GHG emission standards for all heavy-duty vehicles, including ICE vehicles and ZEV, are based on emissions from the vehicle, and these are the standards to which the vehicles are certified. Indeed, this has been EPA's consistent approach to heavy-duty vehicle and engine standards since EPA began regulating the HD industry five decades ago: to establish standards and compliance based on emissions from the vehicle itself, not from other upstream or downstream sources. As EPA stated in the Response to Comments in the recent HD2027 final rule,

> EPA ... disagrees that it is required to perform a lifecycle analysis of vehicle and fuel production before setting engine and vehicle emission standards, or to treat emissions of air pollutants attributable to electricity generation, or the mining, production or disposal of batteries for electric vehicles, as emissions "from" new motor vehicles under CAA section 202(a). The Clean Air Act's entire structure evidences a clear divide between stationary sources (regulated under other sections of the Act, especially Title I) and mobile sources (regulated under Title II). There may be indirect impacts of stationary source regulation on mobile sources and vice versa, and it may be appropriate to consider those impacts in some circumstances. But it would be inappropriate and contrary to the plain text of the Clean Air Act to conflate the consideration of indirect impacts, when appropriate, with actually treating stationary source emissions as mobile source emissions. Cf. Coal. for Responsible Regul., Inc. v. E.P.A., 684 F.3d 102, 128–29 (D.C. Cir. 2012) ("EPA was not arbitrary and capricious by not considering stationary-source costs in its analyses"). EPA interprets the Clean Air Act as generally directing EPA to consider regulation of emissions for each sector according to the applicable statutory requirements for each program. While EPA may also elect to consider upstream emissions in certain appropriate circumstances, such consideration is not required by statute.[857]

EPA has also spoken to the enormous practical difficulties of trying to incorporate a lifecycle approach into the standard setting process. First, "even if we were able to accurately and fully account for life cycle impacts of one technology... this would not allow us to address life cycle emissions for other technologies...Given the complexity of these rules and the number of different technologies involved, we see no way to treat the technologies equitably". 81 FR at 73528/2. Commenters to this proposal did not address this concern. Nor did they address EPA's second reason for not considering the approach: "[t]his rulemaking ...is not regulating manufacturing processes, distribution practices, or the locations of manufacturing facilities. And yet each of these factors could impact life cycle emissions. So while we could take a snapshot of life cycle emissions at this point in time for specific manufacturers, it may or may not have any relation to life cycle emissions in 2027 (sic), or for other manufacturers." Id.

---

[857] HD2027 RTC section 19.3 at 1180-81, available at https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P1016AMU.pdf. See also *Motor & Equip. Mfrs. Ass'n, Inc. v. E.P.A.*, 627 F.2d 1095, 1118 (D.C. Cir. 1979) ("there is no indication that Congress intended section 202's "cost of compliance" consideration to embody "social costs" of the type petitioners advance. Every effort at pollution control exacts social costs. Congress, not the Administrator, made the decision to accept those costs. Section 202's "cost of compliance" concern, juxtaposed as it is with the requirement that the Administrator provide the requisite lead time to allow technological developments, refers to the economic costs of motor vehicle emission standards and accompanying enforcement procedures. … It relates to the timing of a particular emission control regulation rather than to its social implications.").

With respect to comments from alternative fuel providers, EPA notes (again) that there is no reason to "issu[e] rules that effectively would turn th[is] rul[e] into a fuel program." 81 FR at 73500/2 (Oct. 25, 2016). There already is a statutory program which encourages use of renewable fuels in transportation, including in heavy duty engines, which moreover requires EPA to consider lifecycle greenhouse gas emissions. Id.; see also 76 FR at 57124 (Sept. 15, 2011) (Renewable Fuel Standards provisions, not section 202 (a)(1), are the appropriate means of evaluating and encouraging use of alternative fuels). The RFS program is the Congressionally mandated and appropriate means of evaluating lifecycle implications of biofuels, and of encouraging their use, as appropriate.[858] There is no legal mandate or otherwise compelling reason to achieve the same purpose through Section 202(a)(1) -- a provision directed at reducing emissions "from … motor vehicles." Thus, "EPA's engine and vehicle emission standards … have been in place for decades as tailpipe standards. [EPA] find[s] no reasonable basis in the comments or elsewhere to change fundamentally from this longstanding approach." 81 FR at 73528/2. As stated in the HD Phase 2 rulemaking, "[t]he agencies are not issuing rules that effectively would turn these rules into a fuel program, rather than an emissions reduction and fuel efficiency program." 81 FR at 73500.

Lifecycle emissions, especially those related to resource extraction, affect the total environmental footprint of ZEVs and ICE vehicles. However, doing so in the context of modeling emission inventory impacts attributable to the final GHG standards is fraught and presents scope challenges. For example, resource extraction is a very large worldwide industry that supports many other manufacturing industries. Attributing any activity specifically to the standards is very difficult and highly uncertain. Another challenge is that the emissions from the mining sector are constantly changing as processes evolve, power grids become cleaner, and the areas of the mining itself change. See 81 FR at 73528 noting similar concerns. Therefore, calculating future emissions for this sector, especially in later years such as through the 2030s and 40s, is exceedingly difficult. These arguments also exist in the context of battery production itself. We note further that for a comparison to be valid, there would need to be an accounting of emissions associated with all aspects of petroleum extraction, all aspects of mineral extraction needed for catalytic converters (rhodium, palladium, platinum), and all aspects of lead acid battery production and subsequent management, which the commenters do not appear to advocate.

EPA also notes that accounting for these upstream emission processes in the context of an increase in ZEV production while failing to do equivalent accounting for a reduction in ICE production would unreasonably skew the emission impacts estimates. Many of the same metals that are in demand for ZEV production would also be in demand for ICE production, so whether the standards would truly result in an increase in all mining, resource extraction, and production emissions is not clear. And, because such a broad accounting of these emission processes for both ICE and ZEV vehicles would include emissions from around the world, accounting for these emissions presents scope challenges.

[858] To the extent the RFS statute is of any relevance in understanding section 202(a)(1), but see CAA section 211(o)(12) (savings clause), it indicates that when Congress wanted the agency to consider lifecycle emissions, it knew how to say that clearly. See also 26 USC 45V (providing a credit for clean hydrogen considering certain lifecycle emissions). Sections 202(a)(1)-(2) do not contain any such language, and particularly in light of the Act's overall division between mobile and stationary source regulation, any mandate to consider lifecycle emissions ought not to be inferred.

EPA notes further that the emission benefits of certain alternative fuels are recognized at the tailpipe (in addition to whatever credit may be obtained under the RFS program). 76 FR at 57124. In fact, EPA has charted out a non-ZEV compliance pathway that includes substantial percentages of alternative fueled vehicles with ICE. See preamble section II.F.4. In response to comments that alternative fuel vehicles can provide CO_2 emission reduction benefits immediately and without the need for new supporting infrastructure, to the extent that is true for vehicle emissions, EPA notes that pathways like this example potential compliance pathway remain an option. As further discussed in our response in RTC section 9.1, the existing test procedures set out in 40 CFR 1036.505 and 40 CFR 1036.550 allow for carbon-mass-specific net energy content of all carbon containing fuels to be accounted for in GEM. Low carbon fuels, like CNG and LNG, may be accounted for subject to certain requirements if the use of the fuel results in lower CO_2 emissions in the vehicle exhaust. However, to use fuels as part of the engines and vehicles certification, under our existing requirements the manufacturer is required to get approval from the EPA and one of the requirements of this approval is that the manufacturer must show that the vehicle and engine only use the specific fuel when operating in-use.

EPA notes further that the commenters maintaining that use of alternative fuels producing GHG emission benefits sooner (on a lifecycle basis) than ZEV deployment did not address the temporal issue of emissions associated with producing the additional quantities of agricultural biofuels. When crop production is expanded to produce more biofuels, a carbon debt is incurred through land use change emissions, by releasing carbon stored in vegetation and soil as one clears land and prepares it for cropping. That carbon debt must be "paid back" over time by displacing fossil fuel consumption with biofuels using the crops grown on that land. This 'debt' can require decades to pay back.[859]

Certainty of emission benefits (again, on a lifecycle basis) is by no means clear cut either. For example, in its recent RFS volume-setting rulemaking (the "Set Rule"), EPA analyzed the GHG-saving potential of soybean biodiesel, which is both the most widely-used domestic biofuel in the diesel pool and one of the biofuels most capable of increasing production to the magnitude needed for large-scale utilization within the HDV sector. EPA's analysis of the existing literature and comparison of biofuel modeling tools documented significant uncertainty regarding the GHG emissions profile of soybean oil biodiesel, including some uncertainty as to whether this fuel's GHG emission profile is favorable compared to diesel.[860]

EPA also notes the irony that many of the commenters raising concerns about lifecycle accounting are the same ones who claimed EPA's standards implicate the major questions doctrine because they represent a significant and novel expansion of EPA's regulatory authority. Despite their putative concern about the expansion of agency power, these commenters seem to suggest the agency should further extend its regulatory ambit under section 202(a)(1) to include a broad range of stationary sources, including not only major point sources, but area sources and

---

[859] For discussion of the carbon debt and payback time see for example: Fargione, J., Hill, J., Tilman, D., Polasky, S., & Hawthorne, P. (2008). Land clearing and the biofuel carbon debt. Science, 319(5867), 1235-1238. For more recent modeling of the temporal profile of biofuel GHG emissions see Sections 6.7 and 7.7 of the EPA Model Comparison Exercise Technical Document (EPA-420-R-23-017):
https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P1017P9B.pdf

[860] See Chapter 4 of the Regulatory Impact Analysis (EPA-420-R-23-015) accompanying 88 FR 44468 and also EPA's Model Comparison Technical Document (EPA-420-R-23-017) accompanying this FRM.
https://www.epa.gov/renewable-fuel-standard-program/final-renewable-fuels-standards-rule-2023-2024-and-2025

agricultural operations, both domestic and foreign. A comprehensive lifecycle analysis of motor vehicle control technologies could be extraordinarily far ranging, including assessment of factors ranging from practices for clearing agricultural land for farming palm oil in Malaysia, to the environmental standards for cobalt mines in the Democratic Republic of Congo, to spills of diesel fuel at countless retailers across the United States. See the further response in RTC 17.2 below. And while a lifecycle analysis could potentially be less far-reaching, the commenters requesting lifecycle accounting uniformly failed to advance a coherent basis for why the statute requires or permits the lifecycle accounting line to be drawn at a particular industry or degree of nexus. See 81 FR at 73528/2 raising similar concerns. Regardless of whether the agency has authority to account for these or other lifecycle emissions in the manner advocated for by these commenters, we think that so extending the agency's authority is neither necessary nor appropriate for administering a statutory program focused on reducing vehicular emissions.

Responses to specific comments:

Summary:

EPA has legal authority to consider life cycle emissions in the standard setting process under CAA section 202(a)(1) given the breadth of discretion afforded by that provision. Further, the provision does not specify regulation from vehicles. Rather, it refers to standards applicable to emissions of air pollutants from a class or classes of motor vehicles which contribute to that air pollution. (Clear Flame, POET).

Response:

First, these commenters' reading of section 202(a)(1) is problematic. The provision refers to emissions "from any class or classes of new motor vehicles" and EPA's endangerment determination identified new motor vehicles – specifically, passenger cars, light-duty trucks, motorcycles, buses, and medium and heavy-duty trucks – as the classes contributing to the air pollution which endangers. EPA's contribution finding respecting these classes of motor vehicles considered only the emissions from the vehicles in the classes. See 74 FR at 66537-540 (Dec. 15, 2009.)[861] The finding did not consider emissions from other sources of air pollutants (e.g., mines, farms, power plants, refineries, etc.). Therefore, EPA does not perceive that the reference to 'class or classes' in section 202(a) advances the commenter's argument.

If the provision is read as discretionary, as the commenters urge, EPA has explained in past rules why it is inappropriate to exercise that discretion to include lifecycle-based standards. As noted and referenced above, there is both a clear demarcation in the CAA between stationary and mobile sources, and an entire statutory program devoted to consideration of alternative vehicular fuel use. There is no compelling reason to import all of those considerations into the section 202 (a)(1) standard setting process for heavy duty vehicles. As EPA has stated, this would turn an emissions program into a fuel program, and obliviate the distinction between the two now codified in the Act. See, e.g., 81 FR at 73500 (quoted above).

[861] See, e.g., 74 FR at 55538/1 (contribution finding relates to the "emissions from the source category"; id. at 55540/2 (contribution finding relates to "[e]missions from the CAA section 202(a) source categories constitute the major part of the emissions from the transportation sector" and id. showing transportation and electricity sector contributions separately. In addition, "motor vehicle" refers exclusively to vehicles, so the finding can only relate to vehicular emissions. CAA section 216 (definition of 'motor vehicle').

Summary:

CAA sections 202(a)(3)(A) and 202(a)(4)(B) authorize consideration of lifecycle emissions in the standard setting process. (Clean Fuel Dvl. Coal., AmFree, AFPM).

Response:

Section 202(a)(3)(A) is not applicable here. It applies to enumerated pollutants, not to GHGs. (Indeed, commenter POET noted this distinction.) EPA does agree that the provision can be potentially illustrative for purposes of interpreting section 202(a)(1), but disagrees that the reference to subcategorizing based on "type of fuel use" compels lifecycle standards as commenter Clean Fuel Development maintains. The natural meaning of that phrase is subcategorizing based on the fuel used by a vehicle, for example, gasoline versus diesel, not on lifecycle emissions relating to fuel type, recognizing for example that vehicles of different fuel types may have different emissions characteristics. Moreover, section 202(a)(3)(A)(ii) is discretionary ("the Administrator *may* base such classes or categories"), and so cannot be read to compel any particular approach.

Sections 202(a)(4)(A) and (B) are directed to whether emission control devices used to comply with the vehicular emission standards in vehicles might pose unreasonable safety risks. See section 202 (a)(4) (A) ("devices …used in a new motor vehicle"; "if such device … contributes to … unreasonable risk … in its operation or function"); and section 202(a)(4)(B) ("whether … the use of any device" affects emissions of unregulated pollutants, and whether any risk posed by "the use of such device" can be eliminated). These provisions consequently are directed at risks posed by devices used in the vehicle, not to upstream emissions. EPA has carefully evaluated the potential safety risks of ZEV technologies in preamble Section II, RIA Chapter 1, and RTC section 4.6. We note, moreover, the significant expansion of regulatory authority the commenter's approach suggests: to conform to section 202(a)(4) EPA must evaluate the public health, welfare, and safety risks associated with gasoline refining and distribution, electricity generation and transmission, mining, and agriculture, in the U.S. and in foreign nations. It would be odd, to say the least, for such a capacious command to lie hidden in an ancillary provision of the statute.

Summary:

Given that there are upstream and downstream emissions associated with BEVs, terming them zero emission vehicles is misleading. Without accounting for such emissions, EPA is improperly assessing the environmental impacts of its standards, and potentially just transferring pollution from one source to another. This can be demonstrated by an example: if a BEV were to be fueled by electricity from a stationary diesel generator, it would count as a zero emission vehicle, yet its overall impact would be the same as an ICE operating on diesel fuel. EPA's distinctions are consequently arbitrary, and potentially counterproductive. (AFPM, API, CFDC, Delek.)

Response:

EPA is not ignoring emissions from upstream sources. See Preamble section V, RIA Chapter 4, and RTC section 13. These analyses show that the net GHG emission impacts of the Phase 3 rule are overwhelmingly positive, taking into account GHG emissions from both vehicles and upstream sources. With respect to non-GHG emissions, when considering emissions from vehicles, refineries, and EGUs, by 2055 there are net decreases in emissions from all pollutants except $PM_{2.5}$; when the net changes in emissions of $PM_{2.5}$ and $PM_{2.5}$ precursors (e.g., VOC, NOx,

SO_2) are considered together, there are positive $PM_{2.5}$ health benefits beginning in 2040 and, overall, a positive present value and annualized value of $PM_{2.5}$ health benefits when using a 2 percent and 3 percent discount rate. Thus, EPA does not accept the assertion in some of the comments (e.g., AmFree) that the Phase 3 rule fails to positively address the problem which prompts the need for the rule.

Second, the commenters ignore that upstream, and for that matter, downstream potential emission impacts from stationary sources are controlled via other EPA regulatory programs. Thus, electricity generation, battery manufacture, and recycling and disposal of spent batteries are all comprehensively regulated under other EPA programs. For example, EPA regulates electric generating units under many programs such as the Mercury and Air Toxics Standards (CAA), the Cross State Air Pollution Rule (CAA), the Cooling Water Intake Systems Rule (CWA), the Coal Combustion Residuals Rule (RCRA), the Steam Electric Power Generating Effluent Guidelines (CWA), as well as under various actions of particularly applicability such as State and Federal Implementation Plans to implement the National Ambient Air Quality Standards and the visibility protection program. See also 88 FR 24854 (proposing further controls on hazardous air pollutants emitted by steam electric power units), and 88 FR 33240 (May 11, 2023) (proposing GHG emission standards for existing coal- and oil-fired steam generating units, and for new and some existing gas fired steam electric generating units). With respect to the commenters' example of ZEVs being charged by electricity from a stationary source diesel generator, we note that notwithstanding some viral social media videos,[862] there is no evidence that this is happening in a way that significantly affects the emissions reductions achieved by the standards. Moreover, EPA notes that there are emission standards for such generators under the NESHAP for Reciprocating Internal Combustion Engines. 40 CFR subpart ZZZZ. Disposal of lithium-ion batteries, or (more likely) their recycling, is regulated comprehensively under EPA rules implementing the Resource Conservation and Recovery Act, see 40 CFR Part 173, and their transport is regulated comprehensively under DOT Hazardous Material Rules in 49 CFR Parts 171-180 (see RTC section 4.6 "safety" responses, and RTC section 4.7 "recycling" responses.) Moreover, on October 23, 2023, EPA announced plans to propose further regulations adding to the safety standards for management of spent lithium-ion batteries.[863] Many of these same activities are regulated by other jurisdictions as well, including by U.S. States and foreign governments and their local jurisdictions.

As noted above, the delineation between mobile and stationary source standard setting is in keeping with the structure of the Act, whereby Congress directed EPA to control stationary sources under Title I of the Act, and mobile sources under Title II. For these reasons, EPA rejects the assertion of commenters that it has ignored these issues and consequently arbitrarily failed to consider an issue of importance in the rulemaking.

---

[862] See, e.g., https://www.usatoday.com/story/news/factcheck/2023/11/15/ev-charger-is-solar-and-diesel-powered-not-247-diesel-fact-check/71568937007/ (determining that video showing "EV charging station with diesel generator that 'runs 24 hours of the day, seven days a week'" was "false").

[863] The Unified Regulatory Agenda Entry reads, in relevant part, "EPA is proposing universal waste standards specially tailored for lithium batteries, separate from the existing general battery universal waste category. This change in the RCRA regulations would benefit those generating and managing waste lithium batteries by improving the safety standards and reducing fires from end-of-life lithium batteries, while continuing to promote recycling."

Summary:

Commenters had various suggestions as to which lifecycle emissions should figure into the standard setting process. All recommending the approach would include emissions associated with electricity generation. Others would include emissions associated with battery production. (AFPM, NGV America.) Commenters also mentioned inclusion of electricity supply chain-related emissions (CFDC), emissions associated with battery "disposal" (API, Nat'l Ass'n, of Convenience Stores, West Trucking), and mining of materials critical to battery manufacture, including cobalt and other minerals presently supplied primarily from overseas (Western Trucking, Mille Lacs Band of Ojibwe).

Response:

The differing perspectives of commenters on where to draw the line for what is included in a lifecycle analysis illustrates the difficulties of importing a lifecycle approach into the section 202(a) GHG standard setting and compliance process, and reinforces EPA's long- established choice not to do so. Aside from the practical difficulties of making reliable accounting for emissions from overseas extractive activities, these commenters are not advocating consideration of emissions associated with extraction of precious and semi-precious metals used in ICE emission control systems, or extraction of lead used for lead-acid batteries.

As noted above, these commenters do not appear to be advocating a similar approach for fossil fuels, whereby all emissions and other impacts of locating, extracting, and processing fossil fuels, or all emissions associated with growing, harvesting, and transporting biofuels, would be accounted for in the vehicular standard setting process. Nor have the commenters urging consideration of end-of-life battery disposal and recycling emission issues addressed emissions relating to disposal and recycling of lead acid batteries, or of wastes from petroleum refining. [864]

Summary:

Various commenters submitted quantified analyses purporting to show that ICE vehicles operating with biofuels, in particular renewable biodiesel, would actually emit less GHGs (or comparable amounts of GHGs) than comparable BEV or FCEV vehicles when their respective lifecycle GHG emissions are accounted for. (API, Chevron, ClearFlame, NGVAmerica, NACS). Commenter Strong Plug-In Hybrid Ass'n submitted a similar comment with respect to PHEVs.

Response:

These studies pose methodological issues, or scope issues, that make them of limited value for comparison with the Phase 3 final rule. "Decarbonisation potential of on-road fuels and powertrains in the European Union and the United States: a well-to-wheels assessment" (Sustainable Energy Fuels, 2022 6, 4398) (cited by NGV) deals exclusively with light duty vehicles. (See e.g., at 4404). NGV also includes as an Appendix to its comments the study "CO2 Abatement: Costs of mobility and other Road Transport Options" (Frontier Economics 2021). The only heavy-duty vehicles considered in the study are class 8 sleeper cabs (vehicles

[864] Among other things, petroleum refining results in the generation of a number of hazardous wastes, listed as hazardous wastes K048-K052 under the regulations (40 CFR Part 261.32) implementing subtitle C of the Resource Conservation and Recovery Act.

over 40,000 tonnes (sic)), and of these, only FCEVs (study at, e.g., 2, 6, 20). EPA thus does not view either of these studies as making particularly useful comparisons with the Phase 3 rule.

The American Transportation Research Institute study, "Understanding the Impacts of Zero-Emission Trucks" figured in in a number of the comments (API, Ben Banks, Chevron among them). Fuels examined were diesel, biodiesel (B100), renewable diesel, and LNG, compared with BEV and FCEV. The study considers CO_2 emissions from vehicle production – including battery production, operation, and disposal/recycling. Commenters cite the study as showing (correctly) that there are CO_2 emissions associated with battery production and vehicle end-of-life (API), and further cite it as showing that CO_2 emissions from renewable diesel and possibly B100 are less for ICE vehicles considering emissions associated with production and disposal/recycling. This latter assertion is problematic. First, the study evaluates Class 8 sleeper cabs exclusively (study at 17), and thus sheds minimal light on all of the remaining Phase 3 vehicle subcategories. Vehicle disposal and recycling considers only lithium-ion battery recycling CO_2 emissions, but it fails to consider emissions associated with disposal or recycling of lead-acid batteries. The study appears to consider that all hydrogen is produced via the SMR process, and thus fails to account for the IRA incentives for low-emission hydrogen. Most problematically, the study assumes production of a second battery for BEVs, assuming replacement is needed at 500,000 miles (study at 20). The study says without specific citation that this assumption is consistent with the GREET model, and with undocumented conversations with unnamed OEMs. This assumption is counter to EPA's well-documented determinations regarding battery deterioration (see, e.g., Preamble Chapter 2 Battery Component Sizing and Weight: Battery), as well as the provisions relating to warranty and deterioration in the final rule which reasonable posit no battery replacement before 1,000,000 miles (more specifically, 2,000 cycles). EPA thus does not regard this study as of particular comparative value.

"Comparative Life Cycle Analysis of Heavy-Duty Vehicles (Class 7/8) Fueled by Renewable Diesel, Electricity, and Hydrogen" (Univ. of British Columbia, 2022), cited by Chevron, is also a problematic comparison. It shows that GHG emissions of BEVs and FCEVs are superior to any other mode in its lifecycle analysis, although CO_2 emissions from 100% renewable diesel via soybeans are within a comparable order of magnitude (study at 1). The study considers Class 8 vehicles exclusively and assumes operations over 400,000 km (approximately 248,000 miles). Study at 19. The emission benefits of ZEVs over the longer useful life reasonably assumed for Phase 3 would therefore be correspondingly greater than those evaluated in this study. In addition, the study considers lithium-ion battery disposal emissions as part of the embedded emissions in a BEV, but it does not evaluate emissions associated with management of spent lead-acid batteries.

The final study cited is by Ramboll US Consulting, "Multi-Technology Pathways Study" (2021) prepared for the Western States Petroleum Association (cited by Chevron, among others). The study is California-specific, and commenters Chevron and NGV cite it for the proposition that renewable fuel options could deliver GHG reductions sooner and more cost-effectively than a BEV-only approach (the study does not consider FCEVs) if one accounts for upstream emissions from electricity generating sources. (Study at 1.) However, the study analyzes emissions exclusively from heavy heavy-duty trucks (greater than 33,000 lbs) and provides no basis for extrapolation to the rest of the heavy-duty sector.

Summary:

EPA itself has used a lifecycle approach for light-duty electric vehicles, whereby emissions associated with the source of electricity are considered for compliance once there is a given volume of sales in a model year. EPA should not ignore those upstream emissions in the Phase 3 rule, since doing so dilutes the rule's benefits and exaggerates the difference in emission impacts of ICE and BEV vehicles. Nor is the zero emission needed any longer as an incentive. (ACEEE.)

Response:

The commenter notes correctly that the light-duty vehicle rule (although not the heavy-duty rules) included a provision capping the number of BEVs whose tailpipe emissions count as zero. EPA adopted the cap to balance the competing concerns of promoting highly promising (then) relatively new technologies with concerns about decreasing overall emission reductions associated with the program. 77 FR at 62817, 62818 (Oct. 15, 2012). EPA rejected the need for such a cap in the heavy-duty GHG rules. 81 FR at 73500/3 (Oct. 25, 2016). With respect to accounting for electricity production emissions, EPA does so fully in its analysis of emissions impacts. Moreover, as the commenter notes, GHG emissions associated with electricity generation are decreasing with the increased use of renewables. EPA reiterates its prior position that the appropriate means of addressing those emissions is through the Act's stationary source provisions.

Summary:

Several commenters said a lifecycle standard-setting approach was important for protecting disadvantaged communities. (AVE, MFN.)

Response:

EPA notes that BEVs and FCEVs not only have zero tailpipe GHG emissions, but zero tailpipe emissions of all other pollutants. Their operation consequently has very significant collateral benefits, including for disadvantaged communities. See generally RTC section 21. (Commenter MFN recognizes these benefits in its comments urging an aggressive standard for drayage trucks predicated on high adoption rates of ZEVs.) As described in preamble section V, EPA has undertaken an analysis of the upstream and downstream emission impacts of the final rule's standards, which were set consistent with EPA's historic approach to standard setting, and EPA considers that analysis of the net impacts as supportive of the final standards. See also section 18.3 of this RTC addressing issues of Environmental Justice.

Summary:

Commenter AVE points to statements from the House Report to a 2022 appropriations bill, and statements from Executive Order 13990 as support for a lifecycle approach to setting GHG emission standards.

Response:

EPA does not view a statement in legislative history to a post-enactment 2022 appropriation bill as modifying its standard-setting authority under section 202 (a)(1) of the Act 52 years after its enactment. Nor could the cited Executive Order modify that statutory authority, and in any case, it is not on point since the directive is to consider global damages in assessing the social cost of carbon. EPA has done so, which value is reflected in its cost-benefit analysis to this rule.

Summary:

NGV America cites undocumented conversations with unspecified agency staff which the commenter characterizes as EPA staff support for a lifecycle approach to GHG vehicular standard setting.

Response:

Given the absence of documentation of these contacts – indeed, not even a year when the purported conversations occurred – it is impossible to assess the accuracy of the commenter's characterization of them. In any case, agency staff are not the agency decisionmaker. The EPA Administrator is. For the commenter to speak of a 'breached commitment' by the administration is consequently both incorrect and inappropriate.

Summary:

Steven G. Bradbury stated: *They also ignore the upstream emissions of carbon dioxide from the increased electricity generation that would be needed to charge the projected fleet of EVs … EPA's refusal to account for these huge offsetting emissions of carbon dioxide fundamentally distorts its analysis of net benefits in a manner that arbitrarily favors the Agency's preferred regulatory outcome. It is, in fact, false and misleading to label EVs "zero-emission vehicles" when the production of EV batteries and the charging of the batteries over the life of the vehicles both generate enormous amounts of carbon dioxide.*

Response: This comment is incorrect. While EPA uses the name "zero-emission vehicle" to reference vehicles with no tailpipe emissions by convention, EPA never asserts or models the vehicles as having no emissions attributed to their activity. EPA's emission impacts analysis includes EGU emissions resulting from the charging demand (and hydrogen production using electrolysis) in Chapter 4 of the RIA. Specifically, Chapter 4.3.3 details the methodology EPA used to estimate EGU emissions, and results for the standards are presented in Chapter 4.5.

Summary

The comment from KALA Consulting ("KALA"),[865] much of which is directed exclusively to the proposed light-duty vehicle proposed rule, touched on issues pertaining to lifecycle-based standards common to both the light- and heavy-duty rulemakings. The life cycle comment is addressed here. The remainder are addressed in the LMDV RTC.

KALA criticizes EPA for referring to BEVs as "zero emission vehicles" when there are upstream emissions associated with fueling them. As noted in the previous response, EPA has accounted for upstream emissions associated with both electricity generation and petroleum refining and has monetized those reductions in assessing the phase 3 rule's costs and benefits. In this regard, we note that KALA states mistakenly that EPA failed to account for electricity transmission losses in its analysis (Comment p. 13). See RIA chapter 4.1 noting that the 2022 post-IRA version of the Integrated Planning Model accounts for both energy generation and transmission. KALA is also incorrect in asserting that EPA has failed to consider issues associated with time-of-day recharging (Comment p. 34). Assessment of time-of-day charging is

[865] Particularly misguided is the commenter's critique of EPA's statement that OEMs are likely to include BEVs in their compliance strategies independent of the EPA standards as an indication of "zealots … so passionate about their 'Mission from God' that they have to tell everybody about it." Comment p. 8. In fact, OEMs have already introduced HDV BEVs into the market in advance of both the California ACT regulation and EPA's Phase 3 proposal. 88 FR at 25939-942.

in fact is a critical part of EPA's analysis of both emission impacts and costs of the Phase 3 rule. See RIA Chapter 4.2.4.1 (load profiles reflecting total daily demand from HD BEV charging for each vehicle type in MOVES), RIA Figures 4-1 and 4-2 (HD BEV time-of-day charging profiles for weekdays and weekends), and RIA Chapter 2.6.2.1.4 (depot dwell times by HDV BEV vehicle types).

Response:

Like a number of other commenters, KALA believes the section 202(a) GHG emission standards (although not standards for criteria pollutants or air toxics) should reflect upstream emissions along with tailpipe emissions. KALA would draw the line at upstream GHG emissions associated with electricity generation, and it would do the same for gasoline and diesel-fueled vehicles. Comment p. 14 (probably referring exclusively to light-duty vehicles, although the commenter's principle could apply to HDV as well). Among the bases for the commenter's suggestion is its mistaken assumption that EGU GHG emission profiles are unlikely to improve (Comment p. 10), and failing to account for the effect of the IRA or any of the other factors reflected in EPA's IPM modelling showing renewables becoming an increasingly large portion of the EGU power-generating energy source. See RIA Chapters 4.2.4.2 and 4.4.2. Nor does KALA discuss why its upstream analysis stops at the EGU or refinery. For example, there is no discussion of whether to consider methane emissions associated with petroleum extraction.

KALA acknowledges EPA's statement that the Clean Air Act clearly delineates between mobile and stationary sources, but disagrees with EPA's further statement that stationary source GHG emissions can be and are being controlled by EPA regulatory programs addressing stationary sources. We respectfully disagree. KALA also does also does not speak to any potential legal impediments to including stationary source emissions as part of a mobile source section 202(a) standard (e.g., "from any class … of new motor vehicle").

Summary:

Valero expressed concerns about the impact of the rule on secondary petroleum products and said that if we expect refinery throughput to decrease due to reduced US product demand, we must account for the impact of reduced refinery throughput on refinery byproducts: sulfur and petrochemical feedstocks.

Response:

Regarding the consequences of the proposed rule with regard to the byproducts and coproducts of petroleum refining (asphalt to pave roads, tires, other consumer products and pharmaceuticals) and sulfur availability (used in construction materials, traditional batteries, rubber, and a multitude of other products), to the extent that US refinery production volume decreases, there likely would be a lower quantity of some coproducts produced at US refineries as gasoline and diesel fuel demand decreases in the US. Demand for coproducts such as sulfur and petrochemical feedstocks may need to be supplemented with imports from elsewhere.

If US refineries produce less fuel, we would expect elemental sulfur production to diminish in direct proportion to the reduced throughput at refineries. This is because all refineries remove sulfur from their fuels to meet gasoline and diesel fuel sulfur regulations and sell the sulfur, so sulfur production in the US would decrease if their gasoline and diesel production decreases. Sulfur, however, is also produced by refineries around the world, and is also a ubiquitous substance readily found and inexpensively mined from natural sulfur deposits found around the world, including here in the US. We therefore expect the sulfur market to remain adequately supplied.

The refining industry produces numerous petrochemical feedstocks and it is useful to distinguish the aromatic-based petrochemical feedstocks from the nonaromatic ones. Of the petroleum refineries in the US, around one third of them have aromatic extraction units. Refiners produce these aromatic compounds in reformers specifically intended to produce large amounts of aromatic compounds, such as benzene, toluene, xylene, cumene, and ethyl benzene, for the petrochemical industry. The aromatic rich hydrocarbons are then sent to an aromatic extraction facility onsite where the various aromatic compounds are separated and then shipped to petrochemical companies which process the feedstocks into various types of plastics, paints and adhesives.

Another petrochemical feedstock produced at refineries is propylene which is used by petrochemical plants to produce polypropylene. Propylene is a byproduct of refinery fluidized catalytic cracker units (FCCU). If demand for propylene outstrips U.S. supply, refiners have the flexibility to produce more by adding a catalyst additive to the FCCU.

Even if there are refinery closures due to reduced U.S. refined product demand, we likely would not see a similar, or potentially any, drop off in petrochemical feedstock production. Only a portion of the refineries in the U.S. produce petrochemical feedstocks and due to the likely improved refinery margins from producing petrochemical feedstocks along with motor vehicle fuels and other refinery products, it is likely that refineries producing petrochemical feedstocks would tend to keep operating while other refineries would shut down. Another potential source of petrochemical feedstocks is from renewable sources.

17.2 Critical Materials and Supply Chain Considerations

Comments by Organization

Oganization: American Free Enterprise Chamber of Commerce (AmFree) et al.

In sum, the vulnerable and volatile supply chain for critical minerals is a challenge that cannot be overcome in a matter of a few years. Rather than thrusting manufacturers into a sea of risk and uncertainty, EPA should wait until the global market stabilizes or the domestic market develops before effectively mandating a widespread shift to electric vehicles.4 [EPA-HQ-OAR-2022-0985-1660-A1, p. 42]

4 Supply-chain problems are also likely to affect the manufacture of fuel-cell vehicles. Fuel-cell vehicles “rely on a platinum catalyst, which is a major downside to this technology, as platinum group elements are expensive and deposits concentrated enough for economic mining are rare.” *The Effect of Critical Material Prices* at 3. “According to the United States Geological Survey, platinum group elements are among the rarest elements on earth and are found in earth curst in concentrations of around 0.5 parts per billion.” *Id.* at 4. And just like the materials needed for batteries, production of platinum group elements is highly concentrated in South Africa, “accounting for 72% in 2017.” *Id.*

Organization: Arizona State Legislature

The proposed rule is arbitrary and capricious because of erroneous estimates about energy security and critical mineral availability. [EPA-HQ-OAR-2022-0985-1621-A1, p. 31]

EPA calculates a $1.3 billion benefit from energy security resulting from the proposed rule. 88 Fed. Reg. 26,082. The $1.3 billion benefit estimate represents that energy security benefits of reducing U.S. oil consumption and U.S. oil imports. A reduction of U.S. petroleum consumption and imports reduces both financial and strategic risks caused by potential sudden disruptions in the supply of imported petroleum to the U.S. EPA also addresses the issue of mineral security. In EPA's view, 'increased vehicle electrification in the United States will not lead to a critical long-term dependence on foreign imports of minerals or components, nor that increased demand for these products will become a vulnerability to national security.' Id. at 25,962. EPA believes that existing foreign production is adequate simply because of other countries' investment in supply chains, and the Bipartisan Infrastructure Law and Inflation Reduction Act combined with market forces will cause American companies to develop their own supply chains. Id. EPA also reasons that minerals imported into the United States can be reclaimed and thus increase America's supply of those minerals. Id. [EPA-HQ-OAR-2022-0985-1621-A1, p. 31]

EPA's own statistics show that foreign production of critical minerals presents an energy security problem. According to EPA:

- As shown in Figure II–1, in 2019 about 50 percent of global nickel production occurred in Indonesia, Philippines, and Russia, with the rest distributed around the world. Nearly 70 percent of cobalt originated from the Democratic Republic of Congo, with some significant production in Russia and Australia, and about 20 percent in the rest of the world. More than 60 percent of graphite production occurred in China, with significant contribution from Mozambique and Brazil for another 20 percent. About half of lithium was mined in Australia, with Chile accounting for another 20 percent and China about 10 percent.[EPA-HQ-OAR-2022-0985-1621-A1, p. 31]
- According to the 100-day review under E.O. on America's Supply Chains (E.O. 14017), of the major actors in mineral refining, 60 percent of lithium refining occurred in China, with 30 percent in Chile and 10 percent in Argentina. 72 percent of cobalt refining occurred in China, with another 17 percent distributed among Finland, Canada, and Norway. 21 percent of Class 1 nickel refining occurred in Russia, with 16 percent in China, 15 percent in Japan and 13 percent in Canada. Similar conclusions were reached in an analysis by the International Energy Agency, shown in Figure II–2. [EPA-HQ-OAR-2022-0985-1621-A1, pp. 31-32]

Id. at 25963-64. Indeed, the United States imports most of the minerals needed for the current electric vehicle production demand, with a net import reliance of 100% for manganese, 100% for graphite, 76% for cobalt, 48% for nickel, and more than 25% for lithium.76 As the EPA recognizes, 'Currently, the United States is lagging behind much of the rest of the world in critical mineral production.' 88 Fed. Reg. 25,964. [EPA-HQ-OAR-2022-0985-1621-A1, p. 32]

76 Congressional Research Service, Critical Minerals in Electric Vehicle Batteries, Aug. 29, 2022, 9, available at https://crsreports.congress.gov/product/pdf/R/R47227.

EPA's electric vehicle mandate will surge demand for critical minerals that the United States will have to import. According to the International Energy Agency, in the 'global energy transition like the one President Biden envisions, demand for key minerals such as lithium, graphite, nickel and rare-earth metals would explode, rising by 4,200%, 2,500%, 1,900% and 700%, respectively, by 2040.'77 The American Transportation Research Institute estimates that replacing the existing American vehicle fleet with electric cars will require 6.3 to 34.9 years of current global production of critical minerals and 8.4 to 64.4 percent of global reserves, depending on the material.78 EPA does not account for the greenhouse gas emissions resulting from this dramatically expanded mining production. [EPA-HQ-OAR-2022-0985-1621-A1, p. 32]

77 Carrie Sheffield, Hypocrite Biden blocks mineral mining his clean-energy goals require, New York Post, Mar. 22, 2023, available at https://nypost.com/2023/03/22/biden-blocks-mineral-mining-his-clean-energy-goals-require/.

78 American Transportation Research Institute, supra note 50, at 2.

EPA's electric vehicle mandate will force American dependence on China. In 2019, China accounted for 80% of the world's total production of raw materials for electric batteries.79 China's reach extends around the world. In the Democratic Republic of the Congo, for example, 15 of 19 cobalt-producing mines are owned or financed by Chinese companies.80 China also refines 95% of the world's cobalt supply.81 China controls 65% of the global lithium processing and refining capacity and is securing deals to extract lithium from mines in Latin America.82 [EPA-HQ-OAR-2022-0985-1621-A1, p. 32]

85. Id

In the proposed rule, EPA identifies domestic production efforts for only one mineral lithium. 88 Fed. Reg. 25,966. The global supply of lithium needs to increase by 42 times by 2040 or 2050 to meet demand for electric vehicles. But 'getting approval for [new mines] can still take years, if not decades.' And the Biden Administration admits it does not even know where all critical minerals may exist: 'The United States' non-fuel mineral resources are significantly under-mapped relative to those of other developed nations; only 12 percent of U.S. territory has modern high-resolution geophysical surveys of the subsurface, and only 35 percent is covered by detailed geologic mapping of the surface and near-surface.' The Alaska governor noted that the White House's 250-page report on critical minerals mentions Australia 60 times, Canada 32 times, but Alaska only once, in a footnote. 89 [EPA-HQ-OAR-2022-0985-1621-A1, p. 33]

Under the apparent strategy of 'if you subsidize it, they will come,' EPA brushes off these inconvenient facts by focusing on the public and private focus on manufacturing electric batteries in the United States. 88 Fed. Reg. 25,966-967. But even if America builds all of the manufacturing capacity needed to supply EPA's forced electric vehicle demand, manufacturing still requires critical minerals that China has and America does not. Other than recycling critical minerals from old batteries, EPA proposes m1 solutions to this grave energy security problem. [EPA-HQ-OAR-2022-0985-1621-A1, p. 33]

Organization: Bradbury, Steven G.

- Harming our national security. Finally, EPA minimizes the fact that forcing a faster switchover to EVs will threaten America's national security by making us more dependent on China and other unfriendly foreign nations for the production and processing of critical inputs required for EVs. China controls nearly 70 percent of global EV battery manufacturing capacity—including 70 percent of the world's lithium supply; 80 percent of the necessary rare earth minerals; and approximately 75 percent of the magnets needed for EV motors—and it boasts 107 of the 142 lithium-ion battery mega-factories planned or under construction in the world today (with only 9 planned for the U.S.).57 [EPA-HQ-OAR-2022-0985-2427-A2, p. 20]

57 See https://secureenergy.org/safe-urges-bipartisan-coordinated-policy-to-lead-new-tech-in-autoindustry-and-protect-against-chinese-supply-chain-dominance-in-new-report/.

The average EV battery uses about 8-10 kilograms of lithium (even more for higher performance batteries), and the world today mines a total of about 130,000 tons of lithium per year. That means if the EPA succeeds in converting 60 percent of annual U.S. car sales to EVs (about 7.8 million vehicles), those EVs (just for the U.S. market) would require 60 percent of the entire world's current production of lithium.58 [EPA-HQ-OAR-2022-0985-2427-A2, p. 20]

58 See https://pubs.usgs.gov/periodicals/mcs2023/mcs2023-lithium.pdf.

Similarly, each EV battery requires about 10 kilograms of cobalt, which translates into one metric ton for each 100 EVs and 10,000 tons of cobalt for one million new EVs. There are only between 150,000 and 190,000 tons of cobalt mined every year worldwide (the lion's share from the Democratic Republic of the Congo). Here again, if 60 percent of annual U.S. auto sales were EVs by 2030 (7.8 million vehicles), those

EVs (just in the U.S.) would consume about 78,000 tons of cobalt— half the world's supply.59 [EPA-HQ-OAR-2022-0985-2427-A2, p. 20]

59 See https://pubs.usgs.gov/periodicals/mcs2020/mcs2020-cobalt.pdf.

To put these percentages in perspective, according to the International Energy Agency (IEA), "In 2022, about 60% of lithium, 30% of cobalt and 10% of nickel demand was for EV batteries" worldwide.60 Because the U.S. market accounts for less than 20 percent of new vehicle sales globally,61 and other governments, particularly China and the EU, are pushing for similar rapid transitions to EVs, the overall worldwide supply of the critical minerals needed to produce EV batteries will have to increase at a truly astounding rate in the next several years to meet the EPA's assumptions.62 [EPA-HQ-OAR-2022-0985-2427-A2, p. 21]

60 IEA, Global EV Outlook 2023: Trends in batteries, https://www.iea.org/reports/global-ev-outlook-2023/trends-in-batteries.

61 See Alex Kopestinsky, "20 In-Depth Global and US Auto Sales Statistics for 2023," Policy Advice, March 23, 2023, https://policyadvice.net/insurance/insights/us-auto-sales-statistics/.

62 See Doomberg, "Separation Anxiety," June 27, 2023, https://doomberg.substack.com/p/separationanxiety (explaining why it is doubtful "the world can mine a sufficient amount of the necessary battery materials to meet anticipated demand").

EPA predicts all of our strategic dependencies for these inputs will vanish quickly over time, with the assist of government subsidies, as new mines open up in the U.S. and Canada and new factories are built here and production capacity is brought to our shores.63 The reality, of course, is that there is little prospect that the Biden administration or local permitting authorities will fast-track the environmental approvals needed for all of these new mining operations and production facilities, even if the projects were otherwise shovel ready. [EPA-HQ-OAR-2022-0985-2427-A2, p. 21]

Organization: California Air Resources Board (CARB)

In response to U.S. EPA on the supply chain for HD ZEVs, CARB staff finds that increased uptake of HD ZEVs is unlikely to have a negative impact on the supply chain as actions are already underway to expand domestic production of materials necessary for ZEV production. [EPA-HQ-OAR-2022-0985-1591-A1, p.31]

Manufacturers and other suppliers are making significant domestic investments to bolster the supply chain in part due to the recently passed IRA. The IRA strengthens domestic supply chains by incentivizing production of materials and components critical to decrease the U.S.' carbon emissions in line with declared goals. These investments are already occurring at the same time manufacturers are identifying ways to produce key components with less or no use of critical materials. This current trajectory is expected to continue, which alleviates raised concerns regarding supply chain disruptions due to the transition to ZEVs. The IRA is also a clear signal for the nationwide move to ZEVs, and multiple states have already adopted the ACT regulation with many others committed to transitioning to ZEVs. [EPA-HQ-OAR-2022-0985-1591-A1, pp.31-32]

CARB staff note this under all standards in U.S. EPA's proposal, a large portion of sales will remain combustion-powered. The existing fleet is almost completely combustion-powered and can also continue to operate for decades. So, to the extent that ZEVs will cause shifts in the supply chain, these will be gradual over time, and limited, rather than an immediate or complete shift. Through action by industry and government, the transition to ZEVs will occur without negatively impacting the supply chain. [EPA-HQ-OAR-2022-0985-1591-A1, p.32]

As part of the Final Environmental Analysis for the ACF regulation and associated Response to Comments, CARB staff evaluated the usage of critical minerals involved in the production of ZEVs.80,81 CARB staff recognizes that its rules and regulations aimed to decarbonize the state through the use of ZE technology may induce new demand for various metals including lithium, graphite, cobalt, nickel, copper, manganese, chromium, zinc, and aluminum. While the degree to which ZEV production will vary depending on evolving technologies, recycling practices, and how overall demand for ZEVs are met, new sources of critical materials have been identified both domestically and internationally including new mining in the Imperial Valley. [EPA-HQ-OAR-2022-0985-1591-A1, p.32]

80 CARB, Attachment D Final Environmental Analysis for the Proposed Advanced Clean Fleets Regulation, 2023. https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2022/acf22/acffinalea.docx

81 CARB, Response to Comments on the Draft Environmental Analysis for the Proposed Advanced Clean Fleets Regulation, 2023. https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2022/acf22/acfrtc.pdf

The California Energy Commission's (CEC) Lithium Valley Commission estimates that the Imperial Valley may have sufficient lithium supplies to meet 40 percent of the world's total lithium demand, which would be coupled with renewable energy and more sustainable extraction processes. The report notes that lithium recovery technologies proposed for use in Imperial County, direct lithium extraction from geothermal brine, result in a much lower environmental effect than hard rock mining and evaporation ponds. Direct lithium extraction technologies are designed to recover lithium and other minerals as the geothermal brine flows through pipelines and tanks and over a surface or substance that removes the lithium and other minerals before returning the brine deep underground.82

Dec 2022 (web link: https://efiling.energy.ca.gov/GetDocument.aspx?tn=247861&DocumentContentId=82166, last accessed March 2022).

Furthermore, industry is also rapidly moving to batteries with different chemistries or formats to address concerns with mineral supply chain issues or human rights concerns.86 These alternative battery chemistries use different metals and can offer similar performance at a lower cost which will ultimately result in a lower vehicle cost to the fleet owner. For example, there is a growing use of lithium iron phosphate batteries in the LD ZEV market which are generally a lower cost alternative and do not require cobalt mining.87 [EPA-HQ-OAR-2022-0985-1591-A1, p.33]

Mineral demand in proportion to vehicle performance is expected to continue to decline with manufacturers already talking about vehicle lifetime capable battery durability of 1.2 million kilometers (750,000 miles) and 1.5 million kilometers (930,000 miles) for production HDVs--

distances which exceed U.S. EPA's proposed extension of regulatory useful life for class 8 vehicles.88,89 [EPA-HQ-OAR-2022-0985-1591-A1, pp.33-34]

Based on this information, U.S. EPA's findings regarding BEV and FCEV technology may be conservative and underestimate the status of the ZEV market. As a result, there is an opportunity to capitalize on the ZEV market's momentum and establish stronger standards that recognize the capabilities of BEVs and FCEVs. [EPA-HQ-OAR-2022-0985-1591-A1, p.34]

Organization: Chevron

Stakeholders have expressed concern about the supply and availability of critical minerals and supply chains for battery manufacturing, many of which are sourced from China. EPA should quantitatively assess the impact this regulation will have on the nation/worldwide demand of lithium and other rare earth metals, and the emissions that will be produced as a result of mining and shipping these materials. EPA should consider environmental impacts from mining of semi-precious metals and potential mitigations. The proposal does not address the potential hazards, construction, noise, or other impacts and potential mitigations for these impacts. [EPA-HQ-OAR-2022-0985-1552-A1, p.7]

Organization: Clean Air Task Force et al.

c. The critical mineral supply will be able to support increases in HD BEVs, and critical mineral needs should not be considered a constraining factor precluding a rule at least as protective of public health and welfare as the ACT rule implemented nationwide.

As EPA's proposal explains, increased HD BEV penetration rates (along with increasing numbers of BEVs in the light-duty sector) will require a robust supply of critical minerals including lithium, nickel, and cobalt. There are currently substitutes for nickel and cobalt depending on the battery chemistry utilized, and EPA cites research finding that even for lithium, "global supplies of cathode active material (CAM) used as a part of the cathode manufacturing process and lithium chemical product are expected to be sufficient through 2035." 88 Fed. Reg. at 25964.238 As comments submitted by the Moving Forward Network explain in more detail, the critical mineral supply will be able to support increases in HD BEVs, and critical mineral needs should not be considered a constraining factor precluding a rule at least as protective of public health and welfare as the ACT rule implemented nationwide. [EPA-HQ-OAR-2022-0985-1640-A1, p. 57]

238 EPA cites preliminary projections prepared by Li-Bridge for DOE in November 2022. 88 Fed. Reg. at 25964.

EPA's proposal notes the significant influence of increasing investments in the development of a sufficient mineral supply chain. Critical minerals supply—both domestically and from nations with which the United States has friendly relations—will likely increase beyond currently anticipated projects, particularly in light of increasing investment in mining research and development. In 2022, investment in critical mineral mining rose by 30 percent, with companies specializing in lithium development experiencing a "record pace of growth" and increasing their spending by 50 percent.239 These investments will likely lead to additional lithium and other critical mineral supplies, supporting increasing numbers of HD BEVs. For example, according to the California Energy Commission, an emerging project at California's Salton Sea could supply enough lithium to meet all future U.S. demand and 40 percent of the world's demand.240 The Salton Sea's lithium supply has been called "staggering," and the area has been referred to as the "Saudi Arabia of lithium," with "something like 50 to 100 years' worth of lithium production."241 A project conducted by the Lawrence Berkeley National Laboratory, U.C. Riverside, and Geologica Geothermal Group, Inc. to quantify and characterize the lithium in the Salton Sea has received $1.2 million in funding from the Department of Energy's Geothermal Technologies Office.242 [EPA-HQ-OAR-2022-0985-1640-A1, pp. 57 - 58]

242 Id.

Moreover, as EPA's proposal and Moving Forward Network's comments explain, recycling has significant potential to add to the battery critical minerals supply, including lithium supply. Several studies support this proposition243 and some automakers are already implementing and/or preparing for robust mineral recovery from recycling. For example, Tesla has explained that "[n]one of our batteries (manufacturing scrap or fleet returns) go to landfills," that "[s]ignificant resources [have been] put toward the development of scalable battery recycling technology for nickel- and iron-based cathode chemistries, including recovery and re-use of lithium," and that "[t]his will directly decrease the demand for mining in the long term."244 An interactive BEV supply chain map detailing recent investments already shows 18 battery recycling projects in North America, with the potential to support at least 1.2 million BEVs annually.245 These recycling projects have added benefits in that they could "unlock new domestic value streams and job opportunities, and reduce the cost of batteries."246 [EPA-HQ-OAR-2022-0985-1640-A1, p. 58]

243 Alexander Tankou et al., ICCT, Scaling Up Reuse and Recycling of Electric Vehicle Batteries: Assessing Challenges and Policy Approaches, at i (2023), https://theicct.org/wp-content/uploads/2023/02/recycling-electric-vehicle-batteries-feb-23.pdf ("The global demand for raw materials and these associated impacts could be substantially reduced through battery reuse and recycling practices"); Jessica Dunn, Are There Enough Materials to Manufacture All the Electric Vehicles Needed?,

Union of Concerned Scientists (Nov. 15, 2022), https://blog.ucsusa.org/jessica-dunn/are-there-enough-materials-to-manufacture-all-the-electric-vehicles-needed/ (noting that mineral reserves will be sufficient for electrification goals when combined with a high amount of battery recycling and finding that "[i]n 2050, recovered material can supply approximately 45–52% of cobalt, 40–46% of nickel, and 22–27% of lithium demand for EVs"); Jessica Dunn, Transforming Transportation: Opportunity for a Sustainable and Equitable Electric Future, Union of Concerned Scientists (May 8, 2023), https://blog.ucsusa.org/jessica-dunn/transforming-transportation-opportunity-for-a-sustainable-and-equitable-electric-future/; Union of Concerned Scientists, Electric Vehicle Batteries Fact Sheet, at 3 (2021), https://www.ucsusa.org/sites/default/files/2021-02/ev-battery-recycling-fact-sheet.pdf (noting that "recycled materials from used batteries could meet a significant portion of new demand in the future," with battery recycling able to "create a more stable domestic source of materials for battery production" and "reduce the demand for raw materials").

Finally, EPA is correct that "[a]s with any emerging technology, a transition period must take place in which a robust supply chain develops to support production." 88 Fed. Reg. at 25962. The United States government is continuously making plans to support this robust supply chain development.247 [EPA-HQ-OAR-2022-0985-1640-A1, p. 58]

247 See, e.g., Fed. Consortium for Advanced Batteries, National Blueprint for Lithium Batteries, 2021–2030 (2021), https://www.energy.gov/sites/default/files/2021-06/FCAB%20National%20Blueprint%20Lithium%20Batteries%200621_0.pdf; Aakash Arora et al., Li-Bridge, Building a Robust and Resilient U.S. Lithium Battery Supply Chain (2023), https://www.anl.gov/sites/www/files/2023-02/Li-Bridge%20Industry%20Report_2.pdf.

Nor is this the first time that the automotive industry has had to address critical mineral supply chain questions, and the industry has proven that it can rise to such challenges. For example, metal supply chain concerns arose during the move toward catalytic converters, and equipping all new vehicles with catalytic converters was seen at the time as a challenging "awesome prospect."248 At the time, "[c]atalyst companies were concerned about their ability to obtain adequate supplies of noble metals if they would be used extensively in automotive catalytic converters."249 Contemporaneous considerations of the "primary technical barriers" to catalytic converter adoption included "reducing the amount of precious metals used in each converter to a point where aggregate demand can be supplied without exhausting world reserves in the near future."250 The only significant reserves of the necessary platinum group metals were located in the Republic of South Africa and the former USSR, "neither of which [could] be considered secure sources of supply."251 Despite these concerns—which sound very similar to some of the rhetoric surrounding the battery minerals conversation—the automotive industry was able to rise to the challenge and succeed in incorporating catalytic converters in all U.S. vehicles. The industry can do the same today. [EPA-HQ-OAR-2022-0985-1640-A1, pp. 58 - 59]

Organization: Clean Fuels Development Coalition et al.

A transition to an electric heavy-duty fleet also implicates policy matters of national importance well outside of EPA's mission and expertise, including "deciding how Americans will get their energy," West Virginia, 142 S. Ct. at 2612, and the national security implications of importing billions of tons of critical minerals from hostile foreign powers like China, see 88 Fed. Reg. 25,966 (recognizing that "most global battery manufacturing capacity is currently located outside the U.S."). [EPA-HQ-OAR-2022-0985-1585-A1, p. 7]

E. There is not (and will not be) enough international mining and manufacturing capacity for the global EV push.

Beyond price, the proposal also systematically neglects the fact that there are simply not enough minerals, particularly lithium, available to sustain global electric vehicle growth. The U.C. Davis Climate + Community Project explains that the "primary driver of lithium demand—and new lithium mines—is EVs. Global EV sales for 2022 are estimated to reach 10.6 million, a 60 percent increase from 2021 (and a 333 percent increase from 2020) that has been driven largely by China and Europe." Thea Riofrancos et al., Achieving Zero Emissions with More Mobility and Less Mining, U.C. Davis Climate + Community Project (Jan. 2023), https://subscriber.politicopro.com/eenews/f/eenews/?id=00000185-e562-de44-a7bfed7751a00000. In 2021, global lithium production was estimated at just over 100,000 metric tons and consumption at 93,000 metric tons. Id. But "cumulative global lithium demand" could reach "30.3 million metric tons in 2050" and "exhaust[ ] currently existing reserves by 2045." Id. Replacing "the ICE vehicles on the road with EVs on a 1:1 basis is infeasible." Id. [EPA-HQ-OAR-2022-0985-1585-A1, p. 26]

As Gill Pratt, chief executive of the Toyota Research Institute, told reporters "[I]t's going to take decades for battery material mines, renewable power generation, transmission lines and seasonal energy-storage facilities to scale up." Daniel Leussink, Not enough resources for EVs to be only cleaner car option, Toyota says, Reuters (May 18, 2023), https://www.reuters.com/business/autos-transportation/notenough-resources-evs-be-only-cleaner-car-option-toyota-says-2023-05-18/. This is an insuperable obstacle to EPA's proposal. [EPA-HQ-OAR-2022-0985-1585-A1, p. 26]

G. The proposal's purchaser acceptance calculations are based on the availability of tax credits that themselves require domestic manufacturing.

The proposal also repeatedly relies on the tax credits from the IRA to justify the proposed rule. These tax credits are split into two types: 30D credits for "clean vehicles" and 45W credits for "commercial clean vehicles." To qualify for the credit, the former contains a requirement for critical minerals and battery components to be sourced domestically or in a country with which the United States has a free trade agreement. Most—but not all—heavy-duty vehicles fall into the latter category. The proposed rule ignores the effect of domestic sourcing requirements on vehicles in the former category. [EPA-HQ-OAR-2022-0985-1585-A1, p. 29]

As amended by the IRA, the 30D tax credits require an increasing share of minerals to be produced domestically and explicitly exclude vehicles whose components are minerals are sourced from foreign entities of concern—any foreign entity that is "owned by, controlled by, or subject to the jurisdiction or direction of a government of a covered nation (as defined in section 2533c(d) of title 10)"—currently China, Russia, North Korea, and Iran.12 In its proposal, EPA makes no mention of what fraction of minerals are mined domestically and glosses over the fact that China is a key supplier of some 85% of the global stock of critical minerals (including rare earths, copper, cobalt, etc.), Robert Bryce, The Electric-Vehicle Push Empowers China, Wall St. J. (Dec. 23, 2021), and that almost no vehicles will be able to qualify for this credit in the near future. And indeed, as of April 17, 2023, only 16 vehicles qualify for the light duty tax credit and some only qualify for half of the tax credit because they only meet the critical mineral or battery components standards. Hannah Northey, Biden's EV bet is a gamble on critical minerals, E&E News (Apr. 18, 2023), https://www.eenews.net/articles/bidens-ev-bet-is-also-a-gamble-on-criticalminerals/. This list will be further narrowed as the thresholds for domestic sourcing increase and when the foreign entity of concern requirements take effect. [EPA-HQ-OAR-2022-0985-1585-A1, p. 29]

12 The Department of the Treasury and the IRS's proposed regulation interpreting these rules is unlawful. Commentors here have submitted separate comments on that docket to that effect. See Comments of American Free Enterprise Chamber of Commerce on "Section 30D New Clean Vehicle Credit," RIN 1545-BQ52. For all of the reasons stated in that comment, most of this tax benefit will be largely unavailable here.

Neglecting that many vehicles will be excluded from these tax credits further undermines EPA's assertions of feasibility. [EPA-HQ-OAR-2022-0985-1585-A1, p. 29]

F. The proposed rule also gets energy security costs backwards— electric vehicles are worse for energy security, not better.

As discussed above, EPA gives a substantial benefit to energy security from reduced oil consumption but ignores the impacts to energy security that come from an increased importation of minerals.13 EPA waves these increased mineral security costs away saying, "mineral security is not a perfect analogy to energy security" and explaining that once the minerals are here, they are here, and "[b]y 2050, battery recycling could be capable of meeting 25 to 50 percent of total lithium demand for battery production." 88 Fed. Reg. 25,968–25,969. [EPA-HQ-OAR-2022-0985-1585-A1, pp. 35 - 36.]

13 This also ignores that the United States is a net exporter of oil. "The United States is the largest producer of oil, responsible for nearly a fifth of the world's oil production. Thanks to the hydraulic fracturing revolution, the United States is a net exporter of oil. China, on the other hand, is the world's largest net importer of oil. China has few oil reserves, and its dwindling domestic supplies come from legacy fields that require expensive enhanced-recovery methods. China's demand for oil is also rapidly increasing. This explains China's long-term bet on powering transportation with electricity: China can use its abundant coal reserves, hydropower, and growing nuclear capabilities to power battery-electric cars, vans, and trucks." C. Boyden Gray, American Energy, Chinese Ambition, and Climate Realism, 4 American Affairs Journal (Winter 2021), https://americanaffairsjournal.org/2021/11/american-energy-chinese-ambition-and-climate-realism/. "First, policies that restrict the domestic supply of oil and gas and mandate renewable and electric car deployment will reduce U.S. geo-political power. The United States is the world's largest producer of oil and gas. It is a net loser from unilateral restrictions on domestic hydro-carbons, while Russia, Saudi

> Arabia, and Iran have the most to gain, as a decline in U.S. supply increases their power to set cartel prices. China, on the other hand, is the largest net importer of oil and gas, but the dominant producer of 'green' substitutes like solar panels, battery cells, and critical minerals. 'Greening' the U.S. economy at the scale envisioned by the Biden administration would damage U.S. growth while jeopardizing U.S. national security and even global stability. It would empower antagonistic regimes like Russia, Saudi Arabia, and Iran, while reducing U.S. leverage with China." Id.

This is unreasonable. To begin with, EPA's aside about battery recycling only accounts for lithium and not the countless other mineral required in an electrical vehicle battery. Nor does the proposal propose any reasonable account of how the other 50 to 75 percent of even the lithium needed to manufacture a battery will be sourced domestically. [EPA-HQ-OAR-2022-0985-1585-A1, p. 36.]

In the present day, China dominates critical mineral supply chains. China controls nearly two-thirds of all lithium, four-fifths of the refined cobalt market, and nearly all processed natural graphite. The United States has nearly no control of critical mineral supply chains and produces less than a tenth of the world's battery cells, while China is the world's leading producer. China controls much of the extraction of these materials and has 90 percent of the world's rare earth element processing capacity, cornering the market for the core minerals of electric car batteries, and dominating battery and renewable supply chains. See C. Boyden Gray, American Energy, Chinese Ambition, and Climate Realism, 4 American Affairs Journal (Winter 2021), https://americanaffairsjournal.org/2021/11/american-energychinese-ambition-and-climate-realism/. EPA acknowledges that there are very few domestic battery manufacturing plants, but assumes, without justification, that American manufacturers will increase production to a point sufficient to entirely eliminate the energy security costs flowing from this massive transition. DRIA at 172. [EPA-HQ-OAR-2022-0985-1585-A1, p. 36.]

Organization: Daimler Truck North America LLC (DTNA)

EPA Request for Comment, Request #12: We request comment on our assessment of heavy-duty battery designs, critical materials, and battery manufacturing.

- DTNA Response: As discussed in Section II.B.3.a of these comments, EPA should address the impacts of complex supply chains, projected future domestic mining and production capability, and global trade and geopolitics on its battery cost projections, as these projections influence the proposed CO2 standard stringency levels. The Company also suggests that EPA periodically review available technologies, critical materials, and battery manufacturing, to reassess its suitability and cost projections. [EPA-HQ-OAR-2022-0985-1555-A1, p. 160]

Organization: Delek US Holdings, Inc.

II. EPA's Proposed Rule Will Increase Domestic Reliance on Foreign Supply Chains.

Today, the U.S. is virtually independent8 in terms of transportation fuels (i.e., petroleum- and ethanol-based liquid fuel products) for ICE-powered vehicles. Although EPA spends a not insignificant amount of space in its draft Regulatory Impact Analysis ("DRIA") assessing energy security, EPA limits itself to drawing broad conclusions regarding future projections for exports, imports, and consumption of crude oil and refined petroleum products.9 But this ignores the larger concern regarding energy and national security: an unfavorable transition from reliable, abundant, domestically-sourced fuels to a complex supply chain reliant on foreign-sourced critical minerals. [EPA-HQ-OAR-2022-0985-1561-A1, p. 3]

8 While "energy independence" has varying definitions, we are using the term consistent with EPA's use in the Proposed Rule—"[t]he goal of U.S. energy independence is the elimination of all U.S. imports of petroleum and other foreign sources of energy, but more broadly it is the elimination of U.S. sensitivity to the variations in the price and supply of foreign sources of energy"). Proposed Rule at 26,077.

9 EPA, Draft Regulatory Impact Analysis for Proposed Rule, 480 (Apr. 2023) [hereinafter "DRIA"]. Notably, EPA concludes that U.S. oil consumption is projected to be fairly steady for the time period from 2027 to 2050" and will actually increase gradually over that time. Id.

Most illustrative of the future foreign reliance resulting from EPA's Proposed Rule is the lithium-ion battery supply chain controlled nearly entirely by China. China controls each step of battery production and, by 2030, is anticipated to "make more than twice as many batteries as every other county combined."10 This is because China controls 41% of the world's cobalt, 28% of the world's lithium, and 78% of the world's graphite; China also refines 95% of manganese, 74% of cobalt, 70% of graphite, 67% of lithium, and 63% of nickel.11 And even if the U.S. had sufficient resources to extract and refine independent of foreign sources, a refinery takes two to five years just to build—not accounting for the time necessary for permitting, construction, and operations, including waste disposal.12 Beyond the raw materials, China also makes the battery components—73% of NMC cathodes and 99% of LFP cathodes—compared to 1% made domestically.13 Indeed, "[e]xperts say it is next to impossible for any other country to become self-reliant in the battery supply chain, no matter if it has cheaper labor or finds other global partners. Companies anywhere in the world will look to form partnerships with Chinese manufacturers to enter or expand in the industry."14 EPA's reliance on federal funding and tax incentives—such as those under the Bipartisan Infrastructure Law ("BIL")15 and the Inflation Reduction Act (IRA)16—to conclude a domestic supply chain is forthcoming is, therefore, misplaced. Regardless of these funding sources, domestic manufacturing alone is unable to meet the production goals EPA is requiring. [EPA-HQ-OAR-2022-0985-1561-A1, pp. 3 - 4]

15 Public Law 117-58, Nov. 15, 2021.

16 Public Law 117-169, Aug. 16, 2022.

Although EPA has acknowledged that a "transition period must take place in which a robust supply chain develops to support production of [critical minerals]," the limited time afforded under the Proposed Rule is simply insufficient to build this supply chain.17 [EPA-HQ-OAR-2022-0985-1561-A1, p. 4]

17 Proposed Rule at 25,962.

EPA also assumes the power sector is expected to become cleaner over time using wind/solar generation and electricity storage (i.e., batteries), but ignores the environmental impacts of the overall increase in critical minerals demand for electrical grid storage and how that compounds the stress on critical minerals for the ZEVs themselves. But the expansion of electrical grids—even ignoring the Proposed Rule's increased demand—requires a large amount of earth minerals and metals. Indeed, copper and aluminum—both needed for ZEVs—are also the two main materials in wires and cables and, as described above, higher prices could have a major impact on future grid investments.39 The need for expanded grid capabilities simultaneous to expanded ZEV production places a more pressing demand on materials like copper and aluminum thereby increasing extraction and refining efforts throughout the global market. [EPA-HQ-OAR-2022-0985-1561-A1, pp. 8 - 9]

39 International Energy Agency, The Role of Critical Minerals in Clean Energy Transitions (Mar. 2022), 77–80 available at https://iea.blob.core.windows.net/assets/ffd2a83b-8c30-4e9d-980a-52b6d9a86fdc/TheRoleofCriticalMineralsinCleanEnergyTransitions.pdf.

Organization: Electrification Coalition (EC)

While the proposed standards seem feasible considering the expected expansion of U.S. battery production capacity, additional U.S. government support will be needed to expand domestic critical mineral production and battery component manufacturing capacity. [EPA-HQ-OAR-2022-0985-1558-A1, p. 7]

The EPA is specifically requesting comment on their assessment and data to support the assessment of battery critical raw materials and battery production for the final rule.20 The EC notes that overall the proposed standards seem feasible given policies in the Bipartisan Infrastructure Law (BIL) and the IRA that are expected to expand U.S. battery production, yet additional U.S. federal government support will be needed. [EPA-HQ-OAR-2022-0985-1558-A1, pp. 7-8]

20 See page 25962, 25969 of the Environmental Protection Agency's (EPA) proposed rule for Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles-Phase 3 in the Federal Register: https://www.govinfo.gov/content/pkg/FR-2023-04-27/pdf/2023-07955.pdf

SAFE analysis shows that Class 4-8 ZEVs will make up a small share of battery and critical raw materials demand through 2030. Under a 33 percent ZEV penetration rate, electrified medium and heavy-duty trucks and buses are excepted and require a total of 50 GWh of battery production capacity.21 This number rises to 87 GWh when the penetration rate increases to 47 percent.22 In comparison, the DOE expects domestic battery production capacity to reach 1,000 GWh by 2030 to meet our growing demand which is mostly driven by light-duty EVs. [EPA-HQ-OAR-2022-0985-1558-A1, p. 8]

21 The 33 percent penetration rate is based on NREL's ZEV sales penetration rate under the central scenario. Each vehicle category is assumed to be produced with a battery pack tailored to its class: a 600kWh battery for heavy-duty battery electric vehicles, 350 kWh battery for medium-duty battery electric vehicles, and 240 kWh battery for electric buses. Source: SAFE and Roland Berger analysis based on NREL's 2022 Decarbonizing Medium- & Heavy-Duty On-Road Vehicles: Zero-Emission Vehicles Cost Analysis.

22 The 47 percent penetration rate is based on NREL's advanced electricity scenario. Source: SAFE and Roland Berger analysis based on NREL's 2022 Decarbonizing Medium- & Heavy-Duty On-Road Vehicles: Zero-Emission Vehicles Cost Analysis.

An accelerated transition to Class 4-8 ZEVs is not expected to have a significant impact on the readiness of the supply chain to provide the required critical minerals, components, and battery manufacturing capacity. However, as we speed up the transition, it will be even more important to ensure that the demand-pull we are creating is leading to the build-up of robust and reliable supply chains for critical minerals and EV batteries, especially in the upstream. [EPA-HQ-OAR-2022-0985-1558-A1, p. 8]

The battery is the most valuable component of an EV and battery manufacturing is the most labor-intensive step along the EV supply chain. Onshoring battery cell, module, and pack jobs, therefore, is key to minimizing job reductions with ZEV adoption. Under a 33 percent penetration rate, for example, battery manufacturing alone can replace about 80 percent of the jobs at risk. There is already a strong business case for domestic battery manufacturing, and both the manufacturing industry and the U.S. government have been taking steps to promote domestic battery manufacturing. Continued efforts in this space will be critical to replace jobs lost as transportation electrification accelerates. [EPA-HQ-OAR-2022-0985-1558-A1, p. 8]

Battery manufacturing on its own, however, is not enough to address the national security threats of this transition, especially with regard to critical minerals. The U.S. lags behind the rest of the world in critical mineral production, as well as the production of battery components. The U.S. States mines one percent of global nickel and lithium supply, and less than one percent of global cobalt supply.23 It does not produce graphite or manganese, two other critical minerals used in EV batteries.24 A similar case is true for processing. The U.S. processes only one percent of nickel and two percent of lithium used in EVs.25 Furthermore, despite accounting for six percent of global lithium-ion battery cell production capacity, the U.S. was home to less than one percent of cathode and anode production capacity in 2022.26 It is clear that more investment is needed to develop mining, processing, and battery component manufacturing capacity in the U.S.. [EPA-HQ-OAR-2022-0985-1558-A1, pp. 8-9]

24 Ibid.

25 SAFE analysis based on data from Benchmark Mineral Intelligence.

26 Ibid.

While the BIL and IRA provide opportunities to build out a U.S. supply chain, the U.S. government's ability to facilitate robust domestic processing and battery component manufacturing will largely depend on the manner in which BIL and IRA provisions are implemented. Furthermore, permitting delays will continue to inhibit our ability to increase domestic mine production. The proposed rule identifies the 21 U.S. lithium mine projects that can potentially help meet our growing lithium demand. These projects, however, cannot be brought online in a timely manner under our current permitting system. While efforts such as the inclusion of permitting reform provisions in the debt ceiling bill are commendable, a more comprehensive permitting reform bill will be necessary to truly expedite the federal permitting process. [EPA-HQ-OAR-2022-0985-1558-A1, p. 9]

Organization: Energy Vision

Battery electric trucks may have zero tailpipe emissions, but on a lifecycle basis, they actually do have significant emissions (and human rights concerns) from mining lithium and cobalt abroad – such as in the Democratic Republic of Congo and China – as well as from transportation and manufacturing; they also have troublesome battery disposal issues.

Organization: Environmental Defense Fund (EDF)

V. The supply chain for electric vehicle batteries and critical minerals is capable of safely and equitably meeting the demands of strong standards

Domestic production of batteries and battery components is growing rapidly. Analysis by EDF and WSP found that there has been over $79.7 billion in investment in U.S. battery and battery component production announced within the past 8 years, resulting in almost 70,000 new jobs.197 In 2026, these already announced investments will be capable of producing batteries sufficient to supply the equivalent of 11.2 million new passenger vehicles per year.198 [EPA-HQ-OAR-2022-0985-1644-A1, p. 76]

197 U.S. Electric Vehicle Manufacturing Investments and Jobs, Characterizing the Impacts of the Inflation Reduction Act after 6 Months, WSP for EDF, (March 2023). https://blogs.edf.org/climate411/files/2023/03/State-Electric-Vehicle-Policy-Landscape.pdf. (Attachment AA).

198 Ibid.

Much of this investment has occurred within the last year as a result of the IRA's incentives for domestic battery production, which will continue to spur production growth and reduce battery costs throughout the timeframe of this rule.199 The Advanced Manufacturing Production credit, for instance, provides up to $45 per kilowatt-hour for the production of battery cells and modules as well as up to 10% of the cost of critical minerals through 2032.200 Additionally, the IRA's amendments to the Clean Vehicle Credit includes provisions requiring that qualifying vehicles source an increasing percentage of their critical minerals and battery components domestically, which will further incentivize increased domestic production capacity.201 [EPA-HQ-OAR-2022-0985-1644-A1, p. 76]

199 Ibid.

200 Inflation Reduction Act of 2022, P.L. 117-1698, 136 Stat. 1971-81 (2022).

201 Inflation Reduction Act of 2022, P.L. 117-1698, 136 Stat. 1956-57 (2022).

The extraction, processing, and recycling of the critical minerals necessary to support rapid ZEV proliferation is also ramping up and supports the feasibility of protective emission standards. EDF has conducted a review of investments in the critical minerals supply chain, including new investments and expansion of existing capacities in raw minerals extraction (mining), materials separation and processing, and recycling efforts in the U.S, based on publicly available information from company websites and announcements issued by investors, government agencies, and news media on the operators, materials, locations, annual capacities, and timelines of the projects.202 The compilation of projects includes the scale and date of any announced investments in the projects, including OEM investments, as well as the details of partnership agreements. We have also compiled information on specific funding levels secured under the BIL. [EPA-HQ-OAR-2022-0985-1644-A1, p. 76-77]

202 The compilation is attached to this comment as an Excel file titled "Domestic Critical Minerals Projects." We are expanding the review to include countries with which the U.S. has free trade agreements. (Attachment HH)

The numerous projects and partnerships identified demonstrate a growing effort—that is supported by the BIL and motivated by the IRA—to develop a secure supply of the critical minerals. In October 2022, the White House announced $2.8 billion in funding under the BIL for projects to support "new, retrofitted, and expanded commercial-scale domestic facilities to produce battery materials, processing, and battery recycling and manufacturing demonstrations."203 The funding is the first phase of a total $7 billion investment by the federal government to develop domestic supply chains for electric vehicle battery production.204 According to project announcements, these investments in critical minerals projects have been spurred on by downstream consumer tax benefits under the IRA.205 [EPA-HQ-OAR-2022-0985-1644-A1, p. 77]

203 U.S. DOE Office of Manufacturing and Energy Supply Chain Bipartisan Infrastructure Law: Battery Materials Processing and Battery Manufacturing Recycling Selections, available at: https://www.energy.gov/mesc/bipartisan-infrastructure-law-battery-materials-processing-and-battery-manufacturing-recycling

204 U.S. DOE, October 19, 2022 Biden-Harris Administration Awards $2.8 Billion to Supercharge U.S. Manufacturing of Batteries for Electric Vehicles and Electric Grid, available at: https://www.energy.gov/articles/biden-harris-administration-awards-28-billion-supercharge-us-manufacturing-batteries

205 E.g., General Motors announced that, "[m]aterial sourced from Lithium Americas [Thacker Pass mine in Nevada] will help support EV eligibility for consumer incentives under the U.S. clean energy tax credits." Ford noted, in its announcement of a long-term agreement with Nemaska Lithium, that its lithium hydroxide should help qualify Ford vehicles for consumer tax benefits under the IRA. And Livent Corporation, in its announcement of the expansion of its largest lithium hydroxide production site in the U.S. said that its, "leading footprint in North America positions the company to take advantage of long-term growth opportunities and downstream incentives from the recently enacted Inflation Reduction Act (IRA), which encourages use of lithium produced or processed in North America."

In all, our review identified 74 domestic mining, processing, and recycling projects. Investment levels are not known for all projects but announced investments total over $25 billion, including $1 billion funded under the BIL. [EPA-HQ-OAR-2022-0985-1644-A1, p. 78]

It is vital that any increase in minerals mining and processing be undertaken in a way that does not increase pollution burdens on underserved communities, which have historically faced disproportionate harms from these processes. Projects undertaken must be carried out in a way that affirmatively prioritizes the needs of these communities. [EPA-HQ-OAR-2022-0985-1644-A1, p. 78]

Organization: Lynden Incorporated

Finally, batteries require significant amounts of lithium, cobalt, graphite and nickel, the vast majority of which comes from China, the Republic of Congo, and other areas with little concern for environmental impacts and human rights. [EPA-HQ-OAR-2022-0985-1470-A1, p. 4]

Organization: International Council on Clean Transportation (ICCT)

BATTERY MINERAL AVAILABILITY Our analysis shows that the minerals required to produce batteries at the volume required during the period of this rule can be sourced domestically and from close trade partners. Battery supply chain capacity is expected to reach 1 terawatt-hour (TWh) by 2030. The U.S. has ten times more lithium reserves than needed to meet the 2030 EV production goals in its light-duty vehicle proposal. Friendly nations like Australia, Argentina, and Chile combined have two hundred times that amount. Australia and Canada also have one hundred times the amount of nickel, and fifty times the amount of cobalt needed in 2030, while Brazil, France, Indonesia, and the Philippines together have double again that amount. We expect truck manufacturers to favor lithium iron phosphate batteries for their safety and durability, reducing the need for nickel and cobalt supply on the zero-emission transition in the trucking sector. [EPA-HQ-OAR-2022-0985-1553-A1, p. 16]

Organization: MEMA

Supply Chain Challenges Will Continue Throughout Implementation In the supporting documents of the proposed rule, EPA catalogs all public statements of investment in and projections for future availability of critical minerals. This projected sum is then cited as evidence there will be sufficient materials for construction of the future fleet. We disagree with this optimism. To assume that all materials for advanced trucks, which are not available today, in the quantities needed to support the exponential growth in advanced technology vehicle adoption will become available creates significant, unnecessary risk. This risk will be borne by manufacturers and their suppliers. Furthermore, once a company has converted production to new technology lines that company cannot pivot its production capabilities or workforce skills back to the previous technology if EPA projections are not realized by the mid- to late-2020s. [EPA-HQ-OAR-2022-0985-1570-A1, p. 7]

We share the national goal of converting many MHDV platforms to electric and clean-fueled trucks, however where technology falls short due to physical limitations, there must be effective pathways to still serve the U.S. economy and the nation's demands. EPA cannot grant waivers post-2027 to allow greater production of ICE vehicles if electric vehicle technology fails to be adopted sufficiently fast enough. A rule which respects the pace and limitations of technological development is the appropriate pathway. [EPA-HQ-OAR-2022-0985-1570-A1, p. 7]

Recommendation: Battery recycling and disposal costs should be added to EPA's analysis as part of a sustainable BEV deployment to better address scarcity of critical minerals, provide a more resilient domestic supply chain, and over time reduce the added carbon impact of battery manufacturing and associated multi-national logistics. 7 [EPA-HQ-OAR-2022-0985-1570-A1, p. 7]

Recommendation: EPA revises and contains estimates of future (sufficient) materials availability through increased use of scaling factors, confidence levels and sensitivity analyses to prevent overoptimistic projections. [EPA-HQ-OAR-2022-0985-1570-A1, p. 8]

Lightweighting is well-recognized to increase trucking efficiency and there are three primary ways that this occurs:

- By allowing vehicles with equivalent range to use a smaller battery, leading to less consumption of critical raw materials like lithium, cobalt, nickel, and manganese. This helps reduce supply chain risk due to limited availability of critical minerals in the U.S. and reduced demand from mining for these materials, resulting in both environmental and human factors improvements. [EPA-HQ-OAR-2022-0985-1570-A1, pp. 12 - 13]

Organization: Moving Forward Network (MFN) et al.

11. EPA's Weak Proposal is Based on Flawed Assessments of Battery Technologies

11.1. There will be enough materials and battery supply chain production to electrify transportation

We agree with EPA's conclusion that vehicle electrification, including the electrification of heavy, medium, and light-duty fleets, will not lead to energy security risks or dependence on foreign imports in the U.S., but will instead provide the potential for a low impact and domestic energy supply. 88 Fed. Reg. at 25962. This section provides comments on the assessment of battery critical materials and battery production. [EPA-HQ-OAR-2022-0985-1608-A1, p. 85]

The lithium-ion batteries used to power electric vehicles include the following materials deemed critical by the United States Geological Survey: lithium, nickel, manganese, cobalt, graphite, and aluminum. 172 Of these materials, lithium is the only mineral that does not have a substitute currently on the market. Nickel, manganese, and cobalt are in the cathodes nickel-manganese-cobalt (NMC) and nickel-cobalt-aluminum (NCA). These are not the constraining materials because they are now substituted in a growing portion of EVs with the lithium-iron-phosphate cathode. 173 Graphite can also be substituted; synthetic graphite is a direct substitution for mined graphite, 174 and research has also demonstrated the use of silicon mixed with or to replace graphite as the anode. 175 [EPA-HQ-OAR-2022-0985-1608-A1, pp. 85 - 86]

172 U.S. Geological Survey. United States Geological Survey Releases List of 2022 Critical Minerals. (2022). https://www.usgs.gov/news/national-news-release/us-geological-survey-releases-2022-list-critical-minerals

174 Jinrui Zhang, Chao Liang, and Jennifer B. Dunn. Graphite Flows in the U.S.: Insights into a Key Ingredient of Energy Transition. Environmental Science & Technology. V. 57. No.8. (2023). p. 3402-3414. https://pubs.acs.org/doi/10.1021/acs.est.2c08655

175 Xiuxia Zuo, Jin Zhu, Peter Müller-Buschbaum, Ya-Jun Cheng. Silicon based lithium-ion battery anodes: A chronicle perspective review. Nano Energy. V. 31. No. 113-143. (2017). p. 2211-2855.h

Lithium is vital to manufacture lithium-ion batteries – the only type of EV battery used in all EVs purchased in the U.S.; therefore, the analysis correctly points to it as the constraining material for lithium-ion batteries. Yet, this is a slightly conservative estimation for future constraints because alternative battery types are beginning to be marketed globally. For example, sodium-ion batteries have recently been recognized as a potential lithium-ion battery substitute as Chinese automakers unveil their new technology. 176 This type of innovation is likely to reduce lithium demand globally and will be further discussed in the next section. [EPA-HQ-OAR-2022-0985-1608-A1, p. 86]

176 BYD & Huaihai planning Na-ion battery factory in China, Electrive. (June 12, 2023). https://www.electrive.com/2023/06/12/byd-huaihai-planning-na-ion-battery-factory-in-china/

Furthermore, we know advocating for zero-emissions within the Phase 3 GHG Rule, which is an essential step to reducing fossil fuel emissions and addressing the climate crisis, will potentially include mining impacts impacting EJ communities, in particular indigenous communities. Electric vehicles (EVs) also eliminate tailpipe emissions of harmful air pollutants that cause asthma and respiratory diseases, especially among Black, Indigenous, and other communities of color. However, without adequate protections for workers, communities, and environments near mining and processing sites, we risk replicating the harms of fossil fuel extraction. Besides the details below, which talk about opportunities for EV batteries that will not rely on lithium, there are measures that EPA can and should be taking to address potential mining impacts. [EPA-HQ-OAR-2022-0985-1608-A1, p. 86]

EPA points to findings by several sources that concur with its assessment that there will be material and production able to meet EV uptake in the LDV, MDV, and HDV sectors. 177 These include: 1) a report by Li-Bridge that there is expected to be sufficient supplies of cathode active production globally until the date forecasted, of 2035; 178 2) International Energy Agency (IEA) projections of global lithium carbonate until 2028; 179 and 3) Bloomberg New Energy Finance (BNEF) projection of lithium 2028. 180 The 2023 BNEF Electric Vehicle Outlook demonstrates the uptake in demand for minerals has incentivized continued expansion of the supply chain. 181 In addition, academic sources have demonstrated there are enough reserves and recycled content, such that demand for lithium will barely exceed a quarter of the available reserve by 2050 and about half by 2100. 182 [EPA-HQ-OAR-2022-0985-1608-A1, pp. 86 - 87]

11.1.1. Federal investments have spurred private investments in domestic supply

Actions taken by the federal government have increased private investment in U.S. battery production. The impact of the Bipartisan Infrastructure Law and the Inflation Reduction Act on U.S.-based EV manufacturing, repurposing, and recycling growth demonstrates the influence US policy has on rapidly growing a domestically produced supply. Within six months of the Inflation Reduction Act's passage, automakers and battery manufacturers had announced a total of roughly $52 billion of planned investment in North America's EV supply chain with over 70 percent of those investments going towards battery supply chains and recycling. 183 [EPA-HQ-OAR-2022-0985-1608-A1, p. 87]

183 Cory Cantor. US Climate Law Fuels $52 Billion in New EV Investments. BloombergNEF. (March 13, 2023).

About 40% of global commercial vehicle sales are expected to contain LFP batteries in 2023, and LFP batteries are more common in certain vehicle segments like electric buses and in certain countries like China. 210 In the U.S., LFP batteries in heavy-duty BEVs are less common than nickel- and cobalt-based chemistries, and the use of LFP in commercial vehicles globally is expected to continue to decrease over time, reaching around 30% in 2032. 211 The relatively low pack-level specific energy in Table 2-41 of the DRIA shown in Table 10 below appears to only be taking into account the use of LFP, although this assumption cannot be checked because the cathode chemistry breakout/market share forecast was not provided. This is a conservative estimate of energy density considering nickel and cobalt containing cathodes are used in about a third of trucks, and recent advancements, such as the Blade Battery (10 Wh/kg increase), demonstrate density gains faster than historically seen. The EPA forecasts closely align with the lowest limit of specific energy forecasts by Bloomberg in Figure 27, although it would be more accurate to align with a medium forecast scenario considering the share of NMC chemistries used, especially in the U.S. [EPA-HQ-OAR-2022-0985-1608-A1, pp. 96 - 97.] [See Table 10 Battery pack-level specific energy used by EPA in HD TRUCS located on p. 97 of docket number EPA-HQ-OAR-2022-0985-1608-A1 and Figure 28 Historic and Forecasted Specific Energy for Different Battery Chemistries located on p. 98 of docket number EPA-HQ-OAR-2022-0985-1608-A1.]

212 Phase 3 DRIA at 169.

213 BloombergNEF Electric Vehicle Outlook 2022 (subscription required).

In BloombergNEF’s analysis, they used chemistry specific density and forecasted based on linear interpolation demonstrating that in 2027 the 95% confidence lower limit of specific energy is 198 Wh/kg, the same value used in the analysis shown above in Figure 28. 214 BloombergNEF’s lower limit values continue to closely align with the forecast used in EPAs analysis. As previously stated, this is likely an underestimation of the average specific energy we will see in the future, considering the share of nickel and cobalt containing chemistries used in the analysis compared to likely real-world scenarios as well as advancements in battery design. In addition, the linear interpretation forecast does not account for material substitution and large specific energy gains expected from quickly advancing technology. For example, the use of silicon in the anode can increase specific energy as shown in Figure 29 below, 215 and while it is not yet used widely, startups are progressing the technology and constructing commercial-scale manufacturing facilities. 216 [EPA-HQ-OAR-2022-0985-1608-A1, p. 98.] [See Figure 29 Specific energy and capacity for different anode and cathode compositions (silicon carbon composite anodes show higher metrics across the board than graphite alone)located on p. 99 of docket number EPA-HQ-OAR-2022-0985-1608-A1.]

Organization: National Association of Chemical Distributors (NACD)

Economic Analysis

NACD is concerned that the economic impacts resulting from the Environmental Protection Agency's (EPA) Phase 3 Greenhouse Gas (GHG) Emission Standards proposal will cause severe financial and supply chain burdens to the trucking industry and its stakeholders. [EPA-HQ-OAR-2022-0985-1564-A1, p. 2]

Supply Chain Implications

As this rule is being considered, our nation is still reeling from the massive tangling of its supply chains caused by the COVID-19 pandemic. While some of the disruptions have begun to ease, they exposed our supply chain's lack of resiliency. For several months, grocery stores had barren shelves; and shippers were paying record high prices to get products moved into and around the country. Without improved resiliency, this will occur again the next time there is a shock to the supply chain. [EPA-HQ-OAR-2022-0985-1564-A1, p. 3]

If this rule is finalized as proposed, the additional costs associated with acquiring heavy-duty vehicles will most likely price out drivers and businesses from the industry, as noted in the section above. This would have a disastrous impact on the supply chain given the truck driver shortage that has been affecting the industry for years. This proposal would create an additional roadblock in the form of higher upfront prices, preventing independent drivers from entering the industry, removing current ones, and adding financial strains on trucking businesses. In addition, this would increase the severe inflationary pressures that have been plaguing our nation. [EPA-HQ-OAR-2022-0985-1564-A1, p. 3]

Lastly, it is important to note that incorporating more ZEVs into the current heavy-duty trucking fleet will limit the amount of product that can be moved in commerce. A University of California study estimates electric trucks will weigh roughly 5,000 pounds more on average than their diesel counterparts by 2030,4 meaning the adoption of ZEVs will remove 5,000 pounds of potential cargo on each shipment. This requires either weight exemptions for ZEVs which may compromise safety, or more trucks to be on the road just to maintain current freight volume. In addition, the range for zero emission trucks is significantly less than their diesel counterparts, with the typical ZEV range being only about 200 to 240 miles,5 compared to ranges that can surpass 1,000 miles for diesel trucks. Range limitations require ZEVs to be sidelined more often and longer. These issues with range and weight limits will exacerbate congestion on our roads as well as our truck driver shortage. [EPA-HQ-OAR-2022-0985-1564-A1, pp. 3 - 4]

5 Consumer News and Business Channel, "Where EV trucks are going to hit the road first," cnbc.com, CNBC, https://www.cnbc.com/2023/02/10/where-electric-trucks-are-going-to-hit-the-road-first.html

To improve supply chain resiliency, all modes of freight transport must work efficiently, especially trucking as it is responsible for moving over 70% of the nation's freight.6 Trucking is vital to the movement of goods before, after, and between other modes of freight transport. For example, trucks are often required to transport products between ports and railroads, well before they even begin their journeys to the customers. Without reliable truck movement, congestion will impact the entire American supply chain. NACD urges the EPA to impose more flexible standards to allow for the trucking industry to move towards lower emission vehicles without compromising supply chain resiliency. [EPA-HQ-OAR-2022-0985-1564-A1, p. 4]

Forcing the American automotive industry to shift reliance from domestically abundant and secure oil and gas to foreign-supplied critical minerals will have profound impacts on national security. These are only a few of the critical effects of the Proposed Rule that go well beyond EPA's expertise. [EPA-HQ-OAR-2022-0985-1603-A1, p. 11]

Organization: POET

BEVs will also require extracting certain metals at a far larger scale. That extraction can be energy-intensive and much of it occurs in countries where mining can severely degrade the environment, including by clear-cutting rainforests that store vast amounts of carbon.35

35 J. Emont, EV Makers Confront the 'Nickel Pickle,' Wall Street Journal (June 4, 2023), https://www.wsj.com/articles/electric-vehicles-batteries-nickel-pickle-indonesia-9152b1f (describing the EV makers shift from cobalt mining in the Democratic Republic of Congo to nickel mining by clear-cutting Indonesian rainforests).

Further, as described above, U.S. EPA's failure to perform an analysis of the whether or not it is even feasible for the industry to produce the number of HD ZEVs assumed by U.S. EPA in the assumed timeframe has to be added to the list of contradictions to use of the 'payback' analysis in forecasting adoption rates. Such an analysis would begin with an assessment of the ZEV technology supply chain and need to demonstrate, in light of worldwide demand for ZEV technology, that sufficient raw materials, finished batteries, electric motors, fuel cells, controllers, regenerative braking system components, will be available with sufficient lead time and at the costs assumed by U.S. EPA in its payback analysis. [EPA-HQ-OAR-2022-0985-1528-A1, p. 25]

Organization: South Dakota Department of Agriculture and Natural Resources (DANR)

National Security

EV batteries rely on lithium to operate, and recent reports indicate China could control as much as a third of the world's lithium by 2025. South Dakota does not support any regulatory effort making the United States more reliant on China. EPA should consider the potential national security implications of implementing the proposed rules as well as consider the need to, and impact of mining lithium and other battery components domestically. [EPA-HQ-OAR-2022-0985-1639-A1, p. 2]

Organization: State of California et al. (2)

3. Improvements are Expected in the Supply Chain of Critical Minerals

The States and Cities agree with EPA's assessment "that increased vehicle electrification in the United States will not lead to a critical long term dependence on foreign imports of minerals or components, nor that increased demand for these products will become a vulnerability to national security."210 Both Congress and the Biden Administration have taken proactive steps to increase domestic production capacity for the five critical minerals used in the production of rechargeable batteries used in EVs. For example, the Infrastructure Investment and Jobs Act (P.L. 117-58) directs the Secretary of Energy to award over $6 billion in grants related to the research, supply, processing, and recycling of battery critical materials and minerals; 211 the Inflation Reduction Act (IRA) provides for a tax credit designed to accelerate EV battery production in the United States;212 and the Biden Administration has committed to working with the European Union to "diversify[] critical mineral and battery supply chains."213 [EPA-HQ-OAR-2022-0985-1588-A1, p.29]

Spurred both by public incentives, and "business opportunity" presented by "the need for increased domestic production capacity," private industry is also taking steps to increase domestic supply of critical minerals.214 As of March 2023, "at least $45 billion in private-sector investment has been announced across the U.S. clean vehicle and battery supply chain."215 This includes "new and expanded commercial-scale domestic facilities to process lithium, graphite and other battery materials, manufacture components, and demonstrate new approaches, including manufacturing components from recycled materials."216 Companies, such as Volkswagen of America, Audi, and Toyota, have committed to developing recycling programs for end-of-life EV battery packs, which will recover more than 95 percent of the metals found in existing batteries.217 These efforts aim to "create a circular supply chain for EV batteries in the United States that will eventually reduce the cost of batteries and offset the need for mining precious metals."218 Particularly taking into consideration these investments in recycling programs, there are sufficient mineral resources to meet industry needs, both now and in the future.219 [EPA-HQ-OAR-2022-0985-1588-A1, p.30]

Moreover, the States and Cities find EPA's conclusions well supported that the cost to manufacture lithium-ion batteries has dropped significantly over the past several years and will continue to fall over time.220 EPA correctly observed that costs for lithium-ion batteries will decrease as a result of manufacturers' announced plans to invest billions of dollars in battery electric vehicle ("BEV") technology and development, as well as federal incentives in the Bipartisan Infrastructure Law (BIL) and IRA.221 [EPA-HQ-OAR-2022-0985-1588-A1, pp.30-31]

Organization: TCW

Cobalt, Lithium, etc., required to manufacture batteries for BEV's are primarily sourced overseas, with poor environmental standards, mined with equipment with no emission standards and/or with child and slave labor. [EPA-HQ-OAR-2022-0985-1473, p. 1]

Organization: Tesla, Inc. (Tesla)

The Critical Mineral and the Battery Supply Chain Are Not Limiting Factors in Medium- and Heavy-Duty BEV Deployment

Similar to infrastructure, Clean Air Act Section 202 does not direct EPA to consider upstream resource availability in promulgating standards, and so this is factor that need not be given undue weight. More importantly, Tesla does not believe that the critical minerals and battery supply chains will constrain future U.S. manufacturing and deployment of BEVs in any vehicle class. Moreover, there are no fundamental materials constraints when evaluating against 2023 USGS estimated resources.220 Such assertions assume (wrongly) that reserves are fixed and declining. In fact, mineral resources and reserves have historically increased – that is, when a mineral is in demand, there is more incentive to look for it and more is discovered. In comparison, to extent that current critical minerals reserves are viewed as limiting, the agency should point to the long history of Peak Oil and how such predictions have never in themselves limited deployment of ICE vehicles.221 [EPA-HQ-OAR-2022-0985-1505-A1, p. 31]

220 See Tesla, Investor Day Presentation (March 1, 2023) at 28 available at https://digitalassets.tesla.com/teslacontents/image/upload/IR/Investor-Day-2023-Keynote

221 See e.g. Forbes, Peak Oil: The Perennial Prophecy That Went Wrong (Nov. 30, 2022) available at https://www.forbes.com/sites/arielcohen/2022/11/30/peak-oil-the-perennial-prophecy-that-wentwrong/?sh=c64aabb2bbe5

While appropriately assessing the critical minerals supply chain associated with BEVs, EPA should also note it has never undertaken the same assessment related to ICE vehicles. A sustainable energy economy actually involves a lower level of mineral extraction than a fossil fuel-based economy.222 For example, the U.S. oil and gas sector has long been dependent on critical minerals from China for use in oil and gas exploration and development drilling.223 The petroleum industry's reliance on barite has even been used as a case study on U.S. critical minerals dependence.224 Indeed, the American Petroleum Institute has been so concerned about dwindling global reserves that it altered the specifications for the type of barite used in oil and gas drilling.225 At no point has the EPA found that this supply chain constraint has impacted the fuel supply for ICE heavy-duty vehicles or impacted such vehicles' viability for deployment.226 Accordingly, to the extent such conditions are found in the battery supply chain, it should be anticipated that they neither diminish the viability of heavy-duty BEV technology nor will limit deployment volumes for the Phase 3 period of MY 2027-2032. [EPA-HQ-OAR-2022-0985-1505-A1, pp. 31-32]

222 Tesla, Master Plan Part 3 at 31-36 available at https://www.tesla.com/blog/master-plan-part-3

223 See U.S. House of Representatives, Committee on Resources, Subcommittee on Energy and Mineral Resources, Oversight Hearing on ``U.S. Energy and Mineral Needs, Security and Policy: Impacts of Sustained Increases in Global Energy and Mineral Consumption by Emerging Economies Such as China And India' (March 16, 2005), Statement of W. David Menzie, Geologist, U.S. Geological Survey ('There are a significant source of a number of mineral commodities for which the U.S. is dependent for imports of its supplies, and these include things like antimony, barite, fluorspar, magnesium and there are things that are used in batteries, ceramics, electronic components, flame retardants, metallurgical processing and petroleum drilling.') available at https://www.govinfo.gov/content/pkg/CHRG-109hhrg20126/html/CHRG-109hhrg20126.htm

224 U.S. Geological Survey, 'Barite—A Case Study of Import Reliance on an Essential Material for Oil and Gas Exploration and Development Drilling' available at https://pubs.usgs.gov/sir/2014/5230/pdf/sir2014-5230.pdf; See also, U.S. Government Accountability Office, Hardrock Mining: Trends in U.S. Reliance on Imports for Selected Minerals (Apr. 30, 2019) at 3, available at https://www.gao.gov/products/gao-19-434r

225 U.S. Geological Survey, Mineral Commodity Summaries 2020 at 29 ('In response to concerns about dwindling global reserves of 4.2-specific-gravity barite used by the oil and gas drilling industry, the American Petroleum Institute issued an alternate specification for 4.1-specific-gravity barite in 2010.) available at https://pubs.usgs.gov/periodicals/mcs2020/mcs2020.pdf

226 It should be noted that the oil and gas industry's supply chain reliance and constraints have been exemplified by its continued lobbying for exemptions from the Section 301 tariffs for steel and other inputs said to be key to the industry. See e.g., Independent Petroleum Association of America, Steel and Aluminum Tariffs & Quotas available at https://www.ipaa.org/tariffs/ (highlighting supply chain dependence); Daily Energy Insider, API calls for oil, gas industry exemptions from steel tariffs (may 22, 2018) available at https://dailyenergyinsider.com/news/12579-api-calls-oil-gas-industry-exemptions-steel-tariffs/

Nevertheless, the significant and growing investment in the battery supply chain and manufacturing capacity and Tesla's own significant responsible sourcing efforts ensure that BEV deployment will not be limited during the MY 2027-2032 Phase 3 period. As the IEA recently found, the strong investment in BEV and energy storage will double in 2023 to $30 billion (from 2022) and has already led to a wave of new lithium-ion battery manufacturing projects around the world totaling an estimated 5.2 TWh of new capacity that could be available by 2030.227 This has already led overall investment in critical mineral development to increase 30% in 2022, including a 50% increase in lithium resource development followed by similar focuses on copper and nickel development.228 This expansion is occurring and is expanding so fast that battery manufacturing capacity is now on track to meet the 2030 milestones set out in the IEA's scenario for net zero CO2 emissions by 2050.229 [EPA-HQ-OAR-2022-0985-1505-A1, p. 32]

Similarly, the IRA's domestic critical mineral processing and battery manufacturing incentives have led to exponential levels of investment in the battery supply chain.230 In early 2023, it was already estimated that there were $210 billion of announced domestic BEV manufacturing investments.231 This expansion is also happening globally with over $300 billion of announced investment in new battery gigafactories since 2019.232 The U.S. expansion is occurring so rapidly it is already exceeding official government forecasts.233 An ongoing tally of this investment shows that these investments are happening throughout the U.S.234 [EPA-HQ-OAR-2022-0985-1505-A1, p. 32]

Tesla Development of a Robust, Secure Critical Minerals Supply Chain

As extensively detailed in Tesla's Impact Report 2022, Tesla's efforts to expand this supply chain are also accompanied with a commitment to ensuring that companies in our supply chain respect human rights and protect the environment.235 In every location touched by Tesla's supply chain, the company seeks to ensure local conditions for stakeholders are continuously improving as a result of the company's investment and sourcing decisions. This commitment is further detailed in our publicly available Responsible Sourcing Policy, Human Rights Policy, and Supplier Code of Conduct.236 These policies and our supply chain due diligence efforts are aligned with the United Nations Guiding Principles on Business and Human Rights237 and the Organization for Economic Cooperation and Development (OECD)'s Due Diligence Guidance for Responsible Business Conduct.238 [EPA-HQ-OAR-2022-0985-1505-A1, pp. 32-33]

To that end, Tesla has taken significant steps to establish and develop a robust supply chain that will support its future deployment of its Class 8 Semi consistent with the production and deployment estimates Tesla has previously shared with the agency. More specifically, this has included developing and expanding its vertical integration up the supply chain to include expanded cell production, build out of a new cathode production facility at Gigafactory Texas, and breaking ground on the most technologically advanced lithium processing facility in Corpus Christi.239 The blueprint for this activity was originally unveiled during Tesla's Battery Day announcement.240 [EPA-HQ-OAR-2022-0985-1505-A1, p. 33]

Consistent with the Administration's focus on critical minerals, Tesla has continued to focus on creating a secure and sustainable supply chain anchored with domestic sources.241 To that end, following its Battery Day announcement, Tesla established an off-take agreement for a domestic source of lithium with plans to process the lithium hydroxide and manufacture cathode material in the U.S. – creating a first-ever wholly North American upstream advanced battery supply chain. 242 Additionally, Tesla continues to support partnerships for domestic mineral production, establishing supply agreements for North America production from Free Trade Agreement countries.243 Similarly, Tesla has worked to develop commercial relationships with companies onshoring critical mineral processing.244 [EPA-HQ-OAR-2022-0985-1505-A1, p. 33]

244 See, Magnis, Magnis Signs Offtake Agreement for North American Anode Active Material Production (Feb. 20, 2023) available at https://magnis.com.au/asx-announcements/; Canary Media, DOE backs US battery materials production with $107M loan (April 18, 2022) (describing Tesla’s agreement with Syrah for domestic graphite production) available at https://www.canarymedia.com/articles/batteries/doe-backs-us-batterymaterials-production-with-107m-loan

EPA should also consider that recycling of battery material will play a vital role in alleviating some pressure on the need to develop new critical mineral resources. To that end, Tesla seeks to reduce its reliance on primary mined materials and contribute to a more positive environmental footprint through battery and cell recycling – including ensuring that none of our batteries (manufacturing scrap or fleet returns) go to landfills and deploying equipment to recycle 100% of on-site generated manufacturing scrap across manufacturing facilities. In comparison to BEV batteries, it should also be noted the energy source for ICE vehicles – fossil fuels used in combustion – is not recyclable. [EPA-HQ-OAR-2022-0985-1505-A1, pp. 33-34]

Finally, in furtherance of this effort, Tesla is also supporting other emerging domestic suppliers in the advanced battery supply chain as they seek developmental support through various DOE programs, including the Critical Minerals Mining Research and Development Program245 and the Advanced Technology Vehicle Manufacturing program.246 [EPA-HQ-OAR-2022-0985-1505-A1, p. 34]

Organization: Texas Public Policy Foundation (TPPF)

The LMD Tailpipe Rule and the market change it would engender will also make the federal government complicit in the often exploitative practices associated with rare-earth metal mining. The production and acquisition of rare-earth metals used in electric vehicle batteries is a dirty business. The extraction and processing of rare-earth metals can have serious environmental impacts, including soil and water contamination, deforestation, and habitat destruction, negatively affecting ecosystems and biodiversity. In certain areas, rare-earth metal mining has also been linked to labor rights violations, poor working conditions, low wages, child labor, and inadequate safety measures. The batteries that will power the green future the EPA seeks to create through the LMD Tailpipe Rule bear the stain of these violations of human dignity. [EPA-HQ-OAR-2022-0985-1488-A1, p. 6]

Overarching Issues Applicable to the HD and LMD Tailpipe Rules A transition to zero emission vehicles (‘ZEVs’) would expose Americans to supply chain vulnerabilities that are certainly beyond EPA’s authority. Wells Fargo projects a risk of shortages across virtually all of the key components of electric vehicle (‘EV’) batteries,1 and many of these rely on geopolitical rivals who control those supply chains.2 Accordingly, there is a sharp mismatch between the proposed rule and the availability of critical minerals essential to realizing its goals.3 Indeed, ‘mass electrification of the heavy-duty segment on top of the light-duty segment would substantially increase the lithium demand and impose further strain on the global lithium supply.’ 4 Specifically, ‘[t]he results suggest that global lithium resources will not be able to sustain simultaneous mass electrification of both the light duty vehicle (‘LDV’) and HDV segments.’5 It is therefore ‘recommended that both the government and vehicle manufacturers should carefully consider the ambitious promotion of vehicle electrification in the heavy-duty segment.'6 [EPA-HQ-OAR-2022-0985-1488-A1, p. 7]

Organization: The Sulphur Institute (TSI)

Sulphur is a critical element to American manufacturing and is one of the key raw materials necessary for lithium extraction from mined aggregate. We believe in the advancement of domestic lithium battery production as outlined in the administration's "American Battery Materials Initiative" to Strengthen Critical Mineral Supply Chains with one of the goals being developing enough battery-grade lithium to supply approximately 2 million EVs annually. (3) The irony of this initiative is that sulphur, recovered from the oil refining process, is required for extraction of lithium, increasing the importance of a reliable and predictable sulphur supply chain in the future in what appears to be ever-decreasing supply situation in the United States. Mandating the systems by which sulphur is transported seems counterproductive with this goal. [EPA-HQ-OAR-2022-0985-1624-A1, p. 2]

V. ELECTRIC VEHICLE TECHNOLOGIES ARE THE OPPOSITE OF ENERGY INDEPENDENCE

Electric vehicle battery chemistry differs significantly from traditional internal combustion engine batteries. A conventional internal combustion engine uses a typical lead-acid battery. The most common battery chemistry used in an electric vehicle is nickel manganese cobalt. The mining of the raw minerals needed to manufacture the battery packs for electric vehicles is linked to many cases of horrific human rights abuses.4'5'6'7'8'9'10 [EPA-HQ-OAR-2022-0985-1534-A1, p. 3]

There are a limited number of locations around the world where the minerals needed to manufacture electric vehicle batteries are found. 70% of the cobalt used in electric vehicle batteries comes from a single country, the Democratic Republic of the Congo.11 80% of the battery supply chain is owned by China. The United States not owning the electric vehicle battery supply chain is especially concerning when we consider the possibility of a natural disaster or, heaven forbid, an international conflict. As we have seen recently in several local domestic terrorist attacks,12’13’14’15 an attack on the power grid could render electric vehicles located in affected regions useless. [EPA-HQ-OAR-2022-0985-1534-A1, p. 4]

Organization: Transportation Departments of Idaho, Montana, North Dakota, South Dakota and Wyoming

Before closing we also note that there are many other concerns with this proposal that may well be developed by others commenting to this docket. Those could include whether there is authority for the proposal and the dependence of EVs and their batteries on rare earth and other minerals that are largely sourced from and processed in China and other overseas locations. It raises implications for economic security and national security when a sector as important as car, truck and battery manufacturing becomes more dependent on foreign suppliers. [EPA-HQ-OAR-2022-0985-1487-A1, p. 2]

Organization: Truck and Engine Manufacturers Association (EMA)

In a similar vein, EPA generally assumes that, within the next few years, nearly all of the production of the required batteries and fuel cells, perhaps including the mining and processing of all of the critical minerals as well, will occur domestically in the U.S., so that nearly 100% of all of the potential incentives available under the IRA and BIL – down to the last dollar – will be fully utilized between now and 2032. The assumption that battery and fuel-cell manufacturing plants can be built, domestically sourced, and made operational at exponentially increased capacities within the next few years does not match any marketplace reality. Indeed, the expertise does not currently exist in this country to build and operate battery-manufacturing plants capable of producing at scale the size of batteries (with 4000+ cycles) necessary to power ZEV-trucks. It also is unrealistic to assume that battery manufacturers will pass on 100% of the IRA and BIL incentives that they might receive to OEMs in the form of one-to-one battery-cost reductions. Indeed, it can take well more than a year for a manufacturer to realize any net benefits from tax credits. Thus, to treat tax credits as a functional equivalent of dollar-for-dollar cost reductions, as EPA has done in its HD TRUCS model, is unreasonable. [EPA-HQ-OAR-2022-0985-2668-A1, p. 8]

OEMs, all of which have one or more BEV powertrains in production, provided EMA with their December 2022 cost for battery packs, along with the cost from approximately June 2022. The December 2022 average cost was $270/kWh hour, nearly double the cost estimated by ICCT. National labs and third-party expert consultants have consistently estimated that battery costs would fall substantially from 2019 through 2040. But, in fact, those costs have increased recently, rising from an average of $233 in June 2022, to $270 in December 2022. The critical elements for battery manufacturing have been in short supply, driving up prices. The pressure on the supply chain from LD ZEV growth, especially the volume increases from the growing regulatory mandates for more and more ZEVs, will continue to create supply and cost issues for the significantly smaller MHD market. Thus, the projections of falling costs are not accurate. [EPA-HQ-OAR-2022-0985-2668-A1, p. 25]

Organization: Truck Renting and Leasing Association (TRALA)

Critical Mineral Sourcing Remains Problematic

The country's mineral supply chains are not prepared for an abrupt transition to widespread BEV technologies. To produce the lithium-ion batteries that would power the hundreds of thousands of power units needed to meet the Administration's emissions goals, we need tens of millions of tons of cobalt, graphite, lithium, and nickel, and that amount could take as long as 35 years to acquire given current levels of global production.8 Expanding that capacity raises enormous sustainability and ethical questions and costs related to developing nations' exploitive child labor policies and the carbon reduction problem that battery production intends to resolve. [EPA-HQ-OAR-2022-0985-1577-A1, p. 6]

8 Charging Infrastructure Challenges for the U.S. Electric Vehicle Fleet, American Transportation Research Institute (December 2022).

If sourcing concerns are addressed, questions persist regarding disposal of used batteries and its environmental impact. Nearly all lead batteries are recycled.9 In contrast, the U.S. Department of Energy estimates that less than 5% of lithium-ion batteries are collected and recycled.10 This low rate of recycling furthers dependence on imported critical minerals and raises additional lifecycle impact concerns for our members who have comprehensive programs to divert waste from landfills and recycle/reuse most other vehicle waste streams. [EPA-HQ-OAR-2022-0985-1577-A1, p. 6]

9 Durable Goods: Product-Specific Data | US EPA.

10 112306-battery-recycling-brochure-June-20192-web150.pdf (energy.gov).

Organization: United Steelworkers Union (USW)

This proposed rule does not strike a balance between the ambition to reduce emissions and the practicality of the disruption in the supply chain. If EPA requires automakers to achieve far-reaching standards in an unreasonable time frame, they will rely on cheap, readily available components from countries, like the People's Republic of China (PRC), where a large amount of the current ZEV supply chain is located.6 Encouraging sourcing products from the PRC and similar countries does not advance best practices to reduce our environmental footprint as the use of coal to power manufacturing facilities in these countries is still prevalent.7 The potential offshoring of the automotive supply chain not only harms manufacturing workers and communities in the U.S., but it also allows automakers to cut their costs in pursuit of lower environmental and labor standards abroad. [EPA-HQ-OAR-2022-0985-1514-A1, p. 5]

6 Foley & Lardner LLP, "EPA Moves to Tighten Passenger and Heavy-Duty Vehicle Emissions Standards; Seeks to Drive Majority of New U.S. Car Sales to EVs by 2030", April 13, 2023.

7 National Public Radio, "China is building six times more new coal plants than other countries, report finds", March 2, 2023.

Organization: U.S. Chamber of Commerce

Another economic factor that EPA should consider in its regulatory impact analysis is not only the potentially high costs of critical minerals needed to meet these standards, but the forecasted surge in demand for critical minerals in other market segments such as renewable energy, light duty electric vehicles, energy storage, and semiconductors, among others. For example, IEA reports that 40 percent of global platinum demand is for catalytic converters, which also require large amounts of palladium and rhodium. Expected demand growth for these metals is high, and therefore an important factor in the rule's overall cost. Concurrent with this rulemaking, EPA is pursing more stringent NOx standards for the electric power sector that will also contribute to increased demand for these metals.2 [EPA-HQ-OAR-2022-0985-1583-A1, p. 2]

2 Federal Implementation Plan Addressing Regional Ozone Transport for the 2015 Ozone National Ambient Air Quality Standard, 87 Fed. Reg. 20036 (April 6, 2022).

An all of government strategy is needed to ensure the infrastructure needed to support zero-emission fleets in built in a timely manner. The current environmental permitting processes that is a prerequisite for building much of the charging infrastructure, grid interconnections, and other related Infrastructure takes significant time to complete. Currently, it takes 4.5 years to get a permit under the National Environmental Policy Act (NEPA) while some projects take longer, not only delaying but sometimes blocking these infrastructure projects altogether. [EPA-HQ-OAR-2022-0985-1583-A1, p. 3]

Other challenges remain for vehicle manufacturers as consumers and fleet owners may need to make significant investments in charging infrastructure necessary to support zero emitting vehicles. For smaller fleets, it raises more uncertainty as they will increasingly rely on infrastructure investments made at the federal and state levels. [EPA-HQ-OAR-2022-0985-1583-A1, p. 4]

Organization: Valero Energy Corporation

A. EPA fails to adequately address critical minerals supply, availability, and geopolitics.

Citing to the IEA's Special Report dated March 2022, EPA mentions "risk to [the] availability [of critical minerals] may stem from geological scarcity, geopolitics, trade policy, or similar factors."125 But this acknowledgement does not give adequate attention to IEA's analysis. Specifically, IEA states that "[t]his World Energy Outlook special report on The Role of Critical Minerals in Clean Energy Transitions identifies risks to key minerals and metals that – left unaddressed – could make global progress towards a clean energy future slower or more costly, and therefore hamper international efforts to tackle climate change."126 The IEA Report further provides that EVs require significant mineral inputs compared with ICE vehicles.127 For example, the typical electric car contains six times the mineral resources of a kind susceptible to supply chain disruptions and volatility.128 Additionally, demand for EV minerals is growing rapidly and expected to outpace production in the coming years.129 Further, the long lead time for the development of new mines constrains industry's ability to respond to rapid increases in mineral demand.130 [EPA-HQ-OAR-2022-0985-1566-A2, pp. 27 - 28]

In the proposed rulemaking, EPA states that Chile accounts for "20 percent" of global lithium mining131 and that "[a]ccording to the 100-day review under E.O. on America's Supply Chains (E.O. 14017), of the major actors in mineral refining, 60 percent of lithium refining occurred in China, with 30 percent in Chile and 10 percent in Argentina."132 However, recently Chile announced an intention to nationalize its lithium production.133 The announcement has led to questions regarding lithium supply volatility and security, specifically in the context of EV supply chains.134 Other examples of geopolitical and national security risk inherent to EV supply chains include, but are not limited to, as follows:

- "Amid growing demand for lithium in the race for electric vehicle batteries, Mexico last year nationalized the mineral and created the state-run LitioMx, or Litio Para Mexico."135 Recently, on February 18, 2023, Mexican President Andres Manuel Lopez Obrador signed a decree handing over responsibility for lithium reserves to Mexico's energy ministry, after nationalizing lithium deposits in April 2022.136
- "Indonesia is home to 22% of the world's nickel reserves, and its ban on nickel ore exports since 2020 has caused major shifts in the supply chains of strategic products such as electric vehicles and rocket engines."137 Nickel is a crucial material in the production

of EV battery cathodes.138 As stated in EPA's proposal, "in 2019 about 50 percent of global nickel production occurred in Indonesia, Philippines, and Russia".139 [EPA-HQ-OAR-2022-0985-1566-A2, pp. 28 - 29]

138 https://www.iea.org/policies/16084-prohibition-of-the-export-of-nickel-ore

139 EPA's HD Phase 3 GHG Proposal at 25963.

EPA notes "[f]or example, in October 2022, the IEA projected that global Lithium Carbonate Equivalent (LCE) production from operating mines and those under construction may sufficiently meet primary demand until 2028 under the [IEA's] Stated Policies Scenario."140 But EPA ignores that IEA's 2022 Stated Policies Scenario is only "[a] scenario which reflects current policy settings" and does not contemplate any accelerated impacts resulting from EPA's current proposal or any regulatory activity within the current year.141 Moreover, even under the IEA's 2022 stated policies scenario (STEPS) "more conservative benchmark for the future"142, which does not anticipate EPA's HD Phase 3 GHG proposal, lithium supply is still ultimately projected to fall short of demand in 2028, as acknowledged by EPA.143 This is within the first model year of EPA's proposed standards under the HD Phase 3 GHG Rule. [EPA-HQ-OAR-2022-0985-1566-A2, p. 29]

EPA indicates that "[i]n addition, the European Union is seeking to promote rapid development of Europe's battery supply chains by considering targeted measures such as accelerating permitting processes and encouraging private investment. To these ends the European Parliament proposed a Critical Raw Materials Act on March 16, 2023, which includes these and other measures to encourage the development of new supplies of critical minerals not currently anticipated in market projections."144 In support of this statement, EPA cites to, in part, an EU Announcement regarding the European Battery Alliance as well as a New York Times article. Both sources, however, contain statements that undermine EPA's proposal. The European Battery Alliance announcement also states that:

However, Europe is still facing several structural challenges, such as the lack of 800,000 skilled workers by 2025, high energy, land, and permitting costs, as well as the fact that Europe is now home of only 1% of the production of key battery raw materials. The discussion took into account third countries' support schemes for green technologies, most notably in China, affecting the global level playing field. Moreover, while it is positive that the United States have decided to enter in full speed the fight against climate change through the Inflation Reduction Act, some of its provisions risk having a negative impact on the EU's competitiveness and attractiveness for new investments along the battery value chain.145 [EPA-HQ-OAR-2022-0985-1566-A2, pp. 29 - 30]

144 EPA's HD Phase 3 GHG Proposal at 25966.

145 European Union, ''7th High-Level Meeting of the European Battery Alliance: main takeaways by the Chair Maros Sefcovic and the Council Presidency,'' March 1, 2023. https://single-market-economy.ec.europa.eu/system/files/2023-03/Main%20takeaways_7th%20High-Level%20Meeting%20of%20EBA.pdf

The New York Times article cited to by EPA also clarifies that "despite the countries' [U.S. and EU's] deep cultural and historical ties, talks have been repeatedly bogged down by certain thorny issues, such as each government's treatment of its agricultural sector."146 The impacts are insufficiently addressed by EPA. [EPA-HQ-OAR-2022-0985-1566-A2, p. 30]

146 New York Times, ''U.S. Eyes Trade Deals With Allies to Ease Clash Over Electric Car Subsidies,'' February 24, 2023. https://www.nytimes.com/2023/02/24/business/us-europe-electric-car-subsidies-g20.html

EPA also maintains that "[d]espite recent short-term fluctuations in price, the price of lithium is expected to stabilize at or near its historical levels by the mid- to late-2020s."147 In support of this projection, EPA cites to an article148 that paints a more candid reality regarding battery metal price volatility:

"Contrary to anticipation, the global LIB supply chain is currently haunted by market fluctuations. From December 2020 to April 2022, the Chinese spot market has seen a price increase by 830% for lithium carbonate, 100% for cobalt sulfate, and 60% for nickel sulfate, with their per-ton prices rising to $73,000, $18,000, and $7,000, respectively. Skyrocketing costs were transmitted downstream as raw material suppliers were powerless over such huge surges. That made the cathode price increase by 140% for $LiNi_{0.8}Co_{0.1}Mn_{0.1}O_2$ (NCM-811) to $64,000/ton and 330% for $LiFePO_4$ (LFP) to $25,000/ton, and electrolyte price increased by 160% to $17,000/ton. The collective impact prompted an increase in LIB price in the second half of 2021, reversing its 30-year decline that began with the first-ever commercial product in 1991. In April 2022, prices of NCM and LFP prismatic electric vehicle (EV) battery cells reached $130/kWh and $120/kWh, respectively, 30% and 50% higher than their pre-surge levels. To respond, many

EV companies inflated retail prices, typically by 3%–5%, or even discontinued the sales of low-profit EV models, e.g., the Great Wall Ora.”149 [EPA-HQ-OAR-2022-0985-1566-A2, p. 30]

147 EPA’s HD Phase 3 GHG Proposal at 25966.

148 Sun et al., ‘‘Surging lithium price will not impede the electric vehicle boom,’’ Joule, doi:10.1016/j.joule. 2022.06.028

149 Id. (also available at https://www.belfercenter.org/publication/surging-lithium-price-will-not-impede-electric-vehicle-boom Balancing National Policy Considerations. In West Virginia, the Court found it significant that EPA’s rule would put the agency in the position of “balancing the many vital considerations of national policy implicated in the basic regulation of how Americans get their energy.” 142 S. Ct. at 2612. The Court was concerned that the agency would decide “how much of a switch from coal to gas” the grid could tolerate, and “how high energy prices [could] go” before becoming “exorbitant.” Id. Here, too, EPA’s rule puts it in the position of deciding “how much of a switch” to electrification the nation’s power grids can tolerate, and how high vehicle and electricity prices can climb without being “exorbitant.” [EPA-HQ-OAR-2022-0985-1566-A2, p. 55]

EPA’s asserted authority also implicates another key “consideration[] of national policy”: national security. NHTSA has acknowledged that the United States “has very little capacity in mining and refining any of the key raw materials” for electric vehicles. 86 Fed. Reg. 49,602, 49,797 (Sept. 3, 2021). And unlike biofuels and petroleum, most of the supply of critical components of batteries and motors for electric vehicles is controlled by hostile or unstable foreign powers, in particular China. Shifting to electric vehicles would thus make the American automotive industry critically dependent on one of the Nation’s primary geopolitical rivals. [EPA-HQ-OAR-2022-0985-1566-A2, p. 55]

Specifically, China is by far the largest source of graphite, which is used for lithium-ion batteries, and rare-earth elements like neodymium, which are used for permanent-magnet motors. By some estimates, a transition to electric vehicles would raise demand for graphite by 2500% and rare-earth elements by 1500%. International Energy Agency, The Role of Critical Minerals in Clean Energy Transitions 97 (March 2022). Another key component of lithium batteries, cobalt, is controlled by the Democratic Republic of the Congo, which is implicated in significant human-rights concerns (including child labor), and Chinese state-owned enterprises have a controlling interest in 70% of Congo’s cobalt mines. [EPA-HQ-OAR-2022-0985-1566-A2, pp. 55 - 56]

To be sure, with regard to this proposal on HDVs, as well as EPA’s related proposal for LDVs and MDVs, 151 members of the House submitted a letter247 to EPA urging the rescission of the proposals, citing such concerns as the proposal being “unworkable,” “impractical,” a ”deliberate market manipulation to prop up EVs,” a benefit to the Chinese Communist Party (“as China has a stranglehold on the critical minerals supply chain and manufacturing of EV batteries”), “not necessarily better for the environment in terms of emissions reductions,” and “worst of all,” a burden on Americans and their families, forcing them to pay “an excessive amount for a car they do not want and cannot afford.” Similarly, 26 senators issued a letter248 to EPA requesting withdrawal of the LDV, MDV, and HDV proposals, which “effectively mandate a costly transition to electric cars and trucks in the absence of congressional direction.” (emphasis added). The Senate letter further cited the proposal’s increased burden on the electric grid, the lack of supporting charging infrastructure, safety risks associated with EVs, roadway lifespan impacts and planning, consumer choice and affordability, domestic job losses, national security, and questionable cost metrics as concerns with, and flaws under, the proposal and also emphasized the application of the major questions doctrine and EPA's lack of clear authority:

Organization: Volvo Group

In addition to these governing and sectoral challenges, infrastructure development will also be strained by the lack of sufficient domestic production of minerals and materials including copper, aluminum, and electrical steel, the last of which currently has only one domestic supplier. The demand for these materials has surged, driven by the growth in renewable energy projects, the electrification of transportation, and the increasing use of digital technologies. At the same time, utilities and contractors are finding it difficult to secure these materials to complete projects on time and on budget due to supply chain disruptions1, trade tensions, and production limitations. This has led to shortages and price spikes2, thereby undermining the confidence of fleet customers in this new technology. [EPA-HQ-OAR-2022-0985-1606-A1, p. 7]

2 Spiller, B. (2023, May 3). Why Are Electric Truck Prices So High? Resources For the Future blogpost. Accessed on 14 June 2023 at https://www.resources.org/common-resources/why-are-electric-truck-prices-so-high/

b. Batteries

The U.S. battery manufacturing industry is quickly scaling to meet demand driven by transportation electrification. Since January 2021, the U.S. private sector has announced nearly $82 billion in battery manufacturing investments, translating to 96 new or expanded processing and manufacturing plants.91 According to Argonne National Lab, between 2010 and 2021, the private and public sector invested $95 billion in the U.S. battery manufacturing industry.92 This number represents 160 new or expanded critical materials processing and manufacturing facilities, with enough capacity to provide batteries for 10 million EVs each year and create 70,000 new jobs. [EPA-HQ-OAR-2022-0985-2429-A1, p. 23]

91 New US Battery Manufacturing and Supply Chain Investments Announced Under President Biden, US Department of Energy, (February 13, 2023) https://www.energy.gov/sites/default/files/2023-02/Battery%20Supply%20Chains%20Investments%20Map.pdf

92 "A new look at the electric vehicle supply chain as battery-powered cars hit the roads en masse," Argonne National Laboratory, (May 4, 2023) https://www.anl.gov/article/a-new-look-at-the-electric-vehicle-supply-chain-as-batterypowered-cars-hit-the-roads-en-masse

The Bipartisan Infrastructure Law allocated $1.6 billion to the Department of Energy for the funding of "new commercial-scale domestic facilities to extract and process lithium, manufacture battery components, recycle batteries, and develop new technologies to increase U.S. lithium reserves."93 In 2022, the Inflation Reduction Act 45X Advanced Manufacturing Production and Advanced Energy Project Tax Credit provides $35 per kWh in each battery cell, $10 per kWh in each battery module, 10% of the costs of production of the applicable critical materials incurred by the taxpayer. The Advanced Energy Project Tax Credit also appropriated a $10,000,000 fund for tax credits to build clean technology manufacturing facilities, including those that process, refine, and recycle critical minerals.94 Through the 45X credit, the IRA cuts nearly one third of the cost of producing batteries in the United States.95 Together, these historic provisions will drive American battery innovation, ensuring that the sector is equipped to electrify all electric vehicle classes over the coming years. [EPA-HQ-OAR-2022-0985-2429-A1, p. 23]

93 Public Law 117-58

94 "Inflation Reduction Act: What it Is and What it Means for EV Adoption." Zero Emission Transportation Association, (2022) https://www.zeta2030.org/insights/the-inflation-reduction-act-what-it-is-and-what-it-means-for-ev-adoption

95 "U.S.-Made EVs Could Get Massively Cheaper, Thanks to Battery Provisions in New Law," Car and Driver, (February 3, 2023) https://www.caranddriver.com/news/a42749754/us-electric-cars-could-get-cheaper-inflation-reduction-act-section-45x/

i. Manufacturing

There is historic momentum around battery manufacturing as it ramps up to support transportation electrification. Over the past year, battery producers have rapidly invested in new battery capacity in anticipation of strong electric vehicle sales growth. Benchmark's Gigafactory Assessment suggests that a total of 1.4 terawatt hours of new battery capacity was announced in just the last six months and the number of Benchmark-tracked plants more than doubled—from 174 in November 2020 to 379 in April 2023.96 [EPA-HQ-OAR-2022-0985-2429-A1, pp. 23 - 24]

96 "Battery gigafactory plans slow down in April after record 2022," Benchmark Minerals Intelligence, (April 26, 2023) https://source.benchmarkminerals.com/article/battery-gigafactory-plans-slow-down-in-april-after-record-2022?mc_cid=f82a9ac7a8&mc_eid=be723945d8

Below is a list of recently-announced investments in EV battery manufacturing, all of which will help support the transition to an electrified transportation sector:

- In March 2023, ZETA member LG announced a $5.5 billion investment to construct a battery manufacturing complex in Queen Creek, Arizona. The complex will consist of two manufacturing facilities.one for cylindrical batteries for EVs and another for lithium iron phosphate (LFP) pouch-type batteries for energy storage systems. LG plans to invest $3.2 billion in building a cylindrical battery manufacturing facility with a capacity of 27GWh, and $2.3 billion in LFP pouch-type battery facility with the capacity of 16GWh. Both facilities, totaling 43 GWh, plan to break ground this year and will begin production in 2025 and 2026, respectively.97 A more comprehensive list of LGs investments in domestic battery manufacturing can be found in Appendix Figure A.1.
- In April 2023, Hyundai Motor Co. announced it had finalized a $5 billion EV battery joint venture with SK On, a battery unit of SK Innovation Co Ltd. The plant will be located in Georgia and is expected to start manufacturing battery cells in the second half of 2025 with an annual production capacity of 35 GWh.98
- In April 2023, General Motors and Samsung announced they will invest over $3 billion to build a joint venture EV battery manufacturing plant in St. Joseph County, Indiana. Expected to start production in 2026, the plant aims to have an annual production capacity of 30 GWh.99 [EPA-HQ-OAR-2022-0985-2429-A1, p. 24.] [See Docket Number EPA-HQ-OAR-2022-0985-2429-A1, page 57, for Figure A.1]

97 “LG Energy Solution to Invest KRW 7.2 Trillion to Build Battery Manufacturing Complex in Arizona, Step Up EV and ESS Battery Production in North America,” LG, (March 24, 2023) https://news.lgensol.com/company-news/press-releases/1613/

98 “Hyundai Motor bolsters US presence with $5 bln EV battery venture,” Reuters, (April 25, 2023) https://www.reuters.com/business/autos-transportation/hyundai-motors-q1-net-profit-jumps-109-beating-expectations-2023-04-25/

99 “GM, Samsung SDI to invest more than $3 bln to build joint EV battery plant in US,” Reuters, (April 25, 2023) accessed May 17, 2023 https://www.reuters.com/business/autos-transportation/gm-samsung-sdi-plan-build-new-us-battery-plant-sources-2023-04-24/

Organization: Western States Trucking Association (WSTA)

Furthermore, Amnesty International and many other credible organizations have documented serious human rights violations linked to the extraction of the minerals used in lithium-ion batteries. The European Parliament adopted a ZEV Battery Directive Resolution on March 10, 2022, where battery-makers will face assessment of their supply chains to ensure any environmental or human rights abuses are identified and addressed. Carbon emissions caused by battery production should be disclosed, analyzed and used to create a responsible end-of-life recycling solution. [EPA-HQ-OAR-2022-0985-1533-A1, p. 1]

Organization: Zero Emission Transportation Association (ZETA)

6. The EV Supply Chain is Preparing to Support Increased Heavy-Duty Electrification

The widespread transition to electrified transportation is involving industries and companies that have not historically had a major role in supplying products to the transportation sector. Policies like EPA’s proposed Phase 3 GHG emissions standards for heavy-duty vehicles provide regulatory certainty for the entire supply chain supporting the transition to electrification. [EPA-HQ-OAR-2022-0985-2429-A1, p. 17]

As discussed further below, the supply chain is composed of discrete, yet interconnected segments that are continuing to scale up in capacity. Complementary policies in various stages of implementation today will lead to an even more robust and resilient supply chain over the MY 2027-2032 time frame covered by EPA’s proposed standards. [EPA-HQ-OAR-2022-0985-2429-A1, p. 17]

a. Critical Minerals Development

As projected demand for critical minerals (lithium, nickel, cobalt, manganese, copper, graphite, and rare earth elements) for use in EV batteries continues to grow—due in large part to policies such as EPA’s proposed Phase 3 HDV GHG emissions standards—the supply chain is preparing to meet that demand both through new extraction and processing and with additional support from recycling. [EPA-HQ-OAR-2022-0985-2429-A1, p. 17]

The section 30D New Clean Vehicle Tax Credit in the Inflation Reduction Act will ensure these critical minerals are sourced either in the United States or from free trade agreement countries. The credit is composed of two halves: qualifying vehicles will receive $3,750 for meeting each of the critical mineral and battery component sourcing requirements.70 The stringent ramp-up of the domestic sourcing requirements in the IRA over the coming years will lead to a robust supply chain capable of delivering domestically-sourced raw and refined materials. While the 30D credit is only available for eligible light-duty vehicles, the incentive to onshore EV supply chains will have additional effects for HDEVs. [EPA-HQ-OAR-2022-0985-2429-A1, p. 17]

70 "Overview and Analysis: March Treasury Guidance for Clean Car Tax Credit (30D)," ZETA, (April 2023) https://www.zeta2030.org/insights/overview-and-analysis-march-treasury-guidance-for-clean-car-tax-credit-30d

A key element to the success of the supply chain's ability to deliver the critical minerals necessary to support the transition to electrified transportation will be reforming the permitting processes for new extraction and processing operations. The Biden-Harris Administration has placed a much-needed focus on this area71 and ZETA has consistently supported reforms72 that ensure development projects are constructed quickly while meeting the strongest environmental standards. [EPA-HQ-OAR-2022-0985-2429-A1, pp. 17 - 18]

71 "FACT SHEET: Biden-Harris Administration Outlines Priorities for Building America's Energy Infrastructure Faster, Safer, and Cleaner," (May 2023) https://www.whitehouse.gov/briefing-room/statements-releases/2023/05/10/fact-sheet-biden-harris-administration-outlines-priorities-for-building-americas-energy-infrastructure-faster-safer-and-cleaner/

72 "Critical Mineral Permitting Reform Framework," ZETA, (May 2023) https://www.zeta2030.org/insights/critical-mineral-permitting-reform-framework

i. Projected demand for critical minerals

Demand for critical minerals is expected to grow substantially in the coming years.73 Figure 2 shows IEA's projected demand scenarios by 2040 relative to a 2020 baseline. Figure [EPA-HQ-OAR-2022-0985-2429-A1, p. 18.] [See Docket Number EPA-HQ-OAR-2022-0985-2429-A1, page 18, for Figure 2]

73 "Mineral demand growth from new EV sales by scenario, 2040 compared to 2020," IEA, (October 26, 2022) https://www.iea.org/data-and-statistics/charts/mineral-demand-growth-from-new-ev-sales-by-scenario-2040-compared-to-2020

In a scenario that meets the goals of the Paris Climate Agreement, the share of total demand for critical minerals rises significantly over the next two decades to over 40% for copper and rare earth elements, 60-70% for nickel and cobalt, and almost 90% for lithium.74 EVs and battery storage have already displaced consumer electronics to become the largest consumer of lithium and are set to displace the stainless steel industry as the largest end user of nickel by 2040. [EPA-HQ-OAR-2022-0985-2429-A1, p. 18]

74 "The Role of Critical Minerals in Clean Energy Transitions," IEA, (May 2021) https://www.iea.org/reports/the-role-of-critical-minerals-in-clean-energy-transitions

ii. Meeting the forthcoming demand for critical minerals

As demand for critical minerals is expected to grow rapidly, it is first necessary to evaluate the current state of global production. For most minerals, production has grown in the past decade.75 However, while much of the production for certain minerals is concentrated in a handful of countries, the Carnegie Endowment for International Peace and Figure 3 below demonstrate that the demand for most virgin critical minerals can be met through extraction in democratic countries.76 [EPA-HQ-OAR-2022-0985-2429-A1, p. 19.] [See Docket Number EPA-HQ-OAR-2022-0985-2429-A1, page 19, for Figure 3]

75 “bp Statistical Review of World Energy,” British Petroleum, (2022) https://www.bp.com/content/dam/bp/business-sites/en/global/corporate/pdfs/energy-economics/statistical-review/bpstats-review-2022-full-report.pdf

76 Democratic countries include: Argentina, Armenia, Australia, Austria, Belgium, Bhutan, Bolivia, Brazil, Bulgaria, Canada, Chile, Finland, France, Georgia, Germany, Ghana, Iceland, Indonesia, Japan, Mexico, Mongolia, Nigeria, Norway, Peru, Poland, Portugal, Senegal, Sierra Leone, South Africa, South Korea, Spain, Sri Lanka, Sweden, Ukraine, and the United States.

77 “Friendshoring Critical Minerals: What Could the U.S. and Its Partners Produce?,” Carnegie Endowment for International Peace (May 3, 2023) https://carnegieendowment.org/2023/05/03/friendshoring-critical-minerals-what-could-u.s.-and-its-partners-produce-pub-89659

The Net Zero Industrial Policy Lab at Johns Hopkins University finds that partnerships among democratic countries would be able to produce enough minerals to enable the world to limit warming to 1.5 degrees Celsius, the more ambitious target in the Paris Climate Agreement.78 However, while producing enough metals to meet these targets would require extraordinary technological and financial cooperation, the substantial economic development opportunities create a strong incentive to do so. [EPA-HQ-OAR-2022-0985-2429-A1, p. 20]

78 Id.

In regards to lithium specifically, Benchmark Mineral Intelligence found that by the end of 2023, the world’s supply of lithium will be more than double 2021’s output and more than the total produced between 2015 and 2018.79 Such rapid growth provides cause for optimism that supply will be able to keep pace with demand in the coming years. Separately, given the national security implications of ensuring a stable supply of critical minerals, the Defense Advanced Research Projects Agency (DARPA) and the United States Geological Survey (USGS) have partnered to explore the potential of machine learning and artificial intelligence tools and techniques to enhance USGS domestic critical mineral assessments.80 [EPA-HQ-OAR-2022-0985-2429-A1, p. 20]

79 “Global lithium supply forecast to hit 1 million tonnes for first time,” Benchmark Mineral Intelligence, (April 28, 2023) https://source.benchmarkminerals.com/article/global-lithium-supply-forecast-to-hit-1-million-tonnes-for-first-time

80 “Artificial Intelligence for Critical Mineral Assessment Competition,” DARPA, https://criticalminerals.darpa.mil/

iii. ZETA members’ investments in critical mineral production

ZETA members are scaling up capacity to meet the projected demand in the coming years. For example, ioneer’s Rhyolite Ridge project—located in Esmeralda County, NV—holds the largest known lithium and boron deposit in North America.81 Ioneer recently announced a mineral resource update that found a 168% increase in estimated lithium at Rhyolite Ridge.82 [EPA-HQ-OAR-2022-0985-2429-A1, p. 20]

81 Ioneer - Rhyolite Ridge, accessed May 16, 2023 https://rhyolite-ridge.ioneer.com/

82 "New Ioneer Mineral Resource update finds 168% increase in estimated lithium at Rhyolite Ridge," BusinessWire, (April 26, 2023) https://www.businesswire.com/news/home/20230426005886/en/New-Ioneer-Mineral-Resource-update-finds-168-increase-in-estimated-lithium-at-Rhyolite-Ridge

Albemarle Corp. recently announced it is aiming to spend between $1.25 billion and $1.5 billion to double its lithium hydroxide output in Australia to a volume that it estimates could power more than 2 million electric cars a year.83 Albemarle plans to build two additional processing trains at its Kemerton plant south of Perth in Western Australia, which could boost its lithium hydroxide production by 50,000 tons annually. [EPA-HQ-OAR-2022-0985-2429-A1, pp. 20 - 21]

83 "Lithium giant Albemarle eyes $1.5B Australian expansion," E&E News, (May 4, 2023) https://subscriber.politicopro.com/article/eenews/2023/05/04/lithium-giant-albemarle-eyes-1-5b-australian-expansion-00095141

Recently, Lithium Americas provided an update on the status of its various projects around the world.84 Lithium Americas' Caucharí-Olaroz project in Argentina is expected to begin producing lithium in June 2023. Production ramp up at the Caucharí-Olaroz project is expected to produce 40,000 tonnes of battery-quality lithium carbonate per year; the company expects to complete this expansion in Q1 2024. Domestically, Lithium Americas recently announced the start of construction activities at Thacker Pass in Nevada following receipt of notice to proceed from the Bureau of Land Management.85 [EPA-HQ-OAR-2022-0985-2429-A1, p. 21.]
[See Docket Number EPA-HQ-OAR-2022-0985-2429-A1, page 21, for Figure 4]

84 "Lithium Americas Reports First Quarter 2023 Results," Lithium Americas, (May 15, 2023) https://www.lithiumamericas.com/news/lithium-americas-reports-first-quarter-2023-results

85 Id.

With applications well beyond just EVs, ensuring a domestically-sourced supply of copper will be critical to ensuring a rapid transition to electrified transportation. In May 2023, the Department of Energy proposed to characterize copper as critical through its inclusion on the official DOE Critical Materials List.86 In particular, DOE is recommending a designation for copper of "near-critical" in the medium term (2025-2035). To meet the forthcoming increases in demand for copper, a pair of domestic projects are currently in various stages of development: [EPA-HQ-OAR-2022-0985-2429-A1, pp. 21 - 22]

86 "Critical Materials Assessment," U.S. Department of Energy, (May 2023) https://www.energy.gov/sites/default/files/2023-05/2023-critical-materials-assessment.pdf

Resolution Copper, Arizona: This project has the potential to supply up to 25% of the nation's copper demand to power America's clean energy transition with $1B annually into Arizona's economy. The project currently employs 300 people, 80% who live locally in rural communities within 40 miles of the project. When the mine is fully operational, Resolution Copper expects to directly employ about 1,500 workers, paying around $134 million per year in total compensation. In total, the project is expected to support 3,700 direct and indirect jobs, many of them local building trades and U.S. Steel Workers union jobs.87 [EPA-HQ-OAR-2022-0985-2429-A1, p. 22]

87 See: https://resolutioncopper.com/

NewRange Copper Nickel: This project is a 50:50 joint venture of Teck Resources Limited and PolyMet Mining Corp., holding the NorthMet and Mesaba deposits—two large, well defined resources in the established Iron Range mining region of Minnesota. The stand-alone company is creating a path to develop one of the world's largest and lowest cost copper-nickel-PGM producing districts, unlocking a new domestic supply of critical minerals for the low-carbon transition through responsible mining, and delivering significant, multi-generational economic and other benefits to the region and beyond.88 [EPA-HQ-OAR-2022-0985-2429-A1, p. 22]

88 See: https://newrangecoppernickel.com/

iv. Refining and processing

Beyond extraction, ZETA members have recently announced projects to process and refine raw critical minerals:

- In March 2023, Albemarle announced a new lithium processing facility in South Carolina.89 Albemarle expects the facility to annually produce approximately 50,000 metric tons of battery-grade lithium hydroxide from multiple sources, with the potential to expand up to 100,000 metric tons. Production at the facility would support the manufacturing of an estimated 2.4 million electric vehicles annually.
- In May 2023, Tesla announced a new lithium refinery in Southwest Texas which, when completed, is expected to produce enough lithium to build about 1 million EVs by 2025.90 [EPA-HQ-OAR-2022-0985-2429-A1, p. 22]

89 "Albemarle Corporation Announces New U.S. Lithium Mega-Flex Processing Facility in South Carolina," Albemarle Corporation, (March 22, 2023) https://www.albemarle.com/news/-albemarle-corporation-announces-new-us-lithium-megaflex-processing-facility-in-south-carolina–

90 "Elon Musk and Tesla break ground on massive Texas lithium refinery," Reuters, (May 8, 2023) https://www.reuters.com/business/autos-transportation/tesla-plans-produce-lithium-1-mln-vehicles-texas-refinery-elon-musk-2023-05-08/

EPA Summary and Response:

Summary:

There were many comments addressing issues pertaining to minerals critical to battery production. There was near consensus as to which minerals are at issue: lithium, cobalt, nickel, graphite, rare earths, copper, manganese, and (for some commenters) aluminum. AmFree stated that platinum is significant for FCEV production. The Sulphur Institute suggested that sulphur could be critical to the lithium mining process.

Some commenters questioned whether there was sufficient supply of some of these minerals, either in the rule's initial timeframe or thereafter. Commenter AVE quotes a World Bank estimate that "the global need for critical minerals will quadruple to over 3 billion tons by 2035, far exceeding the current supply." AmFree cites a DOE source as stating that global demand for "critical materials" will increase by 400-600% over the next decade. With respect to lithium, CFDC notes that worldwide demand in 2021 was 100,000 tons which is expected to grow to 30.3 million tons by 2050. Valero quotes the International Energy Agency (2022) as projecting demand shortfalls by 2028. Valero state that the same source projects 25 and 15 times increase in demand for graphite and rare earths, respectively. Arizona State Legislature postulates an increase of 42 times current critical mineral levels by 2040. AFPM projects a shortfall by 2030 based on current and anticipated production rates, challenging the finding of the Department of Energy's Li-Bridge that there will be no global shortage of cathode active material or lithium chemical supply through 2035 under current projections of global demand. Citing the same source[866], AFPM maintains that at current production rates, the world exhausts the minable reserves of copper, cobalt, and nickel in the 2030s, without accounting for demand of the proposed rule. The same commenter noted a Bloomberg (2022) projection that by 2030 copper demand is expected to rise by 53% when supply is expected to rise by only 16%, again not accounting for demand from the proposed rule.

Commenters also raised issues regarding extractability of these critical minerals. American Petroleum Inst. quotes BMI that 384 new mines will be needed by 2035 to meet worldwide demand for graphite, nickel, cobalt, and lithium (without regard to demand attributable to the proposed rule). Two commenters stated that mining anywhere in the world involves long lead times before they become operational, and then face the further issue of ore concentrates declining in quality as mining continues. (Valero, AmFree). With regard to domestic mining capability, commenters noted that at present there are no domestic graphite or manganese mines, one lithium mine, one nickel mine (slated to close in a few years), and one cobalt mine, none with capacity needed to support projected demand. (Electricity Coalition, AmFree). Commenters likewise noted the long time horizons and uncertainty of bringing new mining operation into production anywhere in the world (AmFree), and especially domestically (10-30 year estimate) (AmFree). A commenter stated that an additional two years of testing can be added to assure that lithium is of sufficient purity for cathode use. (AFPM). Another commenter stated that of the 275 rare earth extraction projects trying to start up worldwide in 2011, only 1.5% were operating as pilot projects or commercial entities 10 years later. (AmFree).

In these commenters' view, issues of limited supply are compounded by uncertainties due to the limited number of raw material sources, and, in some cases their potential political or geopolitical instability. Commenters stated that most of the world's cobalt comes from the Democratic Republic of the Congo. (e.g., Transfer Flow.) One commenter stated that Gabon is the source of most manganese. (AFPM.) That commenter also stated that fifty per cent of nickel comes from three countries: Indonesia, Philippines, and Russia. (AFPM.) Another commenter stated that sixty percent of graphite from China, and 90 per cent of lithium from Australia, Chile, and China (API). Commenters stated that with so few suppliers, supply shortages can arise due to natural disasters, or non-natural curtailment. Commenters noted the rise of 'resource nationalism' (AmFree), pointing to Indonesia curtailing nickel exports in 2020, and Mexico and Chile making moves to nationalize lithium extraction. (Valero.)

The commenters continue that these same issues arise, in even greater magnitude, due to constraints on refining (i.e., processing) capacity – in particular, that most of that capacity is Chinese. One commenter stated that China controls 60% of lithium refining capacity, 50% of graphite, 35% of nickel, 72% of cobalt, 40% of copper, and 90%of manganese. (AFPM.) Other commenters asserted estimates that are higher. (CATF, Delek, Arizona St. Legislature.). One commenter stated that domestic refining capacity, in contrast, is 1% of nickel, and 2% of lithium. (Electricity Coalition.) Some commenters stated that China likewise makes most battery components—73% of NMC cathodes and 99% of LFP cathodes—compared to 1% made domestically. (Delek, Electricity Coalition.)

[866] Lilly Lee, ENERGY INTELLIGENCE, Mining the Gap to a Net-Zero Future (May 15, 2023) available at https://www.energyintel.com/00000188-1e5f-d806-ad9f-5edfeb1d0000?utm_campaign=website&utm_source=sendgrid.com&utm_medium=email.

Putting this together, these commenters see an uncertain supply chain, that in their view raises significant issues as to whether there can be sufficient materials to support the degree of battery production which would be necessary under the projected potential compliance pathway. Commenters stated that the markets are inefficient and sclerotic (API, AFPM), vulnerable to squeezes in the form of unfair trade practices and outright supply reductions (AmFree, Chevron), as well as vulnerable to the aforementioned threats from resource nationalism and political instability.

Commenters noted the adverse geopolitical implications of these circumstances. Commenters stated that Chinese effective control of so many of these resources means that supply chains cannot exclude China. (e.g., AmFree, CFDC, AFPM.) Some of these commenters stated that this raises issues of critical mineral security, given that (in these commenters' views) at present the United States is essentially completely dependent on imports (with the exception of nickel and copper). (AFPM.) API analogized to the energy security issues raised by the 1970s oil embargo. These commenters found it ironic that the United States would prefer uncertain foreign sources of critical materials, with negative national security implications, when there are ample domestic energy resources. (CFDC, NACS, Delek, API.) CFDC took issue with EPA's statement that "mineral security is not a perfect analogy to energy security" because once the minerals are here they remain here as a recyclable resource (88 FR at 25962), noting the lack of recycling capacity, inability to recover any metal but lithium from batteries, the value of domestic oil exports, and, most important, the issue of dependence on China. The Arizona State Legislature stated that any energy security gains posited for the rule would be cancelled out by the negative mineral security issues.

Several commenters noted negative environmental and human rights implications, particularly those related to critical mineral extraction. Commenters stated that child labor abuses and environmental degradation issues from cobalt mining in the Congo are well documented. (e.g., AmFree, MFN, Lynden Inc.) Other commenters stated that lithium extraction can occur in high water stress areas, or otherwise in areas without environmental best practices. (AmFree, American Highway Users Alliance.) USW commented that "offshoring of the automotive supply chain not only harms manufacturing workers and communities in the U.S., but it also allows automakers to cut their costs in pursuit of lower environmental and labor standards abroad." As summarized and responded to in RTC section 17.1 above, some of these commenters maintained that EPA was required to account for pollutant emissions from these activities in its quantified emissions analysis.

Turning to the issue of cost, several commenters posited potential huge price increases and price volatility. One commented stated that since there are few suppliers and a Chinese-dominated supply chain, any of these entities possesses market power to control prices. (AFPM.) Other commenters stated that demand surges are bound to put upward pressure on prices. (AmFree, DTNA, Chamber of Commerce.) Some commenters stated that critical minerals are priced as specialty chemicals, not commodities, and hence are likely to remain priced high even if supply increases. (API, AFPM.) A commenter asserted that these concerns are not purely hypothetical, as between 2020 and 2021, the price of cobalt doubled. (AmFree.) Another commenter stated that lithium prices increased more than 7-fold between 2021 and 2022 (AFPM.) In response to findings in the proposed preamble that lithium prices had fallen and were likely to fall further as supplies increase, 88 FR at 25966/1-2, AFPM stated that most critical mineral contracts were futures, locking in current high prices. MEMA stated that EPA needed to consider the issue of battery disposal cost.

These commenters considered the question of battery production in light of all of these perceived constraints. Faced with the need to increase battery production by 600% by 2030 and 1500% by 2040 (CFDC, EMA), these commenters did not see how there could be sufficient domestic capacity (where EMA's estimate assumed batteries of 4,000 cycles.) Commenters believed this means that batteries will need to be imported, largely from China which currently dominates production, reinforcing national security concerns. (Arizona State Legis, Delek, CFDC.)

These commenters acknowledged that the IRA and BIL could have some positive effect on promoting domestic supply chains and domestic battery production, but viewed that effect as minimal. With respect to the Clean Vehicle Tax Credit (30D) (sic), these commenters doubted that the domestic content prerequisites and Chinese bar prescriptions can be satisfied, given China's dominance of processing and supply chains. (CFDC, AFPM.) They viewed the Advanced Battery Production Credit (45X) as of little consequence due to insufficient domestic production. (AFPM.) Commenters stated that the tax credit for Commercial Clean Vehicles (45W) is available but will be largely or entirely offset by federal and state excise taxes. (EMA, DTNA.)

These commenters concluded that domestic production of either the raw materials themselves, or battery production, would not be self-sufficient within the rule's initial timeline. These commenters stated that given permitting necessities, and inherent long delays between commencement and commercialization of mining projects, new mining capacity by 2032 is unrealistic, even for copper given the current importation of 45% of demand. (AFPM, Bradbury, Chamber of Commerce, Electrification Coalition ("[t]he proposed rule identifies the 21 U.S. lithium mine projects that can potentially help meet our growing lithium demand. These projects, however, cannot be brought online in a timely manner under our current permitting system"). One commenter stated that robust domestic supply chains likewise appear unrealistic in these timeframes. (Delek.) These commenters therefore took issue with EPA's ultimate conclusion that "increased vehicle electrification in the United States will not lead to a critical long term dependence on foreign imports of minerals or components." 88 FR at 25962. ((API, Ariz. St. Legislature.)

Conversely, other commenters were more optimistic. (CARB, Clean Air Task Force, EDF, ICCT, MFN, State of California, ZETA, Volvo, Tesla). These commenters echoed many of the points raised by EPA at proposal, and expanded on them. With regard to supply, domestic needs can be sourced from democratic foreign sources, or from domestic sources. (ZETA, ICCT ("The U.S. has ten times more lithium reserves than needed to meet the 2030 EV production goals in its light-duty vehicle proposal. Friendly nations like Australia, Argentina, and Chile combined have two hundred times that amount. Australia and Canada also have one hundred times the amount of nickel, and fifty times the amount of cobalt needed in 2030, while Brazil, France, Indonesia, and the Philippines together have double again that amount.") Commenters specifically noted enormous increases in lithium extraction in Australia and Argentina (ZETA), and large domestic reserves in Rhyolite Ridge (Nevada), and Imperial Valley (California) (ZETA, CARB.). ZETA stated that lithium extraction has in fact more than doubled worldwide since 2021. (ZETA). ZETA also pointed to expanded domestic copper and nickel mining (citing Resolution Copper, Arizona a project having the potential to supply up to 25% of the nation's copper demand, and NewRange Copper Nickel in the Mesabi range (a 50:50 joint venture of Teck Resources Limited and PolyMet Mining Corp., holding the NorthMet and Mesaba deposits).

With respect to supply chains, these commenters noted the increase in non-Chinese capacity, in particular, significantly expanded lithium processing capacity in Australia, Argentina, and domestically (Thacker Pass, Nevada, which has received a BLM permit, Albemarle, South Carolina (ZETA), plus Tesla's lithium processing startup in Southwest Texas (ZETA, Tesla)). Tesla noted in detail its steps to establish and develop a supply chain that will support its future deployment of its Class 8 Semi truck. Tesla stated that this vertically integrated operation includes expanded cell production, build out of a new cathode production facility at Gigafactory Texas, and breaking ground on the most technologically advanced lithium processing facility in Corpus Christi. Tesla has also established an off-take agreement for a domestic source of lithium with plans to process the lithium hydroxide and manufacture cathode material in the U.S. – creating a first-ever wholly North American upstream advanced battery supply chain. Tesla further notes its environmental stewardship and other benefits for all of the local communities associated with these projects. Tesla cites its own Responsible Sourcing Policy, Human Rights Policy, and Supplier Code of Conduct, which are aligned with the United Nation (UN) and the Organization for Economic Cooperation and Development (OECD)'s best practices for human rights and responsible business. Tesla also cites its development of an entirely North American battery supply chain. It cites the role that recycling will plan in reducing demand for new mineral resources for batteries, including its own efforts. This company maintained further that EPA has never done critical material assessments for fossil fuel-based standards, and maintains that Chinese control of barite, needed for petroleum extraction, raises issues of mineral security of the same type raised with respect to critical materials for battery production.

State of California et al. stated that "as of March 2023, at least $45 billion in private-sector investment has been announced across the U.S. clean vehicle and battery supply chain", citing the US Dept. of Treasury proposed guidance on new clean vehicle credits.[867] This commenter stated that this includes "new and expanded commercial-scale domestic facilities to process lithium, graphite and other battery materials, manufacture components, and demonstrate new approaches, including manufacturing components from recycled materials", citing to Dept. of Energy announcements. [868]

Like EPA, these commenters further pointed to enormous influx of federal, state, and private investment into domestic critical material extraction, processing, and, in particular, battery production. Commenters stated that the domestic mining operations mentioned above have billions of dollars of capitalization, as do the domestic supply chains. (ZETA, State of Cal.; see also similar comments of EDF, MFN, CATF). Volvo noted that since January 2021, the U.S.

[867] U.S. Department of the Treasury, Treasury Releases Proposed Guidance on New Clean Vehicle Credit to Lower Costs for Consumers, Build U.S. Industrial Base, Strengthen Supply Chains (March 31, 2023), https://home.treasury.gov/news/press-releases/jy1379.

[868]U.S. Department of Energy, Bipartisan Infrastructure Law Battery Materials Processing and Battery Manufacturing & Recycling Funding Opportunity Announcement (Oct. 19, 2022), https://www.energy.gov/sites/default/files/2022-10/DOE%20BIL%20Battery%20FOA-2678%20Selectee%20Fact%20Sheets%20-%201_2.pdf;

private sector has announced nearly $82 billion in battery manufacturing investments, translating to 96 new or expanded processing and manufacturing plants. (Volvo at n. 91.)

These commenters particularly focused on investments through the BIL and IRA. Volvo stated that "The Bipartisan Infrastructure Law allocated $1.6 billion to the Department of Energy for the funding of 'new commercial-scale domestic facilities to extract and process lithium, manufacture battery components, recycle batteries, and develop new technologies to increase U.S. lithium reserves.'" The same commenter stated further that "the Inflation Reduction Act 45X Advanced Manufacturing Production and Advanced Energy Project Tax Credit provides $35 per kWh in each battery cell, $10 per kWh in each battery module, 10% of the costs of production of the applicable critical materials incurred by the taxpayer. The Advanced Energy Project Tax Credit also appropriated a $10,000,000 fund for tax credits to build clean technology manufacturing facilities, including those that process, refine, and recycle critical minerals.94 Through the 45X credit, the IRA cuts nearly one third of the cost of producing batteries in the United States."

Commenters stated that this influx of capital is projected to lead to huge increases in domestic battery manufacturing, and lower costs reflecting this dramatic increase. (State of Cal., noting the decline in battery costs already). Volvo notes that a total of 1.4 terawatt hours of new battery capacity was announced in just the last six months and the number of Benchmark-tracked plants more than doubled—from 174 in November 2020 to 379 in April 2023 (citing Benchmark's Mineral intelligence, April 2023).

Volvo also lists a series of recent announcements of additional domestic battery manufacturing operations:

- In March 2023, ZETA member LG announced a $5.5 billion investment to construct a battery manufacturing complex in Queen Creek, Arizona. The complex will consist of two manufacturing facilities.one for cylindrical batteries for EVs and another for lithium iron phosphate (LFP) pouch-type batteries for energy storage systems. LG plans to invest $3.2 billion in building a cylindrical battery manufacturing facility with a capacity of 27GWh, and $2.3 billion in LFP pouch-type battery facility with the capacity of 16GWh. Both facilities, totaling 43 GWh, plan to break ground this year and will begin production in 2025 and 2026, respectively.

- In April 2023, Hyundai Motor Co. announced it had finalized a $5 billion EV battery joint venture with SK On, a battery unit of SK Innovation Co Ltd. The plant will be located in Georgia and is expected to start manufacturing battery cells in the second half of 2025 with an annual production capacity of 35 GWh.

- In April 2023, General Motors and Samsung announced they will invest over $3 billion to build a joint venture EV battery manufacturing plant in St. Joseph County, Indiana. Expected to start production in 2026, the plant aims to have an annual production capacity of 30 GWh.

Volvo also cited the May 2023 report of Argonne National Laboratory, which concluded "[i]n total, domestic EV battery manufacturing capacity will increase by almost 20-fold between 2021 and 2030."

Several commenters posited that there could be less demand for critical materials due to substitution with more plentiful minerals. These commenters stated that innovations and improvements in battery chemistry, which include sodium-ion and solid state batteries, improvements in the commonly used nickel-manganese-cobalt (NMC cathode), and the use of the alternative lithium-ion-phosphate (LFP), can shift or reduce minerals used in batteries, potentially lowering costs and easing supply chain constraints (MFN, CARB). Although one commenter stated that not all of these battery substitutes are suitable for HDVs (AFPM), another commenter stated that lithium-iron-phosphate batteries could be. (EDF.) Another commenter stated that synthetic graphite is a possible substitute for mined natural graphite, and there is research showing that silicon can replace all or some graphite in the anode. (MFN.) The Electricity Coalition noted that Class 4-8 HDVs are a relatively small part of demand in any case.

Response: Availability of the critical minerals lithium, cobalt, nickel, manganese, and graphite

In response to comments about the availability of critical minerals and the need for development of the supply chain supporting the manufacture of HD BEVs, as well as the uncertainties and risks associated with the same, EPA appreciates the additional information provided by commenters citing recent growth in the global and domestic supply chain. This information is consistent with our continued observation that development of the supply chain for ZEV manufacturing inputs is receiving broad attention in the industry and is progressing in response to market forces and governmental incentives. EPA also acknowledges the arguments relating to risk and uncertainty cited by adverse commenters. Regarding these comments, EPA notes that the presence of uncertainty and risk is a common element in virtually any forward-looking or predictive type of analysis. In general, in establishing appropriateness of standards, neither the Clean Air Act nor general principles of administrative law require that EPA must prove that every potential uncertainty associated with compliance with the standards must be eliminated a priori. It is well-established in case law that "[i]n the absence of theoretical objections to the technology, the agency need only identify the major steps necessary for development of the device, and give plausible reasons for its belief that the industry will be able to solve those problems in the time remaining. Thus, EPA is not required to rebut all speculation that unspecified factors may hinder 'real world' emission control." *NRDC v. EPA*, 655 F.2d 318, 333–34 (D.C. Cir. 1981). Thus, it is not required, nor would it be reasonable to expect, that EPA prove sufficient production capacity already exists today for technologies or inputs that are likely to be required to comply with standards in the future, nor that all potential uncertainties that can be identified regarding the development of that capacity must be eliminated. In fact, past EPA rulemakings have been technology-forcing, and so have required industry to develop and increase production of technologies for which critical inputs and production capacity were not fully developed and proven at the time.

While commenters have presented information to further demonstrate the well-understood concept that currently operating supply capacity must grow in order to meet projected future demand, and have recited many of the uncertainties commonly associated with predicting this or any future response of supply to future demand, they have failed to provide specific evidence to support the implication that the demand resulting from the standards will not or cannot be met by industry in the time available. Commenters question whether market forces and government initiatives and incentives that are already underway will lead to sufficient supply to meet the standards, but do not show specifically why these activities should reasonably be expected to fail. Indeed, EPA has shown that the industry is working actively and effectively to increase supply and secure supply chains for needed materials; that government incentives and initiatives have been defined and are moving forward with intended effect; and that current price forecasts and investment outlooks for the time frame of the rule do not suggest that industry at large foresees a looming inability to meet the standards.

EPA does not agree with the comments projecting shortfalls in the supply of the critical mineral lithium, cobalt, nickel, manganese, and graphite during the time frame of the Phase 3 rule. We also do not agree that there will be insufficient refining capacity for these minerals. See Preamble Section II.D.2.ii.c. Nor do we see indications that the United States will be dependent on adversarial countries for imports or refining capacity of critical minerals during the phase 3 rule's timeframe.

Since the proposal, the Department of Energy (DOE) worked with Argonne National Laboratory (ANL) to provide an independent analysis of the outlook for critical minerals used in BEVs[869] including nickel, cobalt, graphite, lithium, and manganese. DOE consulted the latest available announcements and forecasts to develop an up-to-date assessment of activity in advancing the availability of these minerals on a global and domestic basis. Key findings from this work are discussed in Section II.D.2.ii.c. of the preamble to this final rule and are discussed here. EPA has evaluated this study carefully, and considers it to be important support for our findings of adequate availability of critical minerals and battery supply during the timeframe of the Phase 3 rule. See also additional analyses and sources cited in Preamble section II.D.2.ii.c. and RIA Chapters 1.5 and 1.6 supporting that conclusion.

<u>Lithium</u>

Regarding lithium, DOE finds that there are significant efforts to scale lithium supply both domestically and in Free Trade Agreement (FTA) countries. Both in the near-term and the medium-term DOE projects that lithium production domestically, potentially supplemented by trade and recycling, will be enough to meet domestic demand. Global lithium mining supply is anticipated to more than double in the next five years. In fact, if lithium demand does not match this supply, it could lead to oversupply and create downward price pressure. Globally, the majority of current early stage and exploration projects are in Australia, Canada, and the U.S. Several other FTA and MSP partners, such as Portugal, the Czech Republic, and Germany, are likely to add capacity over the medium term, further strengthening U.S lithium availability. DOE assesses that the U.S is well positioned in securing lithium materials domestically, particularly if all projects underway (particularly later stage projects) are successfully brought online at capacity. Several U.S. projects are in the construction stage, including those at Fort Cady, Thacker Pass, Rhyolite Ridge, and King Mountains cited by commenters.[870] See the more comprehensive list of U.S. lithium projects in development in Preamble section II.D.2.ii.

Regarding lithium, DOE finds that there are significant efforts to scale lithium supply both domestically and in Free Trade Agreement countries. The majority of early stage and exploration projects are in Australia, Canada, and. DOE assesses that the U.S is well positioned in securing lithium materials domestically, particularly if all projects underway (particularly later stage

---

[869] FCEVs also use batteries, albeit smaller batteries than an HD BEV, and so use the same minerals. The discussion in the text is written in terms of BEVs since these are the predominant source of demand.
[870] Argonne National Laboratory, "Securing Critical Minerals for the U.S. Electric Vehicle Industry (ANL-24/06) (March 2024) ("ANL") at 34 .

projects) are successful. Through such projects the U.S lithium supply is expected to more than double by 2025, and the U.S is poised to become a global key player in the lithium industry by 2030 if all ongoing projects come to fruition. The majority of U.S lithium production is likely to come from brines, which are relatively cheaper to produce compared to lithium from spodumene deposits. Both in the near term and the medium term a significant portion of lithium will be available domestically and in FTA countries, likely enough to meet domestic demand. Several FTA and MSP partners, such as Canada, Portugal, the Czech Republic, and Germany, are likely to add capacity over the medium term, further strengthening U.S lithium availability. DOE assesses that the U.S largely has sufficient lithium supply to meet domestic demand of battery manufacturers under a number of reasonable demand scenarios and that trade with FTA countries can supplement any shortfall. In addition, ANL notes that recycling may provide an additional source of lithium in the Phase 3 rule's timeframe.[871] See Preamble Section II.D.2.ii which includes source citations documenting all of these points.

There are thus multiple projections of adequate supply well into the 2030s, and, as noted in the succeeding paragraph of this response, corresponding price stability. Moreover, significant lithium deposits do exist in the U.S. in Nevada and California as well as several other locations,[872,873] and are currently attracting development interest from suppliers and automakers.[874] Since the proposal, several large U.S. lithium resources have continued to be announced and explored for development, including what could be the largest known lithium resource in the world.[875,876,877] The recent discovery of such sources and increased interest in development of known but unutilized sources suggests that resources of lithium, which previously was used only in a limited number of applications, may be underexplored and underdeveloped, and suggests that additional discoveries and developments may continue to modify our understanding of lithium availability.[878] See the further discussion of these points in preamble section II.D.2.ii.

Certain commenters expressed concern that lithium prices would rise to levels rendering the Phase 3 rule infeasible on grounds of cost. In fact, recent drops in lithium prices beginning in

early 2023[879] and persisting to the present[880] reflect the robust growth in lithium supply discussed above. They also lend further support to EPA's expectation that mineral prices will not continually rise as some commenters have suggested but will find an equilibrium within a reasonable range of prices as the rapidly growing supply chain continues to mature. See the further discussion in Preamble Section II.D.2.ii.a and c, and see also Comments of CARB noting the drop in price of lithium carbonate.[881]

We thus reiterate our conclusion from the proposal that the lithium market is responding robustly to demand and that global supply will be adequate at least through 2035, and that lithium prices are unlikely to spike high, but rather are likely to stabilize within this decade at or near historic levels, which does not constrain the projected need under the modeled potential compliance pathway supporting the Phase 3 standards. See 88 FR at 25965-66 and Preamble section II.D.2.ii.a, for more detailed information on projections of lithium prices.

Nickel

In the near- and medium-term, there is sufficient capacity in FTA and MSP countries to meet demand for nickel, although the U.S. will likely need to rely on non-FTA countries given expected competition for these mineral from other countries' decarbonization goals. DOE noted that there are significant efforts to scale nickel supply in FTA countries, with a number of early-stage exploration projects in Australia and Canada. While the ability of these projects to reach full production by 2035 is uncertain, they indicate global efforts are taking place to scale nickel availability to meet global demand. Exploration efforts for nickel in the U.S are currently limited, reflecting current geological sources and technology. Currently, about 50% of global nickel mining is in Indonesia, and Indonesia is expected to remain a major producer of nickel for the next decade, along with the Philippines, Australia, and Canada.[882]

DOE identifies several U.S policy levers that could support build out of nickel battery grade refining and recycling capabilities, for example, the DOE Loan Programs Office (LPO), and funding under the Bipartisan Infrastructure Law (BIL) and Inflation Reduction Act (IRA). Sufficient nickel supply is available, some from free trade agreement (FTA) and Minerals Security Partnership (MSP) partners (Canada, Australia, Finland, Norway), and other countries with whom the United States has bilateral or other types of trade agreements (Indonesia, Philippines and other non – Chinese allies). DOE thus concludes that international trade is likely to be important to strengthening U.S. supply of nickel. DOE outlines substantial efforts already underway with FTA, MSP, and other allies to secure nickel, including among other things, a Trade Investment Framework Agreement with Indonesia. ANL at 24. See the further discussion

[879] New York Times, "Falling Lithium Prices Are Making Electric Cars More Affordable," March 20, 2023. Accessed on March 23, 2023 at *https://www.nytimes.com/2023/03/20/business/lithium-prices-falling-electric-vehicles.html*. "

[880] See The Economist, January 6, 2024 at 54: "[m]ined supply of lithium and nickel is also booming; that of cobalt, a by-product of copper and nickel production, remains robust, dampening green-metal prices."

[881] We consequently disagree with the comment of POET (at p. 6 of Attachment A to its comments, a report by Trinity Consultants) that demand from the light duty sector in combination with the demand from the Phase 3 standards will necessarily result in battery price increases. We are simply not seeing that posited inexorable price increase notwithstanding increasing demand.

[882] ANL at 39.

in Preamble Section II.D.2.ii.a and c. In addition, there are active efforts to develop substitutes for nickel in batteries.[883]

Cobalt

Like nickel, there are significant efforts to scale cobalt supply in the FTA countries and globally. Cobalt and nickel tend to be co-located and co-produced, so the same projects that produce nickel often also produce cobalt. Exploration efforts for cobalt in the U.S. is limited. While the Democratic Republic of Congo (DRC) is and will continue to be a key global source of cobalt mining supply (currently about 70 percent of global cobalt mining supply), other promising sources outside DRC include Canada and Australia.[884] The majority of global mined cobalt is currently refined in China. Cobalt production in the U.S. is very limited and there is no cobalt refinery, but several efforts exist to support build out of domestic cobalt refining.[885] DOE concludes that FTA and MSP partners are unlikely to add sufficient cobalt mining supply to support U.S. and other western nations' decarbonization goals, and trade with trade agreement partners will be key in securing cobalt supply and (as discussed further below) identifies similar policy levers to build domestic production.

This supply is projected to be sufficient to meet demand. BloombergNEF now similarly projects that cobalt and nickel reserves "are now enough to supply both our Economic Transition and Net Zero scenarios," the latter of which is an aggressive global decarbonization scenario.[886] It is also significant that the U.S. cobalt spot price dropped by nearly 42% in the past year (2023-2024), indicating ample current supply.[887] We thus do not accept those comments (e.g. from API and AmFree, among others) postulating unacceptable price increases of these critical minerals due to outstripped demand.

Graphite

In the near-term, meeting U.S. demand with natural graphite supply from domestic, FTA and MSP sources is unlikely; however, in the medium-term, there is potential for new capacity in both FTA and Non-FTA countries, and for synthetic graphite production to scale. Trade and partnership with Non-FTA countries such as Tanzania, Mozambique, Madagascar, Malawi, Brazil, Guinea, and Uganda, given their potential to increase natural graphite production capacity, will likely be crucial. FTA countries (Canada and Australia) are likely to add natural graphite capacity over the medium term.[888] Currently, the major U.S source of imports other

[883] See The Economist (Feb. 10, 2024) ("Cullen Hendrix of the Peterson Institute for International Economics, a think-tank, notes that lithium-iron phsophate batteries, which contain no nickel are becoming more popular, Sodium-ion batteries, which need neither nickel nor lithium, could surpass both types. Last month, JAC Motors, a Chinese carmaker backed by Volkswagen… delivered that first commercial vehicles powered by sodium-ion batteries to customers.").
[884] ANL at 47.
[885] ANL at 48.
[886] BloombergNEF, "Electric Vehicle Outlook 2023," Executive Summary, p. 5. See also The Economist, January 6, 2024 at 54: "[m]ined supply of lithium and nickel is also booming; that of cobalt, a by-product of copper and nickel production, remains robust, dampening green-metal prices."
[887] https://ycharts.com/indicators/us/cobalt/spot/price (last accessed January 23, 2024)
[888] ANL at 52.

than China include Canada, Mexico, Madagascar, Brazil and Mozambique, and these sources are likely to continue to be major sources of import for U.S manufacturers.[889]

There is no current U.S. production of graphite from mine sources, though exploration efforts are ongoing. The earliest U.S. production of natural graphite is anticipated in 2025 from Coosa with capacity of 7,500 metric tons per year, with the biggest project anticipated to come online in 2028 from Graphite Creek with capacity of 51,000 tons per year.[890] In addition to natural graphite from mine sources, synthetic graphite shows promising opportunities with the earliest project anticipated to come online in 2024.

ANL also indicates that synthetic graphite scaling has potential to mitigate graphite risk in the medium term.[891] Another concern, as noted above, is that in 2023, China imposed an export permit requirement on graphite, which will temporarily reduce graphite exports due to a 45-day application period for permits, and suggests that graphite exports from China may be controlled in the future. However, at this time it is not clear that this requirement will meaningfully impact exports over the long term, as similar permit requirements have existed on other exports, including those necessary in ICE vehicle production[892]; Wood Mackenzie reports that a change to material flows is unlikely, and that a graphite supply chain outside of China is rapidly developing.[893] See further discussion in response below concerning mineral security regarding potential mitigative measures with respect to graphite and the more detailed response in preamble section II.D.2.ii.c.

The United States has international initiatives in place to secure nickel, cobalt, and graphite, critical battery minerals from partners and allies around the world. These initiatives and agreements serve to secure supply chain availability, and to balance and counteract influence of potential threats to those supply chains, including Chinese dominance. See Preamble section II.D.2.ii.c for specifics.

Manganese

Manganese is not considered to be a critical mineral. DOE assesses that both in the near term and medium term, a significant portion of manganese will be available domestically from non-FTA countries. While capacity in FTA and MSP partners is concentrated in a few countries such as Australia, Canada and India, it is likely to be sufficient to meet U.S. demand in both the near and medium term. Conversely, because there is limited outlook for manganese production in the U.S. due to the poor quality of ore prospects, the U.S. is likely to depend on FTA-imported mining supply to meet domestic demand for the foreseeable future. See Preamble Section II.D.2.ii and sources there cited.

Further Considerations

In its assessment, DOE notes that a number of uncertainties affect every forward-looking assessment of mineral and manufacturing trends, and EPA has considered this inherent layer of uncertainty which could act to cause these projections to prove either optimistic or pessimistic.[894] It is well known in the forecasting of cyclical commodities industries that price volatility can be driven by demand or supply, or both. While oversupply is positive for battery cost in the short term, it can lead investors to consider some development projects uneconomic. Slow demand growth can be a factor in lower than expected prices. In a near term perspective, something as simple as a temporary drop in consumer demand due to changes in economic fundamentals can contribute to such a situation. Over the medium to long term, the same impact can result from changes in policy, or technology disruption (e.g., substitution of one mineral for another, or alternative chemistries that eliminate the mineral). Another uncertainty, particularly in the U.S., is permitting for new mining projects, which can take several years. Financing is also subject to uncertainty, as mining is considered to be a relatively high risk investment that pays off over a long time frame, subject to the uncertain factors above. We note, however, that large amounts of private domestic capital continues to flow into the domestic and North American critical mineral and battery production sectors. See Preamble Section II.D.2.ii. Political and social risks, for example war, changes in trade policy, and labor disputes are another factor. In some cases, the location of a mine may be remote, leading to potential difficulties in attracting qualified labor.

While all of these uncertainties can have an impact on future projection of progress in mineral production, it is also true that all mineral production currently in operation has transcended these risks, often in periods of far less rapid growth in demand of the minerals involved. With the importance of battery minerals in sectors that are relevant to reducing pollution, including GHG emissions, demand for these minerals is rapidly growing. As these uncertainties are well understood to accompany most if not all mining investments, EPA does not consider these factors to be uniquely restrictive of the ability of the global industry to develop mineral production capacity in response to what is widely understood to be an era of robust demand.

The remainder of this part of the response provides additional detailed evidence of recent developments in the growth of the critical mineral supply chain, and other specific topics relevant to this topic. Citations for all of the examples listed in this section may be found in a Memo to the Docket titled "DOE Communication to EPA Regarding Critical Mineral Projects". See also RIA Chapter 1.5.1.3 describing a number of these on-going efforts.

A number of additional U.S. government efforts are underway to accelerate lithium and critical minerals production and secure the supply chain both domestically and abroad:

- In February 2023, President Biden signed a presidential waiver of some statutory requirements (Waiver) authorizing the use of the Defense Production Act (DPA) to allow the Department of Defense (DoD) to more aggressively build the resiliency of America's defense industrial base and secure its supply chains including for critical minerals and energy storage. Since many of the investments needed in areas like mining and processing of critical minerals can be very costly and take several years, the Waiver permits the DoD to leverage DPA Title III incentives against critical vulnerabilities, and removes the statutory spending limitation for aggregate action against a single shortfall

[894] ANL at 65-68.

exceeding $50 million. This in turn allows the DoD to make more substantial, longer-term investments.

- In December 2022, the Blue Ribbon Commission on Lithium Extraction in California issued a report detailing actions to support the further develop geothermal power with the potential co-benefit lithium recovery from existing and new geothermal facilities in the Salton Sea geothermal resource area. The three owners developing projects in California may produce 600 kt/y LCE from geothermal brines around 2030.
- In June 2022, the United States formed the Minerals Security Partnership, whose goal is to ensure that critical minerals are produced, processed, and recycled in a manner that supports the ability of countries to realize the full economic development benefit of their geological endowments. The MSP will help catalyze investment from governments and the private sector for strategic opportunities —across the full value chain —that adhere to the highest environmental, social, and governance standards.

Preamble Section II.D.2.ii.c discusses the $3.4 billion in DOE Loan Program projects that were recently awarded to aid in the extraction, processing and recycling of lithium and other critical minerals to support continued market growth. Details on these projects are provided below.

- A $50M BIL grant to Lilac plans to build out domestic manufacturing capacity for the company's patented ion-exchange technology to increase production of lithium from brine resources with minimal environmental impact and streamlined project development timelines, and develop domestic lithium projects.
- A $141.7M BIL grant to Piedmont Lithium plans to accelerate the construction of the Tennessee Lithium project in McMinn County as a world-class lithium hydroxide operation, which is expected to more than double the domestic production of battery-grade lithium hydroxide. The project is being designed to produce lithium hydroxide from spodumene concentrate using the innovative Metso:Outotec process flow sheet, enabling lower emissions and carbon intensity as well as improved capital and operating costs relative to incumbent operations.
- A $150M BIL grant to Albemarle plans to support a portion of the cost to construct a new, commercial-scale U.S.-based lithium concentrator facility at Albemarle's Kings Mountain North Carolina location. Albemarle's "mega-flex" conversion facility would be capable of accommodating multiple feedstocks, including spodumene from the proposed reopening of the company's hard rock mine in Kings Mountain; its existing lithium brine resources in Silver Peak, Nevada, and other global resources; as well as potential recycled lithium materials from existing batteries. The facility is expected to eventually produce up to 100,000 metric tons of battery-grade lithium per year to support domestic manufacturing of up to 1.6 million EVs per year.
- A $700 million DOE loan to Ioneer Rhyolite Ridge LLC plans to help develop domestic processing capabilities of lithium carbonate for nearly 400,000 EV batteries from the Rhyolite Ridge Lithium-Boron Project in Esmeralda County, Nevada.
- A $2 billion DOE loan to Redwood Materials plans to construct and expand its battery materials recycling campus in McCarran, Nevada. It would be the first U.S. facility to support production of anode copper foil and cathode active materials in a fully closed-loop lithium-ion battery manufacturing process by recycling end-of-life battery and production scrap and remanufacturing that feedstock into critical materials, supporting

EV production of more than 1 million per year. Redwood Materials will use both new and recycled feedstocks—comprised of critical materials like lithium, nickel, and cobalt—to produce approximately 36,000 metric tons per year of ultra-thin battery-grade copper foil for use as the anode current collector, and approximately 100,000 metric tons per year of cathode active materials.

- A $375 million DOE loan to Li-Cycle plans to help finance a high efficiency, low-emission resource recovery facility for batteries in Rochester, New York. The Li-Cycle project will use hydrometallurgical recycling to efficiently recover battery-grade lithium carbonate, cobalt sulfate, nickel sulfate, and other critical materials from manufacturing scrap materials and used batteries to enable a circular economy.

We note further that several alternatives are under development that may provide an alternative to use of lithium in batteries, either in vehicle batteries, or in non-vehicle applications whose use of these alternatives would reduce competition for lithium in vehicle applications. Citations for these examples may be found in a Memo to the Docket titled "DOE Communication to EPA Regarding Critical Mineral Projects."

- BNEF estimates that sodium-ion batteries are scaling for use in applications that do not require the high-performance capabilities of large EV batteries, including stationary energy storage and 2- and 3-wheeled vehicles. Substitution from lithium to alternative chemistries could alleviate price pressures as soon as 2026.
- A new PNNL molten salt battery design, which uses Earth-abundant and low-cost materials, has demonstrated superior charge/discharge capabilities at lower operating temperatures while maintaining high energy storage capacity compared to conventional sodium batteries.
- NASA's Solid-state Architecture Batteries for Enhanced Rechargeability and Safety (SABERS) research for aerospace applications will likely have spin-off benefits for the automotive sector. As lithium-ion based liquid electrolytes are not suitable for aircraft, the development of a scalable, solid-state battery that is safer, more energy dense, and capable of faster charging has high commercialization potential in on-road vehicles applications, and can reduce lithium demand.

Finally, a large amount of research and development is taking place to increase circularity and effective use of lithium and critical minerals. Beyond commercial technologies, continued research and development with industry and academia through the US Automotive Battery Consortium (USABC), Critical Minerals Institute (CMI), and ARPA-E[895] will expand the recycling and recovery of lithium to help expand the use of unconventional supplies to help pace the growing demand for EVs:

- A $2M USABC grant to American Battery Technology Company (ABTC) in Fernley, Nevada will help develop a recycling development program to demonstrate a scaled, fully-domestic, integrated processing cycle for the universal recycling of large format Li-ion batteries in coordination with partners in the battery supply chain.
- The CMI's EC-LEACH project successfully demonstrated a 10x scale-up of electrochemical leaching for lithium-ion batteries black mass, e-waste comprised of crushed and shredded battery cells, with a capacity up to 500 g/day, achieving over 96%

[895] See also ANL at 30 n. 76.

leaching efficiency for all metals. The scale up demonstrated leaching under higher voltage while maintaining lower currents and used conventional power electronics.

- $39 million in ARPA-E funding for the Mining Innovations for Negative Emissions Resource Recovery (MINER) program will help develop market-ready technologies that will increase domestic supplies of critical elements, including copper, nickel, lithium, cobalt, rare earth elements, that are required for the clean energy transition. The MINER program will fund research that increases the mineral yield while decreasing the required energy, and subsequent emissions, to mine and extract energy-relevant minerals.

In examining mineral supply and demand, the ANL study also pays close attention to the primary uncertainties relevant to increasing mineral production and availability, as well as a number of enabling approaches that U.S. government and industrial actors are pursuing as part of a broad strategy to further increase domestic critical mineral supply. These efforts are generally important to understanding how minerals and related products can be accessed reliably through a combination of domestic sources and through global partners including our FTA partners, MSP partners, and allies. Here we provide a further summary of some of the approaches specifically identified in the ANL study, to provide a sense of some of the enabling activities that are currently being pursued by the U.S. government. Citations, additional detail and further examples of current activities are available in the ANL study.[896]

- Collaboration with trading partners is a major focus of attention. This involves diversifying supply chains beyond existing free trade agreements by strengthening trade with potential countries that have or could have significant capacity, as well as joint efforts with MSP partners to ensure the success of mineral projects in member countries through coordinated financial assistance, mobilizing both government and private capital, providing technical expertise, and streamlining ESG standards to include traceability standards. Collaboration could extend to financing promising projects within non-FTA countries by approaches such as leveraging existing and new interagency efforts across various agencies and departments such as State, Commerce, DOE, USAID, US DFC, USTDA and EXIM, in collaboration with the private financing sector.
- Improving the permitting process for critical minerals projects is another thrust of activity. The Biden-Harris Permitting Action Plan (May 2022) and subsequent implementation guidance (March 2023) identifies key steps including: acceleration of permitting through early cross-agency coordination, establishing clear timeline goals and tracking, engaging in early and meaningful outreach and communication with Tribal Nations, States, territories, and local communities, improving agency responsiveness, technical assistance, and support, and adequately resourcing agencies and using the environmental review process to improve environmental and community outcomes.
- Stockpiling and supply chain readiness is another focus. Strategic stockpiles can serve as a buffer against potential disruptions. This approach could also protect domestic projects to develop mining and recycling from intentional oversupply (product dumping) by actors aimed at reducing global competition. Efforts around stockpiling are already in progress. For example, DOD, DOE, and the State Department are laying the foundation for a new interagency process for stockpiling minerals. Other efforts to stabilize supply

[896] ANL at 70-73.

chain volatility and uncertainty include better data tracking and sharing, alert systems, and international partnerships to respond to supply chain disruptions.

- Increasing domestic recycling capacity can be a strong factor in reducing future need for new critical minerals. The Federal Consortium for Advanced Batteries (FCAB) developed a National Blueprint for Lithium Batteries, outlining near-term objectives to achieve the goal of scaling end-of-life reuse and recycling for minerals. The DOE has also announced $37 million in available funding to improve the economics and industrial ecosystem for battery recycling.
- Advanced recycling techniques such as direct recycling can offer lower costs when, commercialized and scaled. The BIL funds research and development for advanced recycling; DOE has already announced more than $45 million for advanced recycling projects, including direct recycling.
- Identifying non-traditional sources of critical materials that are available domestically, such as industrial by-products and mining waste streams, can also help meet minerals demand over time. The U.S. government is supporting efforts to fund research into non-traditional sources of minerals: for example, in February 2024, DOE announced it would invest $17 million into projects to recover minerals from coal-based resources, and in November 2023 USGS announced $2 million to 14 states to study critical minerals in mine waste. Research suggests that resource recovery from coal and mining waste may also help remediate abandoned mines.
- Workforce development can be promoted by coordination and collaboration with academic institutions and training centers to develop the next-generation workforce to serve the potentially growing domestic mining sector. For example: DOE, in collaboration with DOL, AFL-CIO, and other partners, launched the Battery Workforce Initiative through the National Energy Technology Laboratory (NETL) to develop training up and down the battery supply chain. Talon Metals and the United Steelworkers have also announced a joint workforce development partnership for the Tamarack Nickel Project. The FY24 NDAA directs that the Defense Department study the feasibility for and plan for the creation of a University Affiliated Research Center for Critical Minerals which would assess institutional capabilities and investments needed for workforce development to support needs related to critical materials. The Department of Commerce, through the CHIPS Act is funding workforce development across the battery supply chain in Missouri, New York, and Nevada.
- Strengthening environmental, social and governance (ESG) implementation can be key to reducing risk for mining projects to improve chance of production and reduce impact. Strategies include pursuing robust consultation with communities near where mining resources are located, and adherence to strong labor, human rights and environmental practices. Internationally, some USG efforts already exist to advance ESG compliance and to improve environmental and social outcomes of minerals development. DOE's Advanced Research Projects Agency-Energy (ARPA-E) is funding 16 projects across 12 states that aim to increase mineral yield while decreasing energy and emissions from mineral extraction. The U.S. Department of Labor (DOL) offers resources to companies looking to mitigate risks related to labor violations and programs to raise awareness and address international ESG. Through the IPEF Supply Chain Agreement, the U.S. is also engaged in a Labor Rights Advisory Board to promote worker rights across supply chains. The "Presidential Memorandum on Advancing Worker Empowerment, Rights,

and High Labor Standards Globally" directs the Secretaries of State, Labor, Energy, Treasury, Homeland Security, and Commerce along with the Administrator of USAID and the U.S. trade representative to address labor rights across global supply chains.

- Community and tribal engagement is also important to addressing potential conflict between communities and mining interests, which increase risk and uncertainty to all stakeholders when mineral resources are identified for development. Many grants and loans provided by the Department of Energy under BIL and IRA require applicants to submit a Community Benefit Plan, which is evaluated at 20 percent of the overall application; community agreements such as Community Benefit Agreements (CBAs) and other community and workforce agreements are strongly encouraged by these programs, which may provide funding to mining and materials processing initiatives. The DOE also sponsors programs that incentivize the transition of defunct mines into clean energy sites, including the Biden Administration's $500 Million Program to Transform Mines Into New Clean Energy Hubs and the Qualifying Advanced Energy Project Credit (48C) Program.

We now provide responses to certain additional issues raised in the public comments.

<u>Response: Sufficiency of Battery Production</u>

A number of commenters maintained that there was insufficient North American battery manufacturing capacity to accommodate the Phase 3 standards, so that batteries would have to be imported. We disagree. Based on announced investments in battery cell production, companies have announced over 1,300 GWh/year in battery production in North America by 2030.[897] This is already a significant increase over the estimates discussed in the proposal of 1,000 GWh/year commencing in 2030. 88 FR at 25967/2. EPA estimates that 11 GWh will be required for HDV BEVs in 2027 and 58 GWh in 2032 under the modeled potential compliance pathway. See RIA Chapter 2.10.2. Consequently, although most of this announced capacity is currently intended for light duty vehicles (and some for stationary sources),[898] EPA finds that there is sufficient North American battery production capacity for HDVs within the rule's timeframe, and ANL projects at least 45 GWh of announced cell production will be dedicated to HDV BEVs by 2030. Moreover, end use for some battery cell manufacturing facilities has not been announced, and it is likely that North American capacity can service HDV applications in greater than announced amounts: this North American capacity can service HDV applications in greater than announced amounts if needed (it is the same battery packs whether or not ultimate use is in light- or heavy-duty vehicles). Importantly, in addition to the 13 new domestic battery plants we projected to become operational in the four years from proposal, 88 FR at 25986, the new work performed by ANL indicates that even more battery production capacity has been announced since the release of those previous reports. In addition, capacity from trade allies is another source of supply: the sum of announced battery cell production capacity in MSP countries (outside North America) exceeds the sum in North America, with both reaching 1,300 GWh/year by 2030. See Preamble Section II.D.2.ii, and see also Volvo's comment that "Benchmark's Gigafactory Assessment suggests that a total of 1.4 terawatt hours of new battery capacity was announced in just the last six months and the number of Benchmark-tracked plants more than doubled—from 174 in

---

[897] Planned Battery Supply at 23.
[898] Planned Battery Supply at 22-23.

November 2020 to 379 in April 2023."[899] This final rule also sends a signal to add more dedicated HD BEV battery capacity as needed. This additional announced production capacity adds to EPA's assurance of adequacy of battery cell supply in the rule's timeframe.

In response to comments regarding insufficient ramp-up time, the latest ANL projections estimate the period from announcement to beginning of production for each individual plant based on numerous factors, and uses a baseline estimate of three years from beginning of production to full scale operation, based on historical cell plants.[900] ANL describes this as "a modestly conservative estimate,"[901] acknowledging that plants could reach nominal capacity more quickly or more slowly. This estimate is consistent with the projections of significant increases in domestic production by the commencement of the Phase 3 program. We also continue to see evidence that global lithium-ion battery and cell production is growing rapidly and is likely to keep pace with increasing global demand. In the proposal we noted a 2021 report from Argonne National Laboratory (ANL)[902] that examined the state of the global supply chain for electrified vehicles and included a comparison of recent projections of future global battery manufacturing capacity and projections of future global battery demand from various analysis firms out to 2030. The three most recent projections of capacity (from BNEF, Roland Berger, and S&P Global in 2020-2021) that were collected by ANL at that time exceeded the corresponding projections of demand by a significant margin in every year for which they were projected, suggesting that global battery manufacturing capacity is responding strongly to increasing demand. Since the proposal, we have not seen evidence that this trend is changing.

More recent projections have become available that indicate that projections of future capacity have grown dramatically in only a short time. For example, in May 2023 the International Energy Agency (IEA) projected a global capacity of 3.97 TWh in 2025,[903] more than twice the highest projection of about 1.75 TWh for 2025 made by BNEF in 2020. IEA also projected 6.8 TWh for 2030,[904] which is about triple the highest projection made for 2029 by Roland Berger in 2020. In December 2023, BNEF indicated that its projection of North American lithium-ion cell manufacturing nameplate capacity for 2030 was 76 percent higher than its projection for the same year in 2022, and attributed the increase in part to industry's response to IRA incentives including the 45X production tax credit. The same report indicated that global capacity could increase to as much as 7.4 TWh in 2025 if all project announcements that were public at the time were to be completed.[905] The rate of increase of projections such as these strongly indicate that the capacity of both domestic and global battery production is increasing at a rapid pace that is much greater than anticipated only two to three years ago.

905 BloombergNEF, "Zero-Emission Vehicles Factbook: A BloombergNEF special report prepared for COP28, December 2023, p. 30 and 40.

Further, the IEA indicates that the 6.8 TWh global capacity projected for 2030 would be enough to cover global battery demand under its "Net Zero" scenario, and would cover nearly twice the demand implied by currently announced pledges across the world.[906]

Moving beyond battery and cell manufacturing, we also consider manufacturing of battery components including cathode and anode powders and electrolyte, for which raw critical minerals and precursor chemicals are important manufacturing inputs.

As discussed in Preamble Section II.D.2.ii we note that, overall, ANL finds that approximately half of the demand for lithium-ion battery production for CAM and AAM can be met by North American sources by 2030, with electrolyte production reaching approximately 100% of the North American market.[907] We also note there that this estimated capacity is likely understated, because it does not account for capacity which is co-located with battery manufacture, which is a common arrangement.[908] In fact, rumored and conditional plants for AAM would add enough capacity to meet projected cell production. While AAM production is subject materials availability and therefore retains some uncertainty, noted above in discussing graphite availability, synthetic graphite and graphite substitutes are available as well.[909] See also Comments of MFN at nn. 174 and 175 documenting information relating to synthetic graphite and graphite substitutes.

Globally, the outlook for CAM and AAM production is positive. The following Figure repeats the chart that was shown in the proposal, showing preliminary projections of global cathode supply versus global cathode demand prepared by Li-Bridge for DOE,[910] and presented to the Federal Consortium for Advanced Batteries (FCAB)[911] in November 2022. These projections were largely derived by DOE from projections by BMI, and indicate that global supplies of cathode active material (CAM) are expected to be sufficient through 2035.

DOE Li-Bridge assessment of global CAM supply and demand.

In the figure, the labels T1 and T2 represent supplies that BMI considers as having a track record supplying these materials outside of China and within China, respectively. The label T3 represents supplies that BMI assessed as not having an established track record of production, and thus represent earlier stage efforts, such as for example, new entrants to the market that intend to supply anticipated demand but which may not have established offtake agreements.

To the degree that the Li-Bridge assessment of global demand begins to enter T3 supply in 2029, it is important to note that cathode powder production can generally be constructed or expanded with less lead time than mining or cell production plants and announcements of new capacity may be encountered closer to the time of their construction. That is, in the period between now and 2029 it is likely that increases in demand will motivate increases in supply that would not be announced until much closer to 2029. The ability of production capacity for many cell materials and components to adjust relatively quickly to changes in anticipated demand suggests that these materials do not represent a constraint to ZEV production in the global context any more than in the domestic context. Further, allies and partners outside of North America are likely to contribute to meeting electrode active material demand. Ally nations Japan and South Korea, for example, are the second and third largest producers of electrode active materials and as such are in a better position to increase production via relatively short lead-time actions such as plant expansion.[912]

[912] Argonne National Laboratory, “Quantification of Commercially Planned Battery Component Supply in North America through 2035,” ANL-24/14, February 2024 (“Quantification of Planned Battery Component Supply”)..

ANL does project that some domestic anode and cathode demand will need to be satisfied through imports. See Preamble section II.D.2.ii.b documenting means by which both AAM and CAM can be supplied during the timeframe of the Phase 3 rule..

As described in Section II.D.2.ii.c, the development of mining and processing capacity in the United States is a primary focus of efforts on the part of both industry and the U.S. government toward building a robust domestic supply chain for electrified vehicle production and will be greatly facilitated by the provisions of the BIL and the IRA as well as large private business investments that are already underway and continuing. The IRA and BIL continue to provide significant support to accelerate these efforts to build out a U.S. supply chain for component, cell, and battery production. Specifically, a large amount of funding for battery production is being offered by the federal government through IRA tax credits, loans through the DOE Loans Program Office, and DOE Office of Manufacturing and Energy Supply Chains (MESC), as seen in the following table:[913]

Table 17-1 Summary of Funding Programs for U.S. Battery Production

Program	Funding Allocated*	Total Available**	Period of Availability	Project Examples
Battery Materials Processing Grants & Battery Manufacturing and Recycling Grants (MESC)	~$1.9B	~$4.1B	2022-2026; Until Expended***	CAM and AAM production, separator production, precursor materials production, battery cell production.
Domestic Manufacturing Conversion Grants (MESC)	$0	$2B	To remain available through 9/30/2031	Eligible projects include facilities to produce components for electric vehicles.
ATVM (LPO)	~$15.9B	~$49.8B	No restriction	Battery cell production, lithium carbonate production, AAM production, foil production, CAM production.
Title 17 (LPO)	$398.6M	$60B	No restriction	Zinc bromine battery energy storage systems.
48C Qualifying Advanced Energy Tax Credit (IRS, MESC)	$0	$10B	Until expended	Eligible projects include production and recycling of clean energy technologies, critical minerals processing and recycling.
45X Advanced Manufacturing Production Tax Credit (IRS)	--	No limitation	For critical minerals: permanent; For other items: full credit available between 2023-29 with phase down from 2030-32	Eligible projects include battery components, critical minerals, inverters, components for solar and wind energy technology.

*Funding announced since 2021, as of February 2024, for projects related to the scope of the cited ANL study (cells, packs, CAM, AAM, electrolyte, foil, separator, precursor materials). Includes conditional commitments (LPO only)
**For grants, the total available is the total allocated subtracted from the allocation, and indicates how much grant funding is left. For LPO, this number represents approximate loan authority available as of January 2024, reported by LPO.
***For the purposes of this table, the Battery Materials Processing Grants & Battery Manufacturing and Recycling Grants are combined. These two programs are authorized separately in the IIJA. Their periods of availability are listed respectively.

A substantial portion of this supporting industrial policy is still unfolding. This includes final rulemaking and Treasury guidance for various details of the IRA tax credits; the submission, selection, and award of second round of funding from the Battery Materials Processing and Manufacturing Grants program by January 2025 (IIJA section 40207) and the 48C tax credit

[913] Planned Battery Component Supply Table 1.

(Qualifying Advanced Energy Project Credit), and, respectively, final interpretive guidance and rulemaking from the Department of Energy and the Department of the Treasury on Foreign Entities of Concern (FEOC) and Excluded Entities for the 30D tax credit (Clean Vehicle Credit).

Future battery supply chain funding opportunities from IRA and BIL are described in more detail in the Preamble at section II.D.2.ii and ANL at 2-4.In consideration of this updated information on battery and cell manufacturing, it continues to be our assessment that the industry is well positioned to support the battery and cell demand that is projected under the Phase 3 final standards, and therefore EPA concludes that battery and cell production capacity are unlikely to pose a limitation on manufacturers' ability to comply with the standards under the modeled potential compliance pathway.

Response: Critical Mineral Security

Commenters noted that China is both a source of graphite, and controls a majority of refining capacity of others of the critical minerals, raising a question of the security of the source of supply of these minerals (Comments of, e.g., AFPM and CFDC), or even resulting in critical mineral long-term dependence on China (API, Arizona State legislature). It is our assessment that increased electrification in the U.S. transportation sector projected as a potential compliance pathway for this final rule does not constitute a vulnerability to mineral security. See generally Preamble section II.D.2.ii.c and RIA Chapter 1.5.1.2. which provide additional detail to the response presented here.

Mineral security refers to potential national security risks posed by reliance on sourcing of critical minerals from other countries, and in particular from countries with which the U.S. has fragile trade relations or significant policy differences. Concern for U.S. mineral security relates to the global distribution of established supply chains for critical minerals and the fact that, at present, not all domestic demand can be supplied by domestic production. Currently, the U.S. is trailing much of the rest of the world in critical mineral production, although substantial production occurs in countries that are not "covered nations"[914] for purposes of the IRA.

In light of this information provided in the public comments and additional information that EPA has collected through continued research, it continues to be our assessment that the increase in BEV production projected under the modeled potential compliance pathway is not expected to adversely impact mineral security or national security, and is projected to result in national security benefits by reducing the need for imported petroleum and may result in national security benefits by providing regulatory and market certainty for the continued development of a domestic supply chain for critical minerals. EPA has carefully considered the substantive and detailed comments offered by the various commenters. Taken together, the totality of information in the public record continues to indicate that development of the critical mineral supply chain is proceeding both domestically and globally in a manner that supports manufacturers' compliance with the final standards. More recent information is corroborative. ANL has performed a review of international and domestic critical minerals availability as of February 2024, which EPA considers to be both thorough and up to date. The analysis finds that while the U.S. will need imports to bolster supply for most key minerals, these imports can come

[914] Defined in 10 U.S. Code 2533(c)(d)(2) as the Democratic People's Republic of North Korea, the People's Republic of China, the Russian Federation, and the Islamic Republic of Iran. These countries are also Foreign Entities of Concern (FEOC).

from friendly nations, and can be bolstered by growing domestic supply, especially for lithium. The analysis also finds that, with the appropriate policies and enabling approaches in place, the U.S. can secure the minerals it needs by relying on domestic production as well as trade relationships with allies and partners. See in particular the comprehensive Figure 11 in ANL showing U.S. government initiatives to secure battery minerals and materials. United States government initiatives aimed at shifting the trade landscape can reduce risk in internation supply chains and enhance the resilience of the rapidly growing domestic battery industry, while simultaneously supporting the economies of its partners and allies. The United States possesses a significant and growing portfolio of international engagements to secure minerals supplies including FTAs, Mineral Security Partnerships, Trade Investment Framework Agreements (TIFAs) and other bilateral and multilateral agreements including the Partnership for Global Infrastructure and Investment (PGI). In addition, USGS is engaged in activities that, while not yet quantifiable, are enabling the U.S. to expand a secure supply chain for critical minerals among United States allies and partner nations. There are substantial efforts to scale mining supply domestically and in partner countries underway, further described in Preamble section II.D.2.ii.c.

We also note that the issue of dependence on imported materials and minerals is not unique to battery-critical minerals, but also affects conventional vehicles, which use an array of imported and strategic materials, such as platinum and palladium for catalysts, computer chips for engine control and entertainment systems, and other parts and materials that are sourced from other countries. Materials like these were imported for use in other industries long before the recent growth in their use in electrification. The same issue comes up outside the automotive sector as well. As Tesla noted in its public comments, the U.S. oil and gas sector has long been dependent on barite from China for use in oil and gas exploration and development drilling.[915]

We now expand upon these points in the following discussion, and see generally Preamble section II.D.2.ii.c.

In the response above relating to critical mineral availability, we discussed availability of lithium, cobalt, nickel, manganese, and graphite. With respect to lithium, we documented that there is significant evidence that supplies in the short-, medium- and long-term are adequate, and indeed, that the United States may become a major global producer of lithium during the Phase 3 rule's time frame. This largely alleviates security concerns related to lithium.

We do find, based on DOE's and ANL's updated analysis, that domestic needs for nickel, cobalt, and graphite will not be supplied entirely from domestic sources during the Phase 3 rule's time frame (Preamble section II.D.2.ii.c).

As shown in Preamble section II.D.2.ii.c, in 2019 about 50 percent of global nickel production occurred in Indonesia, Philippines, and Russia, with the rest distributed around the world. Nearly 70 percent of cobalt originated from the Democratic Republic of Congo, with some significant production in Russia and Australia, and about 20 percent in the rest of the world. More than 60 percent of graphite production occurred in China, with significant contribution from Mozambique and Brazil for another 20 percent.

[915] Comments of Tesla at 31. See also "Barite—A Case Study of Import Reliance on an Essential Material for Oil and Gas Exploration and Development Drilling" pubs.usgs.gov/sir2014-5230

According to the Administration's 100-day review under E.O. 14017, of the major actors in mineral refining, 72 percent of cobalt refining occurred in China, with another 17 percent distributed among Finland, Canada, and Norway. 21 percent of Class 1 nickel refining occurred in Russia, with 16 percent in China, 15 percent in Japan, and 13 percent in Canada.[916]

Although the U.S. has nickel reserves, and opportunity also exists to recover significant nickel from mine waste remediation and similar activities, at present it is more convenient to import it from established producers in other countries, with 68 percent coming from Canada, Norway, Australia, and Finland, MSP countries with which the U.S. has good trade relations.[917] According to the USGS, ample reserves of nickel exist in the U.S. and globally, potentially constrained only by processing capacity.[918] ANL notes that currently, there is no Class I (battery grade) nickel production or refining in the U.S, and that there has been an influx of investment by China in Indonesia, a major global producer of nickel.

The U.S. has numerous cobalt deposits, but few are developed, although some have produced cobalt in the past; about 72 percent of U.S. cobalt consumption is currently imported.[919] ANL notes that China controls about 50 percent of cobalt production in the Democratic Republic of Congo (DRC), a major global producer of cobalt, that much of this output is owned by China, and that most refining capacity is presently Chinese. While some battery chemistries include cobalt which carries environmental and other impacts depending on how it is sourced, cobalt content is being rapidly reduced and can be eliminated entirely by use of other chemistries that are already gaining market acceptance. See Preamble section II.D.2.ii.

Similar observations may be made about graphite. The U.S. has significant deposits of natural graphite, but graphite has not been produced in the U.S. since the 1950s and significant known resources remain largely undeveloped.[920] ANL notes that China dominates natural graphite production and has been a major source of U.S imports. ANL also indicates that meeting U.S. demand with natural supply from free trade agreement (FTA) and minerals security partnership (MSP)[921] countries is unlikely in the near term, but medium term synthetic graphite scaling has potential to mitigate graphite risk.[922] Another concern, as noted above, is that in 2023, China imposed an export permit requirement on graphite, which will temporarily reduce graphite exports due to a 45-day application period for permits, and suggests that graphite exports from China may be controlled in the future. However, as noted above, at this time it is not clear that

See also response above noting the comments of MFN describing opportunities for synthetic graphite production and graphite substitutes.

this requirement will meaningfully impact exports over the long term, as similar permit requirements have existed on other exports, including those necessary in ICE vehicle production[923]; Wood Mackenzie reports that a change to material flows is unlikely, and that a graphite supply chain outside of China is rapidly developing.[924] As discussed in the Preamble, synthetic graphite already is filling a significant percentage of market demand, can and is being produced domestically, and is available for further market penetration.

With regard to nickel, cobalt and graphite, ANL also identifies potential enabling approaches to mitigate the potential risks that they identify. For all of the critical minerals, there are prospects for growth among secure sources of supply such that there are adequate supplies of these minerals in the Phase 3 rule's timeframe. For nickel, continued economic partnership and trade with non-FTA, non-MSP countries with significant capacity, such as Indonesia, Philippines, Botswana, South Africa, Papua New Guinea, Madagascar, Tanzania, and Zambia provide an avenue to securing supply.[925] In November 2023, the United States entered a Comprehensive Strategic Partnership with Indonesia, announcing the intention to partner on a roadmap to encourage the creation of a clean nickel supply chain. In addition, the Defense Department signed a Defense Cooperation Agreement to uphold a free and open Indo-Pacific that ensures regional stability.[926] Efforts to strengthen battery recycling in the U.S and ally nations is also identified by ANL, as well as collaborative efforts with FTA and MSP partners to ensure mining project success (for example, financing promising projects in FTA and non-FTA countries). In the longer term, ANL also identifies use of battery chemistries that use less or no nickel.

With regard to cobalt, the same approaches are identified, including economic partnership and trade with non-FTA countries including the Democratic Republic of Congo, Indonesia, Philippines, Zambia, Papua New Guinea and Madagascar. The Democratic Republic of Congo (DRC) is the world's largest source of cobalt, with 70% of current world production and 48% of reserves.[927] The U.S. is partnering with DRC to secure cobalt supply to close the gap between projected domestic demand and projected domestic supply. Through PGI, the United States is supporting the development of the Lobito Corridor, which connects the Democratic Republic of the Congo and Zambia with global markets through Angola, with an initial investment of $250 million in a rail expansion that intends to reduce transport time and lower costs for metals exports from the region.[928] Child and forced labor has been a particular concern for DRC, given the known presence of child workers at artisanal mines across the region, despite these mines making up a minority of cobalt mining operations. The U.S. and allies are partnering with the DRC to combat child and forced labor in the cobalt supply chain. A notable example is the

[923] Rare earths, necessary for catalytic converters and magnet motors are presently subject to Chinese export license restrictions for example. https://www.fastmarkets.com/insights/chinas-commerce-ministry-to-add-rare-earths-to-export-report-directory/.

Department of Labor (DOL)-funded Combatting Child Labor in the Democratic Republic of the Congo's Cobalt Industry (COTECCO) project discussed further below in the following response dealing with issues of human rights in mining operations.[929]

For graphite, ANL identifies similar economic partnership and trade objectives, as well as strengthening synthetic graphite production capacity in the U.S. and ally nations. See Preamble section II.D.2.ii.c for details.

The development of mining and processing capacity in the U.S. is a primary focus of efforts on the part of both industry and the federal government toward building a robust domestic supply chain for electrified vehicle production, and will be greatly facilitated by the provisions of the BIL and the IRA as well as large private business investments that are already underway and continuing. The Inflation Reduction Act and the Bipartisan Infrastructure Law are continuing to be a highly effective means by which Congress and the Administration are supporting the building of a robust supply chain, and accelerating this activity to ensure that it forms as rapidly as possible. An example is the work of Li-Bridge, a public-private alliance committed to accelerating the development of a robust and secure domestic supply chain for lithium-based batteries. It has set forth a goal that by 2030 the United States should capture 60 percent of the economic value associated with the U.S. domestic demand for lithium batteries. Achieving this target would double the economic value expected in the U.S. under "business as usual" growth.[930] More evidence of recent growth in the supply chain is found in a February 2023 report by Pacific Northwest National Laboratory (PNNL), which documents robust growth in the North American lithium battery industry.[931] Since the proposal, the general trend of continued activity to build the domestic supply chain for critical minerals indicates that vehicle manufacturers, suppliers, and investors are taking advantage of the business opportunities that this need presents, and that the U.S. manufacturing industry is well positioned to create a robust supply chain for these products.

As noted above, the United States also has entered into various economic, trade, defense, and other agreements with non-FTA, non-MSP countries providing critical mineral mining and refining capacity. These agreements are another means of assuring secure critical mineral supply chains.

Recycling is also a part of the solution to issues of mineral security and critical mineral availability. 88 FR at 25969; ANL section IV. Over the long term, lithium-ion battery recycling will be a critical component of the ZEV supply chain and will contribute to mineral security and sustainability, effectively acting as a domestically produced mineral source that reduces overall reliance on foreign-sourced products. While growth in the return of end-of-life ZEV batteries will lag the market penetration of ZEVs, it is important to consider the development of a battery recycling supply chain during the time frame of the rule and beyond. We document in Preamble section II.D.2.ii.c and RTC section 4.7 that lithium battery recycling is attracting large amounts of private capital, as well as capital through the BIL and IRA, and is already recovering critical

[929] https://www.dol.gov/agencies/ilab/comply-chain; https://www.dol.gov/agencies/ilab/combatting-child-labor-democratic-republic-congos-cobalt-industry-cotecco. See also the further discussion in RTC section 17.2.
[930] Department of Energy, Li-Bridge, "Building a Robust and Resilient U.S. Lithium Battery Supply Chain," February 2023.
[931] Pacific Northwest National Laboratory, "North American Lithium Battery Materials V 1.2," February 2023. Available at *https://www.pnnl.gov/projects/north-american-lithium-battery-materials-industry-report*.

minerals at commercial scale (albeit almost exclusively from manufacturing scrap; not many vehicular lithium ion batteries have worn out to date). ANL estimates that recycled materials can become a significant source of supply during the timeframe of the Phase 3 rule, for graphite in particular.[932] The report further documents research and funding for an ultimate circular use of critical minerals further offsetting the need for newly mined minerals.[933] The Federal Consortium for Advanced Batteries National Blueprint for Lithium Batteries outlines several near term objectives to achieve the goal of scaling end-of-use and recycling for minerals. The DOE announced the availability of $37 million in funding to improve the economies and industrial ecosystem for battery recycling, and another $30 million to enable a circular economy for EV batteries, to be awarded in 2024.[934] So, we see recycling as contributing to critical mineral availability, and as a source of mitigation of mineral security issues, during the time frame of the Phase 3 rule.

We thus reiterate our conclusion from proposal that there are short-term, medium-term, and long-term means of successfully dealing with issues of mineral security—both mineral availability and supply chains for these minerals' deployment. Many of these are already being implemented. We consequently regard issues of mineral security to be surmountable and not an impediment to feasibility of the Phase 3 standards.

Response regarding Human Rights Abuses Associated with Mineral Extraction:

Several commenters discussed human rights and environmental degradation concerns associated with the extraction and mining of critical minerals used in battery manufacturing, such as lithium, cobalt, and other metals (Valero, AFPM, Tesla, API, MFN, Energy Vision, Transfer Flow). Several commenters suggest that standards that promote vehicle electrification would worsen human rights situations in nations that may be part of ZEV future supply chains such as the Democratic Republic of Congo.

EPA acknowledges the concerns about current and historical impacts of mining, including minerals used in the manufacturing of batteries for hybrids and ZEVs. However, EPA does not agree with commenters' claims that EPA should account for these concerns in setting HD vehicle emission standards, for several reasons.

First, commenters' assumption that these standards require ZEVs is not aligned with the form of the proposed or final standards. The performance-based standards can be met through many different compliance strategies. Although EPA modeled one potential compliance pathway to support the feasibility of these standards and for rulemaking purposes, EPA also assessed additional example potential compliance pathways that also support the feasibility of the final standards and which further show that manufacturers are free to use any combination of vehicle technologies they can successfully deploy that meet the final standards, including ones that do not require additional production of ZEVs to comply with this rule. Preamble section II.F.

---

932 ANL at 31, and see generally ANL section IV.

933 ANL at 31 and Advanced Research Projects Agency for Energy, U.S. Department of Energy Announces $30 million to Develop Technologies to Enable Circular Electric Vehicle Battery Supply Chain, January 31, 2024. Available at https://arpa-e.energy.gov/news-and-media/press-releases/us-department-energy-announces-30-million-develop-technologies-enable

934 ANL at 72. See also ANL at 36-37, 43-44, 49-50 and 56-57 discussing recycling opportunities for lithium, nickel, cobalt, and graphite, respectively

Second, commenters' claim that EPA should take account of international human rights and EJ concerns associated with new supply chains for ZEVs is inconsistent with EPA's longstanding practice in setting vehicle emissions standards under Clean Air Act section 202; EPA has not analyzed every component of vehicles or refining technologies potentially used to meet its standards to the beginning of their manufacturing or extraction lifecycle. It is well-recognized that petroleum fuels, electronic components, plastics, catalytic metals, additives to lubricants or fuels, and other chemical and physical ingredients of vehicles, fuels, and their manufacturing all have lifecycles upstream of vehicle operations, with potential environmental impacts and human rights concerns. It is inappropriate for EPA to only account for international human rights and lifecycle environmental impacts related to ZEVs; see also our response regarding life cycle assessment in RTC section 17.1.

Third, Tesla's and ZETA's comments about their attempts to ensure that their supply chains support human rights and democratic values provide support that relying on adverse assumptions about ZEV supply chains may be unwarranted. Additional commenters note progress in recycling of lithium and other metals (e.g., ZETA).

Fourth, through the Partnership for Global Infrastructure and the JET Green Minerals Challenge, the United States (along with allies and private sector) is both investing in Democratic Republic of Congo infrastructure and partnering with the Democratic Republic of Congo to combat child and forced labor in cobalt supply.[935] In addition, on November 1, 2023, the U.S. Department of State announced the Minerals Investment Network for Vital Energy Security and Transition (MINVEST), a new public private partnership with the nonprofit SAFE's Center for Critical Minerals Strategy. The MINVEST Partnership will promote public-private dialogue and spur investment in strategic mining, processing, and recycling opportunities that adhere to high environmental, social, and governance (ESG) standards. These activities are central to the United States' critical minerals strategic goals, including the Department of State's commitment to the Minerals Security Partnership (MSP), of which the United States is a founding member.[936] See the further discussion of these points in Preamble section II.2.D.c.ii.

Fifth, commenters suggesting that these non-air environmental impacts should deter EPA from setting more stringent vehicle emission standards overlook the clear distinction made by the Clean Air Act and other laws in differentiating emission standards for mobile sources from those from other air sources or other environmental problems (e.g., Resource Conservation and Recovery Act, Clean Water Act). EPA has long interpreted the Clean Air Act as generally requiring EPA to base regulations from each sector on the statutory requirements specific to that sector. In setting these Phase 3 standards, EPA considered statutory and relevant factors under Sections 202(a)(1) and (2).

Regarding comments alluding to child labor or other abuses said to take place in the supply chain for batteries, which appear to primarily refer to cobalt production in the Democratic Republic of Congo (DRC), EPA reiterates that manufacturers are continuing to reduce cobalt content, and proven battery chemistries that do not use cobalt such as lithium-iron phosphate are already in widespread use globally and are increasing their market share in the U.S. Further, although the DRC supplies about 70 percent of global cobalt production, only a relatively small

[935] ANL at 51.
[936] https://www.state.gov/announcement-of-new-partnership-between-state-department-and-safes-minerals-center-to-promote-investment-in-critical-minerals-supply-chains/.

portion of cobalt produced in the DRC (estimated variously at between 10 to 30 percent) is produced in artisanal and small-scale mines (ASM) that are associated with use of child labor.[937] Overall, the global share of cobalt believed to come from ASM sources is approximately 10 percent and is largely exported to China.[938] According to BMI, the share of ASM supply increases when prices are high, and in a May 2023 report stated that recent declines in cobalt prices had caused ASM supply to fall by "more than 50% from the peak."[939] Although business practices and standards for ethical conduct of suppliers in other countries are out of scope for this rulemaking, EPA notes that the Department of Labor operates the COTECCO project[940] which "works to address child labor in the Democratic Republic of the Congo's (DRC) cobalt supply chain, with a focus on artisanal and small-scale mining," supporting the development and implementation of "strategies to reduce child labor and improve working conditions in artisanal and small-scale mines, as well as in the broader cobalt supply chain." Finally, we note that in other parts of the CAA, Congress has acted to require EPA to strengthen standard stringency even if it involved obtaining needed critical materials from foreign sources whose values did not accord with those of the United States. In enacting the CAA Amendments of 1990, Congress recognized the need for the critical mineral rhodium for the production of catalytic converters (a ubiquitous motor vehicle pollution control technology) and that South Africa possessed the vast majority of the world's then-known rhodium deposits.[941] While Congress acknowledged concerns with South Africa's human rights record, it nonetheless proceeded to significantly strengthen the motor vehicle emissions standards, such that the production of the necessary technologies could require dependence on South African rhodium supplies . Thus, Congress understood that the nation may need to look to other countries for critical materials where necessary to improve motor vehicle emissions control technology, but mandated emissions reductions regardless. At the same time, Congress also mandated that EPA study the

[941] See 136 Cong. Rec. 5102-04 (1990). The 1990 CAA Amendment are not the first time that Congress wrestled with potential dependence on South Africa for rhodium. Congress also recognized this issue when developing the 1977 CAA Amendments. See 123 Cong. Rec. 18173-74 (1977).

appropriateness of even stronger standards and expressly reserved the agency's authority to promulgate such standards.[942]

See RTC sections 18.3 and 17.1 for additional responsive information, as well as Preamble section II.D.2.ii c.

Response: Availability of copper

Commenters AFPM and AmFree posited a potential shortage of copper from secure sources during the Phase 3 rule's time frame. We do not agree. Presently, the majority of copper for domestic use is imported from Chile and Peru. Preamble section II, Figure II-6. Neither country is a "covered nation" for purposes of the IRA, and so we do not regard either country as an insecure source of supply. Moreover, as documented in the comments of ZETA, the currently operating Resolution Copper, Arizona project has the potential to supply up to 25% of the nation's copper demand. The NewRange Copper Nickel project, a 50:50 joint venture of Teck Resources Limited and PolyMet Mining Corp., holding the NorthMet and Mesaba deposits—is creating a path to develop one of the world's largest and lowest cost copper-nickel-PGM producing districts, unlocking a new domestic supply of critical minerals.

Response: Availability of platinum

As noted in RIA 1.7.1, platinum is utilized in fuel cell catalysts. Commenter AmFree suggests in n. 4 of its comments that there could be a shortage and that current sources of supply are insecure. The great majority of platinum comes from South Africa, with additional supply available from Russia and Zimbabwe. See Preamble Figure II-6. Neither South Africa nor Zimbabwe is a "covered nation" under the IRA, and EPA consequently does not agree that these are insecure sources of platinum. See ANL at 18 documenting the various bilateral and other trade agreements the United States has with each of these countries.

In 2022, DOE completed a Supply Chain Deep Dive assessment of platinum group metal catalysts in response to Executive Order 14017 on "America's Supply Chains" to identify vulnerabilities and opportunities.[943] The authors identified low volume of end-of life PEM electrolyzers and fuel cells as a barrier to establishing a domestic market for recycling and recovering platinum group metals (PGMs), for example, but it could be possible to leverage existing infrastructure for collecting and recycling catalytic converters (which also contain platinum) in the future.[944] Moreover, efforts are underway to minimize or eliminate the use of platinum in catalysts.[945] For example, DOE issued a Funding Opportunity Announcement (FOA) in 2023 in anticipation of growth in hydrogen and fuel cell technologies and systems. A portion of the FOA is designed to enable improvements in recovery and recycling, and applicants are encouraged to find ways to reduce or eliminate PGMs from catalysts in both PEM fuel cells and electrolyzers to reduce reliance on virgin feedstocks.[946]

Response: IRA

Commenters stated that the section 30D and 45X tax credits set out in the IRA would be of little effect due to insufficient domestic content. As explained in responses in RTC section 2.7, the 30D credit applies to a small fraction of the heavy-duty market, and we did not include this credit in our analysis.

For EPA's assessment of utilization of the section 45X tax credit, see RTC 2.7 and Preamble Section II.E.4.

Response: Use of sulfur

The Sulfur Institute notes that sulfur is used in extraction of lithium, and appears to criticize the proposal for "[m]andating the systems by which sulphur is transported". The final standards mandate nothing except meeting the performance-based numerical standards by whatever compliance strategy the manufacturer employs. The standards do not mandate means of transporting sulfur either directly or indirectly.

Response: Aluminum

A number of commenters suggested a potential shortage of aluminum due to rising demand due to electrification in the transportation sector. (See, e.g., Comments of AFPM.) None of these comments offered specifics or references. EPA sees no evidence of such a shortage. The price of aluminum has been in more or less continual decline since it reached its peak in April of 2022. "The reason for this is simple: The available supply of primary aluminum is shrinking, but the demand for that aluminum is shrinking faster, leading to a relative oversupply in the market."[947] The closing price of aluminum at the end of February 2024 continued this downward trend .[948] The United States itself produces aluminum from both primary and secondary sources, and Canada is one of the largest aluminum exporters to the United States -- a secure source of supply via trade. A large majority of Canada's primary aluminum is exported to the United States.[949] EPA therefore does not accept the unsupported assertions in these comments.

18 Environmental Justice

Comments by Organizations

Organization: California Air Resources Board (CARB)

H. EJ Impact

Affected pages: NPRM 26064-26069 and DRIA 391-398

1. Overall Comments on EJ Impact

Both NPRM and DRIA documents state that they use U.S. EPA's 2016 ''Technical Guidance for Assessing Environmental Justice in Regulatory Analysis" for their method. This guidance specifically addresses the following:

a. Is there evidence of potential EJ concerns in the baseline (the state of the world absent the regulatory action)?

b. Is there evidence of potential EJ concerns for the regulatory option(s) under consideration?

c. Do the regulatory option(s) under consideration exacerbate or mitigate EJ concerns relative to the baseline? [EPA-HQ-OAR-2022-0985-1591-A1, pp.65-66]

Overall, the NPRM and DRIA lay out the argument that GHG, criteria pollutants, and toxic emissions disproportionately affect EJ communities; however, questions b and c above were not addressed in the EJ sections or Benefits of the Proposed Program section of the NPRM and DRIA. U.S. EPA's proposed rulemaking would be stronger if that lens was also used as an overlay for all other related topics subsequently discussed in the NPRM and DRIA, resulting in clear application of those principles in the ultimately proposed program structure and the standard setting. [EPA-HQ-OAR-2022-0985-1591-A1, p.66]

CARB staff recommends the NPRM to outline the ways in which the regulatory structure addresses the different facets of disparate impact. These ideas need to be tied to the rest of the NPRM. Specifically, a discussion of how the regulatory standards were designed using data and literature reviews to limit or reverse possible disparate impacts in communities of concern. The NPRM is clear in identifying "EJ issues" but does not discuss or provide specific examples to clearly illustrate how the EJ section connects back to things like the requirement and analysis to "estimate the benefits and costs of major new pollution control regulations."222 [EPA-HQ-OAR-2022-0985-1591-A1, p.67]Consider the executive summary as an opportunity to highlight how EJ was considered in all major aspects of the proposed GHG standards ("GHG emissions from HD vehicles continue to impact public health, welfare, and the environment" "(DRIA) …estimates the benefits and costs of major new pollution control regulations"). Overall, the EJ analysis should inform the rest of the NPRM by characterizing health, environmental, economic impacts with one of the focuses being communities of concern and outlining the strategies used to prevent or mitigate disparate impacts that could exacerbate pre-existing disparity. [EPA-HQ-OAR-2022-0985-1591-A1, p.67]

Organization: CleanAirNow

The Kansas City, Missouri, public health data demonstrates that the life expectancy difference is between 15 and 18 years. According to the CDC, neighborhoods like Armourdale and Argentine in Kansas City, Kansas, have a shorter life expectancy of 22 years. Kansas City, like many other parts of the nation, experiences high-risk zip codes where asthma, heart disease, and cancer are above the national average and are the same areas sliced by highways, rail, and neighbors to chemical facilities. [EPA-HQ-OAR-2022-0985-1579-A1, p. 2]

In the context of the freight system in the United States, the facilities, corridors, and neighborhoods that are most heavily trafficked by heavy-duty trucks are often located in communities of color that are experiencing cumulative impacts from multiple sources of pollution and compounding socioeconomic factors. This pattern of development is the result of racist redlining practices that have systematically burdened people of color with disproportionate exposure to pollution. [EPA-HQ-OAR-2022-0985-1579-A1, p. 2]

People who live near freight hubs or ‘diesel death zones’—including ports, highways, warehouses, rail and intermodal yards—are disproportionately exposed to high concentrations of pollution from the combined activity of diesel-fueled heavy-duty trucks, equipment, rail, and vessels. Diesel exhaust contains carcinogens and toxic air pollutants that significantly affect the health of communities living in close proximity to truck tailpipe pollution. [EPA-HQ-OAR-2022-0985-1579-A1, p. 2]

On top of disproportionate exposure to air pollution, freight-impacted communities suffer from several additional harms from the freight sector: the paved areas and large, low buildings dominating freight facilities contribute to urban heat island effects, stormwater issues, and other environmental impacts. Other industrial sources are often clustered near freight facilities, which means that communities impacted by diesel trucks are also impacted by other sources of air and water contamination and toxic releases. [EPA-HQ-OAR-2022-0985-1579-A1, pp. 2-3]

Our report Environmental Racism in the Heartland, Fighting for Equity and Health in Kansas City, in collaboration with the Union of Concerned Scientists, exposes how concentrated freight transportation and industrial facilities, and a history of racist redlining practices, have combined to create disproportionate pollution exposures for environmental justice communities living in and around Kansas City. The report discusses community efforts to establish an air monitoring network and recommends policies to advance environmental justice solutions, including a shift to zero-emission trucks. [EPA-HQ-OAR-2022-0985-1579-A1, p. 3]

Organization: Evergreen Action

The transition to zero emissions medium and heavy duty vehicles is feasible and necessary to address long standing public health disparities. For decades the brunt of the pollution burden from heavy duty vehicles has fallen on communities of color and low income populations who suffer greater rates of lung and heart diseases, and even premature death as a result. These communities deserve the same quality of life as their white and wealthier counterparts. The burdens these communities experience have never been acceptable, or consistent with EPA’s or local authorities’ civil rights obligations. Now that there is viable technology available that would eliminate tailpipe pollution from trucks, it would be even more irresponsible and unjust not to compel the most expansive application of this technology to rectify the pollution impacts imposed on people of color and low income communities. [EPA-HQ-OAR-2022-0985-1595-A1, p. 2]

Organization: GreenLatinos et al.

Evidence makes clear how instrumental the swift adoption of stringent HDV and L/MDV standards are for the future of Latino/e communities. The 2023 American Lung Association State of the Air Report finds that more than one-third (36%) of people in the U.S. live in areas with failing grades for ozone or particulate pollution. This is concerning, especially considering the same report found that people of color are 3.7 times more likely than white people to live in a county with failing national air quality standards, putting our communities at even greater risk to severe health impacts and premature death. [EPA-HQ-OAR-2022-0985-2665-A1, p. 1]

Pollution from vehicles makes us sick and kills us. The data shows this over and over again. We need long-term protective regulation now.

For example, Latino/e children are three times more likely than white children to live in counties with low air quality. About 10% of Latino/e children suffer from asthma, and Latino/e children are 40% more likely to die from asthma than non-Latino white children. These disparities have only increased over time relative to the air quality standards set by the U.S. EPA. [EPA-HQ-OAR-2022-0985-2665-A1, p. 2]

Transportation is the largest source of pollution that fuels the climate crisis in the US. Latino/e communities disproportionately suffer harm from tailpipe emissions. While Latino/es are less likely to have access to a car and Latino/e workers commute by public transit nearly three times the rate of white commuters, our community can face up to 75% higher rates of exposure to harmful pollutants. [EPA-HQ-OAR-2022-0985-2665-A1, p. 2]

Today, we are at a critical nexus for clean transportation policy: We must drastically and permanently reduce air pollution from vehicles and transform our transportation landscape.

It is critical that the Biden administration pass regulations to reduce vehicle pollution and accelerate the shift to EVs. This action is crucial to achieving environmental justice. By implementing stringent HDV and L/MDV standards, the U.S. EPA will act on the Biden Administration's stated commitment to environmental justice, which the White House reaffirmed in April 2023 with a new Executive Order, Revitalizing Our Nation's Commitment to Environmental Justice for All. [EPA-HQ-OAR-2022-0985-2665-A1, p. 2]

The Biden administration's leadership in setting strong HDV and L/MDV standards is instrumental to mitigate the inequitable tailpipe pollution experienced by Latino/e and other frontline communities, which triggers asthma and other sometimes fatal respiratory illnesses. [EPA-HQ-OAR-2022-0985-2665-A1, p. 2]

Organization: Moving Forward Network (MFN) et al.

For decades, communities across the country have been fighting for the right to breathe clean air. Environmental racism and a lack of strong and protective regulations result in these frontline/fenceline communities and workers being forced to hold their breath. [EPA-HQ-OAR-2022-0985-1608-A1, p. 3]

The Administration and EPA often note their commitment to placing environmental justice at the center of policies and programs, including the recent Executive Orders 14037 & 14096. Time and time again, these efforts have come up unacceptably short. Nevertheless, MFN continues to remind EPA of the importance of having a justice framework within the regulatory process and advocate for the strongest and most protective standards. We expect EPA to remain faithful to their commitment to quarterly updates with MFN and continue to advocate for greater inclusion. [EPA-HQ-OAR-2022-0985-1608-A1, p. 3]

Advances in this technology are outpacing even the best estimates from just a few years ago—cost and technology assessments of battery-electric trucks from 2018 are already becoming obsolete. The barriers that once relegated ZEVs to a niche solution are shrinking, allowing zero-emission trucks to become a real solution in our battle against air and climate pollution. At every regulatory opportunity, EPA must include policies that center environmental justice solutions and rapidly advance ZEVs not just in specific market segments but for the entire truck sector. MFN members also submitted a detailed letter on the urgency and necessity for the EPA to address the largely unregulated rail and locomotive industry. [EPA-HQ-OAR-2022-0985-1608-A1, p. 4]

4. MFN Demands Zero-Emission Solutions for the Heavy-Duty Truck Sector to Finally Address the Freight System's Impacts on Environmental Justice Communities

MFN and its members have long pressed the federal government to acknowledge the multiple and cumulative harms that environmental justice communities face and their heightened vulnerability to those threats. Cumulative impact analyses recognize that some individuals and communities face more pollution than others and that the same amount of pollution can result in more harm to people facing additional and compounded stressors than to people who do not face such stressors. It also recognizes that these multiple stressors are too often interrelated in their origins. The results are clear— people of color and people with low incomes face some of the highest levels of pollution and are least equipped to ward off the consequences of this pollution. 11 [EPA-HQ-OAR-2022-0985-1608-A1, p. 10]

On top of disproportionate exposure to air pollution, freight-impacted communities suffer from several additional harms from the freight sector: the paved areas and large, low buildings dominating freight facilities contribute to urban heat island effects, stormwater issues, and other environmental impacts. Other industrial sources are often clustered near freight facilities, which means that communities impacted by diesel trucks are also impacted by other sources of air and water pollution and toxic releases. These communities also face racism and other forms of discrimination that increase their vulnerability to environmental threats. In fact, freight-impacted communities are even more vulnerable to the impacts of air and other pollution because of socio-demographic stressors—including racial segregation, high rates of poverty, lack of access to affordable foods, and lack of access to healthcare—compared to communities that do not face these stressors. 27 [EPA-HQ-OAR-2022-0985-1608-A1, p. 13]

Health Affairs 30. No. 5 (2011). p.879-998.

The COVID-19 pandemic has escalated the negative consequences of living in a “diesel death zone” or a region with poor air quality. Numerous studies now show that long-term exposure to air pollution makes people more vulnerable to complications and death from COVID-19. 31 That neighborhoods with high proportions of Black and Latinx residents experience disproportionately high levels of air pollution may help explain why these groups have suffered disproportionately from the COVID-19 pandemic. 32 Indeed, one study found that Los Angeles neighborhoods with the worst air pollution have experienced a 60 percent increase in mortality from COVID-19 compared to Los Angeles neighborhoods with the best air quality. 33 COVID-19 infections have been known to be more severe for people who are already diagnosed with asthma. A study from Harvard University found that a small increase in long-term exposure to PM2.5 leads to a large increase in the COVID-19 death rate. 34 One of the reasons that BIPOC communities are dying at higher rates from COVID-19 is because of underlying health conditions like diabetes, heart disease, and asthma, all of which are diseases that are more prevalent for communities of color and low-income communities and are also linked to the disproportionately high levels of air pollution in these communities. [EPA-HQ-OAR-2022-0985-1608-A1, p. 14]

Many studies have demonstrated the importance of race as a component of cumulative impacts, and the science behind this field is growing. 35 For example, a study released in March 2022 examined the link between port-related traffic and hospital visits for respiratory, heart-related, and psychiatric issues and concluded that people of color are more vulnerable to health impacts as a result of increased goods movement operations. 36 Adding just one vessel or increasing overall vessel tonnage in a nearby port leads to more than three additional hospital visits per year per thousand Black residents, compared to about one visit per thousand for white residents in the same area. 37 Relatedly, the study also found that reducing fossil fuel use in ports would significantly reduce air pollution concentration and have an acute and positive benefit to local Black residents. [EPA-HQ-OAR-2022-0985-1608-A1, p. 15]

37 Id. p. 32

MFN, its members, and allied organizations have published and contributed to numerous reports highlighting the cumulative impacts of freight transportation on frontline communities and workers. These reports include:

- MFN's May 2021 report, Making the Case for Zero-Emission Solutions in Freight: Community Voices for Equity and Environmental Justice provides an overview of the health impacts associated with goods movement and the disproportionate burdens felt by residents that live on the frontlines of polluting ports, warehouses, railyards, and highways, who are largely people of color. 38 The report features frontline voices who are calling for an end to diesel truck pollution and a full transition to zero-emissions. [EPA-HQ-OAR-2022-0985-1608-A1, p. 15]

  38 Moving Forward Network. Making the Case for Zero-Emission Solutions in Freight: Community Voices for Equity and Environmental Justice. (2021). https://www.movingforwardnetwork.com/wp-content/uploads/2021/10/MFN_Making-theCase_Report_May2021.pdf.

- Environmental Racism in the Heartland, Fighting for Equity and Health in Kansas City, a report by MFN members Clean Air Now and Union of Concerned Scientists, exposes how concentrated freight transportation and industrial facilities, and a history of racist redlining practices, have combined to create disproportionate pollution exposures for environmental justice communities living in and around Kansas City. 39 The report discusses community efforts to establish an air monitoring network and recommends policies to advance environmental justice solutions, including a shift to zero-emission trucks. [EPA-HQ-OAR-2022-0985-1608-A1, p. 15-16]

  39 Genna Reed, Beto Lugo-Martinez, and Casey Kalman. Environmental Racism in the Heartland: Fighting for Equity and Health in Kansas City. (2021). Cambridge, MA: Union of Concerned Scientists. https://doi.org/10.47923/2021.14322.

- Newark Community Impacts of Mobile Source Emissions, a community-based participatory research study developed with contributions from the New Jersey Environmental Justice Alliance, members of the Coalition for Healthy Ports including Greenfaith, Ironbound Community Corporation, New Jersey Clean Water Action, and the Natural Resources Defense Council, found that the worst pollution hot spots occurred where freight facilities are concentrated, and along truck routes. 40 The study found that electrifying vehicles can lead to significant local benefits but urged that electrification must coincide with reductions in power plant pollution, as these facilities are often located in the same areas that are disproportionately impacted by freight. [EPA-HQ-OAR-2022-0985-1608-A1, p. 16]

  40 M.J. Bradley & Associates. Newark Community Impacts of Mobile Source Emissions, A Community-Based Participatory Research Analysis (November 2020). p. 12-13. https://www.njeja.org/wpcontent/uploads/2021/04/NewarkCommunityImpacts_MJBA.pdf.

- For Good Jobs & Clean Air, How a Just Transition to Zero Emission Vehicles Can Transform Warehousing, published by Warehouse Workers for Justice, describes the heavy toll that a build-out of warehouse distribution centers is having on Will County, Illinois. The report describes how pollution burdens fall disproportionately on Black and Latinx residents and warehouse workers, who are on the frontlines of truck pollution. 41 The report also provides community air monitoring results, finding unhealthy spikes in PM2.5 pollution. [EPA-HQ-OAR-2022-0985-1608-A1, p. 16]

41 Madison Lisle and Yana Kalmyka. Warehouse Workers for Justice, For Good Jobs & Clean Air, How a Just Transition to Zero Emission Vehicles Can Transform Warehousing. (Nd). p. 13, https://www.ww4j.org/uploads/7/0/0/6/70064813/wwj_report_good_jobs_clean_air.pdf.

- Warehouses, Pollution, and Social Disparities: An analytical view of the logistics industry's impacts on environmental justice communities across Southern California, authored by People's Collective for Environmental Justice and the University of Redlands, analyzed over 3,300 warehouses over 100,000 sq ft in Southern California. 42 The report analyzes the expansion of the e-commerce industry compared to the location of existing pollution sources and sociodemographic data, demonstrating a correlation with health, economics, and racial disparities. [EPA-HQ-OAR-2022-0985-1608-A1, p. 16]

42 Ivette Torres and Anthony Victor. People's Collective for Environmental Justice, and Dan Klooster. Warehouses, Pollution, and Social Disparities: An analytical view of the logistics industry's impacts on environmental justice communities across Southern California. University of Redlands. (April 2021). https://earthjustice.org/wp-content/uploads/warehouse_research_report_4.15.2021.pdf.

As the Agency works to finalize this and similar rules, EPA should communicate regularly with environmental justice groups to learn from the experience of these impacted communities. Doing this will ensure that environmental justice considerations and solutions are appropriately discussed, evaluated, and adopted, with expert input from those on the frontlines of truck impacts. EPA should also use the comments (or letters or other calls to action) the Agency has received from environmental justice groups on this rule (and on other rules) and appropriately evaluate the concerns raised by these groups and the requested solutions. [EPA-HQ-OAR-2022-0985-1608-A1, p. 22]

EPA should consider the robust recommendations contained in the December 2022 Science Advisory Board report assessing EPA's proposed regulation for NOx emissions from heavy-duty trucks, which also supports conducting this analysis. 59 The SAB report found that "current methods used in EPA's Draft Regulatory Impact Analyses (RIAs) are not sufficient to capture community-scale benefits." 60 The SAB concluded and "strongly" recommended that "EPA

develop a strategy for systematic, quantitative evaluation of the environmental justice (EJ) impacts of air pollution regulations." 61 SAB's recommendation included consideration of race-specific health analyses and cumulative impacts, among other specific recommendations for improving regulatory analyses for air quality and greenhouse gas related rulemaking.

Specifically, SAB urged EPA to consider "cumulative exposure to multiple risk factors, including exposure to other air pollutants, heat, and lead" in future rulemaking. 62

[…]

EPA's draft rule qualitatively describes some connections between this rulemaking and cumulative impacts facing truck-impacted communities in the EJ analysis and even goes so far as to include a quantitative analysis of the demographics of households living within 300 feet of roadways. 64 This analysis reveals (unsurprisingly) that more often, communities of color and low-income communities are those impacted by truck routes. 65 EPA should build on this demographic data, conduct air modeling, and develop a racially-stratified health benefits analysis to more accurately quantify the benefits of the rule to EJ communities. If it is not feasible to conduct this analysis for the entire rule, EPA should do this for targeted geographic areas that are high in truck traffic. 66 Moreover, EPA should explicitly acknowledge the practice of redlining and how that has created disparities for communities of color being disproportionately exposed to near-roadway pollution. 67

[…]

As discussed above, environmental racism shows up in multiple ways in the impacts from heavy-duty truck pollution —including, but no not limited to, disproportionately high exposure to pollution, already elevated incidence rates of health risks such as asthma and premature mortality, and amplified effects of environmental exposures from social vulnerabilities such as cumulative physiological "wear and tear" and stress. 71 We recommend that EPA further consider the disparate impacts of the rule and alternatives by analyzing race/ethnicity-stratified health benefits. This analysis would more accurately capture the distribution of health impacts to environmental justice communities and result in a more accurate total health and climate benefits as well.

Third, EPA should consider additional measures to ensure that overburdened EJ communities will receive the benefits of transitioning to cleaner trucks. It is critical that, in this rulemaking, EPA sends a strong signal to the market and regulators that longstanding burdens to communities and increasing disparities in burdens from heavy-duty trucks cannot continue. EPA has obligations under the Clean Air Act and Title VI of the Civil Rights Act to ensure that state agencies receiving funds for their air programs address disparities in burdens from heavy-duty trucks through their State Implementation Plans (SIPs). 73 EPA can and should help support states by setting a standard under Section 202 that ensures robust availability of the cleanest trucks across the country in states, cities, and other municipalities facing the heavy and disparate toll of the logistics industry. [EPA-HQ-OAR-2022-0985-1608-A1, p.32]

> 73 U.S. EPA also may have civil rights obligations to ensure that localities receiving federal funds similarly do not create or perpetuate disparities in pollution and/or cumulative impacts from the logistics sector, as does its federal counterpart the Department of Housing and Urban Development. See 42 U.S.C. § 2000d-1 and 40 C.F.R. 7.15 ("This part applies to all applicants for, and recipients of, EPA assistance in the operation of programs or activities receiving such assistance" (emphasis added).)

Organization: National Association of Mutual Insurance Companies (NAMIC)

Specifically, the EPA, in submissions to the Federal Register, appears to assert that individuals within referenced Environmental Justice populations (defined as people of color and low-income populations in at least some EPA Federal Register notices) have less or limited access to homeowner insurance. [EPA-HQ-OAR-2022-0985-1478-A1, p. 1]

In its posted online EJ 2020 Glossary, the EPA defines 'Environmental Justice' (EJ) as follows: 'The fair treatment and meaningful involvement of all people regardless of race, color, culture, national origin, income, and educational levels with respect to the development, implementation, and enforcement of protective environmental laws, regulations, and policies.' [EPA-HQ-OAR-2022-0985-1478-A1, p. 2]

By presenting statements about homeowners' insurance in the above referenced publications which feature discussions of Environmental Justice, the EPA seems to imply that potential insurance availability or affordability issues may be linked to EJ. Yet, the EPA does not offer specific references or 'scientific assessments' on insurance coverage in such areas to support the implication that homeowner insurance is not being made available in some way based on race, color, culture, national origin. [EPA-HQ-OAR-2022-0985-1478-A1, p. 2]

Respectfully, NAMIC asks the EPA to refrain from such charges regarding homeowners' insurance in its publications moving forward. NAMIC is greatly concerned that an agency of the federal government with minimal expertise in homeowners' insurance would infer such morally repugnant allegations. The Administration's requirement of a 'whole of government' focus on climate and equity does not empower federal agencies to broadly impute blame, particularly in the absence of legal authority in an industry that is highly regulated at the state level. [EPA-HQ-OAR-2022-0985-1478-A1, p. 2]

The Information Quality Act passed through Section 515 of the Consolidated Appropriations Act, 2001 requires that each federal agency disseminating information ensure and maximize the quality, objectivity, utility, and integrity of information (including statistical information) disseminated by the agency, and to allow affected persons to seek and obtain correction of information disseminated by the agency. If the EPA has rigorous scientific assessments to support these statements, NAMIC would greatly appreciate the EPA sharing that information with us. However, if the EPA does not have such scientific assessments, we would respectfully request that the EPA discontinue the inclusion of such statements is support of proposed rules of a federal regulatory agency. [EPA-HQ-OAR-2022-0985-1478-A1, p. 2]

Organization: Our Children's Trust

Our children and future generations are already suffering injury with long-lasting and potentially irreversible consequences at present levels of heating. Moreover, all young people seeking environmental and climate justice, especially youth from frontline and environmental justice communities that have contributed the least to emissions and have long suffered from systemic environmental racism and social and economic injustices, must not only have their voices heard, but have their rights protected. [EPA-HQ-OAR-2022-0985-1633-A1, p. 5]

Organization: Valero Energy Corporation

[These comments also appear in RTC 18.3 and 19.1]

For these reasons, the EJ analysis in the proposal is incomplete per EPA's own EJ assessment criteria. Specifically, when assessing the potential for disproportionately high and adverse health or environmental impacts of regulatory actions on minority populations, low-income populations, tribes, and/or indigenous peoples, EPA should answer three broad questions:

1. Is there evidence of potential EJ concerns in the baseline (the state of the world absent the regulatory action)?

2. Is there evidence of potential EJ concerns for the regulatory option(s) under consideration?

3. Do the regulatory option(s) under consideration exacerbate or mitigate EJ concerns relative to the baseline?

EPA fails to perform this full assessment for its proposal. Consequently, EPA ignores EJ concerns both inherent to the baseline and exacerbated by the proposal. [EPA-HQ-OAR-2022-0985-1566-A2, p. 48.]

Organization: World Resources Institute (WRI)

Electric school buses, which produce zero tailpipe emissions, are the healthiest solution for all students, bus drivers, and the communities they travel through. Black students, children with disabilities and low-income students, ride diesel school buses more than others. Because students from low-income communities are more likely to ride a school bus - 60% of students from low-income families ride the bus to school, compared to 45% of students from families with higher incomes - a more stringent rule will advance the transition to an electric school bus fleet and simultaneously help address this transportation inequity. [EPA-HQ-OAR-2022-0985-1601-A1, p. 3]

EPA Summary and Response:

Summary:

Many commenters note that people of color and lower socioeconomic status face disproportionate and adverse effects of truck-emitted air pollutants (CARB, CleanAirNow, Evergreen Action, GreenLatinos et al., MFN, Our Children's Trust). Comments point to both higher exposure and worse health problems in people of color and lower-income people, noting both higher levels of air pollution in those communities and higher rates of health problems, including greater lung and heart disease rates and lower life expectancies compared to non-Hispanic white and wealthier populations.

Many commenters supported the proposals, while others urged EPA to take more aggressive action. Many references to studies were provided, including many citing the CleanAirNow/UCS report "Environmental Racism in the Heartland, Fighting for Equity and Health in Kansas City." Several comments described how historical government policies such as redlining created modern disparities in exposures to air pollutants, including from traffic (e.g., CleanAirNow, MFN, State of California et al. cited below in 18.1, SELC cited in 18.3).

Commenters shared information about environmental justice issues from other types of transportation infrastructure, not just roads, that can cause health problems: warehouses, ports, rail, and intermodal yards, for example (CleanAirNow, State of CA, ZETA).

Several commenters claim that EPA must base its emission standards on environmental justice. MFN says that EPA must "at every regulatory opportunity… include policies that center environmental justice solutions." Evergreen Action asserted that standards that do not "rectify the pollution impacts imposed on people of color and low income communities" by "compel[ling] the most expansive application zero emission technology would be "irresponsible and unjust." In addition, CARB claims that the "proposed rulemaking would be stronger" if EPA applied an EJ lens to its standards. GreenLatinos et al. claim that accelerating the shift to EV is required to achieve EJ and strong standards are needed to meet President Biden's commitment to mitigate the problems experienced by Latino/e and other frontline communities.

CARB and Valero Energy Corporation asserted that EPA did not consider important elements of EJ analysis as described in the 2016 Technical Guidance for Assessing Environmental Justice in Regulatory Analysis, including determining potential EJ concerns in the regulatory option(s) under consideration and whether regulatory options might exacerbate or mitigate EJ concerns relative to the "baseline" scenario. MFN asserts that EPA should have followed the advice of the 2022 report by the Science Advisory Board (SAB)'s *Regulatory Review of Science Supporting EPA Decisions for the Proposed Rule: Control of Air Pollution from New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards*.

NAMIC requested that EPA refrain from stating that people of color or low-income populations have less or limited access to homeowner insurance.

Response:

In this response, the EPA is focusing on addressing general comments related to environmental justice and environmental justice issues associated with HD vehicles. Comments related to environmental justice and climate change are addressed in Section 18.1 and comments related to environmental justice and non-GHG pollutants are addressed in Section 18.2. Comments related to environmental justice issues associated with lifecycle assessment and cumulative emissions are addressed in Section 18.3. To the extent that these commenters raise other issues, those issues are addressed elsewhere in this RTC or in the final notice for this action.

EPA acknowledges and agrees with commenters' statements that actions to control emissions from heavy-duty vehicles are necessary to improve public health and welfare, including to those who live, work, or attend school close to major roadways and in communities with EJ concerns, as well as in those using buses for travel. After consideration of comments, EPA updated our review of the literature, while maintaining our general approach to considering environmental justice. We have included references that meet our peer review requirements in our citations, and we have updated our description of the scientific literature on environmental justice for populations near major roads to ensure its representativeness of the state of published literature. In Section VI.D.2 of the preamble, we discuss the EJ impacts of this final rule's GHG emission standards from the anticipated reduction of GHGs. We also discuss in Section VI.D.3 of the preamble the potential additional EJ impacts from the non-GHG (criteria pollutant and air toxic) emissions changes we estimate would result from compliance with the CO_2 emission standards, including impacts near roadways and from upstream sources. EPA did not consider potential adverse disproportionate impacts of vehicle emissions in selecting the CO_2 emission standards, but we provide information about adverse impacts of vehicle emissions for the public's understanding of this rulemaking, which addresses the need to protect public health consistent with CAA section 202(a)(1)-(2).

Regarding assertions from CARB, MFN, and Valero Energy Corporation that consideration of EJ or cumulative impacts from multiple air pollution sources or other factors would have resulted in a different regulatory program, EPA is promulgating these standards under our authority in CAA section 202(a)(1)-(2) and has appropriately assessed the statutory factors specified in that section, including consideration of costs and lead time. See preamble sections I and II.G for further discussion. EPA's assessment of the relevant statutory factors in CAA section 202(a)(1)-(2) justify the final standards. We also performed analysis of additional factors, consistent with Executive Orders 12866, 12898, 14096 and others; our assessment of these factors lend further evidentiary support to the final rule.

In addition, independent information cited in the preamble and published since provides strong evidence that emission standards provide benefits that accrue disproportionately to communities with EJ concerns. Demetillo et al. (2021) and Kerr et al. (2021) use “natural experiments” to demonstrate how reductions in heavy-duty truck emissions reduce disparities in exposures to traffic-generated pollution.[950,951]

MFN’s comments that EPA should have followed SAB’s recommendations in conducting high-resolution health and EJ analyses in support of this rule overlook several important considerations. First, SAB called for a “strategy for systematic, quantitative evaluation of the environmental justice” in its final report published in December 2022. Given the timing of this rulemaking process, even a plan that met these objectives and been subject to appropriate public and/or peer review would have been infeasible. As SAB noted in its report, the computational and information requirements for conducting this type of analysis are high. As such, it was not feasible for EPA to conduct such analyses for this rule, even for a subset of targeted geographic areas as suggested by MFN. EPA’s EJ and health benefit assessments are based on all appropriate data available at the time this rule was conducted, as well as a systematic review of the published literature about EJ for people living near major roads. Our assessment is in keeping with EPA’s 2016 Technical Guidance on EJ, which notes the potential suitability of “a suite of methods that can be applied depending on the type of available data, availability of resources, and time needed to conduct the analysis.” EPA continues to work to improve its EJ and benefits analyses to have higher levels of spatial resolution and ability to analyze larger areas. We note that a new draft of EPA’s EJ Technical Guidance has been submitted for public review (88 FR 78358; https://www.epa.gov/environmental-economics/epa-draft-revision-technical-guidance-assessing-environmental-justice).

In response to commenters who cited the three broad EJ-related questions posed in EPA’s EJ Technical Guidance, and who suggest we failed to address each question, we note that the questions are posed as guiding questions when analyzing potential EJ concerns for regulatory actions. EJ concerns related to any given rulemaking are unique and are analyzed on a case-by-case basis. We are not always able to provide quantitative answers to these questions.

NAMIC’s comment and request that we remove mention of limited access to homeowners’ insurance overlooks considerable evidence. The text in the preamble is intended to indicate that individuals who commonly and collectively may be perceived as being “vulnerable” or “sensitive,” and who frequently comprise communities facing environmental justice concerns, often live in locations that face the greatest risks from climate change effects and have fewer resources available to adapt. Environmental justice issues extend beyond issues related to discrimination on the basis of any particular demographic factor; in fact, in many respects, socioeconomic status has a significant effect on environmental justice considerations and resilience with regards to insurance access and homeownership or lack thereof (Gamble et al., 2016; EPA, 2021).[952] As is well documented, areas that experience greater threats of natural

[950] Demetillo, M.A.; Harkins, C.; McDonald, B.C.; et al. (2021) Space-based observational constraints on NO2 air pollution inequality from diesel traffic in major US cities. Geophys Res Lett 48, e2021GL094333. *https://doi.org/10.1029/2021GL094333*.
[951] Kerr, G.H.; Goldberg, D.L.; Anenberg, S.C. (2021) COVID-19 pandemic reveals persistent disparities in nitrogen dioxide pollution. PNAS 118. *https://doi.org/10.1073/pnas.2022409118*.
[952] Auer MR, Hexamer BE. Income and Insurability as Factors in Wildfire Risk. Forests. 2022; 13(7):1130. https://doi.org/10.3390/f13071130

hazards, such as wildfires, hurricanes, or coastal inundation, face higher rates for homeowners' and flood insurances, which may price out individuals from accessing more comprehensive coverage, leave them uninsurable, or may prevent them from being able to rebuild in areas where home values and construction costs have exceeded historic amounts (Gotham 2014; Keenan et al., 2018; Fleming et al., 2018; Wilson et al. 2021; Brown, 2022).[953,954,955,956,957] Low-income and Black, Indigenous, and People of Color (BIPOC) individuals often are more likely to inhabit areas facing greater vulnerability to climate change hazards that can affect home displacement or loss, such as wildfires, sea level rise, or extreme weather events (Gamble et al., 2016; EPA, 2021).[958,959]

There are clear examples of how this is translating into real-time effects. The costs of the National Flood Insurance Program have gone up considerably in recent years, and rates are expected to continue to increase, thus pricing out low-income homeowners (Fleming et al., 2018).[960] We have seen that homeowners' insurance providers are cancelling coverage or failing to insure homes at greater risk of wildfire damage, the greatest burdens of which are being, and will be, borne by low-income individuals (Auer & Hexamer, 2022).[961] This all is irrespective of concerns regarding rising housing costs across the United States (Brooks, 2022), let alone the influence of gentrification and general disparities in socioeconomic and racial demographics

between renters versus homeownership (Kuebler & Rugh, 2013; Tedesco et al., 2022).[962,963,964] Homeownership in desirable areas that are less at risk of climate hazards increasingly is becoming less available to, or less populated by, low-income or BIPOC households (Keenan et al., 2018; Ruhks-Ahidiana, 2021; Tedesco et al., 2022). [13,965,966]In response to commenters who identify potential environmental justices concerns from the effects of criteria and GHG pollutants from heavy-duty vehicles, or additional scientific information, views, or analyses that were not specifically addressed in the proposed or final action, the EPA notes that the evidence regarding the environmental justice impacts of the proposed and final rulemakings is adequately described in Section VI.D of the preamble.

The EPA does not interpret supportive comments related to the environmental justice impacts associated with the proposal as indicating disagreement with the evidence on environmental justice information that was presented in the proposal, but rather understands these comments to suggest that the additional information they provide adds support for finalizing the rulemaking. To the extent that the information introduced by commenters was intended to advocate for more stringent standards, we refer the reader to Section 2 of this RTC document. See Sections 3 and 4 of this RTC document for responses relating to our updated cost and technology assessments for the final rule. For responses related to GHGs and the social cost of GHGs, see Section 20.GHG Impacts on Environmental Justice and Vulnerable or Overburdened Populations

Comments by Organizations

Organization: California Air Resources Board (CARB)

3. GHG and Climate Change as it Relates to EJ

Overall, both EJ sections in the NPRM and DRIA do a good job of highlighting how climate change impacts are disproportionally felt by certain communities and individuals (characteristics and/or circumstance), and by inference, that reducing CO2 equivalent will benefit to those same communities. CARB staff recommends that the NPRM also point out that slowing down climate change is therefore of increased importance for those same frontline communities experiencing disparate impacts to their health, environment, and lived experiences. [EPA-HQ-OAR-2022-0985-1591-A1, pp.66-67]

While regulatory standards benefit everyone, disproportionally burdened communities still encounter unique barriers to accessing regulatory benefits. As such, no discussion of climate change and EJ is complete without considering the disproportionate ways that resources are allocated to mitigate climate impacts, for example: resources to deal with sea level rise

Organization: Evergreen Action

As this administration addresses the climate crisis, the policies and solutions must be grounded in the reality that these same communities who are exposed to greater rates of pollution will also be most vulnerable to climate change impacts, or are already experiencing them. Sharply curbing greenhouse gas emissions from the transportation sector on the fastest timeline possible will reduce harm for pollution burdened communities now, and reduce future impacts. This administration must move at the speed the climate crisis demands, using all available tools and technologies to reduce emissions to the greatest extent at every opportunity, which this proposed rule does not accomplish. [EPA-HQ-OAR-2022-0985-1595-A1, p. 2]

Organization: Moving Forward Network (MFN) et al.

In recent years, the findings have added evidence that a changing climate is making it harder to protect human health—the three years covered by the referenced report ranked among the seven hottest years on record globally. High ozone days and spikes in particle pollution related to heat, drought, and wildfires are putting millions of people at risk and adding challenges to the work that states and cities are doing across the nation to clean up air pollution. [EPA-HQ-OAR-2022-0985-1608-A1, p. 11]Add to all of this the reality that these same communities are also most at risk from the coming climate disaster. The effects of a growing climate crisis are already being felt by port-adjacent communities in deadly and dangerous ways. These effects range from deadly heat waves, to flooding, to superstorms and hurricanes. 28 Indeed, storm surges and hurricane events have significantly increased in severity and frequency in recent years. These superstorms, like Superstorm Sandy, have forced port-adjacent communities to confront new issues that are a direct result of an under-regulated freight transportation system. The increasing frequency and severity of natural disasters hit these communities hardest, and they receive lower levels of reinvestment after these events. Moreover, they are more likely to have inadequate infrastructure and insurance and are "more likely to live near industrial facilities and are therefore at a higher risk for chemical spills and toxic leaks resulting from toxic storms." 29 In total, low-income communities and communities of color "are found to be particularly more vulnerable to heatwaves, extreme weather events, environmental degradation, and subsequent labor market dislocations." 30 [EPA-HQ-OAR-2022-0985-1608-A1, p. 13-14]

C. The Impacts of Climate Change and Poor Air Quality Disproportionately Harm Environmental Justice Communities

1. Environmental Justice Communities Disproportionately Bear the Burden of Climate Change Impacts

The climate change impacts discussed above will continue to disproportionately fall on environmental justice communities.87 Indeed, environmental justice communities already experience more severe climate impacts and are more vulnerable as the climate crisis worsens. [EPA-HQ-OAR-2022-0985-1588-A1, p.11]

87 Environmental justice is defined by EPA as the "fair treatment and meaningful involvement of all people regardless of race, color, national origin or income with respect to development, implementation, and enforcement of environmental laws, regulations and policies." EPA, EPA-300-B-1-6004, EJ 2020 Action Agenda: The U.S. EPA's Environmental Justice Strategic Plan for 2016-2020, at 1 (Oct. 2016). For the purpose of this comment, the term "environmental justice community" refers to a community of color or community experiencing high rates of poverty that due to past and or current unfair and inequitable treatment is overburdened by environmental pollution, and the accompanying harms and risks from exposure to that pollution, because of past or current unfair treatment.

Severe harms from rising temperatures are already a reality for many environmental justice communities. The last nine years have been the nine hottest on record, and that trend is only expected to continue.88 Members of environmental justice communities tend to work in occupations with increased exposure to extreme heat, such as the agricultural, construction, and delivery industries.89 Farmworkers die of heat-related causes at 20 times the rate of the rest of the U.S. civilian workforce.90 Since 2005, the first year California began tracking the number of heat-related fatalities, 36 percent of California's heat-related worker deaths have been of farmworkers.91 Similarly, although construction workers comprise only 6 percent of the national workforce, they account for 36 percent of heat-related deaths.92

92 Xiuwen Sue Don et al., Heat-Related Deaths Among Construction Workers in the United States, 62 Am. J. Indus. Med. 1047-57 (2019).

At home, environmental justice communities suffer disproportionate impacts from extreme heat because they are more likely to lack air conditioning, tree canopy, and greenspace. Environmental justice communities have less access to air conditioning to cool down, and are less able to pay the utility bills required to run air conditioning units or fans.93 In urbanized environments, pavement, cement, and other non-vegetated areas contribute to the heat island effect, in which built environments retain heat, causing daytime temperatures to be 1° to 6° F hotter than rural areas and nighttime temperatures to be as much as 22° F hotter.94 The heat island effect is inequitably distributed—it is most extreme in lower-income communities and communities of color.95 Contributing to this effect is the lack of tree canopy and greenspace in environmental justice communities, often due to lower historical and ongoing investment in these communities. Indeed, tree canopy and greenspace is highly correlated with historical redlining practices, in which federal housing policy directed investment away from "risky" lower-income communities and especially communities of color.96 Moreover, an EPA report found that individuals with lower incomes and individuals of color are 11 to 16 percent and 8 to 14 percent, respectively, more likely to live in areas with the highest projected increases in premature mortality from extreme heat.97 [EPA-HQ-OAR-2022-0985-1588-A1, p.12]

97 EPA, Climate Change and Social Vulnerability in the United States: A Focus on Six Impacts (2021), https://www.epa.gov/system/files/documents/2021-09/climate-vulnerability_september-2021_508.pdf, at 36.

In addition, flooding and drought from extreme weather events already disproportionately affect environmental justice communities, and the inequity will only grow as climate impacts worsen. Due to disinvestment, environmental justice communities often lack sufficient infrastructure to control flooding or ensure steady clean water supplies.98 They also suffer from more severe impacts, such as contaminated water from pollutant flows during floods and increased concentration of contaminants during droughts.99 EPA has also determined that individuals with lower incomes are more likely to live in areas with the highest projected land losses from sea level rise inundation and are more likely to face substantial traffic delays due to climate-driven changes in high-tide flooding.100 These individuals are less able to afford flood insurance and less likely to qualify for emergency relief and other safety net programs.101 [EPA-HQ-OAR-2022-0985-1588-A1, pp.12-13]

The above impacts especially apply to tribal communities. Due to land dispossession and forced migration, tribal communities are more exposed to extreme heat and more likely to rely on local water sources that are less resilient to drought and are more contaminated.102 Beyond those impacts, tribal communities also suffer cultural harms from the decimation or alteration of local ecosystems and species of particular meaning to cultural practices.103 These cultural resources have intrinsic value, and they are also critical to tribal community identity and group cohesion, which translates into direct health benefits.104 Moreover, degradation of these cultural resources threatens traditional ecological knowledge, such as particularized understanding of local ecosystems, agriculture, and sustainable practices, that can help limit the impacts of climate change.105 Tribal communities with sovereign land holdings are also more vulnerable to climate impacts because they are unable to relocate.106 [EPA-HQ-OAR-2022-0985-1588-A1, p.13]

EPA Summary and Response:

Summary:

Commenters stated that the climate change impacts (discussed in section 14 of this RTC document) will disproportionately fall on environmental justice communities. Commenters stated that members of environmental justice communities tend to work in occupations with increased exposure to extreme heat, such as agricultural, construction, and delivery industries. Commenters stated that environmental justice communities suffer disproportionate impacts from extreme heat because they are more likely to lack air conditioning, tree canopy, and greenspace. Commenters stated that flooding and drought from extreme weather events already disproportionately affect environmental justice communities and that the inequity will only grow as climate impacts worsen. Commenters stated that individuals with lower incomes are more likely to live in areas with the highest projected land losses from sea level rise inundation and are more likely to face substantial traffic delays due to climate-driven changes in high tide flooding. Commenters stated that impacts especially apply to tribal communities.

Response:

As discussed in preamble Section VI.D.2, EPA acknowledges and agrees with comments in this RTC section stating that communities with environmental justice concerns are disproportionately impacted by climate change, and that reductions in future warming due to this rule will benefit these communities. Please also refer to our response to comments in Section 2.4 of this RTC document regarding the stringency of the final standards.

18.1 EJ, Non-GHG Impacts

Comments by Organizations

Organization: Allergy & Asthma Network et al.

The impacts of pollution from heavy-duty vehicles are not shared equally. According to EPA, seventy-two million people are estimated to live near truck freight routes.2 They are more likely to be people of color and those with lower incomes. These overburdened communities are directly exposed to pollution that causes respiratory and cardiovascular problems, among other serious and costly health effects. [EPA-HQ-OAR-2022-0985-1532-A1, p. 2]

2 United States Environmental Protection Agency. Fact Sheet: Transportation Pollution and Environmental Justice. March 2022. https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P10144Y3.pdf

This disproportionate impact is echoed in the broader share of those most burdened by poor air quality. According to the American Lung Association's 2023 "State of the Air" report, more than 1 in 3 Americans are living in communities with unhealthy air. People of color are over three times more likely to be breathing the most polluted air than white people.3 [EPA-HQ-OAR-2022-0985-1532-A1, p. 2]

3 American Lung Association. State of the Air 2023: Key Findings. April 2023. https://www.lung.org/research/sota/key-findings

Organization: American Thoracic Society (ATS)

Greenhouse gas and traffic-related air pollutant emissions have significant adverse human health effects, especially for low-income, minoritized, and vulnerable groups.

As outlined in the proposed rule, GHG reductions will improve the cardiopulmonary health of the nation, including individuals from minoritized and excluded communities who typically shoulder the greatest burden of health effects from air pollution. As highlighted by the EPA and others, Black, Hispanic, and poor communities are more likely to live near roadways and therefore have more exposure to the heavy duty truck pollution.7,8 Further, 6.4 million U.S. children attend schools within 250 meters of a major roadway, disproportionately burdening Black and low income children.9 Children are particularly vulnerable as respiratory insults during this critical stage of lung development can leave long lasting impacts into adulthood, including increasing the likelihood of development of adult chronic respiratory diseases such as COPD.10 [EPA-HQ-OAR-2022-0985-1517-A1, p. 2]

Criteria and other hazardous air pollutants, including PM2.5, NOx, ultrafine particulates, and VOCs, are more abundant the closer proximity one is to major roadways. These traffic-related pollutants can induce greater and differing inflammatory impacts compared to ambient air pollution,11,12 and may not be adequately captured by typical air quality monitors, particularly for vulnerable populations.13 Numerous studies have demonstrated the health harms of living near a major-roadways including increased asthma prevalence,14,15 worsened childhood asthma symptoms and control,16,17 reduced lung function,12 childhood asthma exacerbations,18 cardiovascular morbidity,19,20 and lung cancer.21 [EPA-HQ-OAR-2022-0985-1517-A1, p. 3]

Organization: California Air Resources Board (CARB)

2. Non-GHG Impacts (i.e., Criteria Pollutants and Toxics)

The largest EJ-related concern with the NPRM pertains to the benefit analysis of non- GHG emissions. Even more significantly, the NPRM recognizes that EJ communities are disproportionately affected by ICE emissions, and it then erroneously implies that a transition to ZEVs will therefore disproportionally benefit those communities. CARB staff understand the argument that air quality will likely improve for all communities, but the benefit will not necessarily be proportional. Without active management, the newest and cleanest vehicles will come into the fleet to fill the need of lighter duty "vocational" work (delivery vehicles, trash trucks, buses, etc.) while dirtier ICE vehicles will continue to be used for line-haul trucking, around ports, and for heavy industrial (see NPRM Table ES-3). In addition, those new and cleanest HDVs will likely start out life in affluent neighborhoods and will then "trickle down" into EJ communities that are disproportionally burdened by dirty air and need the emissions reduction the most. Such concerns drove CARB and the Section 177s states to adopt ZEV sales requirements that guarantee production of ZE tractor trailers, the largest polluters on the road, and similarly adopt sector specific fleet requirements such as for drayage trucks. U.S. EPA's NPRM has an unrealized opportunity to include the means to assure entire sectors are not unduly delayed, especially those sectors with outsized emissions impact on our communities from the largest engines and significant total fuel usage. [EPA-HQ-OAR-2022-0985-1591-A1, p.66]

Organization: Environmental Defense Fund (EDF)

In addition to the research presented in our previous comments, EDF has since conducted additional analyses that further demonstrate the impact of diesel emissions on vulnerable populations and the need for and benefits of zero-emitting solutions, especially in pollution hot spots. In particular, we highlight two recent analyses that we submit along with these comments. [EPA-HQ-OAR-2022-0985-1644-A1, p. 7-8]

Warehouse Pollution and Proximity Mapping. New research from EDF looks at U.S. warehouse proliferation and the exposure to air pollution from warehouse trucks. EDF researchers analyzed 10 states and combined warehouse industry data with a Geospatial Information System (GIS) application known as Proximity Mapping, which applies areal apportionment to estimate the characteristics of populations living near specific facilities and pollution sources, using the U.S. Census Bureau's American Community Survey 5-Year estimates.7 The analysis found an estimated 15 million people live within a half-mile of a warehouse in 10 states across the country and more than 1 million children under the age of 5 live within a half-mile of a warehouse. Exposure to air pollution from the trucks that frequent warehouses is linked to a range of health issues, including the risk of developing childhood asthma, heart disease, adverse birth outcomes like premature birth and low birth weight, cognitive decline, and stroke. Each warehouse generates hundreds, if not thousands, of truck trips every day, and trucks can emit more pollution while idling or traveling at slow speeds than while driving at faster speeds. [EPA-HQ-OAR-2022-0985-1644-A1, p. 8]

7 Aileen Nowlan. 2023. Making the Invisible Visible, EDF. https://globalcleanair.org/files/2023/04/EDF-Proximity-Mapping-2023.pdf (Attachment B)

The results also show that warehouse proliferation does not distribute the pollution risk evenly. In some states like Illinois, Massachusetts and Colorado, the concentration of Black and Latino residents around warehouses is nearly double the state average. The study notes that zero-emission options already exist for delivery vans, yard trucks and regional haul trucks and manufacturers are investing billions to expand zero-emission technology for long-haul trucking. Increasing deployment of ZEVs would significantly reduce the harmful diesel pollution around warehouses and help protect nearby communities. [EPA-HQ-OAR-2022-0985-1644-A1, p. 8]

Students from low-income families are particularly exposed to the dangers of diesel exhaust because 60% ride the bus to school, compared to 45% of students from families with higher incomes.108 EPA also finds that, of the 10 million students who attend schools within 200 meters of major roadways, "students of color were overrepresented at schools within 200 meters of primary roadways, and schools within 200 meters of primary roadways had a disproportionate population of students eligible for free or reduced-price lunches. Black students represent 22 percent of students at schools located within 200 meters of a primary road, compared to 17 percent of students in all U.S. schools. Hispanic students represent 30 percent of students at schools located within 200 meters of a primary road, compared to 22 percent of students in all U.S. schools."109 [EPA-HQ-OAR-2022-0985-1644-A1, p. 48]

NYC and Atlanta ZEV Case Studies.8 In comments on EPA's March 28, 2022 proposed rule, Control of Air Pollution from New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards,9 EDF submitted preliminary results of a case study on the health and air quality benefits of deploying heavy-duty ZEVs in New York City; for which we now have finalized results. Compared to traditional transportation air quality health benefit tools, our data and methods represent a significant improvement in the ability to ascertain disparities. Conducted by researchers at EDF, Boston University, and the University of North Carolina, we conducted a full chain air pollution health impact assessment to model two electrification scenarios for New York City and Atlanta. [EPA-HQ-OAR-2022-0985-1644-A1, p. 9]

8 Presentation by Jonathan Buonocore, Chet France, Rick Rykowski, Brian Naess, Komal Shukla, Catherine Seppanen, Dylan Morgan, Frederica Perera, Katie Coomes, Ananya Roy, Sarav Arunachalam. 2022. "Distribution of Air Quality Health Benefits of MHEV policies: New York and Atlanta," University of North Carolina, Boston University, Columbia University Mailman School of Public Health and Environmental Defense Fund. (Attachment C)

9 EDF's comments on the Proposed Rule, Control of Air Pollution from New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards, 87 Fed. Reg. 17414 (Mar. 28, 2022) dated May 16, 2022.

Our two medium- and heavy-duty electrification policy scenarios differ in how rapidly on-road electrification occurs, and consequently, how quickly the current medium- and heavy-duty fleet turns over. Scenario 1 assumes 100% sales for zero emission transit and school buses by 2030, with a phased-in approach for other medium- and heavy-duty sales (30% by 2030 and 100% by 2040). Scenario 2 does not phase in ZEV sales, but simply requires 100% on-road zero emission medium- and heavy-duty ZEVs by 2040. We find that full electrification (Scenario 2) would prevent $2.4 billion in health damages every year by 2040 (248 deaths, 173 childhood asthma emergency department (ED) visits) in the New York area. In Atlanta, full electrification

(Scenario 2) in 2040 would prevent $4.14 billion in health damages (428 deaths and 88 childhood asthma ED visits). [EPA-HQ-OAR-2022-0985-1644-A1, p. 9]

Our research in Atlanta and New York also demonstrates that many communities of color and low-income communities with high baseline asthma ED visits also have elevated diesel truck and bus traffic and pollution and therefore face disproportionate impacts. In New York City, census-tracts with 97 percent persons of color bear greater than 35 percent of total childhood asthma ED visits attributable to medium- and heavy-duty vehicles, despite being only 19 percent of the population. Similarly in Atlanta, persons of color make up 36 percent of the population, but account for 46 percent of NO2-attributable deaths, and 40 percent of NO2-attributable asthma ED visits. [EPA-HQ-OAR-2022-0985-1644-A1, p. 9-10]

These recent studies align with and reinforce EPA's conclusions in the proposal regarding the disparate impacts of truck pollution10 and highlight the urgent need for EPA to rigorously consider the health and equity benefits of more protective standards. [EPA-HQ-OAR-2022-0985-1644-A1, p. 10]

Organization: Environmental Protection Network (EPN)

The proposed standards would reduce air pollution near roads. Near-roadway communities are often low income or communities of color, and children who attend school near major roads are disproportionately represented by children of color and children from low-income households. These populations would benefit most directly from the projected emission reductions. Reducing these emissions would also provide cleaner air for communities across the country, prevent health issues like asthma, and ultimately save money, lives, and trips to the hospital. [EPA-HQ-OAR-2022-0985-1523-A1, p. 2]

Organization: GreenLatinos et al.

Evidence makes clear how instrumental the swift adoption of stringent HDV and L/MDV standards are for the future of Latino/e communities. The 2023 American Lung Association State of the Air Report finds that more than one-third (36%) of people in the U.S. live in areas with failing grades for ozone or particulate pollution. This is concerning, especially considering the same report found that people of color are 3.7 times more likely than white people to live in a county with failing national air quality standards, putting our communities at even greater risk to severe health impacts and premature death. [EPA-HQ-OAR-2022-0985-2665-A1, p. 1]

Pollution from vehicles makes us sick and kills us. The data shows this over and over again. We need long-term protective regulation now.

For example, Latino/e children are three times more likely than white children to live in counties with low air quality. About 10% of Latino/e children suffer from asthma, and Latino/e children are 40% more likely to die from asthma than non-Latino white children. These disparities have only increased over time relative to the air quality standards set by the U.S. EPA. [EPA-HQ-OAR-2022-0985-2665-A1, p. 2]

Transportation is the largest source of pollution that fuels the climate crisis in the US. Latino/e communities disproportionately suffer harm from tailpipe emissions. While Latino/es are less likely to have access to a car and Latino/e workers commute by public transit nearly three times the rate of white commuters, our community can face up to 75% higher rates of exposure to harmful pollutants. [EPA-HQ-OAR-2022-0985-2665-A1, p. 2]

Today, we are at a critical nexus for clean transportation policy: We must drastically and permanently reduce air pollution from vehicles and transform our transportation landscape.

It is critical that the Biden administration pass regulations to reduce vehicle pollution and accelerate the shift to EVs. This action is crucial to achieving environmental justice. By implementing stringent HDV and L/MDV standards, the U.S. EPA will act on the Biden Administration's stated commitment to environmental justice, which the White House reaffirmed in April 2023 with a new Executive Order, Revitalizing Our Nation's Commitment to Environmental Justice for All. [EPA-HQ-OAR-2022-0985-2665-A1, p. 2]

The Biden administration's leadership in setting strong HDV and L/MDV standards is instrumental to mitigate the inequitable tailpipe pollution experienced by Latino/e and other frontline communities, which triggers asthma and other sometimes fatal respiratory illnesses. [EPA-HQ-OAR-2022-0985-2665-A1, p. 2]

Organization: Lion Electric, Co. USA

There is $485 billion in health and environmental benefits if there is a MHDV transition by 2040 HD_ZEV_White_Paper.pdf (edf.org), with underserved communities impacted the most by poor air quality. Implementing stringent heavy-duty GHG standards that encourage electrification will help eliminate harmful impacts from emissions on these communities. [EPA-HQ-OAR-2022-0985-1506-A1, p. 2]

As noted by research, disadvantaged students are particularly vulnerable to the impacts of diesel pollution: 70% of all children from low-income families take the bus to school, compared to 50% of children from families with higher incomes. The $150 Billion Road Electric School Buses Can Ride To Create American Jobs And Protect Kids' Health (forbes.com). [EPA-HQ-OAR-2022-0985-1506-A1, p. 2]

Organization: Moving Forward Network (MFN) et al.

Heavy-duty vehicles generate 25% of the total global warming emissions from the transportation sector in the entire country — outsized emissions contribute to the sector that's already contributing the largest share of global warming emissions. 12 In 2020, heavy-duty vehicles represented approximately 6% of the on-road fleet but generated 59% of ozone- and particle-forming NOx emissions and 55% of the particle pollution (including brake and tire particles). 13 With the e-commerce industry rapidly expanding, the US is seeing increases in the overall emissions of the sector. 14 Most heavy-duty trucks on the road today are powered by diesel engines, the exhaust from which poses a direct threat to human health and the environment. Diesel engines emit a mixture of pollutants, including NOx, VOCs, and PM2.5, all of which have been directly linked to severe health consequences, including neurological, cardiovascular, respiratory, reproductive, and/or immune system damage. 15 [EPA-HQ-OAR-2022-0985-1608-A1, p. 10-11]

Heavy-duty trucking contributes massively to the air pollution being inhaled across the country. Nearly 36% of Americans—119.6 million people—still live in places with failing grades for unhealthy levels of ozone or particle pollution. 16 Despite improvements from previous years, the number of people living in counties with failing grades for daily spikes in deadly particle pollution was 63.7 million, the most ever reported under the current national standard. 17

It is well understood that diesel exhaust is "carcinogenic to humans," as determined by the World Health Organization, and leads to tens of thousands of premature deaths each year. 18 Diesel exhaust contains smog precursors, fine particulate matter—which can be inhaled and lodged in the lungs—and more than 40 known cancer-causing compounds. 19 Exposure to pollution from diesel-powered vehicles has also been linked to low birth rate, premature birth, lower IQ, diabetes, stroke, congestive heart failure, heart disease, obesity, asthma, and allergies. 20 [EPA-HQ-OAR-2022-0985-1608-A1, p. 11]

Diesel exhaust particle exposure during pregnancy promotes development of asthma and atopy. The Journal of Allergy and Clinical Immunology. Vol. 134, issue 1. p. 73-74, doi: 10.1016/j.jaci.2014.04.002.

In the context of the freight system in the United States, the facilities, corridors, and neighborhoods that are most heavily trafficked by heavy-duty trucks are often located in communities of color that are experiencing cumulative impacts from multiple sources of pollution and compounding socioeconomic factors. This pattern of development is the result of racist redlining practices that have systematically burdened people of color with disproportionate exposure to pollution. [EPA-HQ-OAR-2022-0985-1608-A1, p. 12]

Although people of color are 41% of the overall population of the U.S., they are 54% of the nearly 120 million people living in counties with at least one failing grade. 21 A person's zip code remains the most significant predictor of health and well-being. In fact, low-income neighborhoods and communities of color breathe an average of 28% more NOx pollution than higher-income and majority white neighborhoods. 22 For residents of environmental justice communities, this means that their lives can be 10 to 20 years shorter because of environmental pollution compared to residents in wealthy white communities. 23 In the counties with the worst air quality, 72% of the 18 million residents are people of color, compared to the 28% who are white. 24 In Kansas City, MO, neighborhoods East of Troost are above the 90th percentile for respiratory health disease. The Kansas City, Missouri, public health data demonstrates that the life expectancy difference is between 15 and 18 years. According to the CDC, neighborhoods like Armourdale and Argentine in Kansas City, Kansas, have a shorter life expectancy of 22 years. 25 Kansas City, like many other parts of the nation, experiences high-risk zip codes where asthma, heart disease, and cancer are above the national average and are the same areas sliced by highways, rail systems in the nation, and neighbors to chemical facilities. People who live near freight hubs or "diesel death zones"—including ports, highways, warehouses, and rail and intermodal yards—are disproportionately exposed to high concentrations of pollution from the combined activity of diesel-fueled heavy-duty trucks, equipment, rail, and vessels. Diesel exhaust contains carcinogens and toxic air pollutants that significantly affect the health of communities living in close proximity to truck tailpipe pollution. Additionally, as many as 40 percent of U.S. ports and many other freight facilities are in areas that are not achieving federal clean air standards for ozone and particulate matter pollution, and freight operations have been identified as significant contributors to nonattainment issues. 26 [EPA-HQ-OAR-2022-0985-1608-A1, p. 13]

The COVID-19 pandemic has escalated the negative consequences of living in a “diesel death zone” or a region with poor air quality. Numerous studies now show that long-term exposure to air pollution makes people more vulnerable to complications and death from COVID-19. 31 That neighborhoods with high proportions of Black and Latinx residents experience disproportionately high levels of air pollution may help explain why these groups have suffered disproportionately from the COVID-19 pandemic. 32 Indeed, one study found that Los Angeles neighborhoods with the worst air pollution have experienced a 60 percent increase in mortality from COVID-19 compared to Los Angeles neighborhoods with the best air quality. 33 COVID-19 infections have been known to be more severe for people who are already diagnosed with asthma. A study from Harvard University found that a small increase in long-term exposure to PM2.5 leads to a large increase in the COVID-19 death rate. 34 One of the reasons that BIPOC communities are dying at higher rates from COVID-19 is because of underlying health conditions like diabetes, heart disease, and asthma, all of which are diseases that are more prevalent for communities of color and low-income communities and are also linked to the disproportionately high levels of air pollution in these communities. Many studies have demonstrated the importance of race as a component of cumulative impacts, and the science behind this field is growing. 35 For example, a study released in March 2022 examined the link between port-related traffic and hospital visits for respiratory, heart-related, and psychiatric issues and concluded that people of color are more vulnerable to health impacts as a result of increased goods movement operations. 36 Adding just one vessel or increasing overall vessel tonnage in a nearby port leads to more than three additional hospital visits per year per thousand Black residents, compared to about one visit per thousand for white residents in the same area. 37 Relatedly, the study also found that reducing fossil fuel use in ports would significantly reduce air pollution concentration and have an acute and positive benefit to local Black residents. MFN, its members, and allied organizations have published and contributed to numerous reports highlighting the cumulative impacts of freight transportation on frontline communities and workers. These reports include:

- MFN's May 2021 report, Making the Case for Zero-Emission Solutions in Freight: Community Voices for Equity and Environmental Justice provides an overview of the health impacts associated with goods movement and the disproportionate burdens felt by residents that live on the frontlines of polluting ports, warehouses, railyards, and highways, who are largely people of color. 38 The report features frontline voices who are calling for an end to diesel truck pollution and a full transition to zero-emissions. [EPA-HQ-OAR-2022-0985-1608-A1, p. 15]

  38 Moving Forward Network. Making the Case for Zero-Emission Solutions in Freight: Community Voices for Equity and Environmental Justice. (2021). https://www.movingforwardnetwork.com/wp-content/uploads/2021/10/MFN_Making-theCase_Report_May2021.pdf.

- Environmental Racism in the Heartland, Fighting for Equity and Health in Kansas City, a report by MFN members Clean Air Now and Union of Concerned Scientists, exposes how concentrated freight transportation and industrial facilities, and a history of racist redlining practices, have combined to create disproportionate pollution exposures for environmental justice communities living in and around Kansas City. 39 The report discusses community efforts to establish an air monitoring network and recommends policies to advance environmental justice solutions, including a shift to zero-emission trucks. [EPA-HQ-OAR-2022-0985-1608-A1, p. 15-16]

- Newark Community Impacts of Mobile Source Emissions, a community-based participatory research study developed with contributions from the New Jersey Environmental Justice Alliance, members of the Coalition for Healthy Ports including Greenfaith, Ironbound Community Corporation, New Jersey Clean Water Action, and the Natural Resources Defense Council, found that the worst pollution hot spots occurred where freight facilities are concentrated, and along truck routes. 40 The study found that electrifying vehicles can lead to significant local benefits but urged that electrification must coincide with reductions in power plant pollution, as these facilities are often located in the same areas that are disproportionately impacted by freight. [EPA-HQ-OAR-2022-0985-1608-A1, p. 16]

- For Good Jobs & Clean Air, How a Just Transition to Zero Emission Vehicles Can Transform Warehousing, published by Warehouse Workers for Justice, describes the heavy toll that a build-out of warehouse distribution centers is having on Will County, Illinois. The report describes how pollution burdens fall disproportionately on Black and Latinx residents and warehouse workers, who are on the frontlines of truck pollution. 41 The report also provides community air monitoring results, finding unhealthy spikes in PM2.5 pollution. [EPA-HQ-OAR-2022-0985-1608-A1, p. 16]

Organization: RMI

Climate, Health, and Quality of Life Benefits

RMI supports EPA's strong claims about the benefits of combatting heavy-duty emissions. Transportation is the leading source of greenhouse gas emissions in America, and pollution from medium- and heavy-duty trucks is a significant contributor to poor air quality. Disadvantaged communities often house a disproportionate number of trucking facilities and experience higher levels of vehicle related air pollution health risks. E-trucks may begin benefiting urban disadvantaged communities as soon as 2023, since urban and regional trucking is most financially and operationally suited to electrification.24 [EPA-HQ-OAR-2022-0985-1529-A1, p. 9]

24 Kahn et al., The Inflation Reduction Act Will Help Electrify Heavy-Duty Trucking, RMI, August 25, 2022, https://rmi.org/inflation-reduction-act-will-help-electrify-heavy-duty-trucking/

Analysis from the REPEAT Project at Princeton University found the Inflation Reduction Act and Bipartisan Infrastructure Law could save 35,000 premature deaths by 2032 from reduced exposure to fine particulate matter from energy activities, with light-, medium-, and heavy-duty trucks and buses comprising over 50 percent of the cause.25 Strategic truck electrification an impactful environmental justice opportunity. [EPA-HQ-OAR-2022-0985-1529-A1, p. 9]

Organization: Southern Environmental Law Center (SELC)

Exposure to this type of pollution is also an environmental justice issue; "[r]elative to the rest of the population, people of color and those with lower incomes are more likely to live near [] truck routes."43 This is in part due to zoning practices and land use decisions, including in the South, that have consistently sited highways and commercial and industrial facilities that often rely on frequent truck deliveries in communities of color and low wealth areas. In Virginia, for example, diesel pollution hotspots are concentrated around high-traffic corridors such as Interstate 95 and overlap with low wealth communities and communities of color already overburdened by other socioeconomic vulnerabilities.44 [EPA-HQ-OAR-2022-0985-1554-A1, p. 5]

Organization: State of California et al. (2)

Furthermore, environmental justice communities, including tribal communities, are already environmentally overburdened due to greater existing pollution exposure.107 This disadvantage manifests in higher rates of chronic disease, premature death, and other adverse public health outcomes.108 Compounding the problem, residents of environmental justice communities also have less access to health care, as they are less likely to have health insurance and less likely to be able to afford necessary tests and procedures, and local health care facilities are poorly staffed and equipped.109 Consequently, residents of environmental justice communities are less able to withstand climate impacts that further damage their health, such as increased local smog conditions.110 [EPA-HQ-OAR-2022-0985-1588-A1, pp.13-14]

In addition to being more vulnerable to the impacts of climate change, environmental justice communities endure structural disadvantages that blunt their ability to adapt to a changing climate. Environmental justice communities have less access to financial resources, such as income and wealth, which are critical to climate resilience.111 More financial resources equate to more mobility, more ability to spend (on utilities, health care, home adaptation, etc.) to reduce climate harms, and more safeguards (such as insurance) in the event of extreme climate events.112 Environmental justice communities also have higher rates of limited English proficiency, which can reduce access to climate resilience programs and increase vulnerability in extreme climate events due to an inability to understand public health information.113 [EPA-HQ-OAR-2022-0985-1588-A1, p.14]

2. Air Pollutant Emissions from Heavy-Duty Vehicles Disproportionately Impact Environmental Justice Communities

Air pollutant emissions from heavy-duty trucks also disproportionately endanger residents of environmental justice communities by exposing them to harmful air pollution that causes significant health impacts. Heavy-duty trucks concentrate their emissions along transportation corridors and near ports and warehouses.114 Communities located near this infrastructure are disproportionately lower-income and communities of color and typically face industrial pollution cumulatively with truck emissions.115 For example, EPA modeling has shown that race and income are significantly associated with living near truck routes nationally, even when controlling for other factors.116 EPA research has also indicated that people of color are more likely to live within 300 feet of major transportation facilities and go to school within 200 meters of the largest roadways.117 Likewise, a comprehensive study by the South Coast Air Quality Management District—which covers Los Angeles and the Inland Empire, the largest logistics hub nationwide—found that communities located near large warehouses scored far higher on California's environmental justice screening tool, which measures overall pollution and demographic vulnerability.118 That study concluded that, compared to the South Coast basin averages, communities in the South Coast basin near large warehouses had a substantially higher proportion of people of color; were exposed to more diesel particulate matter; had higher rates of asthma, cardiovascular disease, and low birth weights; and had higher poverty and unemployment rates.119 [EPA-HQ-OAR-2022-0985-1588-A1, pp.14-15]
