Considering the factors discussed above, we propose that EPA incorporate into its HD TRUCS analysis the alternative adoption rate schedule set forth in Table 6 below, to ensure that actual customer purchasing behavior is more accurately reflected in the standards adopted in the final rule. In the Company's experience, even customer willingness to adopt a new technology and to install infrastructure to support this new technology may not positively impact actual infrastructure availability, so DTNA does not include infrastructure considerations here; rather, we propose that an additional infrastructure scalar be applied to the adoption rate percentages that are ultimately adopted in the Phase 3 final rule, as discussed in Section II.C. [EPA-HQ-OAR-2022-0985-1555-A1, p. 27] [Refer to Table 6 on p.27 of docket number EPA-HQ-OAR-2022-0985-1555-A1]

The Proposed Rule reflects incomplete, inaccurate, and overly optimistic assumptions about ZEV Total Costs of Ownership (TCO). Because EPA's assumptions regarding TCO and calculated payback period appear to be incomplete, inaccurate, and overly optimistic, it is questionable whether fleets will in fact adopt ZEV technologies at the rates that EPA suggests. In this section, DTNA addresses some of the cost inputs in the HD TRUCS tool based upon the Company's own data and advises on additional costs that should be included. DTNA shares EPA's optimism that some costs will fall as technologies develop, but the Company believes that all of the costs EPA uses to inform payback periods and adoption rates relied on for Phase 3 standard-setting should be updated every two years based on the best available market data from OEMs and other sources. [EPA-HQ-OAR-2022-0985-1555-A1, p. 28]

EPA's cost estimates inaccurately reflect or fail to account for a number of key inputs. [EPA-HQ-OAR-2022-0985-1555-A1, p. 28]

Component Costs

EPA's projected pack-level battery costs of $145/kWh in MY 2027, falling to $111/kWh in MY 2032,53 do not appear to accurately reflect the actual cost of battery components. DTNA's battery cost targets for two different pack sizes are shown in Table 7 below. These targets are subject to change, based on raw material and other factors between now and start of production. In the Company's experience, smaller pack sizes are more expensive on a dollars per kilowatt-hour basis, as the cost of manufacturing the non-cell components are spread across a lower energy density. [EPA-HQ-OAR-2022-0985-1555-A1, p. 28] [Refer to Table 7 on p. 28 of docket number EPA-HQ-OAR-2022-0985-1555-A1]

53 See Proposed Rule, 88 Fed. Reg. at 25,981 (Table II-11).

In battery pack manufacturing, a significant portion of the cost is derived from raw materials, which are subject to global price elasticity. Lithium prices over the last two years are shown in Figure 1 below. In 2022, the price of lithium spiked to approximately $85 per kilogram, compared to approximately $30 per kilogram a year previously. [EPA-HQ-OAR-2022-0985-1555-A1, p. 28] [Refer to Figure 1 on p. 29 of docket number EPA-HQ-OAR-2022-0985-1555-A1]

The 2022 price spike likely occurred due to increased demand for lithium and supply pressures brought on by the COVID-19 pandemic. The Company is optimistic that lithium prices will continue to fall and normalize, but battery costs will remain sensitive to raw material prices and may not decrease year-over-year as EPA projects. Table 8 below shows the Company's projected battery costs if lithium were sourced at the peak $85/kg to serve medium- and heavy-duty truck needs. [EPA-HQ-OAR-2022-0985-1555-A1, p. 29] [Refer to Table 8 on p. 29 of docket number EPA-HQ-OAR-2022-0985-1555-A1]

EPA's battery cost estimates rely on assumptions about raw materials and critical minerals, the development of complex supply chains, projected future domestic mining and production, and global trade and geopolitics. EPA does not, however, account for the possibility that mineral costs could rise in the future, as global demand for BEVs increases. It is only appropriate that EPA periodically reassess the battery costs used in the HD TRUCS model to inform the payback period analysis. [EPA-HQ-OAR-2022-0985-1555-A1, p. 29]

EPA Request for Comment, Request #14: We request comment on our assessment and data to support our assessment of battery critical raw materials and battery production for the final rule.

- DTNA Response: As discussed in Section II.B.3.a of these comments, EPA has not adequately considered battery cost sensitivity to raw material pricing, and these costs should be periodically reviewed. [EPA-HQ-OAR-2022-0985-1555-A1, p. 160]

EPA Request for Comment, Request #32: We request comment, including additional data, on our analysis for consideration in the final rule regarding current and projected BEV component costs.

- DTNA Response: See DTNA Response to Request # 20, above. [EPA-HQ-OAR-2022-0985-1555-A1, p. 163]

EPA Request for Comment, Request #33: We request comment, including data, on our approach and projections for battery pack costs for the heavy-duty sector, including values that specifically incorporate the potential impacts of the IRA.

- DTNA Response: See DTNA Response to Request # 20, above. In addition, DTNA is willing to confidentially share battery cost targets with EPA, as its costs are higher than EPA's projections. [EPA-HQ-OAR-2022-0985-1555-A1, p. 163]

Organization: Environmental Defense Fund (EDF)

c) Key EPA assumptions related to ZEV costs and deployment are overly conservative and when corrected, support more protective standards

i. EPA's ZEV technology and adoption modeling assumptions are too conservative

EPA's ZEV assumptions are too conservative and more reasonable assumptions would result in higher ZEV deployment projections, especially in key categories. [EPA-HQ-OAR-2022-0985-1644-A1, p. 53]

EPA is overestimating battery prices. In 2030, EPA assumes batteries without the IRA production tax credits will cost $120/kWh falling to $111/kWh by 2032. In their recent report on tractors, Roush projects that absent IRA credits HDV batteries will cost $98/kWh in 2030 and $88/kWh in 2032.131 Batteries make up the bulk of the powertrain costs for BEVs. As a result, if EPA were to adjust the battery costs used in this proposal, it would have a significant impact on BEV price, payback period, and the final rule stringency. [EPA-HQ-OAR-2022-0985-1644-A1, p. 53-54]

131 Roush conducted their study in 2022$. The prices presented from their study were deflated by 8% to adjust to 2021$ to be consistent with EPA.

Organization: Moving Forward Network (MFN) et al.

11.2. EPA's forecast of factors related to battery technologies are behind current market and future trends

EPA's forecast of battery cost per unit of battery power output ($/kWh) aligns with the best available knowledge and prediction of the market at this time. However, EPA's forecast of some of the other factors related to battery technologies like specific energy are behind where the market is currently and is trending in the future. These inputs can therefore cause the full cost of a heavy-duty BEV to be modeled higher than the most likely real-world scenarios. Therefore, even though the cost per kWh input is appropriate, the cost per BEV is likely an overestimate which would have resulted in a lower ZEV penetration rate than is actually technologically and economically feasible even under EPA's approach. [EPA-HQ-OAR-2022-0985-1608-A1, p. 104]

11.1.3. Modeled heavy-duty BEV costs could potentially decrease based on battery-related modeling inputs

EPA's HD TRUCS tool modeling and subsequent cost-benefit analysis for comparison to the No Action case are thorough, but likely overestimate the battery cost per heavy-duty BEV due to conservative technical assumptions made about the advancements of lithium-ion batteries that would replace materials, increase specific energy, or allow for the longer use of batteries through refurbishment or reuse. Therefore, the heavy-duty BEV sales forecasted through the HD TRUCS tool may be an underestimate if these assumptions had a significant impact on the total cost of ownership of BEVs. Additionally, although the mineral demand forecasts from Li-Bridge and other materials cited in the Proposed Rule's discussion of mineral demand are not directly related to HD TRUCS and EPA's cost analysis, the variables discussed below can also cause mineral demand forecasts to be higher than actual future material demand. [EPA-HQ-OAR-2022-0985-1608-A1, p. 92]

11.1.4. Battery costs per kWh will continue to decrease.

In its model, EPA uses an average HD battery cost (2021$/kWh at the pack-level) based on a literature review by ICCT as the input in the HD TRUCS model. 225 EPA also notes that according to BloombergNEF, global average pack prices were expected to reach $100/kWh by 2026 as the price increase in 2022 due to mineral price volatility will be resolved within a couple of years. We believe these costs are an appropriate representation of the market. Our own analysis, based on data available to BloombergNEF subscribers in their 2022 Lithium-ion Battery Price Survey, yields numbers just slightly below the costs EPA uses in its modeling as shown in Table 13 and Figure 29 below. [EPA-HQ-OAR-2022-0985-1608-A1, pp. 102 - 103.] [See Table 13 ICCT's Average Battery Costs used by EPA and Alternate Cost Forecast, and Figure 30, ICCT's Average Battery Cost Used by EPA is Similar to An Alternative Cost Forecast located on p. 103 of docket number EPA-HQ-OAR-2022-0985-1608-A1.]

Table 13: ICCT's Average Battery Costs used by EPA and Alternate Cost Forecast[226]

Pack-Level Cost Comparison (2021$/kWh)						
	MY 2027	MY 2028	MY 2029	MY 2030	MY 3031	MY 2032
Cost EPA Used in HD TRUCS (Source: ICCT)	$ 145	$ 134	$ 126	$ 120	$ 115	$ 111
Alternate Cost Prediction (Source Data: BloombergNEF)	$ 139	$ 131	$ 123	$ 116	$ 111	$ 105

Organization: PACCAR

II. EPA'S HEAVY DUTY TECHNOLOGY READINESS USE CASE SCENARIO ASSUMPTIONS ARE INACCURATE AND SHOULD BE REVISED

EPA created the Heavy-Duty Technology Readiness Use Case Scenario ("TRUCS") Excel spreadsheet to assess the commercial viability of zero-emission truck technologies. EPA used this detailed analytical tool to calculate HD vehicle energy usage, estimate overall vehicle costs, and forecast ZEV adoption rates. The proposed Phase 3 GHG reduction targets and standards result directly from EPA's TRUCS analysis. Any TRUCS input value variation, therefore, directly and substantially affects the defensibility and technical feasibility of the proposed Phase 3 standards. [EPA-HQ-OAR-2022-0985-1607-A1, p. 4]

Although EPA relied on surveys, research studies, and publicly available data to develop TRUCS input data, the data and the assumptions upon which EPA relied do not align with real-world OEM information. Such real-world information – much of which is confidential business information and includes component costs, efficiency, and performance targets – renders many TRUCS input values overly optimistic and leads to artificially inflated ZEV adoption rate estimates. PACCAR therefore respectfully requests that EPA revise its TRUCS analysis to include more accurate data to recalculate more precisely the predicted adoption rates, and to set the Phase 3 standards according to those revised values. [EPA-HQ-OAR-2022-0985-1607-A1, p. 4]

A. EPA SIGNIFICANTLY UNDERESTIMATES BATTERY COSTS

PACCAR's forecasted battery costs are significantly higher than those in TRUCS, even with certain strategic initiatives in place that PACCAR expects will generate lower battery costs than most competing OEMs. Table 1 below compares TRUCS assumed battery costs used to develop proposed Phase 3 standards with PACCAR's current Confidential Business Information MY2027-2032 battery cost forecast. [EPA-HQ-OAR-2022-0985-1607-A1, p. 5]

Organization: Tesla, Inc. (Tesla)

Battery Costs Continue to Decline

EPA's proposed rule also addresses battery costs as a factor in the rate of heavy-duty fleet adoption.130 The agency assumes the battery pack manufacturing costs for the Phase 3 GHG regulations will be at $111/kWh in MY 2032.131 Tesla believes this cost assumption is far too high and does not fully consider the documented and projected rapid decline in battery cell and pack costs. As DOE has recently documented, the energy density of lithium-ion batteries Increased by more than eight times between 2008 and 2020, allowing for BEVs to travel the same distance with a smaller battery pack, thus saving space, weight, and manufacturing costs.132 Similarly, DOE has found that BEV battery pack cost dropped 90% since 2008.133 [EPA-HQ-OAR-2022-0985-1505-A1, p. 18]

130 88 Fed. Reg. at 25980-81.

131 Id. at 25981.

132 DOE VTO, FOTW #1234, April 18, 2022: Volumetric Energy Density of Lithium-ion Batteries Increased by More than Eight Times Between 2008 and 2020 (Apr. 18, 2022). available at https://www.energy.gov/eere/vehicles/articles/fotw-1234-april-18-2022-volumetric-energy-density-lithium-ion-batteries

133 DOE, FOTW #1272, January 9, 2023: Electric Vehicle Battery Pack Costs in 2022 Are Nearly 90% Lower than in 2008, according to DOE Estimates (Jan. 9, 2023) available at https://www.energy.gov/eere/vehicles/articles/fotw-1272-january-9-2023-electric-vehicle-battery-pack-costs-2022-are-nearly

To the extent reductions have been profound in the light duty sector, the similarity in battery chemistries will carry over to the medium- and heavy-duty sectors. For example, UBS reports that leading manufacturers are estimated to reach battery pack costs as low as $67/kWh between 2022 and 2024.134 Recently, others have also projected costs significantly lower than EPA's past projections. BNEF's recent estimate is that pack prices go below $100/kWh on a volume-weighted average basis by 2024, hit $58/kWh in 2030,135 and could achieve a volume-weighted average price of $45/kWh in 2035.136 The National Academies of Sciences found high-volume battery pack production would be at costs of $65-80/kWh by 2030137 and DNV-GL has predicted costs declining to $80/kWh in 2025.138 The IPCC recently concluded similarly.139 [EPA-HQ-OAR-2022-0985-1505-A1, pp. 18-19]

139 IPCC, AR 6, Working Group III, Climate Change 2022: Mitigation of Climate Change (date) at 10-32 available at https://report.ipcc.ch/ar6wg3/pdf/IPCC_AR6_WGIII_FinalDraft_FullReport.pdf (For example, according to IEA, battery pack costs could be as low as 80 USD per kWh by 2030 (IEA 2019a). In addition, there are clear trends that now vehicle manufacturers are offering vehicles with bigger batteries, greater driving ranges, higher top speeds, faster acceleration, and all size categories (Nykvist et al. 2019). In 2020 there were over 600,000 11 battery-electric buses and over 31,000 batteryelectric trucks operating globally (IEA 2021a).)

These cost estimates all were projected before the IRA passed Congress. IRA adds a significant new element to battery cost reduction as Section 45X provides domestically manufactured cells and finished batteries a production tax credit of $45/kWh.140 This production tax credit is predicted to cut one-third to one-half off the total cost of any BEV battery with both cells and pack built in the U.S.141 [EPA-HQ-OAR-2022-0985-1505-A1, p. 19]

140 Inflation Reduction Act, P.L. 117-169 (Aug. 16, 2022) at Section 13502.

Finally, the agency's assessment should further recognize the technology forcing created by finalization of the proposed regulations by factoring in battery cost reductions that will likely be seen during the Phase 3 period as well, including LFP applications142 and sodium ion batteries.143 Indeed, battery technologies entering the commercialization phase such as silicon anodes, solid state batteries, and sodium-ion batteries are predicted to improve performance and costs and alter current material supply chains.144 The current regulatory impact statement only makes glancing reference to these technologies and the record is deficient in this respect. 144 BloombergNEF, Electric Vehicle Outlook 2023, Executive Summary (June 8, 2023) at 9 available at https://about.bnef.com/electric-vehicle-outlook/

Heavy-duty BEVs Are Rapidly Approaching, If Not At, Total Cost of Ownership Parity

EPA also solicits greater input on medium- and heavy-duty BEV total cost of ownership (TCO).146Reductions in battery costs are projected to lead to cost parity in many vehicle segments by 2025.147 Some analyses have suggested that parity will occur even earlier.148 Continued and expansive research and development in this sector can be expected to further drive down costs.149 Consistent with these declines, other key subsystems of BEV technology will continue to see cost reductions as manufacturers scale production.150 [EPA-HQ-OAR-2022-0985-1505-A1, p. 20]

149 See generally, Energy & Environment Sciences, Determinants of lithium-ion battery technology cost decline (Jan. 3, 2022) available at https://pubs.rsc.org/en/content/articlelanding/2021/ee/d1ee01313k

150 See generally, ICCT, A Meta-Study of Purchase Costs for Zero-Emission Trucks (Feb. 17, 2022) available at https://theicct.org/publication/purchase-cost-ze-trucks-feb22/ (Finding, inter alia, by 2030 key subsystems can achieve up to 40% to 60% cost reduction driven by technology and manufacturing scalability).

A recent ICCT analysis found that battery costs for zero-emission trucks are expected to halve by 2030 compared to 2022, reaching $120/kWh at the pack level with electric drive systems—including the transmission, motor, and inverter— forecasted to see cost reductions of over 60% by 2030, reaching $23/kW.151 Such reductions find upfront cost parity between battery electric trucks and their diesel counterparts achieved in the late 2020s.152 [EPA-HQ-OAR-2022-0985-1505-A1, p. 20]

151 ICCT, Purchase Costs of Zero-Emission Trucks In The United States To Meet Future Phase 3 GHG Standards (March 2, 2023) available at https://theicct.org/publication/cost-zero-emission-trucks-us-phase-3-mar23/

152 Id.

A reduction down to $120kWh per pack plus drivetrain would likely reduce BEVs well below cost parity. Indeed, a recent LBNL study found that recent reductions in battery prices and improvement in energy density have made long haul electric trucking viable in the near term.153 More directly, the study concluded: 'At the current global average battery pack price of $135 per kilowatt-hour (kWh) (realizable when procured at scale), a Class 8 electric truck with 375-mile range and operated 300 miles per day when compared to a diesel truck offers about 13% lower total cost of ownership (TCO) per mile, about 3-year payback and net present savings of about US $200,000 over a 15-year lifetime. This is achieved with only a 3% reduction in payload capacity.'154 [EPA-HQ-OAR-2022-0985-1505-A1, pp. 20-21]

153 LBNL, Why Regional and Long-Haul Trucks are Primed for Electrification Now (Mar. 15, 2021) available at https://etapublications.lbl.gov/publications/why-regional-and-long-haul-trucks-are

154 Id.

Still other recent assessments of the total cost of ownership indicate that EPA stands on firm ground to strengthen the stringency in the rule. Indeed, some OEMs predict BEV cost parity in 2025 well ahead of the proposed rule's 2027 implementation date. Further numerous studies have found that heavy-duty BEVs outperform conventional trucks on a total cost of ownership basis.155 Tesla projects that its Semi will have energy costs that are half those of diesel, provide over $200,000 in fuel savings, and have a two-year payback period.156 Another manufacturer has found that BEVs could save fleets up to 80% on energy costs and 60% on repair.157 Yet another found that the benefits of electrifying heavy-duty truck fleets are significant with recent studies showing that operating costs for electric trucks can be between 14 and 52 percent lower and repair costs around 40 percent lower than their combustion-powered counterparts.158 CARB has found that battery-electric vehicles appear cost competitive with the established combustion technologies by 2025 in many use cases.159 Real world demonstrations have also proven this out.160 [EPA-HQ-OAR-2022-0985-1505-A1, p. 21]

155 See e.g., UC Berkley, 2035 Report: Transportation: Plummeting Costs and Dramatic Improvements in Batteries Can Accelerate Our Clean Transportation Future (April 2021) at 15 available at https://www.2035report.com/transportation/transportation-new/wpcontent/uploads/2020/05/2035_Transportation_Report.pdf?hsCtaTracking=544e8e73-752a-40ee-b3a5-90e28d5f2e18%7C81c0077a-d01d-45b9-a338-fcaef78a20e7 (finding BEV heavy-duty trucks already hold a TCO advantage today and, for heavy-duty trucks, an EV advantage of $0.05/mi in 2020 that increases to $0.22/mi in 2030—magnified by the large number of miles traveled by this class of vehicles. In absolute terms, in 2020 this translates to a $42,800 TCO advantage of electric heavy-duty trucks, which increases to $200,000 in 2030. The TCO advantage of EVs continues to grow through 2050).

Recently, the IEA has concluded, 'In the regions where electric trucks are becoming commercially available, battery electric trucks can compete on a TCO basis with conventional diesel trucks for a growing range of operations, not only urban and regional, but also in the heavy-duty tractor-trailer regional and long-haul segments.'161 Similarly, new analysis looking at the IRA's incentive have medium-duty TCO parity expect in 2024 with the heavy-duty sector to follow in the middle of the decade.162 [EPA-HQ-OAR-2022-0985-1505-A1, pp. 21-22]

In short, BEVs offer the best compliance technology near term and dramatically decreasing battery costs and numerous TCO studies further support emission standards leading to BEV deployment at levels surpassing those proposed by the agency. [EPA-HQ-OAR-2022-0985-1505-A1, p. 22]

Organization: Truck and Engine Manufacturers Association (EMA)

b) Revisions

HD TRUCS has close to 100 inputs that are used, and that can be modified, within the tool. Those multiple inputs cover costs, efficiency factors, and performance factors, to mention a few. During our review, EMA identified a subset of these inputs that we prioritized as elements where corrected values - - values different than were used in the NPRM - - need to be utilized. The five (5) prioritized inputs in need of correction and revision are described below. [EPA-HQ-OAR-2022-0985-2668-A1, p. 25]

Battery Pack Cost and Fuel Cell Stack Cost – These two revised inputs were run together as they are the core components of their respective powertrain systems. EMA's recommended 2027 cost of $183/kWh is used for the battery packs, as compared to the NPRM cost of $145/kWh. The fuel cell stack cost is $498/kW, versus $242/kW for the NPRM. The revised projected ZEV adoption rates from running EMA HD TRUCS with these two updated inputs are shown below for 2027 and 2032: [EPA-HQ-OAR-2022-0985-2668-A1, p. 35.] [See the Projected ZEV Adoption Rates for 2027 and 2032 Table on page 34 of docket number EPA-HQ-OAR-2022-0985-2668-A1.]

Battery Pack Cost ($/kWh) – The HD TRUCS tool utilizes a cost of $138 per kilowatt-hour (kWh) (2019$) for the cost of a battery pack. That cost comes from a February 2022 paper published by ICCT. Within HD TRUCS, an adjustment factor is applied to this cost, which is in 2019 dollars, to bring it up to 2021 dollars, which adjusted cost is used in preparing the NPRM. This results in an assumed battery pack cost of $145/kWh. [EPA-HQ-OAR-2022-0985-2668-A1, p. 25]

OEMs, all of which have one or more BEV powertrains in production, provided EMA with their December 2022 cost for battery packs, along with the cost from approximately June 2022. The December 2022 average cost was $270/kWh hour, nearly double the cost estimated by ICCT. National labs and third-party expert consultants have consistently estimated that battery costs would fall substantially from 2019 through 2040. But, in fact, those costs have increased recently, rising from an average of $233 in June 2022, to $270 in December 2022. The critical elements for battery manufacturing have been in short supply, driving up prices. The pressure on the supply chain from LD ZEV growth, especially the volume increases from the growing regulatory mandates for more and more ZEVs, will continue to create supply and cost issues for the significantly smaller MHD market. Thus, the projections of falling costs are not accurate. [EPA-HQ-OAR-2022-0985-2668-A1, p. 25]

OEMs also provided future battery pack costs based on contracts, pending projects, and active development programs. The average cost for 2027 production is $183. Although notably reduced from current costs, this is still a 26% increase to the value used in the NPRM, making the $183/kWh a more appropriate value for use in the EPA version of HD TRUCS. Accordingly, EMA uses that value ($183/kWh) in the EMA HD TRUCS tool. [EPA-HQ-OAR-2022-0985-2668-A1, pp. 25 - 26]

Organization: Valero Energy Corporation

Similarly, EPA cites to another ICCT study in support of the proposition that "[p]rojected costs [of HD ZEVs] are expected to decrease as manufacturing matures and materials improve."25 However, EPA fails to disclose that the ICCT study is simply based upon a review of recent literature, and caveats that it is predicated on "a dearth of publicly available data about the costs of battery-electric and hydrogen fuel cell trucks, as well as the cost breakdowns for the various systems in these vehicles."26 EPA further provides that it "considered this source to be a comprehensive review of the literature at the time of the HD TRUCS analysis for the cost of battery packs in the absence of the IRA".27 Based on a review of EPA's underlying source material, however, EPA's analysis and proposal is inconsistent and incomplete. [EPA-HQ-OAR-2022-0985-1566-A2, p. 6]

25 EPA's HD Phase 3 GHG Proposal at 25941 (citing to Sharpe, Ben and Hussein Basma. "A Meta-Study of Purchase Costs for Zero-Emission Trucks". The International Council on Clean Transportation. February 2022).

26 Sharpe, Ben and Hussein Basma. "A Meta-Study of Purchase Costs for Zero-Emission Trucks". The International Council on Clean Transportation. February 2022. https://theicct.org/publication/purchase-cost-ze-trucks-feb22/

27 EPA's HD Phase 3 GHG Proposal at 25980-81.

EPA is at a distinct advantage relative to general public commenters in that it has the ability to seek out reliable data and is obligated to provide such. For example, in the recently proposed Renewable Fuel Standard "Set Rule," EPA provided citations to various peer reviewed studies that demonstrated the work of researchers over the decades that the Renewable Fuel Standard has been administered by the EPA. Likewise, EPA has been issuing rules regulating emissions from heavy duty vehicles since 198528 and as the following examples show, EPA has instead chosen to rely on incomplete source material from third parties. [EPA-HQ-OAR-2022-0985-1566-A2, p. 6]

The proposal states that "BloombergNEF presents battery prices that would reach $100 per kWh in 2026."29 But EPA fails to disclose that BloombergNEF also identifies factors that may increase prices:

- “[T]he impact of rising commodity prices and increased costs for key materials such as electrolytes has put pressure on the industry in the second half of the year.”
- “[E]ven low-cost chemistries like [lithium iron phosphate] LFP, which is particularly exposed to lithium carbonate prices, have felt the bite of rising costs throughout the supply chain. Since September [2021], Chinese producers have raised LFP prices by between 10-20%.”
- “Kwasi Ampofo, head of metals and mining at BloombergNEF [has] said: ‘Prices for lithium have risen substantially this year as a result of constraints within global supply chains, rising demand in China and Europe and the recent production curbs in China.’” 30 [EPA-HQ-OAR-2022-0985-1566-A2, pp. 6 - 7]

29 EPA’s HD Phase 3 GHG Proposal at 25980 (citing to Bloomberg NEF. ‘‘Battery Pack Prices Fall to an Average of $132/kWh, But Rising Commodity Prices Start to Bite.’’ November 30, 2021. https://about.bnef.com/blog/battery-pack-prices-fall-to-an-average-of-132-kwh-but-rising-commodity-prices-start-to-bite/).

30 Bloomberg NEF. ‘‘Battery Pack Prices Fall to an Average of $132/kWh, But Rising Commodity Prices Start to Bite.’’ November 30, 2021. https://about.bnef.com/blog/battery-pack-prices-fall-to-an-average-of-132-kwh-but-rising-commodity-prices-start-to-bite/.

EPA’s analysis selectively ignores price volatility in the lithium and battery materials market and national security concerns inherent in these statements and exacerbated by the proposed HD Phase 3 GHG rule. EPA also cites to several sources that warn of rising battery costs, yet EPA does not adequately consider these realities in its analysis. For example, EPA cites to a Bloomberg New Energy Finance (BNEF) blog post for the proposition that “recent information indicates that the [lithium] market is responding robustly to demand”.31 Yet the BNEF source, titled “Lithium-ion Battery Pack Prices Rise for First Time to an Average of $151/kWh,”32 warns that:

“Rising raw material and battery component prices and soaring inflation have led to the first ever increase in lithium-ion battery pack prices since BloombergNEF (BNEF) began tracking the market in 2010. After more than a decade of declines, volume-weighted average prices for lithium-ion battery packs across all sectors [] increased to $151/kWh in 2022, a 7% rise from last year in real terms. The upward cost pressure on batteries outpaced the higher adoption of lower cost chemistries like lithium iron phosphate (LFP). BloombergNEF expects prices to stay at similar levels next year, further defying historical trends.” [EPA-HQ-OAR-2022-0985-1566-A2, p. 7]

31 EPA’s HD Phase 3 GHG Proposal at 25965.

32 Bloomberg New Energy Finance, “Lithium-ion Battery Pack Prices Rise for First Time to an Average of $151/kWh,” December 6, 2022. https://about.bnef.com/blog/lithium-ion-battery-pack-prices-rise-for-first-time-to-an-average-of-151-kwh/.

Further, Kwasi Ampofo, head of metals and mining at BloombergNEF, is quoted as saying: “[l]ithium prices remain high due to persistent supply chain constraints and the slow ramp up in new production capacity.33 [EPA-HQ-OAR-2022-0985-1566-A2, p. 7]

33 Bloomberg New Energy Finance, “Lithium-ion Battery Pack Prices Rise for First Time to an Average of $151/kWh,” December 6, 2022. https://about.bnef.com/blog/lithium-ion-battery-pack-prices-rise-for-first-time-to-an-average-of-151-kwh/.

EPA also claims that "[d]espite recent short-term fluctuations in price, the price of lithium is expected to stabilize at or near its historical levels by the mid-to-late 2020s."34 However, one of EPA's sources on this point is an article covering a Chinese study, which contains analysis specific to the Chinese spot market for lithium, which is inconsistent with the express intent of the IRA.35 For the abovementioned reasons, EPA misrelies on its authorities and must revise the proposal after giving due consideration to the data regarding HD ZEV costs. [EPA-HQ-OAR-2022-0985-1566-A2, p. 7]

34 EPA's HD Phase 3 GHG Proposal at 25966.

Organization: Volvo Group

Phase 3 Proposed Stringencies

- Costs are too low based on current data and internally anticipated cost reductions, especially for batteries.

EPA Summary and Response

Summary:

A number of commenters provided cost estimates for the high voltage battery; these comments are from both industry and NGO groups. EMA shared values they believe are appropriate for battery packs during the time frame of the rule, based on future contracts which are higher than EPA's estimate. EMA recommends that EPA use a figure roughly 26% greater than estimated at proposal. PACCAR, Stellantis, and DTNA provided battery cost projections to the Agency which were submitted under claims of Confidential Business Information. DTNA also commented that EPA should consider all available data including that which can be provided by manufacturers in confidential settings, and asserted that, given data available today is limited, EPA should re-evaluate its assumptions on this issue on a regular basis, using the best available data.

Valero Energy questioned EPA's reliance on the ICCT Working Paper 2022-09 value for battery pack cost given ICCT's caution about uncertainty within the market for this sector. The commenter further maintains that the ICCT Paper did not adequately explain or cite empirical support for averaging of the values, and that instead upper and lower bounds should be adopted for HD TRUCS cost inputs.

Although some commenters believe the battery costs used for the NPRM are too low, others believe the battery costs used are too high; these commenters include CATF, EDF, MFN and Tesla. CATF cited a plethora of sources that all indicated a decrease in battery costs in previous years and in future years. Their sources provided costs as low as $59-68/kWh in 2027. EDF referenced a Roush report of HDV battery cost of $98/kWh in 2030 and $88/kWh in 2032 without IRA adjustment. MFN believes the battery used for HDV will be less conservative than the one modeled by EPA in terms of both specific energy and energy density, this conservativeness is reflected in EPA's estimates of battery costs. The commenter's estimates align with BNEF where battery cost will decline to $100/kWh by 2026 as a result of mineral price stabilization. Tesla referenced an ICCT report where batteries would reach a cost of $120/kWh at the pack level by 2030.

The Clean Fuels Development Coalition, et. al., took exception to EPA applying "both the IRA battery tax credit and vehicle tax credit" to consumer costs on the basis that industry may not be capable of meeting the domestic sourcing requirement and the costs ultimately being paid by taxpayers.

Response:

Please see Chapter 2.4.3.1 of the RIA for a discussion of the battery costs for the final rule.

Regarding the commenter's concern with the inclusion of the IRA battery and vehicle tax credits from purchaser costs despite the costs being paid by taxpayers, this is the proper approach to estimating purchaser costs which are meant to estimate the costs purchasers will incur upon purchasing a new vehicle. Therefore, those tax credits should reduce the price paid by the purchaser. As we did in the NPRM, we have omitted the tax credits and taxes in our calculation of costs to society (see Section IV.E of the preamble) as these are transfers from taxpayers to purchasers and we present those transfers for full transparency in Section VIII.B of the preamble.

Regarding concerns over industry being capable of meeting the domestic sourcing requirements to realize the IRA tax credits, please refer to our response in Section 2.7 of this document.

Comments on minerals critical to battery production are addressed in Preamble Section II.D.2.ii.c and in Section 17.2 of this document.

EPA has carefully considered information made available to EPA. As further explained in preamble Sections I and II, in setting future emission standards under our CAA section 202(a)(1)-(2) authority, given the prospective nature of the factors Congress directed EPA consider, EPA must necessarily identify potential technologies, evaluate the rate each technology could be introduced, and project associated cost of compliance. Thus, while we acknowledge that future projections inherently are subject to uncertainties, EPA has carefully analyzed the uncertainties and identified the considerations we found persuasive. Consistent with our standard setting authority the analysis EPA conducted for this final rule appropriately makes use of the best data available to us, as described in RIA Chapter 2.

3.4.2 E-Drive

Comments by Organizations

Organization: Daimler Truck North America LLC (DTNA)

EPA's projections for e-Drive costs may also be inaccurate. Table II-12 in the Proposed Rule appears to reflect a combined cost per kilowatt for the eMotor, inverter, and gearbox combination. DTNA's e-Drive cost estimate, which includes EPA's components plus an eAxle, is shown in Table 9 below. EPA should consider the inclusion of an eAxle for some applications, as eAxles increase driveline efficiency by reducing gear losses and can offer the additional needed packaging space in the chassis for other components like battery packs. DTNA recommends that EPA apply eAxle costs to weight-sensitive applications with constrained packaging space, and that the Agency periodically reassess e-Drive cost inputs used in the HD TRUCS tool. [EPA-HQ-OAR-2022-0985-1555-A1, p. 29] [Refer to Table 9 on p. 30 of docket number EPA-HQ-OAR-2022-0985-1555-A1]

EPA Request for Comment, Request #34: We request data on e-axle costs that we could consider for the final rule.

- DTNA Response: See DTNA Response to Request # 20, above. In addition, DTNA is willing to confidentially share e-drive costs with EPA, including an eAxle, and recommends EPA incorporate eAxle costs for at least some population of vehicles. [EPA-HQ-OAR-2022-0985-1555-A1, p. 163]

EPA Request for Comment, Request #35: We welcome comment, including data, on our assessment of e-drive costs.

- DTNA Response: See DTNA Response to Request # 20 and 34, above. [EPA-HQ-OAR-2022-0985-1555-A1, p. 163]

Organization: Dana Incorporated

eDrive Direct Manufacturing Costs

As an eDrive manufacturer, Dana believes that various configurations such as direct-drive, etransmissions, and e-axle will co-exist in the market. Each of these vehicle powertrain configurations has a certain level of manufacturing complexity. Dana believes that the market will demand multi-speed etransmissions and e-axles solutions that will drive higher product as well as manufacturing costs. Therefore, EPA must consider different direct manufacturing cost values for each vehicle powertrain configuration. [EPA-HQ-OAR-2022-0985-1610-A1, p. 5]

Dana also believes using only $1 kW unit may not accurately compare the cost of different powertrain configurations. For instance, a motor with 450 kW of power and 2,500 Nm of torque used as a direct drive would provide 2,500 Nm at the driveshaft, but with the same motor paired with a multi-speed eaxle, it would provide 450 kW but it could provide 28,000 Nm of peak torque, allowing it to be used in a much heavier type of vehicle platform. The cost to achieve 28,000 Nm of peak torque is higher even though $/ kW is the same. This exemplifies the issue of using power only as a cost metric. [EPA-HQ-OAR-2022-0985-1610-A1, p. 5]

Organization: Environmental Defense Fund (EDF)

Additionally, EPA's projection of motor costs are too high. In the same Roush study they project motor and inverter costs will be $8/kW in 2030 and 2032. EPA projects in their proposal these costs will be $16/kW and $15/kW for 2030 and 2032 respectively. [EPA-HQ-OAR-2022-0985-1644-A1, p. 54]

EPA Summary and Response

Summary:

Commenters focused on differing aspects of the e-drive[292] in their comments. Dana and DTNA both commented that there will be various configurations of e-drives for ZEV vehicles, and that EPA should reflect the variety of costs that may occur as a result of using different technologies such as eAxles, and multispeed transmissions. In particular, Dana was concerned that using only $/kW unit may not accurately compare the cost of different powertrain configurations, and DTNA requested that EPA apply eAxle costs to weight-sensitive applications with constrained packaging space. DTNA also commented that EPA should consider all available data including that which can be provided by manufacturers in confidential settings, and asserted that, given data available today is limited, EPA should re-evaluate its assumptions on this issue on a regular basis, using the best available data.

EDF says that the HD TRUCS costs for e-motors are too high, and references Roush reports with e-motor costs of $8/kW for 2030 and 2032, much lower than EPA's e-motor value. DTNA provided CBI values of e-Drive system costs that include the combined eMotor, inverter, gearbox, and eAxle costs and are higher than the e-motor cost used in the NPRM. Tesla cited an ICCT report that projected cost reductions of 60% by 2030 and that the price of electric powertrain systems including the transmission, motor, and inverter would reach $23/kW (see Section 3.4.1 for Tesla Comment).

Response:

In the NPRM, the e-drive system in EPA's HD TRUCS included the electric motor (e-motor), power electronics and electrical accessories, and a driveshaft which can include a transmission system or gearbox. Although EPA used a $/kW cost estimate for e-motors, the gearbox costs are distinguished by application and weight categories that were developed for the Autonomie tool. The e-motor and gearbox cost, together with the power electronics, power accessories, and the final drive costs, sum to create the entire e-drive cost for each vehicle in HD-TRUCS. These costs were not a constant $/kW across all applications. We are retaining this methodology for the final rule as it reflects different e-drive costs for each vehicle in HD TRUCS depending on weight class, duty cycle, and axle configuration. For additional discussion on the components and costs associated with the e-drive system in HD TRUCS, see Chapter 2.4.3.2 of the RIA.

EPA did not estimate different costs for all potential e-drive permutations with emerging technologies. Instead, we relied on the components as described in the BEAN and Autonomie tools, so that we used underlying inputs for various e-drive components that are self-consistent. For example, we recognize that some emerging technologies, like e-axles, have the potential to realize further efficiency gains because they have fewer moving parts. EPA finds that the various configurations considered represent a reasonable approximation of the technology costs of e-drives.

There is no consensus about what is included in e-drive or e-motor costs, and these terms are sometimes used interchangeably. In fact, EPA's proposal included a table (Table II-12) of e-motor costs that were mistakenly labeled as e-drive costs. The other e-drive component costs were described in the surrounding NPRM preamble text, but the caption for Table II-12 may

[292] See Chapter 2.4.3.2.1 of the RIA for description of the HD TRUCS e-drive components and costs.

have led to confusion about whether the entire e-drive costs were all based on a constant $/kW and commenters may have misunderstood the total e-drive costs that are used in HD TRUCS, which are much higher than just the $/kW cost of the e-motor. The final rule includes the correct caption for the e-motor cost table, as shown in preamble Section II.E.1 and RIA Chapter 2.4.3.2, along with the costs for the other e-drive components.

EPA has carefully considered information made available to EPA. As further explained in preamble Sections I and II, in setting future emission standards under our CAA section 202(a)(1)-(2) authority, given the prospective nature of the factors Congress directed EPA consider, EPA must necessarily identify potential technologies, evaluate the rate each technology could be introduced, and project associated cost of compliance. Thus, while we acknowledge that future projections inherently are subject to uncertainties, EPA has carefully analyzed the uncertainties and identified the considerations we found persuasive. Consistent with our standard setting authority the analysis EPA conducted for this final rule appropriately makes use of the best data available to us, as described in RIA Chapter 2.

3.4.3 FC Stack & H2 Tank Costs

Comments by Organizations

Organization: California Air Resources Board (CARB)

4. FCEV Technology Costs

Affected pages: DRIA 185-194

CARB staff finds U.S. EPA's assumptions for component costs to be reasonable given available information and literature projections. CARB staff for the ACF regulation performed a similar analysis which determined the upfront costs of FCEVs through a component cost analysis. As noted by U.S. EPA and ICCT,217 there are a wide range of projections for fuel cell components in the future. U.S. EPA's assumptions appear, generally, to be on the conservative (higher) end of that range. [EPA-HQ-OAR-2022-0985-1591-A1, pp.63-64]

217 ICCT's A meta-study of purchase costs for zero-emission trucks, Working Paper 2022-09, February 2022. https://theicct.org/wp-content/uploads/2022/02/purchase-cost-ze-trucks-feb22-1.pdf

Organization: Daimler Truck North America LLC (DTNA)

FCEVs will likely not see significant availability and uptake until at least 2032, thus accurate cost projections cannot be made at this time. Existing FCEV technologies must be adapted, not simply scaled, to achieve HD performance requirements. EPA's cost estimates for hydrogen tanks may be reasonable for compressed hydrogen given the current market, but in the long-term, liquid hydrogen will be the primary fuel in the HD market to enable the 500 - 600 mile range that achieves comparable range to conventional diesel vehicles today. Gaseous hydrogen occupies too much volume to be carried on board in the required quantities to achieve a 500 - 600 mile range. [EPA-HQ-OAR-2022-0985-1555-A1, p. 30]

As neither liquid hydrogen tanks nor heavy-duty fuel cell stacks are being produced at scale today, DTNA does not have data to assist the Agency in estimating costs. In its April 2023 white paper on TCO for Class 8 alternative powertrain technologies, ICCT estimates 2030 fuel cell costs at $301/kg and hydrogen tank costs at $844/kg, which are notably higher than EPA's HD TRUCS projections of $200/kg and $660/kg respectively.55 These projected major component costs have significant impacts on the payback period calculation, thus they must be regularly reviewed to account for technology and market developments. [EPA-HQ-OAR-2022-0985-1555-A1, p. 30]

> 55 See ICCT, Total Cost of Ownership of Alternative Powertrain Technologies for Class 8 Long-Haul Trucks in the United States (April 2023), https://theicct.org/wp-content/uploads/2023/04/tco-alt-powertrain-long-haul-trucksus- apr23.pdf (ICCT TCO White Paper) at Table 4.

EPA Request for Comment, Request #39: We request comment, including data, on our approach and cost projections for FCEV components

- DTNA Response: EPA should consider all available data including that which can be provided by manufacturers in confidential settings; however, given that the HD ZEV market is currently in a nascent state, any data available today is necessarily limited. DTNA believes HD FCEV technology costs cannot be accurately predicted today. EPA should thus re-evaluate its assumptions on this issue on a regular basis, using the best available data. See Section II.C.2 of DTNA's comments. [EPA-HQ-OAR-2022-0985-1555-A1, p. 164]

EPA Request for Comment, Request #44: We request comment on this approach for both ICE vehicles and ZEVs, in addition to data on battery and fuel stack replacement costs, engine rebuild costs, and expected component lifetime periods.

- DTNA Response: See DTNA Response to Request # 20, above. [EPA-HQ-OAR-2022-0985-1555-A1, p. 165] [Refer to section 2 of this comment summary]

Organization: Dana Incorporated

Fuel Cells

Dana is a component supplier of bipolar plates for fuel-cell and electrolyzer stacks and relies largely on publicly available information or customer shared information as knowledge of fuel cell costs. Given this, it appears that the direct cost of a fuel cell stack noted in the proposed rule is excessively high, if it is referring only to the stack and not to the entire fuel-cell system. For reference, below are some targets set by the European Joint Undertaking (https://www.clean-hydrogen.europa.eu/about-us/keydocuments/strategic-research-and-innovation-agenda en). This reference shows a fuel cell stack cost at less than €100 / kilowatt and a 2030 target of less than €50 / kilowatt versus $200 USD (approx. €185) in 2030. [EPA-HQ-OAR-2022-0985-1610-A1, p. 3.] [See Docket Number EPA-HQ-OAR-2022-0985-1610, page 4, for reference.]

Organization: MEMA

Take-away: Like motorcoach and sleeper applications, liquid fueling (hydrogen) or other renewable fuel capability, provided through publicly available infrastructure would be the best solutions path to address the variable performance demands and extended use these applications. [EPA-HQ-OAR-2022-0985-1570-A1, pp. 18 - 19]

Recommendation: EPA expands the HD TRUCS model feasibility and cost sections to include the preceding applications and fuel sources. [EPA-HQ-OAR-2022-0985-1570-A1, p. 19]

Organization: PACCAR

B. EPA SIGNIFICANTLY UNDERESTIMATES FUEL CELL COSTS

PACCAR is developing and commercializing fuel cell powertrains and has received suppliers' fuel cell stack cost quotes. None of PACCAR's projected costs are as low as the values EPA used in TRUCS. Even the ICCT paper upon which EPA relied to estimate fuel cell stack costs acknowledges there is a great degree of cost uncertainty, e.g., ICCT estimated MY2025 fuel cell costs ranging from $50/kW to $750/kW.2 [EPA-HQ-OAR-2022-0985-1607-A1, p. 5]

2 "A Meta-Study of Purchase Costs for Zero Emissions Trucks" (Sharpe and Basma, 17 Feb. 2022)

ICCT recently published another paper that estimates fuel cell stack costs will be $301/kW in MY2030, which is significantly higher than TRUCS's $200/kW value (see Table 4 below).3 Based on the ICCT analysis, estimated MY2027 fuel cell stack will be $498/kW if linearly interpolating between MY2022 and MY2030, or $365/kW if using EPA's "learning curve" approach, working backwards from the $301/kW value. Considering (i) TRUCS assumes a typical tractor fuel cell power of 200 kW, and (ii) the difference between the ICCT paper MY2030 $301/kW estimate and EPA's assumed $200/kW MY2030 cost, TRUCS underestimates fuel cell cost by approximately $20,100. PACCAR therefore respectfully requests that EPA revise the TRUCS analysis with more accurate fuel cell cost figures. [EPA-HQ-OAR-2022-0985-1607-A1, pp. 5 - 6.] [See table 4 on page 6 of EPA-HQ-OAR-2022-0985-1607-A1.]

3 "Total Cost of Ownership of Alternative Powertrain Technologies for Class 8 Long-Haul Trucks in the United States" (Basma et. al., April 2023)

Organization: Truck and Engine Manufacturers Association (EMA)

Fuel Cell Stack Cost – Fuel cell systems are an emerging technology within the MHD market. As such, there is significant uncertainty regarding the development of MHD fuel cells and their ultimate production costs. For EPA's HD TRUCS model, the Agency chose to rely on the fuel cell cost from an ICCT paper published in February 2022. That 2027 cost is $242 per kilowatt (kW). Significantly, a more recent ICCT paper on ZEV total cost of ownership (TCO), dated April 2023, includes a notably higher cost for the fuel cell stack, estimated at $498 for 2027. That value was determined through a linear interpolation of the ICCT data in Table 9 of the April paper, which noted stack costs of $827 in 2022 and $301 in 2030. [EPA-HQ-OAR-2022-0985-2668-A1, p. 26]

The estimated $498/kW value is consistent with the spread of data that EMA received from OEMs. As such, $498/kW is the value that EMA is using in EMA's version of HD TRUCS. [EPA-HQ-OAR-2022-0985-2668-A1, p. 26]

Battery Pack Cost and Fuel Cell Stack Cost – These two revised inputs were run together as they are the core components of their respective powertrain systems. EMA's recommended 2027 cost of $183/kWh is used for the battery packs, as compared to the NPRM cost of $145/kWh. The fuel cell stack cost is $498/kW, versus $242/kW for the NPRM. The revised projected ZEV adoption rates from running EMA HD TRUCS with these two updated inputs are shown below for 2027 and 2032: [EPA-HQ-OAR-2022-0985-2668-A1, p. 35.] [See the Projected ZEV Adoption Rates for 2027 and 2032 Table on page 34 of docket number EPA-HQ-OAR-2022-0985-2668-A1.]

Organization: Valero Energy Corporation

4. EPA's technological feasibility analysis relies on aspirational projections of EV battery, fuel cell stack and hydrogen fuel tank costs, while failing to discuss the associated uncertainties or probability of success.

EPA relies on a recent ICCT working paper46 for its projections of EV battery, fuel cell stack and hydrogen fuel tank costs over MY 2027-2032.47 The ICCT working paper compiles retail price projections for ZEV trucks based on a literature review of U.S. and EU sources, each of which provides projections, goals, or targets for 2025/2030. ICCT's summary of the range and average of the literature-projected costs are shown below.48 [EPA-HQ-OAR-2022-0985-1566-A2, pp. 9 - 10]

46 ICCT Working Paper 2022-09, "A meta-study of purchase costs for zero-emission trucks," February 2022.

47 EPA HD TRUCS spreadsheet (Document ID EPA-HQ-OAR-2022-0985-0830), "Inputs" tab, Rows 4, 5, 44, 45, 103 and 104.

48 ICCT Working Paper 2022-09 at Figure 2.

ICCT acknowledges that "due to the nascent nature of the market, there is a lack of publicly available data on the costs of heavy-duty zero-emission vehicles and powertrains, especially for freight trucks."49 EPA nevertheless adopts the average costs from the ICCT working paper as fact, without any reference to the ICCT's expression of uncertainty in the surveyed literature projections. Moreover, EPA fails to consider the magnitude of cost ranges presented in the ICCT working paper and evaluate the sensitivity of its modeled impacts to the ranges of uncertainty. For example, the upper bounds of the ranges of the cost projections in the ICCT working paper in 2027 for energy battery, fuel cell and hydrogen storage are interpolated to be approximately 60% higher, 100% higher, and 60% higher than the respective average values.50 [EPA-HQ-OAR-2022-0985-1566-A2, p. 10]

49 ICCT Working Paper 2022-09 at 1.

50 ICCT Working Paper 2022-09 at Figure 2.

EPA fails to offer any explanation why it is reasonable to assume the average cost values from the ICCT working paper while disregarding the upper or lower bounds of the cost ranges, nor does it evaluate the sensitivity of its HD ZEV adoption modeling to these uncertainties. [EPA-HQ-OAR-2022-0985-1566-A2, p. 10] [See Figures 2 through 4, ICCT Costs, on page 10 and 11 of docket number EPA-HQ-OAR-2022-0986-1566-A2]

It should also be noted that EPA's input into HD TRUCS for the 2027 fuel cell stack cost of "230*Adj_Factor"52 does not match the average projection in Figure 2 of the ICCT Working Paper and is incorrect, according to EPA's approach. [EPA-HQ-OAR-2022-0985-1566-A2, p. 11]

52 EPA HD TRUCS spreadsheet (Document ID EPA-HQ-OAR-2022-0985-0830), "Inputs" tab, Cell G45.

EPA Summary and Response

Summary:

Several commenters addressed EPA's estimates for fuel cell costs. CARB agreed that EPA's estimates are reasonable, noting they used similar estimated values in their Advanced Clean Fleets rule proceeding. Dana thought the NPRM fuel cell cost estimates were too high, particularly if they represent the fuel cell stack alone, based on targets published by the European Joint Undertaking. EMA, however, referred to values from a more recent (2023) ICCT White Paper that shows a higher estimate than EPA's, and indicated that their members concurred with the higher ICCT estimates. DTNA (an EMA member) felt that fuel stack technology is too nascent to make any type of realistic cost estimate. They noted that existing component technologies still need to be adapted for the HD market and that fuel cell stacks are not being produced at scale now, and they stated that they do not believe accurate HD FCEV technology costs can be predicted now. They further said that because costs of major components impact payback, they must be reviewed regularly as the market matures to account for the best available data. DTNA, EMA, and PACCAR pointed to ICCT's revised estimates, which they say are more in line with available data, but they also noted that ICCT also recognizes there is significant uncertainty. Valero said that EPA failed to fully evaluate the uncertainties associated with the projected costs in HD TRUCS and identified a potential error in the HD TRUCS tool.

Only two commenters mentioned onboard hydrogen storage tank costs. DTNA noted that EPA's estimates for compressed hydrogen tanks may be reasonable. But they said that to accommodate long-distance ranges of over 500 miles in the longer-term, liquid hydrogen will be the primary fuel, and it is too soon to offer costs estimates for liquid tanks. Both DTNA and Valero referenced the 2023 ICCT study for onboard hydrogen storage tank costs.

MEMA also suggested that liquid hydrogen or other liquid renewable fuels, should be considered in HD TRUCS when evaluating feasibility and costs, provided through publicly available infrastructure to support them.

Response:

Hydrogen infrastructure is addressed in RTC Section 8.

As discussed in RTC Section 5.3 on storage tank packaging and in RIA Chapter 1.7.3, we did not consider liquid hydrogen explicitly in this rule and only evaluate HD FCEVs with 700 bar gaseous tanks that can accommodate a range of up to 500 miles prior to refueling, given that gaseous hydrogen technologies are predominantly used today and the readiness of liquid storage and refueling technologies is relatively low. However, compliance with the GHG standards in this rule is possible through numerous potential pathways as long as testing and other requirements are met.

Fuel Cell Costs:

For the NPRM, we relied on an average of costs from an ICCT meta-study that found a wide variation in fuel cell costs in the literature (Sharpe and Basma et. al, 2022). Valero suggested there was an error in our fuel cell cost estimate in HD TRUCS for MY 2027. In fact, there was an error in the writeup about our approach. In the DRIA Chapter 2.5.2.1, we said that we "averaged the 2025 cost values from the Sharpe and Basma meta-study, averaged the 2030 values, and then linearly interpolated to get MY 2027 values and adjusted to 2021$; we then applied the learning curve shown in DRIA Chapter 3.2.1 to calculate MY 2028– 2032 values.” We actually used the average values from 2030 ($191 per kW), and then applied our learning rates backwards[293] to get a MY 2027 value. Then we applied an adjustment factor to get from 2019$ to 2021$ and applied the learning curves shown in DRIA 3.2.1 to calculate MY 2028 to 2032 values.

For the final rule, we revised our fuel cell cost estimates from those in the NPRM. The revised fuel cell system cost estimates for the final rule are described in RIA Chapter 2.5.2.1.

We reviewed the ICCT paper that several commenters referenced. In March 2023, ICCT published a meta-study (Xie et. al, 2023)[294,295] that revised a meta-study from 2022 (Sharpe and Basma et. al, 2022).[296] Xie et. al adjusted estimates based on average inflation between 2020 and 2022. They replaced one source from the previous review of the literature (Transport & Environment) with another source (Interact Analysis)[297]. For fuel cells, they developed a cost curve by weighting primary research (Ricardo, Interact Analysis, and Roland Berger) twice as highly as secondary research. All sources referenced by ICCT appear to account for fuel cell system costs that include both the fuel cell stack and balance of plant (BOP).

[293] After applying our learning rates backwards, if one applied the learning rates to the newly calculated MY 2027 value, they would calculate the 2030 value we started with.

[308] In the NPRM, we used the average values from 2030 and then applied our learning rates backwards to get a MY 2027 value. Then we applied an adjustment factor to get from 2019$ to 2021$ and applied the learning curves shown in DRIA 3.2.1 to calculate MY 2028 to 2032 values.

In Xie et. al, ICCT shows a range of costs used to calculate their estimates and lists minimum and maximum values from the literature. The volumes associated with the costs included in their assessment are not clear. For example, the high costs that they cite in 2020, which the sources indicate were identified in consultation with experts, appear to correspond with very low volumes without any economies of scale; projected costs decline as volume grows but the associated volumes are not clear. According to Ballard, a fuel cell developer, PEM stack and fuel cell balance of plant cost reductions of about 60 to 65 percent are possible even at a relatively small annual production volume of 10,000 trucks per year due to a low dependency on commodities compared to batteries.[309,310]

Both the Ricardo study and Burke and Sinha considered an analysis conducted by Strategic Analysis that was used to develop the DOE Class 8 technical targets for long-haul FCEV trucks.[311,312,313] The Hunter and Burnham analyses were conducted by DOE labs. DOE's work generally speaks about costs in terms of kWnet, or net system power. (According to James et. al, they design fuel cells for a net system power.[314]) DOE's targets estimated the heavy-duty fuel cell system cost to be $190 per kW in 2019 (2016$) based on a low manufacturing volume of 1000 units per year. DOE assumes 100,000 production units per year for their interim (2030) Class 8 target of $80 per kW and ultimate target of $60 per kW.[315]

During the DOE Hydrogen and Fuel Cell Technology Office's Annual Merit Review in 2023, DOE shared durability-adjusted modeled costs for a 275 kWnet fuel cell (2022). At 1,000 units per year, the cost of $302 per kWnet appears to be higher than the previous estimate of $190/kW, but it is still in line with future targets when considering volume projections. They noted that the cost at 50,000 systems per year of $196 per kWnet in 2021 could drop to a new interim target of $140 per kWnet by 2025 to meet the $80 per kW target for 100,000 units by 2030.[316]

Due to the wide range of projected costs in the literature, EPA contracted with FEV[317] to independently evaluate direct manufacturing costs of heavy-duty vehicles with alternative powertrain technologies, and EPA conducted an external peer review of the final FEV report.[318] In the report, FEV estimated costs associated with a Class 8 FCEV-dominated long-haul tractor with graphite fuel cell stacks, which are more durable than stainless steel stacks typically used in light-duty vehicle applications. FEV leveraged a benchmark study of a commercial vehicle fuel cell stack from a supplier that serves the Class 8 market. They also built prototype vehicles in-house and relied on existing expertise to validate their sizing of tanks and stacks.[319] When considering a range of costs based on lower production volumes from the literature, the FEV 2027 costs (in 2022$) came in on the lower end of projections. Table 2 includes FEV cost estimates for the fuel cell system, based on cost of both the stack and the BOP. They are in terms of kWgross (or gross system power):

Table 2 FEV Fuel Cell System Costs[320]

# Units	10,000	5,000	1,000
FC System	$89/kW	$114/kW	$147/kW

For the final rule, as described in RIA Chapter 2.5.2.1, we established MY 2032 fuel cell system DMCs using cost projections from FEV and ICCT.[321] We weighted FEV's work twice as much as ICCT's because it was primary research and because some of the values in ICCT's analysis were not transparent. We note that this method of weighting primary research more heavily than secondary research is generally appropriate for assessing predictive studies of this nature; indeed, it is consistent with what ICCT itself did. For FEV's work, we selected costs that align with the HD FCEV production volume that we project in our modeled potential compliance pathway's technology packages developed for this final rule, which is roughly 10,000 units per year in MY 2032, for a DMC of $89 per kW. (As noted above, Ballard points out that economies of scale are possible even at small production volumes of about 10,000 trucks.) For ICCT's work, we used the 2030 value of $301 per kW for MY 2032, since 2030 was the latest year of values referenced by ICCT from literature. Our weighted average yielded a MY 2032 fuel cell system DMC of $160 per kW, shown in Table 3. In order to project DMCs for earlier MYs, we used our learning rates shown in RIA Chapter 3.2.1. This yielded the MYs 2030 and 2031 DMCs shown in Table 3.

[317] FEV Consulting. "Heavy Duty Commercial Vehicles Class 4 to 8: Technology and Cost Evaluation for Electrified Powertrains—Final Report". Prepared for EPA. March 2024.
[318] FEV Consulting. "Heavy Duty Commercial Vehicles Class 4 to 8: Technology and Cost Evaluation for Electrified Powertrains—Final Report". Prepared for EPA. March 2024.
[319] ICF. "Peer Review of HD Vehicles, Industry Characterization, Technology Assessment and Costing Report". September 15, 2023.
[320] Daniels, Jessica and Alex Wang. Memorandum to docket EPA-HQ-OAR-2022-0985. FEV Component Cost Estimates. March 2024.
[321] Since the ICCT estimates do not indicate if the costs are in kWgross or in kWnet power, we treated them like the FEV values, or as if they were kWgross costs. This assumption is conservative because, if the costs are in kWnet, they would need to be adjusted down before combining them with FEV values.

Table 3 Fuel Cell System Direct Manufacturing Costs (2022$)

Year	MY 2030	MY 2031	MY 2032
FC System	$170/kW	$165/kW	$160/kW

See Section 12.3 of the RTC for comments and responses on learning curves.

We agree with DTNA's comment that FCEV component technology is still being adapted for the HD market, and we recognize their work with DOE through SuperTruck 3[322] and the efforts of DOE's Million Mile Fuel Cell Truck partnership to meet HD FCEV targets,[323] as described in RIA Chapter 1.7.6. In RIA Chapter 1.7.5, we also note that FCEV technology is being developed and demonstrated now while fuel cell and HD FCEV production is gearing up, and we expect that this final rule will provide greater certainty to the market to support timely supply of technologies. Our overall assessment is that early market HD FCEV production volumes to support the updated FCEV adoption levels in the modeled potential compliance pathway are possible in the MY 2030 to MY 2032 timeframe.

Onboard Hydrogen Fuel Tank Costs:

In the NPRM, similar to our approach for fuel cell costs, we relied on an average of costs from an ICCT meta-study that found a wide variation in onboard hydrogen storage tank costs in the literature (Sharpe and Basma et. al, 2022). And similar to the response to our fuel cell costs, commenters referred to ICCT's revised meta-study for better estimates.[324]

As mentioned above, ICCT published a revised meta-study with adjusted estimates based on average inflation between 2020 and 2022 (Xie et. al, 2023).[325,326] For the onboard hydrogen storage tank costs, they added one source (Interact Analysis[327]) to their assessment, and they weighted primary research (Ricardo and Interact Analysis) three times as high as secondary research to develop a cost curve. All referenced sources appear to be for usable hydrogen in Type IV 700 bar gaseous tanks made of carbon fiber.

NREL: $533/kg (2025); $480/kg (2030)	= Hunter et. al (2021)
UC Davis: $375/kg (2025); $250/kg (2030)	= Burke and Sinha (2020)
$660/kg (EPA estimate, 2030)[329]	**$844/kg (ICCT estimate, 2030)**

* Considered primary research by ICCT

In Xie et. al, ICCT shows a range of costs used to calculate their estimates and lists minimum and maximum values from the literature. Like fuel cell costs, onboard gaseous hydrogen tank costs are dependent on manufacturing volume. The volumes associated with the costs included in ICCT's assessment are not clear. For example, the Ricardo analysis appears to consider volumes that range from 1,000 to 30,000 dual tank configuration units per year but the scaling assumed based on this data is not clear. According to the Hydrogen Council, tanks can achieve costs reductions of roughly 50 percent with an annual production of about 10,000 FCEVs.[330]

We contracted FEV[331] to independently evaluate onboard hydrogen storage tanks costs for 2027 (2022$) based on manufacturing volume, and EPA conducted an external peer review of the final FEV report.[332] FEV evaluated onboard hydrogen storage tanks costs for 2027 (2022$) based on manufacturing volume and estimated the following:

Table 5 FEV Costs for Onboard Hydrogen Storage Tanks[333]

# Units	10,000	5,000	1000
Onboard H2 Tank	$504/kg	$562/kg	$722/kg

These costs account for total hydrogen stored in a tank if only 80 percent of the tank's hydrogen is useable.[334]

Using the same approach taken for fuel cell system costs, as described in RIA Chapter 2.5.2.2, we established MY 2032 onboard storage tank DMCs using cost projections from FEV and ICCT. We weighted FEV's work twice as much as ICCT's because it was primary research and because some of the values in ICCT's analysis were not transparent. We note that this method of weighting primary research more heavily than secondary research is generally appropriate for assessing predictive studies of this nature; indeed, it is consistent with what ICCT itself did. For FEV's work, we selected costs for roughly 10,000 units per year in MY 2032, for a DMC of $504 per kg. For ICCT's work, we used the 2030 value of $844 per kW for MY 2032, since 2030

329 In the NPRM, we used the average values from 2030 and then applied our learning rates backwards to get a MY 2027 value. Then we applied an adjustment factor to get from 2019$ to 2021$ and applied the learning curves shown in DRIA 3.2.1 to calculate MY 2028 to 2032 values.

334 HD TRUCS assumes that 95 percent of the hydrogen in a tank can be accessed, or is useable, plus there is a 10 percent buffer added to the tank to avoid complete depletion of hydrogen. We have seen ranges of between 80 and 90 percent in the literature and did not receive comment on this input.

was the latest year of values referenced by ICCT from literature. Our weighted average yielded a MY 2032 fuel cell system DMC of $617 per kW. In order to project DMCs for earlier MYs, we used our learning rates shown in shown in RIA Chapter 3.2.1. This yielded the MYs 2030 and 2031 DMCs shown in Table 6.

Table 6 Onboard Hydrogen Storage Tank Direct Manufacturing Costs (2022$)

Year	MY 2030	MY 2031	MY 2032
Onboard H2 Tank	$659/kg	$636/kg	$617/kg

See Section 12.3 of the RTC for comments and responses on learning curves.

3.7 Maintenance and Repair

Comments by Organizations

Organization: Advanced Energy United

A large percentage of emissions reductions from the transportation sector will be accomplished by replacing gas- and diesel-powered buses, trucks and vans with EV models. EVs are not only much more energy efficient than gas-powered cars but are also less expensive to fuel and maintain over their lifetimes. Thus, the EPA's proposed rule presents an opportunity to decarbonize the largest source of emissions in the American economy while scaling up an emerging domestic market. Electrified transportation reduces our reliance on fossil fuels, strengthens America's energy independence, and produces economic benefits across the value chain of the automotive industry. [EPA-HQ-OAR-2022-0985-1652-A2, pp. 1 - 2]

Organization: American Free Enterprise Chamber of Commerce (AmFree) et al.

First, EPA concludes that electric vehicles come with substantial savings in maintenance and repair. See Draft RIA at 185. That conclusion is based on a 2022 study finding that the maintenance and repair costs for battery-electric vehicles will be 29 percent lower than those for internal-combustion-engine vehicles. Id. (citing Guihua Wang et al., Estimating Maintenance and Repair Costs for Battery Electric and Fuel Cell Heavy Duty Trucks, Univ. of Cal., Davis, at 10 (Feb. 2022)). But the authors of that study emphasize the uncertainty underlying that finding: To sum up, currently there are very limited data on [maintenance and repair] costs for battery electric and fuel cell trucks. Even for the transit bus segment which has the most experience in advanced HD technology applications, there is no consensus on the maintenance cost comparison among diesel, battery, and fuel cell buses. [EPA-HQ-OAR-2022-0985-1660-A1, p. 27]

Wang et al., Estimating Maintenance and Repair Costs at 10 (emphases added). Although the study notes a consensus in existing research that maintenance and repair costs for electric vehicles, in the future, will be smaller than for conventional vehicles generally, see id., the degree of difference is critical to EPA's estimate of future sales: If the maintenance and repair costs for electric and conventional vehicles are not as far apart as EPA assumes, the payback period could be longer—and, in turn, the adoption rates of electric vehicles could be much lower. According to EPA's own analysis, the adoption rate could drop by 10 percent if the payback period is off by even one month. See Draft RIA at 232–33. The existing data, however, are inadequate to make reliable calculations of the degree of difference. [EPA-HQ-OAR-2022-0985-1660-A1, p. 28]

Second, EPA estimates operational savings without considering "midlife overhaul costs," which include "the cost resulting from an engine rebuild for a conventional diesel vehicle, a battery replacement for a battery electric vehicle, or a fuel cell stack refurbishment for a hydrogen fuel cell vehicle." Wang et al., Estimating Maintenance and Repair Costs at 10–11. EPA disregarded these costs on the ground that its "payback analysis typically covers a shorter period of time than the expected life of these components." Draft RIA at 185. That reasoning is illogical. Assuming (as EPA does) that net costs drive purchasing decisions, commercial-fleet owners are unlikely to buy an electric model if they anticipate that such vehicles will require costly midlife repairs that would erase any initial savings. Some evidence suggests that this will occur. For example, one report (performed by the California Air Resources Board) cited in the Wang study noted above posits that electric trucks will require battery replacement every 300,000 to 500,000 miles—much sooner than a comparable conventional vehicle is likely to require an engine rebuild. See Draft Advanced Clean Fleets Total Cost of Ownership Discussion Document, Cal. Air Res. Bd., at 26 (Sept. 9, 2021) (indicating that a Class 8 heavy-duty diesel truck is likely to require an engine rebuild after 800,000 miles). The cost of major midlife repairs for electric vehicles also may be substantially greater. Compare, e.g., Certified Diesel Sols., When to Overhaul a Diesel Engine, https://tinyurl.com/2dch6xv3 (estimating cost of a diesel-engine rebuild between $20,000 and $40,000), with EPA, Heavy- Duty Technology Resources Use Case Scenario, at 2_BEV Tech (Apr. 10, 2023), https://www.epa.gov/system/files/other-files/2023-04/hd-tech-trucs-tool-2023-04.xlsm (Columns AJ & AK) (EPA's modeling suggesting that the cost of manufacturing batteries may be several multiples higher). The Senior Vice President of the American Transportation Research Institute cautions that heavy duty-vehicle operators are "going to be switching out the batteries on a Class 8 truck every four to seven years" and "pay between $85,000 and $120,000 for a replacement set." Cristina Commendatore, Report Pinpoints Top Challenges for Widespread Battery-Electric Vehicle Adoption, FleetOwner (Dec. 7, 2022), https://tinyurl.com/243euzxr. Thus, owners of electric heavy-duty vehicles could find themselves saddled with new and substantial midlife overhaul costs that cut into their operational savings. EPA should assess—not ignore—this issue before calculating the payback period. [EPA-HQ-OAR-2022-0985-1660-A1, pp. 28 - 29]

Fourth, EPA explains that the operating costs for a battery-electric vehicle include "insurance" and "labor." Draft RIA at 182. Nevertheless, the agency does not evaluate either of these costs because it assumes that they will not "differ significantly" for owners of electric and internal-combustion-engine vehicles. Id. Available evidence suggests otherwise. According to a recent study, fleets considering electric-vehicles "are facing higher insurance costs," which "may be due to new and unfamiliar technology, overall higher purchase costs, and higher costs of repair after accidents." Medium- and Heavy-Duty Vehicle Electrification at 10. And although the labor costs associated with electric and internal- combustion-engine vehicles may eventually even out, owners will incur additional costs when they first begin incorporating electric vehicles into their fleets. Managers and maintenance staff will need to be retrained in the new technology or replaced by workers who are already up to speed. Id. at 11. These costs should likewise be factored into the agency's calculation. [EPA-HQ-OAR-2022-0985-1660-A1, pp. 29 - 30]

Second, EPA concluded that the costs of the proposed rule would be offset by $250 billion in "operational savings" that heavy-duty operators would experience by shifting to electric vehicles. 88 Fed. Reg. at 26,082. This conclusion is doubly erroneous. As an initial matter, as explained above, the bulk of these purported savings come from $200 billion saved in repair-and-maintenance costs—an enormous sum that EPA bases on a single study that itself undercuts EPA's calculation. And the remainder of the operational savings that EPA estimates, including from pre-tax fuel savings and diesel exhaust fluid savings, are also unreliable for the reasons already stated. [EPA-HQ-OAR-2022-0985-1660-A1, p. 64]

More broadly, EPA's conclusion that these operational savings exist defies common sense. As EPA acknowledges, if abandoning internal-combustion-engine vehicles in favor of electric vehicles could actually be expected to result in huge operational savings, rational users of heavy-duty vehicles would likely already be switching. See 88 Fed. Reg. at 26,071; Draft RIA at 417 (noting that a "normally functioning competitive market" would "lead buyers to purchase [electric vehicles] willingly"). The fact that they are not doing so is a strong indication that EPA's asserted operational savings do not in reality outweigh the costs of switching to electric vehicles. [EPA-HQ-OAR-2022-0985-1660-A1, p. 64]

Organization: American Highway Users Alliance

Repair and servicing of the EV was reported as costly because 'danger' in servicing the EV requires two technicians rather than one. [EPA-HQ-OAR-2022-0985-1550-A1, p. 7]

Organization: American Trucking Associations (ATA)

Fleet maintenance of a ZEV needs to be better understood than it is currently. As a non-capital expense, estimating any expected savings over its lifespan is especially difficult. The previously mentioned fleet manager said their fleet relies on the OEM to repair their ZEVs but anticipates transitioning to in-house maintenance after the warranty expires. This fleet manager was not alone in his approach. All the fleets that we surveyed that had ZEVs in their fleets are currently contracting out the maintenance for the vehicles. Fleet operators need to gain knowledge on accurately calculating and assessing repair turnaround times, workforce training requirements, and occupational risks of maintaining and servicing high-voltage batteries (ranging from 600 to 800 volts) but see a benefit to doing the work in-house rather than sending the vehicle away. The same fleet manager highlighted that for the TCO to be justifiable, the acquisition costs of their box trucks would need to decrease by $100,000. Maintenance costs are unknown once battery warranties expire. Fleets told us these costs can have outsized impacts on their TCO. For example, a large national carrier cautioned that one outside-of-warranty battery repair or replacement job of $30,000 to $100,000 could be detrimental to an entire TCO structure. The calculation on BEV maintenance costs, they say, should only be assumed at a certain percentage if real-world average savings over the life of a vehicle can be proven. [EPA-HQ-OAR-2022-0985-1535-A1, p. 11]

Technicians' new skills to service

As EPA has noted, performing standard maintenance on BEVs leads to new or increased risk compared to ICE vehicles and requires corresponding safety training due to the following:29

- the presence of high voltage components and cabling capable of delivering a fatal electric shock;
- the storage of electrical energy with the potential to cause explosion or fire;
- components that may retain a dangerous voltage even when a vehicle is switched off;
- electric motors or the vehicle itself that may move unexpectedly due to magnetic forces within the motors;
- manual handling risks associated with battery replacement;
- the potential for the release of explosive gases and harmful liquids if batteries are damaged or incorrectly modified;
- the possibility of people being unaware of vehicles being in motion because when they are electrically driven, they are silent in operation; and the potential for the electrical systems on the vehicle to affect medical devices such as pacemakers. [EPA-HQ-OAR-2022-0985-1535-A1, p. 20]

29 U.S. Environmental Protection Agency, Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles: Phase 3: Draft Regulatory Impact Analysis, pgs. 38-39, EPA-HQ-OAR-2022-0985, April 27, 2023.

EPA further notes that hydrogen-related fuel cell vehicles carry additional risks that can be mitigated through:30

- proper no/low leak designs for infrastructure, hydrogen fill equipment, vehicle connectors, and vehicle storage and supply;
- ambient hydrogen concentration monitoring and alarm;
- hydrogen pressure monitoring in the vehicle and infrastructure to indicate leaks;
- proper ventilation in and around hydrogen fueling equipment and fuel cell vehicles;
- vehicle controls to ensure the vehicle cannot be driven while fueling equipment is attached; and
- vehicle controls that isolate hydrogen storage in the case of an accident. [EPA-HQ-OAR-2022-0985-1535-A1, p. 20-21]

30 Ibid, pg. 76

Fleets will need to expand existing technician safety training and education to manage these potential risks. Maintenance facilities upgrades will also be needed to accommodate BEV and FCEV vehicles. For example, because hydrogen is lighter than air, shop ventilation and monitoring will be needed for fleets servicing FCEVs. For BEVs, isolating high-voltage service bays has been mentioned as a potential maintenance strategy. Fleets are in the initial stages of understanding how to adapt existing maintenance shops to accommodate BEVs and/or FCEVs. As many fleets conduct in-house maintenance on their vehicles, EPA should further investigate the proposed rule's impact on maintenance practices and facilities. [EPA-HQ-OAR-2022-0985-1535-A1, p. 21]

Organization: Arizona State Legislature

EPA believes 'lower maintenance and repair costs for [zero-emission vehicle] technologies as compared to [internal combustion engine] technologies, etc.' help justify the rule. 88 Fed. Reg. 25926, 25936 (Apr. 27, 2023). EPA acknowledges that '[d]ata on real-world [maintenance and repair] costs for [heavy-duty zero-emission vehicles] is limited due to limited [heavy-duty zero-emission vehicle] technology adoption today.' Id. at 25986. EPA speculates that fewer moving parts, not requiring fluids or exhaust filters, and regenerative braking systems will lead to lower maintenance and repair costs. Id. at 25986-987. Based on this speculation, EPA calculates the proposed rule will save a staggering $24 billion in repair and maintenance costs. Id. at 26,082. [EPA-HQ-OAR-2022-0985-1621-A1, p. 23]

EPA's assumptions are not supported by actual data. An analysis of the service and repair visits for about 19 million vehicles between the 2016 and 2021 model years found that electric vehicles cost more to repair than gas-powered vehicles.24 The study found that electric vehicles were 2.3 times more expensive than gas-powered vehicles to service in the first three months of ownership, and 1.6 times more expensive at the twelve-month mark.25 The study blamed the increased time that technicians spent as well as the fewer number of technicians that could work on electric vehicles charging a higher hourly rate.26 [EPA-HQ-OAR-2022-0985-1621-A1, p. 23]

Organization: California Air Resources Board (CARB)

5. Maintenance and Repair Operating Costs

Affected pages: 25986-25987

CARB staff concurs with U.S. EPA's methodology regarding maintenance and repair costs. Many recent announcements by manufacturers indicate that key components of BEVs and FCEVs, including batteries, will be able to last for ten years or longer.218,219 This supports U.S. EPA's assumptions that no midlife battery replacement or fuel cell refurbishment is necessary for a 10-year analysis. [EPA-HQ-OAR-2022-0985-1591-A1, p.64]

Organization: Clean Fuels Development Coalition et al.

E. The proposal overestimates maintenance savings.

Without any justification, EPA assumes that "the maintenance and repair savings are substantial due again to electrification of the HD fleet, with HD BEVs and FCEVs projected to require 71 percent and 75 percent, respectively, of the maintenance and repair costs required of HD vehicles equipped with internal combustion engines." 88 Fed. Reg. 26,080. The evidence points to the opposite conclusion: that Heavy Duty EVs are more costly to maintain than conventional alternatives. In testimony before the EPA, a representative from American Truck Dealers explained that owing to the immense danger of working on heavy-duty electric vehicles, a second repair technician is required to supervise work and to be at the ready to rescue—literally with a hook—the first technician if something goes wrong. See The American Truck Dealers Division, Dkt. No. EPA-HQ-OAR-2022-0985-1445 (May 3, 2023). [EPA-HQ-OAR-2022-0985-1585-A1, p. 35]

Organization: Daimler Trucks North America LLC (DTNA)

EPA Request for Comment, Request #20: We request comment on our approach, including other data we should consider in our assessment of energy consumption.

- DTNA Response: EPA should consider all available data including that which can be provided by manufacturers in confidential settings; however, given that the HD ZEV market is currently in a nascent state, any data available today is necessarily limited. EPA should thus re-evaluate its assumptions on this issue on a regular basis, using the best available data. See Section II.C.2 of DTNA's comments. [EPA-HQ-OAR-2022-0985-1555-A1, p. 161]

EPA Request for Comment, Request #43: We followed this approach and applied a maintenance and repair cost scaling factor of 0.71 for BEVs and 0.75 for FCEVs to the maintenance and repair costs of diesel-fueled ICE vehicles. The scaling factors are based on an analysis from Wang et al. that estimates a future BEV heavy-duty truck would have a 29 percent reduction, and a future FCEV heavy-duty vehicle would have a 25 percent reduction, compared to a diesel-powered heavy-duty vehicle.488,489 We welcome comment on our approach and these projections.

- DTNA Response: See DTNA Response to Request # 20, above. [EPA-HQ-OAR-2022-0985-1555-A1, p. 165]

Organization: Lion Electric, Co. USA

The absence of complex engine components, such as pistons, valves, and camshafts in a Lion vehicle reduces the likelihood of mechanical failures and may result in extended vehicle lifespan. This inherent simplicity can contribute to longer service life, reduced maintenance costs and fewer scheduled service visits compared to vehicles with internal combustion engines (ICEs). [EPA-HQ-OAR-2022-0985-1506-A1, p. 2]

Lion’s customers and partners say the savings between electric vehicles and diesel-powered ones is very clear: 80% in energy cost reduction and 60% maintenance cost decrease when organizations transition to all-electric MHDVs. (Source: Lion fact sheet). In fact, a school district operating an electric school bus can expect to see over $100,000 in lifetime fuel and maintenance savings, compared to an equivalent diesel bus. All About Total Cost of Ownership (TCO) for Electric School Buses | Electric School Bus Initiative [EPA-HQ-OAR-2022-0985-1506-A1, p. 2]

Organization: National Association of Chemical Distributors (NACD)

The largest savings calculated by the EPA are reductions in maintenance costs. Again, current demand for reduced emissions vehicle maintenance (particularly for trucks) is nearly non-existent, and the EPA uses data from 2019, when even less information was available on the repair costs for low emissions vehicles. One thing is for certain, if trucking firms were forced to quickly move toward these technologies, there would not be a sufficient supply of mechanics or vehicle parts to maintain all of these vehicles, even if they required less service than diesel powered trucks. This would certainly increase the cost of maintenance.6 The EPA relies on a single source for its estimate that the cost of maintenance for the required vehicles would be 71 percent of that of diesel trucks.7 Even this source provides a very large range for differential costs, with some estimates being as low as a 10 percent difference (not the 29 percent difference used in the RIA). Assuming that the cost differential for maintenance and repair is at this lower end would lead to a savings of $13.944 billion, or $1,066 per truck. This would amount to a savings of $1.2 billion for the chemical distribution industry. [EPA-HQ-OAR-2022-0985-1564-A2, pp. 2 - 3]

6 In addition, according to the RIA: Data on real-world maintenance and repair costs for heavy-duty BEVs is limited due to limited heavy-duty BEV technology adoption today. We expect the overall maintenance costs to be lower for heavy-duty BEVs than a comparable ICE vehicle for several reasons. First, an electric powertrain has fewer moving parts that accrue wear or need regular adjustments. Second, BEVs do not require fluids such as engine oil or DEF, nor do they require exhaust filters to reduce particulate matter or other pollutants. Third, the per-mile rate of brake wear is expected to be lower for BEVs due to regenerative braking systems. Several literature sources propose applying a scaling factor to diesel vehicle maintenance costs to estimate BEV maintenance costs. We followed this approach and applied a repair cost scaling factor of 0.71 to the maintenance and repair costs for diesel-fueled ICE vehicles that are shown in Table 2-29. The 0.71 scaling factor is based on an analysis from Wang et al. 2022, that estimates a future BEV HD vehicle would have a 29 percent reduction compared to a diesel-powered HD vehicle. In our payback analysis in HD TRUCS, we did not account for potential diesel engine rebuild costs for ICE vehicles, potential replacement battery costs for BEVs, or potential replacement fuel cell stack costs for FCEVs because our payback analysis typically covers a shorter period of time than the expected life of these components. Typical battery warranties being offered by HD BEV manufacturers range between 8 and 15 years today.97 A BEV battery replacement may be practically necessary over the life of a vehicle if the battery deteriorates to a point where the vehicle range no longer meets the vehicle’s operational needs.

7 The citation in the RIA refers back to a broken link. The paper is Wang, G. et. al., White Paper: The Current and Future Performance and Costs of Battery Electric Trucks: A Review of Key Studies and a Detailed Comparison of their Cost Modeling Scope and Coverage, National Center for Sustainable Transportation, June 7, 2022. It is a white paper, not a study published in any sort of journal, meaning that it has not been peer reviewed. The research was funded by the Federal Government.

Moreover, forcing more zero emission vehicles (ZEVs) on the road, as this proposal aims to do, may create backlogs in maintenance for these vehicles. As the National Automobile Dealers Association noted in their testimony before the EPA, ZEVs require more specialized labor that is less available for their maintenance compared to traditional diesel trucks.3 This adds additional strain on the limited technicians available to service heavy-duty trucks and will create backlogs in necessary services, again removing trucking capacity from the supply chain. [EPA-HQ-OAR-2022-0985-1564-A1, p. 3]

3 National Automobile Dealers Association, “Comment submitted by National Automobile Dealers Association, American Truck Dealers Division,” nada.org, NADA, https://www.regulations.gov/comment/EPA-HQ-OAR-2022-0985-1445

Organization: National Automobile Dealers Association (NADA)

I. ATD dealers support continuous improvements in environmental and fuel economy performance of the fleet.

Without a doubt, alternative-fueled HDV sales have grown and will continue to grow. And America’s car and truck dealers are doing their part to embrace this technological revolution and facilitate the introduction of alternative vehicles into the fleet. As evidenced by activities at the 2022 and 2023 NADA/ATD Shows4, and by its work with the U.S. Departments of Transportation and Energy on the deployment of critical public charging facilities, ATD is committed to supporting alternative-fueled vehicles. To this end, NADA/ATD estimates that franchised dealerships are on track to spend billions in EV infrastructure.5 [EPA-HQ-OAR-2022-0985, p 1-2]

4 See Appendix A: “Everything Electric” at NADA/ATD Show 2022-2023.

5 This projection is based on available data from a selection of vehicle manufacturer brands and dealerships. This number reflects data from franchised dealerships that sell new light-, medium-, and/or heavy-duty vehicles.

Dealership investments necessary to sell and service ZEV HDVs vary widely with cost estimates costs ranging from $100,000 to over $1 million per store. These estimates do not necessarily include all the specialized equipment purchases needed to service ZEVs or the additional costs from local utilities for extending new power lines or adding transformers. In many cases, installing electric chargers requires a more comprehensive electric system, including new transformers and power lines. Installations of this magnitude can involve major construction, which is accompanied by permits, supply chain delays, and environmental safety requirements, all barriers that HDV dealers are working to overcome. [EPA-HQ-OAR-2022-0985, p 2]

As the frontline of customer education, HDV dealers are investing in staff training across departments so that prospective ZEV purchasers receive the most accurate, current, and complete information about ZEVs. Some dealers are taking that work to the next step with dedicated ZEV education programs. This includes bringing ZEV HDVs to local auto shows and customer events and even educating first responders on proper battery safety when responding to crashes involving ZEVs. [EPA-HQ-OAR-2022-0985, p 2]

These investments echo ATD’s long-standing support of continuous emission improvements for HDVs. At the same time, ATD has suggested consistently that new emissions mandates must not compromise the affordability, reliability, fuel economy, and/or serviceability of HDVs. This position reflects the fact that prospective customers will avoid purchasing or leasing new HDVs that cost too much, offer performance compromises, or pose risks of unacceptable downtime. [EPA-HQ-OAR-2022-0985, p 2]

This rulemaking occurs at a time when HDV dealerships and their customers are just beginning to evaluate alternative HDV technology options and to understand the infrastructure that is necessary to support those options. [EPA-HQ-OAR-2022-0985, p 2]

Organization: Tesla, Inc. (Tesla)

Still other recent assessments of the total cost of ownership indicate that EPA stands on firm ground to strengthen the stringency in the rule. Indeed, some OEMs predict BEV cost parity in 2025 well ahead of the proposed rule's 2027 implementation date. Further numerous studies have found that heavy-duty BEVs outperform conventional trucks on a total cost of ownership basis.155 Tesla projects that its Semi will have energy costs that are half those of diesel, provide over $200,000 in fuel savings, and have a two-year payback period.156 Another manufacturer has found that BEVs could save fleets up to 80% on energy costs and 60% on repair.157 Yet another found that the benefits of electrifying heavy-duty truck fleets are significant with recent studies showing that operating costs for electric trucks can be between 14 and 52 percent lower and repair costs around 40 percent lower than their combustion-powered counterparts.158 CARB has found that battery-electric vehicles appear cost competitive with the established combustion technologies by 2025 in many use cases.159 Real world demonstrations have also proven this out.160 [EPA-HQ-OAR-2022-0985-1505-A1, p. 21]

155 See e.g., UC Berkley, 2035 Report: Transportation: Plummeting Costs and Dramatic Improvements in Batteries Can Accelerate Our Clean Transportation Future (April 2021) at 15 available at https://www.2035report.com/transportation/transportation-new/wpcontent/uploads/2020/05/2035_Transportation_Report.pdf?hsCtaTracking=544e8e73-752a-40ee-b3a5-90e28d5f2e18%7C81c0077a-d01d-45b9-a338-fcaef78a20e7 (finding BEV heavy-duty trucks already hold a TCO advantage today and, for heavy-duty trucks, an EV advantage of $0.05/mi in 2020 that increases to $0.22/mi in 2030—magnified by the large number of miles traveled by this class of vehicles. In absolute terms, in 2020 this translates to a $42,800 TCO advantage of electric heavy-duty trucks, which increases to $200,000 in 2030. The TCO advantage of EVs continues to grow through 2050).

Organization: Zero Emission Transportation Association (ZETA)

i. Fuel and maintenance costs

EVs have fewer moving parts than their ICE counterparts, which makes them simpler to maintain and reduces the probability of a major malfunction. Reduced maintenance saves both time and money, particularly for fleet managers operating on tight margins. School districts, in particular, tend to lack the economic and labor resources to make repairs to their existing vehicles, thus making EVs a more attractive alternative. [EPA-HQ-OAR-2022-0985-2429-A1, p. 12]

A Class 8 electric truck costs 4.7 cents less per mile to maintain compared to its diesel counterpart and these maintenance savings alone can equate to thousands of dollars over the vehicle's lifetime.48 The EIA expects a 55% growth in total MHDV VMT between 2019 and 2050, largely driven by the rise of e-commerce.49 Due to HDVs' higher VMT and lower fuel economy, they stand to see significant cost savings from increased efficiency and lower dollar-per-mile costs with electrification. [EPA-HQ-OAR-2022-0985-2429-A1, p. 12]

EPA Summary and Response:

Summary:

EPA indicated at proposal that HD ZEVs would experience significant maintenance and repair savings relative to their ICE counterparts. This finding was based on the simpler design of ZEVs, notably absence of pistons and valves, and fewer moving parts in general. 88 FR 25986-87. Multiple commenters, such as Lion Electric, a producer of HD BEVs, Advanced Energy United, CARB, EDF (located in Section 2), MFN (located in Sections 2 and 23 of the RTC), RMI (located in Section 3.11 of the RTC), Tesla (citing sources in addition to those cited by EPA), and ZETA agreed that BEVs or ZEVs would have lower maintenance and repair costs.

Other commenters questioned EPA's finding, however. These commenters include the American Free Enterprise Chamber of Commerce (AmFree), Arizona State Legislature, Clean

Fuels Development Coalition, National Association of Chemical Distributors, and Valero. Both American Highway Users and Clean Fuels Development Coalition indicated that it would take two technicians rather than one to service an HD BEV. ATA and NADA said that mechanics will require safety training for ZEV maintenance and repair. Arizona State Legislature (located in Section 5 of the RTC) said that EPA did not estimate the cost or timetable for safety training. NACD noted that even finding a sufficient number of qualified technicians would be an issue, and Borg Warner commented that EPA should look at how the lack of qualified BEV technicians could impact TCO. Other commenters, such as ATA (see also Section 19 of the RTC), NADA (see also Sections 6 and 19 of the RTC), and TRALA (located in Section 19 of the RTC) said that maintenance facility upgrades will be needed in order to service ZEVs.

More basically, several of these commenters challenged the empirical basis for EPA's estimates. In HD TRUCS, ZEV maintenance and repair costs are estimated by first calculating the baseline diesel maintenance and repair costs which are based on equations in the BEAN model which are based on work by Burnham, et al.[335], and then by applying BEV and FCEV scaling factors based on Wang, et al.[336] The Arizona State Legislature noted that EPA was relying on a single source, which itself quoted a large range of potential values. Arizona Legislature noted a multi-year study of light duty electric motor vehicles which showed repair costs averaging 2.3 times that of ICE vehicles due to the longer diagnosis time and lack of qualified technicians. AmFree noted that the paper that EPA used to support the scaling factors for ZEVs (Wang et al., Estimating Maintenance and Repair Costs for Battery Electric and Fuel Cell Heavy Duty Trucks, University of California, Davis, 202) mentions limited data and uncertainty about maintenance cost comparisons. AmFree also notes that the degree of difference between diesel and BEV/FCEV maintenance and repair costs are critical to EPA's estimates of future sales. Other commenters, such as ATA and Valero mentioned concern about general levels of uncertainty.

Several commenters suggested that ZEV insurance rates would be higher due to higher costs for repairs due to workforce development and other factors. These comments are addressed in Chapter 3.8.2 of the RTC.

Several commenters also expressed concern about battery replacement costs or "midlife overhaul costs." These comments are addressed in Section 3.8.3 of the RTC.

DTNA commented that EPA should consider all available data including that which can be provided by manufacturers in confidential settings, and asserted that, given data available today is limited, EPA should re-evaluate its assumptions on this issue on a regular basis, using the best available data.

[335] Burnham, Andrew, David Gohlke, Luke Rush, Thomas Stephens, Yan Zhou, Mark A. Delucchi, Alicia Birky, Chad Hunter, Zhenhong Lin, Shiqi Ou, Fei Xie, Camron Proctor, Steven Wiryadinata, Nawei Liu, and Madhur Boloor. "Comprehensive Total Cost of Ownership Quantification for Vehicles with Different Size Classes and Powertrains". April 2021. Accessible online: https://publications.anl.gov/anlpubs/2021/05/167399.pdf.

[336]See Table 6 on page 17. Wang, et al." Estimating Maintenance and Repair Costs for Battery Electric and Fuel Cell Heavy Duty Trucks." February 2022. Available at: https://escholarship.org/content/qt36c08395/qt36c08395_noSplash_589098e470b036b3010eae00f3b7b618.pdf?t=r6zwjb.

Response:

Commenters did not dispute the fact that ZEV vehicles have fewer moving parts, which is typically indicative of fewer serviceable parts and fewer potential failures. Multiple cost assessment papers and the California Advanced Clean Fleets Regulation, Appendix G: Total Cost of Ownership,[337] use cost reduction factors for ZEV maintenance compared to internal combustion engine maintenance, and multiple commenters agreed with the assessment that ZEV maintenance and repair costs will be less expensive than those for internal combustion engines.

However, EPA agrees with commenters that there is some uncertainty in predicting cost reductions for maintenance and repair of ZEV heavy-duty vehicles before they are produced and operated at scale, since the available information about the costs for maintaining and repairing heavy-duty ZEV vehicles generally comes from pilot programs. A further uncertainty involves a potential need to retrain technicians to work on ZEVs. To address this concern EPA has phased in the ZEV cost reduction factors as discussed below.

The NPRM version of HD TRUCS calculated BEV maintenance and repair by applying a constant scaling factor of 71% to diesel vehicle maintenance and repair estimates for 2027 and beyond and calculated FCEV maintenance and repair by applying a constant scaling factor of 75% to diesel vehicle maintenance and repair estimates for 2030 and beyond. However, EPA agrees with some of the commenters that there may be a transition period during which costs for maintaining and repairing ZEVs will not yet be at their full savings potential due to the need to train more of the workforce specifically for ZEV maintenance and repair. To account for this period, EPA has phased in the ZEV scaling factors for maintenance and repair. As NACD pointed out, the Wang, et al.,[338] paper includes a range of cost reductions, for current and future battery electric and fuel cell trucks; therefore, for the version of HD TRUCS used for the final rule, instead of applying a single scaling factor for every year commencing in 2027 (for BEVs) or 2030 (for FCEVs) as at proposal, EPA is starting with a higher scaling factor and gradually decreasing it (i.e. gradually increasing the projected cost savings) over a 5-year period. The initial higher scaling factor comes from Wang et al. and reflects estimates for 2022. (See RIA Chapter 2.4.4.1 for more details on the phase-ins of the scaling factors for BEV and FCEV vehicles). EPA's approach of applying this factor commencing in 2027 or 2030 is consequently conservative given that technicians in those later years will be more experienced than they were in 2022.

The criticism that EPA used a single source to derive the scaling factors does not paint a full picture of EPA's selection of these values. EPA examined multiple papers with proposed scaling factors, see DRIA at 265 and sources cited in notes 93, 94 and 95, and selected the values in the Wang et al. paper because its methodology was supported by a ground up assessment of the

[337] See page G-20. California Advanced Clean Fleets Regulation, Appendix G: Total Cost of Ownership. Available at: https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2022/acf22/appg.pdf.

[338] See Table 6 on page 17. Wang, et al." Estimating Maintenance and Repair Costs for Battery Electric and Fuel Cell Heavy Duty Trucks." February 2022. Available at: https://escholarship.org/content/qt36c08395/qt36c08395_noSplash_589098e470b036b3010eae00f3b7b618.pdf?t=r6zwjb.

differences in BEV, FCEV and diesel components, and the cost reduction (scaling factor) values in the paper fell within the range of other suggested scaling factor values in the literature.[339]

Regarding the maintenance and repair cost savings estimates themselves (as opposed to costs relating to service technicians), as noted in the comment summary above, the diesel M&R costs in HD TRUCS were developed from two equations in the BEAN model that were based on curves in the Burnham, et.al.[340] paper: one equation for semi-tractors, which EPA used for long haul tractors, and another equation based on box trucks, which EPA used for all vocational vehicles and for short-haul tractors. The box truck equation has a higher slope and intercept than the semi-tractor which means that the HD TRUCS vocational vehicle and short haul tractor diesel maintenance costs per mile (and therefore also the ZEV M&R savings per mile) were much higher than the long-haul tractors M&R costs (and savings) per mile.

Even though EPA did not receive any comments that specifically challenged the underlying diesel M&R estimates, EPA chose to take a conservative approach for the final HD TRUCS M&R savings calculations by using the semi-tractor equation for calculating diesel maintenance and repair costs per mile for all vehicles. This change reduced the overall maintenance cost estimates for diesel vehicles, which in turn reduces the overall savings from ZEV M&R, since the savings values are estimated as a cost reduction from the diesel maintenance and repair values. Lowering the diesel maintenance and repair costs, along with phasing in the ZEV scaling factors, together resulted in a substantial reduction in ZEV maintenance and repair savings estimates between the NPRM and the final rule. As such, this change further addresses the uncertainties associated with future ZEV maintenance and repair costs.

The article cited by the Arizona State Legislature from Kelly Blue Book[341] refers to an analysis of light-duty, not heavy-duty, vehicles.[342] While this article says that a predictive analytics firm, We Predict, found that EVs "cost more to repair than their gasoline engine counterparts," that article also states that that "EVs cost less in maintenance because they have fewer regular maintenance procedures." The reason it finds that EVs are more expensive is because technicians are spending more time working on EVs than they are on gasoline cars, and that those technicians cost more per hour. As noted earlier in this response above, EPA understands that costs for servicing ZEVs may be more expensive in the very near term than they will be once technicians are retrained and have gained some experience; EPA expects the service technician workforce to transition to a workforce that has the skills and experience needed to

---

[339] NACD stated, mistakenly, that EPA's citation to Wang et al. in the DRIA (at 265 n. 96 and at 269 n. 139) refers back to a broken link. NACD refers to this paper as "Wang, G. et. al., White Paper: The Current and Future Performance and Costs of Battery Electric Trucks: A Review of Key Studies and a Detailed Comparison of their Cost Modeling Scope and Coverage, National Center for Sustainable Transportation, June 7, 2022." In fact, EPA cited (and utilized) Wang et al. "Estimating Maintenance and Repair Costs for Battery Electric and Fuel Cell Heavy Duty Trucks (2022). The links in the DRIA are functioning. See docket number EPA-HQ-OAR-2022-0985-0681.

[340] See page 91. Burnham, Andrew, David Gohlke, Luke Rush, Thomas Stephens, Yan Zhou, Mark A. Delucchi, Alicia Birky, Chad Hunter, Zhenhong Lin, Shiqi Ou, Fei Xie, Camron Proctor, Steven Wiryadinata, Nawei Liu, and Madhur Boloor. "Comprehensive Total Cost of Ownership Quantification for Vehicles with Different Size Classes and Powertrains". April 2021. Available at: https://publications.anl.gov/anlpubs/2021/05/167399.pdf.

[341] Tucker, Sean. "Study: EVs Cost More to Repair, Less to Maintain." Kelly Blue Book. Aug. 17, 2021. Available at: https://www.kbb.com/car-news/study-evs-cost-more-to-repair-less-to-maintain/.

[342] Heavy-duty ICE vehicle maintenance and repair may have some correlation with light-duty maintenance and repair, but the comparison does not consider the maintenance and repair costs of diesel engine and exhaust aftertreatment systems which are greater than the costs associated with light-duty vehicles maintenance and repair.

service ZEVs.[343] The Kelly Blue Book article supports EPA's expectation: the article states that, "The cost issue may fade as EVs become more common" and quoted We Predict "believes that EVs may prove less expensive in the long run." The article goes on to quote the We Predict CEO, James Davies: "The cost of keeping the vehicle in service for the EV, even as the EV gets older, becomes smaller and smaller and actually less than keeping an ICE [internal combustion engine] vehicle on the road, …That's not just maintenance costs, but all service costs."[344] EPA is not aware of any large datasets tracking heavy-duty ZEV maintenance and repair, and commenters who disputed maintenance and repair savings estimates did not supply any comprehensive heavy-duty ZEV maintenance and repair data for the industry as a whole. As described above, EPA phased in the scaling factors in HD TRUCS to address the near-term uncertainty of costs for heavy-duty ZEV maintenance and repair.

While commenters, such as NADA, expressed concerns about facility upgrade costs for some dealers, NADA also acknowledges that facility upgrades will vary significantly, and NADA did not provide supporting details for numeric inputs into the range of costs they asserted in their comments for EPA to evaluate or an estimate as to what proportion of dealers would see higher versus lower costs. EPA agrees that when new products are introduced dealers may encounter new costs. EPA accounts for dealer costs in the retail price equivalent (RPE) multipliers in assessing the costs of the rule. EPA's heavy-duty RPE factor for "Dealer new vehicle selling costs" includes a 6% markup over manufacturing cost for dealer costs, and EPA's assessment is that this appropriately addresses the costs identified by NADA that are associated with the final rule. Importantly, these costs discussed in RIA Chapter 3 are in addition to the costs incurred by dealerships prior to the commencement of this rule, the latter of which we view as not appropriately separated in NADA's general comment on this issue and which are not costs of the final rule. As shown in Section V.A.1 of the preamble, the reference case includes ZEV adoption that is projected to occur absent this final rulemaking. The ZEV adoption that has been occurring in the heavy-duty sector since MY 2021 drove the need for some dealers to already invest in facility modifications to accommodate ZEVs. Also, additional dealers will see ZEV sales, including beginning in 2024 as the first year of the ACT program begins in states, so they also will be investing separate from this final rule. Furthermore, the costs associated with significant build-out of infrastructure, such as new transformers, are not anticipated because a dealer would not need the number of EVSE installations that a fleet with a large number of vehicles at a depot that are charged simultaneously would need. (Indeed, as shown in our analysis of grid distribution impacts at the level of high-traffic freight corridors and localized parcels, we do not project the Phase 3 rule as resulting in significant buildout needs even for such depots. See RTC section 7 (Distribution.). We also have included grid infrastructure distribution costs, such as these, in our electricity prices in our analysis. See RIA Chapter 2.4.4.2.

EPA has carefully considered information made available to EPA. As further explained in preamble Sections I and II, in setting future emission standards under our CAA section 202(a)(1)-(2) authority, given the prospective nature of the factors Congress directed EPA consider, EPA must necessarily identify potential technologies, evaluate the rate each technology could be introduced, and project associated cost of compliance. Thus, while we acknowledge that

[343] For example, APTA has already developed and published recommended practices for Zero-Emission Bus Maintenance Training. See https://www.apta.com/wp-content/uploads/APTA-BTS-ZBT-RP-001-23.pdf.
[344] Tucker, Sean. "Study: EVs Cost More to Repair, Less to Maintain." Kelly Blue Book. Aug. 17, 2021. Available at: https://www.kbb.com/car-news/study-evs-cost-more-to-repair-less-to-maintain/.

future projections inherently are subject to uncertainties, EPA has carefully analyzed the uncertainties and identified the considerations we found persuasive. Consistent with our standard setting authority the analysis EPA conducted for this final rule appropriately makes use of the best data available to us, as described in RIA Chapter 2.

Comments on both BEV and FCEV safety and comments about the need for two service technicians rather than one for BEV maintenance and repair are addressed in Section 4.8 and 5.2 of the RTC.

Comments on infrastructure and EVSE maintenance are addressed in Section 6 of the RTC.

Comments related to economic impacts are addressed in Section 19 of the RTC.

3.8 Additional Costs

3.8.1 Other Costs

Comments by Organizations

Organization: American Fuel and Petrochemical Manufacturers (AFPM)

EPA also fails to account for infrastructure impacts from increased operation of heavier ZEVs on the road including road and bridge deterioration and commensurate reduced funding for infrastructure from fuel tax collections as EPA fails to account for the fact that ZEVs do not pay federal and state liquid transportation fuel taxes. [EPA-HQ-OAR-2022-0985-1659-A2, p. 30]

Organization: American Highway Users Alliance

Further, the lengthy NPRM and its lengthy draft Regulatory Impact Analysis (RIA) do not appear to include any consideration of the adverse impacts of the proposal on revenues flowing to the Highway Trust Fund (HTF) and resulting Federal highway infrastructure investment. The proposed rule in this docket seeks to accelerate a shift from the public's use of internal combustion engine (ICE) vehicles to electric vehicles (EVs). A substantial erosion of revenue into the HTF would result,3 placing major downward pressure on needed highway and bridge investment, which already faces an investment backlog of $786 billion per USDOT's latest 'Conditions and Performance Report.' Moreover, that $786 billion estimate was developed before recent significant inflation. [EPA-HQ-OAR-2022-0985-1550-A1, pp. 2-3]

3 The draft RIA includes a brief reference (page 429) that, under the proposed rule, fuel consumption would be 'reduced.' Fuel sales, which are subject to a Federal excise tax, generate the largest share of HTF revenue.

Failure to Consider Adverse Impact on Highway Investment

As noted earlier, the lengthy NPRM and its draft Regulatory Impact Analysis do not evidence any consideration of the adverse impacts of the proposal on revenues flowing to the Highway Trust Fund (HTF) and resulting Federal highway infrastructure investment. For decades, the largest source of Federal transportation infrastructure funding has been the HTF, which is largely dedicated to highway funding distributed to states. The proposed rule in this docket seeks to accelerate a shift from the public's use of ICE vehicles to EVs or other alternate fueled vehicles, or more fuel-efficient ICE vehicles. A substantial erosion of revenue into the HTF would result, placing major downward pressure on needed highway investment, which already faces an investment backlog of $786 billion per USDOT's latest 'Conditions and Performance Report.' [EPA-HQ-OAR-2022-0985-1550-A1, p. 8]

Moreover, that backlog estimate was developed before recent inflation of 50% or more just from Q1 2021 to Q3 2022 in the Federal Highway Administration's (FHWA's) highway construction cost index. That index also shows significant inflation from 2017 through the third quarter of 2022 – approximately 72%.7 EPA must reconsider what it proposes after seriously weighing, among other issues noted, the impact of the proposal on the HTF and highway investment, particularly given all of the benefits from those investments for highway safety and the economy. [EPA-HQ-OAR-2022-0985-1550-A1, p. 8]

7 For the NHCCI see – https://explore.dot.gov/views/NHIInflationDashboard/NHCCI?%3Aiid=1&%3Aembed=y&%3AisGuestRedirectFromVizportal=y&%3Adisplay_count=n&%3AshowVizHome=n&%3Aorigin=viz_share_link. The last entry for 2022 is an index reading of 2.786 (with 2003 as 1.000), while the index was at 1.62 at the start of 2017 (thus, an increase of 72% since the start of 2017).

Organization: Daimler Truck North America LLC (DTNA)

There are a number of TCO Inputs that EPA has not accounted for. [EPA-HQ-OAR-2022-0985-1555-A1, p. 34]

There are a number of TCO inputs that EPA has not accounted for in the HD TRUCS tool that should be included to more accurately inform payback periods and adoption rate projections for the Proposed Rule, including:

- Federal Excise Tax. As explained in Section I.B.4 of these comments, the FET adds 12% to the first retail sale of all new HD trucks, truck trailers, semitrailers, and tractors. Because of their higher upfront incremental cost, ZEV purchases will be subject to a significantly higher FET than conventional vehicle purchases. EPA should thus include FET in the HD TRUCS calculation because it impacts TCO. [EPA-HQ-OAR-2022-0985-1555-A1, p. 34]
- State Sales Tax. State sales tax is also applied to the purchase price of HDVs. Again, due to the higher incremental upfront cost of ZEVs, fleets will pay a significantly higher state sales tax on the purchase of an HD ZEV as compared to the tax paid on a conventional HDV purchase. To reflect these costs, EPA should apply an average state sales tax of approximately 5.5% in the HD TRUCS tool. [EPA-HQ-OAR-2022-0985-1555-A1, p. 34]
- State ZEV Registration Fees and Per-Mile Taxes. As described in more detail below in Section II.b.3.e, in recent years a number of states seeking to recoup gasoline tax revenues that are declining with increased ZEV uptake have enacted measures to impose extra registration fees or per-mile taxes on ZEV owners. EPA should ensure that these costs are captured in the HD TRUCS tool, especially as they become more widespread and are adopted by new states.62 [EPA-HQ-OAR-2022-0985-1555-A1, p. 35]

62 See National Conference of State Legislatures, 'Special Fees on Plug-In Hybrid and Electric Vehicles' (March 27, 2023), available at https://www.ncsl.org/energy/special-fees-on-plug-in-hybrid-and-electric-vehicles.

Organization: Dana Incorporated

Speculative Residual Resale Values

Residual values are essential when fleets determine their expected total cost of ownership (TCO) on new vehicles. Residual equipment values affect buying, financing, and leasing decisions for fleets. Far ZEVs, it is becoming a prevalent issue for their wide-scale adoption both in the initial and aftermarket applications. However, EPA should not include residual value estimates in its TCO and payback period estimations at this time. Any market valuation forecasts are speculative at this stage without a guarantee of the residual resale values for ZEVs for the transitional period. An overstatement/understatement of resale values will have an impact on adoption rates. [EPA-HQ-OAR-2022-0985-1610-A1, p. 2]

Organization: National Automobile Dealers Association (NADA)

1. State sales and FET taxes

In assessing payback periods, EPA has neglected to account for FET and state sales taxes. These taxes are additional costs levied on new HDV purchases. Because they are based on a percentage of an HDV's sales price, they are necessarily higher for ZEV HDVs due to their higher upfront costs. The chart below provides a real-world price comparison illustrating how FET and sales taxes compare across ZEV HDVs and comparable ICE HDVs. In this example, an average 5% state vehicle sales tax12 was used with Class 8 HDVs subject to an additional 12 percent FET. [EPA-HQ-OAR-2022-0985-1592-A1, p. 7.] [See Docket Number EPA-HQ-OAR-2022-0985-1592-A1, page 7, for referenced chart.]

12 Rachael Brennan, Auto tax rate by state, POLICYGENIUS (Jan. 20, 2023).

Throughout its regulatory impact analysis, EPA relies heavily on provisions arising from the IRA and the Infrastructure Investment and Jobs Act (IIJA) to promote ZEV HDV market growth. ATD believes that, in reality, these ambitious pieces of legislation will have limited impact on the adoption of ZEV HDVs. For example, the maximum $40,000 IRC Section 45W Clean Commercial Vehicle Tax credit is likely to be more than offset by the FET on a Class 8 ZEV tractor. Moreover, EPA incorrectly assumes that manufacturers will pass on all of the BEV manufacturing tax credits they receive in the form of lower ZEV HDV pricing. [EPA-HQ-OAR-2022-0985-1592-A1, p. 7]

2. Resale values

Resale value and vehicle depreciation is a key factor in determining HDV TCOs and first purchaser behaviors. ATD submits that the Phase 3 proposal fails to consider the impact of resale values. Resale values are based on the work a vehicle is capable performing and the expected maintenance and repair costs for a given period. Currently, there is no established resale history for ZEV HDVs. As a result, most dealerships and new HDV customers are conservatively factoring in the resale value as zero for purposes of their TOC calculations. HDV tractors typically have a 3-5 year trade cycle and HDV trucks range from 7-10 for most operations. Any reduction in resale value ultimately negatively impacts the TCO for first owners and increases payback periods. Consequently, first owners/adopters will be cautious when considering the purchase of ZEV HDVs. [EPA-HQ-OAR-2022-0985-1592-A1, pp. 7 - 8]

3. Charging rates and charging downtime

A common phrase is the commercial truck space is – “Trucks that don’t move don’t make money.” EPA ignores this reality when it points to savings from lower fuel, DEF, and maintenance costs but fails to account for the costs associated with the necessary downtime for ZEV HDV charging. It appears that EPA assumes all ZEV HDVs will return to a centralized location to recharge for 12 hours overnight. This is unrealistic. For example, many HDVs drive exclusively at night to avoid traffic or operate with multiple duty cycles each day. These HDVs will incur significant charging and downtime costs, especially if Level 2 chargers are used.13 [EPA-HQ-OAR-2022-0985-1592-A1, p. 8]

13 According to the U.S. DOT the estimated BEV charge time from empty on a Level 2 charger is 4 – 10 hours and the estimated range added per hour of charging is 10 – 20 miles. Charger Types and Speeds, U.S. DOT (May 4, 2023).

4. Recommendations

ATD recommends that EPA act as follows:

- Work with EMA and its members to determine the appropriate assumptions, data, and calculations that should be included in HD TRUCS related to the price, feasibility, and timelines of technology packages and related components.
- Factor in FET and sales taxes, resale values, and charging-related downtime to more accurately determine HDV ZEV purchaser costs and related payback periods.
- Work with HDV fleet and owner/operators to ensure the accuracy of purchaser costs.

The above recommendations serve as a starting point. EPA must revise HD TRUCS to include additional and more accurate data points using feedback from stakeholders. These revisions must be reflected in the final Phase 3 GHG rule to help accurately forecast realistic payback periods and adoption rates. [EPA-HQ-OAR-2022-0985-1592-A1, pp. 8.]

Organization: PACCAR

In addition, as electric-powered trucks displace diesel-powered trucks, they will also displace the transportation infrastructure-funding model that currently relies on revenue from diesel fuel taxes. As the diesel fuel-based tax base decreases, governments will need to replace that revenue, possibly through increased vehicle registration costs, but more likely by taxing energy flow through chargers. Although EPA specifically included state and federal diesel taxes in fuel costs, the Agency did not account for the inevitable corollary tax on charging costs for electrically powered vehicles needed to maintain transportation infrastructure tax revenue. EPA should therefore revise its TRUCS assumptions accordingly to take into account taxes on energy flow charging costs. [EPA-HQ-OAR-2022-0985-1607-A1, p. 8]

Organization: POET

EPA’s comparative cost analysis for ZEVs themselves also fails to address several important factors. As the Trinity report has identified, EPA compares powertrain, fuel, and maintenance costs of conventional vehicles and heavy-duty ZEVs, assumed to be incurred over the first ten years of those vehicles’ lifetimes.70 That limited list ignores other important costs:

- Resale value;
- Costs associated with vehicle downtime due to inoperability, repair, and recharging/refueling.71 [EPA-HQ-OAR-2022-0985-1528-A1, p. 17]

70 Attachment A at 5.

71 Id. at 6.

Organization: Truck and Engine Manufacturers Association (EMA)

Federal Excise Tax (FET) and State Vehicle Sales Tax – These two additions to the EMA HD TRUCS tool were run in parallel. For this scenario, the FET is set at 12% and the average State vehicle sales tax is set at 5.02%. The resultant revised adoption rates are in the table below: [EPA-HQ-OAR-2022-0985-2668-A1, p. 38. See the Projected ZEV Adoption Rates for MYs 2027 and 2032] [State Sales Tax Table on page 38 of docket number EPA-HQ-OAR-2022-0985-2668-A1.]

c) Additions

In the course of our analysis of HD TRUCS, EMA also identified three significant elements that EPA failed to include as inputs to the Agency's payback and adoption rate calculations: federal excise taxes, state vehicle sales taxes, and insurance cost differentials. EMA recommends that all three of these elements be incorporated into the HD TRUCS for the final rulemaking. These additions are included in EMA's HD TRUCS tool. [EPA-HQ-OAR-2022-0985-2668-A1, p. 30]

The incorporation of the additional elements required modifications to the HD TRUCS tool. Columns of data were added to several worksheets in order to create the needed calculations and to display summary data, as was done by EPA in HD TRUCS. Numerous equations in Excel were modified to include the new data elements. The Payback macro on the Summary worksheet was revised to account for the added columns of data on specific worksheets. Where possible, the columns added and altered in the spreadsheets were changed using red text to help denote the affected content of the tool. [EPA-HQ-OAR-2022-0985-2668-A1, p. 30]

Federal Excise Tax – Federal law requires that a 12% excise tax be applied to the purchase of all Class 8 vehicles, based on the purchase price of the vehicle. For HD TRUCS, this tax was not included. EMA recommends that the 12% tax be included on the difference between the ICE powertrain cost and the corollary ZEV powertrain cost for each vehicle type. Where the ZEV is more expensive than the ICE powertrain, the FET will add to the purchase costs for the owner. In years where the ZEV may be less expensive than the ICE, especially in the later years of the Phase 3 proposed regulation, the FET differential will reduce the overall purchase price for the owner. It should be noted that the FET only applies to Class 8 vehicles. [EPA-HQ-OAR-2022-0985-2668-A1, pp. 30 - 31.]

State Vehicle Sales Tax – Each state is allowed to collect a tax on the sale of any vehicle within that state. Most states have a declared vehicle sales tax, while a few do not. Research shows that the average State vehicle sales tax is currently 5.02%. The table below shows the vehicle sales tax for each state. EMA recommends that the state vehicle sales tax be included in the final version of HD TRUCS. It should be noted that the state vehicle sales tax applies to all classes of vehicles. [EPA-HQ-OAR-2022-0985-2668-A1, p. 31. See the State Vehicle Sales Tax table on pages 31-32 of docket number EPA-HQ-OAR-2022-0985-2668-A1.]

b) Residual / Resale Value – The Phase 3 regulation fails to consider the cost impact that the first owner may experience when a ZEV is sold on the secondary market. Tractors typically have a 3-5 year trade cycle. Truck trade cycles range from 7-10 years in most operations. At the time of resale, the value of the vehicle is defined either by the leasing company, through the residual value in the lease contract, or by the value that the next purchaser pays for the vehicle. That value is based on the work the vehicle is capable of doing for a given time period, and the expected maintenance and repair costs that can be anticipated during its second life. The replacement cost of a BEV battery set, if needed, will be substantial as a service item. [EPA-HQ-OAR-2022-0985-2668-A1, p. 48]

Since there is no established resale history for BEV trucks, the secondary market for BEV trucks is most likely to be highly cautious in its assessment of future residual value and costs. That could work to decrease the value of a BEV truck in the secondary market versus its equivalent diesel vehicle. The reduction in resale value negatively impacts the TCO for the first owner, thus increasing the payback period and reducing the willingness of first owners to adopt the BEV technology and to purchase the ZEV. [EPA-HQ-OAR-2022-0985-2668-A1, p. 48]

These trade cycle effects and secondary market values are not considered in the current version of HD TRUCS (and are ignored in EPA's misuse of ACT's payback-based adoption rates). EMA recommends that these effects also be factored into the final rulemaking version of HD TRUCS. [EPA-HQ-OAR-2022-0985-2668-A1, p. 48]

Organization: Valero Energy Corporation

3. EPA fails to account for key BEV and FCEV cost considerations in its payback analysis.

In the DRIA, EPA states that

"Given the wide range of diversity in the trucking industry, HD TRUCS analyzes a vehicle's operation during the first 10 years of ownership. We selected 10 years to include high mileage years and to reflect changes in maintenance and repair costs over time, since vehicle use (measured in VMT) and operating costs can change over the course of ownership and as a vehicle ages."36 [EPA-HQ-OAR-2022-0985-1566-A2, p. 8]

36 DRIA at 116.

While EPA believes that "the payback period is the most relevant metric to determine adoption rates in the HD vehicle industry,"37 the agency's total cost of ownership payback analysis fails to consider significant costs relative to BEVs and FCEVs, specifically costs related to battery/fuel cell stack replacement, resale value, repairs, insurance premiums, and motor vehicle accidents. [EPA-HQ-OAR-2022-0985-1566-A2, p. 8]

37 EPA's HD Phase 3 GHG Proposal at 25991-25992.

While EPA considers fuel saving as a component of the total cost of ownership for BEVs in an effort to portray BEV's as being cost competitive, or even advantageous versus their ICE counterparts, EPA fails to properly address insurance and depreciation, claiming they excluded them based on the unsupported and incorrect assumption that these costs are similar for BEVs and ICE vehicles.38 [EPA-HQ-OAR-2022-0985-1566-A2, p. 8]

Regarding resale value, EPA fails to consider the resale value disparity between HD ICEVs and HD BEVs/FCEVs. Even if the original owner of a ZEV is able to avoid having to replace a battery or fuel cell stack, a potential secondary owner would rightfully have serious reservations about buying a used HD BEV or FCEV versus a used HD ICEV. This uncertainty is likely to affect inventory values for fleets, which in turn may have consequences for financing. [EPA-HQ-OAR-2022-0985-1566-A2, p. 9]

Reducing reliance of liquid fuels will also lead to a direct decrease in both federal and state excise tax revenues from gasoline and diesel, as has been demonstrated in the numerous states that have already adopted ZEV mandates.228 This, in turn, will decrease state and federal funding for construction and maintenance of transportation infrastructure in the US, which is primarily funded from these tax revenues.229 Thus, not only will ZEV centric policy destroy the domestic production of asphalt used primarily for road construction and repairs, it will also lead to a precipitous decline in each state's ability to pay for road maintenance. [EPA-HQ-OAR-2022-0985-1566-A2, p. 47]

228 See Berkeley Research Group, Policy Briefs, The Effect of Zero-Emission Vehicle Policies on Dedicated Highway Infrastructure Funding in Maryland, Minnesota, New Jersey, Nevada, New York, Oregon, and Virginia, available at https://www.thinkbrg.com/insights/publications/effect-of-zev-policies-on-dedicated-highway-infrastructure-funding/.

EPA Summary and Response:

Summary:

Several commenters raised concerns about costs that were not included in the HD TRUCS model. These concerns include Federal Excise Tax (DTNA, EMA, NADA); State Sales Tax (DTNA, EMA, NADA); BEV component replacement costs (which purportedly will be higher for BEVs than for ICEVs) (TRALA, Valero); lower resale value (Dana, EMA, NADA, Valero, POET); costs associates with downtime for repairs (POET); additional cost due to vehicle accidents (Valero); more rapid depreciation (Valero); additional costs to account for charging during the work day (NADA, POET); additional state taxes to replace lost gasoline and diesel tax revenue, and state ZEV registration fees (AFPM, AHUA, PACCAR, DTNA, Valero).

Response:

Based on comments received and further analysis, as explained in RIA Chapter 2, we have added certain additional costs in HD TRUCS that are affected by the incremental purchase price differences of ZEVs and ICE vehicles. Our assessment is that these costs will be factored into purchasing decisions and are therefore appropriate to consider in our analysis of payback period for the final rule. Commenters correctly stated that EPA did not consider federal excise tax, state sales tax, and ZEV-specific registration fees at proposal, and EPA has accordingly added consideration of these three costs in HD TRUCS for the final rule. Please see Chapter 2 of the RIA for more information about these costs. As discussed in Section 3.8.2 of the RTC, we have also included consideration of incremental insurance costs (as part of annual operating costs).

Regarding comments on component replacement costs and costs associated with downtime for repairs, in both the proposal and final rule we have included the cost of vehicle maintenance and repair, which includes costs for maintenance components for both ICE and ZEV vehicles. We do not expect maintenance downtime to be greater for ZEV vehicles than for ICE vehicles; additionally, ZEVs will generally need less maintenance than ICE vehicles, as discussed in Section 3.7 of the RTC. For further discussion on our M&R analysis see RIA Chapter 2.4.4.1 and the previous comment response in section 3.7.

For a discussion of our change in approach from proposal for battery replacement in the final rule, see Section 3.8.3 of the RTC.

While commenters have pointed out that there is limited information on the resale of HD ZEVs, concerns regarding adequate information to project resale values and future ZEV resale values being lower than comparable ICE vehicles are addressed through our payback calculations and analysis approach. In our payback analysis, we have only included ZEV technologies in our technology packages that pay back within their typical first ownership period and therefore resale value does not impact this analysis. In other words, even if hypothetically the resale value of the BEV powertrain is $0 (which is obviously not a reasonable assumption for a ZEV during the timeframe of the Phase 3 standards), we project that ZEVs will pay back within their first ownership period (and so the purchaser will have recovered the equivalent of their upfront purchase cost before taking into account any resale value). Additionally, for the final rule, we have conducted a supplemental TCO analysis that includes the impact of residual value as a proxy for resale value. The results from our TCO analysis (RIA Chapter 2.12) show that the costs for owning and operating a ZEV will be lower than a comparable ICE vehicle for all MY 2032 BEVs and FCEVs in our technology packages to support the modeled compliance pathway when evaluated over a five-year time horizon including the impact of residual value. RIA Chapter 2.7.1 discusses in more detail our preference in using payback years over total cost of ownership in our assessment of feasibility of ZEV adoption in our modeled potential compliance pathway (although both metrics support the feasibility of the standards). We also note that there is uncertainty as to how future technological advances will affect the resale value of ICE vehicles; it is reasonable to expect that as purchasers become more used to ZEVs and realize the considerable operational savings, that may also reduce the resale value of ICE vehicles.

As for additional costs due to motor vehicle accidents for the final rule, we have addressed the incremental difference in costs of a vehicle accident through accounting for incremental insurance costs for both ICE and ZEV technologies. HD vehicles are generally insured for accidents, and insurance companies account for the cost of paying out claims in pricing their plans. Thus, we find that accounting for insurance costs reasonably reflects the costs for motor vehicle accidents. See Section 3.8.2 of this RTC for further discussion on ZEV insurance premiums and RTC Section 4.8 for further discussion on the safety of ZEVs.

We do not think it is appropriate to include an additional cost for opportunity charging for electric vehicles. In our analysis for the final rule, we have sized the batteries for the majority of vehicles to perform a single day's worth of work on a single charge, such that the vehicle would be recharged during its typical downtime (dwell period). With respect to the eight BEV types in HD TRUCS for which we project en-route charging in our modeled compliance pathway (these include tractors and coach buses), we have sized the battery of the mid-and long-range tractor vehicle types such that they can be driven the 50^{th} percentile daily VMT on one charge. For the longest range day cabs and sleeper cabs, on days when these vehicles are required to travel longer distances, we find that less than 30 minutes of mid-day charging at 1 MW is sufficient to meet the HD TRUCS 90th percentile VMT assuming vehicles start the day with a full battery). For further discussion on en-route charging see RTC Section 4 and RTC Section 3.3.4 and RIA Chapter 2.6.3. For an explanation of our projected costs for en-route charging, please see RIA Chapters 2.4.4.2 and 2.6.3.

For the final rule analysis, we have also included a cost for state registration fees that are specific to ZEVs. At this time, 18 states do not have any additional registration fee for ZEVs. For the states that do, the registration fees are generally between $50 and $225 per year.[345] While EPA cannot predict whether and to what extent other states will enact ZEV registration fees, we have nonetheless conservatively added an annual additional registration fee to all ZEV vehicles in our HD TRUCS analysis. Regarding lost state fuel tax revenue, see our response in RTC section 2.

Issues of additional cost relating to electrification infrastructure are addressed in Section 6 and 7 of this RTC.

3.8.2 Insurance

<u>Comments by Organizations</u>

Organization: American Fuel and Petrochemical Manufacturers (AFPM)

Yet EPA has not considered this interaction, on safety directly or the associated increase in insurance costs,51 which is all the more critical to the Proposed Rule as commercial trucks are involved in 13 percent of all fatal crashes on U.S. roadways and these trucks will be heavier and faster under the Proposed Rule.52

> 51 Jason Metz & Michelle Megna, Electric Car Insurance: Why It Costs More (Jan. 4, 2023), https://www.forbes.com/advisor/car-insurance/electric-vehicle/ (explaining that electric vehicles are costlier to insure)
>
> 52 U.S. DOT, Federal Motor Carrier Safety Administration, “2020 Pocket Guide to Large Truck and Bus Statistics,” available at https://www.fmcsa.dot.gov/sites/fmcsa.dot.gov/files/2020-10/FMCSA%20Pocket%20Guide%202020-v8-FINAL-10-29-2020.pdf.

EPA also fails to account for the massive increase in insurance costs that must occur when significantly more expensive vehicles are mandated to be on the road, particularly when they are vehicles that insurance companies frequently “total”, i.e., scrap, after low-impact crashes due to liability concerns associated with battery fires. [EPA-HQ-OAR-2022-0985-1659-A2, p. 30]

Organization: Arizona State Legislature

Insurance claims data includes similar findings. A study found repairing mid-size and luxury-brand SUVs cost 53% more for electric vehicles than comparable gas-powered vehicles, and

[345] National Conference of State Legislatures. “Special Fees on Plug-In Hybrid and Electric Vehicles” March 2023, Available at: https://www.ncsl.org/energy/special-fees-on-plug-in-hybrid-and-electric-vehicles.

27% more for small, non-luxury electric vehicles.27 The study found that electric vehicles had more expensive driver assistance system sensors that were more likely to be damaged in a collision, heavier battery packs that resulted in collisions with greater momentum as well as more expensive materials to offset battery weight, and battery pack removal and reinstallation in order to spray paint.28 [EPA-HQ-OAR-2022-0985-1621-A1, p. 24]

27 Jim Henry, Repairing an Electric Vehicle Could Cost More Than Gasoline Cars: A New Kind of Sticker Shock, FORBES, July 25, 2022, available at https://www.forbes.com/sites/jimhenry/2022/07/25/repairing-an-electric-vehiclecould-cost-more-than-gasoline-cars-a-new-kind-of-sticker-shock/?sh=17c649ff5eee.

28 Id.

Organization: Clean Fuels Development Coalition et al.

Insurance costs: Electric vehicles are more costly to insure than conventional vehicles both because they have a higher upfront sticker cost and "because of higher repair and replacement costs for damaged parts."

Mark Rosanes, Do Electric Vehicles Cost More to Insure Than Gasoline-powered Cars?, Insurance Business (Oct. 28, 2022), https://www.insurancebusinessmag.com/us/news/auto-motor/doelectric-vehicles-cost-more-to-insure-than-gasolinepowered-cars-425631.aspx; see also Benjamin Preston, Electric Vehicles May Cost More to Insure Than Gasoline-Powered Cars, Consumer Reports (Apr. 27, 2023), https://www.consumerreports.org/money/carinsurance/electric-vehicles-cost-more-to-insure-than-gasoline-powereda6372607024. [EPA-HQ-OAR-2022-0985-1585-A1, p. 6]

Organization: Daimler Truck North America LLC (DTNA)

There are a number of TCO Inputs that EPA has not accounted for. [EPA-HQ-OAR-2022-0985-1555-A1, p. 34]

There are a number of TCO inputs that EPA has not accounted for in the HD TRUCS tool that should be included to more accurately inform payback periods and adoption rate projections for the Proposed Rule, including:

- Increased Insurance Premiums. Because the cost to purchase and replace an HD ZEV is higher than such costs for a conventional vehicle equivalent, EPA should account for the increased premiums that fleets will likely have to pay to insure their vehicles. DTNA does not have data that could be used to estimate these increases, but recommends EPA work with fleets to understand the increased cost of ZEV insurance. [EPA-HQ-OAR-2022-0985-1555-A1, pp. 34-35]

Organization: POET

EPA's comparative cost analysis for ZEVs themselves also fails to address several important factors. As the Trinity report has identified, EPA compares powertrain, fuel, and maintenance costs of conventional vehicles and heavy-duty ZEVs, assumed to be incurred over the first ten years of those vehicles' lifetimes.70 That limited list ignores other important costs:

- Vehicle insurance costs;

Organization: Truck and Engine Manufacturers Association (EMA)

Insurance Cost Differential – The average insurance rate of 3% was run in the EMA tool to calculate the impact of annual insurance costs based on the difference in powertrain costs between an ICE vehicle and the corollary ZEV for each truck type and year. Below are the results from that model run: [EPA-HQ-OAR-2022-0985-2668-A1, p. 38] [See the Projected ZEV Adoption Rates for MYs 2027 and 2032, Insurance Table on page 38 of docket number EPA-HQ-OAR-2022-0985-2668-A1.]

We expect fueling and charging costs and [maintenance and repair] costs to be different for ZEVs than for comparable diesel-fueled ICE vehicles, but we do not anticipate other operating costs, such as labor and insurance, to differ significantly, so the following subsections focus on [maintenance and repair] and fueling or charging costs. (Draft RIA, p. 162) [EPA-HQ-OAR-2022-0985-2668-A1, p. 32]

The percentage charged for insurance on commercial vehicles is determined by a variety of factors and will vary depending on the size of the fleet. ICCT in their April 2023 white paper on ZEV TCO (p.17), uses what they feel is an average insurance rate of 3% for determining annual insurance cost. OEMs have provided data of higher rates that their customers pay, but EMA believes the ICCT value of 3% is directionally correct for this rulemaking. As with taxes, some ZEV-truck types in certain years will carry insurance differential costs that add to the annual operating cost of the vehicle, and in other years, this factor will result in a cost reduction. [EPA-HQ-OAR-2022-0985-2668-A1, pp. 32 - 33]

As such, EMA recommends that differential insurance costs be included in the annual operating cost for the final rulemaking assessment based on the powertrain differential cost calculated in HD TRUCS. [EPA-HQ-OAR-2022-0985-2668-A1, p. 33]

Organization: Truck Renting and Leasing Association (TRALA)

Anecdotal evidence acquired by TRALA suggests that fleets considering ZEVs will face substantially higher insurance costs due to new and unfamiliar ZEV technologies, overall higher purchase costs of ZEV trucks, and higher costs of repair after accidents. It remains unclear whether EPA accounted for this cost in its Regulatory Impact Analysis (RIA). [EPA-HQ-OAR-2022-0985-1577-A1, p. 10]

Organization: Valero Energy Corporation

As for repairs, EPA's assessment of maintenance and repair costs focuses on the EV components and fails to consider that BEV manufacturers often reduce frame weight to compensate for heavy batteries, e.g., by using composite rather than metal frames, which are more susceptible to cracking and damage.45 In particular, EPA overlooks the fact that BEVs are more likely than ICEVs to be "totaled" following a motor vehicle accident due to the flimsiness of the composite frame metal frame and the integration of the batteries into the vehicle frame. As a result, the cost to insure a BEV or FCEV can be considerably higher than the cost to insure ICEVs. EPA does not appear to have included these costs in its consideration of the cost of ownership. [EPA-HQ-OAR-2022-0985-1566-A2, p. 9.]

45 https://whyy.org/articles/septas-cracking-battery-buses-raise-questions-about-the-future-of-electric-transit/.

EPA Summary and Response:

Summary:

Several commenters maintained that the proposed version of HD TRUCS failed to reflect a difference in insurance costs for BEVs when compared to ICE vehicles. AFPM commented that EPA did not account for higher insurance costs for more expensive vehicles. The Arizona State Legislature cited a study of light duty vehicles that found the cost to repair electric vehicles is higher than repair costs for comparable ICE vehicles due to advanced materials, advanced sensors, and battery pack removal and installation which all would increase insurance premiums. The Clean Fuels Development Coalition et al. cited a different study than the Arizona State Legislature, but the study had the same findings: BEVs are more expensive to insure because of higher repair costs. DTNA commented that due to purchase price and replacement cost of HD ZEVs, insurance premiums would be higher than for a comparable ICE vehicle and this differential should be included in HD TRUCS but did not suggest a value to use. POET referenced the Trinity report which stated that the EPA had not considered additional insurance costs in our payback calculations. EMA suggested that we should consider adding a 3% cost to the cost differential of BEVs and ICE vehicles in HD TRUCS, citing a 2023 ICCT paper, that EMA said was directionally correct for this rulemaking. TRALA cited anecdotal evidence that insurance costs, among others, would be significantly higher for BEVs than for ICE vehicles and requested clarity on the inclusion of increased insurance costs in HD TRUCS. Valero cited an article that found BEV transit buses were reducing their weight of the vehicle by making the frames out of composite material which caused cracking due to the weight of the vehicle. Their conclusions were that lightweighting vehicles by changing the material of the frame allows BEVs to be more susceptible to frame damage in the case of an accident and this would cause insurance rates to increase.

Response:

EPA received many comments regarding insurance rates for BEVs, and we agree with commenters that insurance costs should be included in our final analysis. EMA provided the only quantitative suggestion for estimating insurance premiums, based on an ICCT paper, that uses the differential upfront cost of the vehicle to calculate insurance differences. We consider this to be a reasonable approach. It is generally typical for more expensive vehicles to have higher insurance premiums, so an approach that relies on the upfront cost differences among technologies is a logical way to estimate the differences in annual insurance premiums, including differences associated with higher up-front, components, and repair costs. This value was added as an additional operating cost in HD TRUCS. See Chapter 2 of the RIA for insurance cost calculations.

Valero cites an instance of an EV bus using a composite frame which did not hold up under stress and maintains that this type of breakdown should be reflected as a cost of a Phase 3 rule. EPA's modeled potential compliance pathway does not consider composite construction or other forms of lightweighting. We project the same chassis construction for ZEVs (including all transit buses in HD TRUCS) as for ICE vehicles. We note, moreover, that lightweighting is not a phenomenon limited to ZEVs; manufacturers could also choose to implement lighter frames on

ICE vehicles in order to reduce their manufacturing costs and increase fuel efficiency.[346] However, the final GHG standards are not premised on the use of lightweighting in any vehicles.

See Section 3.7 above for our response to the Arizona State Legislature comment citing a study of light-duty vehicles and the effect on insurance costs.

3.8.3 Battery Replacement

Comments by Organizations

Organization: American Free Enterprise Chamber of Commerce (AmFree) et al.

Second, EPA estimates operational savings without considering "midlife overhaul costs," which include "the cost resulting from an engine rebuild for a conventional diesel vehicle, a battery replacement for a battery electric vehicle, or a fuel cell stack refurbishment for a hydrogen fuel cell vehicle." Wang et al., Estimating Maintenance and Repair Costs at 10–11. EPA disregarded these costs on the ground that its "payback analysis typically covers a shorter period of time than the expected life of these components." Draft RIA at 185. That reasoning is illogical. Assuming (as EPA does) that net costs drive purchasing decisions, commercial-fleet owners are unlikely to buy an electric model if they anticipate that such vehicles will require costly midlife repairs that would erase any initial savings. Some evidence suggests that this will occur. For example, one report (performed by the California Air Resources Board) cited in the Wang study noted above posits that electric trucks will require battery replacement every 300,000 to 500,000 miles—much sooner than a comparable conventional vehicle is likely to require an engine rebuild. See Draft Advanced Clean Fleets Total Cost of Ownership Discussion Document, Cal. Air Res. Bd., at 26 (Sept. 9, 2021) (indicating that a Class 8 heavy-duty diesel truck is likely to require an engine rebuild after 800,000 miles). The cost of major midlife repairs for electric vehicles also may be substantially greater. Compare, e.g., Certified Diesel Sols., When to Overhaul a Diesel Engine, https://tinyurl.com/2dch6xv3 (estimating cost of a diesel-engine rebuild between $20,000 and $40,000), with EPA, Heavy- Duty Technology Resources Use Case Scenario, at 2_BEV Tech (Apr. 10, 2023), https://www.epa.gov/system/files/other-files/2023-04/hd-tech-trucs-tool-2023-04.xlsm (Columns AJ & AK) (EPA's modeling suggesting that the cost of manufacturing batteries may be several multiples higher). The Senior Vice President of the American Transportation Research Institute cautions that heavy duty-vehicle operators are "going to be switching out the batteries on a Class 8 truck every four to seven years" and "pay between $85,000 and $120,000 for a replacement set." Cristina Commendatore, Report Pinpoints Top Challenges for Widespread Battery-Electric Vehicle Adoption, FleetOwner (Dec. 7, 2022), https://tinyurl.com/243euzxr. Thus, owners of electric heavy-duty vehicles could find themselves saddled with new and substantial midlife overhaul costs that cut into their operational savings. EPA should assess—not ignore—this issue before calculating the payback period. [EPA-HQ-OAR-2022-0985-1660-A1, pp. 28 - 29]

[346] See, e.g., Constructing Lightweight Bus Structures with Stainless Steel, https://www.mobilityengineeringtech.com/component/content/article/48578-sae-ma-07195

Organization: American Fuel and Petrochemical Manufacturers (AFPM)

Nor does it account for the emissions impacts from the full life cycle of ZEVs, particularly heavy-duty ZEVs with batteries that may not achieve either "useful life" standards or mandatory emission control technology warranties applicable to other vehicles with emission standards issued under the Clean Air Act. To the extent heavy-duty ZEVs and their batteries have not been demonstrated to achieve useful life standards and minimum emission control warranty requirements, in real-world operation, EPA must include their replacement costs as part of their analysis; EPA has not. [EPA-HQ-OAR-2022-0985-1659-A2, p. 14]

Organization: Arizona State Legislature

EPA recognizes that replacing an electric truck's battery 'may be practically necessary over the life of a vehicle if the battery deteriorates to a point where the vehicle range no longer meets the vehicle's operational needs.' 88 Fed. Reg. 25,987. EPA does not calculate the frequency or likelihood that a truck will need to replace its battery due to wear or accident. Nor does EPA calculate the cost of battery replacement. Battery replacement for a heavy-duty track can cost between $85,000 to $120,000.29 One battery replacement would obviate any cost savings estimated by EPA. [EPA-HQ-OAR-2022-0985-1621-A1, p. 24]

Organization: Clean Fuels Development Coalition et al.

Vehicle maintenance costs: This includes the standard maintenance that electrified heavy-duty vehicles would need to undergo (which the proposal underestimates, see generally The American Truck Dealers Division, Dkt. No. EPA-HQ-OAR-2022-0985-1445 (May 3, 2023), as well as vehicle battery replacement costs (which the proposal ignores) and battery disposal or recycling costs (which the proposal also ignores). EPA also ignores “midlife overhaul costs,” which include “the cost resulting from an engine rebuild for a conventional diesel vehicle, a battery replacement for a battery electric vehicle, or a fuel cell stack refurbishment for a hydrogen fuel cell vehicle.” G. Wang et al., Estimating Maintenance and Repair Costs for Battery Electric and Fuel Cell Heavy Duty Trucks, UC Davis, at 10–11 (Feb. 2022). The proposal illogically chooses to disregard these costs, ignoring its assumption in other areas of the rule that net cost drives purchasing decisions. DRIA at 185. [EPA-HQ-OAR-2022-0985-1585-A1, p. 5]

Organization: Daimler Trucks North America

EPA Request for Comment, Request #44: We request comment on this approach for both ICE vehicles and ZEVs, in addition to data on battery and fuel stack replacement costs, engine rebuild costs, and expected component lifetime periods.

- DTNA Response: See DTNA Response to Request # 20, above. [EPA-HQ-OAR-2022-0985-1555-A1, p. 165]
- Response to Request # 20: EPA should consider all available data including that which can be provided by manufacturers in confidential settings; however, given that the HD ZEV market is currently in a nascent state, any data available today is necessarily limited. EPA should thus re-evaluate its assumptions on this issue on a regular basis, using the best available data. See Section II.C.2 of DTNA’s comments.

Organization: MEMA

Additionally, specialized vehicle bodies are more unique to end-users’ needs, so there is higher cradle-to-grave ownership cycle costs, which means that battery replacement costs are going to weigh higher into fleet-level business cases and decision-making. These end-users with longer ownership cycles tend to adopt technology more cautiously, with a more measured approach due to limited resale markets. [EPA-HQ-OAR-2022-0985-1570-A1, p. 17]

Organization: Valero Energy Corporation

With regard to costs to replace key ZEV components such as batteries and fuel cells, EPA explains that it “did not account for potential diesel engine rebuild costs for ICE vehicles, potential replacement battery costs for BEVs, or potential replacement fuel cell stack costs for FCEVs because our payback analysis typically covers a shorter period of time than the expected life of these components.”39,40,41 While data is sparse due to the immaturity of heavy-duty ZEV technologies, some literature sources indicate that these components may require replacement well before the expiration of typical payback period. For example, E-Mobility Engineering reports:

“Packs designed with high cycle numbers for their lifetimes are expected to reach 80% of their nominal capacities – a figure widely accepted as their ‘end of life’ in the e-mobility world – between 4 and 10 years after their initial delivery.”42 [EPA-HQ-OAR-2022-0985-1566-A2, p. 8]

39 DRIA at 185.

40 For BEV, EPA indicates “we assumed the deterioration of the battery to be 20 percent over its life,” without any indication of the basis of the assumption or the projected length of the BEV life. DRIA at 217.

41 For FCEV, EPA cites an “interim target fuel cell system lifetime for a Class 8 tractor-trailer is 25,000 hours, which is equivalent to more than 10 years if a vehicle operates for 45 hours a week for 52 weeks a year,” without any indication of the basis of the target. DRIA at 195.

42 E-Mobility Engineering, “Challenge of batteries for heavy-duty EVs”, https://www.emobility-engineering.com/challenge-of-batteries-for-heavy-duty-evs/.

“Expected life” aside, the potential need for replacement of an EV battery or fuel cell stack carries a significant cost differential to the potential rebuild of a diesel engine, and EPA’s failure to consider the replacement of these components is a glaring gap in its payback analysis. Even if a battery replacement occurs outside the payback period considered by EPA, payback can be expected to “un-occur” quickly when a HDV owner is faced with the choice of whether to replace the battery/fuel cell stack or to terminate the life of the HDV. [EPA-HQ-OAR-2022-0985-1566-A2, pp. 8 - 9]

EPA Summary and Response:

Summary:

Several commenters raised concerns about the cost of replacing a vehicle battery. They stated that battery replacement is a very large cost that should be accounted for as it will have a large effect on the payback calculation since the cost of batteries make up a large portion of the cost of an electric vehicle. (Clean Fuel Development Coalition, MEMA, Valero). Valero cites an article for the proposition that batteries with high cycle numbers are expected to reach the end of their useful life within 4-10 years in support of its contention that battery replacement cost should be included as a cost of the rule, and further maintains that EPA lacks authority for its statement at proposal that HD BEV battery warranties are typically for 8 to 15 years. CARB stated that batteries will be able to last for ten years or longer. DTNA commented that EPA should consider all available data, however since data is limited EPA should re-evaluate its assumptions on this issue on a regular basis.

Response:

EPA appreciates the concern expressed about battery replacement; we understand that the cost of batteries for HDVs is a significant portion of the overall cost of the vehicle and that replacing the battery would result in a different payback analysis than that contained in the NPRM for HD BEVs. As discussed in Chapter 2.7 of the RIA, we limit the BEVs in our technology packages to those that pay back in 10 years or less. Therefore, for the final rule we changed from proposal our process for sizing the BEV batteries in HD TRUCS so that they are designed to meet at least 10 years of operation before the battery range degradation exceeds 20%.

Specifically, in the analysis to support this final rule, EPA used a constraining factor to address this concern by setting 2,000 cycles as the expected life for a HD battery.[347,348] We chose

[347] Preger, Yuliya, et. al. “Degradation of Commercial Lithium-Ion Cells as a Function of Chemistry and Cycling Conditions”. Journal of The Electrochemical Society. September 2, 2020. Available online: https://iopscience.iop.org/article/10.1149/1945-7111/abae37.

[348] Tankou, Alexander, Georg Bieker, and Dale Hall. “White Paper—Scaling Up Reuse and Recycling of Electric Vehicle Batteries: Assessing Challenges and Policy Approaches”. International Council on Clean Transportation.

2,000 cycles as a conservative sizing value based on studies that show LFP batteries can maintain 80 to 95 percent state of charge at 3,000 cycles and NMC batteries can retain 80 percent state of charge at 2,000 cycles under typical operating conditions (discharge and charging power of 0.5 C or less and SOC swings of 20 to 80% or less). Our use of a 2,000 cycle limitation is consequently conservative because we project that many heavy-duty truck applications where durability is a primary concern will utilize LFP batteries. Thus, the final rule analyzes need for battery replacement and engine rebuilds in the same manner: we are sizing batteries and engines such that neither need replacement during the normal 10-year operating period (as well as the maximum payback period we consider reasonable in our analysis). In HD TRUCS, we calculate the number of battery cycles for each of the 101 vehicles and compare it to 2,000 cycles. We then increased the size of the battery if the number of cycles for a particular vehicle was greater than 2,000 cycles. A more thorough discussion of this topic can be found in Chapter 2.4.1.1.3 and 2.4.1.1.4 of the RIA.

We do, however, recognize that while the BEV batteries are sized in a way that batteries will not need replacement for the initial payback calculation, this does not necessarily extend to the entire life of the vehicle. Some vehicles, particularly tractors with high number of charge and discharge cycles may need replacement beyond the first 10 years of use. Therefore, for the final rule, we have added both battery replacement and ICE rebuild costs into the operating costs of our program cost analysis in RIA Chapter 3. Since this replacement occurs after the initial purchase and may be beyond the period of first ownership of the vehicle, we calculated the replacement cost of the battery and compared it to the engine-rebuild cost as described in Chapter 3.4.7.5 of the RIA. The cost of battery replacement and engine-rebuild are added to the final program costs.

Valero cited an undated article containing the anecdotal statement that batteries with high cycle numbers (unquantified) can be expected to reach the end of their useful life within 4-10 years.[349] The article fails to provide any data or analysis in support of this conclusion. EPA's well-documented analysis summarized above responds to this comment by documenting how EPA conservatively sized batteries for purposes of our HD TRUCS analysis such that no replacement is needed for the first 10 years of HD BEV operation.

3.9 Alternative Inputs and Sensitivities

3.9.1 Fuel Price Adjustments

<u>Comments by Organizations</u>

Organization: Daimler Truck North America LLC (DTNA)

Fuel Costs There is significant risk in projecting diesel, electricity, and hydrogen costs to inform payback periods four to nine years in advance. Diesel prices are sensitive to global

---

February 2023. Available online: https://theicct.org/wp-content/uploads/2023/02/recycling-electric-vehicle-batteries-feb-23.pdf.

[349] https://www.emobility-engineering.com/challenge-of-batteries-for-heavy-duty-evs/. (unpaginated), statement appearing in ninth paragraph from the end of the article.

politics and economics and are highly volatile, as observed over the last several years. Prices fell drastically during the COVID-19 pandemic, followed by a sharp price increase when demand resurged faster than supply, creating a price spike in 2022, as shown in Figure 2 below. As fuel prices are a major piece of the TCO equation, high diesel prices will make the ZEV TCO case more attractive, whereas low diesel prices will keep conventional technologies competitive. DTNA also notes many fleet customers have bulk supply agreements and purchase diesel fuel for costs well below the retail price at the pump. EPA should ensure that the diesel prices projected in HD TRUCS reflect the price paid by fleets, and not the national average retail price. [EPA-HQ-OAR-2022-0985-1555-A1, pp. 31-32] [Refer to Figure 2 on p. 32 of docket number EPA-HQ-OAR-2022-0985-1555-A1]

Organization: Environmental Defense Fund (EDF)

Under a high diesel fuel scenario, most BEV tractors have a payback period of less than 1 year.

In this sensitivity analysis, Roush used the high oil price scenario from AEO2023. The last couple years have seen record high diesel prices. Under such a scenario, the savings from BEV adoption increase tremendously. The TCO per mile of BEVs under the high diesel cost scenario is between 36% and 47% lower than ICEV. [EPA-HQ-OAR-2022-0985-1644-A1, p. 36] [See Figure 5 on p. 36 of Docket Number EPA-HQ-OAR-2022-0985-1644-A1]

Organization: Moving Forward Network

In addition to providing significant absolute fuel cost savings relative to gasoline or diesel, driving on electricity also provides a significant price-stability advantage. As shown in Figure 17, for more than the last two decades, driving a passenger EV on residential electricity prices has been the cost equivalent of driving on dollar-a-gallon gasoline, whereas the price of gasoline itself jumps up and down in response to world events beyond our control. 168 [EPA-HQ-OAR-2022-0985-1608-A1, pp. 79 - 80.] [See Figure 17, Equivalent Electricity and Diesel Prices: January 2001-April 2023 located on p. 80 of docket number EPA-HQ-OAR-2022-0985-1608-A1.]

168 Source data: EIA, Short Term Energy Outlook. Electricity prices shown in “eGallons” a Department of Energy metric that “represents the cost of driving an electric vehicle (EV) the same distance a gasoline powered vehicle could travel on one (1) gallon of gasoline.” Methodology available at: https://www.energy.gov/articles/egallon-methodology

The contrast is even more stark between electricity and diesel prices, as shown in Figure 18, which shows the cost of diesel compared to the “dollar-per-diesel-gallon-equivalent” cost of driving a Class 5 Step Van on electricity. 169 [EPA-HQ-OAR-2022-0985-1608-A1, p. 80.] [See Figure 18, Equivalent Commercial Electricity and Diesel Prices for Class 5 Step Van: January 2001-January 2023 located on p. 81 of docket number EPA-HQ-OAR-2022-0985-1608-A1.]

169 Source data for fuel prices: EIA, Short Term Energy Outlook. In this instance the Department of Energy’s “eGallon” methodology developed using the efficiencies of light-duty vehicles was adapted to reflect the fuel economy (mpg) and electricity consumption (kwh/mi) of a Class 5 Step Van, as documented by the California Air Resources Board, available at: https://ww2.arb.ca.gov/sites/default/files/2018-11/180124hdbevefficiency.pdf

The price stability advantage of electricity should further both consumer and fleet manager acceptance of EVs. In addition to saving money on fuel, fleet operators stand to benefit from no longer having to pay financial institutions hefty commissions and fees associated with hedging against fuel price volatility, and their customers will benefit from no longer being subject to "fuel surcharges" designed to reduce fleet exposure to the volatility of the world oil market. [EPA-HQ-OAR-2022-0985-1608-A1, p. 81]

Organization: Volvo Group

- EPA should update their analysis based on the most recent data, including the Energy Information Administration's 2023 Annual Energy Outlook. [EPA-HQ-OAR-2022-0985-1606-A1, p. 17]

EPA Summary and Response

Summary:

Some commenters believe the fuel prices, in particular, should include alternative scenarios beyond the AEO 2021 reference case scenario. EDF believes that high diesel cost scenario may be a more appropriate price for diesel, whereas DTNA asserts fuel price including diesel, electricity and hydrogen prices are difficult to predict into the future and that fleets have bulk agreements instead of retail pricing. Volvo said that EPA should update its analysis based on the latest data, including AEO 2023.

Response:

For the final rule, we have updated diesel prices to AEO2023 values using the Reference Case scenario. We have used AEO Reference Case scenarios in each of our HD GHG rulemakings to date, and are continuing to do so for Phase 3. The Energy Information Administration (EIA) is the recognized official source for such projections. The Reference Case fuel prices are lower than those suggested by EDF, but may be higher than what some fleets pay. We agree with the commenter that price stability for electricity compared to the volatility of oil prices may benefit BEV owners.

3.9.2 Inflation Adjustment

Comments by Organizations

Organization: Daimler Truck North America LLC (DTNA)

- Inflation and Rising Interest Rates. The Proposed Rule and supporting DRIA do not address the impacts of inflation and corresponding interest rate increases on vehicle prices and purchase costs. The majority of commercial vehicle purchases are financed through equipment loans, lines of credit, and other financing mechanisms. These financing options have become significantly more expensive in recent years due to rising interest rates. It is not clear how EPA has factored into its TCO estimates the substantial borrowing costs associated with financing the purchase of an HD ZEV, which will almost certainly be felt by purchasers over the next few decades unless interest rates decline substantially. Indeed, EPA's purchaser cost analysis is entirely devoid of any discussion of borrowing and financing costs for HD ZEVs, which are a substantial expense given the capital outlays needed to purchase the new technology.63 [EPA-HQ-OAR-2022-0985-1555-A1, p. 35]

63 See, e.g., CARB, Advanced Clean Fleets, Initial Statement of Reasons (Aug. 30, 2033), Appendix G: Total Cost of Ownership Discussion Document at G-15, available at https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2022/acf22/appg.pdf (estimating that 80% of fleets will finance new HD ZEV purchase at 5% annual percentage rate, and that 20% of fleets will finance at 15%, resulting in an average financing rate of 7%).

- Inflation and Other Economic Conditions. According to the U.S. Bureau of Labor Statistics, the purchasing power of the dollar declined about 7.4% between 2021 and 2022 because of inflation.42 Consumer price inflation (CPI), as measured by the 12-month change in the price index for personal consumption expenditures (PCE), was at 5.4 percent in January 2023,43 well over average inflation rates of the last 20 years.44 In projecting consumer uptake of new ZEV technologies, EPA does not consider that, given the current economic environment of high inflation, eroding purchasing power, and high interest rates, fleets likely do not have the appetite to take on or finance significant capital outlays over the next few years. This would especially include expensive investments in new technologies and supporting infrastructure. [EPA-HQ-OAR-2022-0985-1555-A1, p. 26]

42 See U.S. Bureau of Labor Statistics, 'Consumer Price Index,' available at https://www.bls.gov/cpi/factsheets/purchasing-power-constant-dollars.htm#:~:text=This%20means%20that%20the%20purchasing,%2C%20on%20average%2C%20in%202021.

43 See Federal Reserve, Monetary Policy Report (March 3, 2023), available at https://www.federalreserve.gov/monetarypolicy/2023-03-mpr-summary.htm.

44 See U.S. Bureau of Labor Statistics, Databases, Tables, and Calculators by Subject, available at https://data.bls.gov/pdq/SurveyOutputServlet.

EPA Summary and Response:

Summary:

DTNA commented that EPA's purchaser cost analysis does not consider inflationary pressures that can discourage purchase of BEVs.

Response:

In the final rule, we have adjusted all dollar values to 2022 dollars which reflects the most recent data available regarding inflation and its impacts on the costs we estimate. Discussions for adjustment to 2022 dollars can be found in introduction of Chapter 3 of the RIA. By doing so, our cost analysis reflects purchasing power, including impacts of inflation, as of the most recent time for obtaining reliable, comprehensive data. Potential inflation (either increased or decreased inflation) after that cut-off date is beyond the scope of our analysis for this rule. See *Arkansas Dairy Co-op Ass'n v. U.S. Dept. of Agriculture,* 573 F. 3d 815, 831 (D.C. Cir. 2009) (upholding evidence consideration cutoff, stating "at some point the Secretary must stop reviewing evidence, and review the rulemaking record").

3.9.3 Other sensitivities

Comments by Organizations

Organization: Daimler Truck North America LLC (DTNA)

EPA should conduct a sensitivity analysis of all cost inputs used in the HD TRUCS analysis to understand the range of alternative ZEV uptake rates under different scenarios.

As discussed above, there is significant uncertainty in a number of EPA's cost projections, which have major implications for the calculated ZEV adoption rates and proposed CO2 standard stringency levels. DTNA strongly recommends that EPA conduct a sensitivity analysis of all costs used in the HD TRUCS tool, especially component costs and fuel costs, and calculate what the impact on ZEV uptake would be in those alternate scenarios. EPA should use this sensitivity analysis when conducting the periodic reviews of the appropriateness of the Phase 3 CO2 standards, as discussed in Section II.C.3 of these comments. [EPA-HQ-OAR-2022-0985-1555-A1, p. 39]

EPA Request for Comment, Request #45: We request comment on our approach and assessment of future fuel, electricity, and hydrogen prices for the transportation sector.

- DTNA Response: Fuel prices are a critical piece of the TCO calculation and will have significant impacts on ZEV adoption rates. Future fuel, electricity, and hydrogen prices cannot be accurately be predicted four to nine years in advance, as these prices are subject to global economics, supply-demand relationships, infrastructure buildout rates, etc. EPA should consider all available data and re-evaluate fuel costs on a regular basis, as discussed in Section II.C of these comments. [EPA-HQ-OAR-2022-0985-1555-A1, p. 165]

Organization: Valero Energy Corporation

C. The outcome of EPA's HD TRUCS modeling is highly sensitive to its unsupported assumptions.

As described above, EPA frequently and significantly relies on assumptions, estimates, and aspirational goals in the place of actual performance data for HD BEVs and FCEVs. Not only does EPA fail to discuss the uncertainties in the data, it also fails to adequately consider a scenario in which these assumptions, estimates, and aspirational goals do not come to perfect and complete fruition in the rulemaking timeline. [EPA-HQ-OAR-2022-0985-1566-A2, p. 18]

Figure 8 demonstrates the sensitivity of EPA's HD TRUCS modeling to following individual assumptions, estimates, and aspirational goals upon which EPA relies, as well the aggregate sensitivity to all of the listed modifications:

- Acceptable payload impact tolerances are reduced from 30% in EPA modeling to 5% or 0% (refer to Section III.A.1 of this letter);87
- The 2027 battery cost, fuel cell stack cost, and hydrogen fuel tank cost reflect the upper bound of the ICCT projected ranges (refer to Section III.A.4 of this letter);88

- The costs to install EVSE are increased to more realistic values (refer to Section III.A.6 of this letter);89 and
- The "learning gains" are reduced to 75% of EPA's predictions (refer to Section III.A.9 of this letter). 90 [EPA-HQ-OAR-2022-0985-1566-A2, pp. 18 - 19.] [See Figure 8, HD TRUCS Sensitivity Analysis, on page 20 of docket number EPA-HQ-OAR-2022-0986-1566-A2.]

87 The sensitivity run modified EPA's original HD TRUCS run by changing cell F108 of the "Inputs" tab to 5% and 0%, respectively, and by changing cell H4 of the "A4a_Adoption Rates (BEV)" tab to 5% and 0%, respectively.

88 The sensitivity run modified EPA's original HD TRUCS run by changing cell G5 to "220*Adj_Factor," cell G45 to "680*Adj_Factor," and cell G58 to "1150*Adj_Factor" in the "Inputs" tab.

89 The sensitivity run modified EPA's original HD TRUCS run by changing cell F17 to 150,000; cell F19 to 20,000; cell F21 to 250,000; and cell F23 to 86,000 in the "Inputs" tab.

90 The sensitivity run modified EPA's original HD TRUCS run by changing cell H95 to 0.941, I95 to 0.900, J95 to 0.868, K95 to 0.843, and L95 to 0.823 in the "Inputs" tab.

Adjusting these four variables to be more closely aligned with reality, EPA's HD TRUCS model projects only a 4% ZEV adoption by MY 2027 and 11% by MY 2032, a significant reduction from the 16.8% and 46% adoption in EPA's original modeling: [EPA-HQ-OAR-2022-0985-1566-A2, p.19.]

Organization: Volvo Group

- The agency referenced many studies and analyses in their determination (ACT Research, ICCT, EDF/ERM, etc.), but many of those studies have already been shown to be outdated based on their model year 2021 and 2022 heavy duty ZEV sales projections when compared to actual industry sales volumes and vehicle registrations.
- EPA should update their analysis based on the most recent data, including the Energy Information Administration's 2023 Annual Energy Outlook. [EPA-HQ-OAR-2022-0985-1606-A1, p. 17]

EPA Summary and Response

Summary:

DTNA expressed concern over uncertainty in the cost projections in the modeled potential compliance pathway which have an effect on ZEV adoption rates. They recommended that we conduct a sensitivity analysis on all costs used in HD TRUCS, especially component costs and fuel costs, and how these changes affect adoption rates in the technology packages. They further suggested using the sensitivity analysis when conducting the DTNA-recommended periodic reviews of the Phase 3 standards. Volvo also recommended EPA update the final rule analysis using the more up-to-date information such as the AEO 2023. They also highlighted some sources EPA used, such as the ICCT report, which Volvo stated are outdated in their projections based on actual sales. Valero believes many data sources EPA relies on for the proposal are assumptions, estimates and aspirational goals, which Valero states does not match actual data for ZEVs. Valero states that they believe EPA fails to discuss uncertainties in data or assumptions and that if they do not come to true will lead to impacts on ZEV adoption rates.

Response:

As further explained in preamble Sections I and II, in setting future emission standards under our CAA section 202(a)(1)-(2) authority, given the prospective nature of the factors Congress directed EPA consider, EPA must necessarily identify potential technologies, evaluate the rate each technology could be introduced, and project associated cost of compliance. Thus, while we acknowledge that future projections inherently are subject to uncertainties, EPA has carefully analyzed the uncertainties and identified the considerations we found persuasive[350] Consistent with our standard setting authority the analysis EPA conducted for this final rule appropriately makes use of the best data available to us, including using data from AEO 2023 and other data as described in RIA Chapter 2.

DTNA suggested EPA include a sensitivity analysis as part of a periodic review of Phase 3. See preamble Section II.B.2.iii and section 2.9 of this RTC document for a discussion of reviews we may consider in post-rule implementation of the Phase 3 rule.

DTNA and Valero suggested that EPA conduct sensitivity analysis for the final rule using alternative inputs for HD TRUCS. As EPA notes above, and in the preamble and RIA for this final rule, EPA has used what we consider to be the most appropriate inputs for the HD TRUCS model for the analysis which informed the CO_2 emission standards established in this final rule. As described throughout preamble Section II and RIA Chapter 2, in many instances in determining inputs for HD TRUCS, EPA determined that the most appropriate inputs were a conservative approach based on the best data available l. Furthermore, EPA developed and assessed additional example potential compliance pathways that support the feasibility of the final standards including without producing additional ZEVs to comply with this rule (see RIA Chapter 2.11 for this example and others). These additional technology packages support that the performance-based standards are feasible at reasonable costs with even lower ZEV adoption rates than discussed in Valero's comment.

[350] Certainty is essentially impossible in making predictive judgments, and agencies are not absolved from decision making due to lack of prescience. See Rural Cellular Ass'n v. F.C.C., 588 F.3d 1095 (D.C. Cir. 2009 ("Where, as here, the FCC must make predictive judgments about the effects of increasing subsidies, certainty is impossible. … In circumstances involving agency predictions of uncertain future events, `complete factual support in the record for the Commission's judgment or prediction is not possible or required' since "`a forecast of the direction in which future public interest lies necessarily involves deductions based on the expert knowledge of the agency.'… Thus, when an agency's decision is primarily predictive, our role is limited; we require only that the agency acknowledge factual uncertainties and identify the considerations it found persuasive." See also, in the context of assessing future economic conditions, N. Am.'s Bldg. Trades Unions v. Occupational Safety & Health Admin., 878 F.3d 271, 299 (D.C. Cir. 2017) ("OSHA concluded that 'even in a lower price environment, hydraulic fracturing entrepreneurs will be able to implement the controls required by th[e] final rule without imposing significant costs, causing massive economic dislocations to the ... industry, or imperiling the industry's existence.' Given the inherent uncertainty in forecasting future economic conditions, OSHA's thorough consideration of Industry's concerns, and the delayed implementation timeline, OSHA's finding that the rule is economically feasible in hydraulic fracturing finds ample support in the record").

3.10 Feasibility

3.10.1 Payload

Comments by Organizations

Organization: American Fuel and Petrochemical Manufacturers (AFPM)

6. EPA Proposes Standards that Fail to Consider ZEV Market Demands.

EPA improperly relied on the general characterization of the heavy-duty vehicle and engine market as supplemented by incentives in the BIL and IRA to support its proposition that there will be a rapid increase in ZEV market penetration. But these ZEVs simply do not have the same range, load capacity, and intended use of existing fleets. To illustrate the needs the BEV market must meet, we are providing at Appendix I information on the sales and uses of Class 7 (26,001–33,000 pound) and Class 8 (33,001 pounds and over) HD vehicles from the U.S. Department of Energy.114 EPA's Proposed Rule provides little to no information regarding how— or whether—the ZEV mandate can meet current market needs for HD vehicles given the higher range115 and load capacity116 of current ICE HD engines, particularly diesel. [EPA-HQ-OAR-2022-0985-1659-A2, pp. 30 - 31.] [See Appendix I on page 43-45 of docket number EPA-HQ-OAR-2022-0985-1659-A2.]

114 Stacy C. Davis and Robert G. Boundy, OAK RIDGE NAT'L LABORATORY – U.S. DEP'T OF ENERGY, "Transportation Energy Data Book," 40th ed. (June 2022), 5-4–5-13, available at https://tedb.ornl.gov/wp-content/uploads/2022/03/TEDB_Ed_40.pdf.

115 Beia Spiller et al., Medium- and Heavy-Duty Behicle Electrification: Challenges, Policy Solutions, and Open Research Questions (May 3, 2023), https://www.rff.org/publications/reports/medium-and-heavy-duty-vehicle-electrification-challenges-policy-solutions-and-open-research-questions/ ("The current available range for electric trucks is less than 200 miles on a single charge—much shorter than the range of comparable diesel vehicles, which . . . can go 2,000 miles without refueling.").

116 Id. ("The high density of batteries generally makes an MHDEV heavier than its diesel equivalent, and the payload may need to be reduced to compensate for the extra weight (Phadke et al. 2021). The extent to which the payload needs to be reduced is unclear, however, and likely depends on several factors, such as fleet operations and vehicle type.").

Notably, the cost to consumer also fails to account for the decreased range and loads for ZEV HDs in accounting for the payback occurring between three and seven years for long-haul tractors.. [EPA-HQ-OAR-2022-0985-1659-A2, p. 30]

Organization: American Highway Users Alliance

- Long-haul trucks require significantly heavier batteries (anywhere from 6,000 to 17,000 lbs.), which leads to reduced payload capacity. When trucks are less productive due to decreased payload capacity, limited mileage range, and downtime for charging, the consequence is that more trucks and drivers are needed to move the same amount of freight. Some of our large members running limited-scope BEV operations report the need for a 3:2 and sometimes even 2:1 ratio of battery-powered trucks relative to what their diesel trucks produce. Couple the need for more trucks with the fact that each BEV truck costs 2-3x that of today's clean diesel truck (a roughly $300,000 upcharge per unit) and it's easy to see that the negative economics of BEVs would be felt severely by the trucking industry and in turn shared by shippers and consumers... [EPA-HQ-OAR-2022-0985-1550-A1, p. 6]

Organization: American Soybean Association (ASA)

However, ZEV heavy-duty vehicles powered by electric battery technology create other problems for farmers. When hauling large cargos, shippers must consider whether they will box out (run out of space) or weigh out (reach the federal or state weight limit) first. When hauling soybeans, a truck will almost always weigh out first. A University of California, Davis, study estimated the average electric heavy-duty truck battery will weigh an additional 5,000 pounds compared to a semi with an internal combustion engine (ICE) on the road today.2 This means each truckload of soybeans will need to carry as many as 85 fewer bushels per trip. Given that one ICE semi can currently haul 910 bushels of soybeans before it weighs out, this would limit capacity by 9%. [EPA-HQ-OAR-2022-0985-1549-A1, p. 2]

Organization: American Trucking Associations (ATA)

Performance is key to whether heavy-duty ZEVs meet a given duty cycle's range, performance, and battery capacity requirements. Drivers regularly run short and long-haul routes, often including regional and interstate journeys. For example, a carrier transporting perishable agricultural products to and from a West Coast port runs routes to inland destinations like Colorado, St. Louis, Reno, and California's Central Valley. This operation's range and battery performance needs differ significantly from shorter hauls primarily within ten miles of a point of origination. Battery weight is a crucial factor. A bulk agricultural hauler moving mixed commodities to and from a facility can easily come up against weight limits with added batteries. [EPA-HQ-OAR-2022-0985-1535-A1, p. 10]

In addition to range and battery capacity, other performance factors also play a role in heavy-duty ZEVs. Power output, acceleration, and overall vehicle performance are crucial to ensuring vehicles can meet the demands of their duty cycles, regardless of climate or topographical conditions. ZEVs must be capable of the same payload while climbing steep inclines, maintaining high speeds on highways, and handling challenging extreme temperatures in a way that compares favorably with ICEVs. [EPA-HQ-OAR-2022-0985-1535-A1, p. 10]

Organization: Arizona State Legislature

Electric trucks cease to be profitable long before they reach the 30% payload capacity threshold. Electric-powered trucks can legally weigh a maximum of 82,000 pounds, 2,000 pounds more than diesel-powered trucks. 23 U.S.C. 127(s). Electric batteries can weigh up to 16,000 pounds, or almost one-fifth of the truck's weight.38 Using the University of California – Davis estimate that electric trucks will weigh 5,000 pounds more than diesel-powered trucks (6.1% of payload) results in cargo loss for electric trucks equivalent to 17,000 t-shirts, 16,000 apples, or one full car less than a diesel-powered truck.39 Trucking company net margins are generally between 2.5% and 6%, meaning a 6.1% payload loss can eliminate any profitability.40 Other studies put the payload loss at almost 14,000 pounds.41 Payload lost by electric battery weight will affect company decisions to purchase electric trucks in the first place, but EPA does not consider this issue. [EPA-HQ-OAR-2022-0985-1621-A1, p. 26]

The smaller cargo capacity will impact traffic and emissions as well. According to the American Transportation Research Institute, 'Battery weight increases price and vehicle range, but decreases cargo revenue weight. Ultimately more [battery electric vehicle] trucks will be needed on already congested roadways to haul the same amount of freight.'42 EPA does not calculate the increased emissions that will come from these additional trucks upstream or downstream, nor does it calculate the increased emissions from additional traffic congestion that may result from more trucks on the roads. Increased costs incurred by companies by additional trucks and trips to haul the same amount of goods no doubt will be passed on to consumers and increase the cost of goods families need; EPA does not consider this issue, either. a[EPA-HQ-OAR-2022-0985-1621-A1, p. 26]

42 American Transportation Research Institute, Charging Infrastructure Challenges for the U.S. Electric Vehicle Fleet, Dec. 2022, 2, available at https://truckingresearch.org/wp-content/uploads/2022/12/ATRI-Charging-Infrastructure-Challenges-for-the-U.S.-EV-Fleet-Summary-12-2022.pdf.

EPA's failure to adequately consider weight limit issues is arbitrary and capricious. [EPA-HQ-OAR-2022-0985-1621-A1, p. 26]

Organization: Chevron

One performance issue of concern is the loss of cargo hauling efficiency associated with heavier battery electric vehicles. Battery electric trucks would carry heavy batteries which would reduce their load carrying capacity. Smaller cargo loads will require additional truck trips to deliver the same quantity of goods, reducing the overall utilization efficiency of the trucking fleet. [EPA-HQ-OAR-2022-0985-1552-A1, p.5]

Organization: Daimler Truck North America LLC (DTNA)

There are a number of TCO inputs that EPA has not accounted for in the HD TRUCS tool that should be included to more accurately inform payback periods and adoption rate projections for the Proposed Rule, including:

- Weight Penalty. EPA assumes that fleets will accept up to a 30% weight penalty for BEVs in certain applications. Fleets are likely to account for this reduction in payload capacity in the TCO calculation as the cost per ton of goods moved will increase, thus it should be factored in to HD TRUCS. [EPA-HQ-OAR-2022-0985-1555-A1, p. 35]

Likewise, EPA asserts that most vehicles 'cube out' (fill up with goods or passengers before reaching the maximum vehicle weight) before they 'gross out' (reach maximum vehicle weight before filling up with goods or passengers) and estimates that battery technology is suitable for applications up to a 30% weight penalty.45 EPA references a report prepared by the North American Council for Freight Efficiency (NACFE) in support of this weight penalty threshold.46 The referenced NACFE report explains that vehicle weight distribution data is often misinterpreted, due to the fact that data reflecting vehicle loads 'per run' is often misunderstood as vehicle loads 'per truck,' leading many to conclude that a significant percentage of trucks on the road operate well below their maximum weight capacity.47 As NACFE explains, however, the relevant metric for understanding weight distribution data 'is loads, not trucks.'48 'Because many loads are unpredictable, one day a truck may cube out and the next it might weigh out.'49 Fleets are thus unlikely to purchase vehicles with a weight penalty outside of very specific applications that have predictable loads, as they cannot be used as flexibly as a diesel-powered alternative. For these reasons, EPA's HD TRUCS tool does not adequately consider application suitability with respect to weight. [EPA-HQ-OAR-2022-0985-1555-A1, pp. 26-27]

Subject: Battery powered trucks will not work for expedited team freight

2. The batteries are too heavy and will not allow enough payload for a trade off. [EPA-HQ-OAR-2022-0985-1461-A1, p. 1]

Organization: Lynden Incorporated

An electric truck weighs approximately 9,000 pounds more than a diesel truck. This means that trucks will need to make additional trips to get the job done, increasing the total cost to deliver freight and ultimately increasing the number of trucks on the road and overall emissions. EPA-HQ-OAR-2022-0985-1470-A1, p. 3]

Organization: National Association of Convenience Stores (NACS), NATSO, and SIGMA

Beyond cost, a wide variety of barriers to heavy-duty truck electrification are not sufficiently addressed in the Proposal. Battery weight is likely to significantly curtail the long-haul capabilities of heavy-duty electric trucks. As noted above, the battery can add an additional 16,000 pounds to an HD truck. This reduces the amount that trucks can carry and will result in a need for substantially more vehicles on the road to transport the same amount of cargo. Truck carriers near the maximum allowable weight will likely have to modify their operations in order to comply with the Proposal.

Organization: Owner-Operator Independent Drivers Association (OOIDA)

BEVs with heavier weights will displace payload capacity and require more trucks on the road. [EPA-HQ-OAR-2022-0985-1632-A1, p. 4]

Organization: POET

- Costs associated with the need for purchase of more than one ZEV or the continued use of conventional vehicles following purchase of a single HD ZEVs due to limited range, limited cargo carrying capacity, as well as poor gradeability when fully loaded; and [EPA-HQ-OAR-2022-0985-1528-A1, p. 17]

Beyond the issues with HD ZEV technology cost and U.S. EPA's payback analysis, there are other issues with the agency's technology assessment that led to overestimation of adoption rates for HD ZEVs. These include the assumption that vehicle purchasers will deem a HD ZEV with a 30% lower cargo carrying capacity as equivalent to a conventional vehicle (Chapter 2.8.1 of the DRIA) and the assumption that purchasers of HD BEVs will accept the relatively low electric ranges upon which the U.S. EPA has based its cost estimates for HD BEVs (Table 2-33) – many of which are considerably less than 100 miles. Further, although U.S. EPA considered gradeability in determining electric motor sizes for HD BEVs (Chapter 2.4.1.2) it is not clear how U.S. EPA accounted for the impact of grade on BEV range which would increase the need for larger more expensive batteries again making a favorable payback analysis more difficult to achieve. [EPA-HQ-OAR-2022-0985-1528-A1, p. 29]

Organization: Schneider National Inc.

The EPA assumes up to a 30% payload penalty is acceptable for BEV.

- Cutting payload would have an impact on shipper costs, staffing, inventory, etc. More loads would also potentially require more capacity. In our experience, as an example, approximately 20% of intermodal loads already max out due to weight under the current diesel truck equipment configuration (and, on belief, a ZEV would weigh ~4,000-6,000 pounds more than a diesel truck). [EPA-HQ-OAR-2022-0985-1525-A1, p. 2]

Organization: The Sulphur Institute (TSI)

TSI's concerns echo many concerns of other industry stakeholders when it comes to this rulemaking. One main concern is that heavier electric battery or hydrogen powered heavy trucks will reduce cargo payload for commercial tank trucks, requiring truck companies to either 1) increase their fleet size or 2) incur more trips per day in and out of the refineries to load and transport recovered sulphur. In a day of commercial vehicle driver shortage and government imposed electronic logging, making more trips per day or having more trucks to operate creates an even bigger challenge for an already stressed industry and is untenable in the long run, not to mention increased congestion on roads and highways. Many of the truck companies supporting sulphur recovery operations are small niche operating companies, with small fleets of trucks compare to over-the-road national companies. Having to increase fleet size to more expensive trucks and expand driver pools is an expensive proposition, and frankly, something these companies simply cannot sustain over the long run. [EPA-HQ-OAR-2022-0985-1624-A1, p. 1]

Organization: Truck and Engine Manufacturers Association (EMA)

The NPRM and HD TRUCS incorrectly assume that all commercial BEVs will be depot-charged at night, and that any commercial ZEVs that need to operate further from home will be FCEVs. The NPRM also assumes that trucking fleets will be able to devote up to 30% of each vehicle's cargo carrying capacity for batteries large enough to provide enough power for the vehicle's entire daily work. If a commercial vehicle cannot carry enough batteries to complete its daily work, or if it must travel too far from its home terminal, the NPRM assumes that a FCEV will be used instead of a BEV. Of course, those FCEVs will require an entirely separate infrastructure of hydrogen-refueling stations, which still needs to be designed and developed. [EPA-HQ-OAR-2022-0985-2668-A1, pp. 45 - 46]

c) Payload Limitation Criteria for Vocational Vehicles – Vocational vehicle types and applications, in general, can be more sensitive to the loss of payload. In fact, the purchasers of concrete mixers, some dump truck applications, and tanker trucks will go to great lengths to reduce the chassis and body weight to enable additional payload to be carried to the job site. The vehicles are “spec’d” with smaller engines, aluminum components, even aluminum frame rails at times, no passenger seats, and the lightest and smallest necessary component options, as examples of the length purchasers will go to maximize payload. For these applications in particular, reduced payloads of 30% from using a BEV powertrain will be highly detrimental to their overall utility. Reduction in payloads of even 5% to 10% likely will require additional vehicles or vehicle trips to perform the same work as a diesel-powered vehicle. [EPA-HQ-OAR-2022-0985-2668-A1, pp. 48 - 49]

HD TRUCS does not take this critical payload limitation into account for these types of vocational vehicles. This is the most evident in the Custom Chassis – Concrete Mixer regulatory subcategory, which has an 18% adoption rate of BEVs in 2027 and 35% in 2032. Those same vehicles are added into the HHD subcategory as well. [EPA-HQ-OAR-2022-0985-2668-A1, p.49]

EMA recommends that an adjustment be made to the payload loss limitation criteria in the final rulemaking HD TRUCS for these weight-critical vehicle types. [EPA-HQ-OAR-2022-0985-2668-A1, p.49]

Organization: Truck Renting and Leasing Association (TRALA)

Securing National Weight Exemptions for BEVs and FCEVs Will be Difficult

Battery electric or fuel cell trucks will incur a substantial weight penalty that can put truck gross vehicle weights over their allotted federal limits. Roughly 10-15% of truckloads hit their maximum federal weight limits due to the types of payloads they carry. Federal legislation passed in 2019 allows a 2,000-pound weight exemption for battery powered heavy-duty trucks. The problem is the additional battery weight for a Class 8 BEV could add up to16,000 pounds depending on the battery configuration. This is one of the primary reasons why Class 8 trucks will rely upon the development and advancement of Fuel Cell Electric Vehicles (FCEVs). Fuel cell vehicles will also experience additional weight issues but not to the extent of BEVs. OEMs estimate the additional weight of an FCEV compared to a comparable ICE vehicle will be somewhere in the range of 8,000 pounds. The longer the vehicle range the more battery cells or fuel cell modules required which in turn has a direct correlation to overall added vehicle weight. [EPA-HQ-OAR-2022-0985-1577-A1, p. 15

Federal legislation was introduced in May to secure a 2,000-pound weight exemption for hydrogen-powered trucks. However, a 2,000-pound weight allowance for either BEVs or FCEVs is a mere drop in the bucket. Federal legislation to acquire additional weight exemptions to offset added ZEV technology weight will be extremely difficult given strong opposition from select industry, safety, and infrastructure interests. [EPA-HQ-OAR-2022-0985-1577-A1, p. 15]

With respect to infrastructure concerns, the American Society of Civil Engineers' (ASCE) 2021 Infrastructure Report Card gave the nation's roads a 'D' grade and its bridges a 'C' grade.22 Roads and bridges need continual repair, rebuilding, and investment. Added vehicle weights and the high torque rates of ZEVs has the potential to accelerate the degradation of our nation's road networks. TRALA requests further analysis be undertaken to ensure that the increased use of all on-road ZEVs will not result in any detrimental impacts and unanticipated costs related to maintaining our nation's existing highway infrastructure. [EPA-HQ-OAR-2022-0985-1577-A1, pp. 15-16]

Organization: Valero Energy Corporation

Due to federal weight constraints for tractor trailers, a long-haul BEV trucks would lose 20% of payload capacity compared with a diesel truck, reducing the available revenue per mile and increasing the number of trucks needed to avoid delay or interruption of nationwide freight services.108 [EPA-HQ-OAR-2022-0985-1566-A2, p. 24]The weight limitations for HDVs are based on the Dwight D. Eisenhower System of Interstate and Defense Highways, which limit the maximum gross heavy-duty vehicle weight, including the vehicle and cargo, to 80,000 pounds for ICE vehicles and 82,000 pounds for natural gas and electric battery vehicles, however different, lower, weight limits can be applicable depending upon various vehicle axle configurations.153 Given the enormous weight of the batteries deployed in HD BEVs, EPA's proposal will significantly increase the curb weight for HDVs and therefore reduce their ability to haul cargo. [EPA-HQ-OAR-2022-0985-1566-A2, p. 31]

153 23 U.S.C.A. § 127. Vehicle weight limitations - - Interstate System

By assuming that payload loss is acceptable, EPA arbitrarily dictates how businesses can and cannot use HDVs. [EPA-HQ-OAR-2022-0985-1566-A2, p. 5]

. EPA assumes, with no supporting evidence, that a 30% loss of gravimetric payload is acceptable, across all classes of HDVs.

EPA assumes for the purposes of its HD TRUCS modeling that a gravimetric payload reduction (caused by battery weight) of less than 30% is acceptable, "since most vehicles cube out (fill up with goods or passengers before reaching maximum vehicle weight) before they gross out (reach maximum vehicle weight before filling up with good or passengers)."14 EPA bases the assumption on "publicly available data that was available at the time frame of this proposal" and cites a report by the North American Council for Freight Efficiency (NACFE) titled "Electric Trucks Have Arrived: The Use Case for Heavy-Duty Regional Haul Tractors."15 [EPA-HQ-OAR-2022-0985-1566-A2, p. 4]

14 DRIA at 234.

15 DRIA at 234.

However, the NACFE report makes no such claim. In fact, in several places the NACFE report discusses longer BEV ranges as coming "at the sacrifice of significant payload capacity."16 Further, EPA cites a figure from the NACFE report for its data on freight weight data, maintaining that trucks "cube out" before they "weigh out." However, this data is from 2010.17 The trucking industry has undergone drastic changes and increased efficiencies since 2010. This data is now thirteen years old and does not account for the "e-commerce" boom, not to mention other developments in supply chain logistics. For example, online sales in 1998 were only $5 billion. Today, e-commerce sales top $800 billion.18 All of these additional sales have undoubtedly impacted freight weight data. Additionally, UPS, FedEX, and USPS have all changed their shipping rates since 2010, charging based on dimensions rather than weight with the goal of encouraging more efficient shipping practices and avoid cubing out before weighing out.19 Therefore, it could very well be the case that today's delivery trucks weigh out before cubing out. Even if the NACFE report did support EPA's assumption that a 30% payload reduction is acceptable, the NACFE report refers only to regional haul trucks – it would be inappropriate for EPA to extend the assumption to all types of heavy-duty vehicles. [EPA-HQ-OAR-2022-0985-1566-A2, p. 4]

16 NACFE, "Electric Trucks Have Arrived: The Use Case for Heavy-Duty Regional Haul Tractors," 2022, at 3 and 25.

17 "In several reports, NACFE has cited freight weight data, including data shown in Figure 14, Figure 15, and Figure 16 from M.J. Bradley and New West Technologies. The graphs were originally reported in a 2010 National Academies of Sciences, Engineering and Medicine Transportation Research Board (TRB) report, Technologies and Approaches to Reducing the Fuel Consumption of Medium- and Heavy-Duty Vehicles." 19 See, e.g., New FedEx and UPS Dimensional Weight

EPA also fails to account to the flexibilities inherent in diesel fueled trucks versus battery powered trucks. For example, a diesel truck could be fueled with the precise amount needed to haul the freight to the destination and return to the origin point. With a diesel truck, the weight of a vehicle plus the freight and the fuel can be fine-tuned for each trip. However, this is not the case with a BEV truck, which has the same battery weight for each and every trip. This does not allow the shipper to fine tune the weight of the vehicle just for the trip at hand. Even worse, the battery truck must be recharged every night, making it far less efficient than a diesel-powered model beyond just the lost cargo space due to the size of the batteries.20 [EPA-HQ-OAR-2022-0985-1566-A2, pp. 4 - 5]

20 Fan Tong et al., Energy consumption and charging load profiles from long-haul truck electrification in the United States, Environmental Research: Infrastructure and Sustainability (Sept. 2, 2021), https://iopscience.iop.org/article/10.1088/2634-4505/ac186a/pdf (finding that even under the most optimistic case, electric trucks technical performance in terms of payload and range is still lower than that of a future diesel truck and that assuming the current technologies available today, the electric trucks would require a 65% increase in total vehicle distance traveled to make up for the reduced payload capacity).

EPA Summary and Response:

Summary:

Many commenters raised concerns about the reduction in payload due to increased tare weight of ZEVs. Their concerns include need for additional trips to carry the same amount of freight due to reduction in payload, consequent concerns over having additional drivers and trucks to meet freight demands, loss of operating margins, and increased congestion from the additional trucks, again, due to assumed reduction in payload .

The principal concern raised is that battery size and weight constrain payload so much as to render BEVs not economically viable. Several commenters indicated that BEVs would weigh out before cubing out—that is, due to added weight from the BEV powertrain, otherwise available cargo capacity would be lost. (American Soybean Ass'n, Arizona State Legislature, ATA, Chevron, Hills Bros., NACS, OOIDA, TRALA, TSI, Valero.) The American Soybean Association elaborated, indicating that BEVs on average weigh over 5,000 pounds more than their ICE counterparts[351], AHUA indicating an addition of 6,000 to 17,000 pounds, Schneider National indicating batteries would add 4,000 to 6,000 pounds to a truck, Lynden Incorporated indicating batteries would add 9,000 pounds, the NACS indicated that batteries would add 16,000 pounds to a HD truck as did the Arizona State Legislature and TRALA who further stated that FCEVs would weigh 8,000 pounds more than a HD truck. These commenters stated that this necessarily lost capacity raises significant questions as to BEV economic viability.

Several commenters had specific issues with EPA's proposed metric of a 30% payload loss; these commenters include AFPM, Arizona State Legislature, DTNA, EMA, Schneider, Valero, POET. TRALA further commented that loads weigh out before cubing out 10-15% of the time while Schneider National approximated from their own data that 20% of intermodal loads weigh out. Daimler commented that the assumed 30% weight penalty used in the analysis for the rule should be included in the cost of the vehicle as fleets would account for the additional cost of making up for the lost payload through additional trips or vehicles. Several commenters stated that EPA misunderstood the NACFE report. Daimler further commented that EPA had misinterpreted the NACFE report on which the agency had based its statement at proposal that HD vehicles would cube out before weighing out. DTNA maintains that: "[t]he referenced NACFE report explains that vehicle weight distribution data is often misinterpreted, due to the fact that data reflecting vehicle loads "per run" is often misunderstood as vehicle loads "per truck," leading many to conclude that a significant percentage of trucks on the road operate well below their maximum weight capacity." DTNA comment at pp. 29-30. The relevant metric is load, not trucks: "[b]ecause many loads are unpredictable, one day a truck may cube out and the next it might weigh out." Id. [2]Fleets are thus unlikely to purchase vehicles with a weight penalty outside of those few applications that have predictable loads. Valero Energy shares similar thoughts that NACFE does not make claim that 30% payload loss is acceptable. In addition, the NACFE report is from 2010, the industry has gone through significant changes since then as a result of e-commerce as well as new shipping practices. Furthermore, the NACFE report only accounts for regional haul vehicles; this value should not be extended to all heavy duty vehicles. Valero further stipulates that diesel trucks offer the flexibility in that it can be refueled as needed for the payload whereas BEVs battery size are fixed. EMA believes payload penalty from battery limit is too high for vocational vehicles; for some, even a 5 to 10% loss is too much to achieve their required duty cycle. EMA recommends adjustment to the payload cut off. POET also share similar belief that 30% payload loss is too high.

AHUA proports reduced payload capacity, limited mileage range, and downtime for charging will increase the need for additional trucks and drivers; this similar sentiment is expressed by POET and OOIDA. Likewise, Chevron and Lynden comments additional trips will be necessary for reduction in payload; Lynden further explains this will increase the number of vehicles on the

[351] Harvey, J., PhD, Saboori, A., et al. (2020) Effects of Increased Weights of Alternative Fuel Trucks on Pavement and Bridges. Available online: https://escholarship.org/uc/item/4z94w3xr

road and overall emissions. Valero comments on diesel trucks can fine tune their fuel amount for the work it needs to do, whereas BEVs has the same battery weight for every trip.

Response:

At proposal, EPA assumed that if a BEV could accommodate at least 70 percent of the standard payload used to demonstrate compliance with Phase 2 (see 40 CFR 1037.801) of a comparable ICE vehicle, the BEV would be considered to have sufficient payload capacity. DRIA at 234.As explained in Chapter 2.9.1 of the RIA, based on consideration of comments received, for the final rule we are not using a 30% payload reduction as an *a priori* metric for determining BEV suitability or the related NACFE study. Instead, we concluded that it is more appropriate and robust to assess each application in HD TRUCS on an individual basis and determine the suitability of each application for BEVs based on the payload difference between ICE vehicles and BEVs. . See RIA Chapters 2.9.1.1 and 2.9.1.2 discussing EPA's case-by-case determinations regarding payload for vehicles in HD TRUCS. EPA conducted two separate individualized types of determinations: one for battery payload weight, the other for battery volume. See RIA Chapter 2.9.1.1 and 2.9.1.2. We note further that this delineation responds to those comments relating to weighing out and cubing out, since we are conducting separate analyses for each of these issues.

Commenters are incorrect in asserting that added battery weight will impede HD BEVs from being able to negotiate steep grades. In HD TRUCS, we determined the motor power requirements to meet four performance metrics. These performance metrics are the peak power requirement of the ARB transient cycle, 0–30 MPH vehicle acceleration times, 0–60 MPH vehicle acceleration times, and the ability of the vehicle to maintain a constant cruise speed at 6 percent grade as described in RIA Chapter 2.4.1.2 and 2.8.5.4.

The comment from ATA that added payload can decrease ability of HD BEVs to operate across various (unspecified) duty cycles is also misplaced. Inputs to HD TRUCS include power requirements adequate to assure that each of the GEM test cycles are met. See RIA Chapter 2.4.1.2 and 2.8.5.4

Comments regarding payload penalty are exaggerated. As shown in RIA Chapter 2.9.1.1, many BEVs in HD TRUCS would not incur a weight penalty. For those that do, we conducted a further evaluation of the impact of the BEV weight on maximum payload capacity, including an analysis of the impact of selecting battery chemistries with higher specific energy (lower weight for a given battery range) on payload capacity. For the Class 8 dump trucks, the payload difference (loss) was modest: 2.6 percent or with the NiMn battery chemistry specific energy (226 Wh/kg) the payload loss is 1.3 percent. The tanker payload loss was 2 percent of maximum payload. EPA did not view these differences as sufficient to preclude utilization of BEV technology at the rates projected in EPA's modeled compliance pathway. See RIA Chapter 2.9.1.1 for detailed explanations, by vehicle. On the other hand, for concrete mixers and pumpers, EPA determined that battery size, energy demand, and corresponding costs were all significantly higher than EPA had projected at proposal and accordingly determined that EPA's optional custom chassis standards for Concrete Mixers/Pumpers and Mixed-Use Vehicles will remain unchanged from the Phase 2 MY 2027+ CO_2 emission standards. We found the weight to be reasonable for most of the tractors in HD TRUCS. EPA further examined when tractors are utilized at maximum load[352] and found that many commodities do not require transport at maximum load, for further discussion on our analysis of tractor loading based on commodities, see Chapter 2.9.1 of the RIA. Our ultimate conclusion was that our modeled compliance pathway projects a majority of these vehicles remain ICE vehicles, that ICE vehicles therefore would be available to accommodate those commodities for which maximum loads are needed, and that BEVs remain a viable alternative for other commodities. See RIA 2.9.1.1 for a vehicle-by-vehicle discussion. We likewise show in RIA Chapter 2.9.1.2 why BEVs in our analysis would not incur a volumetric penalty.

We also do not agree with the comments that BEVs will prove economically infeasible to operate because they will need to make so many more trips than their ICE counterparts. As discussed in RTC section 4.3.1 and in RIA Chapter 2.9.1.1, EPA has completed further analysis since the NPRM on the effect on payload comparing an ICE to BEV powertrain.[353] This analysis was performed to ensure that HD BEVs are capable of performing the same amount of work as ICE vehicles without incurring additional trips.

We have not included a cost for additional ZEVs required to perform the same work as ICE vehicles because, in general, we expect that our component sizing methodology (see RTC Section 3.3.1) describes ZEVs that can perform in full the work of a comparable ICE vehicle. As further explained in our response in RTC section 2.4, we acknowledge that there are some uses cases, including those with extreme daily VMT demands, for which ICE vehicles may be better suited during the timeframe of this rule. Our modeled potential compliance pathway accounts for this and includes ICE vehicles. For all of the HDV subcategories, that pathway projects that there would be ICE vehicles available to meet the needs of those vehicles that operate under extreme daily VMT demands.

Please see Section 3.3 of this RTC for responses to comments relating to range and battery sizing.

Battery Length Calculation in 2_BEV Tech worksheet – EPA included an assessment of battery volume in the NPRM (see Draft RIA Section 2.4.2, p.166). The volume assessment drives the calculation of the width of the battery based on the battery volume that is determined for each vehicle type within HD TRUCS. The calculation divides the battery volume by the presumed battery height (110% of the frame rail height) and by the battery length (wheelbase) of each vehicle type to calculate a battery width. However, if this entire rectangle is used for

---

[352] DOE. Vehicle Technologies Office. Fact of the Week #1293. “In 2019, More Heavy Trucks Operated at 34,000 to 36,000 Pounds than Any Other Weight Category”. Available online: https://www.energy.gov/eere/vehicles/articles/fotw-1293-june-5-2023-2019-more-heavy-trucks-operated-34000-36000-pounds-any

[353] See Landgraf, Mike. Memorandum to docket EPA-HQ-OAR-2022-0985. “HD GHG Phase 3 Rule BEV Payload Analysis” February 26, 2024.

batteries on a BEV, there will be no room for the front or rear tires, since the prescribed dimensions violate the space envelope required for the tires. EMA recommends that the battery length factor be reduced to allow for a more realistic volume requirement for the batteries in HD TRUCS. Specifically, EMA reduced the length by 26 inches for non-tractors to allow space for the front tire. The overlap with the rear tire may be able to go between the frame rails behind the axle, since trucks have more frame extended behind the rear axle(s). For Class 7 tractors, which are a 4x2 axle configuration, the length should be reduced by 26 inches for both the front and rear axle, for a total reduction of 52 inches. The after-frame on tractors is very short to provide clearance for the landing gear of a trailer, so there is no space behind the axle for additional batteries. On Class 8 tractors, which have a tandem rear axle (6x4), the battery length needs a reduction of 26 inches for the front axle and 52 inches for the rear axle. The wheelbase on 6x4 configurations is measured to the centerline of the two rear axles, which necessitates additional reductions over Class 7 tractors. These battery-length errors allow HD TRUCS to include various tractors as BEVs when, in fact, there is insufficient space for the required battery. Those vehicles should be treated as FCEVs instead. The space needed for the frame rails also needs to be considered. Each of the two rails are about 3.5 inches wide. EMA believes this is a less significant issue in the battery width limitation evaluation, so it is not included in the corrections to EMA HD TRUCS. [EPA-HQ-OAR-2022-0985-2668-A1, p. 24]

EPA Summary and Response:

Summary:

EMA commented that the calculation used in determining the length of battery in the battery volume calculation in HD TRUCS was inaccurate. They commented that the calculation did not account for wheels and tires when determining the length of the battery and that the value we used (wheelbase) should be shortened to account for the steer tire and the drive tires. EMA gave values that could be used to account for wheels and tires in determining the overall length of the battery. They also pointed out that the calculation for width did not account for the width of the frame rails and gave a value that can be used for the width of the frame.

Response:

EPA generally agrees with EMA that our calculation for battery length in the proposal should have accounted for wheels and tires, and we also understand the criticisms about factoring in the width of the frame. However, we have taken a different approach for the final rule. Instead of calculating the specific volume of the battery for each vehicle, we have compared the battery size in kWh of the vehicles in HD TRUCS to comparable current BEVs. If the comparison showed that the battery size of the vehicle in HD TRUCS was similar to or smaller than current production BEVs, that battery was determined to have no packaging constraints. If the battery size of the vehicle in HD TRUCS was significantly larger than current production BEVs, then that battery was determined to have packaging constraints and would not be possible to package on the vehicle. This is a conservative approach as we are presume that battery energy density will increase over time allowing the same amount of energy to be stored in a physically smaller battery. This new approach is more robust because it compares packaging to existing BEVs, so we are confident that similar battery volumes can be packaged. For further discussion on our analysis for battery volume and packaging see Chapter 2.9.1.2 of the RIA.

a. Current Adoption Of Electric Vehicles

Today, electric vehicles are barely used in the heavy-duty industry. Manufacturers offer very few models, and heavy-duty vehicle operators do not buy them. The few that have been purchased are almost all show-pieces purchased by local governments. [EPA-HQ-OAR-2022-0985-1660-A1, p. 19]

Battery-Electric Vehicles. For the current model year, there are only 120 heavy-duty battery-electric vehicle models available for purchase. See U.S. Dep't of Energy, Alternative Fuels Data Ctr., Alternative Fuel and Advanced Vehicle Search, https://tinyurl.com/4pmta4a6 (last accessed June 12, 2023).2 Those models are spread between several categories, including step vans, vocational/ cab chassis vehicles, street sweepers, refuse haulers, tractors, passenger vans, shuttle buses, transit buses, and school buses. Id. The limited number of options may be a result of exceedingly low demand. In 2022, for example, there were a mere 2,000 electric buses registered in the United States, making up only 2 percent of buses overall. See IEA, Electric Bus Registrations and Sales Share by Region, 2015-2022 (Apr. 26, 2023), https://tinyurl.com/yckwdj3e. In that same year, there were a mere 3,100 electric trucks registered in the United States, making up only 0.4 percent of trucks overall. See IEA, Electric Truck Registrations and Sales Share by Region, 2015-2022 (Apr. 26, 2023), https://tinyurl.com/4z2c2rm5. [EPA-HQ-OAR-2022-0985-1660-A1, pp. 19 - 20]

Fuel-Cell Vehicles. The number of heavy-duty fuel-cell vehicle models is even lower. For the current model year, there are only four heavy-duty fuel-cell models available for purchase. See U.S. Dep't of Energy, Alternative Fuels Data Ctr., Alternative Fuel and Advanced Vehicle Search, https://tinyurl.com/ymvf2u6z (last accessed June 13, 2023).3 Three are transit buses, and the fourth is a street sweeper. Id. There are thus zero available 2023 fuel-cell models for many of the vehicle categories in the heavy-duty industry. And the models that are available are barely used in the United States. In 2022, for example, there were approximately 200 fuel-cell buses registered nationwide, accounting for only 0.2 percent of buses overall. See IEA, Trends in Electric Light- Duty Vehicles (2023), https://tinyurl.com/mpwrhuev. [EPA-HQ-OAR-2022-0985-1660-A1, p. 20]

> 3 EPA reports that there are 16 available heavy-duty fuel-cell models. Draft RIA at 76–77. Again, EPA includes models from prior and future years, as well as internal-combustion-engine models that can be retrofitted into electric vehicles through a costly conversion process. See id.

By and large, the heavy-duty industry has not embraced a shift from internal- combustion-engine vehicles to electric ones. [EPA-HQ-OAR-2022-0985-1660-A1, p. 20]

Organization: Clean Air Task Force et al.

A. EPA must use an accurate baseline in promulgating vehicle standards.

Under section 202(a)(1), EPA must, as a consequence of its Endangerment Finding, adopt standards that address the threat that GHG emissions from heavy-duty vehicles pose to public health and welfare. See 42 U.S.C. § 7521(a)(1). Standards that do no more than track anticipated market trends, when stronger standards are technically and economically feasible, do not satisfy this statutory mandate in the face of ever-growing risks and impacts of climate change. A factual prerequisite to determining whether proposed emission standards will have any independent effect or will instead merely track, or trail, anticipated market developments, is to develop an accurate baseline (or "reference case," as EPA refers to it in the proposal). Reflecting this reality, OMB's Circular A-4 provides that identifying an appropriate baseline is a "key element" of a regulatory analysis.40 Accordingly, an agency's failure to use an appropriate baseline in developing its regulatory action is arbitrary and capricious. See Leather Indus. of Am., Inc. v. EPA, 40 F.3d 392, 404-05 (D.C. Cir. 1994) (holding that EPA's selenium limits for land-applied sewage sludge were arbitrary and capricious because they were based on overly conservative baseline exposure assumptions); Stewart v. Azar, 366 F. Supp. 3d 125, 154 (D.D.C. 2019) (striking down Department of Health and Human Services' approval of state Medicaid demonstration project because it was based on an irrational baseline); cf. Am. Equity Inv. Life Ins. Co. v. SEC, 613 F.3d 166, 178 (D.C. Cir. 2010) ("The SEC could not accurately assess any potential increase or decrease in competition, however, because it did not assess the baseline level of price transparency and information disclosure under state law."); Or. Nat. Desert Ass'n v. Jewell, 840 F.3d 562, 568 (9th Cir. 2016) (noting that in the context of NEPA, "[t]he establishment of a baseline is not an independent legal requirement, but rather, a practical requirement in environmental analysis often employed to identify the environmental consequences of a proposed agency action.") (citation and internal quotation marks omitted). It is therefore imperative that EPA develop an accurate baseline of HD ZEV penetration and use that baseline to help inform the stringency of its final standards. [EPA-HQ-OAR-2022-0985-1640-A1, p. 20]

40 OMB, Circular A–4: Regulatory Analysis, at 2 (Sept. 17, 2003), https://www.whitehouse.gov/wp-content/uploads/legacy_drupal_files/omb/circulars/A4/a-4.pdf.

B. The proposal underestimates baseline HD ZEV penetration levels.

EPA's proposed standards are too lenient in part because they rely on underestimates of future baseline HD ZEV market penetration levels, which causes EPA to underestimate the feasibility of higher stringency levels that would be achievable through greater deployment of zero-emission technologies. Finalizing the standards as proposed would fail to achieve the emissions reductions necessary to meet EPA's statutory mandate to protect public health and welfare, including by facilitating greater use of improved emission control technologies. See, e.g., NRDC v. EPA, 655 F.2d 318, 328 (D.C. Cir. 1981) (stating that "Congress intended the agency to project future advances in pollution control capability" and noting that Clean Air Act section 202(a)(2) embodies Congress's intent that EPA "press for the development and application of improved technology rather than be limited by that which exists today."); 88 Fed. Reg. at 25949 (noting that EPA "has clear authority to set standards under [Clean Air Act] section 202(a)(1)–(2) that are technology forcing when EPA considers that to be appropriate.").41 EPA has recognized in the past that underestimating the baseline has a direct impact on the stringency of emission regulations. See, e.g., Control of Air Pollution From New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards 87 Fed. Reg. 17414, 17561 (proposed Mar. 28, 2022) (recognizing that considering a more accurate (higher) baseline HD ZEV market penetration could lead to more stringent standards). [EPA-HQ-OAR-2022-0985-1640-A1, pp. 20 - 21]

41 See also 81 Fed. Reg. 73478, 73809 (Oct. 25, 2016) (EPA's HDV GHG Phase 2 standards were "predicated on performance of technologies not only currently deployed but those which reasonably can be developed during the phase in period.").

Here, EPA's baseline HD ZEV penetration rates are too low because they unreasonably assume essentially no baseline ZEV adoption due to natural market forces and instead model the level of ZEVs resulting only from the ACT rule in California and some of the other states that have adopted the ACT rule.42 This approach results in an unrealistic underestimate of baseline HD ZEV sales. [EPA-HQ-OAR-2022-0985-1640-A1, p. 21]

42 See EPA, Draft Regulatory Impact Analysis (DRIA), at 317 ("To estimate the adoption of HD ZEVs in the reference case, we assumed a national level of ZEV sales based on volumes expected from ACT in California and the other states that have adopted ACT. We used those volumes as the numeric basis for a projection of the number of ZEVs nationwide in the 2024 and later timeframe.") Here, EPA considered ZEV sales that would occur in California and five ACT-adopting states (Oregon, Washington, New York, New Jersey, and Massachusetts), but did not account for two additional states that have since adopted the rule (Vermont and Colorado). See Sierra Club, Vermont Adopts Rules for Cleaner Cars and Trucks (Dec. 1, 2022), https://www.sierraclub.org/vermont/vermont-adopts-rules-cleaner-cars-and-trucks; Colo. Dep't Pub. Health & Env't, Colorado Adopts New Measures to Increase Availability of Zero-Emission Trucks That Offer Lower Operating and Fuel Costs (Apr. 21, 2023), https://cdphe.colorado.gov/press-release/colorado-adopts-new-measures-to-increase-availability-of-zero-emission-trucks-that.

In fact, as explained in this section, the level of ZEV sales EPA models for its proposed standards—which is based on payback period as the driver of ZEV adoption43—is actually a more reasonable assessment of a likely baseline level of ZEV sales. Specifically, the ZEV penetration rates that EPA anticipates will result from the standards merely track one projection of market trends rather than reflect any additional feasible adoption of emissions-reducing technology. The payback period approach on which EPA relies to set its standards, then, more appropriately informs baseline ZEV adoption, i.e., what the heavy-duty ZEV market would be expected to achieve without considering the effect of Phase 3 standards on ZEV adoption. [EPA-HQ-OAR-2022-0985-1640-A1, p. 21]

43 EPA based its payback periods on a report by ACT Research titled "Charging Forward: 2020-2040 BEV & FCEV Forecast & Analysis: Commercial Electric and Fuel Cell Vehicle Multi-Client Study." DRIA, at 231-32 ("[W]e relied on the ACT Research method to assess adoption rates, which we modified to account for the effects of our proposed regulation."). Citing a licensing agreement, EPA declined to make the ACT Research report available in the public docket. Memorandum from George C. Mitchell, Mem. to Docket No. EPA-HQ-OAR-2022-0829 (Apr. 7, 2023), https://www.regulations.gov/document/EPA-HQ-OAR-2022-0985-0931. Furthermore, the report is not available in the EPA Reading Room. Instead, it is available only for purchase from ACT Research by paying a $25,000 fee. ACT Research, Are You Charging Forward to Zero Emissions?, https://www.actresearch.net/consulting/special-projects/commercial-vehicle-decarbonization-forecast-reports (last visited June 10, 2023) (PDF of pricing information attached to this comment letter). Thus, we cannot make an assessment of the accuracy, reasonableness, or appropriateness of ACT Research's data, assumptions, methodology, analysis, findings, and conclusions. This, in turn, prevents us from assessing and commenting on the reasonableness of EPA's heavy reliance on the report and on EPA's approach to determining payback periods. We object to EPA's withholding of this critical material from the public docket, which has prevented us from offering meaningful comment on a key aspect of the proposal.

Several additional analyses project baseline levels of HD ZEV penetration that are very close to the level of ZEVs that EPA anticipates manufacturers will produce to comply with the proposed standards, further supporting a higher baseline and calling into question EPA's approach. And data on government, manufacturer, and fleet policies, investments, and commitments underscore the accuracy of these higher levels of baseline HD ZEV penetration. EPA should revise its baseline in the final rule to reflect what would actually occur under baseline circumstances, which would result in higher baseline HD ZEV sales shares. A more accurate baseline would involve ZEV penetration levels closer to those that EPA projected would result from the proposed standards. See EPA, Draft Regulatory Impact Analysis (DRIA) at 319, Tbl. 4-7 (showing projected ZEV adoption rates under EPA's proposed standards). Assuming a more accurate and reasonable HD ZEV baseline, it becomes clear that a national stringency level at least as protective of public health and welfare as the ACT Rule, implemented nationwide, is entirely feasible and more aligned with EPA's mandates under the Clean Air Act. [EPA-HQ-OAR-2022-0985-1640-A1, pp. 21 - 22]

1. The payback period analysis that EPA relies on in proposing the stringency of its standards should instead be used to inform EPA's regulatory baseline.

Circular A-4, which provides guidance to federal regulatory agencies on the rulemaking process, explains that a regulatory baseline "should be the best assessment of the way the world would look absent the proposed action," and should include consideration of the "evolution of the market."44 In EPA's proposal, the Agency explains that in setting its proposed standards it relied primarily on a method developed by ACT Research based on technology payback period to inform its ZEV adoption level because "payback is the most relevant metric to the HD vehicle industry," and "only ACT Research's work directly related payback period to adoption rates." DRIA at 232. Payback period, however, is of key relevance to a baseline-level analysis—especially for heavy-duty vehicles. EPA's proposal does not consider payback period to inform its baseline HD ZEV penetration rates, but it should. Heavy-duty vehicles are generally purchased to fulfill a business need such as delivery services, municipal work, transporting people or goods, construction, refuse collection, and freight delivery. 88 Fed. Reg. at 25938. As EPA notes, "[b]usinesses that operate HD vehicles are under competitive pressure to reduce operating costs, which should encourage purchasers to identify and rapidly adopt new vehicle technologies that reduce operating costs." 88 Fed. Reg. 26071. Thus, market trends, payback periods, and total cost of ownership of vehicles are and have always been relevant to a baseline-level inquiry. While it is possible that some HDV purchasers refrain from purchasing ZEVs even when they make economic sense, it is unreasonable to wholly disregard payback periods in setting the baseline—especially when Circular A-4 directs EPA to consider "market trends" in doing so—and consider them only in setting the standards. [EPA-HQ-OAR-2022-0985-1640-A1, p. 22]

44 OMB, Circular A-4, at 15.

EPA also explains that ZEV adoption rates typically follow an S-curve, DRIA at 231, and cites several additional sources modeling HD ZEV adoption, including research by government, nonprofit, and private entities.45 These additional sources, however, actually consider and/or project HD ZEV penetration rates in a baseline scenario—i.e., what would happen under market conditions absent the Phase 3 standards—and each projects ZEV penetration consistent with or even higher than that EPA anticipates will result from its proposed standards. Essentially, EPA appears to simply propose to codify a baseline level of HD ZEV penetration, rather than drive additional feasible adoption of emission control technologies to achieve the emissions reductions necessary to protect public health and welfare. [EPA-HQ-OAR-2022-0985-1640-A1, pp. 22 - 23]

45 EPA notes that it considered the following studies: Ellen Robo & Dave Seamonds, ERM, Technical Memo to Environmental Defense Fund: Analysis of Alternative Medium- and Heavy-Duty Zero Emission Vehicle Business-As-Usual Scenarios (May 16, 2022) [hereinafter Robo & Seamonds, Technical Memo], https://www.erm.com/contentassets/154d08e0d0674752925cd82c66b3e2b1/edf-zev-baseline-technical-memo-16may2022.pdf; Peter Slowik et al., ICCT & Energy Innovation, Analyzing the Impact of the Inflation Reduction Act on Electric Vehicle Uptake in the United States, at ii (2023), https://theicct.org/wp-content/uploads/2023/01/ira-impact-evs-us-jan23-2.pdf; Baha M. Al-Alawi et al., Calstart, Global Sales Targets for Zero-Emission Medium- and Heavy-Duty Vehicles—Methods and Application (2022), https://globaldrivetozero.org/site/wp-content/uploads/2022/02/CALSTART_Global-Sales_White-Paper.pdf. EPA also considered several models: MA3T-TruckChoice, see Zhenhong Lin et al., Oak Ridge Nat'l Lab'y, Presentation of Transportation Energy Evolution Modeling (TEEM) Program (June 22, 2021), https://www.energy.gov/sites/default/files/2021-07/van021_lin_2021_o_5-28_1126pm_LR_FINAL_ML.pdf; Oak Ridge Nat'l Lab'y, Transportation Energy Evolution Modeling (TEEM) Program, https://www.energy.gov/eere/vehicles/articles/transportation-energy-evolution-modeling-teem-program-1 (last visited June 14, 2023); Nat'l Renewable Energy Lab'y (NREL), T3CO: Transportation Technology Total Cost of Ownership, https://www.nrel.gov/transportation/t3co.html (last visited June 14, 2023); Argonne Nat'l Lab'y, BEAN: Benefits Analysis, https://vms.taps.anl.gov/tools/bean/ (last visited June 14, 2023); and Pacific Northwest Nat'l Lab'y, GCAM: Global Change Analysis Model, https://gcims.pnnl.gov/modeling/gcam-global-change-analysis-model (last visited June 14, 2023).

The baseline HD ZEV penetration projections from the analyses EPA cites, along with those of other relevant analyses, are shown in comparison to projected ZEV penetration rates in EPA's baseline and proposed standards in Table 2, below. Comparing the levels in each of these baseline projection analyses to EPA's baseline, and the proposed standards highlights that EPA's baseline HD ZEV sales projections are unreasonably low, and that in fact EPA's proposed standards would merely codify a reasonably anticipated market-driven heavy-duty ZEV penetration level. [EPA-HQ-OAR-2022-0985-1640-A1, p. 23.] [See Docket Number EPA-HQ-OAR-2022-0985-1640-A1, pages 23-24, for Table 2]

Each of the analyses in Table 2 endeavors to model what the market is likely to do absent the Phase 3 standards. The values show a range due to differing underlying assumptions regarding the impact of state and federal policies, along with assumptions regarding market trends, but all show baseline ZEV penetration rates much higher than EPA's baseline and more consistent with the level of ZEV penetration that EPA predicts will result from its proposed standards. A payback period approach like the one EPA uses in its standard-setting analysis is by no means the only consideration relevant to estimating HD ZEV baseline penetration levels, but payback periods are reasonable and important factors to consider in setting the baseline ZEV penetration rate. In considering payback period for the baseline, however, EPA should consider sources in addition to the ACT Research report. As explained in footnote 43, the Agency has not made that report available in the public docket, making it impossible for commenters to understand whether the ACT Research payback periods are accurate or reasonable. In addition to considering payback period, EPA should consider other relevant factors that inform baseline HD ZEV sales, such as federal and state rules, programs, and incentives, and fleet and manufacturer commitments—many of which also inform the baseline analyses listed in Table 2. [EPA-HQ-OAR-2022-0985-1640-A1, pp. 24 - 25]

2. EPA's HD ZEV baseline should account for all state-level rules and investments.

EPA's proposal correctly notes that "a number of states have signaled interest in greater adoption of HD ZEV technologies and/or establishing specific goals to increase the HD electric vehicle market." 88 Fed. Reg. at 25947.57 EPA highlights a few of these state-level goals, such as the Multi-State Medium- and Heavy-Duty Zero Emission Vehicle Memorandum of Understanding (MOU) organized by Northeast States for Coordinated Air Use Management (NESCAUM), but the Agency underestimates the depth and breadth of state-level commitments and fails to incorporate their effects on HD ZEV sales directly into the baseline. For the final rule, EPA should utilize a baseline that takes into account (1) the projected HD ZEV sales to be achieved in all states that have adopted the ACT rule,58 including the most recent states to have adopted that rule; (2) projected sales to be achieved in all states that have signed the NESCAUM MOU; and (3) at least some modest level of ZEV adoption by other states based on factors that will independently drive adoption of HD ZEVs: extensive and growing government, fleet, and manufacturer commitments, achieved or near-term HD ZEV cost favorability, and the impacts of the BIL and IRA on market-based adoption. [EPA-HQ-OAR-2022-0985-1640-A1, p. 25]

57 See also 87 Fed. Reg. at 17440, 17595–17598 (noting that numerous states "have announced plans to shift the heavy-duty fleet toward zero-emissions technology," and detailing examples such as states' and cities' expansion of electric bus fleets).

58 Advanced Clean Trucks Regulation, Cal. Code Regs. tit. 13, §§ 1963-1963.5, 2012-2012.2 (2019), https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2019/act2019/fro2.pdf.

a. EPA's baseline should account for all states that have adopted the ACT rule.

EPA notes that for its baseline, the Agency "assumed a national level of ZEV sales based on volumes expected from ACT in California and the other states that have adopted ACT," and "used those volumes as the numeric basis for a projection of the number of ZEVs nationwide in the 2024 and later timeframe." DRIA at 317. EPA has now granted California's ACT rule waiver request, 88 Fed. Reg. at 25947 n.186, and the Agency should continue to include sales required under the ACT in its final baseline HD ZEV penetration levels. For the proposal, EPA assumes ACT-level ZEV sales in California plus five additional states that have adopted ACT under Clean Air Act section 177: Oregon, Washington, New York, New Jersey, and Massachusetts. DRIA at 317 n.iii; 88 Fed. Reg. at 26040 n.656. EPA also notes that Vermont recently adopted ACT under section 177 and that Vermont's adoption was not included due to timing issues, but that it "provides additional support for the ZEV levels in our reference case." Id. at 26040 n.657. In fact, Vermont and Colorado both have adopted the ACT rule,59 and the ACT-level HD ZEV sales requirements for both states should be calculated and included in EPA's baseline for the final rule. HD ZEV sales in ACT-adopting states will need to reach between 30 percent (Class 7–8 tractors) and 50 percent (Class 4–8 trucks) by 2030, and 40 percent (Class 7–8 tractors) to 75 percent (Class 4–8 trucks) by 2035 in order to meet the ACT targets.60 [EPA-HQ-OAR-2022-0985-1640-A1, pp. 25 - 26]

59 See Sierra Club, Vermont Adopts Rules for Cleaner Cars and Trucks (Dec. 1, 2022), https://www.sierraclub.org/vermont/vermont-adopts-rules-cleaner-cars-and-trucks; Colo. Dep't Pub. Health & Env't.

60 Advanced Clean Trucks Regulation, Cal. Code Regs. tit. 13, § 1963.1, Table A-1 (2019); see also Rachel MacIntosh et al., EDF, Electric Vehicle Market Update 15 (April 2022) [hereinafter MacIntosh et al., April 2022 EV Market Update].

b. EPA's baseline should account for significant ZEV adoption in the states that are in the process of adopting ACT and the states that have signed the NESCAUM multi-state MOU.

As EPA correctly explains, "there have been multiple actions by states to accelerate the adoption of HD ZEVs" in addition to the ACT rule. 88 Fed. Reg. at 25930. EPA notes that 17 states and the District of Columbia have signed the NESCAUM MOU, "establishing goals to support widespread electrification of the HD vehicle market." 88 Fed. Reg. at 25931. The multi-state MOU targets ZEV sales equaling 30 percent of all HDV sales by 2030 and 100 percent of all HDV sales by 2050.61 In July 2022, NESCAUM and the MOU states issued a comprehensive and detailed Action Plan to meet their goals.62 An analysis by ICCT estimates that 36 percent of all HDV sales in MOU states (excluding California) would be ZEVs in 2030 if all states implement the goals set out in the MOU.63 [EPA-HQ-OAR-2022-0985-1640-A1, p. 26]

61 NESCAUM, Multi-State Medium- and Heavy-Duty Zero Emission Vehicle Memorandum of Understanding, at 3-4 (2022) [hereinafter NESCAUM, MOU], https://www.nescaum.org/documents/mhdv-zev-mou-20220329.pdf; 88 Fed. Reg. at 25947.

62 NESCAUM, Multi-State Medium- and Heavy-Duty Zero-Emission Vehicle Action Plan: A Policy Framework to Eliminate Harmful Truck and Bus Emissions (2022) [hereinafter NESCAUM, Action Plan], https://www.nescaum.org/documents/multi-state-medium-and-heavy-duty-zev-action-plan-dual-page.pdf.

63 Arijit Sen et al., ICCT, Benefits of the 2020 Multi-State Medium- and Heavy-Duty Zero-Emission Vehicle Memorandum of Understanding 5 (2022), https://theicct.org/wp-content/uploads/2022/04/md-hd-mou-benefits-apr22.pdf.

Moreover, EPA correctly "anticipate[s] more jurisdictions will follow" with proposals to fully adopt the ACT rule. 88 Fed. Reg. at 25948. In April 2022, Connecticut passed legislation authorizing the state's Department of Energy and Environmental Protection to adopt the ACT rule.64 Rhode Island is currently in the midst of a rulemaking process to adopt the ACT rule, with the comment period having just closed on May 24, 2023,65 and in April 2023, Maryland's General Assembly passed a bill directing the state to adopt the ACT rule.66 [EPA-HQ-OAR-2022-0985-1640-A1, p. 26]

64 See Sierra Club, Connecticut General Assembly Passes Legislation for Clean Trucks, Clean Air (Apr. 29, 2022), https://www.sierraclub.org/press-releases/2022/04/connecticut-general-assembly-passes-legislation-for-clean-trucksclean-air.

65 See R.I. Dep't Env't Mgmt., Advanced Clean Cars II (ACCII) & Advanced Clean Trucks (ACT), https://dem.ri.gov/environmental-protection-bureau/air-resources/advanced-clean-cars-ii-advanced-clean-trucks (last visited June 15, 2023).

66 Calstart, By Paving the Way for Clean Trucks, Maryland Reaffirms Its Position as a Climate Leader, https://calstart.org/calstart-applauds-maryland-for-adopting-clean-truck-legislation/ (last visited June 15, 2023).

HDV sales in ACT and MOU states, including California, make up a significant portion of national HDV sales—about 36.5 percent.67 Despite mentioning the MOU, the proposal does not factor into its baseline the fact that ZEVs will be added to the heavy-duty fleet more rapidly in these 17 states and the District of Columbia, which make up more than a third of national HDV sales, or that several of these states are poised to adopt the ACT rule soon.68 EPA's baseline must reflect the impact of these significant commitments to ZEVs by the MOU signatories. [EPA-HQ-OAR-2022-0985-1640-A1, p. 27]

67 Claire Buysse et al., Racing to Zero: The Ambition We Need for Zero-Emission Heavy-Duty Vehicles in the United States, ICCT (Apr. 8, 2022), https://theicct.org/racing-to-zero-hdv-us-apr22/. This is consistent with MOVES projections for MY 2027, which show 215,328 heavy-duty sales in all the MOU states, as compared to 589,910 total heavy-duty sales nationally, or 36.5 percent of all sales.

68 The MOU signatories are: California, Colorado, Connecticut, Hawaii, Maine, Maryland, Massachusetts, Nevada, New Jersey, New York, North Carolina, Oregon, Pennsylvania, Rhode Island, Vermont, Virginia, Washington, and the District of Columbia. See NESCAUM, MOU.

c. EPA should consider the impacts of California's Advanced Clean Fleets rule.

On April 28, 2023, the California Air Resources Board (CARB) approved the ACF rule, which will result in even faster growth in heavy-duty ZEV sales in California.69 The ACF rule will regulate public and private fleets, new mobility fleets, large employer fleets, rental fleets, and delivery fleets, with the "goal of achieving a zero-emission public bus and truck fleet in California by 2045 and significantly earlier for certain market segments like last mile delivery and drayage trucks."70 The ACF regulations are expected to be fully effective by 2024, increasing HD ZEV uptake in California even more than the ACT rule alone.71 [EPA-HQ-OAR-2022-0985-1640-A1, p. 27]

69 CARB, California Approves Groundbreaking Regulation That Accelerates the Deployment of Heavy-Duty ZEVs to Protect Public Health (Apr. 28, 2023), https://ww2.arb.ca.gov/news/california-approves-groundbreaking-regulation-accelerates-deployment-heavy-duty-zevs-protect.

70 MacIntosh et al., April 2022 EV Market Update, at 15.

71 Id.

CARB has explained that the ACF regulation "is projected to significantly increase the number of medium- and heavy-duty ZEVs in California beyond the ZEV sales expected from the ACT regulation," with ZEV sales greater under ACF and ACT together than ACT alone for all model years covered by EPA's proposed standards, and beyond.72 Although the ACF Rule has not yet been fully finalized under California state law, fleets are already planning for ACF implementation; as one industry compliance expert has advised fleets, "[t]here is a lot of coordination that's going to be required between groups like operations, finance and vehicle procurement," and "coordination needs to start happening now."73 If the ACF regulation is finalized and enforceable before finalization of EPA's rule, EPA should include ACF-related HD ZEV sales in its baseline. Otherwise, EPA should conduct a sensitivity analysis of the impact of ACF on its baseline. Regardless, the fact that the industry is already planning to increase HD ZEV deployment in response to ACF provides further support for strong Phase 3 standards. [EPA-HQ-OAR-2022-0985-1640-A1, p. 27]

72 CARB, Public Hearing to Consider the Proposed Advanced Clean Fleets Regulation, Staff Report: Initial Statement of Reasons 1, Fig.1 (2022), https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2022/acf22/isor2.pdf (showing ZEV increases under ACF for all years through 2049).

73 John Kingston, Advanced Clean Fleets Rule: Like It or Not, It's Time to Get Ready, Freight Waves (June 1, 2023), https://www.freightwaves.com/news/advanced-clean-fleets-rule-like-it-or-not-its-time-to-get-ready (comments of Sean Cocca, director of compliance at the advisory firm of Gladstein, Neandross & Associates).

3. EPA's baseline should account for other government, fleet, and manufacturer commitments and investments.

While including all ACT-adopting and MOU states in the baseline would result in more accurate projections and therefore more appropriate standards, even these more accurate estimates would fail to reflect growing HD ZEV deployment in other states. Significant future HD ZEV deployment will be driven by other federal government programs, local government programs, and private sector investments. The proposal notes a few of these public and private programs, investments, and commitments, but it fails to capture the depth and breadth of the pace at which these commitments are being announced. This section offers a non-exhaustive survey of some of the many investments already made. Several sources are regularly updated and available to EPA to track the rapidly expanding HD ZEV market.74 [EPA-HQ-OAR-2022-0985-1640-A1, p. 28]

74 For updated information, EPA should consult the following resources: EDF, Electric Fleet Deployment & Commitment List, https://docs.google.com/spreadsheets/d/1l0m2Do1mjSemrb_DT40YNGou4o2m2Ee-KLSvHC-5vAc/edit#gid=1902784037 (last visited June 15, 2023) (tracking, under the "Production" tab, fleet-level orders, vehicles in operation, commitments, production, and EV certified dealerships); CALSTART, Zero-Emission Technology Inventory, https://globaldrivetozero.org/tools/zeti/ (last visited June 15, 2023) (tracking HDV ZEV models and commercial availability); DOE, Federal and State Laws and Incentives, Alternative Fuels Data Center, https://afdc.energy.gov/laws (last visited June 15, 2023) (tracking federal, state, and local laws and commitments within all ZEV sectors).

a. State policies and commitments and local government actions

On the state level, commitments and incentives extend beyond the ACT rule and the multi-state MOU, even in states that have adopted ACT and/or signed the MOU. For example, CARB's Innovative Clean Transit regulation directs large transit agencies to make 25 percent of new bus purchases zero-emission in 2023, increasing to 50 percent by 2026 and 100 percent by 2029.75 [EPA-HQ-OAR-2022-0985-1640-A1, p. 28]

75 Sandra Wappelhorst & Felipe Rodríguez, Decarbonizing Bus Fleets: Global Overview of Targets for Phasing Out Combustion Engine Vehicles, ICCT (Dec. 9, 2021), https://theicct.org/decarbonizing-bus-fleets-global-overview-of-targets-for-phasing-out-combustion-engine-vehicles; CARB, Innovative Clean Transit Fact Sheet (May 16, 2019), https://ww2.arb.ca.gov/resources/fact-sheets/innovative-clean-transit-ict-regulation-fact-sheet.

Significant state-level commitments have been made in other states beyond the ACT and MOU states as well. In fact, all 50 states plus the District of Columbia have announced goals, made commitments, promulgated regulations, and/or provided financial incentives (such as rebates and funding) specific to the heavy-duty sector.76 These heavy-duty sector programs are in addition to many broader state and local programs targeted at ZEV adoption generally (across all vehicle sectors), which also exist in all 50 states,77 and include programs such as: medium- and heavy-duty or diesel emissions reduction funding, rebates, or HDV replacement grants in states such as Delaware, Idaho, Indiana, Iowa, Michigan, Montana, New Mexico, Ohio, South Dakota, Texas, and Wyoming;78 allowance for HD ZEVs to exceed weight limits in Arizona; ZEV school and/or transit bus programs and incentives in Illinois, Minnesota, Missouri, Oklahoma, Texas, West Virginia, and Wisconsin; and a diesel refuse truck replacement program in Nebraska.79 Additionally, states beyond those that have adopted the ACT rule or signed the MOU have been forming smaller regional collaborations aimed at HD ZEV adoption. For example, Illinois, Indiana, Michigan, Minnesota, and Wisconsin signed an MOU establishing the Regional Electric Vehicle Midwest Coalition, which "aims to create [a] cohesive regional framework to accelerate the transition to electric vehicles."80 One of the Regional Electric Vehicle Midwest Coalition's three key foundations is to accelerate medium- and heavy-duty fleet electrification.81 These state actions—reaching across the nation—should be considered when setting a nationwide level of ZEV penetration for EPA's baseline. [EPA-HQ-OAR-2022-0985-1640-A1, pp. 28 - 29]

76 See DOE, Federal and State Laws and Incentives.

77 Information on regulations and programs in all states, including those that have signed the MOU or adopted ACT regulations, is available in id., and from the N.C.Clean Energy Tech. Ctr., Database of State Incentives for Renewables and Efficiency (DSIRE), https://programs.dsireusa.org/system/program (last visited June 15, 2023).

78 Many of these programs are funded as part of the Volkswagen Environmental Trust/Volkswagen settlement.

79 This list is compiled from information available at DOE, Federal and State Laws and Incentives. This list is a non-exhaustive sample of programs and investments and does not include the vast array of programs and incentives available in the MOU and ACT states.

80 MacIntosh et al., April 2022 EV Market Update, at 16.; Regional Electric Vehicle Midwest Coalition, Memorandum of Understanding Between Illinois, Indiana, Michigan, Minnesota, and Wisconsin 1 (2021), https://www.michigan.gov/documents/leo/REV_Midwest_MOU_master_737026_7.pdf.

81 Id

Cities and local entities are also committing to ZEV technologies in the heavy-duty sector. The Los Angeles Department of Transportation has committed to electrifying its entire transit fleet by 2030 or sooner.82 Numerous other cities and localities across the country have set zero-emission transit and/or school bus commitments or piloted zero-emission bus programs, including programs in Chicago, Seattle, New York City, and Washington, D.C. 87 Fed. Reg. at 17597. Arizona—not an ACT or MOU state—had the largest year-over-year increase in zero-emission transit bus deployment in the past year, with an increase of 280 percent.83 Forty-seven U.S. states and the District of Columbia had funded, ordered, or deployed full-size zero-emission HD transit buses as of September 2022.84 Notably, the region comprised of Arkansas, Louisiana, New Mexico, Oklahoma, and Texas—none of which are ACT or MOU states—had the highest growth rate in zero-emission buses (129 percent compared to 2021), and seven out of ten of the states with the largest numerical increases in full-size zero-emission transit buses (compared to 2021) were states that had not adopted the ACT rule or signed the multi-state MOU.85 [EPA-HQ-OAR-2022-0985-1640-A1, p. 29]

84 Id. at 6–8.

85 Id. at 9.

According to data from the World Resources Institute (WRI), there are now electric school bus commitments in districts in all 50 states and the District of Columbia.86 These commitments are growing especially rapidly in the South. Prior to October 2022, over 50 percent of electric school bus commitments were in California, but now, California's share accounts for only 39 percent of commitments—"only a little more than the South's 34% share of commitments."87 Moreover, these commitments are being announced not only in cities and suburbs, but also in rural areas. In September 2022, only 19 percent of school districts with at least one committed electric school bus were in rural areas; by December 2022, 41 percent of districts with at least one committed electric school bus were classified as rural.88 At least 5,612 electric school buses have been ordered, delivered, put in operation, or funded through government awards as of December 2022, in more than 895 school districts.89 WRI notes that "[t]his is almost double the number of both buses and districts with electric school buses in just three months" since WRI's previous dataset.90 States and cities across the country also have ordered not just electric school and transit buses, but other Class 4–8 ZEVs, such as refuse and fire trucks. Again, these orders are happening in states beyond those that have signed the MOU or adopted the ACT rule, such as Wisconsin, Florida, Oklahoma, Tennessee, Arizona, Texas, and Alaska.91 [EPA-HQ-OAR-2022-0985-1640-A1, pp. 29 - 30]

89 Id.

90 Id.

91 EDF, Electric Fleet Deployment & Commitment List (listing, under the "Deployments" tab, HD ZEVs already deployed or ordered by public entities nationwide).

By accounting for ZEV adoption only in states that have adopted the ACT rule, EPA's proposal fails to capture the speed and breadth of state and local government actions, including and beyond the ACT rule and the multi-state MOU. At least some modest level of HD ZEV uptake in states that have not adopted the ACT rule or signed the MOU is likely—and already taking place—and would lead to baseline HD ZEV penetration rates closer to those EPA models for its proposed standards. [EPA-HQ-OAR-2022-0985-1640-A1, p. 30]

b. Private fleet commitments

While EPA's proposal mentions a few examples of private fleet ZEV commitments, again it fails to capture the speed and breadth of these commitments, which are driven not only by governmental policy but also by private industry interests.92 These purchases are happening throughout the nation. [EPA-HQ-OAR-2022-0985-1640-A1, p. 30]

92 See Section III.D, infra for a further discussion of these private industry interests and purchaser acceptance of and preference for ZEVs.

According to EDF's Electric Fleet Deployment & Commitment List, commercial fleets have already ordered or deployed at least 27,510 Class 4–8 HD ZEVs.93 These orders cover the full range of heavy-duty applications—from last-mile delivery vehicles to trucks intended to cover longer distances—and include large orders such as 300 Class 8 tractors by A.P. Moller-Maersk; 871 Class 8 tractors by Anheuser-Busch Co.; 105 Class 5 step vans by Bimbo Bakeries USA; 104 Class 8 tractors by DHL Worldwide Express; 500 tractors and box trucks by Pride Group Enterprises; 4,000 Class 5 vans by Ryder System, Inc.; 851 Class 8 tractors by Sysco; and 11,644 Class 4–8 tractors, vans, and box trucks by UPS Inc.94 EPA should factor such commitments and deployments into its HD ZEV baseline market penetration estimates. At the very least, these fleet commitments show significant momentum toward greater HD ZEV deployment within private fleets nationwide and offer further evidence that baseline HD ZEV market penetration rates in EPA's proposal are too low. [EPA-HQ-OAR-2022-0985-1640-A1, pp. 30 - 31]

93 EDF, Electric Fleet Deployment & Commitment List.

94 Id.

In addition, numerous tools and resources are available to fleet managers who are considering or in the process of transitioning their fleets to ZEVs. These resources build off of the extensive fleet commitments cited above and can help smooth the adoption of ZEVs across the HD market.95 [EPA-HQ-OAR-2022-0985-1640-A1, p. 31]

95 See, e.g., Electrification Coalition, Piloting the Transition to Freight Electrification: Lessons Learned in Electrifying On-Road Medium- and Heavy-Duty Vehicles (2023), https://electrificationcoalition.org/wp-content/uploads/2023/06/Piloting-Freight-Web.pdf; Electrification Coalition, Dashboard for Rapid Vehicle Electrification: DRVE Tool, https://electrificationcoalition.org/resource/drve/ (last visited June 13, 2023); EDF, Fleet Electrification Solution Center, https://www.electricfleet.org/ (last visited June 13, 2023); Ryan Kennedy, Overcoming roadblocks to fleet electrification, Freightwaves (June 12, 2023), https://www.freightwaves.com/news/overcoming-roadblocks-to-fleet-electrification.

c. Manufacturer commitments

Government and fleet commitments work in connection with manufacturers producing HD ZEVs, and manufacturers are in fact planning to rapidly increase HD ZEV production to meet growing demand. Manufacturers have comprehensive plans to produce HD ZEVs, and have indicated that they expect additional states to adopt the ACT and ACF rules.96 EPA should consider manufacturers' vehicle offerings, plans, and commitments when estimating baseline HD ZEV market penetration for the final rule, as well as when considering the appropriate stringency of emission standards that drive adoption of zero-emission technologies. [EPA-HQ-OAR-2022-0985-1640-A1, p. 31]

96 David Taube, California Truck Emissions Rules Appear Poised to Spread Across North America, TransportDive (May 17, 2023), https://www.transportdive.com/news/ceos-say-states-will-follow-california-emissions-regulation/650369/.

At May 2022's Advanced Clean Transportation Expo, manufacturers such as Cummins and Navistar announced commitments to deploying zero-emission technologies at a rapid pace. Cummins CEO Tom Lineburger stressed the need "to move faster for the sake of our kids and grandkids,"97 and Navistar CEO Mathias Carlbaum suggested that "[b]y 2030…50% of all trucks by volume will be BEVs."98 Navistar's CEO reiterated to reporters that "[w]e believe 50% of our sales will be electric by 2030," and that 100 percent of sales would be ZEVs by 2040.99 Cummins (the largest supplier of diesel engines for HDVs) also announced a partnership with Daimler on FCEVs, and Amy Davis, the president of Cummins' New Power unit, noted that the partnership was "an important milestone for both companies as we work to accelerate the shift to a carbon-free economy."100 Navistar plans to sunset their diesel development programs starting in 2027,101 and in July 2022, the company announced that its newest combustion vehicle would be its last for North America.102 Similarly, HD manufacturer Daimler Truck North America recently announced the "beginning of the end of the diesel era."103 [EPA-HQ-OAR-2022-0985-1640-A1, pp. 31 - 32]

103 Gladstein, Neandross & Associates, State of Sustainable Fleets, at 7.

According to the American Council for an Energy-Efficient Economy, "[g]rowing numbers of electric truck and bus models are reaching the market or are scheduled to be on the market soon, with models ranging from heavy-duty pickup trucks to 18-wheel tractor-trailers."104 The pace of innovation in this sector has accelerated in recent years. In 2016, Oak Ridge National Laboratory identified just eight commercially available medium- and heavy-duty ZEV options.105 By 2019, there were about 70 HD models available from 27 manufacturers,106 and that number has continued rapid growth. EPA's DRIA includes updated information showing that currently there are "over 170 models produced by over 60 manufacturers that cover a broad range of applications, including school buses, transit buses, straight trucks, refuse haulers, vans, tractors, utility trucks, and others, available to the public through MY 2024." 88 Fed. Reg. at 25961, DRIA at 44–51. EPA notes that the number of available models is expected to grow to about 200 models by 2024. Id. at 44. CALSTART's Zero-Emission Technology Inventory provides further evidence that the growth of zero-emission medium- and heavy-duty models in the United States and Canada has been rapid, with more manufacturers entering the market and the number of available ZEV models growing.107 [EPA-HQ-OAR-2022-0985-1640-A1, p. 32]

107 CALSTART, Model Availability to Follow Upward Trajectory, ZETI Analytics, https://globaldrivetozero.org/tools/zeti-analytics/ (see table titled "Growth of Models Available by Region and OEMS by Region Trending Upwards").

These numbers are certain to increase further, as is evidenced by the increasing frequency of new HD ZEV product announcements and commitments by manufacturers. A sampling of these are included below in Table 3. [EPA-HQ-OAR-2022-0985-1640-A1, p. 32.] [See Docket Number EPA-HQ-OAR-2022-0985-1640-A1, pages 32-36, for Table 3]

While the above table includes a sample of relevant product announcements and commitments, new commitments, technological developments, and investments are being announced every day. The progress and potential in the manufacturing sector further underscores both that EPA's proposed baseline HD ZEV market penetration projections are underestimated, and that much higher deployment is eminently feasible. EPA should consider manufacturers' vehicle offerings, plans, and commitments when estimating baseline HD ZEV market penetration for the final rule, as well as when considering more stringent emission standards that drive adoption of zero-emission technologies. EPA is correct to note that "[s]tandards…can create conditions under which companies invest in major innovations," DRIA at 420, and this is especially true if the standards are set at a level that exceeds the technology's market-based penetration rate. Because EPA's proposed standards essentially mirror what would happen in a world "if the proposed rule is not adopted,"142 they reflect the baseline rather than an appropriate level of stringency under section 202(a) of the Clean Air Act. EPA should instead set its final standards at a level that will lead to greater deployment of zero-emission technologies (and produce greater emission reductions) than the market would otherwise achieve. [EPA-HQ-OAR-2022-0985-1640-A1, p. 36]

142 See Circular A-4, at 2.

4. Recent cost estimates support the viability of HD ZEVs across vehicle segments and should inform EPA's baseline.

Declining costs for HD ZEVs also support a baseline market penetration rate higher than EPA's baseline and more consistent with rates EPA projects may occur under its proposed standards. EPA notes that "[t]he lifetime total cost of ownership (TCO)...is likely a primary factor for HD vehicle and fleet owners considering BEV and FCEV purchases," and cites analyses by ICCT, Phadke et al., and the Rocky Mountain Institute (RMI) showing near-term TCO parity. 88 Fed. Reg. at 25942. [EPA-HQ-OAR-2022-0985-1640-A1, p. 37]

Numerous cost studies, including those cited by EPA, estimate that at least some categories of HD ZEVs have already reached TCO parity with their diesel counterparts—even prior to accounting for IRA incentives and credits—and more categories will reach TCO parity prior to 2027, or faster now that IRA is in effect. EPA should consider these favorable cost projections in its estimates for baseline HD ZEV market penetration. [EPA-HQ-OAR-2022-0985-1640-A1, p. 37]

The estimates cited by EPA include: (1) pre-IRA projections from ICCT (2019),143 which concluded that at least some HD ZEVs could reach cost parity in the "early 2020s;" (2) pre-IRA projections from Phadke et al. (2021), which suggested "that BEV TCO could be 13 percent less than that of a comparable diesel combustion vehicle if electricity pricing is optimized," 88 Fed. Reg. at 25942;144 and (3) a post-IRA RMI analysis showing that the IRA will result in the TCO of electric trucks falling below the TCO of comparable diesel trucks about five years faster than without the IRA.145 See 88 Fed. Reg. at 25942. Several additional recent studies not included in EPA's proposal also estimate when various classes of HD ZEVs will reach cost parity with their conventional counterparts. These studies generally show that transit buses, refuse trucks, school buses, and Class 4–7 short-haul rigid trucks such as delivery and utility vehicles—which together make up approximately 47 percent of the entire HD market—either have already reached cost parity with their diesel counterparts for some vehicle categories, or will do so by 2027 for nearly all categories.146 And these studies were conducted pre-IRA, meaning that for most of these categories, TCO parity could be sped up by at least 5 years based on the RMI analysis cited in EPA's proposal,147 with parity already achieved for at least some additional vehicles. [EPA-HQ-OAR-2022-0985-1640-A1, pp. 37 - 38]

147 Kahn et al., The Inflation Reduction Act.

Several very recent post-IRA analyses of TCO parity have found even more encouraging estimates of near-term parity. In comparing BEV, FCEV, and diesel long-haul tractor-trucks, ICCT found that long-haul BEVs are expected to have the lowest TCO by 2030 in all of the states ICCT investigated.148 The ICCT study also found that even at high daily mileages, BEVs would still achieve a better TCO compared to their diesel counterparts, because day-to-day mileage variability for these vehicles is low.149 An analysis by Roush considering seven segments of medium- and heavy-duty trucks found that, for vehicles purchased in 2027, ZEV TCO was projected to be lower than diesel TCO for all segments.150 [EPA-HQ-OAR-2022-0985-1640-A1, p. 38]

148 Hussein Basma et al., ICCT, Total Cost of Ownership of Alternative Powertrain Technologies for Class 8 Long-Haul Trucks in the United States, at i (2023), https://theicct.org/publication/tco-alt-powertrain-long-haul-trucks-us-apr23/.

149 See Hussein Basma & Ray Minjares, ICCT, Battery-Electric Trucks: The Most Affordable Path to Decarbonizing Tractor-Trailers 9 (Apr. 27, 2023), https://theicct.org/wp-content/uploads/2023/04/Battery-electric-trucks_-The-most-affordable-path-to-decarbonizingtractor-trailers.pdf.

150 This analysis considered the following HDV market segments: transit bus (Class 8); school bus (Class 7); shuttle bus (Class 3-5); delivery and service van, box and stake truck (Class 3); short haul delivery, service, box, and stake truck (Class 6-7); short haul delivery and service van, box and stake truck (Class 4-5); and refuse hauler (Class 8). Nair et al., Technical Review, at 18, 20.

Another recent ICCT analysis considered upfront cost parity (i.e., the purchase price, separate from total cost of ownership), and found that even upfront cost parity between BEVs and their diesel counterparts is expected in the late 2020s or early 2030s for most truck segments.151 And, as EPA cited in the proposal, RMI's latest analysis concluded that "with the IRA, the total cost of ownership of electric trucks will be lower than diesel ones approximately five years sooner than without the law," finding this to be "true for urban trucks that travel locally in cities an average of 50–100 miles a day; regional trucks that move 100–250 miles per day and return to the same depot; and long-haul trucks that travel 250 or more miles between cities and need to recharge en route."152 [EPA-HQ-OAR-2022-0985-1640-A1, pp. 38 - 39]

151 Yihao Xie et al., ICCT, Purchase Costs of Zero-Emission Trucks in the United States to Meet Future Phase 3 GHG Standards 22 (2023), https://theicct.org/publication/cost-zero-emission-trucks-us-phase-3-mar23/.

152 Kahn et al., The Inflation Reduction Act.

EPA should comprehensively consider the numerous relevant studies pointing to rapidly declining costs for HD ZEVs in the classes and time periods covered by the proposal. The cost studies show that many HD ZEVs were already both technically feasible and cost effective, or would become so prior to MY 2027 in the absence of the IRA, and the IRA's incentives and credits increased the number of feasible and cost-effective options. As Daimler Truck AG's chief technology officer explained, "In the very moment that the customer starts benefiting more from a zero-emission truck than from a diesel truck, there is no reason to buy the diesel truck anymore."153 By failing to consider the full literature of cost projections in informing the baseline, EPA assumes inappropriately low baseline HD ZEV adoption and, as a result, proposes standards that are too lenient and themselves actually reflect a reasonable baseline ZEV penetration rate. [EPA-HQ-OAR-2022-0985-1640-A1, p. 39]

153 Cristina Commendatore, Daimler Truck to Ramp Down ICE Spending, Focus on ZEVs, Fleetowner (May 25, 2021), https://www.fleetmaintenance.com/equipment/emissions-and-efficiency/article/21224178/daimler-truck-to-ramp-down-ice-spending-focus-on-zevs.

5. EPA should more fully account for the extent to which BIL and IRA incentives will independently drive adoption of HD ZEVs.

The BIL and IRA will channel billions of dollars into the HD ZEV sector. EPA included two provisions of the IRA within its quantitative analysis of HDV technology adoption and costs, the Advanced Manufacturing Production Credit and the credit for Qualified Commercial Clean Vehicles. See 88 Fed. Reg. 25985. While these credits will have important effects in driving adoption of HD ZEVs, EPA errs in not including additional impacts of the BIL and IRA in its analysis. Furthermore, EPA should ensure that impacts of the BIL and IRA are included in its calculation of the baseline as well as in the costs and outcomes of the standards. [EPA-HQ-OAR-2022-0985-1640-A1, p. 39]

The IRA and BIL will drive significant HD ZEV adoption independent of the Phase 3 standards. Numerous analyses conducted in the wake of BIL and IRA passage have found that these laws will dramatically increase HD ZEV adoption.154 For example, ICCT finds that HDV

ZEV sales penetration will rise from 48 percent in 2035 to up to 56 percent when accounting for the IRA.155 EPA should accordingly ensure that these important laws are reflected in its estimate of baseline HD ZEV market penetration. [EPA-HQ-OAR-2022-0985-1640-A1, p. 39]

154 See, e.g., Kahn et al., The Inflation Reductin Act; Clean Air Task Force, Federal Funding Programs to Support Advanced Clean Trucks Implementation: A Guide for States (2023), https://cdn.catf.us/wp-content/uploads/2023/04/13154057/act-federal-funding-resource.pdf;

155 Slowik et al., at ii (2023).

As EPA appropriately describes in section 1.3.2 of the DRIA, the BIL and IRA include numerous incentives, grants, and other programs that will help to spur deployment of low emission HD vehicles, including BEVs and FCEVs. These programs will, among other things, provide both direct grants and tax credits to lower acquisition costs of vehicles and increase the range of cost-effective applications,156 help entities conduct planning for fleet electrification,157 enable deployment of charging and hydrogen fueling infrastructure,158 and facilitate advances in technology that can lower future vehicle costs. These programs also invest in vehicle and battery manufacturing and recycling, driving cost reductions and increasing domestic supply. [EPA-HQ-OAR-2022-0985-1640-A1, pp. 39 - 40]

156 See, e.g., 42 U.S.C. § 7432 (appropriating $1 billion to EPA to create a program that awards grants and rebates for the costs of replacing existing class 6 and 7 HDVs with ZEVs, purchasing, installing, operating, and maintaining infrastructure needed for ZEVs, associated workforce development and training, and planning and technical activities needed to support the deployment of ZEV); 26 U.S.C. § 45W (providing up to $40,000 in tax credits to assist with vehicle replacements and reduce the effective cost of commercial ZEVs).

157 See, e.g., 42 U.S.C. § 7432.

158 See, e.g., 26 U.S.C. § 30C (providing tax credits to qualified alternative fuel vehicle property); 42 U.S.C. § 16161a (providing $8 billion to DOE to fund regional hydrogen hubs across the country); 23 U.S.C. § 151 (appropriating $2.5 billion to support the build-out of clean charging and fueling infrastructure projects along designated alternative fuel corridors of the National Highway System).

An ERM analysis found that, considering only a portion of these programs, the BIL would provide over $19.4 billion in funding toward medium- and heavy-duty ZEV purchases.159 A further analysis of a portion of IRA programs calculated an additional $2.8 billion in funding toward medium- and heavy-duty ZEV purchases, resulting in a 46 percent increase in ZEV sales projections in 2029 compared to a scenario not including the IRA.160 However, EPA does not consider the full range of BIL and IRA programs, accounting only for the Advanced Manufacturing Production Credit and the credit for Qualified Commercial Clean Vehicles. While it may be difficult to quantify the aggregate impact of these programs on the scale and cost of deployment of HD ZEVs, EPA should nevertheless ensure that this impact is accounted for in its analysis. As it stands, not assessing the impact of these programs quantitatively results in an inaccurate and overly conservative baseline and cost analysis. [EPA-HQ-OAR-2022-0985-1640-A1, p. 40]

159 Robo & Seamonds, Technical Memo, at 7

160 Robo & Seamonds, IRA Supplemental Assessment, at 1–2.

In sum, EPA's proposal underestimates the baseline HD ZEV market penetration in several ways, as the Agency itself recognizes. See DRIA at 417 ("It is possible that EPA's reference case is underestimated, and adoption of ZEVs, and other technologies, will occur more rapidly than EPA predicts in this proposal.") EPA should update its baseline assessment to account for the vast amount of highly relevant data and information showing strong ZEV sales even in a world absent the proposed action. EPA should reconsider its baseline in light of (1) current market projections indicating significantly higher baseline HD ZEV sales, including those upon which EPA relies to set the ZEV penetration levels under the proposed standards; (2) federal, state, local, and private sector actions supporting a much higher baseline HD ZEV penetration rate; (3) recent HD ZEV cost estimates supporting the viability of ZEVs across vehicle segments; and (4) the extent to which BIL and IRA incentives will independently drive adoption of HD ZEVs. All of these factors make clear that EPA's standards essentially codify what the market would do at baseline. To comply with its duties to protect public health and welfare, EPA must go well beyond this level in its Phase 3 emission standards. [EPA-HQ-OAR-2022-0985-1640-A1, p. 40]

Organization: ClearFlame Engine Technologies

EPA should integrate State Low-Carbon Fuel Standards and other SLF-focused programs, just as it is integrating ZEV-focused state programs [EPA-HQ-OAR-2022-0985-1654-A2, p. 11]

In the ABT section of the Proposal, EPA seeks comment on how California's Advanced Clean Truck Rule and its adoption by other states (collectively, referred to herein as the '177 States,' for the Clean Air Act section that authorizes states to adopt California vehicle emission standards for which California has received an EPA waiver from the federal standards) might shape the future truck and bus market.30 We agree that EPA should rely on current trends that are propelled by the certainty of state regulation in determining nationwide production volumes. Just as EPA may rely on the actions of California and the 177 States to accelerate heavy-duty electrification to determine future nationwide production volumes, it should integrate and rely on trends in California and other states that have or are planning to adopt a Low Carbon Fuel Standard (or comparable Clean Fuel Standards) to gauge the decarbonization potential of a transition to lower-carbon intensity fuels. This change in the carbon intensity of the nation's fuels is equally important to the overall structure and success of the Final Rule. [EPA-HQ-OAR-2022-0985-1654-A2, pp. 11-12]

30 See, e.g., Proposal at 43, and at 235.

Organization: Daimler Truck North America LLC (DTNA)

EPA's assumptions about the existing Phase 2 rule are inaccurate and must be accounted for when setting Phase 3 standard stringencies.

The technology packages upon which the proposed Phase 3 CO2 standards are based assume ICE vehicles that comply with the existing Phase 2 MY 2027 CO2 standards using emission-reduction technologies such as low rolling resistance tires; tire inflation systems; efficient engines, transmissions, and drivetrains; weight reduction; and idle reduction technologies.94 As EPA explains, '[t]hese vehicles are used as baselines from which to evaluate costs and effectiveness of additional technologies and more stringent standards on a per-vehicle basis.'95 [EPA-HQ-OAR-2022-0985-1555-A1, p. 42]

94 See Proposed Rule, 88 Fed. Reg. at 25,958 ('For each regulatory subcategory, we selected a theoretical ICE vehicle with CO2-reducingtechnologies to represent the average MY 2027 vehicle that meets the

existing MY 2027 Phase 2 standards.'); 25,959, Tables II-1 and II-2 (reflecting GEM inputs used by EPA to make the fleet average technology package that meets existing MY 20207 CO2 tractor and vacation vehicle emission standards).

95 Id.

Despite EPA's statement in the Proposed Rule that its Phase 2 CO2 standards were not 'in any way premised on the application of ZEV technologies,'96 DTNA's understanding is that many manufacturers may have incorporated ZEVs into the strategies they use under the Phase 2 program to meet currently-applicable CO2 standards using an averaging approach because they are not able to achieve the necessary level of emissions performance using conventional Phase 2 technologies alone, given slower-than-anticipated adoption rates. EPA does not acknowledge this in the Proposed Rule, nor the implications for Phase 3—that because manufacturers are already relying on ZEV production volumes to certify vehicle families under the Phase 2 standards, they will have to produce ZEVs at levels that significantly exceed EPA's projected ZEV uptake rates to comply with the Phase 3 CO2 stringency levels that EPA proposes. [EPA-HQ-OAR-2022-0985-1555-A1, p. 42]

96 Id. at 25,957.

The GHG-reduction technologies upon which the Phase 2 standards were based have proven to be less effective and adopted at lower rates than what the Agency projected during that rulemaking. For instance, the Agency projected ambitious adoption rates for technologies like advanced aerodynamic features and tire rolling resistance that did not come to pass, due to cost, feasibility, application suitability, and other issues.97 EPA's predictions about adoption rates for improved gear efficiency and idle reduction technologies also proved to be overly ambitious.98 Other technologies, like waste heat recovery, that EPA predicted would reduce GHG emissions from diesel engines, may not be feasible to bring to production due to complexity and cost issues, as well as conflicting priorities with regard to the new Low NOx emissions standards set by the EPA. The result has been that manufacturers have had to incorporate significant numbers of ZEVs into their fleets to obtain certification under the current Phase 2 standards, a consequence that was unanticipated by EPA. [EPA-HQ-OAR-2022-0985-1555-A1, p. 43]

97 See EPA, Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles—Phase 2; Final rule, 81 Fed. Reg. 73,478, 73,709 (Oct. 25, 2016) (projecting 100% adoption rates for low rolling resistance tires); 73,557 (projecting WHR adoption rates of 1% of tractor engines by 2021, 5% by 2024, and 25% by 2027, with nearly all being used on sleeper cabs).

98 As examples, in DTNA's experience, customers have chosen not to adopt start-stop and idle shutdown technologies at all, citing convenience and other factors.

There is a further unintended consequence of the Agency using overly ambitious technology projections as the basis for its GHG standards that EPA should consider carefully: the significant detrimental impacts on the emissions performance of manufacturers' conventional fleets, for which there will still be a market for years to come. Manufacturers needing to produce and sell large volumes of ZEVs to meet stringent CO2 standards are likely to transition their high-performing conventional vehicles to a ZEV platform first. This is because the customers who are most likely to buy high-performing conventional vehicles are the ones most likely to have a compelling business case for reducing fuel costs—thus they are already highly motivated to transition their fleet to ZEVs. As a result, manufacturers will prioritize transitioning their high-performing conventional vehicles to ZEVs, as these vehicles are the most likely to have willing buyers, leaving a worse-performing conventional fleet. It is thus incorrect for EPA to assume that the remaining ICE fleet will maintain, on average, compliance with the existing Phase 2 MY 2027 standards. To address this imbalance and to avoid unintended consequences that may have a net-negative impact on emissions performance, EPA should perform a new feasibility analysis on the existing Phase 2 standards, re-evaluating the level at which the remaining conventional fleet will perform. [EPA-HQ-OAR-2022-0985-1555-A1, p. 43]

Organization: Environmental Defense Fund (EDF)

d) EPA's primary proposal reflects a conservative assessment of ZEV deployment in the coming years.

EPA uses a reference case that assumes ACT levels of ZEV sales in California and the five states that had already adopted ACT at time the proposal was issued: Oregon, Washington, New York, New Jersey, and Massachusetts. The reference case does not assume any additional ZEV sales as a result of regular market trends. EPA's primary proposal sets a stringency level roughly equivalent to ZEV adoption projected under ACT Research's adoption curve based on payback period. [EPA-HQ-OAR-2022-0985-1644-A1, p. 60]

EPA's reference case should more accurately reflect ZEV deployment that will occur due not only to ACT but to the landscape of factors that will facilitate ZEV sales, including market trends, other state actions like ACF, the NESCAUM MOU, and federal government and private investments. The payback period analysis discussed above, which EPA relies on in setting its proposed stringency level, is better suited to inform the reference case. EPA's proposed standards should build on this improved baseline to achieve emissions reductions consistent with ACT-level ZEV deployment nationally and additional reductions in the tractor and bus categories. [EPA-HQ-OAR-2022-0985-1644-A1, p. 60-61]

Organization: National Parks Conservation Association (NPCA)

Regarding EPA's proposed baseline for HD ZEV market penetration, NPCA agrees with numerous other commenters the approach taken by EPA in this rulemaking is far too conservative, and severely underestimates potential HD ZEV sales that will take place in the near future. For instance, EPA's analysis appears to look only at outdated projections conducted by CARB regarding HD ZEV adoption under California's Advanced Clean Trucks rule and fails to take into consideration additional factors such as additional state regulatory requirements, dropping costs, improving technology, and growing public interest in HD ZEVs. EPA's California-focused analysis of ACT HD ZEV potential fails to account for the growing list states that have adopted ACT, Omnibus, or HD Memorandum of Understanding (MOU), nor does it consider additional commitments at the federal, state, local, and private level. It also fails to account for California's recent enactment of its even more stringent Advanced Clean Fleets Rule. This underestimation of HD ZEV potential unjustly diminishes justifications for the feasibility of stringent ZEV advancements in the coming years. EPA's final rule must adequately account for all of the above listed factors in determining baseline HD ZEV sales. [EPA-HQ-OAR-2022-0985-1613-A1, p. 4]

Organization: RMI

Electric Heavy-Duty Market

The electrification of specific trucking applications can be economically advantageous today, yet, in some respects, electric heavy-duty truck adoption is inhibited by the lack of adequate vehicle supply and the need for a greater variety of Medium Duty Trucks (MDT) and Heavy Duty Trucks (HDT) vehicle models to meet the diverse requirements of freight hauling. The EPA tailpipe emissions standards could galvanize greater vehicle supply in these segments. [EPA-HQ-OAR-2022-0985-1529-A1, p. 3]

The following analysis focuses on tractor-trailers, also referred to as semi-trucks, as these trucks drive 177 billion miles per year while consuming an average of six times more energy per mile than a passenger car in the United States. Because they drive so many miles and use so much energy, semis will be the majority of the US heavy-duty electric truck load. Over the past seventy years, trucking and America's two million licensed heavy-duty truck drivers have become increasingly essential. Truck trips have increased 30% in the past 30 years and are projected to increase 66% more by 2050.4 The fact that these energy-intensive trucks are also frequently concentrated in depots with dozens or hundreds of vehicles will have profound implications for the grid as those vehicles electrify.5 [EPA-HQ-OAR-2022-0985-1529-A1, p. 3]

4 Ari Kahn, Emily Yang, and Wouter Vink, Making Zero-Emissions Trucking Possible, Mission Possible Partnership, 2022, https://missionpossiblepartnership.org/wp-content/uploads/2022/11/Making-Zero-Emissions-Trucking- Possible.pdf.

5 Kahn et al., Preventing Electric Truck Gridlock, RMI, 2023 https://rmi.org/insight/preventing-electric-truck-gridlock/?utm_medium=email&utm_source=spark&utm_content=spark-a&utm_campaign=2023_06_01

Most of these trucks have the economic and technical potential to electrify. Currently, electric trucks (e- trucks) are most viable for short- and medium-haul trucking, which are not a majority of truck miles traveled, but are the majority of trucks in operation. Loosely speaking, semi-trucks fit into three operational categories: short, medium, and long haul. Short- and medium-haul trucks travel fewer than 100 and 300 miles per day respectively. They return to a depot or home location, unlike long-haul trips that can traverse the country. And while these long-haul trucks make up around a quarter of the stock, they contribute to over half of total miles traveled. The North American Council on Freight Efficiency (NACFE) estimates that 50% of the approximately 1 million medium haul heavy-duty trucks are electrifiable based on route lengths today6, while RMI analysis for New York State and California indicates that 49% of all HDT using less than 300 miles per day and returning to a base are also electrifiable today.7 [EPA-HQ-OAR-2022-0985-1529-A1, pp. 3-4] [Refer to Figure on p. 4 of docket number EPA-HQ-OAR-2022-0985-1529-A1]

6 Roeth et al., Electric Trucks Have Arrived: The Use Case for Heavy-Duty Regional Haul Tractors, NACFE, May 5, 2022, https://nacfe.org/wp-content/uploads/edd/2022/05/HD-Regional-Haul-Report-FINAL.pdf

7 Jessie Lund et al., Charting the Course for Early Truck Electrification, RMI, 2022, https://rmi.org/insight/electrify-trucking/.

The market for e-trucks is growing and electric trucks are improving, with greater efficiency and battery capacity extending trucks' range and capabilities. Incumbent and new manufacturers have trucks that offer sufficient range and reliability for many customers today, and those trucks are improving, following the trend of electric cars that increased efficiency, improved range, and increased charging speed. Vehicle drivetrains, manufacturing efficiency, and battery cells are continuously improving, reducing average vehicle costs by approximately 5% per year.8 [EPA-HQ-OAR-2022-0985-1529-A1, p. 4]

Thanks to Existing Policy EV Trucks are Affordable

State Policy Driving Demand

Policy at the state level is already driving heavy-duty fleet electrification. Over the next several years, state regulations that require the sale of zero-emissions trucks and government incentives for vehicles, chargers, and electric or hydrogen fuel are the carrots and sticks that will help generate e-truck sales. Starting in 2024, California's Advanced Clean Trucks (ACT) regulation requires electric truck sales phase ins, culminating in 40% to 70% of new truck sales being zero emissions by 2035.9 California is not alone. Six states have codified their commitment to ACT, while seven other states and the District of Columbia are in various stages of rulemaking.10 [EPA-HQ-OAR-2022-0985-1529-A1, pp. 4-5]

9 The 2035 sales requirement is: 40% for tractor trailers, 55% for class 2b-3 medium-duty trucks, and 75% for medium- and heavy-duty 'straight trucks'(https://www.freightwaves.com/news/california-gets-epa-waiver-to-move-ahead-with-advanced-clean-trucks-rule).

10 'Advanced Clean Trucks Fact Sheet,' California Air Resources Board, August 20, 2021, https://ww2.arb.ca.gov/resources/fact-sheets/advanced-clean-trucks-fact-sheet.

Organization: Southern Environmental Law Center (SELC)

In order to properly evaluate the feasibility of the proposed standards, EPA must develop an accurate projection of the ZEV adoption that will occur in the heavy-duty vehicle sector without the proposed standards. An inaccurate model that assumes artificially low baseline ZEV adoption rates is likely to cause EPA to adopt standards that are too lenient or that could be achieved under business-as-usual conditions. A recent report by the International Council on Clean Transportation, for example, estimated that 15 percent of all Class 4-8 vehicle sales will be ZEVs by model year 2025 and 39 percent by 2030, even without the proposed Phase 3 standards.50 These projections seem to be much higher than the ZEV adoption rate used by EPA in its reference case and technology package modeling.51 As noted throughout the proposed rulemaking, there are a number of factors that have resulted in increased ZEV adoption in the heavy-duty vehicle sector in recent years, and ZEV deployment is expected to continue to accelerate. EPA must therefore improve its modeling to account for higher rates of baseline ZEV adoption to ensure it adopts the strongest standards possible. [EPA-HQ-OAR-2022-0985-1554-A1, p. 7]

50 Pierre-Louis Ragon et al., INT'L COUNCIL ON CLEAN TRANSP., Potential Benefits of the U.S. Phase 3 Greenhouse Gas Emissions Regulation for Heavy-Duty Vehicles, app. A (Apr. 2023), https://theicct.org/wp-content/uploads/2023/04/hdv-phase3-ghg-standards-benefits-apr23.pdf. The "potential market growth" projection in this report is "based on market conditions in combination with state ACT rule adoption and federal subsidies under the Inflation Reduction Act." Id. at 5.

51 Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles—Phase 3, 88 Fed. Reg. 25926, 25932 (Apr. 27, 2023); U.S. EPA, Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles: Phase 3 Draft Regulatory ImpactAnalysis 318 (Apr. 2023) [hereinafter "Phase 3 Draft Regulatory Analysis"].

Among other things, EPA must fully account for the ACT program that has been adopted by California and eight other states.52 The ACT program establishes binding requirements in participating states that progressively increase the percentage of medium- and heavy-duty ZEVs that must be sold in these states starting in model year 2025. By model year 2035, ZEVs will be required to make up approximately 55 percent of Class 2b-3 vehicle sales, 75 percent of Class 4-8 vehicle sales, and 40 percent of Class 7-8 tractor sales in participating states,53 which make up over 20 percent of the nation's medium- and heavy-duty vehicle fleet.54 Proper consideration of the ACT program is especially important if EPA moves forward with its proposal to use a "nationwide production volume" as part of the averaging, banking, and trading program.55 Based on conflicting statements in the regulatory documents, it is not clear how EPA incorporated the ACT program into its assessment.56 What is clear is that this program will have a direct impact on ZEV deployment in states that have adopted the program and an indirect impact on ZEV deployment in other states as more heavy-duty ZEVs are made available in the market. [EPA-HQ-OAR-2022-0985-1554-A1, p. 7-8]

55 Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles—Phase 3, 88 Fed. Reg. 25926, 26009-10 (Apr. 27, 2023).

56 Compare id. at 25989 ("The approach we used to select the proposed standards . . . does not specifically include accounting for ZEV adoption rates that would result from compliance with the California ACT program.") with Phase 3 Draft Regulatory Analysis, supra note 51, at 317-18 ("Because the ACT waiver was only recently granted, for this proposal EPA used the ZEV sales volumes projections that could be expected from ACT in the reference case as an overall projection for national ZEV sales volumes, as we made this projection prior to the granting of the ACT wavier.").

EPA must also incorporate consideration of other regulatory programs and state policies that are likely to impact nationwide baseline ZEV adoption rates into its assessment. For example, 11 jurisdictions in addition to the states that have adopted the ACT program have committed to a goal of having at least 30 percent of all new medium- and heavy-duty vehicle sales be ZEVs by no later than 2030, and 100 percent of sales being ZEVs by no later than 2050 under the Multi-State Medium- and Heavy-Duty Vehicle Memorandum of Understanding (MOU).57 Other regulatory programs and state fleet commitments, like California's Innovative Clean Transit rule58 and Advanced Clean Fleets rule,59 may also impact baseline ZEV adoption rates. [EPA-HQ-OAR-2022-0985-1554-A1, p. 8]

In addition to state level programs and policies, vehicle manufacturers and other companies have made public announcements of their intent to shift their fleets to ZEVs.60 This shift, as well as declining costs and other economic forces, are likely to drive higher deployment of medium- and heavy-duty ZEVs in coming years. A study by the National Renewable Energy Laboratory found that ZEVs in all medium- and heavy-duty vehicle classes could reach cost parity with diesel vehicles by 2035, even without incentives.61 Coupled with the deployment of charging and refueling infrastructure, this could result in ZEVs accounting for 42 percent of medium- and heavy-duty sales by 2030, and over 99 percent of sales by 2045.62 [EPA-HQ-OAR-2022-0985-1554-A1, p. 8]

Deployment of Medium- & Heavy-Duty Vehicle Electrification Will Scale Rapidly

In general, EPA's proposed standards are set at a level less stringent than the depth and pace of electrification technology deployment that has already occurred and will be accelerated through market forces and numerous other state and federal policies. BEV deployment, like other technologies, will follow a S curve leading to a much more rapid pace of adoption between now and when the Phase 3 regulations take hold. Indeed, many manufacturers have rapidly placed innovative technology across major portions of their new vehicle offerings in only a few model years.78 BEV technology will continue to follow similar paths, and deployment has already been shown to outperform the traditional S curve.79 [EPA-HQ-OAR-2022-0985-1505-A1, p. 13]

78 See e.g. Hula, et al, Analysis of Technology Adoption Rates in New Vehicles, SAE International (April 1, 2014) available at https://www.epa.gov/sites/default/files/2016-10/documents/2014-01-0781_0.pdf

79 Ark Investment, Electric Vehicles Are Outperforming the Traditional S-Curve Dynamics (July 2, 2019) available at https://ark-invest.com/articles/analyst-research/ev-growth-outperforming-the-traditional-s-curve-dynamics/

In its proposal, EPA utilizes the latest EIA estimates to characterize heavy-duty BEV sales that project out BEV sales share of less than 1% in key market segments in 2050.80 This assumed baseline is woefully low, cuts against many projections, and is not fully supported by the record. Indeed, as EPA indicates, the BEV market is dynamic and changing rapidly.81 One recent report published two months before passage of the Inflation Reduction Act (IRA) found that revenue from the electric truck market was growing at a compound annual growth rate of 54%.82 In another example, NREL has found economics will drive much faster adoption with ZEV sales possibly reaching 42% of all medium- and heavy-duty trucks by 2030.83 It even projects out a scenario where ZEV sales reach >99% by 2045, and 80% of the sector transitions to ZEVs by 2050, reducing CO_2 emissions by 69% from 2019.84 A new analysis views the heavy-duty haul market as 50% electrifiable right now.85 Still other analyses have found that most ‘market segments have the potential to be fully mature by 2025, with EV models available from multiple companies, including the majority of major OEMs that currently have 90% market share of the inuse fleet.’86 Further, it is predicted the pace of electrification in the truck sector will increase rapidly over the next decade.87 Recent sales suggest this pace of adoption is already occurring.88 [EPA-HQ-OAR-2022-0985-1505-A1, pp. 13-14]

As with EPA’s proposal, these estimates do not take into account the BEV sales impacts that will result from California’s newly adopted Advanced Clean Fleets (ACF) program. 89 ACF will require last mile delivery and yard trucks to transition to ZEVs by 2035, work trucks and day cab tractors must be zero-emission by 2039, and sleeper cab tractors and specialty vehicles must be zero-emission by 2042.90 Moreover, the ACF rule has accelerated the rate of BEV deployment under the original ACT rule to embrace an end to combustion truck sales in 2036.91 In California alone, the original ACT rule was estimated to require the deployment of 100,000 heavy-duty ZEVs in 2030 and 300,000 by 2035.92 [EPA-HQ-OAR-2022-0985-1505-A1, p. 14]

The adoption of forward-looking heavy-duty electrification policies in numerous other states will also drive more rapid electrification of the medium- and heavy-duty sectors.93 As the agency discusses, the ACT regulation will drive significant emission reductions and medium- and heavy-duty vehicle electrification through Model Year (MY) 2035.94 Additionally, seven states – Colorado95, Massachusetts, New Jersey, New York,96 Oregon, Vermont, and Washington – have already adopted those standards. Several additional states, including Connecticut, Maine, Maryland, and Rhode Island,97 are expected to adopt the rule soon. [EPA-HQ-OAR-2022-0985-1505-A1, pp. 14-15]

If the eighteen states98 that have adopted the current California light duty ZEV standards also adopt California's ACT rule, it is estimated that 1 in 8 trucks sold in 2030 will be electric.99 Importantly, the ACT rule incentivizes early action from manufacturers, further supporting a significant increase in deployment of zero emissions trucks in the near term in states that adopt the ACT rule. Further, the adoption of the ACF will only serve to accelerate this through required sales. [EPA-HQ-OAR-2022-0985-1505-A1, p. 15]

99 Union of Concerned Scientists, We Can Electrify One in Three Heavy Duty Trucks by 2030: Here's How. (Mar. 22, 2022) Available at https://blog.ucsusa.org/sam-wilson/we-can-electrify-one-in-three-heavy-duty-trucks-by-2030-heres-how/

While the agency also notes the multi-state NESCAUM Memorandum of Understanding (NESCAUM MOU),100 it should ensure that the deployment of BEV technology envisioned under the agreement is included in the NOX (and GHG) baseline assessment. More specifically, in July 2020,101 fifteen states and the District of Columbia announced that they entered the joint NESCAUM MOU wherein they committed to working together to advance and accelerate the market for electric medium- and heavy-duty trucks. The parties agreed to a goal that 100% of new medium- and heavy-duty vehicle sales would be zero emission by 2050, with an interim goal of 30% sales by 2030. A recent analysis found that expanding the NESCAUM MOU nationally would result in more than half of the fleet being electric by 2045 and reduce annual GHG emission reductions 5% of U.S. truck emissions in 2035 increasing to an 18% reduction in U.S. truck emissions in 2045.102 Another found that these states adopting the ACT rule would lead to over 756,000 medium- and heavy-duty ZEVs deployed between 2024 and 2035.103 [EPA-HQ-OAR-2022-0985-1505-A1, p. 15]

100 88 Fed. Reg. at 25947(This effort was organizing by the Northeast States for Coordinated Air Use Management (NESCAUM). The state signing on to the MOU were California, Connecticut, Colorado, Hawaii, Maine, Maryland, Massachusetts, New Jersey, New York, North Carolina, Oregon, Pennsylvania, Rhode Island, Vermont, and Washington.).

Interest in the NESCAUM MOU and its goals continues to expand. 104 In September 2021, the Province of Quebec signed on to the NESCAUM MOU. Virginia followed suite in December 2021, and Nevada just joined at the end of March 2022, bringing the total number of signatories to seventeen states, one province, and the District of Columbia. The signatory states have committed to working together through the existing multi-state ZEV Task Force105 to develop and implement an Action Plan to help states meet these ambitious goals. In March, the Draft Multi-State Medium-and Heavy-Duty Zero-Emission Vehicle Action Plan was released for public comment.106 Notably, the first recommendation in the draft Action Plan called for the signatory states to adopt the ACT regulation. As noted in the plan:

- While market-enabling programs such as incentives are also important, regulatory requirements mandating MHD ZEV sales provide market certainty needed to drive investments in zero-emission technologies and charging and fueling infrastructure at the pace and scale required for rapid electrification. Indeed, the ZEV sales mandate for passenger vehicles, established by California and adopted by other states, has prompted unprecedented investment in light-duty zero-emission technologies and substantial growth in the market share of light-duty ZEVs. The ACT regulation may be an even more important driver of electrification of the MHD vehicle sector given the costs and characteristics of trucks and buses.107 [EPA-HQ-OAR-2022-0985-1505-A1, pp. 15-16]

104 Transport Dive, States band together to push for nationwide fleet electrification (May 5, 2022) available at https://www.transportdive.com/news/nevada-joins-nescaum-multi-state-zero-emissions-vehicle-mou/622520/

105 NESCAUM, ZEV Task Force, Multi-State ZEV Action Plan (2018) available at https://www.nescaum.org/documents/2018- zev-action-plan.pdf/

106 NESCAUM, Releases Draft Multi-State Medium-and Heavy-Duty Zero-Emission Vehicle Action Plan for Public Comment (March 10, 2022) available at https://www.nescaum.org/documents/announcement-mhd-zev-ap-public-draft.pdf/

Moreover, a new analysis indicates adoption of the ACT rule in these states would significantly expand the BEV market and lead to 36% of all new medium- and heavy-duty vehicles being powered by zero-emission engines in 2030.108 [EPA-HQ-OAR-2022-0985-1505-A1, p. 16]

108 ICCT, Benefits of the 2020 Multi-State Medium- and Heavy-Duty Zero-Emission Vehicle Memorandum of Understanding (Apr. 27, 2022) available at https://theicct.org/publication/md-hd-mou-benefits-apr22/

Electrification of the Federal Medium- and Heavy-Duty Fleet

The agency's Phase 3 proposal also does not appear to consider the role electrification of the federal medium and heavy-duty fleet will play in driving the transition to electrification. In late 2021, the President issued Executive Order 14057 directing all federal agencies, inter alia, to maximize acquisition and deployment of zero emission medium- and heavy-duty vehicles.109 In seeking to decarbonize the federal fleet, the President directed the U.S. Government to procure '100 percent zero-emission vehicle acquisitions by 2035.'110 Turning over the U.S. Government fleet will require the transition of 103,00 medium-duty trucks and 39,000 heavy-duty trucks.111 Not only will this significantly reduce the fleets' cost per mile to operate the vehicles and the fleet's collective GHG emissions, these procurement policies will further accelerate the demand for and heavy-duty technologies.112 [EPA-HQ-OAR-2022-0985-1505-A1, p. 16]

3. EPA must consider the regionality of the increased electrical demand.

EPA fails to anticipate a regional roll-out of HD PEVs and makes no attempt to model the impacts of regionalized PEV charging demand on the electric power sector. In contrast, in the proposed Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles, EPA expects and attempts to account for a "highly regionalized initial rollout of electric vehicles under the California ZEV program."189 EPA's failure to consider the regional adoption of HD ZEVs and the associated regionalization of PEV charging demand is a major flaw in EPA's otherwise weak analysis of electrical grid impacts. [EPA-HQ-OAR-2022-0985-1566-A2, p. 39.]

189 88 Fed. Reg. 29303 (May 5, 2023).

EPA explains in the DRIA that it "granted the ACT [(Advanced Clean Trucks)] rule waiver requested by California under CAA section 209(b) on March 30, 2023, which did not allow enough time for EPA to consider a different approach for this proposal."190 The coordination and timing of EPA's approval of the ACT waiver request and EPA's proposed motor vehicle tailpipe standards were wholly within EPA's control – self-imposed time constraints are no excuse for an inadequate regulatory impact analysis. [EPA-HQ-OAR-2022-0985-1566-A2, p. 39.]

190 DRIA at 255.

EPA further explains

"With the recent granting of the ACT waiver, we intend to consider how vehicles sold to meet the ACT requirement in California and other states that may adopt it under CAA section 177 would impact or be accounted for in the standard setting process approach described in the preamble in Section II. For example, we may adjust our reference case to reflect the ZEV levels projected from ACT in California and other states. We also may consider increasing the technology adoption rates in the technology packages and correspondingly increase the stringency of the proposed Phase 3 emission standards to account for the incremental difference in the projected ZEV adoption levels from the proposed Phase 3 emission standards and the adoption levels projected from ACT in those states."191 [EPA-HQ-OAR-2022-0985-1566-A2, pp. 39 - 40.]

191 DRIA at 255

When EPA adjusts the reference case and Phase 3 emission standards to reflect projected impacts of ACT, EPA must perform a more comprehensive and regionally disaggregated analysis of impacts to the electrical grid and provide additional opportunity for review and comment on that new analysis. This information is central to the proposed rule and should be made available for comment before EPA can issue a final rule on the basis of such information. [EPA-HQ-OAR-2022-0985-1566-A2, p. 40.]

EPA Summary and Response:

Summary:

AmFree states that the heavy-duty industry has not embraced a shift from internal-combustion-engine vehicles to electric ones, citing a limited number of models of BEVs and FCEVs available today and a limited number of registrations as well.

ClearFlame Engine Technologies supports the use of trends that are propelled by state regulations in determining nationwide production volumes, such as California's Advanced Clean Trucks rule. They recommend integrating and relying on trends in California and other states that have or are planning to adopt a Low Carbon Fuel Standard (or comparable Clean Fuel Standards) to gauge the decarbonization potential of a transition to lower-carbon intensity fuels.

Daimler Trucks North America comments that many manufacturers have incorporated ZEVs into the strategies they use under the Phase 2 program to meet currently-applicable CO2 standards and that the ICE vehicles in their fleets are lower-performing than EPA anticipated. They stated this is due to lower adoption rates of the GHG-reduction technologies upon which the Phase 2 standards were based. Additionally, they stated that customers who are more likely to purchase high-performing ICE vehicles are more likely to purchase ZEVs, leaving a worse-performing ICE vehicle fleet. Thus, they assert that it is incorrect for EPA to assume that the remaining ICE vehicle fleet will maintain, on average, compliance with the existing Phase 2 MY 2027 standards and we should perform a new feasibility analysis on the existing Phase 2 standards, re-evaluating the level at which the remaining ICE vehicle fleet will perform.

Valero Energy Corporation criticized EPA for not modeling regional roll-out of HD plug-in electric vehicles and asserted that EPA must perform a more comprehensive and regionally disaggregated analysis of impacts to the electric grid and provide additional opportunity for review and comment on that new analysis.

The other commenters maintained that the baseline from which EPA assessed standard stringency and associated costs and benefits was mistakenly conservative. (CATF, EDF, National Parks Conservation Ass'n, RMI, SELC, Tesla.) These comments assert that the proposed standards merely reflect what the market would otherwise produce in violation of the requirements of section 202(a)(1) (as interpreted by the D.C. Circuit) to adopt standards which go beyond this 'business as usual' outcome. They also cite studies estimating greater future HD ZEV adoption than our baseline and point to state policies, such as California's ACT and ACF programs, as supporting greater HD ZEV adoption in the baseline. For example, CATF argued that the baseline must necessarily reflect all of the following, since they state that all of these indicate what will happen in the absence of federal regulation:

- California ACT standards
- California ACT standards as adopted by the so-called section 177 states;
- California ACF program
- NESCAUM MOU states
- The effects of federal funding beyond the Advanced Manufacturing Credit and Qualified Commercial Vehicle Credit considered by EPA at proposal;
- State and local initiatives (itemized and discussed in detail in the comment);
- Manufacturer and fleet production and purchase public commitments;
- ZEV adoption for vehicles for which EPA's payback analysis shows ready payback;
- ZEV adoption for vehicles where there are reliable indications of price parity with ICE vehicles before or during the model years of the proposal, including transit buses, refuse trucks, school buses, delivery vehicles, and (by MY 2030) long-haul tractors (citing ICCT April 2023 White Paper);
- The commenter includes citations to cases holding agency action arbitrary and capricious due to miscalculation of a baseline, and also cites OMB Circular A-4 for

the need to properly state a baseline as part of the process of calculating costs and benefits of agency actions. The commenter further maintains that the proposal violates CAA section 202(a)(1) by proposing standards which produce no emission reductions beyond those which would occur without the regulation.

Response:

Regarding AmFree's comments on the current state of the heavy-duty industry, we agree that there are relatively few models and registrations of BEVs and FCEVs today as discussed in the Executive Summary of the preamble and RIA Chapter 1. However, we also note in those sections significant interest, commitments, and investments towards applying such technologies to HD vehicles from manufacturers, fleets, state and local governments, as well as incentives under the IRA and BIL. We expect that the number of models and registrations of BEVs and FCEVs will increase significantly in the coming years. EPA also finds that the final rule provides sufficient lead-time for the development and application of BEV and FCEV technologies.

We appreciate ClearFlame's support for considering state regulations in determining nationwide production volumes of ZEVs. Regarding integrating or relying on trends in California and other states that have or are planning to adopt a Low Carbon Fuel Standard (or comparable Clean Fuels Standards) to gauge the decarbonization potential of a transition to lower-carbon intensity fuels, the requested action is outside the scope of this rulemaking. See also our responses in RTC Section 9.

Regarding Daimler Trucks North America's comments, we do not agree that our modeling baseline is improper. For the purposes of modeling the projected impacts of the Phase 3 standards, our approach appropriately reflects the emissions associated with the regulatory baseline, including among other things HD GHG Phase 2 and ACT, and the reduction in emissions attributable to this rule. This approach is consistent with Circular A-4, which states "Your baseline should reflect, when appropriate and feasible, the future effect of current government programs and policies. More specifically, the baseline should attempt to reflect relevant final rules (especially if their requirements are being modified by the regulation under consideration) …."[354] The Phase 2 Rule is an existing regulation, and therefore it is appropriate to consider that rule in the baseline. The same is true for ACT.

We acknowledge that the baseline reflects one potential compliance pathway for the regulations modeled (not including Phase 3). While this baseline is not necessarily consistent with any individual firm's compliance pathway, it is a reasonable projection to represent the baseline emissions from the industry as a whole. That is the case even taking as true DTNA's premise that it and some other manufacturers may produce more ZEVs and worse-performing ICE vehicles in MY 2027 than projected by Phase 2. This is not a situation where regulated entities are unable to comply with a prior regulation; rather we expect, and DTNA does not contest, that it and the industry generally are capable of complying with Phase 2. The fact that DTNA may employ different technologies than we projected in Phase 2 is a feature of the performance-based nature of the standards, not a defect in modeling. Further, in our evaluation of MY 2021 and MY 2022 heavy-duty GHG certification results, we find that there are ICE vehicles being built that already meet the Phase 2 MY 2027 emission standards, well in advance of MY 2027. Thus, given that Phase 2 is an existing final rule, the only question is how to model

[354] Circular No. A-4 (Nov. 9, 2023), 11-12.

Phase 2 compliance in the baseline. We think the agency's chosen modeling, which is based on the Phase 2 rule's projections of technology adoption, is a reasonable way to model the industry as a whole.

We note that similar to our modeling of Phase 2, our modeling of the final standards also represents one potential compliance pathway, which may differ from the pathway that any specific manufacturer or the industry ultimately take, and which reasonably estimates the emission reductions under the Phase 3 standards. For discussion of the notion that the ICE vehicle fleet will be worse performing than the Phase 2 MY 2027 standards, see RTC Section 2.4.

Regarding Valero's comments, we have updated from proposal our baseline to account for regional differences in HD ZEV adoption and we have modeled the impacts of these differences. See preamble Sections V, II.D, and II.E and RIA Chapter 4.

See also RIA Chapter 4 and RTC section 2.4 for our response regarding EPA's consideration of CARB's ACT regulation, including uncertainties in the final rule baseline for ZEV adoption and our final rule reference case ZEV adoption sensitivity analysis.

We agree that the baseline we presented in the proposal was conservative in part because it did not fully account for the ACT rule. As described in Section V.A.1 of the preamble, and Chapter 4.2.2 of the RIA, our baseline for this final rulemaking ("FRM baseline", and also referred to as our final rule reference case) shows increased ZEV adoption for all heavy-duty vehicle types compared to the baseline for the proposal. This FRM baseline reflects manufacturers' compliance with ACT in eight states and a lower, non-zero level of ZEV adoption in the other 42 states.[355]

We acknowledge that our FRM baseline does not explicitly reflect many of the items in the bulleted list in our comment summary above such as the ACF rule, NESCAUM MOU states, and public commitments by manufacturers and fleets for production and purchase of ZEVs, respectively, with the exception of the ACT rule in eight states who have finalized its adoption and which we have accounted for in the FRM baseline. Many of these items do not represent enforceable requirements, and they may or may not occur in the absence of the Phase 3 program. For example, we are not including CARB's ACF regulation in our baseline because at the time of this rulemaking, EPA is still reviewing the waiver request for the ACF regulation. However, we recognize and have taken into consideration that these other measures may have an impact on the market regardless of whether they are enforceable. To provide one example, in summer 2023, major manufacturers signed an agreement committing to meet the Advanced Clean Fleets 100% ZEV sales requirement in California, subject to certain conditions.[356] For the reasons detailed in

---

[355] At the time we performed the inventory modeling analysis, seven states had adopted ACT in addition to California. Oregon, Washington, New York, New Jersey, and Massachusetts adopted ACT beginning in MY 2025 while Vermont adopted ACT beginning in MY 2026 and Colorado in MY 2027. Three other states, New Mexico, Maryland, and Rhode Island adopted ACT (beginning in MY 2027) in November and December of 2023, but there was not sufficient time for us to incorporate them as ACT states in our modeling.

[356] See CARB-EMA Agreement i-ii ("The OEMs Commit to Meet CARB Truck Regulations *** The OEMs commit to meet, in California, the requirements of the relevant regulations as specified below and any agreed upon modifications per this Agreement, regardless of the outcome of any litigation challenging the waivers/authorizations for those regulations, or CARB's overall authority to implement those regulations. *** The ACT regulation, as it

preamble Section V and RIA 3, our FRM baseline generally has higher ZEV adoption rates than the baseline used in the proposal. Further discussion of the FRM baseline can be found in Preamble Section V.A.1.

The commenters do not sufficiently explain how to include the requested items in estimating the baseline ZEV adoption. They, in particular CATF, support their comments with citations to the literature. However, the literature estimations vary over a wide range—indicating uncertainty in the methodologies—and the literature doesn't appear to consider several important real-world factors which would in general be expected to slow down or reduce ZEV sales. These include such factors as ZEV product research and development timelines, ZEV manufacturing timelines, the availability of ZEV models, manufacturing or infrastructure constraints, driver preferences, and other factors. For example, EDF and ERM conducted a follow-up analysis of their HD ZEV sales projections after the IRA passed in 2022 in which they anticipate that approximately six percent of medium- and heavy-duty sales would be ZEVs.[357] In fact, EPA certified approximately 3,400 HD BEVs in MY 2022, which represents less than one percent of the market—significantly less than EDF and ERM's projection. This difference can likely be attributed in part to their omission of the real-world factors stated above.

CATF suggests that the adoption rates we presented in the proposal are actually a reasonably anticipated market-driven HD ZEV penetration level and so should be included in the baseline. We disagree because, while the payback-adoption rate analysis indicates what is achievable when limited only by the economics associated with payback, there are additional, important real-world factors that may affect ZEV adoption. EPA's analysis considers these additional factors, which include ZEV product research and development timelines, ZEV manufacturing timelines, the availability of ZEV models, manufacturing or infrastructure constraints, driver preferences, critical mineral and related supply chain availability, and other factors.

CATF also recommends considering payback period for the baseline. As described in Section V.A.1 of the preamble, among vocational vehicles in the FRM baseline, ZEV adoption rates increase with weight class which trends inversely with payback period as shown in RIA Chapter 2.9.2. Similarly, ZEV adoption rates are greater for short-haul tractors than long-haul tractors in the FRM baseline, which is also consistent with our payback analysis. We do not anticipate the payback period at the individual vehicle level to be affected by the Phase 3 standards, so the payback periods shown in RIA Chapter 2.9.2 are indicative of payback periods we would expect in the baseline.

We do not agree that the standards violate the Act because they produce no emission reductions. As we explain in preamble Section V, we expect the standards to produce significant GHG reductions. We further explain our interpretation of the statute in preamble Section I and II.G, and in RTC section 2.4.

3.11.2 Payback Period

Comments by Organizations

Organization: American Council for an Energy-Efficient Economy (ACEEE)

Assumptions in EPA's analysis of ZEV adoption rates are too limiting

Fully incorporating the results of state actions as recommended above would not be sufficient to bring EPA's projections of ZEV adoption to highest feasible levels. Certain key elements of EPA's ZEV analysis tool, HD TRUCS, are overly conservative, leading to low projections of ZEV adoption. These include battery and payback period requirements. [EPA-HQ-OAR-2022-0985-1560-A1, p. 5]

Payback requirements may also unnecessarily constrain ZEV adoption. Time to payback determines projected ZEV penetration through the HD TRUCS adoption rate schedule set out in in Table 2-73 (p.232) of the Draft Regulatory Impact Analysis (DRIA) .16 The schedule imposes onerous payback requirements in part because it does not differentiate by vehicle type. Typical first vehicle ownership period varies across type, affecting the payback period sought by the prospective buyer. An adoption rate under 45% in MY 2032 for a 1-2 year payback, as HD TRUCS dictates, is surprisingly low, even for the long-haul tractors purchased by large fleets that may sell their trucks after a few years. Indeed, fleets commonly cited 18 months as an acceptable payback period for efficiency technology in the Phase 1 and Phase 2 heavy-duty rulemaking processes. For a vocational fleet likely to own its vehicles for many years, one would expect that a payback period of several years would be acceptable and that MY 2032 adoption rates would reflect that. Furthermore, the Phase 3 program should be expected to play a role in tuning the vehicle market to properly value fuel cost savings for used as well as new vehicles. Hence, assigning high adoption rates to vehicles that pay back well within the life of the vehicle would be reasonable and would lead to adoption rates substantially higher than the proposed standards reflect. [EPA-HQ-OAR-2022-0985-1560-A1, p. 6]

Organization: American Trucking Associations (ATA)

4. The Upfront Costs of ZEVs are High and Fleets are Looking for Proof Prices Will Come Down

ZEVs' upfront acquisition costs are generally much higher than ICEVs, making it difficult for fleets to embrace electrification until they see meaningful year-over-year upfront purchase price declines. Before incentives, costs can be two to three times higher for BEVs and up to seven times higher for hydrogen fuel cell Class 8 trucks.13 Across the industry, acquisition costs are often greater than or equal to three-fifths of the TCO.14 For many fleets, calculating the TCO is a complex math problem that cannot be easily confirmed without significant expense and trial and error. Case studies alone are insufficient to validate assumptions due to each fleet's unique operating characteristics, including configuration, duty cycle, and cost.15 [EPA-HQ-OAR-2022-0985-1535-A1, p. 10]

13 Class 4-6 battery electric delivery vehicles can range from $100,000 to $200,000, while Class 8 over-the-road vehicles can cost $400,000 or more before incentives. Diesel MDV is around $75,000 and HDV is $165,000.

14 See, e.g., Volvo Trucks North America, Press Releases, "Volvo Trucks' New Electromobility Total Cost of Ownership Tool Demonstrates Financial, Environmental Benefits of Volvo VNR Electric," October 23, 2022; and Dana, Inc., Total Cost of Ownership Tool, n.d.

15 These variable inputs can be non-linear, colinear, and frequently interconnected, further complicating the TCO calculation process.

In calculating TCO, fleets generally think about capital and non-capital expenses. Capital expenses can be depreciated to offset some, though not all, of the significantly higher MSRP on a ZEV. Capital expenses are also expected to retain some residual value at the end of their useful lives, but there is little data to estimate these values for heavy-duty ZEVs. The fleet survey conducted by ATA confirms that most fleet respondents were uncertain about ZEVs' residual value. Reducing MSRP would be an impactful way to offset the uncertainty around TCO and encourage adoption. However, many fleets worry about the uncertainties of EPA's BEV price and cost assumptions because the technology is a new product category. They worry capacity improvements in batteries or efficiency gains in the cost-per-unit capacity will not necessarily translate into direct price reductions in the near to medium term, as projected under the proposed rule. Notably, battery and component costs have remained comparatively stable in the light-duty market for BEVs. Similarly, a midsize fleet manager running a mixed truckload and less-than-truckload operation shared they have seen prices increase year-over-year due to component pricing. [EPA-HQ-OAR-2022-0985-1535-A1, p. 11]

Another way to view these cost increases is their relationship to vehicle purchase prices. EPA estimated the Phase 2 2027 costs would increase the price of tractors by 12 percent and vocational vehicles by 3 percent.18 Using EPA's minimum vehicle price estimate of $100,000 for tractors and vocational vehicles, this equates to a 2027 ZEV price increase of 9 to 15 percent for vocational vehicles and 61 percent for tractors. For perspective, even with the IRA vehicle tax credits in place, these increases will be on par and surpass the U.S. consumer price increases of 9 percent in 2022, reaching its highest level in more than 40 years. The projected price increases associated with the proposed rule is a significant concern and requires further analysis of how purchasers will respond. [EPA-HQ-OAR-2022-0985-1535-A1, p. 14]

Organization: California Air Resources Board (CARB)

In its recent ACF rulemaking, CARB staff estimated the impact that regulation would have on vehicle costs for both ICE vehicles and ZEVs. CARB staff developed those estimates through a lengthy public process and through literature reviews of numerous sources discussing ZEV costs. CARB staff determined that although the vehicle acquisition costs for battery electric vehicles (BEV) and fuel cell electric vehicles (FCEV) will exceed the respective acquisition costs for their ICE counterparts until at least 2030, the costs for some categories of BEVs and FCEVs will decrease to below the costs of their ICE counterparts after 2030 as declining battery and component costs and economies of scale are expected to decrease the incremental costs of ZEVs as the market for ZEVs expands.26 CARB staff's findings are corroborated by numerous other studies evaluating ZEV prices—including in markets beyond California—over time. 27,28,29,30,31,32,33,34,35,36,37,38 [EPA-HQ-OAR-2022-0985-1591-A1, pp.17-18]

CARB staff further evaluated the total cost of ownership (TCO) of ZEVs versus ICE vehicles39 by comparing TCOs of gasoline, diesel, natural gas, battery electric, and hydrogen fuel cell vehicles in six applications on a per-vehicle basis. CARB staff's analysis indicates that the TCO for BEVs appears to be cost competitive with established combustion technologies by 2025 in a variety of use cases, and that BEVs offer significant savings in the walk-in van, refuse truck, and day cab categories, even by 2025. FCEVs also appear to be cost competitive with combustion-powered technologies in the 2025 to 2030 timeframe for some vehicle types. Moreover, despite the higher upfront costs associated with vehicle costs and infrastructure, cost savings from lower fuel costs and operational costs will result in a positive TCO for ZEVs, and the TCO for ZEVs is expected to further decrease over time as costs continue to decline. G. Estimated Cost and Economic Impact

1. Overall Comments on Economic Impact Analysis

Affected pages: NPRM 25974-25998 and DRIA 157-261

In assessing U.S. EPA's economic analysis, CARB staff performed a comparison versus the cost and economic analysis performed for the recently adopted ACF regulation. The ACF analysis included direct costs on affected businesses including upfront costs, operating costs, and other miscellaneous costs associated with transitioning MD vehicles and HDVs from ICE vehicles to ZEVs. Staff's ACF analysis was developed through a lengthy public process. Staff held public workgroup meetings on December 9, 2020, September 9, 2021, and February 11, 2022, to discuss costs associated with ZEVs and their infrastructure. Through these meetings, staff solicited feedback on data sources to use, updated our assumptions discussing CARB's economic analysis for the regulation, and solicited public input on appropriate sources. CARB staff also performed literature reviews to identify sources discussing ZEV costs. Through this process, CARB was able to ensure the analysis was using up-to-date information which reflects the current state of the truck market and future projections on ZEV costs. [EPA-HQ-OAR-2022-0985-1591-A1, p.59]

U.S. EPA's findings that ZEVs have lower costs than ICE vehicles and a positive payback period are well supported by literature and consistent with CARB's ACF analysis. In addition to CARB staff's recent economic analysis for the ACT regulation194,195 and ACF regulation,196,197 numerous other third-party analyses have found similar conclusions.198,199,200,201,202,203,204,205,206,207,208 While ZEVs have higher upfront costs due to incremental vehicle costs and infrastructure costs, lower operating costs from fuel savings and reduced maintenance expenses deliver a positive TCO to fleet operators. CARB staff finds broadly that U.S. EPA has performed a robust analysis on the economic impact of ZEVs. However, staff has identified numerous areas where U.S. EPA's assumptions may be overly conservative and are resulting in potentially higher costs than expected. By assuming vehicles are more costly, U.S. EPA's analysis generates lower payback periods which in turn result in lower standards per U.S. EPA's methodology to tie the Proposed Standards to the payback period. [EPA-HQ-OAR-2022-0985-1591-A1, pp.60-61]

CARB staff also note that U.S. EPA's analysis is based on solely BEVs or FCEVs for each vehicle configuration. In reality, manufacturers are developing both BEV and FCEV models for the same vehicle configurations, and as a result a greater portion of the market will be addressed than any technology can do individually. BEVs and FCEVs can address the needs of fleets with different preferences, so U.S. EPA's methodology will underestimate the number of ZEVs which can be deployed through development of multiple low and zero-carbon technologies. [EPA-HQ-OAR-2022-0985-1591-A1, p.61]

3. BEV Powertrain Cost Calculation

Affected pages: NPRM 25974 and DRIA 177-181

CARB staff has noted the cost of a BEV's powertrain in the NPRM for numerous vehicle configurations behaves in an unexpected manner. Costs decline from 2027 to 2030, then increase from 2030 to 2032. Given that the component costs and learning factors lead to cost reductions over time, this increase in cost appears to be unwarranted. CARB staff seeks further clarification in this regard. [EPA-HQ-OAR-2022-0985-1591-A1, p.63]

6. Payback Period

Affected pages: 25989-25996

U.S. EPA's economic analysis is used to determine a payback period for BEV and FCEV technologies versus diesel, which is the main input in setting the Proposed Standards for the Phase 3 rulemaking. [EPA-HQ-OAR-2022-0985-1591-A1, p.64]

Typically, new vehicles are purchased by larger fleets who operate these vehicles for a length of time, then sell them into the secondary market to predominantly smaller fleets.220,221 Larger fleets typically have a thorough, data-driven process to procure vehicles which is commonly based off a TCO analysis comparing different options. Smaller fleets typically have less sophisticated procurement decision making and face challenges such as access to capital which leads to the short-term payback period being a more critical determining factor. Given that U.S. EPA's NPRM applies to new vehicle sales, it is important to recognize that the decisions of larger fleets will be the key driver, not smaller fleets or fleets as a whole. As a result, TCO is a key parameter which must be assessed. [EPA-HQ-OAR-2022-0985-1591-A1, pp.64-65]

220 ICCT, No Fleet Left Behind: Barriers and Opportunities for Small Fleet Zero-Emission Trucking, 2022 (web link: https://theicct.org/wp-content/uploads/2022/10/small-fleet-ze-trucking-oct22.pdf, last accessed June 2022).

221 CCJ, New Truck Buyers Dictate the Portfolio Planning of Used Truck Buyers, 2023 (web link: https://www.ccjdigital.com/trucks/used-trucks/article/15307006/new-truck-buyers-dictate-used-truckselection, last accessed June 2023)

U.S. EPA's analysis for 2032 shows ZEVs in nearly all applications have a payback period under six years with many applications having a payback period of less than two years. On a TCO basis, this means the entire upfront cost has been recouped and the ZEV will deliver operational savings versus its diesel counterpart for the rest of its operations. Given this information, fleets will see a major cost advantage in purchasing ZEVs and risk falling behind competitors if they do not expeditiously transition to ZEVs. [EPA-HQ-OAR-2022-0985-1591-A1, p.65]

Based on these facts, the adoption rates reflected by U.S. EPA in 2027 and 2032 are far too pessimistic regarding uptake of ZEVs by fleets. Larger fleets who purchase ZEVs are conscious of all costs associated with operating a vehicle over its lifetime and will make decisions on the expected total costs. Given this, the adoption rates for vehicle configurations which pay back between zero and four years is far too low, with some values as low as 18 percent. U.S. EPA's own analysis notes that a typical ownership period can be ten years, indicating that the ZEV technology will deliver significant savings to the vehicle's operator over the expected lifetime. In addition, U.S. EPA should consider whether the cap of adoption rate above 80 percent is warranted – if a technology option simultaneously has lower upfront costs and lower operating costs, it is hard to imagine a reason one out of five fleets will consciously avoid that technology. [EPA-HQ-OAR-2022-0985-1591-A1, p.65]

CARB staff also recommends U.S. EPA reevaluate the Proposed Standards after reassessing the payback period given how the standards are dependent on the payback period. CARB staff recognizes that HD ZEV technology is in its nascent stages, especially in some categories, but this development is already underway and will continue improving between now and 2027 and then further before 2032. [EPA-HQ-OAR-2022-0985-1591-A1, p.65]

Organization: Daimler Truck North America LLC (DTNA)

In the Proposed Rule, EPA establishes a direct relationship between payback period and technology adoption rates, which are used to project future adoption levels for each vehicle category considered in the HD TRUCS tool. In doing, so, it appears that EPA has made a number of questionable assumptions about purchaser behavior that will likely undermine the accuracy of its adoption rate projections. There are also a number of real-world factors and fleet considerations not addressed by the Agency or the sources it relies upon that could further preclude future ZEV adoption at the rates that EPA projects. [EPA-HQ-OAR-2022-0985-1555-A1, p. 19]

EPA's analysis of payback periods and adoption rates is distorted by incorrect assumptions about the impacts of the Phase 3 regulations and future technology improvements on purchaser behavior. EPA performed a literature review to establish the payback period/adoption rate relationship, including the Americas Commercial Transportation Research Company LLC (ACT Research) 'Charging Forward' report, the National Renewable Energy Laboratory (NREL) Transportation Technology TCO tool, Oak Ridge National Laboratory's Market Acceptance of Advanced Automotive Technologies model, Pacific Northwest National Laboratory's Global Change Analysis Model, ERM's market growth analysis done on behalf of the Environmental Defense Fund (EDF), Energy Innovation's United States Energy Policy Simulator used in analysis by the International Council for Clean Transportation (ICCT) and Energy Innovation, and CALSTART's Drive to Zero Market Projection Model.29 All of these sources project adoption rates based on their own sets of assumptions and predictions, which should be reviewed as the market matures and new data becomes available. [EPA-HQ-OAR-2022-0985-1555-A1, pp. 19-20]

29 See id. at 231-32.

EPA relies most heavily on ACT Research's Charging Forward report methodology, but makes several modifications that DTNA believes are not supported by data. Table 3 below shows EPA's proposed adoption rates compared to the adoption rates derived from the ACT Research 'Charging Forward' report: [EPA-HQ-OAR-2022-0985-1555-A1, p. 20] [Refer to Table 3 on p. 20 of docket number EPA-HQ-OAR-2022-0985-1555-A1]

ACT Research's adoption rate model assigns an adoption percentage rate based on payback year, stated to be based on experience. ACT Research then uses the percent difference in TCO to provide another driver of adoption.31 EPA asserts that a faster adoption rate compared to the ACT Research schedule is reasonable due to the assumed impact of the Phase 3 regulations and the more modest 80% constraint that the Agency applies to the less-than-zero-year payback period.32 EPA further increases the adoption rate in 2032, stating that 'ZEV technology will be more mature; fleet owners and drivers will have had more exposure to ZEV technology, which may alleviate concerns of reliability and result in a lower impression of risk of these newer technologies; and infrastructure to support ZEV technologies will have had more time to expand.'33 [EPA-HQ-OAR-2022-0985-1555-A1, p. 20]

31 See ACT Research, 'Charging Forward' 2020-2040 BEV & FCEV Forecast & Analysis (December 2021) at 105, available at https://www.actresearch.net/consulting/special-projects/commercial-vehicle-decarbonizationforecast-reports.

32 See DRIA at 232.

33 Id.

DTNA disagrees with these reasons for increasing ACT Research's projected adoption rates, as the requirements in the Proposed Rule will apply to manufacturers and will not directly impact consumer purchasing decisions, as discussed in more detail in Section II.B.3.c of these comments. Despite its estimation that more than 150 HD BEV models were available in the United States in 2021,34 EPA cites data provided in the EIA 2022 AEO that BEV and FCEVs made up less than 0.1% of Class 7-8 sales in that year.35 As adequate supply is already available in the market with limited demand, it is unreasonable to assume that a regulation impacting only ZEV supply will have a significant impact on purchaser behavior and adoption rates.36 [EPA-HQ-OAR-2022-0985-1555-A1, pp. 20-21]

34 See id. at 44.

35 See id. at 11 (citing U.S. Energy Information Administration, Annual Energy Outlook 2022, Table 49: Freight Transportation Energy Use (March 2022), https://www.eia.gov/outlooks/aeo/data/browser/#/?id=58-AEO2022®ion=0).

36 EPA notes that EIA's AEO forecasts do not account for incentives provided by tax credits enacted under the IRA, see DRIA at 12; however, it is unlikely that IRA tax credits will alter the payback period/adoption rate relationship, only the calculated payback period.

While future ZEV technology improvements have a positive impact on purchaser behavior, EPA already accounts for this in the declining costs and improved efficiencies used to calculate improved payback periods year-over-year in the HD TRUCS tool. It is not appropriate to consider technology improvement in both the TCO and adoption rate calculations. Fleet owners and drivers may have some increased exposure to ZEVs by 2032, but significantly increasing adoption rate projections fails to account for the additional challenges discussed below, and FCEV technologies will still be new to the market compared to BEV options. Further, infrastructure expansion is unlikely to enable this increased adoption rate in 2032, as discussed in Section II.B.3.b of these comments. [EPA-HQ-OAR-2022-0985-1555-A1, p. 21]

Finally, in our experience, most large on-highway fleets operate on a regular 3-5 year vehicle trade cycle. Fleets invest in new technologies to earn a payback, not simply to break even, so adoption rates are highest for technologies where payback occurs in less than half the trade cycle. The Company has observed a rapid decline in adoption rates for payback periods that exceed 2 years. Vehicle resale values generally begin to decrease after 4 years, further reducing the adoption rates of technologies with payback periods of 4 years or more. The adoption rates projected by both EPA and ACT Research, as shown in Table 3 above, thus appear to over-estimate adoption rates for ZEVs with payback periods longer than 2 years. [EPA-HQ-OAR-2022-0985-1555-A1, p. 21]

Historical adoption rates for fuel-economy improvement technologies do not provide a sound basis for predicting customer acceptance of ZEV technologies. The ACT Research method and other literature relying on historical adoption rates of fuel-economy improvement technologies for conventional vehicles to predict ZEV adoption rates will result in significant over-projection, as minimally invasive options like aerodynamic components naturally see much greater adoption rates than ZEVs that require dedicated charging infrastructure and are more limited to specific route and weight applications. Furthermore, the adoption rate models that EPA references in the DRIA are based on existing GHG reduction technologies, which are well-established and are minimally invasive compared to ZEVs. It is unlikely ZEVs will see uptake rates higher than the uptake rates for minimally-invasive aerodynamic and other changes. Finally, historically the highest GHG technology adoption rates have been in the long-haul segment, where the cost-per-mile metric is compounded by the high daily mileage driven. These applications are the least suitable for BEVs and FCEVs, until technologies and charging and fueling infrastructure networks are significantly expanded. [EPA-HQ-OAR-2022-0985-1555-A1, p. 21]

The Zero Emission Truck Market Assessment prepared by CARB in support of its ACT regulations evaluated ZEV application suitability based on range, weight, and vehicle space constraints, and considered charging/fueling infrastructure access as return-to-base operations, but did not necessarily consider whether infrastructure can be made available at those bases.38 CARB evaluated Class 4-7 and Class 8 categories, and determined what percentage of vehicles may be suitable for BEV and FCEV technologies, shown in Table 5 below. CARB determined 72-73% of Class 4-7 vehicles could be suitable for ZEVs, but found only 29-36% of Class 8 vehicles could be suitable for ZEVs.39 Given these findings, DTNA believes 73% should be the maximum possible Class 4-7 adoption rate, and 36% should be the maximum possible Class 8 adoption rate, in lieu of the values that EPA proposes in Table II-23 of the Proposed Rule. [EPA-HQ-OAR-2022-0985-1555-A1, p. 23] [Refer to Table 5 on p. 23 of docket number EPA-HQ-OAR-2022-0985-1555-A1]

38 See CARB, Advanced Clean Trucks, Initial Statement of Reasons (Oct. 22, 2019), Appendix E: Zero Emission Truck Market Assessment, available at https://ww3.arb.ca.gov/regact/2019/act2019/appe.pdf.

39 Id. at 4.

In DTNA’s experience, a favorable payback period does not by itself guarantee high rates of technology adoption. While payback period is certainly an important factor for fleets considering technology adoption, a favorable payback period alone does not guarantee high rates of technology adoption. For example, drive wheel fairings are a mature, relatively low cost technology that typically result in a fuel economy payback within the fleet trade cycle. However, DTNA’s drive wheel fairing adoption rate in the HD fleet is less than 5%. Fleets are often deterred from utilizing this technology because drive wheel fairings are easily damaged, increasing overall cost and vehicle downtime. [EPA-HQ-OAR-2022-0985-1555-A1, p. 23]

DTNA has observed similarly low uptake of tire pressure monitoring systems (TPMS), due in part to a longer calculated payback period (greater than 2 years) and added complexity for tire changes. If a roadside tire replacement occurs, the TPMS sets diagnostic errors, requiring additional downtime to repair after the tire change. [EPA-HQ-OAR-2022-0985-1555-A1, p. 24]

To illustrate this phenomenon, we take the example of DTNA's experience with ZEV uptake in California, which has the most developed ZEV market in the United States. To assess the accuracy of the payback period/adoption rate relationship on which the Proposed Rule is based, DTNA used California's HVIP TCO estimator tool to estimate the current payback period for a Class 8 tractor.40 Using a 200 mile/day use case, we adjusted the calculator's default values to represent the Company's vehicle pricing and current estimates of California diesel and electricity prices. We included the Federal Excise Tax (FET) but excluded Low Carbon Fuel Standard (LCFS) program participation. Two example payback periods using these inputs and two different incentive values are shown below: [EPA-HQ-OAR-2022-0985-1555-A1, p. 24] [Refer to Scenarios 1 and 2 on p. 24 of docket number EPA-HQ-OAR-2022-0985-1555-A1]

40 See California HVIP, 'Total Cost of Ownership Estimator,' available at https://californiahvip.org/tco/.

DTNA believes these estimated payback periods in the 3 - 6 year range to be reasonably accurate for the scenario described. Based on EPA's proposed adoption rate table, these payback periods should result in 13 - 18% ZEV adoption. However, the Company is currently experiencing Class 8 BEV tractor uptake of less than 1% in California, despite additional regulatory drivers for fleet adoption. [EPA-HQ-OAR-2022-0985-1555-A1, p. 25]

Based upon these considerations of ZEV suitability, EPA should adopt more conservative maximum adoption rates. EPA states in the Proposed Rule that it limited the maximum penetration rate to 80% to account for the 'actual needs' of purchasers related to two primary areas of its analysis, namely application suitability and infrastructure availability.37 DTNA submits, however, that an 80% maximum adoption rate over-represents the fraction of the market where BEVs or FCEVs are suitable in the near-term and that application suitability is inadequately addressed in the HD TRUCS methodology. [EPA-HQ-OAR-2022-0985-1555-A1, p. 23]

37 Proposed Rule, 88 Fed. Reg. at 25,992.

EPA Request for Comment, Request #18: We request comment on this approach [payback period] and any supporting data on the potential for these and additional technologies to be available in the HD market in the MY 2027 through MY 2032 timeframe.

- DTNA Response: EPA's approach to the payback period/adoption rate relationship underpinning its proposed CO2 standard stringency levels does not accurately reflect the HD ZEV market, and overlooks a number of complex considerations including infrastructure challenges, reluctance to adopt new technology, inflation and other economic concerns, and vehicle suitability, as discussed in Section II.B.3 of these comments. EPA should not consider proposed penetration rates of any vehicle types outside of the BEV and FCEV categories included in the Proposed Rule. [EPA-HQ-OAR-2022-0985-1555-A1, p. 161]

EPA Request for Comment, Request #48: Thus we request comment and data on our proposed adoption rate, including schedule and methods. We also request comment and data to support other adoption rate schedules; see also Section II.H.

- DTNA Response: EPA's ZEV uptake projections in the Proposed Rule are overly optimistic and do not account for a number of fleet considerations including infrastructure availability, reluctance to adopt new technology, inflation and other economic conditions, and vehicle suitability to fleet operations, as discussed in Section II.B.3 of these comments. DTNA therefore proposes an alternate adoption rate schedule based on CARB's estimate of ZEV suitability and the Company's experience with GHG technology uptake rates, as detailed in Section II.C of these comments. [EPA-HQ-OAR-2022-0985-1555-A1, p. 166]

EPA Request for Comment, Request #49: For example, some owners may not have the ability to install charging infrastructure at their facility, or some vehicles may need to be operational 24 hours a day. Under our proposed standards, ICE vehicles would continue to be available to address these specific vehicle applications. We request comment, data, and analysis on both of these considerations and our use of an 80 percent volume limit.

- DTNA Response: EPA's 80% volume limit significantly over-estimates ZEV suitability with respect to infrastructure and operational needs. As discussed in Section II.B.3 and Appendix A to these comments, DTNA's telematics data indicates that only a small fraction of vehicles are returning to base at the end of their workdays. In addition, return-to-base operations depend on ready availability of infrastructure at a given site, which is not at all guaranteed. CARB assessed 72% maximum suitability in Classes 4 through 7, and 36% in Class 8 applications based on range, weight, and return-to-base operations. DTNA recommends EPA cap its ZEV maximum volumes at these rates, as explained in Section II.B.3.a. [EPA-HQ-OAR-2022-0985-1555-A1, p. 167]

EPA Request for Comment, Request #51: We request comment and data on our projected adoption rates in the technology packages [ZEV + assumption that ICE meets 2027] as well as data supporting higher or lower adoption rates than the projected levels. We also request comment on projecting adoption rates out through MY 2035.

- DTNA Response: See DTNA Response to Request # 2, above. [EPA-HQ-OAR-2022-0985-1555-A1, p. 167] [Refer to section 2 of the comment summary]

EPA Request for Comment, Request #76: We request comment and data on acceptance of HD ZEVs.

DTNA Response: Throughout its comments on the Proposed Rule, DTNA provides details and supporting data on the factors influencing acceptance of HD ZEVs, including ZEV suitability, TCO, and infrastructure availability. [EPA-HQ-OAR-2022-0985-1555-A1, p. 172]

Organization: Energy Innovation

II. THE EPA SHOULD UTILIZE OTHER INDEPENDENT ANALYSIS AND TRANSPARENT METHODS TO FORECAST ZEV ADOPTION RATES. THE EPA SHOULD ALSO ACCOUNT FOR THE IMPACT OF ADDITIONAL FACTORS THAT MAY ACCELERATE LEARNING CURVES FOR HDV BEVS IN THE NEAR FUTURE.

In response to the EPA's request for comments on its approach to selecting ZEV technology adoption rates based on payback, we offer the following observations and propose adjustments to the methodology for the EPA's consideration. [EPA-HQ-OAR-2022-0985-1604-A1, p. 7]

First, nine states have adopted California's Advanced Clean Trucks (ACT)v rules (as of June 2023). According to the National Automobile Dealers Association, medium- and heavy-duty truck sales from franchised dealerships in these nine states made up nearly 24 percent of total HDV sales volume nationwide in 2022.14 As such, applying a uniform approach to forecast ZEV technology adoption rates in all states does not fully reflect the impact of ACT states on the share of HDV sales (nor does it capture the ripple effect on the HDV market as a whole). Accordingly, ZEV adoption in ACT states should be accounted for separately in the EPA's methodology and should mirror the adoption rates defined by each state's standard. As more ZEVs are produced and sold in ACT states, production costs will decline, making them cheaper across state borders. [EPA-HQ-OAR-2022-0985-1604-A1, p. 7

iv California, Colorado, Maryland, Massachusetts, New York, New Jersey, Oregon, Vermont, and Washington.

v The Advanced Clean Trucks (ACT) rule, adopted first by the California Air Resources Board in June 2020, requires truck manufacturers to transition from diesel trucks and vans to electric zero-emission trucks, phasing in available heavy-duty zero-emission technology starting in 2024 with full transformation over the next two decades. See https://ww2.arb.ca.gov/our-work/programs/advanced-clean-trucks.

14 "ATD Data 2022: Annual Financial Profile of America's Franchised New-Truck Dealerships" (National Automobile Dealers Association, 2022), https://www.nada.org/media/5008/download?inline, 6.

Second, in the original Draft Regulatory Impact Assessment (DRIA),vi the EPA cites the ACT Research report ChargeForward (December 2021) as the source of equation 2-61 that defines the relationship between payback period and technology adoption rates for HDVs.15 The now-redacted equation 2-61 was used to inform EPA's methodology to produce the adoption rate schedule for model year (MY) 2027 and MY 2032 in EPA's model, HD TRUCS. The assumptions derived from the ACT Research study impact forecasted ZEV technology adoption rates, which influence the stringency of the rule and the future of the HDV market. The EPA states that "the adoption rate method used for this proposal was developed after considering methods in the literature to estimate adoption rates in the HD vehicle market," and it provides a list of other methods they considered (including a January 2023 study by the International Council on Clean Transportation (ICCT) and Energy Innovation, Analyzing the Impact of the Inflation Reduction Act on Electric Vehicle Uptake in the U.S. (ICCT-EI Study), among several others).16 But, it states "of these methods explored, only ACT Research's work directly related payback period to adoption rates…and thus we relied on the ACT Research method to assess adoption rates."17 The EPA's reliance on a method from a single proprietary study (with the hefty price tag of $25,000 for access18) to estimate technology adoption rates is highly concerning because it restricts transparency and accessibility of data and underlying assumptions and methodologies. All interested stakeholders should have the opportunity to review any underlying assumptions, methods, data, and approaches used to determine the proposed rule. Energy Innovation did not purchase the ACT Research study and therefore lacks insight into the details underlying the methodology to derive the equation and other assumptions regarding payback and adoption rates. We see the EPA's reliance on this source as a limitation in the proposed rule's core assumptions about adoption rates. We suggest the EPA take an alternative approach to its methodology and use sources that are transparent, independently verifiable, and available at no cost for interested stakeholders. [EPA-HQ-OAR-2022-0985-1604-A1, p. 7]

vi The original DRIA was subsequently edited after being posted online. The new version online contains redacted information (equation 2-61 and table 2-72), presumably because they were proprietary to ACT Research.

15 "Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles: Phase 3, Draft Regulatory Impact Analysis (DRIA)" (Assessment and Standards Division Office of Transportation and Air Quality U.S. Environmental Protection Agency, April 2023), https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P10178RN.pdf. 231.

17 "DRIA," 32.

18 "Are You Charging Forward to Zero Emissions?," ACT Research, n.d., https://www.actresearch.net/consulting/specialprojects/commercial-vehicle-decarbonization-forecast-reports.

Third, the EPA applied the "conservative limit" of 80 percent market share for all vehicle classes "after consideration of the actual needs of the purchasers."19 The EPA states that it does "not expect heavy-duty OEMs to design ZEV models for the 100th percentile VMT daily use case for vehicle applications" and it recognizes "there is a wide variety of real-world operation even for the same type of vehicle."20 While it is always challenging to predict which technology evolutions will occur in the future, assuming the HDV market will be the same as it is today a decade from now ignores the likelihood that technology advances in EV models, batteries, charging infrastructure, and real-world HDV operations will be notably different by 2032. [EPA-HQ-OAR-2022-0985-1604-A1, pp. 7 - 8]

19 U.S. EPA, "Proposed Rules," 25992.

20 U.S. EPA, 25992

Applying a static limit on market adoption for the duration of the proposed rule (i.e., model years 2027 – 2032) puts an arbitrary constraint on the model and heavily discounts the likelihood of breakthrough technological advances (as well as market and consumer adaptations) over the next decade. It also ignores recent trends in EVs that will impact learning curves for the HDV sector (discussed further below). [EPA-HQ-OAR-2022-0985-1604-A1, p. 8]

The light-duty vehicle (LDV) EV market provides several illustrative examples of the fast pace of technology evolution and market adaptation (which were unanticipated just a few years ago). Figure 4 shows the exponential growth in the number of models with a range of 300 miles or greater in less than a decade. And Figure 5 shows a similar trend between 2010 and 2021 for global EVs. Other non-transportation examples further illustrate this point, such as smartphones, semiconductors, cloud storage, and cryptocurrency—all game-changing technologies whose rapid growth was near-impossible to accurately predict in their nascent years. [EPA-HQ-OAR-2022-0985-1604-A1, p. 8.] [See Figure 4, Light-Duty EVs with Range of 300 Miles or Greater,on page 8 of docket number EPA-HQ-OAR-2022-0985-1604-A1 and Figure 5, Evolution of Average Range of EVs by Powertrain, on page 9 of docket number EPA-HQ-OAR-2022-0985-1604-A1.]

Considering the aforementioned issues, Energy Innovation conducted an independent analysis of technology adoption rates that we hope the EPA considers as it develops the final rule. Below is an overview of our methodology, the results of our analysis for different HDV vehicle classes, and key takeaways. We have also attached with our comments the spreadsheet used to develop the analysis. We are happy to discuss this analysis in greater detail with the EPA and any interested stakeholders. [EPA-HQ-OAR-2022-0985-1604-A1, p. 9]

A. HDV Sales Adoption Methodology

To estimate the sales of HDVs with different engine types, we used a logit allocation based on total cost of ownership (TCO). This approach follows our methodology from the ICCT-EI Study with a few modifications. The logit allocation assigns sales shares to different vehicle technologies based on the TCO of different vehicles using an assumed financial horizon and discount rate. Vehicle costs, maintenance costs, fuel prices, vehicle distances, and remaining inputs to the TCO paper are all sourced from the referenced ICCT-EI Study. [EPA-HQ-OAR-2022-0985-1604-A1, p. 9]

We made two modifications for this analysis to estimate sales for a rule affecting future sales. First, our prior modeling used an inflated share-weight for ICE HDVs, depending on vehicle class. This assumption limited the uptake of BEVs, even at TCO parity. For this analysis, we use a value of 1 for all engine types across all vehicle classes to reflect the growth in market supply along the timeline on which the rule takes effect. A share-weight of 1 results in higher BEV shares at a given TCO, but reflects the potential for vastly increased supply of BEV HDVs over the next 5-10 years. Second, we updated the financial horizons used for different vehicle classes from our prior modeling. Previously we assumed a financial horizon of 6 years (as an average duration of first owner vehicle ownership) across all HDV classes. In this analysis, the financial horizon varies from 5 to 12 years depending on the vehicle class and the typical owner type (for example, municipal buses will have a longer financial horizon given that cities typically own and finance fleets over a longer period than commercial trucking companies). Our results are also translated into sales shares for different payback periods to align with the approach the EPA used in its proposed rule. [EPA-HQ-OAR-2022-0985-1604-A1, pp. 9 - 10]

B. HDV Sales Adoption Analysis Findings

Applying the methodology outlined above, we generated market sales share curves based on payback period for the years 2027 (orange line) and 2032 (blue line), and compared them with the EPA/Act Research curves (gray line) for the following HDV classes: Rigid Trucks (4-5, 6-7, and 8); Tractor Truck (short-haul and long-haul); Refuse Truck; and Buses (school bus, other bus 6-8, small bus 4-5, and transit bus 6-8). We removed the 80 percent cap to allow for 100 percent market sales share where the payback was <0. For all vehicle classes, we see greater market sales share for both 2027 and 2032 than what the EPA forecasts in its proposed rule. [EPA-HQ-OAR-2022-0985-1604-A1, p. 10.] [See Figures 6(a) – 7(i). Market sales share adoption for 2027 and 2032, on pages 10-11 of docket number EPA-HQ-OAR-2022-0985-1604-A1.]

C. Key Takeaways from HDV Sales Adoption Analysis

We observe similar levels of adoption when the payback period is zero or negative, with values typically at or above 80 percent. However, given projected cost trends (taken from the ICCT-EI Study) and especially when layered with IRA incentives, there will be several classes of HDV BEVs with paybacks of <0 years in the future. [EPA-HQ-OAR-2022-0985-1604-A1, p. 11]

While our model captures the ability of sales share to exceed 80 percent when this occurs, the EPA's current approach, as noted above, caps sales shares at 80 percent, regardless of the payback period (even if zero or negative). Based on our analysis, we observe that this cap artificially constrains the deployment of BEVs in the EPA's modeling and does not reflect changes in consumer purchasing behavior as BEV prices fall. In addition, a static 80 percent cap applied for all vehicles fails to differentiate across vehicle classes and vehicle types. For example, while it may be true that a BEV may not be a viable technology for certain long-range heavy-duty tractor trailers, given today's technologies and charging infrastructure, a class 4 truck that travels long distances could be a BEV far more easily, based on charging needs and usage patterns. The EPA should consider amending its methodology to increase the limit when payback periods are highly beneficial to the end user, adjust the cap for differences across vehicles and end uses, and/or gradually increase the cap over time to account for future technology improvements and adjustments to HDV use cases and consumer behavior. Furthermore, the EPA should consider binning sales estimates in vehicle miles traveled (VMT) deciles, to capture very high adoption in the lower and medium tier deciles. For example, for certain vehicle classes, for the first 90 percent of VMT, sales could reach 100 percent, but might only be 80 percent for the last 10 percent of VMT. This would yield an adoption rate of 98 percent, as opposed to a ceiling of 80 percent. [EPA-HQ-OAR-2022-0985-1604-A1, p. 12]

In addition, our approach yields significantly higher BEV adoption than the EPA's approach for all payback periods, especially those beyond 2 years. This is due to a combination of using a logit function that is less price sensitive (our function parameters are derived from the Pacific Northwest National Laboratory's Global Change Analysis Model (GCAM)21 and methodology) and a discount rate of 15 percent. Using our methodology, we ran some sensitivity analyses to approximate the deployment curves in the EPA's proposed rule, and it required applying some extreme assumptions (e.g., discount rates of 80 percent or higher and a logit exponent of around -40 compared to a value of -8 from the GCAM model). [EPA-HQ-OAR-2022-0985-1604-A1, p. 12]

21 "GCAM: Global Change Analysis Model," Global Change Intersectoral Modeling System (GCIMS), n.d., https://gcims.pnnl.gov/modeling/gcam-global-change-analysis-model.

Absent more detailed documentation from the ACT Research methodology and EPA's approach to determine adoption rates, and with only the outputs from the TRUC tool available, we call into question the methodology and assumptions the EPA is relying on to inform ZEV technology adoption for the proposed level of stringency of the rule. The EPA's more conservative approach relies on a more limited set of assumptions for technology adoption rates that may reflect today's limitations for BEVs in the HDV market but fail to fully account for future technology advancements and relevant factors impacting learning curves (discussed below). We urge the EPA to consider updating its methodology and use other curves, like our analysis or other independent and verifiable analyses that are aligned with published and publicly available models. [EPA-HQ-OAR-2022-0985-1604-A1, p. 12]

III. MODELING SHOWS THAT NEW FEDERAL POLICIES COMBINED WITH STATE POLICIES WILL ADVANCE THE HDV ZEV MARKET FASTER, WHICH SUPPORTS THE EPA'S ADOPTION OF ALTERNATIVE, MORE STRINGENT TAILPIPE STANDARDS.

We appreciate that the EPA has "considered new data and recent policy changes [the BIL and IRA] and [is] now projecting that ZEV technologies will be readily available and technologically feasible much sooner than [it] had projected."35 The EPA also notes that the "IRA in particular provides significant incentives for GHG reductions in the HDV sector."36 We agree, and our modeling supports these findings. [EPA-HQ-OAR-2022-0985-1604-A1, p. 16]

vii Available at https://theicct.org/publication/ira-impact-evs-us-jan23/ and attached to these comments.

35 U.S. EPA, "Proposed Rules," 25929 and 25939.

36 U.S. EPA, 25929.

In the ICCT-EI Study, we examined the impact of the IRA on the sale of new EVs in the LDV and HDV sectors in the U.S. through 2035.vii We used a customized Excel model based on Energy Innovation's U.S. EPS, using updated data on vehicle costs, battery pack estimates, efficiencies, charging behavior, future fuel prices, and state adoption of Advanced Clean Cars II (ACC II) rules and ACT rules. We have attached the full study with our comments. [EPA-HQ-OAR-2022-0985-1604-A1, pp. 16 - 17]

We evaluated three IRA Scenarios: Low, Moderate, and High, with different assumptions for each scenario to reflect how certain provisions of the IRA (the Personal Tax Credits for Clean Passenger Vehicles (30D), the Commercial Vehicle Tax Credits (45W), and the Advanced Manufacturing Production Tax Credit (45X)) are implemented and the value of incentives passed on to consumers. We compared these scenarios to a Baseline (no IRA with just California adoption of ACC II and ACT rules). We also evaluated the impact of state adoption of clean car and truck standards. For HDVs, for all scenarios, we assume the ACT rule is followed in states that had adopted it as of October 2022 (California, Massachusetts, New Jersey, New York, Oregon, and Washington).viii The ACT rule requires HDV manufacturers to sell ZEVs as increasing shares of their annual sales from 2024 to 2035. By 2035, ZEV sales would need to be 75 percent of Class 4–8 straight truck sales and 40 percent of tractor truck sales to meet these requirements.37 [EPA-HQ-OAR-2022-0985-1604-A1, p. 17]

viii Notably, more states have since adopted ACT rules for a total of nine states (California, Colorado, Maryland, Massachusetts, New York, New Jersey, Oregon, Vermont, and Washington).

37 "Advanced Clean Trucks Fact Sheet," California Air Resources Board, n.d., https://ww2.arb.ca.gov/resources/fact-sheets/advanced-cleantrucks-fact-sheet.

We found that the IRA will accelerate electrification in both the light-duty and heavy-duty sectors. For heavy-duty, we find a range of 39 to 48 percent ZEV sales share by 2030 and 44 to 52 percent by 2032. See Figure 11. [EPA-HQ-OAR-2022-0985-1604-A1, p. 17.] [See Figure 11, Projections of ZEV Sales for HDVs, on page 17 of docket number EPA-HQ-OAR-2022-0985-1604-A1.]

As shown in Figure 12, taken from the ICCT-EI Study, BEVs across different categories of HDVs make up increasing shares of new sales during the years that IRA incentives are available. When the IRA expires, some HDV classes will experience a drop in overall BEV shares of new sales, indicating the impact of the IRA on those vehicle markets. [EPA-HQ-OAR-2022-0985-1604-A1, pp. 17 - 18.] [See Figure 12, ZEV Shares of HDV by Category, on page 18 of docket number EPA-HQ-OAR-2022-0985-1604-A1.]

A primary takeaway from our analysis is that the IRA’s financial incentives for vehicles and manufacturers enable and support the adoption of more stringent federal vehicle standards at a lower cost and higher benefit to consumers.38 However, ZEV sales shares from our analysis are not guaranteed. Federal tailpipe standards are a critical tool that give truck manufacturers a clear mandate to retool their production lines to produce zero-emission trucks at scale. [EPA-HQ-OAR-2022-0985-1604-A1, p. 18]

38 Slowik et al., “Analyzing the Impact of the Inflation Reduction Act on Electric Vehicle Uptake in the United States.”

Another notable finding from our analysis is that new sales shares of BEVs exceed FCEVs by a wide margin for all vehicle classes, due to greater cost differentials for the vehicles (even with IRA incentives) and limited availability of hydrogen infrastructure, relative to electric charging infrastructure. While we support technology-neutral standards and believe they are most appropriate to ensure optimal flexibility, our analysis suggests that the economics and logistics of FCEVs may make BEVs the leading choice for compliance for the foreseeable future. [EPA-HQ-OAR-2022-0985-1604-A1, pp. 18 - 19]

We invite the EPA to rely on our analysis to support adopting a more stringent set of emission standards that would be based on higher ZEV adoption rates on a national level. Specifically, the EPA has requested input on several alternative proposals, including “values in between the proposed standards and those that would reflect ZEV adoption levels (i.e., percent of ZEVs in production volumes) used in California’s ACT, values that would reflect the level of ZEV adoption in the ACT program, and values beyond those that would reflect ZEV adoption levels in ACT such as the 50- to 60-percent ZEV adoption range”39 and “represented by the publicly stated goals of several major OEMs for 2030.”40 See Table II-35 below from the proposed rule. We believe any of these alternatives would be advantageous in terms of accelerating the adoption of ZEVs and spurring a faster transition to clean vehicles in the HDV sector. Alignment with California’s ACT (and the nine states that have adopted that rule) would help create greater market consistency across the country and ensure all states and communities can benefit from clean, non-polluting trucks on the road. Although the vehicle categories are different in the ICCT-EI Study (Figure 5) from those in Table ES-441 below, we note that the adoption rates from our analysis are generally aligned and the ACT adoption rates are also aligned with what is needed for climate stability. [EPA-HQ-OAR-2022-0985-1604-A1, p. 19. See Table ES-4 Aggregated Projected ZEV Adoption Rates (from the proposed rule), on page 19 of docket number EPA-HQ-OAR-2022-0985-1604-A1.]

Organization: Environmental Defense Fund (EDF)

These laws have also led to a significant decrease in upfront and lifetime ownership costs of EVs for consumers and fleets. An updated study by Roush Industries for EDF in May 2023 assessed and quantified, where possible, the key impacts of the IRA on the cost of electrifying medium- and heavy-duty vehicles that have access to overnight recharging at a central location (assessing the same vehicle classes from the earlier 2022 report, including Class 8 transit buses, Class 7 school buses, Class 3–7 shuttles and delivery vehicles, and Class 8 refuse haulers), using the previous study costs as a baseline.41 The analysis found that IRA credits help absorb the near-term higher upfront cost of battery electric vehicles (BEVs) and will accelerate the purchase parity with the segments analyzed. According to the research, all segments analyzed will now meet purchase price parity with their diesel counterparts if purchased as early as MY 2024, assuming reasonable economies of scale for BEV production. [EPA-HQ-OAR-2022-0985-1644-A1, p. 20-21]

41 H. Saxena, S. Pillai. 2023. Impact of the Inflation Reduction Act of 2022 on Medium- and Heavy- Duty Electrification on MYs 2024 and 2027, Roush for EDF (Attachment M).

The earlier cost projections by Roush in 2022 also showed that BEV operating costs are always lower than internal combustion engine vehicle (ICEV) operating costs.42 Because of this, the original analysis found that the time needed for a BEV to achieve total cost of ownership (TCO) parity with an ICEV could occur at the time of purchase in 2027 for a few of the segments analyzed and 1-4 years later for other segments. As shown in Table 3, the new IRA credits for BEVs and chargers will reduce the amount of time needed for BEVs to achieve TCO parity with ICEVs by an additional 1-2 years so that many segments analyzed will see TCO parity at the time of purchase as early as 2024. [EPA-HQ-OAR-2022-0985-1644-A1, p. 21] [See Table 3, p. 21 of Docket Number EPA-HQ-OAR-2022-0985-1644-A1]

42 Nair, V., Stone, S., Rogers, G., Pillai, S. 2022. Medium- and Heavy-duty Electrification Costs for MY 2027-2030, Roush for EDF.

As a result of the IRA, the purchaser of a BEV in MY 2024 could save an estimated $18,000 on a Class 3 delivery van and $500,000 on an urban transit bus over the life of the BEV compared to a comparable diesel vehicle (Figure 1). If we assume that diesel fuel prices return to the prices occurring during the summer of 2022 ($5.18/gallon versus $3.25/gallon the lifetime savings due to switching to a BEV would increase to $33,000 for a Class 3 delivery van and $700,000 for an urban transit bus.43 [EPA-HQ-OAR-2022-0985-1644-A1, p. 21-22] [See Figure 1, p. 21 of Docket Number EPA-HQ-OAR-2022-0985-1644-A1]

43 H. Saxena, S. Pillai. 2023. Impact of the Inflation Reduction Act of 2022 on Medium- and Heavy- Duty Electrification on MYs 2024 and 2027, Roush for EDF.

The IRA also includes tax credits and other incentives for several aspects of battery production. These IRA provisions could lead to lower-priced batteries and batteries with competitive prices where much of the manufacturing occurred in the U.S. and North America. [EPA-HQ-OAR-2022-0985-1644-A1, p. 22]

3. EPA’s ZEV adoption curve is overly conservative

Compounding the agency’s conservative cost assumptions, discussed above, several additional factors result in EPA’s modeled rate of ZEV adoption being overly conservative. First, EPA relies on an overly conservative estimation of the relationship between payback period and technology adoption percentage. Second, EPA artificially caps ZEV adoption at 80% even for vehicle types for which the upfront cost is lower for ZEVs than ICE vehicles. [EPA-HQ-OAR-2022-0985-1644-A1, p. 56]

One of the crucial elements in EPA's estimation of ZEV adoption in HD TRUCS is the relationship between payback period and adoption percentage. This equation has a first order impact on the stringency of the rule. In the DRIA, EPA identifies numerous studies that project the rate of zero-emission technology adoption in MHDVs. EPA surveyed this data though appear to have largely adopted a curve based on an ACT Research report.139 [EPA-HQ-OAR-2022-0985-1644-A1, p. 57]

139 Section 2.7.9 Technology Adoption in Greenhouse Gas Emission Standards for Heavy-Duty Vehicles: Phase 3 Draft Regulatory Impact Analysis

In addition, in their modeling, EPA caps adoption for any one of the 101 vehicle types at 80% even if the upfront cost of the ZEV is cheaper than the ICE vehicle. No other study, including the ACT Research equation included in the DRIA, makes such an assumption. EPA offers several rationales for the cap, including their choice to size the batteries to the 90th percentile of daily VMT, as well as the assumption that some uses or fleet owners may not be able to electrify their vehicles due to their need to operate the vehicles 24 hours per day or their inability to install EVSE.140 While it is a reasonable assumption, particularly in the first few years of increased HD ZEV adoption, that some vehicles would be less suited to electrification even with a short payback period, that impact should decrease as fleet owners become more familiar with the technology, business practices surrounding ZEVs become more robust, and a wider range of ZEV models become available. As such, we believe the imposed cap on ZEV adoption should lessen through the rule years and be substantially higher by 2032. [EPA-HQ-OAR-2022-0985-1644-A1, p. 57]

140 Ibid.

Additionally, an 80% cap in 2027 is too high. The same vehicles that need to operate 24 hours a day are presumably the ones with higher daily mileage. EPA provides no supporting evidence for the assumption that on top of the daily mileage concerns, there are an additional 10% of each vehicle type that could not be electrified in the next decade. [EPA-HQ-OAR-2022-0985-1644-A1, p. 57]

Central to establishing this relationship is an understanding of the impact of payback period on fleet owners' decisions to purchase vehicles with higher capital costs but lower operating costs such as many ZEVs. In their March 2022 study, NREL assumed the financial horizon for Class 3 vehicles is 3 years, Class 4-6 vehicles is 4 years, and Class 7-8 vehicles is 5 years.141 In a 2019 report by the National Academies of Sciences, Engineering, and Medicine, authors stated they "heard from manufacturers and purchasers that they look for 1.5- to 2-year paybacks or, in other cases, for a payback period that is half the expected ownership period of the first owner of the vehicle."142 With EPA's proposed rule, the assumed adoption of ZEVs drops from 80% if the payback period is less than 0 years to 55% if the payback period is between 0 and 1 years. In practice, this means that for vehicles with a payback period of one day only around half of vehicle purchasers would select the ZEV even though they would see savings starting on day 2 of the vehicle's life. This is inconsistent with the literature around financial horizons for vehicle owners. The adoption rate should remain high through at least a two-year payback period at which time a decline in adoption after that point would be more reasonable. [EPA-HQ-OAR-2022-0985-1644-A1, p. 57-58]

141 Muratori, Matteo et al. 2022. Decarbonizing Medium- and Heavy-Duty On-Road Vehicles: Zero-Emission Vehicles Cost Analysis, NREL Transforming Energy. https://www.nrel.gov/docs/fy22osti/82081.pdf.

142 National Academies of Sciences, Engineering, and Medicine 2019. Reducing Fuel Consumption and Greenhouse Gas Emissions of Medium- and Heavy-Duty Vehicles, Phase Two: Final Report. Washington, DC: The National Academies Press. https://doi.org/10.17226/25542. (Attachment V)

In both cases, studies stated one of the reasons vehicle owners might require shorter payback periods was uncertainty connected to the new technology. As a result, it should be expected that the adoption curve based on payback period EPA is utilizing will evolve between the beginning and end of the rule. [EPA-HQ-OAR-2022-0985-1644-A1, p. 58]

EDF acquired the inputs and results from a study on HD ZEV adoption conducted by NREL using their TEMPO model, referenced above, to create an alternative adoption curve based on payback period.143 144 Additional details about the methodology used to establish this curve are in Appendix BA.145 [EPA-HQ-OAR-2022-0985-1644-A1, p. 58-59]

143 Catherine Ledna et al. 2022. Decarbonizing Medium- and Heavy-Duty On-Road Vehicles: Zero-Emission Vehicles Cost Analysis, NREL Transforming Energy. https://www.nrel.gov/docs/fy22osti/82081.pdf

144 Matteo Muratori er al. 2021. Exploring the future energy-mobility nexus: The transportation energy & mobility pathway options (TEMPO) model. Transportation Research Part D, https://doi.org/10.1016/j.trd.2021.102967

145 The interpretation of the results and opinions stated are EDF's alone. EDF would like to thank NREL and Catherine Ledna for providing the underlying data and inputs.

Figure 10 shows the TEMPO data points, the curve based on the data, the two step-wise functions used by EPA in HD TRUCS, and the ACT Research curve from Equation 2-61 of the DRIA. The curve based on TEMPO data (the solid red curve) projects 100% adoption of ZEVs when the ZEV and ICE vehicle are the same price or the ZEV is cheaper (i.e., a payback period of less than 0 years). The ACT Research curve assumes only a 71% adoption of ZEVs when there is purchase price parity. While the adoption begins to decrease once there is a non-zero payback period, it declines at a slower rate than ACT Research's curve, particularly up to one year of payback. Analysis of the TEMPO model outputs indicates that the general shape of the ACT Research curve is reasonable but the adoption levels assumed for low payback periods is far too modest. Particularly for short payback periods (less than 2 years), this analysis shows that EPA is profoundly underestimating the resulting ZEV adoption. High adoption rates for technologies that start providing meaningful savings to vehicle owners after only a few years is also consistent with the available literature. [EPA-HQ-OAR-2022-0985-1644-A1, p. 59] [See Figure 10 on p. 60 of Docket Number EPA-HQ-OAR-2022-0985-1644-A1]

EPA must reassess their technology adoption curve and better align the values they are using to curves such as the TEMPO model based curve presented here that have strong scientific backing and better align with the existing literature on financial horizons of fleet owners. [EPA-HQ-OAR-2022-0985-1644-A1, p. 60]

Organization: International Council on Clean Transportation (ICCT)

FORECAST OF ZEV ADOPTION

EPA proposes to define the stringency of its greenhouse gas standard based on a projection of future zero-emission vehicle sales. While the approach in principle is sound, our analysis has identified several improvements that, if corrected, would increase the potential benefits of this rule. [EPA-HQ-OAR-2022-0985-1553-A1, p. 2]

EPA has selected a model of technology adoption rates that we do not support. Central to the EPA approach is a market forecast of zero-emission vehicle (ZEV) adoption based on Equation 2-61 of the Draft Regulatory Impact Assessment. This model of ZEV technology adoption rates is taken from a proprietary study prepared by ACT Research. We find EPA's selection of the ACT Research study to be arbitrary. Furthermore, the selection of this study presents significant obstacles to public comment. The study is not available in the public docket and is not available from the EPA Reading Room. The study is available today for purchase at a cost of $25,000. This approach is not consistent with traditional standards of transparency that we think are necessary for the agency to defend and support its rulemakings. [EPA-HQ-OAR-2022-0985-1553-A1, p. 2]

To provide meaningful comment on this aspect of the rule, ICCT purchased the ACT Research report. Due to licensing limitations, we cannot comment on the specifics of the report. Based on our thorough review, we conclude that the report contains no empirical basis for equation 2-61 and cannot be used as the basis for the standards EPA proposes. [EPA-HQ-OAR-2022-0985-1553-A1, p. 2]

We consulted with several other research groups cited by EPA as the source of alternative technology adoption curves. We conclude and recommend that EPA adopt the TEMPO model, developed by the National Renewable Energy Laboratory (NREL), as the basis for projecting ZEV technology adoption rates. This model overcomes key deficiencies of the ACT Research-based curve by being based on validated empirical data, subject to peer-review, and freely available to the public. [EPA-HQ-OAR-2022-0985-1553-A1, p. 2]

Adoption of the TEMPO model would change the stringency of the proposed rule. All else being equal, we find replacing the EPA curve with a TEMPO-based curve would project a 37% ZEV market share in model year 2027 and a 60% market share in model year 2032. These estimates reflect the average share across all vehicle categories. We conclude that the selection of the TEMPO model, or a similarly robust and transparent model, is necessary for EPA to not only maintain traditional standards of transparency necessary to defend and support its rulemaking but to also utilize the best available data to project zero-emission vehicle sales. As a co-benefit, the rule will ensure greater benefits to public health and welfare. [EPA-HQ-OAR-2022-0985-1553-A1, p. 2]

Another element of the proposal that deserves reconsideration is the treatment of state zero-emission vehicle sales requirements in setting the stringency of the proposed standards. California and at least eight other states (Oregon, Washington, New York, New Jersey, Massachusetts, Vermont, Colorado, and Maryland) to-date have adopted the Advanced Clean Trucks (ACT) regulation, which sets minimum zero-emission truck sales requirements that exceed the ZEV technology adoption rate of the proposal. The stringency of the proposed standards does not take into consideration these higher state-mandated sales of zero-emission vehicles, but the proposal would nevertheless allow manufacturers to use these higher ZEV sales to demonstrate compliance. This compliance approach deviates from the approach taken in the Phase 2 standards. [EPA-HQ-OAR-2022-0985-1553-A1, p. 2]

Treating ZEV sales in manufacturer compliance determinations differently than for standard setting as EPA has proposed will result in adverse impacts. The higher ZEV sales in the nine states could be used by manufacturers to reduce the sales volume of ZEVs in the other states to a level far less than EPA's current market projection, potentially impeding investment in ZEV fleets and infrastructure in non-ACT states. Another result could be the higher ZEV sales in the nine states could allow manufacturers to certify and sell ICE vehicles with higher CO2 emissions in the non-ACT states. Either outcome could result in fewer zero-emission vehicles and less efficient ICE vehicles deployed in non-ACT states, which would generate an inequitable distribution of benefits among states. [EPA-HQ-OAR-2022-0985-1553-A1, p. 3]

This inconsistency can be resolved in one of two ways. The first and simplest way is for EPA to retain the Phase 2 provision that would exclude vehicle sales in the ACT states when determining compliance with the EPA standards. The second way is for EPA, in determining the stringency of its greenhouse gas (GHG) standards, to proportionally weight the higher sales of ZEVs in the nine states with its revised market-based projection of sales in the other 41 states. As an example, we conclude that a national weighted average 2032 ZEV sales for Class 4–8 vehicles would be 33% using data given in Table 5 instead of 27% as projected in EPA's proposal. EPA would set a corresponding numerical lower average national GHG standard based on this weighted average. The adoption of one of these two approaches would ensure greater overall benefits and a greater distribution of benefits from the rule. [EPA-HQ-OAR-2022-0985-1553-A1, p. 3]

ZEV TECHNOLOGY ADOPTION RATE This section responds to EPA's request for comment on their approach to selecting technology adoption rates for battery electric and fuel-cell electric vehicles based on payback period. While we support the approach in principle, we have identified changes to the approach that we think would strengthen the rule. [EPA-HQ-OAR-2022-0985-1553-A1, p. 6]

First, the EPA's approach to estimating technology adoption rates can be improved by reducing its reliance on a proprietary study. In section 2.7.9 of the Draft Regulatory Impact Assessment, EPA cites the ACT Research report ChargeForward published in December 2021(Mitchell, 2023). This report is the source of equation 2-61, which reflects a relationship between the payback period and the technology adoption rates given in Table 2-72, and which produces an adoption rate schedule for model years 2027 and 2032 in HD TRUCS given in Table 2-73. EPA cites other studies, including studies by CALSTART, NREL, and ICCT, but in our view chooses to arbitrarily rely exclusively on the ACT Research study to produce Table 2-73. [EPA-HQ-OAR-2022-0985-1553-A1, p. 6]

Mitchell, G. (2023, April 7). ACT Research: "Charging Forward: 2020-2040 BEV & FCEV Forecast & Analysis: Commercial Electric and Fuel Cell Vehicle Multi-Client Study" [Memorandum]. https://www.regulations.gov/document/EPA-HQ-OAR-2022-0985-0931

In light of the sensitivity of the EPA proposal to equation 2-61, ICCT sought to understand the empirical basis of this formula by securing a copy of the study. The ACT Research

ChargeForward report is not licensed for publication and is not available in the public docket or in the EPA reading room (Mitchell, 2023). An ACT Research website lists the price of the full North America version of the report at $25,000.2 This circumstance does not meet traditional standards of transparency and public access that have historically been necessary to justify EPA rulemakings. [EPA-HQ-OAR-2022-0985-1553-A1, p. 6]

2 https://www.actresearch.net/consulting/special-projects/commercial-vehicle-decarbonization-forecastreports

Mitchell, G. (2023, April 7). ACT Research: "Charging Forward: 2020-2040 BEV & FCEV Forecast & Analysis: Commercial Electric and Fuel Cell Vehicle Multi-Client Study" [Memorandum]. https://www.regulations.gov/document/EPA-HQ-OAR-2022-0985-0931 T

In order to provide comment on the empirical basis and technical underpinning of Equation 2-61, ICCT purchased the report from ACT Research. In purchasing the report, ICCT accepted a licensing agreement that restricts its ability to distribute or reproduce the report or selected data outside of the organization under any circumstance. For the purposes of these comments, we are limiting ourselves to generalizations of what we find in the report in order to honor the licensing agreement with ACT Research. [EPA-HQ-OAR-2022-0985-1553-A1, p. 6]

We conclude that the ACT Research report provides no data or any other empirical basis to support Equation 2-61. The equation is contained in a total-cost-of-ownership model provided with the report. This equation generates a projected share of ZEV sales in each calendar year that is applied equally across twelve vehicle categories selected to represent class 4-8 vehicles. The report is 200 pages in length and contains a one-paragraph description of the equation. This paragraph contains no citations, data or analysis. The paragraph points to the experience of the authors as the source of the equation. [EPA-HQ-OAR-2022-0985-1553-A1, p. 6]

Considering how fundamental this equation is to the stringency of the rule, we find its justification to be wholly inadequate, out of step with traditional standards of scientific rigor, and not representative of the deep technical research and scientific knowledge we know is available to support this rule. We do not support this equation as the basis for defining technology adoption rates. We are very concerned about the viability of the rule without a change in approach. [EPA-HQ-OAR-2022-0985-1553-A1, p. 6]

Furthermore, EPA claims that the considered technology adoption curve follows an S-shape curve. While ICCT takes no issue with the shape of the curve, we disagree with the decision to convert a smooth scurve into a step curve, where a discrete single value of adoption rate is assigned to a bin of payback periods. A step curve is not conceptually consistent with technology diffusion and should be revised. ICCT examined the impact of converting the s-curve into a step curve on the total ZEV adoption rate and found the s-curve shows a 7% higher total ZEV adoption rate by 2032. ICCT recommends using a smooth s-curve to represent technology adoption rates. [EPA-HQ-OAR-2022-0985-1553-A1, pp. 6-7]

Moreover, EPA has modified the ACT research technology adoption curve to a seemingly arbitrary maximum adoption rate of 80%, a value below what we find in the ACT Research report. To justify this cap, EPA assumes that not all truck owners and fleets will have the financial and technical capacity to install and access chargers at their convenience. The proposal does not present an analysis of infrastructure needs to support this assumption. ICCT supports a 90% cap, which aligns with the assumption EPA makes that the energy storage system of the vehicle is sized to meet the 90th percentile of the truck's daily mileage. ICCT finds this assumption reasonable and a more appropriate basis for the cap. To support this point and respond to EPA's request for comment on infrastructure availability, we discuss trucks' infrastructure needs and the progress in fulfilling them in other sections of these comments. [EPA-HQ-OAR-2022-0985-1553-A1, p. 7]

Our view is the EPA rule can be strengthened through the adoption of an alternative technology adoption curve derived from empirical data, free to access, and open to public scrutiny. We propose EPA select a technology adoption curve which we refer to here as the TEMPO curve. The curve was derived by the Environmental Defense Fund (EDF) from the Transportation Energy & Mobility Pathway Options (TEMPO) Model (Muratori et al., 2021) and shared with the ICCT.3 The curve is capped at 90%, in line with our recommendation. The EPA curve, TEMPO curve, and combined EPA and TEMPO curves are presented in Figure 2 and tabulated in the appendix in Table A. 1. [EPA-HQ-OAR-2022-0985-1553-A1, p. 7] [Refer to Figure 2, Summary of the different Technology Adoption Curves, on p. 7, and Appendix Table A.1., Technology Adoption Curves Data, on p. 27 of docket number EPA-HQ-OAR-2022-0985-1553-A1]

Muratori, M., Jadun, P., Bush, B., Hoehne, C., Vimmerstedt, L., Yip, A., Gonder, J., Winkler, E., Gearhart, C., & Arent, D. (2021). Exploring the future energy-mobility nexus: The transportation energy & mobility pathway options (TEMPO) model. Transportation Research Part D: Transport and Environment, 98, 102967. https://doi.org/10.1016/j.trd.2021.102967

EPA has applied a faster adoption rate in comparison to the ACT research rates for the high payback periods bins due to the impact of the proposed regulation. ICCT supports this assumption. The proposed TEMPO curve doesn't take into account the impact of the proposed regulation on technology adoption. We develop another variant of the TEMPO curve considering EPA's adoption rates for payback periods above 6 years in 2027, and above 4 years in 2032. [EPA-HQ-OAR-2022-0985-1553-A1, pp. 7-8]

We then examined the impact of the three different technology adoption curves on the total ZEV adoption rates: (1) EPA rates schedule, (2) TEMPO curve, and (3) TEMPO curve modified to include the impact of the proposed regulation (TEMPO+EPA). The total ZEV adoption rates are presented in Figure 3 for different technology adoption curves. The total ZEV adoption rate in 2027 is more than doubled when using the TEMPO curve, reaching 37%. In 2032, the total ZEV adoption rate reaches 60% under the TEMPO s-curve versus 46% under EPA's curve. In addition, when considering the impact of the proposed regulation on the technology adoption for the TEMPO curve (TEMPO + EPA), higher adoption rates are obtained, reaching 66% in 2032. [EPA-HQ-OAR-2022-0985-1553-A1, p. 8] [Refer to Figure 3, Total ZEV Adoption, on p. 8 of docket number EPA-HQ-OAR-2022-0985-1553-A1]

Based on the analysis presented in this section, ICCT recommends that EPA consider different technology adoption rates than the ones presented in Table 2-73 in the draft regulatory impact analysis and consider technology adoption curves that are derived from empirical data and follow a smooth s-curve such as the ones proposed by ICCT in this section (TEMPO and TEMPO+EPA curves). [EPA-HQ-OAR-2022-0985-1553-A1, p. 8]

SENSITIVITY OF ZEV ADOPTION RATES OF VOCATIONAL VEHICLES TO LEVEL 2 CHARGING ASSUMPTIONS EPA assumes that each Level 2 charging station (AC charging up to 19.2 kW in this context) will not be shared by more than one truck. EPA explicitly states that this is a conservative assumption. Level 2 charging is considered the main charging technology for step vans, box trucks, shuttle and school buses, and utility trucks. Given the long dwell times of these vehicles and their relatively smaller battery sizes, it is technically possible to share charging ports between at least two trucks, and fleets will take advantage of port sharing among several trucks to reduce their capital investment. ICCT modified this assumption in the HD TRUCS model to investigate the impact on the payback period and adoption rates. The total ZEV adoption rate of vocational vehicles increased by 6% in 2027 and 4% in 2032 under this new assumption. [EPA-HQ-OAR-2022-0985-1553-A1, p. 8]

BENEFITS OF A RULE REFLECTING ICCT PROJECTIONS OF TECHNOLOGY FEASIBILITY, COST AND COMPLIANCE

The ICCT estimated the benefits of EPA's proposed ZEV uptake proposal and compared it against three more ambitious scenarios. In total, the four scenarios modeled were:

- EPA proposal: This assumes EPA's projected ZEV uptake for different classes of heavy-duty vehicles and no additional ICE technology improvement beyond the requirements to meet Phase 2 standards.
- EPA proposal + Cost-effective ICE technology improvements: This scenario combines EPA's projected ZEV uptake with ICE technology improvement outlined in Table 4 of this document.
- EPA proposal + Cost-effective ICE technology improvements + ICCT projected ZEV market growth including state ACT adoption: This scenario has more aggressive ZEV uptake until 2032 compared to EPA proposal in vehicle segments such as refuse trucks, Class 4-7 single unit short haul trucks, and Class 4-7 single unit long-haul trucks. This scenario considers market conditions in combination with state ACT rule adoption and federal subsidies under the Inflation Reduction Act (Slowik et al., 2023) This means that there is further increase in ZEV adoption beyond 2032, leading to 66% of the new HDV sales being ZEVs by 2045. The ICE technology improvements are carried over from the previous scenario.
- National ACT aligned ZEV pathway + Cost effective ICE improvements +100% ZEV sales in 2040: This scenario assumes every state adopts California's ACT, i.e. 100% new HDV sales being ZEVs by 2040 (Ragon, Buysse, et al., 2023). This scenario also aligns with the Global HDV MoU (Drive to Zero, 2021) that the United States is a signatory to. The ICE technology improvements are carried over from the previous scenario. [EPA-HQ-OAR-2022-0985-1553-A1, p. 19]

Drive to Zero. (2021). Global Memorandum of Understanding on Zero-emission Medium- and Heavy-duty Vehicles. https://globaldrivetozero.org/mou-nations/

In 2032, the ZEV market growth scenario projects a 46% ZEV sales share of Class 4-8 HDVs, compared to 27% estimated by EPA's proposal. (See Table 5.) The National ACT scenario's

ZEV sales share is almost double that of EPA's projection in 2032, at 53%. [EPA-HQ-OAR-2022-0985-1553-A1, p. 19] [Refer to Table 5, ZEV Sales Shares for Class 4-8, on p. 20 of docket number EPA-HQ-OAR-2022-0985-1553-A1]

EPA's proposal is estimated to reduce tank-to-wheel (TTW) CO2 emissions 9% compared to 2019 levels by 2032 and 20% by 2050. EPA's proposal combined with cost effective ICE technology improvements results in an 11% TTW CO2 emission reduction compared to 2019 by 2032 and a reduction of 28% by 2050. The EPA proposal and ICE improvements combined with additional ZEV market growth potential projected by ICCT in previously published work leads to a 19% TTW CO2 emission reduction compared to 2019 by 2032 and a reduction of 48% by 2050. A final scenario aligned with a National ACT schedule would deliver a 21% TTW CO2 emission reduction compared to 2019 by 2032. The addition of a 100% zero-emission sales milestone to this scenario by 2040 would deliver a reduction of 91% by 2050. [EPA-HQ-OAR-2022-0985-1553-A1, p. 20]

In terms of cumulative emissions reductions between 2023 and 2050 compared to the EPA proposal, the addition of cost-effective ICE technology improvements alone reduces cumulative TTW CO2 emissions by 537 million tonnes. A scenario that includes these additional ICE efficiency improvements and additional ZEV sales in line with previously published ICCT projections would deliver a reduction of over 1.8 billion tonnes compared to the EPA proposal. And a scenario that reflects a National ACT schedule plus a 100% zero-emission sales milestone in 2040 would deliver a reduction of over 3.8 billion tonnes. [EPA-HQ-OAR-2022-0985-1553-A1, p. 21] [Refer to Figures 5 on p. 21 and 6 on p. 22 of docket number EPA-HQ-OAR-2022-0985-1553-A1]

Organization: Moving Forward Network (MFN) et al.

The IRA included a first-ever federal purchase incentive for ZE MHDVs, which helps to bridge the cost gap between ZEV and ICE models in many cases today. A recent study by ICCT examined the impact of IRA funding on the MHDV market. 155 The study found that, even before IRA incentives, ZE models are approaching upfront purchase price parity. By 2030, battery-electric Class 4-7 rigid trucks, refuse trucks, and transit buses will have favorable sticker prices, according to the study. When considering IRA incentives, this list grows substantially (see Table 6). [EPA-HQ-OAR-2022-0985-1608-A1, p. 75.] [See Table 6, Year of Retail Price Preference for HD BEV vs. ICE with IRA Qualified Commercial Clean Vehicles Tax Credit located on p. 76 of docket number EPA-HQ-OAR-2022-0985-1608-A1.]

155 Slowik, P. et al. Analyzing the Impact of the Inflation Reduction Act on Electric Vehicle Update in the United States. The International Council on Clean Transportation. (January 2023). https://theicct.org/publication/ira-impact-evs-us-jan23/

156 Id.

Total cost is perhaps even more relevant when considering MHDVs, given that they are crucial capital assets to businesses and must provide a meaningful return on investment. Due in large part to the significant fuel and maintenance savings offered by ZEVs, many studies estimate a total-cost preference for ZEVs over ICE models in the coming years, if not today (See Table 7). Notably, much of the literature on ZE MHDV total cost was published pre-IRA, meaning that lifetime cost parity would be reached sooner in many cases. However, post-IRA studies on total cost are emerging. One from ICCT examined the total cost of ownership of various propulsion technologies for long-haul Class 8 tractor trucks in seven key freight states: Georgia, California, Florida, Illinois, New York, Texas, and Washington. The study estimated that battery-electric long-haul Class 8 tractors would have a preferred total cost of ownership before 2030 in each of these states, and in Texas as soon as 2027. 157 The most recent BloombergNEF Electric Vehicle Outlook corroborated ICCT's results, finding that all classes of ZE MHDVs – even long-haul tractors – would have a preferred total cost of ownership in the U.S. by 2030. 158 Our analysis on incremental savings to fleets in Section 8.8 of this letter further confirms these findings. [EPA-HQ-OAR-2022-0985-1608-A1, pp. 76 - 77.] [See Table 7, Earliest TCO Advantage for BEV Trucks over Fossil-fueled Trucks located on p. 77 of docket number EPA-HQ-OAR-2022-0985-1608-A1.]

Other clean air regulators are taking note of this. In April 2023, CARB adopted the Advanced Clean Fleet rule, which will require the largest truck fleets operating in California to begin transitioning to ZE MHDVs in 2024. This rule is anticipated to save California commercial fleets nearly $48 billion through 2050. 163 [EPA-HQ-OAR-2022-0985-1608-A1, pp. 77 - 78]

163 California Air Resources Board. Appendix B: Updated Costs and Benefits Analysis. (2023). https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2022/acf22/acf15db.pdf

Although aspects of both upfront cost and total cost of ownership were considered in the proposal, we find it particularly arbitrary that the ZEV Adoption Rates in no way reflects recent economic projections in the literature. 164 For example, while battery-electric refuse haulers have both preferred upfront and total costs today, the current proposal would only affect a 36 percent market-wide ZEV adoption rate in 2032 – nearly a decade after purchase price parity. The same is true across the board for this proposal. EPA anticipates that the ZEV adoption rate under the proposal for daycab tractors, a truck type that bears significant responsibility for pollution in port- and warehouse-adjacent communities, would be merely 12 percent the year they are expected to reach purchase price parity. [EPA-HQ-OAR-2022-0985-1608-A1, p. 78]

164 U.S. EPA. Proposed Rule: Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles – Phase 3. (2023). p. 210 https://www.epa.gov/regulations-emissions-vehicles-and-engines/proposed-rule-greenhouse-gas-emissions-standards-heavy

When faced with the overwhelming economic upsides for ZE MHDVs, opponents of clean trucks often suggest that long-haul electric trucks will either have penalized revenue or increased fleetwide VMT due to payload capacity loss from battery weight. These arguments, however, are undercut by recent studies showing that advancements in battery efficiency and density will close the payload capacity gap in the coming years. 165 [EPA-HQ-OAR-2022-0985-1608-A1, p. 78]

165 Ricardo Strategic Consulting. E-Truck Virtual Teardown. Prepared for The International Council on Clean Transportation. (June 2022). https://theicct.org/wp-content/uploads/2022/01/Final-Report-eTruck-Virtual-Teardown-Public-Version.pdf

Lastly, as EPA notes, there are several tax credits from the Inflation Reduction Act (including the §48C Advanced Manufacturing and the §45X Advanced Manufacturing Production tax credits) available to battery manufacturers that will reduce costs below what is represented in EPA's and our own analyses. [EPA-HQ-OAR-2022-0985-1608-A1, p. 104]

Organization: National Automobile Dealers Association (NADA)

C. EPA's assessment of upfront HDV costs and payback is incomplete and inaccurate.

After accounting for the IRC Section 45W HDV tax credits provided for in the Inflation Reduction Act (IRA), EPA estimates that the typical buyer of a new HDV ZEV would:

- Pay an average of between $900 and $11,000 more in upfront costs for a MY 2032 vocational ZEV HDV than for a comparable ICE HDV but would recoup those costs in 3 years or less through yearly operational savings.
- Pay an average of $17,000 more in upfront costs for a MY 2032 day-cab tractor ZEV HDV than for a comparable ICE HDV and would recoup these costs in 3 years or less though yearly operational savings.
- Pay an average of $15,000 more in upfront costs for a MY 2032 sleeper cab tractor ZEV HDV than for a comparable ICE HDV but would recoup these costs in 7 years or less though yearly operational savings. [EPA-HQ-OAR-2022-0985-1592-A1, p. 6]

These estimates were built using HD TRUCS. To develop HD TRUCS, EPA relied on literature to determine the cost of components and technology packages, and then applied TCO calculations and other data assumptions. EPA then used HD TRUCS to perform payback period calculations to determine the number of years it will take for the TCO of a ZEV HDV to be equal to that of a comparable ICE HDV. While HD TRUCS is a strong tool for the assessment of ZEV technologies in the marketplace, ATD submits that there are several aspects of HD TRUCS and the underlying data or assumptions that are incomplete and inaccurate. EPA must rectify these issues finalizing its Phase 3 GHG mandates to ensure that forecasted payback periods and adoption rates reflect reality. [EPA-HQ-OAR-2022-0985-1592-A1, p. 6]

ATD defers to the comments submitted by the Truck and Engine Manufacturers Association (EMA) and its members regarding HDV and technology package pricing and feasible timelines. Today, new ZEV HDV sales prices are approximately 3-5 times that of comparable ICE HDV prices, before any tax incentives or grants. Industry studies that align with this observation report that the cost of a 450-kWh ZEV HDV battery would be between $144,000 and $243,000 before taxes and fees, which pushes the base price of a Class 8 BEV tractor to $350,000 to $500,000 or three to five times the price of a new diesel HDV.11 While it is projected that battery prices may come down over time, it makes no sense to suggest that the prices of new ZEV HDVs will average a mere 10-20% above the price of new ICE HDVs in 2032. [EPA-HQ-OAR-2022-0985-1592-A1, pp. 6 - 7]

11 Sustainable Fleets 2023: The Road from Diesel to ZEVs, HEAVY DUTY TRUCKING, (May 22, 2023); See also, Claire Buysse, How Much Does An Electric Semi Really Cost?, ICCT (Feb. 24, 2022).

Organization: RMI

Overall, the total cost of ownership (TCO) for electric vehicle ownership is less than that of diesel vehicle ownership. Electric drivetrains, the vehicle components that connect the engine to the wheels, are simpler than diesel drivetrains. These simpler mechanics result in significant reductions in maintenance costs. Additionally, electric vehicles are more energy-efficient than their diesel counterparts. Coupled with the price of electricity, EVs benefit from dramatic reductions in fueling costs. [EPA-HQ-OAR-2022-0985-1529-A1, p. 6]

IRA credits can dramatically shift the TCO parity for heavy-duty (HD) ZETs: for the long-haul segment, parity is expected in 2027, but not until 2038 without the credits. For urban and regional segments, the IRA credits enable the TCO for HD ZETs to be lower than that of HD diesel trucks today. Without the credits, the TCO parity would occur between 2026 and 2028.13 [EPA-HQ-OAR-2022-0985-1529-A1, p. 6] [Refer to Figure on p. 6 of docket number EPA-HQ-OAR-2022-0985-1529-A1]

13 Marie McNamara et al., How Policy Actions Can Spur EV Adoption in the United States, RMI, 2023, https://rmi.org/insight/how-policy-actions-can-spur-ev-adoption-in-the-united-states/.

The overall sales penetration of HD ZETs is projected to reach 59% without IRA credits and 78% with IRA credits. This penetration translates to an additional cumulative sales of 428,216 HD ZETs between 2022 and 2032.15 [EPA-HQ-OAR-2022-0985-1529-A1, p. 6] [Refer to Figure on p. 7 of docket number EPA-HQ-OAR-2022-0985-1529-A1]

15 Marie McNamara et al., How Policy Actions Can Spur EV Adoption in the United States, RMI, 2023, https://rmi.org/insight/how-policy-actions-can-spur-ev-adoption-in-the-united-states/.

Economic modeling of IRA incentives by both RMI and the International Council on Clean Transportation have projected that battery electric vehicles will reach cost parity with internal combustion engine vehicles within the next few years for most HDT duty cycles. If vehicle costs come down as expected and fleets can both procure and charge their vehicles, electric trucks could be 50% of sales in many locations by 2030.17 [EPA-HQ-OAR-2022-0985-1529-A1, p. 7]

17 Peter Slowik, et al., Analyzing the Impact of the Inflation Reduction Act on Electric Vehicle Uptake in the United States, The International Council on Clean Transportation, 2023, https://theicct.org/wp-content/uploads/2023/01/ira-impact-evs-us-jan23.pdf.

A fleet's purchase decision can be based on environmental commitments, fueling access, financial resources, and operating requirements, but for most fleets, cost is the driving concern; once electric trucks make the most economic sense for fleets, they increasingly adopt them. By getting to cost parity sooner, the IRA jumpstarts a virtuous cycle. Fleets start adding charging to their depots and look for e-trucks that meet their operational needs. Truck manufacturers and charger manufacturers respond to this demand with new and better products further improving electric truck costs and operational viability, driving even more adoption. Because of this, RMI projects that the IRA will lead to far greater electric truck sales, market constraints such as grid electricity supply, e-truck availability, and the time it takes to introduce new vehicle models.18 [EPA-HQ-OAR-2022-0985-1529-A1, p. 7]

18 Kahn et Al, The Inflation Reduction Act Will Help Electrify Heavy-Duty Trucking, RMI, 2022, https://rmi.org/inflation-reduction-act-will-help-electrify-heavy-duty-trucking/

Organization: State of California et al. (2)

1. Evidence Suggests Robust Zero-Emission Vehicle Adoption Rates in the Heavy-Duty Sector

Heavy-duty electrification technologies already exist today, and sales of these electric vehicles are expected to grow significantly in the coming years due to municipal, state, and national policies, manufacturer commitments, and growing industry demand. [EPA-HQ-OAR-2022-0985-1588-A1, p.20]

As of 2019, when the California Air Resources Board ("CARB") promulgated its Advanced Clean Trucks ("ACT") regulations, discussed in more detail below, nearly one hundred models of zero-emission trucks and buses were commercially available in California, with many more projected to be added to the market in the near future.147 As of 2022, the number of models available in the United States was closer to 200 and that number continues to grow.148 Original equipment manufacturers have made robust projections about the future of ZEVs in this sector. These manufacturers project that between 50 to 70 percent of their heavy-duty truck sales will be ZEVs by 2030 and 100 percent by 2040:

- Navistar's executives expect 50 percent heavy-duty ZEV sales by 2030 and 100 percent electric vehicle ("EV") or fossil free by 2040;149
- Daimler Truck has stated ZEVs will make up 60 percent of its sales by 2030 and 100 percent of sales by 2040;150
- Volvo Trucks set a global target of 50 percent of all new trucks sales to be battery or fuel cell electric in 2030, and 100 percent by 2040;151 and
- PACCAR predicts electric vehicle production in the U.S. will ramp up exponentially in the coming years to 100 percent by 2040.152 [EPA-HQ-OAR-2022-0985-1588-A1, pp.20-21]

And businesses that purchase heavy-duty vehicles are creating a robust demand for these vehicles—with many major companies making significant commitments in recent years towards electrifying their heavy-duty fleets. Some examples include:

- Walmart has committed to a 100 percent zero-emission vehicle fleet globally, including long-haul trucks, by 2040;153
- Amazon has pledged that half of its deliveries globally will be carbon neutral by 2030,154 and has purchased 100,000 battery-electric delivery vans with an eye towards that goal;155
- DHL Group has committed to a 60 percent electric last-mile delivery fleet by 2030 globally;156
- FedEx has projected that battery-powered vehicles will make up half of all of its van purchases by 2025, and 100 percent by 2030;157
- Ingka Group (parent company of Ikea) has committed to 100 percent zero-emission customer deliveries and services by 2025 globally;158
- PepsiCo has committed to reducing its direct emissions by 75 percent by 2030, which includes a wide-scale rollout of electric vehicles for its vehicle fleet;159 towards this goal, FritoLay (a division of PepsiCo) announced it will deploy over 700 electric delivery vehicles in the United States by the end of 2023;160
- Sysco Co. committed to electrify 35 percent of its fleet by 2030, and signed a letter of intent in 2022 to deploy up to nearly 800 battery electric Class 8 tractors by 2026;161
- And a significant number of companies, including Bayer, Biogen, ClifBar, DeLoitte, Genentech, GlaxoSmithKline, HP Inc., Lyft, and Siemens have joined the EV100 coalition, whereby they commit to fully electrify their fleets by 2030.162 [EPA-HQ-OAR-2022-0985-1588-A1, pp.21-22]

In April 2023, EPA issued a Notice of Decision granting CARB's requested waivers of preemption under Section 209 of the CAA for several regulations governing heavy-duty vehicles in California, including the ACT regulations.164 The ACT regulations aim to accelerate the widespread adoption of ZEVs in the medium- and heavy-duty vehicle sector,165 and, to that end, set manufacturer ZEV sales requirements for vehicles with a gross vehicle weight rating ("GVWR") greater than 8,500 pounds, commonly referred to as medium- and heavy-duty vehicles.166 ACT specifies that by 2035, zero-emission truck/chassis sales would need to be 55 percent of Class 2b – 3 truck sales, 75 percent of Class 4 – 8 straight truck sales, and 40 percent of truck tractor sales. California also received a waiver for its Zero Emission Airport Shuttle (ZEAS) regulation, which will accelerate the adoption of ZEV technology in California airport shuttles.167 Under the ZEAS regulation, by December 31, 2027, at least 33 percent of each regulated airport shuttle fleet must be ZEVs.168 By December 31, 2031, the requirement goes up to 66 percent, and by December 31, 2035, 100 percent of each fleet must be ZEVs.169 [EPA-HQ-OAR-2022-0985-1588-A1, p.23]

164 88 Fed. Reg. 20,688 (April 6, 2023) (granting waivers of preemption under CAA Section 209 for California's Heavy-Duty Vehicle and Engine Emission Warranty Regulations and Maintenance Provisions, the Advanced Clean Trucks Regulation, the Zero Emission Airport Shuttle Regulation, and the Zero-Emission Power Train Certification Regulation).

165 ACT ISOR at ES-1, V-1.

166 The requirements specify percentages of ZEVs and near-zero emission vehicles (NZEVs). CARB Waiver Request Support Document for ACT, ZEAS, and ZEP Regulations (Dec. 20, 2021) at 2 & n.2 ("Waiver Request for ACT") (EPA-HQ-OAR-2022-0331-0003). ACT ISOR at ES-3, ES-4; Cal. Code Regs., tit. 13, §§ 1963, et sec. The ACT regulation implements the ZEV sales requirement through a "credit and deficit system," which allows manufacturers to "determine the vehicle types that are most cost effective for them to produce and to serve the [vehicle category] markets they choose and to make adjustments as the market expands." Manufacturers can generate a "ZEV credit" by "producing and selling a ZEV into California." Starting with the 2024 model year, truck manufacturers subject to the ACT regulation will "annually incur deficits based on the manufacturer's annual sales volume of on-road vehicles produced and delivered for sale in California." The deficits increase incrementally each year from model year 2024 (with required ZEV sales percentages ranging from 5% to 9% depending on weight class) to model years 2035 and beyond (ranging from 40% to 75%). For each model year, manufacturers must comply by retiring credits to offset their deficits. The ACT regulation also allows manufacturers to "bank" and trade credits. Manufacturers are subject to civil penalties if they fail to "retire an appropriate amount of ZEV . . . credits" and then fail to "make up those deficits" by the end of the next model year.

167 ZEAS ISOR at ES-1.

Recent incentive programs and commitments made at the federal level further underscore the changing landscape for ZEVs in the heavy-duty sector since EPA finalized the Phase 2 GHG Standards. The International Council on Clean Transportation projects the Inflation Reduction Act ("IRA") alone will cause HD ZEV sales to increase significantly, from 10 percent sales for the business-as-usual case to roughly 25 percent of sales in 2030 with the IRA in place.196 In November 2022 the Biden Administration added the United States as a signatory to the Global Memorandum of Understanding on Zero-Emission Medium- and Heavy-Duty Vehicles, which commits the United States to a goal of 100 percent zero-emission truck and bus sales by 2040, with an interim goal of 30 percent new sales by 2030,197 commitments that the federal government confirmed in its Blueprint for Transportation Decarbonization.198 [EPA-HQ-OAR-2022-0985-1588-A1, p.27]

Organization: Truck and Engine Manufacturers Association (EMA)

ACTResearch's Payback-based Adoption Function

In the DRIA Section 2.7.9 "Technology Adoption", the EPA references its use of ACTR's technology agnostic zero-emission vehicle (ZEV) adoption function based on payback period. ACTR's payback-based adoption function is one-half of what ACTR uses to calculate the financially driven adoption rates of ZEVs. We also use a TCO savings-based adoption formula (described more fully in a later section). Each factor, payback and TCO savings, is equally weighted in its contribution towards our final ZEV adoption rate. First, it should be noted that the EPA has now redacted the ACTR's payback-based adoption function and the corresponding binned adoption rate table from the DRIA upon ACTR's request as the specific formula is ACTR's copyrighted proprietary information. However, since EMA viewed the formula before the EPA updated the DRIA, we will discuss the exact equation here. [EPA-HQ-OAR-2022-0985-2668-A3, p. 3]

[FORMULA REDACTED]

ACTR's payback-based adoption formula was correctly written in the DRIA. We think of adoption in terms of "steps". The first step is essentially the minimum threshold, which in our modeling is 10 years. This means that adoption share points are only granted when the payback period is under 10 years. The way the formula above can be understood is as follows1:

- Step 1: The threshold. If under the 10-year threshold, "A" share point is awarded for every year under 10.

- Step 2: An additional “B” points are awarded for every year under seven years.
- Step 3: An additional “C” points are awarded for every year under four years.
- Step 4: An additional “D” points are awarded for every year under two years.
- Step 5: An additional “E” points are awarded for every year under one year. [EPA-HQ-OAR-2022-0985-2668-A3, p. 3]

1 Formula described with the exact share point values omitted and instead substituting “A, B, C, D, E”.

For example, if the payback period is 1.5 years, the payback-based adoption share points would be 32% (FORMULA REDACTED). Our payback period only starts to grant 100% adoption based on payback when the net manufacturing and infrastructure cost is less than the net operating cost. In other words, with respect to payback criteria, we apply 100% adoption when payback is immediate and there is upfront price parity. [EPA-HQ-OAR-2022-0985-2668-A3, p. 3]

EPA’s Use of ACTR’s Payback-based Adoption Function

The EPA uses ACTR’s payback-based adoption function with some modifications as described below.

The EPA imposes a maximum ZEV adoption rate of 80 percent for any given vehicle application. The EPA’s basis for this rate cap is that its HDTRUCS model is based on its use of the 90th percentile of average VMT data to size batteries and needs for each of its vehicle types. In this way, EPA is acknowledging that the assumptions in its model are not applicable to 100 percent of applications due to the myriad of operating characteristics that exists. EPA also notes that its 80 percent cap recognizes that some owners will have a hard time installing necessary on-site charging infrastructure. ACTR doesn’t take issue with the EPA placing the 80 percent cap on its adoption rates in this scenario. Typically, ACTR is supportive of applying measured, conservative assumptions when assessing adoption rates or new technologies, particularly when the expected benefits are based on assumed improvements over an extended timeframe. [EPA-HQ-OAR-2022-0985-2668-A3, p. 4]

On the other hand, the EPA also applies a faster adoption rate compared to ACTR’s methodology for payback periods greater than four years “due to the assumed impact of this proposed regulation and the additional 80 percent constraint” (DRIA p. 232). While the 80 percent cap on payback-based adoption rates makes sense to ACTR and shows an effort to factor in real-world variability, the decision to increase adoption rates for payback periods over four years is certainly a less conservative approach and would minimize the effects of the 80% cap. ACTR does not impose an assumed maximum ZEV adoption target when we perform our TCO analysis and ZEV forecasting. [EPA-HQ-OAR-2022-0985-2668-A3, p. 4]

The result of the EPA’s decision to increase adoption rates for payback periods of over four years means that EPA is expecting higher payback-based adoption rates for those payback years than ACTR would forecast. The specific ways in which the EPA increased adoption rates for payback periods greater than four years, as compared to ACTR, are further described below. [EPA-HQ-OAR-2022-0985-2668-A3, p. 4]

ACTR's payback-based adoption formula does not account for any amount of payback-based adoption if the payback period is 10 years or greater. Not only has the EPA increased its payback-based adoption rates for years 5-10, it has also added in additional bins for 10–15-year payback period and >15-year payback period (which indicates that the EPA has modified ACTR's formula to include additional steps). In ACTR's payback and TCO modeling, the useful life of our various vehicle applications ranges from 12-20 years – 12 years for higher mileage applications such as long-haul truck load and 20 years for lower mileage applications like school bus. Commercial vehicles are not typically held by one owner over their useful life and often change owners multiple times. Payback is an important factor in the decision to purchase a vehicle, and the aim for the original owner is typically to recover payback before or when reselling it. [EPA-HQ-OAR-2022-0985-2668-A3, p. 4]

While ACTR concedes that our first payback step for payback period below 10 years will not fit that criterion for every application, we make sure that the first step at 10 years is, at the very least, not longer than the assumed useful life of any of our commercial vehicle applications. In our experience, granting any shares of adoption based on payback periods that are longer than 10 years is not prudent, based on the inherent risk of adopting new technology for first purchasers. ACTR disagrees with the EPA's methodology in this regard. [EPA-HQ-OAR-2022-0985-2668-A3, pp. 4-5]

The table below compares ACTR's binned adoption rates based on payback period and the EPA's 2027 and 2032 binned adoption rates based on payback period.

[See TABLE, EPA-HQ-OAR-2022-0985-2668-A3, p. 5]

The EPA's payback-based adoption rates for payback periods greater than four-years are higher, compared to ACTR in its 2027 assumptions for BEV adoption. The EPA's model increases those adoption rates, as well as the adoption rate for payback periods of 1-2 years, in 2032. The EPA assumes that in 2032, FCEVs will be widely available, in addition to BEVs, and has modified the adoption rate criteria on the assumption that increased model availability will drive significantly higher adoption rates for the same payback timeframe. ACTR's adoption rate assumptions are propulsion system agnostic, so the wider availability of FCEVs would not change our formula in the outer years of our forecast. [EPA-HQ-OAR-2022-0985-2668-A3, p. 5]

Again, we will reiterate here that ACTR does not agree with the EPA's modification to ACTR's formula where payback-based adoption is granted for payback periods greater than 10 years. We would especially like to note the EPA's 2032 payback-based adoption rate for its >15 years payback bin. It is highly unlikely that any ZEV adoption would occur if solely based on a payback period of >15 years. [EPA-HQ-OAR-2022-0985-2668-A3, p. 5]

The EPA states in the DRIA that the MY 2032 schedule applies higher adoption rates than in MY 2027 due to the assumption that "ZEV technology will be more mature; fleet owners and drivers will have had more exposure to ZEV technology…and infrastructure to support ZEV technologies will have had more time to expand" (DRIA p. 232). ACTR does not inherently disagree with the assumption that there will be more infrastructure to support ZEVs and that fleets will have more exposure and comfort with these new technologies. However, we would not agree that those factors would specifically change payback-based adoption behavior. The decision to choose a ZEV vehicle based on payback is quantitative. The decision to choose a

ZEV vehicle based on having more exposure to ZEV technology is qualitative. [EPA-HQ-OAR-2022-0985-2668-A3, p. 5]

Missing Piece of the ZEV Adoption Equation

While the EPA is correct that payback period is an important factor in considering the adoption of ZEVs, we think that the EPA is failing to consider the impact that TCO has on adoption rates. ACTR uses both the payback-based adoption function as well as an adoption function based on TCO savings to determine ZEV adoption rates. Each criteria receives an equal weighting in determining our ZEV adoption rate. [EPA-HQ-OAR-2022-0985-2668-A3, p. 6]

It is interesting that the EPA does not make use of a TCO savings-based adoption function when the DRIA does include broad discussion of its expectations for ZEV TCO and purchaser behavior in Section 6.2 “Purchaser Acceptance”. The EPA does expect that the ZEV options will have lower TCO compared to comparable ICE vehicles (DRIA p. 417). The EPA also recognizes that there is an interplay in purchasing decisions between upfront costs and TCO. [EPA-HQ-OAR-2022-0985-2668-A3, p. 6]

ACTR uses a TCO savings-based adoption formula similar to our payback-based adoption formula. It works similarly – a certain number of adoption share points are awarded based on the incremental percentage of TCO savings compared to the determined threshold. It follows a similar step design to the payback-based function. The formula can be expressed as follows:

TCO Savings:

- If TCO delta < X% = 0 share points attributed towards adoption
- If TCO delta > X% = threshold share points, plus additional points depending on the magnitude of the incremental TCO savings beyond the threshold value [EPA-HQ-OAR-2022-0985-2668-A3, p. 6]

As mentioned previously, we give equal weight to our payback-based function and TCO savings-based function when determining ZEV adoption rates. This is our recognition that these two important decision-making factors should not be considered as stand-alone sole criteria, when, in fact, both considerations determine adoption rates. While some may favor payback to TCO-savings (and vice versa), our model looks at what the ZEV adoption rate would be, on balance, when considering both. [EPA-HQ-OAR-2022-0985-2668-A3, p. 6]

The result of not utilizing both criteria for adoption rates would yield potential scenarios where a payback only based criteria would suggest higher adoption on its own than when both the payback and TCO savings function results are combined. The opposite can also be true, in cases where the combination of TCO savings and payback would suggest higher adoption rates. We think it is important to highlight that our resulting ZEV adoption rates based on both payback and TCO savings are often less aggressive than payback-based rates alone. [EPA-HQ-OAR-2022-0985-2668-A3, p. 6]

Our research has shown that more than one single quantitative factor is used in the decision-making to switch to a ZEV, and the method for determining adoption rates based on financial assumptions should be reflected as such. ACTR disagrees with the EPA’s decision to base its ZEV adoption rates solely on payback periods. [EPA-HQ-OAR-2022-0985-2668-A3, p. 6]

In conclusion, there are multiple ways in which the EPA has modified ACTR's payback-based adoption equation that are not aligned with our view of how the function should be used. [EPA-HQ-OAR-2022-0985-2668-A3, p. 6]

- The EPA has increased the rate of ZEV adoption for payback periods greater than four years. Our quantitative and qualitative analyses do not support those increased adoption rates.
- The EPA has added adoption based on payback periods greater than 10 years and greater than 15 years (longer than most of ACTR's prescribed vehicle applications' useful lives). We would not expect payback-based adoption to occur if the payback period is greater than 10 years, particularly in the hands of the first purchaser.
- The EPA further increases the rate of ZEV adoption based on payback period again in 2032. While ACTR agrees that many improvements in infrastructure and familiarity with vehicles will occur, those are not always purely financial decisions. For this reason, ACTR's formula does not change over time.
- The EPA only considers a payback-based function for technology adoption. The absence of the addition of a TCO-based adoption function used in conjunction with the payback-based adoption function shows a lack of full consideration for all factors owners utilize when making truck buying decisions, especially when related to switching technologies. [EPA-HQ-OAR-2022-0985-2668-A3, p. 6]

Ultimately, a payback-period calculation is performed in HD TRUCS to determine the number of years it will take for the TCO of the ZEV technology/vehicle to be equal to that of the corollary ICE technology/vehicle for each of the 101 vehicle types. The payback period considers the differential powertrain costs, the EVSE costs, annual maintenance, repair and operation costs, along with tax and other credits from IRA and BIL to determine the number of payback years. [EPA-HQ-OAR-2022-0985-2668-A1, p. 22]

EPA then uses the calculated number of payback years to determine the associated ZEV-truck adoption rate for each vehicle type. HD TRUCS uses a table that correlates payback years with percentage-of-sales-based adoption rates for ZEV trucks. EPA claims that the table is based on work performed by ACT Research Company (ACT). However, EPA modified the table to include adoption rates for payback years beyond those used by ACT, and EPA also assigned higher adoption rates for certain payback periods based on its "good engineering judgment." Later in these comments, EMA will discuss ACT's detailed critique of EPA's use of ACT's work. [EPA-HQ-OAR-2022-0985-2668-A1, p. 22]

In that regard, and as further detailed in Ricardo's infrastructure needs assessment, installing the requisite ZEV-truck infrastructure over the next decade is a massive undertaking with a massive price tag. Because of the magnitude of that challenge, there is a significant risk that not all or even close to all of the required battery-recharging and hydrogen-refueling stations will be in place when and where needed, such that some significant numbers of anticipated ZEV-truck purchases and deployments will not be feasible. To account for that substantial likelihood, a suitable discount factor needs to be applied to the adoption rates and GEM-based standards derived through EMA HD TRUCS. [EPA-HQ-OAR-2022-0985-2668-A1, pp. 41 - 42.]

The discount factor is one that should be large enough to cover the risk that a fully sufficient ZEV-truck infrastructure will not be developed on-time. Accordingly, the scope of the percentage discount should equate to the percentage of the necessary infrastructure that might reasonably be expected to not be fully operational during the 2027-2032 regulatory time period. This is especially likely given the finite resources available in the ZEV market and the concurrent ZEV infrastructure build-out that is occurring in the LD sector. More specifically, if it is reasonable to expect that 25% of the required numbers of ZEV-truck recharging and refueling stations may not be in place and operational on-time, then a corresponding 25% discount should be applied to the ZEV-truck adoption rates and resultant GEM-based standards generated through EMA HD TRUCS. EMA believes that such a discount is warranted given the magnitude of the infrastructure challenge, as detailed in Ricardo's report (Exhibit "1"). [EPA-HQ-OAR-2022-0985-2668-A1, p. 42] [See the Exhibit 1, Ricardo Report, at docket number EPA-HQ-OAR-2022-0985-2668-A2.]

An additional discount is necessary from the starting-point adoption rate percentages calculated through EMA HD TRUCS to account for the fact that EPA has misapplied the payback-based adoption function that ACT Research Company (ACT) developed and that the Agency purports to have relied on. (See DRIA, Section 2.7.9.) In that regard, ACT has prepared a written critique of how EPA has misused ACT's payback-based adoption function. A copy of that written critique is attached to these comments as Exhibit "3." [EPA-HQ-OAR-2022-0985-2668-A1, p. 42] [See the Exhibit 3, ACT Report, at docket number EPA-HQ-OAR-2022-0985-2668-A4.]

As ACT explains, EPA: (i) has failed to include the TCO savings-based adoption formula that equally informs ACT's calculated adoption rates, and instead has solely utilized ACT's payback-based adoption function; (ii) has improperly utilized inflated adoption rates for payback periods greater than four years; and (iii) has improperly included payback-based adoption rates for payback periods beyond ten years, which is beyond the reasonable payback period that would be assessed and experienced by the original purchaser of a ZEV truck. Thus, ACT concludes in its written critique that "there are multiple ways in which EPA has modified ACT's payback-based adoption equation that are not aligned with ACT's view of how the function should be used." (ACT Response to DRIA, p. 7.) [EPA-HQ-OAR-2022-0985-2668-A1, p. 42]

ACT has prepared the following table depicting how EPA's overstated and overextended adoption rates differ from ACT's: [EPA-HQ-OAR-2022-0985-2668-A1, p. 42] [See the Exhibit 3, Payback-based Binned Adoption Rates, at docket number EPA-HQ-OAR-2022-0985-2668-A4.]

Given the material discrepancies between ACT's analyses and EPA's misapplication thereof, an additional corresponding discount will need to be applied to the starting-point adoption rate percentages that EMA has generated through its revised and corrected version of HD TRUCS. [EPA-HQ-OAR-2022-0985-2668-A1, p. 43.]

Organization: Truck Renting and Leasing Association (TRALA)

EPAs methodology within its Heavy-Duty Technology Resource Use Case Scenario (HD TRUCS) also assumes that all customers will choose minimal on-site charging power to keep capital costs low. 27 The agency's assumption for 19-50KW charging across many vehicle applications in medium heavy-duty vehicles seems fundamentally incorrect based on what TRALA is hearing from end-users about intentions to install 150KW-350KW charging on-site. This assumption does not match many end-users plans to future-proof their charging infrastructure to enable use across more vehicles and opportunity charging for multi-shift or peak operational periods. [EPA-HQ-OAR-2022-0985-1577-A1, p. 19]

27 EPA's Heavy-Duty Technology Resource Use Case Scenario (HD TRUCS) was specifically developed by EPA to evaluate HD ZEV technologies and costs under Phase 3.

Some MD truck applications, such as Class 4-8 box trucks, port drayage tractors, Class 4-7 step vans, and Class 6-7 flatbed trucks are used for routes similar to those of regional haul tractors which are projected in HD TRUCS to need 150-350KW charging. However, in HD TRUCS the applications mentioned above are only assumed to require 19-50KW chargers. TRALA recommends EPA issue a request for information (RFI) to end-users to acquire information on charging power needs for commercial vehicle operations and test these sensitive up-front cost assumptions that are used to project end-user willingness to adopt ZEVs. [EPA-HQ-OAR-2022-0985-1577-A1, p. 19]

To demonstrate the importance of testing this assumed critical input, EPA should run a sensitivity analysis to project the payback for all vehicle applications that are assumed to require 19-50KW charging if they require higher power DC charging. If, as many in industry suspect, most medium heavy-duty end-users require higher power charging in the 150-350KW and beyond range to maintain 1:1 productivity, this will change HD TRUCS model payback and ZEV projections. [EPA-HQ-OAR-2022-0985-1577-A1, p. 19]

Organization: Volvo Group

- The agency's payback vs. adoption rate table (RIA 2.7.9, Table 2-73), shows fleets purchasing BEVs and FCEVs at payback periods of up to 15 years in 2027, and beyond 15 years in 2032. This is unrealistic, as most fleets look for a payback period of two years or less.

Organization: Zero Emission Transportation Association (ZETA)

b. Electric HDVs Have Lower Total Cost of Ownership than Comparable ICE Vehicles

HDEVs can offer substantial economic advantages to fleet operators. Fuel and maintenance costs, in particular, are areas with substantial cost reduction potential. In a survey of fleet managers, the most commonly cited motivation for electrifying their fleets was to meet sustainability goals (83%); lower total cost of ownership (TCO) was the second-most common reason (64%).39 [EPA-HQ-OAR-2022-0985-2429-A1, p. 10]

39 Steven Nadel and P. Huether, "Electrifying Trucks: From Delivery Vans to Buses to 18-Wheelers," ACEEE, (June 2021) https://www.aceee.org/sites/default/files/pdfs/t2102.pdf

Fleet managers are particularly sensitive to costs, and economics drive the majority of their business decisions. Currently, evaluating the upfront cost—rather than lifecycle—of vehicle acquisition is standard practice for both private and public fleet managers. When analyzed this way, fossil fuel-powered vehicles often outcompete HDEVs; however, TCO analyses regularly demonstrate that HDEVs are significantly cheaper than their ICE counterparts. Transitioning from an upfront cost-based decision-making model to one that considers the vehicle's entire lifespan—including purchase cost, depreciation, financing, fuel costs, insurance costs, maintenance costs, taxes, fees, and operational expenses—provides a more accurate picture of the true costs incurred via vehicle ownership. Under such considerations, HDEVs like transit buses, school buses, and vocational vehicles are already cost competitive with equivalent ICEVs.40 [EPA-HQ-OAR-2022-0985-2429-A1, p. 10]

40 Id.

Even before the passage of the Inflation Reduction Act (IRA), the International Council on Clean Transportation (ICCT) found that HDEVs have a TCO advantage over ICEVs in some U.S. regions and they are expected to reach cost parity nationally by 2035.41 That should be expected to accelerate with the passage of the IRA's 45W commercial clean vehicle tax credit, as discussed further below. ICCT also found that TCO savings hold even assuming lower-than-expected oil prices or higher electricity rates in the future. Even without the IRA tax credits, most classes of HDVs will have a payback period of less than 5 years by 2025. Considering most HDVs today have an average lifespan of 15 years, these cost savings make a strong economic case for fleet operators to make the switch to electric technologies. [EPA-HQ-OAR-2022-0985-2429-A1, p. 10]

41 "Purchase Costs of Zero-Emission Trucks in the United States to Meet Future Phase 3 GHG Standards" ICCT, March 2023 https://theicct.org/publication/cost-zero-emission-trucks-us-phase-3-mar23/

These savings are expected to grow in the coming years. By 2030, an electric day cab is expected to lower the TCO by more than 31% for savings of $239,000 over a vehicle's lifetime.42 Fleets that experience the highest fuel and maintenance costs from their diesel trucks would see the greatest cost reductions from an EV transition. Class 8 electric trucks with trips fewer than 500 miles will see the greatest TCO savings, largely when operating in environments with higher fuel prices and relatively low electricity prices.43 Because the upfront cost is paid back via savings on operations mile-by-mile, fleets with higher VMT would see the greatest reductions, which bodes well for long-haul trucking.44 See Figure 1 for a breakdown of the average yearly VMT by different HD vehicle classes. [EPA-HQ-OAR-2022-0985-2429-A1, p. 11.] [See Docket Number EPA-HQ-OAR-2022-0985-2429-A1, page 11, for Figure 1]

<u>EPA Summary and Response:</u>

<u>Summary:</u>

Note that much of this material is summarized in RTC 2.4 above, and responded to there as well.

There were many comments regarding EPA's use of a payback metric at proposal as a means of developing a compliance pathway predicated on use of ZEVs. DTNA and EMA said, considered alone, payback is an incomplete metric. Commenters stated that other factors to consider are reluctance to utilize a new technology, effects of inflation, vehicle suitability, resale value, end of the IRA and other price incentives, critical material availability, and, most importantly, availability of supportive electric infrastructure. Commenters stated that in costing out payback, projecting fuel, raw material, and electricity costs far out into the future is problematic (noting, for example, the overall effect of decarbonization efforts on electricity prices and how uncertain that effect will be).

NGO commenters advocated for more stringent standards (see section 2.4 in this document). ACEEE discussed the length of a payback period, asserting that payback well within vehicle lifetime should be sufficient, noting especially that vocational fleets may own vehicles "for many years." They also questioned the relatively low percentages of projected ZEVs where EPA had estimated payback periods of 1-2 years. MFN noted that EPA's projected compliance path showed less ZEV utilization than many estimates in the literature, citing BloombergNEF, various of the ICCT White Papers, as well as the California ACF levels. RMI noted generally that total cost of ownership of BEVs would necessarily be less than for ICE vehicles due to their simpler drivetrains, which would occasion less maintenance costs.

Other NGO commenters were more specific. A number of commenters questioned the 80 percent cut off EPA had proposed as a cap on consideration of ZEV adoption in the NPRM's potential compliance pathway. Both EDF and Energy Innovation found some merit to EPA's premise that a cap reflected that ZEVs would not be suitable for all applications, but both of these commenters maintained that this would be less and the less the case over time. Consequently, they assert that EPA's methodology should at the least reflect a declining cap in the standard's out years. Both of these commenters also maintained that 80 percent was too conservative even for MY 2027, especially when coupled with the 90th percentile sizing VMT for the battery. EDF also argued that a cap makes no sense for those instances where EPA projects lower upfront costs for ZEVs than for their ICE vehicle counterparts. ICCT, on the other hand, supported a cap of 90 percent. DTNA challenged the 80 percent cap both because it is inconsistent with DTNA's telematics data, and also because the sales requirements for various HD vehicle categories in the ACT legislation are less than 80 percent. DTNA questioned why EPA's cap for those categories can be higher, that is, less restrictive, than the applicable ACT sales requirement.

As noted here and in RTC 2.4 above, commenters criticized EPA's use at proposal of the ACT Research payback equation. The comments pertained to alleged lack of transparency – stating that the equation was proprietary and so did not appear in the DRIA making comment difficult without getting access – as well as comments about the ACT Research payback equation. ICCT obtained the equation and alleged there was no substantive basis for it. ACT Research itself stated that EPA had misapplied the equation by leaving out various factors, including consideration of total cost of ownership.

Energy Innovation preferred an alternative method for assessing a ZEV-based compliance pathway. Their model uses a logit function less sensitive to price, developed by the Pacific Northwest National Laboratory, and also uses a 15 percent discount rate. They also removed the 80 percent cap where their model showed immediate payback. Under this alternative methodology, the commenter projected higher ZEV penetration for many of the vehicle classes:

2-4, 6-7, refuse trucks, and almost all bus segments. Moreover, the commenter stated that these estimates did not consider the effects of the IRA.

Both EDF and ICCT agreed that technology adoption follows an S-shape, as EPA posited. DRIA at 231. However, they believed the TEMPO model (developed by NREL, and noted by EPA at proposal, id.) was a better way to assess that shape. They posited standards of significantly increased stringency using this model.

These commenters also noted that the effect of the IRA, considered along with this different methodology, would justify standards more stringent still, based on price parity achieved in even earlier model years. EDF maintained that "An updated study by Roush Industries for EDF in May 2023 assessed and quantified, where possible, the key impacts of the IRA on the cost of electrifying medium- and heavy-duty vehicles that have access to overnight recharging at a central location (assessing the same vehicle classes from the earlier 2022 report, including Class 8 transit buses, Class 7 school buses, Class 3–7 shuttles and delivery vehicles, and Class 8 refuse haulers), using the previous study costs as a baseline.41 The analysis found that IRA credits help absorb the near-term higher upfront cost of battery electric vehicles (BEVs) and will accelerate the purchase parity with the segments analyzed. According to the research, *all segments analyzed will now meet purchase price parity with their diesel counterparts if purchased as early as MY 2024*, assuming reasonable economies of scale for BEV production." See Att. M to the EDF comment. They continued that "As a result of the IRA, the purchaser of a BEV in MY 2024 could save an estimated $18,000 on a Class 3 delivery van and $500,000 on an urban transit bus over the life of the BEV compared to a comparable diesel vehicle (Figure 1). If we assume that diesel fuel prices return to the prices occurring during the summer of 2022 ($5.18/gallon versus $3.25/gallon the lifetime savings due to switching to a BEV would increase to $33,000 for a Class 3 delivery van and $700,000 for an urban transit bus)." Citing H. Saxena, S. Pillai. 2023. Impact of the Inflation Reduction Act of 2022 on Medium- and Heavy- Duty Electrification on MYs 2024 and 2027, Roush for EDF.

Energy Innovation maintained that the IRA would accelerate electrification in the heavy-duty sector by 39-48% by MY 2030, and 44-52% by MY 2032 (using their suggested methodology and then modeling various estimates (low, medium, and high) for IRA effects, plus effects of ACT).

TRALA expressed concern that EPA's assumption of 19-50kW charging for certain applications of vehicles in HD TRUCS may be inaccurate. They stated that since box trucks, port drayage tractors, step vans, and flatbed trucks are more like "Regional Haul" tractors, HD TRUCS should apply the same 150-350 kW charging to those applications. They indicate that the difference would impact upfront costs, which would affect customers' willingness to adopt ZEVs. They requested EPA obtain more information from end-users and perform a sensitivity analysis for the impact on payback and ZEV projections.

DTNA provides an example of a BEV with a payback period in the 3 - 6 year range, but states that they are currently experiencing Class 8 BEV tractor uptake of less than 1% in California, despite additional regulatory drivers for fleet adoption. DTNA also believes 73% should be the maximum Class 4-7 adoption rate and 36% should be the maximum Class 8 adoption rate.

ICCT noted that manufacturers' compliance with the ACT rule in California and the at least eight other states who have adopted ACT would allow manufacturers to sell fewer ZEVs and/or more-emitting ICE vehicles in non-ACT states than ACT states while maintaining compliance with the proposed standards (since the proposed standards are less stringent than ACT). This could impede investment in ZEV fleets and infrastructure in non-ACT states and generate an inequitable distribution of benefits among states.

The State of California et al. (2) noted numerous considerations that support HD ZEV adoption including the ACT regulation (and EPA's granting of waivers of preemption for CARB's ACT and Zero Emission Airport Shuttle regulation), manufacturer goals for ZEV sales, businesses' commitments towards electrifying their heavy-duty fleets, states' policies to promote electrification of the HD vehicle sector, and federal actions including the IRA and the federal government's Blueprint for Transportation Decarbonization.

Response:

We evaluated the comments regarding the appropriateness of ACT Research payback and adoption rate relationship, and we agree with commenters that the approach developed by NREL for use in the TEMPO model is more transparent and its methodology otherwise appropriate. For the final rule, we are continuing to use the same payback period method we used in the proposal, but have revised the adoption rates that correspond to the payback period bins based on data from NREL's TEMPO model instead from the ACT Research-based model. See RIA Chapter 2.7 for additional details.

Regarding EMA's request for a discount factor and DTNA's requests for certain maximum adoption rates, we note that the final rule assessment of payback includes a cap that simulates a discount factor (e.g., in the MY 2027 payback table at 20% and 37% cap in 2030). We also note that we are committing to post-rule implementation monitoring, including monitoring of infrastructure deployment, as discussed in Preamble II.B.2.iii.

We have retained the caps on adoption rates in our modeled potential compliance pathway. As explained in Preamble Section II.G.5 and RTC section 2.4, the caps serve as proxies for uncertainties that can affect feasibility of the standards, including timing of infrastructure deployment, purchaser risk aversion and other unwillingness to invest in new technology, availability of critical minerals and associated supply chains, and adequacy of battery manufacture. EPA has necessarily had to make predictive judgments as to all of these factors and believes there are reasoned solutions to all of them. At the same time, EPA is allowing for potential constraints posed be these uncertain factors and has done so by means of the caps, consistent with EPA's structuring of the standards to carefully phase in the stringency of the standards in the earliest years of the Phase 3 rule. EPA thus does not accept the comments of Energy Innovation and others that adoption rates in the modeled compliance pathway should be a function of payback alone. That would ignore the effects of all of these considerations, which EPA believes must be or are appropriate to account for and which EPA has thus done in a balanced and measured approach to support the stringency of the final standards. For a similar reason, we consider ICCT's suggested cap of 90% to reflect insufficient consideration of these potentially constraining factors.

The cap levels reflect EPA's best engineering judgment, consistent with these principles. Rather than the undeviating 80% cap which EPA proposed, 88 FR at 25992, we revised our final approach so that the cap level varies by model year, starting at a much lower adoption cap of 20% in MY 2027, and increases to a 70% adoption cap in MY 2032. See RIA Chapter 2.7.2.

These cap levels fall within the range suggested by a number of commenters. The maximum cap of 70% in 2032 reflected consideration of the noted range of comments from DNTA that suggested 36% for Class 8 vehicles. DTNA suggested that Class 4-7 ZEVs with payback rates of <0 years would have an adoption rate of 72 percent, and Class 8 ZEVs with payback rates of <0 years would have an adoption rate of 36 percent, noting that these rates are consistent with CARB's 2019 initial market assessment for the ACT rule for vehicles that scored a 1 or a 2 in their suitability assessment. However, we note that for the final ACT program, CARB increased the ZEV requirements compared to those that were initially proposed. In addition, for purposes of responding to this commenter's comparison to CARB's assessment and the ACT rule, we note that the category 1 and 2 suitability totals in CARB's 2019 assessment are aggregated totals and are therefore not directly comparable to the 101 vehicle-type level of aggregation to which we have applied the 70 percent cap in 2032 (and 20 percent cap in 2027) in HD TRUCS; the 2019 CARB market assessment report's category 1 and 2 totals would be more appropriate to compare to our final adoption rates by regulatory grouping. We note that our 70 percent cap for MY 2032 is consistent with the 70% of Class 4-7 ZEVs with suitability scores of 1-2 and therefore the ZEV adoption rates in any subcategory will necessarily be below that level as well (see RIA Chapter 2.10, for the percentage of ZEVs in the modeled potential compliance pathway by regulatory grouping and MY). We also note that our HHD vocational and sleeper cab tractor adoption rates in the modeled compliance pathway do not reach 36 percent. While the day cab subcategory adoption rate reaches 40 percent in MY 2032, we note that CARB's final regulation order requires 40 percent for all tractors starting in MY 2032.

Energy Innovation's payback versus adoption rate curves by vehicle segment allowed for 100 percent adoption if the payback was negative, with which we disagree for the reasons stated above. Our cap level is within the commenter's suggested adoption rate of 55 percent to 70 percent for payback that is less than one year.

With respect to DTNA's comment that they are currently experiencing Class 8 BEV tractor uptake of less than 1% in California, despite additional regulatory drivers for fleet adoption, this is not consistent with what California is experiencing in the heavy-duty market. California found that 7.5% of the medium- and heavy-duty vehicle sales in MY 2022 (two years prior to the first year of ACT implementation) in California were ZEVs.[358]

In addition, see RIA Chapter 2.7 and section 2.4 of the RTC, for further discussion of our consideration of comments that informed the final numeric values of the caps.

After considering comments from EMA, TRALA and others relating to on-site charging power, we have updated our consideration of EVSE costs as described in RTC section 6.3.

Regarding the effect of the IRA, we discuss this topic and respond to comments in RTC Section 2.7, preamble Section II.E.4, and RIA Chapter 2.

Energy Innovation, regarding estimates of HD ZEV adoption that would occur in the absence of the Phase 3 rule (i.e., the baseline), see RTC Section 3.11.1. This includes comments related

[358] California Air Resources Board. "Advanced Clean Trucks Compliance and Incentives Update." Last accessed on March 18, 2024. Available online: https://ww2.arb.ca.gov/resources/documents/advanced-clean-trucks-compliance-and-incentives-update.

to inclusion of the following factors in the baseline: the IRA and its estimated impacts (see also RTC Section 2.7), the ACT rule.

Regarding the impact of compliance with ACT on compliance with the Phase 3 standards, we agree that manufacturers may sell fewer ZEVs in non-ACT states than ACT states as shown in RIA Chapter 4. However, as discussed in RTC Section 2.4, the final standards are based on our feasibility assessment as explained in preamble Section II, which assesses ZEV adoption across the entire United States and not in each individual state. Some states may experience above-average ZEV sales while others experience below-average ZEV sales, but our feasibility assessment stands when considering the United States market as a whole. The possibility of state-to-state differences in technology adoption is a fundamental characteristic of federal standards, such as the Phase 3 standards. See also RTC Section 10.2.2 regarding U.S.-directed production volume.

Regarding the many considerations mentioned by the State of California et al. (2), see RTC Section 2.7. Additionally, our feasibility assessment supporting the final standards is explained in preamble Section II and is independent of many of these factors (notably, those which are not enforceable). Our baseline and its consideration of these items is described in RIA Chapter 4 and RTC Section 3.11.1.

3.12 General Errors and Missing Information

Comments by Organizations

Organization: Truck and Engine Manufacturers Association (EMA)

a) Corrections

EMA identified five corrections that are needed in HD TRUCS and as a result, are incorporated into EMA HD TRUCS. [EPA-HQ-OAR-2022-0985-2668-A1, p. 23]

Annual BEV Electricity Cost in A3a_Cost worksheet – HD TRUCS calculates the annual cost of electricity based on the energy that is consumed by the vehicle from the batteries rather than from the electricity that is used to recharge the batteries. The latter includes the wall-to-battery loss factor for the charging process. The current formula in HD TRUCS underestimates the annual electricity cost by approximately 11%. [EPA-HQ-OAR-2022-0985-2668-A1, p. 23]

Battery Width Limitation Factor in A4a_Adoption Rates (BEV) worksheet – The formula used for the 2027 and 2032 adoption rates includes an assessment of the battery width as calculated by HD TRUCS. The limitation on the width for a BEV is 8.5 feet per the Draft RIA (p. 234). The formula incorrectly uses 13 feet rather than 8.5 feet in assessing the viability of the needed battery space fitting within the allowable vehicle space. This error allows various tractors to be included as BEVs when, in fact, there is insufficient space for the required battery. Those vehicles should be treated as FCEVs instead. [EPA-HQ-OAR-2022-0985-2668-A1, pp. 23 - 24]

Battery Length Calculation in 2_BEV Tech worksheet – EPA included an assessment of battery volume in the NPRM (see Draft RIA Section 2.4.2, p.166). The volume assessment drives the calculation of the width of the battery based on the battery volume that is determined for each vehicle type within HD TRUCS. The calculation divides the battery volume by the presumed battery height (110% of the frame rail height) and by the battery length (wheelbase) of each vehicle type to calculate a battery width. However, if this entire rectangle is used for batteries on a BEV, there will be no room for the front or rear tires, since the prescribed dimensions violate the space envelope required for the tires. EMA recommends that the battery length factor be reduced to allow for a more realistic volume requirement for the batteries in HD TRUCS. Specifically, EMA reduced the length by 26 inches for non-tractors to allow space for the front tire. The overlap with the rear tire may be able to go between the frame rails behind the axle, since trucks have more frame extended behind the rear axle(s). For Class 7 tractors, which are a 4x2 axle configuration, the length should be reduced by 26 inches for both the front and rear axle, for a total reduction of 52 inches. The after-frame on tractors is very short to provide clearance for the landing gear of a trailer, so there is no space behind the axle for additional batteries. On Class 8 tractors, which have a tandem rear axle (6x4), the battery length needs a reduction of 26 inches for the front axle and 52 inches for the rear axle. The wheelbase on 6x4 configurations is measured to the centerline of the two rear axles, which necessitates additional reductions over Class 7 tractors. These battery-length errors allow HD TRUCS to include various tractors as BEVs when, in fact, there is insufficient space for the required battery. Those vehicles should be treated as FCEVs instead. The space needed for the frame rails also needs to be considered. Each of the two rails are about 3.5 inches wide. EMA believes this is a less significant issue in the battery width limitation evaluation, so it is not included in the corrections to EMA HD TRUCS. [EPA-HQ-OAR-2022-0985-2668-A1, p. 24]

Operation VMT (50%) in A1a_VMT_ID worksheet – Operation VMT (50th percentile) for many vehicles is calculated as the average of the 50th percentile data from NREL's fleetDNA data and NREL UCR's data. For six (6) vehicle types, the formula in HD TRUCS has an inconsistency versus other vehicle types, resulting in the average VMT being incorrectly calculated. Vehicle IDs 11 through 16 use the fleetDNA data 50th percentile along with the NREL UCR maximum daily mileage value to determine the daily average operation VMT value. This gives an inflated average daily VMT. This error increases the electricity cost and impacts other factors used in determining payback years and adoption rates. [EPA-HQ-OAR-2022-0985-2668-A1, p. 24]

Absolute Sizing VMT (90%) in A1a_VMT_ID worksheet – Absolute Sizing VMT (90th percentile) for many vehicles is calculated as the average of the 90th percentile data from NREL's fleetDNA data and NREL UCR's data. For six (6) vehicle types, the formula in HD TRUCS has an inconsistency versus other vehicle types, resulting in the average VMT being incorrectly calculated. Vehicle IDs 11 through 16 use the fleetDNA data 90th percentile along with a text cell to calculate the average mileage value for this data element. This gives an inflated average absolute sizing VMT. This error increases the battery size, battery weight, battery cost and impacts other factors used in determining payback years and adoption rates. [EPA-HQ-OAR-2022-0985-2668-A1, p. 25]

As stated earlier, all the above corrections are incorporated into the EMA HD TRUCS tool. [EPA-HQ-OAR-2022-0985-2668-A1, p. 25]

Adoption Rate and Stringency Calculations – The Draft RIA provided details on EPA's methodology for using the ascribed ZEV adoption rates for the 101 vehicle types to generate the adoption rates at the vehicle regulatory subcategory level, but EMA was unable to find a spreadsheet or tool in HD TRUCS or in the docket that actually performed those calculations.

Also, no tool or spreadsheet was found that carried out the conversion of ZEV adoption rates to the calculation of the GEM-based GHG stringencies. Therefore, EMA has included its version of those spreadsheets in EMA's version of HD TRUCS. Multiple new worksheets are involved in the EMA approach to replicating the EPA results on stringencies, and modifications to an existing worksheet were needed for the summation process. [EPA-HQ-OAR-2022-0985-2668-A1, p. 33]

EMA's summation of the 101 vehicle types into the regulatory subcategories matches all EPA values. The conversion to stringencies also is a 100% match for 2027 and 2032, while the interpolation for the intervening years are close but not exact. EPA has included special rules for incorporating Custom Chassis vehicles into the vocational stringencies. Although an outline of the process is in the Draft RIA, it was not found to be clear enough to allow EMA to replicate the EPA calculations. [EPA-HQ-OAR-2022-0985-2668-A1, p. 33]

EPA Summary and Response

Summary:

EMA stated that they identified five corrections or omissions in the NPRM version of HD TRUCS. These included: (1) the annual electricity cost is underestimated because charger and battery efficiency are not included in the formulas; (2) there is a formula error in the NPRM version of HD TRUCS for the maximum battery width; (3) EPA's assessment of packaging battery volume did not account for wheels and tires when determining the length of the battery; (4) incorrect calculation of the 90th percentile VMT on six HD TRUCS vehicle types; and (5) EMA stated that HD TRUCS did not include formulas for the aggregation of the 101 vehicles into regulatory subcategories, calculation of the proposed standards, nor the interpolation of model years between MY 2027 and MY 2032, though EMA acknowledges those calculations were described in the DRIA and that EMA was able to replicate the calculation of the standards for MY 2027 and MY 2032 and was able to come close to replicating the calculation for the intervening model years.

Response:

We appreciate EMA's thorough analysis of HD TRUCS which included some errors in our formulas and calculations. The NPRM version of HD TRUCS did include both the battery and charger efficiency in the annual electricity cost in A3a_Cost. These values were calculated earlier in the spreadsheet and were used to calculate the operating energy of a BEV on a daily basis. We have continued to use both the battery efficiency and charger efficiency to calculate the annual electricity cost for the final rule, though we have updated our methodology. For further detail on how the battery and charger efficiencies were used in the FRM for annual electricity cost, see RIA 2.8.8.1. The battery volume assessment (related to the battery width and length comments) has been updated in the final rule; please see Section 3.10.3 of this RTC for more information. EPA agrees with EMA that we had errors in the calculation of the 90th percentile VMT for six vehicles; therefore, in the FRM version of HD TRUCS we have rectified the error in the 90th percentile VMT formula for those six vehicles which had the effect of reducing their sizing VMT. For the final rule, in addition to describing the calculations in the RIA, we have also included in HD TRUCS all of the calculations for the standards for all model years.

4 BEV Technologies

4.1 Technology Readiness and Model Availability

4.1.1 Model Availability

Comments by Organizations

Organization: American Trucking Associations (ATA)

A significant point of frustration is the need for more specification options available for battery electric truck chassis. There is no such thing as a generic truck in the U.S. Heavy-duty vehicles produced for the U.S. market are highly customized to meet fleets' unique duty cycles and maximize ROI. Customizations can include nearly every critical vehicle component, such as its body, suspension, engine, transmission, and axles. ZEVs present unique economic and engineering challenges when integrated into an existing fleet. Because the ZEV market is nascent, customization options will not be available at scale under EPA's proposed adoption timelines. Specifications and customizations will continue to be important as fleets incorporate ZEVs into their operations. [EPA-HQ-OAR-2022-0985-1535-A1, p. 8]

While most battery electric vocational and short-haul vehicles follow a similar configuration and design, there are trade-offs on battery capacity, range, and wheelbase size, which can still greatly impact operations. One company invested in a startup partner to acquire a large number of highly customized electric delivery vans to meet its last-mile delivery needs, which are scheduled to be fully delivered in 2030. This level of customization is generally not available to all fleets purchasing vehicles, even in vocational and short-haul segments. Another company initially focused on electrifying last-mile vehicles but pursued another technological solution instead of ZEV because of the limited options. [EPA-HQ-OAR-2022-0985-1535-A1, p. 8-9]

Product availability

EPA's proposed and alternative adoption cases, Tables 1 and 2, assume OEM-announced product availability will be a major driver of the ZEV transition. However, product availability alone is insufficient to enable heavy-duty ZEVs at scale. In 2021, over 150 HD BEV models were available; but they accounted for less than 0.1 percent of Class 7 & 8 sales, which does not suggest an adoption rate that can accommodate the industry's needs from MY 2027 to 2032.10 ZEVs must meet a highly customized set of performance requirements and product specifications to scale. Said one fleet, "allow more time for unproven technologies to be real-world tested," which in the fleet context means—verify that ZEVs meet the current operational duty cycle vehicles are assigned to perform.

One truck leasing and rental company we spoke with noted that some light-duty commercial products are available for operations needing only 100 miles of range, but significantly fewer in heavier weight class applications requiring 200 miles or more. OEMs are currently developing and testing medium- and heavy-duty vehicles under varying specifications; however, options remain limited. For example, the introduction of electric power take-off systems is a recently available technology that utilizes an electric motor to power auxiliary equipment. [EPA-HQ-OAR-2022-0985-1535-A1, p. 8]

Organization: BorgWarner Inc.

BorgWarner sees strong growth in certain HD weight classes of the BEV market.

We see strong growth of BEVs in several commercial heavy-duty vehicle segments (CV). EPA's forecasts appear in line with industry experts for Class 2 through 6. BorgWarner recognizes that CV BEV forecasts are rapidly shifting. Industry forecasts increasingly expect more CV BEVs and consequently we believe that, even with adjustments, EPA is underestimating the level of ZEV penetration at certain weight classes. [EPA-HQ-OAR-2022-0985-1578-A1, p. 3]

Organization: CALSTART

The ZE-MHDV space is constantly changing, and the numbers of models increases as new OEMs enter the market as well as add additional models (Figure 1). For instance, Mack Trucks in the United States offered essentially one model at the beginning of 2023, the Electric LR product for refuse applications. However, at the recent ACT Expo, Mack launched two additional electric models, the Class 6 and Class 7 MD electric.8F9 [EPA-HQ-OAR-2022-0985-1656-A1, p. 6.] [See Docket Number EPA-HQ-OAR-2022-0985-1656-A1, page 6, for Figure 1]

9 https://electrek.co/2023/03/08/mack-trucks-first-medium-duty-electric-truck/

The number of models globally has grown by nearly 40 percent since 2021. As of June 2023, there were more than 840 total ZE-MHDV models worldwide, 444 of which were specifically MHD trucks and 128 specifically heavy-duty (Class 7–8) trucks. In the U.S. and Canada alone, there are nearly 210 models, 86 of which are MHD trucks and 37 specifically heavy-duty. Interestingly, while the total number of models is highest in China, the U.S. and Canada rank second and ahead of Europe in total models and lead the world in growth of OEMs appearing in the region (Figure 2). [EPA-HQ-OAR-2022-0985-1656-A1, pp. 6 - 7.] [See Docket Number EPA-HQ-OAR-2022-0985-1656-A1, page 7, for Figure 2]2023 ZET market update: While overall volumes remain low compared to the full on-road inventory, the rate of growth of ZET sales reflects the rapid growth of available models and vehicle capability. According to the May 2023 edition of CALSTART's Zeroing in on Zero-Emission Trucks report, the cumulative deployment of new ZETs (January 2017–December 2022) has now reached nearly 5,500 vehicles with more than 3,500 ZETs deployed in 2020 alone (Figure 4). The year-over-year sales growth shows strong and accelerating momentum for the technology, growing by 397 percent in 2021 and 163 percent in 2022. These numbers are for deployed vehicles and do not include the large backlog of orders for trucks that are yet to be delivered. [EPA-HQ-OAR-2022-0985-1656-A1, p. 8.] [See Docket Number EPA-HQ-OAR-2022-0985-1656-A1, page 9, for Figure 4]

As new vehicle models are steadily being introduced, so too are vehicle capabilities increasing. ZETI tracks range, energy storage, and payload and has seen significant increases year-over-year in all categories (Figure 3). For instance, in 2020, the longest-range trucks were at the 200-mile mark, and those with highest payload limited to 150 miles. In 2023, a full payload Class 8 battery-electric tractor has reached 500 miles of range, and the median range across the category is more than 150 miles. [EPA-HQ-OAR-2022-0985-1656-A1, p. 7.] [See Docket Number EPA-HQ-OAR-2022-0985-1656-A1, page 8, for Figure 3]

Interestingly, 59 percent of these deployed vehicles were in states that have adopted the ACT regulation, though regulatory requirements have not yet gone into effect in these states. Seven percent of the deployments were in states that have signed the Multi-State MOU for ZE-MHDVs, while a meaningful 34 percent were in the remaining states. These trends continued with the 2022 deployments: 44 percent were in ACT-adopting states; 10 percent were in MOU states that have yet to enact ACT; and 46 percent were in non-MOU states. The non-MOU states with the highest numbers of deployed ZETs include Texas, Florida, Michigan, New Hampshire, Illinois, Ohio, and Georgia. 10 [EPA-HQ-OAR-2022-0985-1656-A1, p. 9]

State of the Zero-Emission Industry

As the preamble and contextual portion of the EPA Phase 3 NPRM establishes very well, zero-emission technology for MHDVs has made significant strides since the Phase 2 rulemaking and is now a real option for deployment and rapid scaling. Indeed, ZEVs are the declared and primary strategy for the major original equipment manufacturers (OEMs) to reach their commitments to carbon neutrality by 2040. While some OEMs include a mix of fossil-free vehicles in the 2040 timeline, they are predominately planning on battery-electric vehicles (BEVs) and fuel cell electric vehicles (FCEVs). [EPA-HQ-OAR-2022-0985-1656-A1, p. 6]

Zero-Emission Technology Inventory (ZETI) overview and projections: As part of its role supporting global governments, fleets, and industry in tracking the progress and momentum toward this goal, CALSTART and its Drive to Zero program operate and maintain the ZETI tool, which tracks existing and planned ZEV (BEV and FCEV) model offerings in all primary commercial vehicle classes (including cargo vans and shutles but not pickups). It currently tracks vehicle offerings across seven geographic regions (U.S.-Canada, Europe, China, India, Mexico, South America, and Oceania), 10 vehicle application classes, 63 OEMs, and hundreds of vehicle models through 2024. [EPA-HQ-OAR-2022-0985-1656-A1, p. 6]

Global industry impacts on the United States: The rapid pace of change in ZE-MHDV capability, production, and sales is part of a global trend with significant implications and benefits for the U.S. market. Most of the major truck makers in the United States are part of global OEM groups and as such are able to tap global engineering and supply chain assets and therefore enact more rapid technology transfer and product development. [EPA-HQ-OAR-2022-0985-1656-A1, p. 9]

As an example, Navistar and its International Trucks brand are part of the global Traton Group (Volkswagen Truck and Bus). Scania, a key brand of the group, has announced a long-haul bate ry-electric tractor for the 2024 model year capable of moving 80,000 pounds (40 tons) for four and a half hours, then recharging in 45 minutes.11 Scania has recently tested megawat charging standard (MCS) chargers from ABB and can already offer MCS-capable trucks. The plan is to introduce the next generation of MCS by late 2024.12 As part of the group, these common powertrain components are all available to Navistar International, which has signaled its own long-range bate ry-electric truck could be available in the United States as soon as 2025.13 [EPA-HQ-OAR-2022-0985-1656-A1, pp. 9 - 10]

11 https://www.scania.com/group/en/home/newsroom/news/2021/Scanias-electrifica..on-roadmap.html

12 https://new.abb.com/news/detail/103008/abb-e-mobility-and-scania-successfully-undertake-first-test-in-development-of-megawat-charging-system

13 https://www.forbes.com/sites/alanohnsman/2022/05/13/big-rigs-going-electric-as-navistar-cummins-daimler-rev-up-next-genera..on-trucks/?sh=19d47132419d

This is not an isolated example. Daimler Trucks, the global parent of Freightliner, Freightliner Custom Chassis, and Thomas Built Buses, among many others, recently unveiled its long-haul version of the E-Actros electric truck with an 80,000 pound range (40 tons) of 310 miles.14 Several major firms including Amazon and Rhenus have agreed to pilot the truck as it prepares for series production in 2024.15 As with other groups, the Freightliner E-Cascadia shares a common architecture and similar components with all Daimler ZETs including the E-Actros,16 and E-Actros long-haul capabilities could be expected in the U.S. market by 2025. [EPA-HQ-OAR-2022-0985-1656-A1, p. 10]

14 https://www.electrive.com/2022/09/20/daimler-truck-presents-eactros-longhaul-prototype/

15 https://www.ajot.com/news/db-schenker-goes-electric-for-the-long-haul

16 https://www.freightwaves.com/news/daimler-will-package-own-components-for-electric-trucks

Volvo has used a similar strategy to share a common electric powertrain and bate ry configuration among its European and North American truck models to reach market more quickly, sharing a common architecture.17 Volvo also recently added two new electric trucks to its North American Mack brand by procuring powertrains from SEA Electric under a five-year agreement for its MD6 and MD7 Class 6 and Class 7 vocational trucks.18 This partnership allows Volvo to more rapidly extend electric offerings into medium-duty truck segments. SEA Electric also provides powertrains to Hino Trucks in North America and converts multiple OEM trucks on its own in eight countries, including the United States, Canada, Australia, New Zealand, Indonesia, and India. [EPA-HQ-OAR-2022-0985-1656-A1, p. 10]

17 https://www.sae.org/news/2020/06/volvo-batery-electric-trucks

18 https://www.sea-electric.com/sea-electric-partners-with-mack-trucks/

PACCAR has used a similar approach in the near term to speed its production of electric products, partnering with both Meritor (now a part of Accelera by Cummins) and Dana to provide electric powertrains for its Kenworth and Peterbilt brands.19 20 Kenworth has also announced a partnership to use Toyota fuel cell assemblies and electric powertrains in its Class 8 T680 tractor.21 [EPA-HQ-OAR-2022-0985-1656-A1, p. 10]

20 https://kenworth.com/about-us/news/ces/

21 https://landline.media/kenworth-peterbilt-fcev-hydrogen-fuel-cell-trucks-coming-soon/

The ability to transfer technology from the light-duty (passenger car) realm to MHDVs is an additional factor that has enabled a much faster pace for commercial truck electrification. It can be seen in the Tesla Semi, which uses multiple passenger car motors to build up its truck system.22 General Motors (GM) and Ford have both rapidly entered the commercial electric vehicle space, Ford with the eTransit electric delivery van23 and GM with its “spinoff” BrightDrop electric van.24 This tech transfer capability is also spurring unusual partnerships that connect and leverage global capabilities. In late May 2023, Daimler Trucks and Toyota Motors agreed to merge their Mitsubishi Fuso and Hino Motors groups to produce future trucks and buses with a shared vision of how to achieve carbon neutrality. The goal of the merger was to focus on zero emissions and advanced capabilities (i.e., connected/autonomous and automated/shared/electric).24F25 [EPA-HQ-OAR-2022-0985-1656-A1, pp. 10 - 11]

25 https://www.carscoops.com/2023/05/toyota-and-daimler-to-merge-hino-and-fuso-truck-businesses-into-a-single-unit/

These observations illustrate that EPA needs to revise its assumption that ZET penetration rates into Class 8 long haul will be delayed until fuel cell platforms are at scale. EPA's assumption of the battery size and weight needed to enable Class 8 long haul and the minimum distances required specifically need to be revised. The reality is heavy regional transport and point-to-point priority corridor operation, a key part of the changing long-haul application, are fully capable with products already in the market or arriving in the U.S. market by 2025 and improving over the course of the proposed regulation. [EPA-HQ-OAR-2022-0985-1656-A1, p. 11]

The key takeaways are:

- The pace of the OEM strategy shift to electrification is staggering and accelerating.
- Year-over-year sales of zero-emission products are rapidly expanding at a non-linear pace spurred by a steadily growing portfolio of models from global and North American manufacturers.
- This portfolio includes expanding capabilities, including heavy-duty tractors capable of hundreds of miles of travel. TCO parity between battery-electric and diesel tractors could come by 2030 for most payloads.26
- European designers are balancing smaller battery loads with faster-charge opportunities that match driver break periods and will enable high-utilization freight movement on priority corridors. [EPA-HQ-OAR-2022-0985-1656-A1, p. 11]

Organization: MEMA

EPA recognizes ZEV deployment in commercial vehicle will have an added challenge compared to Light Duty due to the necessity for manufacturers to efficiently allocate capital expenditures (CAPEX) towards the highest market segment opportunities, and release BEV chassis according to resources available and prioritized business case. Therefore, EPA should expect that serial production of specialized vocational applications will take longer due to diffuse volume across many vehicle configurations. [EPA-HQ-OAR-2022-0985-1570-A1, p. 17]

Organization: California Air Resources Board (CARB)

C. Projected Technologies for Meeting Standards

1. ZE Technologies

Affected pages: 25961-25974

Although CARB staff generally concurs with U.S. EPA's assessment of ZE technologies, U.S. EPA's findings regarding BEV and FCEV technology may be conservative and underestimate the status of the ZEV market. As discussed extensively in the ACF regulation's rulemaking documents, ZE technologies are commercially available today, and the market is developing rapidly.62 As of October 2022, 148 ZE medium-duty vehicles (MDV) and HDV models are available to purchase, with 135 models having already reached customer hands. These vehicles are available in all weight classes and a variety of configurations. Today, these models are somewhat focused on higher volume applications, while more specialized applications are being demonstrated across a wide array of applications. [EPA-HQ-OAR-2022-0985-1591-A1, p.28]

62 CARB, Public Hearing to Consider the Proposed Advanced Clean Fleets Regulation Staff Report: Initial Statement of Reasons, 2022. https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2022/acf22/isor2.pdf

<u>EPA Summary and Response:</u>

<u>Summary:</u>

ATA was concerned about the currently available models of ZEVs and their ability to cover the diversity of the heavy-duty industry. They argued that vehicles need to be heavily customizable to be able to meet the specific needs of each fleet and that the ZEV industry is new, such that customization will not be broad enough during the timeframe of the rule to support the adoption rates set out in the proposed compliance pathway. ATA also expressed concern about the current rate of uptake of BEVs and how that is projected to the timeframe of the rule. They stated that of the 150 available BEV models, they accounted for less than 0.1 percent of class 7 and 8 vehicle sales and suggests that industry's needs will not be met between MY 2027 to 2032. ATA expressed concern over the lack of available ZEV models to choose from especially for MD and HD applications that require 200+ miles of range. Borg Warner expressed concerns about the estimated ZEV adoption at specific weight classes from classes 2 – 6. Borg Warner commented that EPA forecasts match industry expert forecasts, but that they believe we are underestimating ZEV penetration in LHD and MHD segments. CALSTART commented about the availability of ZEVs. Their comments indicated that the number of models available is increasing as is the number of OEMs entering the ZEV market. Their comment stated that the number of models available in the U.S and Canada is second only to China. CALSTART also discussed the number of sales of HD ZEVs and that the year over year growth in ZEV deployments is a strong indicator of accelerating momentum for ZEVs. CALSTART also talked about the increasing capabilities of ZEVs and how range, energy storage, and payload have all seen significant increases year over year. They also discussed where the sales of ZEVs are occuring, whether in states that have adopted the California ACT regulation, states that have signed the Multi-State MOU for ZE-MHDVs, or any of the remaining states. Their comment states that sales of ZEVs are split almost evenly between ACT states and non-MOU states indicating that the number of ZEVs deployed will increase in all states, not just in ACT states.

CALSTART also pointed out that most major truck manufacturers in the United States are part of global OEM groups and are therefore able to access to global engineering and supply chains which allow them to be more capable of rapid technology transfer and product development. MEMA expressed concern about the order in which different vehicle types would become electrified. Their comment argued that since manufacturers have limited budgets for product development, the vehicles that have the highest market segment and that benefit the most from GHG-saving technology will be the highest priority for electrification while specialized vocational applications will take longer to electrify since volumes are smaller and more vehicle customization is required. They further suggested that CO_2 standards should be set lower for high volume applications that require less specialization and operate in moderate environments and the standards for low volume highly specialized vehicles should be set higher to account for the differences in electrification priority from manufacturers.

Response:

ATA asserts that HDV applications are typically highly customized, and that this degree of customization is not (and, in their view, probably cannot be) fully reflected in either HD TRUCS or in OEM announcements about planned ZEV introductions. EPA understands that the market for battery electric trucks is still developing and that, at present, they account for a small fraction of the overall sales in the HD industry. Based on this information, we have changed the approach from the proposal to more gradually increase the stringency of the standards to address concerns about vehicle availability as well as infrastructure build out, particularly in the initial years of the Phase 3 standard. We have modified the stringency of the standards in those initial years from that proposed. These changes will allow manufacturers more lead time to ramp up production for MY2032 to meet the stringency of the final rule. We also note that the Phase 3 program includes compliance flexibilities, including changes from those proposed.

We agree with ATA that HDV applications are diverse. This fact, however, does not only pertain to ZEVs but also to ICE HD vehicles. That is to say, any HD vehicle emissions rule must be evaluated in light of the diverse uses of these vehicles. EPA has done so in this rule, as described in RIA Chapter 2 with our evaluation of 101 vehicle types in HD TRUCS. Among other things, we have carefully considered the suitability and lead-time for various vehicle types, and we have adopted feasible and appropriate standards for each regulatory subcategory supported by technology penetrations in each subcategory under the modeled potential compliance pathway. For instance, we are not establishing new Phase 3 standards for certain subcategories (e.g., HHD vocational vehicles and day cab tractors) until later years of the program; we are also leaving in place the Phase 2 standards for certain optional custom chassis vehicles. In addition, for all subcategories, our modeled potential compliance pathway includes ICE vehicles in all years of the program; as such, purchasers who require ICE vehicles to perform specific tasks (e.g., those with extreme daily VMT requirements) can continue to do so. We also note that, as discussed further in RIA Chapter 2.11, while our modeled potential compliance pathway includes HD ZEVs, we also assessed several additional example potential compliance pathways that support the feasibility of the standards relative to the reference case without the use of HD ZEVs . Manufacturers may choose to follow one of the pathways evaluated by EPA or may choose their own compliance strategy to meet the standards and may do so without HD ZEVs. We further address the diversity of the HDV market in RTC 4.1.2.

There are currently 22 class 6-8 straight truck BEVs available from 13 different manufacturers through the California's Hybrid and Zero-Emission Truck and Bus Voucher Incentive Project (HVIP) program with battery ranges from 100-250 miles.[359] We expect additional models with ranges meeting or exceeding 200 miles to become available during the timeframe of our rule. A list of BEVs available through MY 2024 can be found in RIA Chapter 1.5.5.

Borg Warner suggested that the EPA underrepresented the number of ZEVs that would be present in the market during the timeframe of the rule. We are taking a balanced and measured approach to setting the final standards, which reflects consideration of the statutory and other relevant factors and uncertainties such as those concerning availability of infrastructure (distributive infrastructure buildout in particular). Compared to the proposed Phase 3 standards, in general, after further consideration of the lead times necessary for the standards (including both the vehicle development and the projected infrastructure needed to support the modeled potential compliance pathway that supports the feasibility of the standards), we are finalizing CO_2 emission standards for heavy-duty vehicles that, compared to the proposed standards, include less stringent standards for all vehicle categories in MYs 2027, 2028, 2029 and 2030 than those proposed. For further discussion on critical minerals, see Preamble Section II.D.2.ii and RTC section 17.2, and see RTC 7 (Distribution) and 7.1 for further discussion on infrastructure deployment. The standards we have set in MY2032 reflect EPA's consideration of Borg Warner's suggestion that we underrepresented LHD and MHD ZEVs in the modeled compliance pathway at proposal. Upon further analysis in HD TRUCS, we have found that the payback of LHD and MHD vehicles is quicker than projected in the proposal and have therefore increased standard stringency for the relevant subcategories to reflect that a more stringent standard is feasible at reasonable cost.

CALSTART commented that the availability and deployment of ZEVs has been increasing year over year and represents an increasing momentum in the deployment of ZEVs in the marketplace. They also commented that the performance of ZEVs has been increasing year over year and that the sales of ZEVs have been nationwide and not just in ACT states or MOU states. As discussed in the previous paragraph, we have tailored our phase-in approach of the final standards to allow for a more gradual ramp up compared to the proposed standards. See further responses regarding standard stringency in RTC 2.4. We appreciate the point CALSTART raised about truck manufacturers in the United States being part of global OEM groups which allows increased access to engineering and supply chain assets. Even though we expect OEM groups to share information and resources across their brands, we have no way of quantifying how this will affect the speed at which manufacturers will be able to produces ZEVs. Because of this, we have kept our analysis focused on inputs that are quantifiable in nature based on information received in comments on the proposal, research reviews, and stakeholder outreach.

MEMA commented that the order of vehicle electrification should be considered based on vehicle customization when setting the standards as well as the volume of each vehicle type and operating conditions. When setting standards for this rulemaking, we took a balanced and measured approach which considered the resources of manufacturers as well as infrastructure and decreased the level of the stringency of the standards in the early years of the Phase 3 program compared to the proposal, especially for the heavy heavy-duty vocational vehicles.

[359] https://californiahvip.org/vehicle-category/straight-truck/?size=247,261,230&t_type=378

Furthermore, as discussed in preamble Section II.F, we are not finalizing new emission standards for several of the optional custom chassis subcategories. This change allows more time for manufacturers to complete development of different ZEV models. . We set our standards based on best available data for inputs into HD TRUCS received from comments, literature review, and stakeholder outreach. We used a VMT weighted temperature distribution to represent miles traveled across the nation at different temperatures and modeled our vehicles accordingly rather than creating different standards based on zones of operation to create a cohesive program applied evenly across the country. We note further that a transitional flexibility introduced in Phase 3 allows compliance to be averaged across all of the HDV averaging sets, so that performance of the types of harder-to-optimize vocational vehicle applications can have their performance offset by any of the easier-to-optimize HDV applications.

4.1.2 Technology Readiness

Comments by Organizations

Organization: American Trucking Associations (ATA)

Performance is key to whether heavy-duty ZEVs meet a given duty cycle's range, performance, and battery capacity requirements. Drivers regularly run short and long-haul routes, often including regional and interstate journeys. For example, a carrier transporting perishable agricultural products to and from a West Coast port runs routes to inland destinations like Colorado, St. Louis, Reno, and California's Central Valley. This operation's range and battery performance needs differ significantly from shorter hauls primarily within ten miles of a point of origination. Battery weight is a crucial factor. A bulk agricultural hauler moving mixed commodities to and from a facility can easily come up against weight limits with added batteries. [EPA-HQ-OAR-2022-0985-1535-A1, p. 10]

In addition to range and battery capacity, other performance factors also play a role in heavy-duty ZEVs. Power output, acceleration, and overall vehicle performance are crucial to ensuring vehicles can meet the demands of their duty cycles, regardless of climate or topographical conditions. ZEVs must be capable of the same payload while climbing steep inclines, maintaining high speeds on highways, and handling challenging extreme temperatures in a way that compares favorably with ICEVs. [EPA-HQ-OAR-2022-0985-1535-A1, p. 10]

Organization: American Petroleum Institute (API)

d. Technical Feasibility

i. Vehicle readiness

1. Technology readiness

The proposed rule identified various HD ZEVs available in the marketplace or in production, as well as select manufacturer goals and commitments to producing HD ZEVs by a certain timeframe. However, given the nascent technology, there is significant uncertainty regarding EPA's expectation for rapid availability of ZEV powertrains. Further, it should be noted that these vehicles are small in number, some are not able to perform the work that a comparable

ICEV would perform (due to charging, range, and duty-cycle constraints), and all are for localized operations; long-haul ZEVs are in the pilot stage and have significant challenges. OEM goals and commitments, coupled with IRA/BIL funding may help to increase the availability of HD ZEVs; however, it will be extremely challenging to meet the proposal's implementation schedule. We have concerns that vehicles may not be available at the rates that EPA is projecting for the 2027-2032 timeframe. [EPA-HQ-OAR-2022-0985-1617-A1, p. 10.]

Even with a fully stocked HD ZEV market, key barriers to entry include customer uptake, capital costs to purchase vehicles, and infrastructure readiness. [EPA-HQ-OAR-2022-0985-1617-A1, p. 10.]

Organization: Daimler Trucks North America

EPA Request for Comment, Request #19: We request comment on our approach that focuses primarily on BEVs, which currently are more prevalent in the HD vehicle market, and whether there are additional vehicle types that should be evaluated as FCEVs along with BEVs.

- DTNA Response: DTNA agrees in principle with EPA's primary focus on BEVs at this time, as these vehicles are more prevalent in the market. EPA should not consider FCEVs until at least MY 2032, due to the current state of the technology and refueling infrastructure. EPA also should not project ZEV uptake for any vehicle types outside of the BEV and FCEV categories included in the Proposed Rule. [EPA-HQ-OAR-2022-0985-1555-A1, p. 161]

Organization: Manufacturers of Emission Controls Association (MECA)

Future BEV/FCEV Powertrain Efficiency Standards

Today, vehicle manufacturers are deploying the first generation of electric and fuel cell commercial vehicles. On the other hand, suppliers are already looking ahead and developing the next generation of advanced efficient powertrain components such as batteries, power electronics, transmissions, e-motors and integrated drive units. Technology innovation has strived for greater efficiency and power for the past 50 years of combustion engines and similarly, electric component suppliers continue to innovate electric technology. Some of these innovations will be revealed in the five funded projects under the DOE's SuperTruck III program. [EPA-HQ-OAR-2022-0985-1521-A1, pp. 12 - 13.]

As such, it is important that EPA begins to consider ways to incentivize and reward more efficient vehicles just as it has for combustion engine technology. In the light-duty sector, where EVs have been around for much longer, we are already seeing significant differences in the energy efficiency of similarly sized vehicles. This is a result of some manufacturers deploying more advanced technology and investing in efficient powertrain integration which reduces the impact on the environment across the vehicle life-cycle from manufacturing to recycling and disposal. [EPA-HQ-OAR-2022-0985-1521-A1, p. 13.]

EPA Summary and Response:

Summary:

Several commenters alleged ongoing technical difficulties in ZEV performance reflecting their views of the current state of the market ("nascent" in a commenter's terminology). For example, EPA received a comment from ATA that raised concerns about the performance characteristics of ZEVs; the performance characteristics included power, range, payload, battery weight, acceleration, gradeability, maintaining highway speeds, and performance in extreme temperature. API described uncertainties surrounding ZEV technology and that long-haul vehicles are in pilot stage. On the other hand, MECA expressed that the first generation of ZEVs have already been deployed, and they also believe there will be efficiency improvements and that it is important to incentivize more efficient vehicles.

Response:

Both EPA and manufacturers[360] themselves project that by 2027 vehicle applications of ZEV technologies will be significantly more mature and suitable for performing work compared to a comparable ICE vehicle. EPA's assessment includes consideration of comments on the proposed rule, meetings with stakeholders, and our analysis using HD TRUCS discussed in detail in RIA Chapter 2. See also comments from Tesla citing an EDF report on the "rapidly declining costs of ZEV trucks and buses".[361] HD TRUCS is designed precisely to allow for analysis of each of the 101 applications considered there and whether each application can perform comparable work to its ICE vehicle equivalent, as noted more fully in the following paragraph.

In the analysis conducted for this rulemaking, EPA found that commercial BEVs and FCEVs have similar performance and durability characteristics to ICE vehicles in most instances. In performing our analysis for the modeled compliance pathway, we benchmarked ICE vehicle performance characteristics such as vehicle activity, payload capacity, acceleration from 0-30 mph and 0-60 mph, gradeability, and peak power during the regulatory test cycles. This information was used to size BEVs and FCEVs to determine the suitability of each technology for different commercial vehicle applications. These calculations were performed in HD TRUCS and can be found in RIA Chapter 2.

We carefully undertook this assessment, and note that we did not find that ZEVs would be suitable for all HDV applications during the timeframe of the Phase 3 standards. Reasons for this for certain applications include prohibitively large battery sizes to do comparable work on a single charge, issues of diminished payload, and for those applications (and portions of applications) that it is relevant to, the ability to operate in extreme weather conditions. For vehicle types that we considered not suitable for ZEVs during the timeframe of the Phase 3 standards in our analysis, as described in more detail in preamble Section II and RIA Chapter 2, we do not project use of ZEVs in our modeled potential compliance pathway for the final rule.

Our modeled potential compliance pathway supporting the feasibility of the final standards thus includes a mix of technology to meet the final standards, including BEVs, FCEVs, and ICE

[360] See, e.g., Miller, Neil. Memorandum to the Docket EPA-HQ_OAR-2022-0985. "Stakeholder Meeting Log". March 2024 for a complete list of stakeholder meetings.

[361] EDF, New Study Finds Rapidly Declining Costs for Zero-Emitting Freight Trucks and Buses (Feb. 10, 2022) Available online: https://www.edf.org/media/new-study-finds-rapidly-declining-costs-zero-emitting-freight-trucks-and-buses

vehicles. With respect to projected ZEV suitability, generally, vehicles with shorter range and stop and go type of operation are most suited for depot-charged BEVs while vehicles with higher VMT and constant speeds are more suitable for en-route charged BEVs and FCEVs. Current ZEV market offerings meet many ICE baseline performance metrics, and through our analysis we predict that future models will continue to meet or exceed ICE performance metrics.

4.2 Upfront ZEV Cost

Comments by Organizations

Organization: American Council for an Energy-Efficient Economy (ACEEE)

Additionally, California's TCO assessment of six different vehicle types shows that, even before accounting for cost reductions that will likely come from the ZEV sales requirements in the states that have adopted ACT, BEVs and FCEVs will be cost-competitive with ICEVs as soon as 2025 thanks to the declining cost of batteries and fuel cell components.20 ACEEE supports EPA's consideration of ACF levels of ZEV penetration nation-wide to set appropriate targets in the final rule.

20 https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2022/acf22/appg.pdf

Organization: American Highway Users Alliance

Consistent with that recent testimony, ATA has advised the Highway Users that it estimates the cost of a new EV truck at $450,000, and the cost of a comparable new diesel truck at $165,000. [EPA-HQ-OAR-2022-0985-1550-A1, p. 7]

Further, for truck operators that finance the acquisition of a new EV, the added interest cost will be significant and a factor in whether to make a purchase (not to mention that such higher costs will then be passed on to consumers).

Consistent with the information from the American Trucking Associations, above, ATD stated that truck costs are much higher for a new Class 8 electric truck than for its diesel counterpart. Importantly, ATD noted that new tax incentives, if available for a model, would represent just a 'fraction' of the cost differential between an EV model and a diesel counterpart.

Organization: American Petroleum Institute (API)

2. ZEV penetration/customer uptake and adoption rates

HD ZEVs are currently not available in sufficient quantities or at affordable levels to significantly displace ICEVs. Further, the cost to purchase a ZEV is currently prohibitive – not only is the purchase price currently higher than that of an ICEV, some fleet owners and operators are finding that HD ZEVs result in more work or trips needed to accomplish the same task as with an ICEV. This is largely due to battery range and charging, but can also be affected by temperature, road grade, and other factors. A study by ATA noted vehicle and fleet owner concerns with regard to total cost of ownership, despite IRA and BIL funding.13 14 [EPA-HQ-OAR-2022-0985-1617-A1, p. 10.]

13 Advanced Clean Transportation (ACT) Expo 2023 Mainstage - Monday - 2023 State of Sustainable Fleets: https://vimeo.com/824774094.

14 Advanced Clean Transportation (ACT) Expo 2023 Keynote Address: https://vimeo.com/824772504.

Owners may choose to continue to use and extend the life of ICEVs, along with lower carbon fuels and/or other low carbon technologies, to avoid these issues. And at lower costs than those of ZEVs. [EPA-HQ-OAR-2022-0985-1617-A1, p. 10.]

3. Capital cost to purchase vehicles

The average cost of a HD tractor is about $180,000, while the electric version of the same vehicle can be nearly $400,000. Expending this additional capital for a vehicle that may not meet the duty-cycle, is significantly heavier (and thus reduces the payload of the vehicle), and may require additional vehicles to achieve the same job, creates massive challenges that may not be able to be overcome. [EPA-HQ-OAR-2022-0985-1617-A1, pp. 10 - 11.]

Organization: Banks, Ben

Electric trucks cost in excess of three times the amount we currently pay for a new Peterbilt day cab. Those additional expenses would be passed along in transportation expenses, astronomically impacting our already existing inflation issues related to supply chain constraints.

Organization: State of California et al. (2)

And similar patterns are observed in the supply chain for fuel-cell electric vehicles, an alternative vehicle technology that can be used to meet stringent GHG emission standards, especially for long-haul trucks.222 The technology for hydrogen-powered electric trucks is already available, with buy-in from industry,223 and costs associated with these vehicles are expected to fall.224 Moreover, businesses are investing in the manufacture of hydrogen to power these vehicles.225 [EPA-HQ-OAR-2022-0985-1588-A1, p.31]

Organization: Chevron

Chevron is concerned that the rapid increases in forecasted BEV sales rate are optimistic and may overstate the benefits of the proposals. The proposals may limit choices and increase costs for consumers, including those in economically disadvantaged groups and smaller businesses. A study by the American Transportation Research Institute (ATRI8) found zero tailpipe emission vehicle costs will be a strong barrier to entry and customer acceptance. While a new Class 8 diesel truck tractor may cost roughly $135,000 to $150,000, the purchase price of a new Class 8 BEV can be as much as $450,000. The same issue will likely impact the FCEV. Estimates for fuel cell truck costs range from $200,000 to $600,000 with 60 percent of the overall cost solely credited to the fuel cell propulsion system. [EPA-HQ-OAR-2022-0985-1552-A1,pp.6-7]

Organization: Lynden Incorporated

Electric trucks cost roughly three times as much as a diesel truck, the chargers themselves cost as much as a diesel truck and the electrical upgrades needed to power the chargers cost millions of dollars.

We are the leading bulk milk hauler in the Pacific Northwest, responsible for picking up 2 million gallons of milk per day on rural roads for dairy farms. Any disruption in reliability of service would be catastrophic to dairy farmers and the milk supply chain and any increase in operating costs will quite literally raise the price of a gallon of milk and other necessities for American families. [EPA-HQ-OAR-2022-0985-1470-A1, p. 3]

Similarly, we provide transportation for most of the food, medicine, and other essential goods that reach Alaskan communities, including rural and Native Alaskan communities. This will exacerbate the inflationary impact on food prices that we have seen in the last few years for the people who can afford it least. [EPA-HQ-OAR-2022-0985-1470-A1, p. 3]

Organization: NTEA - The Association for the Work Truck Industry

EPA NOx Rule

The EPA recently promulgated regulations that could add as much as $40,000 to the cost of a new truck. The regulations aim to further reduce NOx (nitrogen oxides) emissions from heavy duty engines. [EPA-HQ-OAR-2022-0985-1510-A1, p. 2]

Heavy duty truck emissions are already 98% cleaner than in 2010 and truck manufacturers are diligently working on the development of ZEV's (zero emission vehicles) that will eliminate tailpipe emissions. [EPA-HQ-OAR-2022-0985-1510-A1, p. 3]

Unintended Consequences

This proposal would once again increase the cost of a new truck. [EPA-HQ-OAR-2022-0985-1510-A1, p. 3]

As indicated, today's trucks that are already 98% cleaner than older trucks. Currently, more than 50% of the trucks operating are pre-2010. An old (pre-2010) truck emits some 30 times more emissions than today's engines. EPA should be incentivizing the sale of current trucks not making them more expensive and creating a disincentive to the replacement of old trucks. [EPA-HQ-OAR-2022-0985-1510-A1, p. 3]

Community Based Air Quality

Many localities that face significant air quality concerns are in and around areas of heavy truck traffic, such as ports, warehouses, terminals and urban areas. Because of the economic challenges in many of these places the trucks operating locally are often older. As mentioned, pre-2010 trucks emit significantly more tailpipe emissions than newer trucks. The best and fastest way to improve air quality in these areas is to replace the numerous older trucks with newer and cleaner ones. Unfortunately, regulations that make new trucks marginally cleaner but dramatically more expensive than existing post 2010 trucks will only serve to keep those much older (pre-2010) trucks in operation longer. [EPA-HQ-OAR-2022-0985-1510-A1, p. 3]

What is needed from these regulations are trucks that are affordable, durable and meet the customer's vocational needs. The regulations must not act as a financial barrier to cleaner trucks and ultimately ZEV's. Rather, federal regulations should focus on reducing the current high costs associated with new trucks and ZEV development while building the infrastructure needed to operate the next generation of work trucks. [EPA-HQ-OAR-2022-0985-1510-A1, p. 3]

Organization: Tesla, Inc. (Tesla)

Medium- and Heavy-Duty BEV Costs Are Rapidly Declining

Tesla agrees with the agency that the feasibility of BEV deployment in the medium and heavy-duty sector is more cost-competitive than ever.125 In addition to the marketplace announcements, regulatory environment, and federal fleet adoption driving significant electrification, cost-related issues will ensure that electrification of the heavy-duty sector occurs rapidly. As one analysis sums up, 'Electrification is also making inroads into heavier vehicles. In urban duty cycles, battery electric trucks of any size become the cheapest option for several use cases in the 2020s.'126 [EPA-HQ-OAR-2022-0985-1505-A1, p. 18]

125 88 Fed. Reg. at 25930.

126 BNEF, Electric Vehicle Outlook 2021 available at https://about.bnef.com/electric-vehicle-outlook/

Similarly, other studies find that when considering upfront purchase price alone, by 2027 electric freight trucks and buses will be less expensive than their combustion engine counterparts in almost all categories.127 As the agency finds, the new federal commercial vehicle purchase incentive enacted under the IRA – Section 45W – will further reduce upfront purchase costs up to $40,000 per vehicle.128 This incentive should drive down costs significantly more than many predicted. For example, Rhodium has modeled that by 2030, a modest 10% investment tax credit for medium- and heavy-duty BEVs and an excise tax exemption for such vehicles would drive BEVs to or below TCO parity with conventional vehicles in some smaller vehicle classes and reduce the gap in others.129 [EPA-HQ-OAR-2022-0985-1505-A1, p. 18]

127 EDF, New Study Finds Rapidly Declining Costs for Zero-Emitting Freight Trucks and Buses (Feb. 10, 2022) available at https://www.edf.org/media/new-study-finds-rapidly-declining-costs-zero-emitting-freight-trucks-and-buses

128 Id. at Section 13403.

129 Rhodium, Pathways to Build Back Better: Investing in Transportation Decarbonization (May 13, 2021) available at https://rhg.com/research/build-back-better-transportation/

Organization: Texas Public Policy Foundation (TPPF)

Electric trucks typically have a higher upfront purchase price compared to traditional diesel trucks. The HD Tailpipe Rule will effectively bar diesel trucks from sale, forcing trucking companies seeking to replace their fleet to take on more costs to do so. This will strain the financial resources of some companies, especially smaller ones. Shifting from diesel trucks to electric ones will also require adapting to new technologies and training drivers to effectively operate electric vehicles. This transition period will likely lead to disruptions in the supply chain and additional costs — both temporal and monetary — for trucking companies. [EPA-HQ-OAR-2022-0985-1488-A1, p. 5]

Finally, EPA should assess impacts to the national economy as a result of potentially accelerating ZEV freight transport that would cease to be reliable or functional outside of a geographically confined network of charging/fueling infrastructure and support systems. [EPA-HQ-OAR-2022-0985-1488-A1, p. 7]

Organization: Valero Energy Corporation

HD ZEVs are more expensive than their ICEV counterparts. The International Council on Clean Transportation's ("ICCT's") literature survey of purchase costs for zero-emission trucks found the cost to purchase new battery-electric tractor trucks ranged from $200,000 to $800,000, and similarly, the cost of new hydrogen fuel cell trucks ranged from $200,000 to $600,000.117,118 Even considering tax credits established under the Inflation Reduction Act for new commercial vehicles (26 U.S.C. 45W), there is still a significant cost difference between ICEV and their ZEV counterparts.

In addition, vehicle costs are often too high for the HD payback period (the length of time required for an investment to recover its upfront costs).119 Battery packs for HDVs must be specifically suited for high lifetime mileage, deeper discharges per cycle, overall ruggedness, resistance to temperature extremes, and for production at low sales volumes. These characteristics push costs for HDV battery packs toward the uppermost end of cost-range. The relatively high daily range needed by commercial vehicles results in battery costs that drive vehicle incremental costs as high as 50%–100% of the price of a conventional truck.120 [EPA-HQ-OAR-2022-0985-1566-A2, pp. 25 - 26.]

117 ICCT Working Paper 2022-09, A Meta-Study of Purchase Costs for Zero-Emission Trucks, at 4 (February 2022) https://theicct.org/publication/purchase-cost-ze-trucks-feb22/.

118 Per CARB's own estimate, final capital costs for a hydrogen fuel cell Class 8, day cab tractor used in regional operation were $629,189 in 2018 compared with $134,000 for an analogous diesel vehicle. In 2024, CARB estimates that a hydrogen fuel cell tractor truck will cost $431,480 compared to $144,101 for a new diesel tractor. CARB, Appendix H: Draft Advanced Clean Trucks Total Cost of Ownership Discussion Document at 1 (October 22, 2019) https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2019/act2019/apph.pdf. Consistent with CARB's estimates, the ICCT recently forecast that composition costs for a hydrogen fuel cell tractor-truck in 2025 will exceed $400,000. CARB has also recognized that operating costs for a regional-hydrogen tractor in 2024 will exceed those for tractor trucks powered by diesel or battery electric. Sharpe, Ben & Basama, Hussein, ICCT Working Paper 2022-09, "A meta-study of purchase costs for zero-emission trucks" at 12 (February 2022), https://theicct.org/wp-content/uploads/2022/02/purchase-cost-ze-trucks-feb22-1.pdf.

Organization: Westport Fuel Systems

The EPA has asked for comments on the incremental vehicle cost and IRA incentives

The cost of compliance in the Phase 3 Rule is estimated at $6 billion for manufacturers after accounting for an estimated $3 billion from battery tax credits from the Inflation Reduction Act (IRA). Given the state of technologies in the heavy-duty class 8 sleeper cab segment, the incentives listed at in the IRA at $40,000 per "qualifying" ZEVs such as BEVs and FCEVs are not significant enough to warrant purchasing and will require matching funds from other jurisdictions. The incremental costs7 are suggested to be on average $15,0008 (including the IRA Advanced Manufacturing and Production Credit and the Qualified Commercial Clean Vehicle Credit) more for a ZEV MY 2032 sleeper cab compared to a conventional vehicle. These costs are expected to be recouped over 7 years or less in operational cost savings. Given the current costs of fuel cell vehicles in the class 8 category, these estimates seem at face value to be underestimated. Even if this figure is accurate, that leaves 75% of the market requiring alternative technology and fuel solutions (RNG, H2 combustion) or continue to operate diesel vehicles powered by ICE engines. [EPA-HQ-OAR-2022-0985-1567-A1, p. 11]

7 See Phase 3 Rule, page 25998 – Incremental costs include 2 IRA incentives, lower operating costs and calculated payback period

8 Proposed Standards to Reduce Greenhouse Gas Emissions from Heavy-Duty Vehicles for Model Year 2027 and Beyond - Regulatory Announcement (EPA-420-F-23-011, April 2023)

The average incremental cost listed in the table below is very ambitious compared to current market pricing and payback periods. For comparison, the estimated cost of an H2 HPDI powered vehicle is likely to be closer to that of an LNG powered vehicle, which will have additional costs for fuel storage, compared to diesel vehicles. Current pricing for lighter duty FCEVs is orders of magnitude higher. [EPA-HQ-OAR-2022-0985-1567-A1, p. 11.] [See Docket Number EPA-HQ-OAR-2022-0985-1567-A1, page 11, for Table 3.]

EPA Summary and Response:

Summary:

EPA received comments from multiple stakeholders that were concerned that the initial purchase price of a ZEV was too high relative to its ICE counterpart to be economically feasible, regardless of payback period (AHUA, API, Ben Banks, Chevron, Lynden Inc., NTEA, Valero, TPPF). Various commenters pointed to large difference in current ZEV tractor prices versus the price of a comparable diesel vehicle. EPA received a comment from API that raised concerns about an additional cost for multiple trucks to make up for the payload loss due to battery weight in BEVs. EPA received comments from AHUA and Valero that the current tax incentives are not high enough to make up for the increase in initial purchase price from an ICEV to a ZEV (plus comments from many other entities, including EMA, that the federal excise tax would offset those IRA savings). AHUA also commented that any interest payments made on ZEVs would be much higher than for ICEVs due to the increased upfront cost. Lynden Inc. commented that the cost of upgrading infrastructure and the cost of battery chargers was too high to be economical. We received comments from Tesla saying that most freight trucks and buses would reach cost parity with ICEVs by 2027.[362] Tesla also cited a paper from Rhodium group that stated a 10% tax credit and excise tax exemption for BEVs would drive BEV TCO to parity with ICEVs in smaller vehicle classes and reduce the gap in others. ACEEE cited California's TCO assessment of six different vehicle types that they will be cost-competitive with ICE vehicles as soon as 2025 due to declining battery and fuel cell costs. Ben Banks commented that additional expenses for upfront purchase price would be passed on to consumers and impact inflation. TPPF and Chevron raised concerns about the impact of high initial purchase price on small companies, the cost of training drivers, as well as the impact of the rule on the national economy due to infrastructure concerns. NTEA commented that the increased cost of new trucks would decrease customer acceptance and slow fleet turnover keeping older higher emitting trucks on the road. They stated that this, in turn, would cause EJ concerns as these higher emitting trucks would remain in service rather than be replaced by cleaner vehicles.

Response:

First, the commenters sometimes conflate the separate issues of purchaser price and the various components of purchaser costs. In assessing payback in our modeled potential compliance pathway for both the proposal and the final rule (as well as TCO in the final rule), we consider cost to the purchaser, not merely the vehicle price. See RIA Chapters 2.7, 2.9 and 2.12. Purchaser price is generally equivalent to the upfront cost of the vehicle in our analysis; however, as we explain in preamble Section V we do not attempt to estimate how manufacturers will price their products. Purchaser costs in our analysis include that upfront vehicle cost as well as other upfront costs (e.g., EVSE upfront costs) and operating costs, which we analyze both in our HD TRUCS analysis (see RIA Chapter 2 for a full discussion) and for our program costs analysis (see RIA Chapter 3 for a full discussion). In RIA Chapter 2.7 and 2.12, we assessed payback and total cost of ownership with regard to such purchaser costs. We project the ZEV upfront vehicle purchaser cost to be similar to or lower than the price of comparable ICE vehicles for some vehicle types. See, e.g., RIA Chapter 2.9.2. See also various studies cited by

---

[362] EDF, New Study Finds Rapidly Declining Costs for Zero-Emitting Freight Trucks and Buses (Feb. 10, 2022) Available at: https://www.edf.org/media/new-study-finds-rapidly-declining-costs-zero-emitting-freight-trucks-and-buses

EDF (summarized in RTC 2.4) projecting price parity for many HDV ZEV applications, in some cases, before Phase 3 even commences. Additionally, the upfront cost to a purchaser for many BEVs under the modeled potential compliance pathway would also include supporting depot charging infrastructure, namely the cost to purchase and install EVSE. Purchaser costs for ZEVs also include consideration of other operating costs. We also included consideration of tax credits, as applicable within these various purchaser costs.

Part of the basis for these commenters' assertions is pricing, but they are quoting current HD ZEV prices, which reflect the prices of primarily initial model years of HD ZEV vehicles. Some commenters document persuasively that these prices (in our analysis, in RIA Chapter 2, manufacturer costs and then correspondingly purchaser upfront vehicle costs) will come down sharply when production volumes increase and later iterations of ZEVs reflecting learning reach the market in the rule's time frame. The costs that we have used in the proposal and updated for the final rule analysis come from assessing the best projections currently available including DOE values as well as values received in comments from manufacturers and manufacturer trade organizations. See RIA Chapter 2.7 and Preamble Section II.E.6 for further discussion on payback and payback calculations used in the final rule. Also see RTC Section 19.5 for additional discussion on purchaser acceptance.

The commenters' assertion that higher purchase "price" (Valero, API, Chevron) and therefore interest payments (AHUA) of vehicles would by themselves dissuade purchases regardless of payback is not borne out in the literature. Similarly, Chevron raised concerns about the impact of high initial purchase price on small companies. In response to comments received on the proposal, we included financing costs as part of our TCO analysis to reflect that not all vehicles are purchased outright. See RIA Chapter 2.12. The results of our analysis show that costs for owning and operating a ZEV will be lower than a comparable ICE vehicle for all MY 2032 BEVs and FCEVs in our technology packages to support the modeled potential compliance pathway. In fact, all vehicles show several thousands of dollars in net TCO savings at the five-year point. As EPA has explained in this rulemaking and in previous rulemakings, even where initial purchase cost is higher, overall purchaser costs can be considered as non-constraining or supportive when those costs are recovered in a reasonable amount of time. See generally, 81 FR at 73621-22 (Phase 2 tractor standards) and 73719 (Phase 2 vocational vehicle standards). Long term payback or savings within the period of first ownership, and positive TCO in that period, can lead to decisions to purchase, which was also emphasized in many of the public comments. See Comments of ACEEE and Tesla as well as RIA Chapters 2.7 and 2.12.

The comment that some HD ZEVs will be less effective due to limited range and payload also reflects current (pre-2024) conditions for some vehicles. This is not reflective of the state of technology reasonably projected by EPA (and reflected in some manufacturers' comments) during the rule's timeframe. See, e.g., Tesla's comments that it has already introduced a tractor with a 500 mile range. See EPA-HQ-OAR-2022-0985-1505-A1, p.6. We analyze issues of payload capacity (see RIA Chapter 2.9.1 and RTC 4.3.2) and range (see RTC 4.3 below) during the rule's timeframe and find that most vehicles in HD TRUCS would incur a payload loss of less than 10% as shown in RIA Chapter 2.9.1.1 and that the vehicle types analyzed have a battery sized to perform one day's worth of work as detailed in RTC 4.3 below. See also our response to comments on payload in RTC section 3.10.1.

With respect to financial incentives in the IRA, EPA does not maintain that these offset all differences for all vehicle types in purchaser upfront cost, or overall costs. But they certainly partially defray those costs in instances where they do not offset all differences. As described in RIA Chapters 2.4.3.5, 2.5.2.3, and 2.6.2.1.2 EPA has appropriately considered that purchasers will make use of these incentives as applicable, (see also RIA Chapter 2.4.3.1 regarding battery costs and associated IRA tax credit for manufacturers). Therefore, our manufacturer and purchaser cost analyses, including payback analysis, for the modeled potential compliance pathway, reflect some utilization of the applicable tax credits. See RTC 2.7 and sources there cited.

With respect to federal excise tax, as explained in RIA Chapters 2.4 and 2.5, the final rule accounts for federal excise tax and state taxes in our costs analysis and continues to find payback and significant operational savings under the modeled potential compliance pathway.

With respect to whether the upfront purchase price would be passed by HD vehicle purchasers onto consumers, the final rule does not regulate how and whether any specific fleet operator passes costs to consumers. However, given the assessment of payback and operational savings, we expect that the rule will reduce the economic costs of HD vehicle fleets and the work they perform, such as the cost to transport goods via truck.

NTEA commented with respect to the possibility of delayed purchase of vehicles that comply with the standards due to their higher cost relative to owners continuing to use a current vehicle. As discussed in RIA Chapter 6.1.1, this is referred to as “low-buy,” a scenario in which there would be a decrease in HD vehicle sales after the regulation becomes effective. In a low-buy scenario, sales of HD vehicles would decrease in the months after the regulation becomes effective, compared to what would have happened in the absence of the regulation, due to purchasers either pre-buying or delaying a planned purchase. We expect low-buy, to the extent it might occur, to be mitigated under the same circumstances discussed in RIA Chapter. 6.1.1, including our payback analysis which shows that any increases in upfront incremental costs to purchasers will be offset through operational savings in relatively short periods of time (within a few years of ownership, and within the period of first ownership). We also note that low-buy, were it to occur, is a short-term phenomenon. With respect to possible purchaser anxiety over being unable to purchase an ICE vehicle after promulgation of the regulation, we note that these final standards do not mandate the production or purchase of any particular technology in vehicles, but rather require that the manufacturer comply with performance-based emission standards. As described in Preamble Section II.F, we modelled a potential compliance pathway to meet the standards with a diverse mix of ICE vehicle and ZEV technologies, and also assessed additional example potential compliance pathways to meet the standards that do not include increasing utilization of ZEV technologies relative to the reference case. In addition, the phasing-in of the standards will allow ample time for purchasers to make decisions about their vehicle of choice and the potential compliance pathway modeled for this rule reflects that the majority of vehicles will remain ICE vehicles, even in MY 2032. See further discussion in the preamble for the final rule.

EPA expects the costs of driver training for BEVs to be minimal because for the most part driving a BEV is very similar to driving an ICE vehicle. The driving methods that help improve the efficiency of ICE vehicles are the same as the driving methods to extend range of a BEV. The difference is in the refueling process, but recharging vehicles is conducted successfully by millions of EV drivers daily. Furthermore, the BEV driver benefits from quieter driving conditions, which should reduce driver fatigue. We also noted the persuasive comments of the Clean Air Task Force (pp. 71-72) documenting positive driver response to HD BEVs:

"ZEVs have many additional attributes that appeal to drivers and operators. RMI has recognized that "[a] truck is also an office," explaining that "[t]he operator has to be happy being in the cab, or else they just quit. Driver retention is a huge problem in trucking." But research by RMI and NACFE has made clear that "drivers love electric trucks." NACFE research sponsored by PepsiCo, Cummins, and Shell found that electric trucks are quieter ("no need to crank up the radio and drivers can hear what's going on around them"); offer better visibility and cleaner, simpler operation; have smoother torque; have superior air conditioning; and "d]riving in traffic seems easier and safer" Members of the trucking industry have made the following positive comments about HD ZEV operation:

- "They don't vibrate, they don't smell, they accelerate properly, so you're not constantly the slow one in traffic off a red light. Drivers don't come home at the end of the day and feel exhausted or feel like they've been operating a jackhammer for the past eight hours."
- "The truck is so quiet, everything is smooth. It gives you time to focus on what's going on around you. With the diesel trucks there's rattling, there's driver fatigue, things you don't even know are going on. But as soon as I got in the electric truck, I realized this is the way of the future."
- "EVs won't tow your boat? This beast will actually tow a bloody big boat, and a gross load of up 44 tonnes. And it will do so with ease. It will also do it in relative silence, with no crunching of gears, no loud braking, and no emissions . . . . These huge machines are remarkably simple to drive. First of all, they are quiet. If you are outside, the noise reduction is 50 per cent [sic]. If you are inside, the noise reduction is nearly one-third. That means a lot for the community, and for the well-being and working conditions of the driver."
- "I've had a positive experience and enjoyed driving the truck. It's a whole different experience and it's a step up . . . . Driving the electric truck is smooth, quiet and it doesn't shift, so it's smooth from the take off . . . . The only noise you hear is the little whine from the motors, the tires rolling down the road and your radio. You kind of get used to it after a while and have to get back in the diesel to really notice the difference again . . . . You're helping the environment and the electric is definitely smoother and quicker.
- "The guys love it, because it's like a Tesla. The truck is quiet."
- "I can't help but think that EVs may be a great way to attract the next generation of both drivers and technicians. The fact that EVs are 'clean' is a big plus; the fact that they are 'cool' might just be the boost we need to put the driver and technician shortages to bed."

(Citations omitted)

Comments concerning vehicle and upstream emissions are addressed in RTC 17.1 and Preamble Section II.G.

4.3 Range

4.3.1 General EV Range

Comments by Organizations

Organization: American Council for an Energy-Efficient Economy (ACEEE)

To demonstrate that ACF is realistically achievable, California uses findings from their one-time fleet reporting requirement for ACT to highlight that most fleets of MDVs and HDVs can be serviced by ZEV models on the market today.18 The Initial Statement of Reasons (ISOR) issued by the Air Resources Board for the ACF regulation finds that the majority of trucks operating in California drive, on average, less than 100 miles a day and most of the ZEVs available today have batteries and energy storage systems big enough to satisfy those driving requirements.19 [EPA-HQ-OAR-2022-0985-1560-A1, pp. 6 - 7]

Organization: American Highway Users Alliance

Vehicle range is short. Vehicle range for one EV was reported at 150 miles, compared to 1,000 miles and up for a diesel vehicle; the shortage of public charging for EVs and other alternate fueled vehicles was also cited. [EPA-HQ-OAR-2022-0985-1550-A1, p. 7]

Organization: American Trucking Associations (ATA)

One truck leasing and rental company we spoke with noted that some light-duty commercial products are available for operations needing only 100 miles of range, but significantly fewer in heavier weight class applications requiring 200 miles or more. OEMs are currently developing and testing medium- and heavy-duty vehicles under varying specifications; however, options remain limited. For example, the introduction of electric power take-off systems is a recently available technology that utilizes an electric motor to power auxiliary equipment. [EPA-HQ-OAR-2022-0985-1535-A1, p. 8]

Organization: Banks, Ben

Most of the freight we haul is international intermodal, with gross weight ranging from 70,000 to 90,000. With current electric truck capacity, we would have a service radius of 125 miles vs. a current radius of 250+ miles. Additional relay points would be required, and with the 50% reduction in service radius, we would need twice the number of trucks to service lanes that exist today.

Organization: Lynden Incorporated

An electric truck's range is 1/5th that of a diesel truck. This means additional fueling stops, additional driver time, and in many cases, additional trucks to do the job that a single diesel truck can do.

Even if the trucks were operationally feasible, they are not economically viable.

- Even with generous state and federal subsidies, our analysis shows an increase in operating costs of between $1 and $4 per mile with an electric truck. [EPA-HQ-OAR-2022-0985-1470-A1, p. 3]

The additional cost associated with the capital investment, loss of payload, reduced range, and increased labor costs far exceeds any fuel savings that might be achieved with electric trucks, even with significant subsidies and especially for rural communities. These additional costs will be passed down to the consumer in the cost of delivered freight which will have a significant damaging inflationary impact on our customers, small businesses, individuals, and the overall economy. [EPA-HQ-OAR-2022-0985-1470-A1, p. 3]

Recommendations:

- Consider the additional weight of emission reduction options and associated impact on payload on overall emissions. In other words, trucks that weigh more haul less freight and must make additional trips producing additional emissions to accomplish the job.
- Create exemptions for applications where ‘Zero-Emission Vehicles’ are not feasible, including extreme cold or hot weather, long-range routes, gravel roads, steep grade, rural communities, and high-horsepower heavy-haul applications. [EPA-HQ-OAR-2022-0985-1470-A1, p. 5]

Organization: Valero Energy Corporation

Current BEV technology is not suitable for long-haul trucks. Considering the present lithium-ion battery technology, to achieve a range of 600 miles, a battery pack on a long-haul truck would need to store 1,200 kilowatt-hours (kWh) of energy, weigh 6,300 kilograms (13,900 pounds), have a volume of 2,700 liters (95 cubic feet), and cost about $180,000.107 [EPA-HQ-OAR-2022-0985-1566-A2, p. 24]

107 Assumes a battery pack energy density of 170 Wh/kg. Burke, Andrew, Assessment of Requirements, Costs, and Benefits of Providing Charging Facilities for Battery-Electric Heavy-Duty Trucks at Safety Roadside Rest Areas: A Research Report from the National Center for Sustainable Transportation, at page I (Feb. 2022) https://ncst.ucdavis.edu/research-product/assessment-requirements-costs-and-benefits-providing-charging-facilities-battery.

At a range of 150 miles, a long-haul BEV truck would need to stop three times to recharge over a 600-mile day. Even if a network of 350-kilowatt (kW) fast-chargers was widely available, charging time would reduce a driver’s effective work day by over 2 hours, further requiring an increase in the number of trucks to maintain the pace and demand of freight services.109 [EPA-HQ-OAR-2022-0985-1566-A2, p. 24]

109 Based on the Volvo Class 8 Box truck, having a range of 150 miles and an energy capacity of 1.75 kWh/mi. Id at 3.

B. EPA has failed to adequately address critical on-road implications of requiring heavy-duty trucks to be zero emission.

EPA fails to adequately address critical on-road implications of the proposed rule, including the impact of decreased payload capacity and decreased range resulting in a significant increase in the number of trucks on the road, increased road wear and congestion, and the increased risk of crash-related fatalities to the motoring public. [EPA-HQ-OAR-2022-0985-1566-A2, pp. 30 - 31]

1. EPA fails to address the impact of HD ZEV's lower payload capacities and decreased range resulting in a significant increase in the number of heavy-duty trucks on U.S. roadways.

As described in the Biden-Harris Administration Trucking Action Plan to Strengthen America's Trucking Workforce, 72 percent of goods in the U.S. are moved by truck, placing the industry at the center of critical supply chains and economic competitiveness.150 Heavy duty trucks are used in a wide variety of applications across the US economy, many of which operate on multi shift schedules and/or 24-7 operations. While today's fleet of heavy-duty vehicles can fuel up in as little as 15 minutes and can achieve as much as 1,200 miles on a single fueling event, current HD BEVs have a typical range of 150 to 380 miles, with the very largest battery systems touting 500-mile ranges, however these systems require 10 or more hours to recharge before being able to re-engage in the business of hauling freight.151 Moreover, the batteries powering HD-BEVs typically weigh 8,000 pounds per battery pack, with a typical configuration requiring at least two, if not four, packs to achieve the 150 to 380 mile ranges indicated above.152 Actual drive time aside, the reduced range coupled with the exorbitant recharge time required, results in an HD BEV requiring additional transit time of 3.3 to 1.3 days, depending on range, to cover the same 1,200 miles achieved in only 15 minute of refueling in an ICE heavy-duty truck. [EPA-HQ-OAR-2022-0985-1566-A2, p. 31]

150 The Biden-Harris Administration Trucking Plan to Strengthen America's Trucking Workforce, The White House (Dec. 16, 2021)

151 Verbal testimony of Andrew Boyle before the Unites States Senate Committee on Environment and Public Works Subcommittee on Clean Air, Climate, and Nuclear Safety, Hearing on "Cleaner Vehicles: Good for Consumers and Public Health", April 18, 2023

152 Id.

HD BEVs' decreased range (increased transit time due to charging) coupled with the decreased cargo capacity will result in significant increases (3:2 or even 2:1 increases154) in the number of HDVs required to be on the road to haul the same quantity of cargo, weakening our critical supply chains and economic competitiveness. The increase in number of trucks will burden the U.S. roadways and increase risks to all road users, including the commuting public who transit the nation's highways in LDVs. [EPA-HQ-OAR-2022-0985-1566-A2, pp. 31 - 32]

Organization: Zero Emission Transportation Association (ZETA)

A common misconception is that range anxiety continues to pose a significant barrier to adoption across all vehicle classes. This concern is particularly acute for HDEV operators, as the average MHDV travels over 100 miles per day.117 Likewise, trucks with the longest routes drive a maximum of 600 miles but average closer to 300 miles per day.118 Figure 6 provides the average range of various vehicle classes; as many EV models have a similar range, the MHDV models currently available can meet up to 60% of operational needs.119 Trucks capable of traveling longer distances (370 miles) are being produced today and those with ranges greater than 620 miles are expected after 2023.120 [EPA-HQ-OAR-2022-0985-2429-A1, p. 28.] [See Docket Number EPA-HQ-OAR-2022-0985-2429-A1, page 28, for Figure 6]

120 How Zero-Emission Heavy-Duty Trucks Can Be Part of the Climate Solution," CALSTART, (May 2021) https://calstart.org/wp-content/uploads/2021/05/How-Zero-Emission-Heavy-Duty-Trucks-Can-Be-Part-of-the-Climate-Solution.pdf

EPA Summary and Response:

Summary:

EPA received many comments about the range of electric vehicles. Two commenters expressed support for the ranges of current vehicles and the ability of current BEVs to meet the majority of operational needs: ACEEE commented that the average VMT in California is just over 100 miles, and that this mileage can be met by currently available BEVs. They also commented that the market for BEVs will only improve over time with additional models and more options for range. ZETA commented that the average MHDV travels over 100 miles per day and current BEVs can meet 60% of operational needs, and that BEVs with 370 miles of range already exist and BEVs with ranges in excess of 620 miles are expected after 2023.

EPA received comments from multiple stakeholders expressing concern about the range of current HD BEVs and how the range of these current BEV applications fail to match the range of corresponding ICEVs (AHUA, ATA, API, Chevron, Ben Banks, Lynden Inc, SD DANR, and Valero). AHUA raised a concern that range for one EV was reported at 150 miles when compared to a comparable diesel vehicle with a range of 1,000 miles. ATA was concerned about the availability of different models with 200 miles of range. API was concerned about additional trips or more work required due to limited battery range and long charging times which can be affected by ambient temperature and road grade among other factors. Chevron was concerned about the increased downtime for electric vehicles due to battery charging which is caused by limited range. They were also concerned about the effect of cold ambient temperatures having a negative impact on the rate of charge and vehicle range. They also stated that these factors contribute to reduced efficiency in the trucking industry requiring additional trucks, drivers, and trips to deliver the same amount of freight.

Ben Banks was concerned that current electric trucks would halve his service radius from 250+ miles to 125 miles and this would lead to double the relay points and double the number of trucks to continue their current operations. Lynden Inc. and Valero were concerned that the range of an electric truck range is significantly less than that of a comparable diesel truck which would require additional fueling stops, driver time, and additional trucks to complete the same amount of work as a diesel truck. The South Dakota Department of Agriculture and Natural Resources was also concerned with the range of electric trucks. They cited an unnamed study that purported EVs consistently do not achieve EPA range estimates. They also cited an unnamed report that claimed EV batteries will degrade between 10 and 40 percent over 10 years which leads to depth of discharge limitations further decreasing battery range. They expressed further concern over the effect of ambient weather conditions saying vehicle range can be reduced between 20 and 40 percent as well as reduce the reliability of EVs.

Response:

EPA appreciates the additional sources provided by ACEEE and ZETA on daily VMT that support that, even today, several vehicle applications are suitable for BEVs based on VMT and available models and that the operating range of the most recently released HD BEVs is higher than previous models.

EPA appreciates the comments that raised concern about the range of BEVs and the effects this could have on the trucking industry. We note that many of these comments referenced pre-2024 models which are not reflective of projected (and more recent) HDV applications. We note as well that the comments assume depot charging in all cases, reflecting EPA's proposal; however, in response to consideration of comments, as described in RIA Chapter 2, EPA is now including consideration of en route charging for certain applications with the highest daily VMT in the HD TRUCS analysis. In the analysis performed for this rulemaking on the payback of BEVs, for the majority of the vehicles, we sized the battery to meet the 90th percentile daily VMT. Further discussion on the 90th percentile VMT can be found in RIA Chapter 2.2.1.2.2. and Section 3.3.1 of the RTC. Battery sizing also accounts for the depth of discharge as well as battery degradation through the number of cycles each battery will see over 10 years (see Section 3 of the RTC responding to the issue of how our cycling metric reasonably accounts for battery degradation without needing battery replacement under the HD TRUCS analysis.)

For the longest range day cabs and sleeper cabs that are assessed using public charging, on days when these vehicles are required to travel longer distances, we find that less than 30 minutes of mid-day charging at 1 MW is sufficient to meet the HD TRUCS 90th percentile VMT assuming vehicles start the day with a full battery. For further discussion on en-route charging, see RIA Chapter 2.6.3 and Section 3.4.3 of the RTC. For further discussion on slip seating see our response in section 4.3.3 below.

Since issuance of the NPRM, EPA has completed further analysis on the effects of payload caused by a change in powertrain weight between a BEV and ICE vehicle.[363] This analysis was undertaken to show that under the modeled potential compliance pathway impacts on payload are minimal and will not require additional trips for a BEV to complete the same amount of work as ICE vehicles. For a comprehensive discussion on this topic see RIA Chapter 2.9.1.1.

We address comments regarding the effects of ambient weather conditions in section 4.3.2 below.

[363] See Landgraf, Michael. Memorandum to docket EPA-HQ-OAR-2022-0985. "HD GHG Phase 3 Rule BEV Payload Analysis". February 29, 2024.

4.3.2 Effects of Ambient Temperature on Range

Comments by Organizations

Organization: American Petroleum Institute (API)

HD ZEVs are currently not available in sufficient quantities or at affordable levels to significantly displace ICEVs. Further, the cost to purchase a ZEV is currently prohibitive – not only is the purchase price currently higher than that of an ICEV, some fleet owners and operators are finding that HD ZEVs result in more work or trips needed to accomplish the same task as with an ICEV. This is largely due to battery range and charging, but can also be affected by temperature, road grade, and other factors. A study by ATA noted vehicle and fleet owner concerns with regard to total cost of ownership, despite IRA and BIL funding.13 14 [EPA-HQ-OAR-2022-0985-1617-A1, p. 10.]

Organization: Chevron

Trucking utilization is also affected by the increased downtime required for recharging battery electric vehicles. A BEV truck may be idle for several hours while recharging the batteries and may have to recharge more frequently due to range limitations. Cold ambient temperatures can also affect the rate of charge and available range. All of these factors will have a negative impact on efficiency, requiring more trucks, drivers, and trips to deliver the same quantity of cargo. [EPA-HQ-OAR-2022-0985-1552-A1, p.5]

Organization: Lynden Incorporated

Lynden operates in some of the harshest conditions in Alaska and the Pacific Northwest where reliability is a safety issue for both drivers and customers who depend on delivery of critical goods and services. [EPA-HQ-OAR-2022-0985-1470-A1, p. 2]

For example, a routine Lynden route between Fairbanks and Prudhoe Bay, Alaska traverses the Dalton Highway: a 414-mile-long treacherous, mostly gravel road, with grades of more than 12%, limited resources and only three fuel stops. A truck running out of battery in minus 50 degrees Fahrenheit on this route is not an option. The extreme temperatures combined with auxiliary heating needs, would reduce the range by at least 30%2, increase charging time, and diminish battery life3. To provide electric charging facilities in these remote, off-grid conditions would prove completely unrealistic and would require diesel generators to produce the electricity – a process that is far less efficient than a diesel-powered truck. [EPA-HQ-OAR-2022-0985-1470-A1, p. 2]

3 Extreme temperatures affect Electric Truck Batteries. (April 2019). https://www.ttnews.com/articles/extreme-temps-affect-electric-truck-batteries

Organization: Morales, Jorge

How will these EVs retain charge in extreme climate States or when traveling through multiple different climates on one trip? Have you ever used a battery charged device in the extreme cold winter of North Dakota or Minnesota? Or tried to start anything outside when there is a Polar Vortex reaching through the entire Midwest? It's quite challenging for batteries to retain charge during extreme cold or heat. When that happens, how will Evs allow people to get to work? Sounds like people living paycheck to paycheck will no longer have the means to reliably get to work if they don't have access to a garage. I understand its not requiring people in the blink of an eye to purchase EVs, however these are the unintended consequences and the concerns that are not being addressed while EPA/individual States/certain political administrations push a hot button item to "look good". [EPA-HQ-OAR-2022-0985-1691.html, p. 1]

Organization: National Association of Convenience Stores (NACS), NATSO, and SIGMA

Further, ambient temperatures can influence the battery performance of electric vehicles. In northern states, fleets that operate in cold weather conditions will have to account for slowed chemical and physical reactions in truck batteries, leading to significantly longer charging times and a temporary reduction in range.13 [EPA-HQ-OAR-2022-0985-1603-A1, p. 6]

13 See AMERICAN TRANSPORTATION RESEARCH INSTITUTE, 'Understanding the CO2 Impacts of Zero-Emission Trucks,' (May 3, 2022) available at https://truckingresearch.org/2022/05/understanding-the-co2-impacts-of-zero-emission-trucks/. Evs lose significant range in cold weather and Consumer Reports has found that driving short trips with frequent stops in cold weather can reduce EV range by as much as 50 percent. See also Jeff S. Bartlett and Gabe Shenhar, Consumer Reports, 'How Temperature Affects Electric Vehicle Range' (Aug. 22, 2022) available at https://www.consumerreports.org/cars/hybrids-evs/how-temperature-affects-electric-vehicle-range-a4873569949/.

Organization: South Dakota Department of Agriculture and Natural Resources (DANR)

Electric Vehicle Battery and Range Limitations

South Dakota is a large state with significant driving distance between many of our communities. Although several new electrical vehicles indicate they have a 200 mile or greater range (note – it is 224 miles one way from Pierre to Sioux Falls), a recent study shows electric vehicles (Evs) do not consistently achieve EPA' s range estimates. In addition, all batteries degrade over time. Reports indicate EV vehicle batteries will degrade between 10 and 40 percent over a 10-year life span. To maintain the battery's life, manufactures recommend batteries are not frequently depleted below 10 percent capacity or charged above 90 percent capacity. This means that an electrical vehicle should be limited to 80 percent of its capacity range to maintain the battery's life. In addition, cold, hot, and windy weather conditions may reduce an EV vehicle's range between 20 to 40 percent and may further impact the reliability of EV. South Dakota is known to have cold and windy winters and hot and windy summers, which, with current EV ranges, batteries conditions, and availability of charging stations, makes widespread use of EV s impractical in South Dakota. [EPA-HQ-OAR-2022-0985-1639-A2, p. 2]

Public Safety

This past year South Dakota had a long, harsh winter. During the previous two winters the South Dakota Department of Transportation (DOT) maintenance crews covered about 1.4 million miles and used about 540,000 gallons of diesel fuel. This past winter, DOT totaled 3.2 million miles, used about one million gallons of fuel, and clocked approximately 178,000 man-hours to keep our roads safe. DANR is concerned the proposed emissions standards and push to heavy-duty vehicle EV use could significantly limit DOT's and South Dakota municipalities' ability to keep our roads safe during winter conditions. [EPA-HQ-OAR-2022-0985-1639-A2, p. 2]

Organization: The Sulphur Institute (TSI)

One last area we would like to address is that many refineries and gas plants are located in areas not well suited for electric vehicles, especially in states that are rural, are at high altitude, or both. Long distance travel and extreme temperature ranges can significantly impact EV range and the ability of the sulphur truck fleets to access refineries for sulphur loading and transport. [EPA-HQ-OAR-2022-0985-1624-A1, p. 2]

Organization: Valero Energy Corporation

Extreme climate conditions have been shown to significantly reduce the battery range and efficiency of BEVs.122 In the proposal, EPA acknowledges that "[c]old temperatures, in particular, can result in reduced mobility of the lithium ions in the liquid electrolyte inside the battery; for the driver, this may mean lower range." Further, battery thermal management is also necessary "during hot ambient temperatures to keep the battery from overheating."123 In fact, a yearlong study conducted by the Gunnison County Electric Association using a Chevrolet Bolt found that at temperatures of 1 to 32 degrees Fahrenheit, the Bolt performed at only 80% of the EPA estimated average battery range; at -8 degrees Fahrenheit, the Bolt performed at only 37% of the EPA estimated average battery range.124 Although this study examined a smaller batter used in light-duty vehicle, the results at minimum suggest that the cold-weather performance of larger batteries used in heavy-duty vehicles warrants further study. [EPA-HQ-OAR-2022-0985-1566-A2, pp. 27]

123 EPA's HD Phase 3 GHG Proposal at 25961.

124 See https://energynews.us/2019/08/12/in-colorado-electric-vehicle-ambitions-meet-extreme-peaks-and-weather/.

EPA Summary and Response:

Summary:

Several commenters were concerned about the effects of extreme weather conditions on battery range due to temperature and environmental effects such as elevation and high wind. These commenters also raised the issue of effect on batteries of HVAC systems used for cabin heating (API, Chevron, Jorge Morales, Lynden Inc., NACS, SD DANR, TSI, and Valero Energy

Corp). They asserted that the already limited range of BEVs would also be impacted by the low number of chargers in remote locations.

Response:

As EPA noted at proposal, temperature can have an influence on the performance of the battery. DRIA at 29. We acknowledge concerns about the effects of low temperatures on battery range, including due to the additional use of heaters, as well as the effect of low temperatures on charging speed. In the analysis performed for the NPRM using HD TRUCS, we took into account the mileage weighted ambient temperature for commercial vehicles in the United States and used these values to estimate the additional energy required to condition both the cabin and batteries of each vehicle in HD TRUCS. This method accounts for the temperature variation vehicle miles traveled for heavy duty vehicles; while some miles are traveled in the 30 F and below or 80 F and above, most vehicle miles traveled for heavy duty vehicles are in the milder temperatures, following a bell-curve shape. Energy consumption from HVAC systems follows the inverse shape, where highest consumption occurs at the higher and lower temperatures. Temperature-weighting over the nation accounts for the higher energy consumption from high and low ambient temperature as well as the limited miles traveled in those climate extremities. This methodology did not include the effects of windy weather on the energy consumption of ZEVs. Based on the literature that we reviewed and comments we received, no data was found on the effects of wind on the range of ZEVs so this effect was not a part of our analysis.

This method of analysis is maintained for the FRM with an adjustment for HVAC use and battery conditioning in higher temperatures. While the energy consumption calculated in HD TRUCS differs from the value estimated for the extremes of heating and cooling, it represents the majority of vehicles on the road today. We expect that fleets operating in the extremes of the of the United States, whether it be temperature, altitude, or remoteness, will adopt ZEVs more slowly than most areas of the country where the extremes are more moderate, and our modeled potential compliance pathway includes ICE vehicles for all subcategories in all model years. Furthermore, as explained in preamble Section II.F.1, the composition of the overall HD on-road fleet in future years with the final rule under our modeled potential compliance pathway and accounting for ZEVs in the reference case, is projected to include the following:

- In 2027: 1 percent of the on-road fleet are ZEVs
- In 2032: 7 percent of the on-road fleet are ZEVs
- In 2040: 22 percent of the on-road fleet are ZEVs

This leaves a significant portion of the HD fleet as ICE vehicles. Under this analysis, there would be ample opportunities for ICE vehicles to be utilized in those certain areas with temperature and environmental extremes. See RIA chapter 2.4.1.1.1 (effects of HVAC) and 2.4.1.1.2 (effects of temperature generally).

We disagree with the comment regarding high altitudes having a negative effect on ZEVs. ZEVs provide multiple benefits compared to ICE vehicles at high elevations. ZEVs do not require combustion for tractive power so they maintain full power at any elevation. When transporting commodities from high elevation to low elevation, ZEVs can take advantage of regenerative braking systems while transporting goods from the refineries and use that energy while returning to the original or different location with potentially no load.

4.3.3 Hours of Service and Slip-Seating

Comments by Organizations

Organization: Banks, Ben

We currently operate 320 day cab tractors in the southeast, with 434 drivers. So, we 'slip-seat' trucks, assigning a day shift and night shift driver in many trucks. With BEV's, we would need down time to charge, so we would need to purchase an additional 114 trucks to provide a tractor for every driver.

Organization: Hill Bros. Inc.

Subject: Battery powered trucks will not work for expedited team freight

1. Surface transportation truck lanes that require team operations due to time constraints cannot wait for battery charging. [EPA-HQ-OAR-2022-0985-1461-A1, p. 1]

Organization: Valero Energy Corporation

EPA's proposed HD GHG Phase 3 rule will not only require an increase in the number of trucks to accommodate HD EV charging, but an increase in the number of truck drivers as well in order to comply with federal hours-of-service regulations. The United States Department of Transportation's Federal Motor Carrier Safety Administration ("FMCSA") regulates the number of hours commercial drivers may drive and work per day and week. According to the 11-hour driving limit, a property-carrying driver may drive a maximum of 11 hours after 10 consecutive hours off duty.110 And per the 14-hour rule, a property-carrying driver may not drive beyond the 14th consecutive hour after coming on duty, following 10 consecutive hours off duty.111 Given the time intensity of EV charging, additional drivers will be needed to ensure HD fleets' charging needs are satisfied while complying with the applicable hours-of-service regulations. For independent operators, the time spent charging will directly impact their revenues. [EPA-HQ-OAR-2022-0985-1566-A2, p. 24]

110 See https://www.fmcsa.dot.gov/regulations/hours-service/summary-hours-service-regulations.

111 Id.

EPA Summary and Response:

Summary:

A few commenters stated that the need for long haul BEVs to recharge could significantly reduce range available when slip-seating. (Ben Banks and Hills Bros. Inc.) Ben Banks also commented that his company would have to purchase additional trucks to be able to provide a tractor for every driver in their operation to allow for operation with vehicles that perform both day and night shift operation. Valero also expressed concerns about how the time to charge electric vehicles would interfere with hours of service regulations and reduce driving time which would necessitate additional trucks and drivers to perform the same amount of work as ICE vehicles.

Response:

Three commenters challenged EPA's assumption at proposal that tractor daily range for a single shift is inherently limited by the need for drivers to operate a specified number of hours. See DRIA at 117. Two commenters noted that drivers can "slip-seat" – that is, a second driver takes the place of the first so that the vehicle can operate more or less continuously. We note that in our analysis for the proposal, we predicted that the first adopters of HD ZEVs would be single shift operations and generally be able return to base for depot charging. DRIA at 209. However, in response to comments, in developing a potential compliance pathway for tractors for the final rule, EPA is now projecting en route charging for certain applications with the highest daily VMT, including long-haul tractors.

Specifically, we have assumed that certain BEV tractors would use en-route charging. In our analysis in HD TRUCS, we have calculated the amount of time it would take to charge these vehicles, and with less than 30 minutes of charge time, would be able to increase their operational range to the 90th percentile daily VMT. For the longest range day cabs and sleeper cabs, on days when these vehicles are required to travel longer distances, we find that less than 30 minutes of mid-day charging at 1 MW is sufficient to meet the HD TRUCS 90th percentile VMT. The cost of en route charging infrastructure has been included in our analysis by using a higher electricity price for en route charging than for depot charging. See RIA Chapters 2.2.1.2.2, 2.4.2.2, and 2.6.3.

For fleets that utilize slip seating and are unable to meet their daily operational requirements with ZEVs even with en-route charging as outlined in the previous paragraph, we expect that they will continue to operate ICE vehicles. Commenters did not provide data on the number of fleets that use slip seating, and it is our understanding that only a portion of fleets, specifically a portion of tractors, use this type of operational model. To reflect this our modeled compliance pathway is based on a mix of ZEV and ICE vehicles, and we project in this technology package that the majority of sleeper cabs and day cabs will remain ICE vehicles. In MY 2027, the modeled pathway projects that 5% of day cabs will be ZEVs while the Phase 2 standards for sleeper cabs will be unchanged until MY 2030 when the Phase 3 standards will take effect. We project that ZEV technology will have matured by MY2032 and project 40% day cabs and 25% of sleeper cabs will be ZEVs under the modeled potential compliance pathway. We consequently have not included a cost for lost operating time where slip seating is utilized. Furthermore, as explained in preamble Section II.F.1, the composition of the overall HD on-road fleet in future years with the final rule under our modeled potential compliance pathway and accounting for ZEVs in the reference case, is projected to include the following:

- In 2027: 1 percent of the on-road fleet are ZEVs
- In 2032: 7 percent of the on-road fleet are ZEVs
- In 2040: 22 percent of the on-road fleet are ZEVs

This leaves a significant portion of the new HDV fleet as ICE vehicles, even without taking into account the overwhelming percentage of HD ICE vehicles in the current on-highway heavy duty fleet.

For a response to additional vehicles being required to perform the same amount of work as comparable ICE vehicles, see RTC 4.3.1.

4.3.4 Alternative Battery Chemistry

Comments by Organizations

Organization: Moving Forward Network (MFN) et al.

11.1.3.2. Technological advancements resulting in decreased mineral demand can also further decrease battery costs

In addition to the substitution of lithium discussed above, advanced lithium-ion batteries, such as solid-state or lithium-air batteries, could decrease the amount of lithium required to provide the same kWh and miles. Innovation will increase battery specific energy and energy density, therefore reducing the amount of materials needed as well as battery cost. [EPA-HQ-OAR-2022-0985-1608-A1, p. 93]

Solid-state battery startups such as QuantumScape 196 are already partnering with automakers to ensure the technology is suitable for EVs. Quantumscape has partnered with Ford and BMW and begun shipping their batteries for trial in 2022. 197 Solid-state batteries have increased specific energy, with Quantumscape reporting their Li-Metal NMC batteries having up to 400 Wh/kg or 1,100 Wh/L depending on the anode. This increase is graphically represented in Figure 25 below, which was produced by QuantumScape. [EPA-HQ-OAR-2022-0985-1608-A1, p. 93.] [See Figure 25 Energy Density Improvements as Projected by QuantumScape located on p. 94 of docket number EPA-HQ-OAR-2022-0985-1608-A1.]

198 Ding, Y., Cano, Z.P., Yu, A. et al. Automotive Li-Ion Batteries: Current Status and Future Perspectives. Electrochem. Energ. Rev. 2, 1–28 (2019). https://doi.org/10.1007/s41918-018-0022-z

199 Yang, Xiaofei, et al. “Recent advances and perspectives on thin electrolytes for high-energy-density solid-state lithium batteries.” Energy & Environmental Science 14.2 (2021). p. 643-671.

Sodium-ion batteries are also making their way to the market and providing an alternative to lithium minerals and potentially reducing future lithium demand. CATL, the world’s largest EV battery maker, invested in the technology in 2021 200 and in China the batteries go on sale later this year in the Chery iCAR. Globally there are 20 sodium battery factories under construction or planned around the world, demonstrating the uptake of this technology. 201 [EPA-HQ-OAR-2022-0985-1608-A1, p. 94]

200 Magdalena Petrova. Here’s why sodium-ion batteries are shaping up to be a big technology breakthrough. CNBC. (2023). https://www.cnbc.com/2023/05/10/sodium-ion-batteries-shaping-up-to-be-big-technology-breakthrough.html#:~:text=The%20technology%20is%20now%20getting,supply%20chain%20by%20this%20year.

Organization: Volvo Group

iii. Alternative chemistries

As battery manufacturing and recycling ramps up, so too does the development of innovative alternative battery chemistries that will transform the range, durability, and cost of HDEVs. One chemistry with particular promise is that of lithium iron phosphate (LFP) batteries, touted for its potential application in MHD contexts.111 LFP batteries do not require nickel or cobalt, reducing cost, and reportedly generate 15% less emissions during manufacturing.112 Importantly, LFP batteries have twice as many charge cycles in their useful vehicle life.113 [EPA-HQ-OAR-2022-0985-2429-A1, p. 27]

111 "Driving Sustainability with Evolving Battery Chemistries," Chris Nevers, accessed May 18, 2023 https://www.zeta2030.org/insights/driving-sustainability-with-evolving-battery-chemistries

112 Id.

113 Id.

Another potentially promising technology is sodium-ion batteries. In April 2023, Contemporary Amperex Technology Co. Limited (CATL)—the world's largest battery producer—said its first sodium-ion battery would power electric vehicles built by Chinese brand Chery.114 Because they substitute lithium for sodium, sodium-ion batteries tend to be cheaper and may have significant applications for lower-range EVs. However, their commercial viability will likely be determined by lithium prices going forward. [EPA-HQ-OAR-2022-0985-2429-A1, p. 27]

114 "What If Your Tesla Could Run on Sodium?" Wall Street Journal, (April 19, 2023) accessed May 17, 2023 https://www.wsj.com/articles/what-if-your-tesla-could-run-on-sodium-3c18df30

The Department of Energy's SLAC National Accelerator Laboratory115 and Stanford University recently announced the launch of a new joint battery center at SLAC.116 It will bring together the resources and expertise of the national lab, the university, and Silicon Valley to accelerate the deployment of batteries and other energy storage solutions. [EPA-HQ-OAR-2022-0985-2429-A1, p. 28]

116 "New Battery Center Launches In USA," CleanTechnica, (April 13, 2023) https://cleantechnica.com/2023/04/13/new-battery-center-launches-in-usa/

iv. Range and durability

In the LDV segment, a recent study found that a majority of EVs retain at least 90 percent of their original range capacity left even after driving more than 100,000 miles—a testament to battery durability.122 While HDVs operate under different duty cycles and applications, there is good reason to believe advances in LDV battery technologies and durabilities will extend into other vehicle classes. CATL—recently announced a new "condensed" battery with 500 Wh/kg. CATL expects to start mass production of the model in 2023,123 and such an increase in battery capacity will benefit HDEVs in an outsized way. Bloomberg recently reported that the average range for a U.S. EV in the U.S. has quadrupled since 2011. In 2022, it stood at 291 miles and today is a third higher than the global average.124 Policies such as EPA's emissions standards are critical to helping maintain the U.S.'s position as a global leader. [EPA-HQ-OAR-2022-0985-2429-A1, p. 29.]

122 "New Study: How Long Do Electric Car Batteries Last?" Recurrent Auto, (March 27, 2023) https://www.recurrentauto.com/research/how-long-do-ev-batteries-last

123 "World's largest battery maker announces major breakthrough in energy density," TheDriven, (April 21, 2023) https://thedriven.io/2023/04/21/worlds-largest-battery-maker-announces-major-breakthrough-in-battery-density

124 "US Electric Cars Set Record With Almost 300-Mile Average Range," Bloomberg, (March 9, 2023) https://www.bloomberg.com/news/articles/2023-03-09/average-range-for-us-electric-cars-reached-a-record-291-miles#xj4y7vzkg

EPA Summary and Response:

Summary:

At least two commenters, including MFN and Volvo Group, noted other battery chemistries including lithium iron phosphate, sodium-ion and a new "condensed" battery will improve the range of electric vehicles, lower cost, increase durability and reduce critical minerals required for battery production.

Response:

We agree with the commenters that battery chemistry and technology will continue to improve from today's reported values. This could have positive implications not only for specific energy and energy density, but for critical mineral utilization as well, since some of these chemistries are less dependent on minerals currently evaluated as critical. See Preamble Section II.D.2.ii.c and RTC 17.2. The final rule projects a 50/50 mix of nickel-based (NMC) and iron-phosphate based (LFP) battery chemistries for 2027–2032 to analyze cost, specific energy, and energy density as parameters for demonstrating reasonableness and feasibility, since both chemistries are widely used for transportation applications today. We recognize that future chemistries under development, such as sodium-ion, may prove advantageous to the existing, commercial-scale chemistries we considered, so they may result in improvements to cost, specific energy, and energy density beyond what we anticipate in this final rule.

4.3.5 Towing Capacity

Comments by Organizations

Organization: Morales, Jorge

Have you researched towing capacity of EVs? How are people supposed to be expected to transport horses, cows, sheep, etc. What would take an 8hr drive towing would almost triple the drive due to needing to stop and recharge. You're unintentionally driving the economy backwards to local markets only, because the EVs don't have long enough battery charge to sustain long distance driving. Or will we all be required to bring back up batteries while driving? [EPA-HQ-OAR-2022-0985-1691.html, p. 1]

EPA Summary and Response:

Summary:

Jorge Morales expressed concern over the range of a BEV when towing and how that will affect the trucking industry.

Response:

First, we note that Class 2b and 3 complete pickups and vans are not included in this Phase 3 rulemaking. In the analysis for HD vehicle at issue in this rule, each vehicle had an assumed payload that corresponds to the value used in the GEM 2 compliance tool and can be found in the Tables in RIA Chapter 2.2.2.1.1. These values were used in the proposal and have been retained for the final rule. The vehicles covered in this rule are engine certified vehicles from class 2b-3 through class 8. Since we used the GEM values for payload, we model tractors towing trailers. The payload used for these vehicles includes additional mass from the curb weight of the vehicle to simulate commercial use. For example, LHD vehicles have an assumed mass of 16,000 pounds. This is about 8,000 pounds more than a typical Class 4 dual rear wheeled pickup truck that has a curb weight of about 8,000 pounds.[364] This could reflect, for instance, the vehicle towing a significant load nearing 8,000 pounds. As long as the combined weight of the vehicle, trailer, and cargo is at or below the assumed mass of the vehicle modeled for the rule, the vehicle should perform as well as or better than the modeled vehicle with respect to energy consumption. The assumptions we used in our analysis for daily VMT will not be the same for every fleet or operator. Most vehicles were sized to accommodate the 90th percentile VMT based on the datasets we used. See RIA Chapter 2.2.1.2 for more information on how the VMT was calculated for each vehicle type. Since we did not take into account every possibility for daily range, our modeled potential compliance pathway projects that ICE vehicles will still be sold during the timeframe of the rule, including at a rate of 40% for LHD vehicles in MY 2032.

4.4 Intentionally Left Blank

4.5 Intentionally Left Blank

4.6 Vehicle Weight

Comments by Organizations

Organization: Bradbury, Steven G.

Increasing highway infrastructure costs. Similarly, the cost of increased wear and tear on highway infrastructure, including the cost of increased frequency of required repairs, should also be recognized in the proposals. If, as EPA envisions, EVs were to comprise more than half of new light-duty vehicle sales, and if a large percentage of new medium- and heavy-duty trucks were battery powered, that would have a definite negative impact on highway infrastructure. The batteries in EVs are heavy, and, as a consequence, EVs tend to be considerably heavier than comparably sized ICE vehicles. The greater weight of EVs would cause faster wear and tear on

[364] https://www.ford.com/trucks/super-duty/models/f450-xlt/

highways if the number of EVs on the road were to increase significantly. [EPA-HQ-OAR-2022-0985-2427-A2, p. 19]

Organization: Clean Air Task Force et al.

While batteries add weight to vehicles, that incremental weight is unlikely to meaningfully affect HD BEVs' safety performance or their impact on roads and road safety infrastructure. Heavy-duty vehicles, no matter their powertrain type, are just that: heavy. Weight-related safety issues are universal to all heavy-duty vehicles. And federal interstate highway laws already prohibit BEVs from weighing more than 2,000 pounds in excess of comparable vehicles, capping their maximum weight at 82,000 pounds (compared to 80,000 pounds for combustion vehicles).257 As heavy-duty BEVs come onto the market in increasing numbers, federal, state, and local authorities can further modify vehicle weight and other road safety standards as appropriate. Furthermore, anticipated developments in solid state batteries258 and other weight-reducing technologies259 hold promise for achieving future reductions in BEV weight. [EPA-HQ-OAR-2022-0985-1640-A1, p. 60]

Light-weighting is Changing the Automotive Industry, https://www.stanleyengineeredfastening.com/en/News%20and%20Stories/How%20Electric%20Vehicle%20Light-weighting%20is%20Changing%20the%20Automotive%20Industry (last visited June 15, 2023).

Organization: Owner-Operator Independent Drivers Association (OOIDA)

OOIDA has consistently opposed increases to federal truck size and weight standards. The U.S. Department of Transportation (DOT) has long studied the impact of various longer and heavier truck configurations on interstate and U.S. highways and found that the additional cost of damage to both roads and bridges would require billions of dollars in new federal spending. As BEV development evolves, we are learning that battery components can be much heavier than traditional combustion engine parts. Federal regulations limit CMVs to 80,000 pounds; we've seen reports that truck batteries can weigh up to 16,000 pounds. For example, the Freightliner eCascadia electric semi-truck, which was released in 2022, weighs up to 4,000 pounds more than a regular diesel truck.7 On the other hand, permitting higher weight allowances would shift freight from other modes onto American highways, worsening congestion rather than helping to alleviate it. DOT has also found thousands of bridges on our Interstate system that would be overstressed by heavier CMVs, causing damage to many spans that are already considered structurally deficient or functionally obsolete. [EPA-HQ-OAR-2022-0985-1632-A1, p. 4]

Organization: Volvo Group

The frame rail packaging not only impacts the trailer gap, but also our ability to protect for bodybuilders' 'clean back of cab' requirements. While the NPRM expects us to move away from carbon-based products, the electrification of multi-purpose vehicles and refuse trucks classified in the urban subcategory complicates our ability to close the immense power gap required to drive the bodybuilder functions. Additional battery packs take away from customer payload while simultaneously creating new concerns around front axle loading to ensure we meet federal bridge laws. Some body builders have started to incorporate batteries into the body to power all the hydraulic features, but this is not yet available for all applications within the multipurpose and urban subcategories. [EPA-HQ-OAR-2022-0985-1606-A1, p. 13]

Similarly, as we look to develop concepts for hydrogen fuel cells and/or internal combustion engines (ICE), we will face similar space constraints associated with battery electric vehicles. Heavier weights on the front axle will need to be balanced with limits to customer payload to ensure bridge law compliance. In this case the weight studies are focused on the hydrogen fuel tank assemblies and the structure required to mount and protect the tanks in the event of an accident. With the utmost interest in the safety of our drivers and the surrounding environment, we must ensure designs can pass the standard frontal crash test. This requires simulation efforts to ensure all hydrogen is evacuated and properly vented within a fraction of a second upon front impact. [EPA-HQ-OAR-2022-0985-1606-A1, p. 13]

Organization: Truck Renting and Leasing Association (TRALA)

With respect to infrastructure concerns, the American Society of Civil Engineers' (ASCE) 2021 Infrastructure Report Card gave the nation's roads a 'D' grade and its bridges a 'C' grade.22 Roads and bridges need continual repair, rebuilding, and investment. Added vehicle weights and the high torque rates of ZEVs has the potential to accelerate the degradation of our nation's road networks. TRALA requests further analysis be undertaken to ensure that the increased use of all on-road ZEVs will not result in any detrimental impacts and unanticipated costs related to maintaining our nation's existing highway infrastructure. [EPA-HQ-OAR-2022-0985-1577-A1, pp. 15-16]

EPA Summary and Response:

Summary:

Several commenters raised concerns about the weight of BEVs. A number of commenters maintain that the battery packs needed for heavy-duty applications invariably add considerable weight, and that these heavier vehicles (in comparison to their ICE counterparts) will necessarily damage highways and bridges at a rate greater than comparable ICE vehicles. (OOIDA, citing a Department of Transportation study without identifying it, Steven Bradbury). Other commenters disputed this, pointing to a maximum weight differential of 2,000 lbs. for the heaviest applications, plus the financial incentive of BEV OEMs to reduce vehicle weight. (CATF.)

Several commenters expressed concerns over the increased tare weight of ZEVs. The concern was that the additional weight of the vehicles themselves and the torque from the electric motors would increase the rate of deterioration of the nation's roads and bridges.

Certain commenters further maintained that added weight of BEVs adversely affect front axles, with one commenter raising the issue that added weight from the BEV powertrain could exceed (or pose the potential of exceeding) gross axle ratings and therefore could potentially violate federal bridge standards. (Volvo) TRALA commented about the impact of the additional torque that ZEVs produce at low motor speeds. The commenter stated that the additional torque will accelerate roadway deterioration.

Response:

In response to comments concerning the increased tare weight of ZEVs, we note that in our analysis for this rule, we have targeted ZEVs to perform the same amount of work in a single shift as comparable ICE vehicles. To this point, not all vehicles in our analysis increased in tare weight due to the daily VMT requirements of the vehicles we analyzed. See the results of our payload analysis which calculates the difference in weight between ICE vehicles and BEVs in RIA Chapter 2.9.1.1. What we have concluded from our analysis is that the tare weight of vehicles analyzed in HD TRUCS can be both higher or lower than a comparable ICE vehicle depending on the application and the daily VMT. Most trucks on the road contain some amount of freight which increases the weight of the vehicle above the tare weight. Because most trucks do not drive at their tare weight and not all BEVs have a higher tare weight than comparable ICE vehicles, we can infer that BEVs would not significantly increase the deterioration rate of our country's roads and bridges and, as shown in the response in section 4.3.1 above, we do not generally anticipate additional trips will be required for BEVs to perform the same work as comparable ICE vehicles. As also discussed in RIA Chapter 2.9, we also note that there is a 2000 pound upper bound on the amount a BEV vehicle's maximum gross weight can exceed that of an ICE vehicle. This is a small relative increase as a percent of the HD vehicle, as HD vehicles are already heavy. See 23 USC section 127(s). Issues of the relation of weight to payload are addressed in RIA Chapter 2.9.1.

In response to the comment alleging that the higher torque of electric motors over diesel engines would deteriorate roadways at a higher rate, we acknowledge that electric motors generally have more torque than diesel engines at low rpm which allows electric vehicles to accelerate more quickly, especially when loaded, providing a benefit to the vehicle operator. Diesel engines, moreover, can also have more or less torque depending on their specifications. In addition, the electric motors are computer controlled and the amount of torque delivered to the road can be tailored by software to match that of existing ICE vehicles. The final rule does not regulate the manufacturer's decisions regarding how they choose to control electric motor torque. It is up to the manufacturer to decide how much torque is applied by BEVs and by what rate.[365] We lack data to reasonably estimate how different manufacturers will control electric motor torque, and commenters raising this concern did not provide any such data. Therefore, it would not be practical for the EPA to estimate roadway deterioration due to the torque of electric motors.

In response to the comment asserting that the increased front axle weight due to batteries would necessitate payload reduction to comply with federal bridge laws, we disagree with Volvo that the federal bridge laws will be a concern, Chapter 1.5.3 of the RIA describes the different configurations of current BEVs. The elimination of the combustion engine and fuel system will likely reduce the amount of weight on the front axle and many existing designs for BEVs show the addition of battery pack spread along the ladder frame, again reducing weight on the front axle. In addition, Chapter 1.5.5 of the RIA includes a comprehensive list of 180 HD BEV models expected to be on the market by 2024, ranging from class 3-8 as well as many of the vehicle

[365] Dorsch, C., Wang, X. & Küçükay, F. Objective Rating of the Launch Behavior of Conventional, Hybrid and Electric Vehicles. *Automot. Innov.* **4**, 70–80 (2021). Available online: https://doi.org/10.1007/s42154-020-00131-z

types covered in HD TRUCS. This shows that there are BEVs available in the near future that meet federal bridge laws, and we expect this trend to continue through the timeframe of the rule.

EPA appreciates and agrees with the comment from CATF stating that laws already exist that limit the additional mass that ZEVs can weigh over comparable ICE vehicles. See 23 USC 127(s) noted above. HD trucks are limited by manufacturer GVWR rather than their tare weight and so will not weigh significantly more than ICE vehicles while loaded, meaning that any effect on infrastructure will be insignificant. Responses pertaining to payload concerns can be found in RTC 3.10.1 and RIA Chapter 2.9.1.

4.7 Recycling and Environmental Issues

Comments by Organizations

Organization: American Free Enterprise Chamber of Commerce (AmFree) et al.

EPA asserts that the United States will be able to bolster supply significantly by recycling minerals from spent batteries that enter the domestic market. See 88 Fed. Reg. at 25,968–69. That hope is also misplaced, especially given the proposed rule's compressed timeline. Electric-vehicle batteries cannot be recycled until they are retired. According to the International Energy Agency, based on "the dates of expected retirement of EV fleets and their battery chemistry compositions," recycled minerals will be able to supply less than 1 percent of projected global demand for lithium, less than 1 percent of global projected demand for nickel, and only 2 percent of global projected demand for cobalt by 2030. Global Supply Chains at 60. And even if those numbers increase over time, many steps will need to be taken before American companies can effectively enter the recycling space. That includes establishing "protocol or industry best practices" on how to collect and transport spent batteries to a recycling center, navigating the "increasingly complex disassembly" process, and entering earlier phases of the manufacturing cycle where the recycled materials can actually be used. White House Report at 106, 109–11. "[W]ithout critical material refining and processing and battery manufacturing capacity, the captured materials from recycling end-of-life batteries will be exported for processing at foreign facilities and re-imported in the form of processed or manufactured products." Id. at 111. [EPA-HQ-OAR-2022-0985-1660-A1, p. 41]

Organization: American Fuel and Petrochemical Manufacturers (AFPM)

Another critical aspect of the Proposed Rule not comprehensively considered is that recycling of the battery and related electrical components of BEV is in a state of infancy and poses unique materials handling and safety challenges. EPA should consider the environmental profiles of both BEVs and ICEVs in light of the production, operation, and disposal of the vehicle (its useful life). The following list provides just some of the electric battery disposal-related issues that are likely to impact the environment and need to be addressed by EPA in the Proposed Rule: [EPA-HQ-OAR-2022-0985-1659-A2, p. 28]

Battery packs could contribute 250,000 metric tons of waste to landfills for every 1 million retired BEVs.103 [EPA-HQ-OAR-2022-0985-1659-A2, p. 28]

103 Kelleher Environmental, "Research Study on Reuse and Recycling of Batteries Employed in Electric Vehicles: The Technical, Environmental, Economic, Energy and Cost Implications of Reusing and

Recycling EV Batteries", (September 2019) available at https://www.api.org/oil-and-natural-gas/wells-toconsumer/fuels-and-refining/fuels/vehicle-technology-studies.

Less than five percent of lithium-ion batteries, the most common batteries used in BEVs, are currently being recycled "due in part to the complex technology of the batteries and cost of such recycling."104 [EPA-HQ-OAR-2022-0985-1659-A2, p. 28]

104 Gavin Harper, Roberto Sommerville, et al., NATURE, "Recycling lithium-ion batteries from electric vehicles" (Jan. 21, 2020) available at https://www.nature.com/articles/s41586-019-1682-5.

Economies of scale will play a major role in improving the economic viability of recycling. Currently, cost is the main bottleneck. Increasing collection and sorting rates is a critical starting point.105 [EPA-HQ-OAR-2022-0985-1659-A2, p. 28]

105 IEA Report 2022.

The cathode is where the majority of the material value in a lithium-ion battery is concentrated. Currently, there are numerous cathode chemistries being deployed. Each of these chemistries needs to be known, and then the appropriate method of recycling identified, which poses a challenge, as batteries pass through a global supply chain and all materials are not well tracked. [EPA-HQ-OAR-2022-0985-1659-A2, p. 28]

Lithium can be recovered from existing lithium-ion recycling practices but is not economical at current lithium prices. [EPA-HQ-OAR-2022-0985-1659-A2, p. 28]

Benchmark forecasts suggest that near-term recyclers are likely to use scrap material from the increasing number of gigafactories coming online versus used electric vehicle batteries. Scrap is anticipated to account for 78 percent of recyclable materials in 2025.106 [EPA-HQ-OAR-2022-0985-1659-A2, p. 28]

106 Benchmark Minerals Intelligence, "Battery production scrap to be main source of recyclable material this decade" (Sept. 5, 2022) available at https://source.benchmarkminerals.com/article/battery-production-scrap-to-be-main-source-of-recyclable-material-this-decade.

In 2022, Benchmark expected over 30 gigawatt hours of process scrap to be available for recycling, growing ten-fold across the next decade. Loss rates vary by region and tend to be higher in earlier years of a gigafactory.107 [EPA-HQ-OAR-2022-0985-1659-A2, p. 28]

107 Id.

EV batteries are high-cycle batteries and are made to function for approximately 10 years for a light-duty vehicle, and a shorter time for medium- and heavy-duty vehicles. [EPA-HQ-OAR-2022-0985-1659-A2, p. 29]

EV batteries lose approximately 3 percent of their charging capacity and associated range per year of operation. These percentages likely are higher for higher mileage utilization for typical heavy-duty vehicles. EPA has not made any effort to account for battery degradation, and associated reductions in charging efficiency, charging capacity, customer impacts and accelerated battery replacement and costs. [EPA-HQ-OAR-2022-0985-1659-A2, p. 29]

Many 'spent' EV batteries still have 70-80 percent of their capacity left, which is more than enough to be repurposed into other uses such as energy storage and other lower-cycle applications.108 This will extend the time that batteries and raw materials remain in use and therefore increase the demand for virgin critical minerals. [EPA-HQ-OAR-2022-0985-1659-A2, p. 29]

108 Engel, H., Hertzke, P., & Siccardo, G. (2019, April). Second-life EV batteries: The newest value pool in Energy Storage. McKinsey Center for Future Mobility. https://www.mckinsey.com/~/media/McKinsey/Industries/Automotive%20and%20Assembly/Our%20Insights/Second%20life%20EV%20batteries%20The%20newest%20value%20pool%20in%20energy%20storage/Second-life-EV-batteries-The-newest-value-pool-in-energy-storage.pdf

Clear guidance on repackaging, certification, standardization, and warranty liability of spent EV batteries would be needed to overcome safety and regulatory challenges reuse poses at scale.109 [EPA-HQ-OAR-2022-0985-1659-A2, p. 29]

109 IEA Report 2022.

Recycling BEV batteries to recover high-value metals has not been proven to a commercial scale. The majority of analysts are aligned that recycling will not become an integral supplier of raw materials until the 2030's, and at that point, it only will provide approximately 20 percent of demand.110 [EPA-HQ-OAR-2022-0985-1659-A2, p. 29]

110 Benchmark Minerals Intelligence, supra at n. 105.

Acknowledging the fire risks posed by lithium-ion batteries, EPA has recently stated that ZEV batteries should be handled as hazardous waste in accordance with RCRA universal waste requirements, further driving up the cost of such recycling efforts and limiting the facilities qualified to manage used batteries.111 [EPA-HQ-OAR-2022-0985-1659-A2, p. 29]

111 Letter from Carolyn Hoskinson, Director, EPA Office of Resource Conservation and Recovery, "Lithium Battery Recycling Regulatory Status and Frequently Asked Questions," (May 24, 2023).

EPA must, therefore, conduct a full lifecycle analysis to compare all environmental impacts caused by the proposal. [EPA-HQ-OAR-2022-0985-1659-A2, p. 29]

Organization: American Petroleum Institute (API)

V. Recycling of batteries and related electrical components is in its infancy.

Another critical aspect to be considered with this proposal is that recycling of the battery and related electrical components of BEVs are in a state of infancy and poses unique materials handling and safety challenges. The environmental profiles of both BEVs and ICEVs should be considered in light of the production, operation, and disposal of the vehicle (its useful life). Electric battery disposal-related issues are likely to impact the environment and need to be addressed in EPA's proposal:

- Battery packs could contribute 250,000 metric tons of waste to landfills for every 1 million retired BEVs.44
- Less than five percent of lithium-ion batteries, the most common batteries used in BEVs, are currently being recycled "due in part to the complex technology of the batteries and cost of such recycling."45
- Economies of scale will play a major role in improving the economic viability of recycling, which currently cost is the main bottleneck. Increasing collection and sorting rates is a critical starting point.46

- The cathode is where the majority of the material value in a Lithium-ion battery is concentrated. Currently, there are numerous cathode chemistries being deployed. Each of these chemistries needs to be known, and then the appropriate method of recycling identified, which poses a challenge, as batteries pass through a global supply chain and all materials are not well tracked.
- Lithium can be recovered from existing Lithium-ion recycling practices, but it is not economical at current lithium prices. Cobalt, one of the highest supply risk materials for BEV in the short- and medium-term, is currently being profitably recovered.
- Benchmark forecasts near-term recyclers are likely to use scrap material from the increasing number of gigafactories coming online versus used electric vehicle batteries. Scrap material is anticipated to account for 78 percent of recyclable materials in 202547
- In 2022, Benchmark expected over 30 gigawatt hours of process scrap to be available for recycling, growing ten-fold across the next decade. Loss rates vary by region, and tend to be higher in earlier years of a gigafactory.48
- EV batteries are high-cycle batteries and are made to function for approximately 10 years, shorter time for a mid-duty vehicle.
- Many ‘spent’ EV batteries still have 70-80 percent of their capacity left, which is more than enough to be repurposed into other uses such as energy storage and other lower-cycle applications.49 This will extend the time that batteries and raw materials remain in use.
- Repurposing used EV batteries could generate significant value and help bring down the cost of residential and utility-scale energy storage to bring forth further penetration of renewable power to electricity grids. Initial trials are underway.50
- Clear guidance on repackaging, certification, standardization, and warranty liability of spent EV batteries would be needed to overcome safety and regulatory challenges reuse poses at scale.51
- Recycling BEV batteries to recover high-value metals has not been proven at commercial scale. The majority of analysts are aligned that recycling will not become an integral supplier of raw materials until the 2030s, and at that point, only will provide approximately 20 percent of demand.52 [EPA-HQ-OAR-2022-0985-1617-A1, pp. 27 - 29]

The recycling of lithium-ion batteries is also increasing to ensure that minerals are recovered and reused instead of discarded.83 Batteries that power vehicles will be recycled at recycling facilities, where they will be transformed into valuable scrap commodities like cobalt, copper, nickel, and lithium carbonate, which can then be used to produce another battery more efficiently. Battery recycling can also reduce the demand for virgin materials used in the production of new batteries. Circularity has the potential to contribute to an 8 to 44 percent reduction in the global resource use associated with lithium-ion batteries in 2050.84 On average, Redwood Materials can recover greater than 95 percent of the critical battery elements in an end-of-life battery (including lithium, nickel, cobalt, manganese, and copper), and then use those metals to manufacture anode and cathode components domestically for U.S. battery cell manufacturers.85 U.S. EPA could support battery materials recycling through battery pack labelling of battery chemistry and charge capacity. d. BEVs cannot be recycled at the same level of ICE-powered vehicles.

EPA asserts that "minerals become part of the vehicle and have the potential to be recovered and recycled."40 This not only ignores the recycling capabilities of lead-acid batteries used in ICE HDs, but also the limited capabilities to recycle lithium-ion batteries. The Proposed Rule once again relies on vague predictions of the future to support its unrealistic standards. For example, EPA asserts that a "growing number of private companies are entering the battery recycling market," "manufacturers are already reaching agreements to use these recycled materials for domestic battery manufacturing," and that "Panasonic has contracted with Redwood Materials Inc. to supply domestically processed cathode material."41 But this is hardly sufficient to support EPA's proposal to entirely overhaul the ICE HD market in as few as four–seven years. [EPA-HQ-OAR-2022-0985-1561-A1, p. 9]

40 Proposed Rule at 25,969.

41 Id.

In reality, only five percent of lithium-ion batteries for BEVs are currently recycled.42 In contrast, 99% of lead-acid batteries are currently recycled.43 Despite recognizing the novel nature of lithium-ion battery recycling (as well as other critical minerals used for ZEVs),44 EPA's analysis falls short in examining the broader impacts of its proposal—on energy independence, national security, and emissions of criteria pollutants. [EPA-HQ-OAR-2022-0985-1561-A1, p. 9]

43 Id.

44 Proposed Rule at 26,969.

Organization: MEMA

Recommendation: Battery recycling and disposal costs should be added to EPA's analysis as part of a sustainable BEV deployment to better address scarcity of critical minerals, provide a more resilient domestic supply chain, and over time reduce the added carbon impact of battery manufacturing and associated multi-national logistics. 7 [EPA-HQ-OAR-2022-0985-1570-A1, p. 7]

Organization: Moving Forward Network (MFN) et al.

11.1.2. Recycled content can provide additional domestic mineral supply

The current oil-dependent system not only impacts the climate and health of the U.S. population, it also requires continual drilling, production, and importing of fuel. This is in stark contrast to the use of materials needed for electrified transportation, which can be continually recycled to produce the next generation of more efficient vehicles. This results in the continued growth of U.S. material stock even when importing minerals not mined domestically. As the Proposed Rule states, in 2050, 25 to 50 percent of lithium EV material demand can be met with recycled content. 184 This finding has been highly studied and documented by additional academics to the two listed in the report (Sun et al., 2022; Ziemann et al., 2018), including findings by Xu et al. 185 and Dunn et al. 186 Xu et al. demonstrate the material demand, which could be met by retiring and recycled supply, is highly impacted by innovation and advancing energy density. As batteries become more advanced and energy-dense, either through innovation of chemistries used (e.g., the progress made in NMC), or through different chemistries (e.g., lithium-sulfur or lithium-air batteries), the mineral demand decreases to meet the same energy storage needs. This means that a high percentage of material demand can be met with the retiring supply of less material-efficient and lower density batteries, as is demonstrated in Figure 22 below. 187 [EPA-HQ-OAR-2022-0985-1608-A1, pp. 87 - 88.] [See Figure 22 Closed-loop recycling potential of battery materials in a STEP scenario located on p. 88 of docket number EPA-HQ-OAR-2022-0985-1608-A1.]

187 Xu, C., Dai, Q., Gaines, L. et al. Future material demand for automotive lithium-based batteries. Commun Materials. V.1. No. 99. (2020). https://doi.org/10.1038/s43246-020-00095-x

Dunn et al. 188 demonstrate that the choice of cathode materials can also highly increase potential circularity. Figure 23 below shows that a future with high lithium-iron-phosphate (LFP) market concentration can significantly increase the amount of lithium, cobalt, manganese, and nickel demand met with recycled content. [EPA-HQ-OAR-2022-0985-1608-A1, p. 88.] [See Figure 23 Circularity potential of materials as additional years are added to battery lifespan located on p. 89 of docket number EPA-HQ-OAR-2022-0985-1608-A1.]

189 Id.

The recycled content also varies based on the collection rate and the material recovery rate. There is potential for high material recovery due to the 95 percent recovery rate of lithium, nickel, cobalt, and manganese by commercial-scale hydrometallurgical recyclers in the U.S. such as Lithion, Redwood Materials, Licycle, and Cirba Solutions. In addition, direct cathode recycling, which can recover a cathode without breaking it down into separate materials, is under development by several startups as well as the National Lab research group, ReCell. Direct recycling currently has a recovery rate of 40% for lithium, but increasing the lithium recovery rate is a priority area for ongoing research. 190 The Argonne National Lab model, BatPaC, lists the following recovery rates shown in Table 8. 191 [EPA-HQ-OAR-2022-0985-1608-A1, pp. 89 - 90.] [See Table 8 Recovery Rates of Battery Materials from Different Recycling Processes located on p. 90 of docket number EPA-HQ-OAR-2022-0985-1608-A1.]

191 Argonne National Laboratory. BatPaC: battery manufacturing cost estimation. (2022). https://www.anl.gov/partnerships/batpac-battery-manufacturing-cost-estimation

Recycling facilities are operational and under development in the US. Table 9 from Atlas Public Policy attempts to capture all these developments. 192 [EPA-HQ-OAR-2022-0985-1608-A1, p. 90.] [See Table 9 EV Battery Recycling Facilities in the U.S. located on p. 91 of docket number EPA-HQ-OAR-2022-0985-1608-A1.]

192 Atlas Public Policy. The EV Transition: Key Market and Supply Chain Enablers. (2022). https://atlaspolicy.com/the-ev-transition-key-market-and-supply-chain-enablers/

Appropriately representing higher specific energies that align with today's technologies and forecasts also has implications for vehicle range and weight. Batteries with higher specific energies can provide the same amount of power while weighing less than batteries with lower specific energies. This means that vehicles with more efficient batteries can travel farther with the same amount of energy because the battery significantly impacts the weight, and therefore, efficiency of BEVs. Lower battery weight has additional implications for heavy-duty BEVs by allowing for additional freight per trip since the battery would contribute less weight towards the total vehicle weight allowance. [EPA-HQ-OAR-2022-0985-1608-A1, p. 101]

11.1.3.4. Design for disassembly

Battery design parameters discussed in the Proposed Rule include "considerations related to cost and performance including specific energy and power, energy density, temperature impact, durability, and safety." 220 A key design parameter not included in this is the design for disassembly (Dfd), also referred to as design for recycling or design for reuse. Dfd is the factoring in of the end of life into the design of the vehicle, meaning that the battery is designed to be taken apart so that cells and modules can be refurbished, reused, or replaced, or so that the battery can be more efficiently and safely disassembled for recycling. 221 This disassembly is typically a difficult, lengthy, and therefore expensive process because Dfd is not included in the design phase. 222 [EPA-HQ-OAR-2022-0985-1608-A1, pp. 101 - 102]

220 U.S. EPA. Proposed Rule: Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles – Phase 3. 88 Fed. Reg. 25926, 26074 (Apr. 27, 2023). NPRM, 2.i Battery Design Parameters, pg 112. https://www.epa.gov/regulations-emissions-vehicles-and-engines/proposed-rule-greenhouse-gas-emissions-standards-heavy

221 Kendall, A., Slattery, M., Dunn, J. Lithium-ion car battery recycling advisory group report. (2022). https://calepa.ca.gov/lithium-ion-car-battery-recycling-advisory-group/

222 Baazouzi S, Rist FP, Weeber M, Birke KP. Optimization of Disassembly Strategies for Electric Vehicle Batteries. Batteries. V. 7. No.4. (2021). p. 74. https://doi.org/10.3390/batteries7040074

As reuse and recycling become more prevalent and policies begin to require it, we expect that Dfd will also be more common. If Dfd occurs, it is assumed that more reuse, refurbishment, and replacement will occur. As a result, batteries will have a longer lifespan and the amount of new batteries necessary for electrification will be reduced. 223 The disassembly of a battery from a vehicle and down to the cell level currently represents approximately a third of light duty vehicle recycling costs. 224 If Dfd occurs, these recycling costs will also lessen, therefore leading to more prevalent recycling and more availability of recycled supply. [EPA-HQ-OAR-2022-0985-1608-A1, p. 102]

Spurred both by public incentives, and “business opportunity” presented by “the need for increased domestic production capacity,” private industry is also taking steps to increase domestic supply of critical minerals.214 As of March 2023, “at least $45 billion in private-sector investment has been announced across the U.S. clean vehicle and battery supply chain.”215 This includes “new and expanded commercial-scale domestic facilities to process lithium, graphite and other battery materials, manufacture components, and demonstrate new approaches, including manufacturing components from recycled materials.”216 Companies, such as Volkswagen of America, Audi, and Toyota, have committed to developing recycling programs for end-of-life EV battery packs, which will recover more than 95 percent of the metals found in existing batteries.217 These efforts aim to “create a circular supply chain for EV batteries in the United States that will eventually reduce the cost of batteries and offset the need for mining precious metals.”218 Particularly taking into consideration these investments in recycling programs, there are sufficient mineral resources to meet industry needs, both now and in the future.219 [EPA-HQ-OAR-2022-0985-1588-A1, p.30]

Organization: Tesla, Inc. (Tesla)

EPA should also consider that recycling of battery material will play a vital role in alleviating some pressure on the need to develop new critical mineral resources. To that end, Tesla seeks to reduce its reliance on primary mined materials and contribute to a more positive environmental footprint through battery and cell recycling – including ensuring that none of our batteries (manufacturing scrap or fleet returns) go to landfills and deploying equipment to recycle 100% of on-site generated manufacturing scrap across manufacturing facilities. In comparison to BEV batteries, it should also be noted the energy source for ICE vehicles – fossil fuels used in combustion – is not recyclable. [EPA-HQ-OAR-2022-0985-1505-A1, pp. 33-34]

Organization: Truck Renting and Leasing Association (TRALA)

If sourcing concerns are addressed, questions persist regarding disposal of used batteries and its environmental impact. Nearly all lead batteries are recycled.9 In contrast, the U.S. Department of Energy estimates that less than 5% of lithium-ion batteries are collected and recycled.10 This low rate of recycling furthers dependence on imported critical minerals and raises additional lifecycle impact concerns for our members who have comprehensive programs to divert waste from landfills and recycle/reuse most other vehicle waste streams. [EPA-HQ-OAR-2022-0985-1577-A1, p. 6]

ii. Recycling

A key element of meeting the coming demand for EV batteries and critical minerals will be recycling existing batteries at their end-of-life (EOL). As shown in Figure 5, North American battery recycling capacity is growing rapidly. Available EOL battery feedstocks are projected to increase in tandem as EVs on the road today approach the end of their useful life. [EPA-HQ-OAR-2022-0985-2429-A1, pp. 24 - 25.] [See Docket Number EPA-HQ-OAR-2022-0985-2429-A1, page 25, for Figure 5]

In recognition of the potential solutions that battery recycling can provide, the Bipartisan Infrastructure Law requires EPA to develop battery recycling best practices and battery labeling guidelines by September 30, 2026. Congress allocated $10 million and $15 million to each issue respectively.101 While there will likely be more work needed, potentially through voluntary consensus standards bodies, a framework is beginning to take shape to ensure increased recycling capacity is built out in the coming years. [EPA-HQ-OAR-2022-0985-2429-A1, p. 25]

101 Public Law 117-58

The global market for EV battery recycling alone is estimated to reach $17.1 billion by 2030.102 By 2025, Benchmark Minerals Intelligence forecasts that scrap will account for 78% of the pool of recyclable materials.103 This growth is largely driven by the growing number of EVs approaching EOL. The volume of EOL batteries from EVs and large storage applications is less than 2 GWh today but could reach 100 GWh by 2030 and 1.3 TWh by 2040.104 [EPA-HQ-OAR-2022-0985-2429-A1, pp. 25 - 26]

104 "The Role of Critical Minerals in Clean Energy Transitions - Reliable supply of minerals," IEA, (2021) https://www.iea.org/reports/the-role-of-critical-minerals-in-clean-energy-transitions/reliable-supply-of-minerals

Below is a list of recently-announced investments in EV battery recycling, all of which will help support the transition to an electrified transportation sector:

- In October 2022, ZETA member Princeton NuEnergy Inc. (PNE) opened a new 500 t/a plant capable of direct recycling lithium-ion consumer electronics and EV batteries with its strategic partner, Wistron GreenTech in McKinney, Texas.105 This end-to-end facility ingests end of life batteries fully separating copper, aluminum, plastics, electrolyte, cathode and anode materials. Cathode materials are cleaned by surface etching with low-temperature plasma (LPAS™) and reformed into new cathode materials equivalent to OEM specifications that can be directly reused in battery production. The factory will be certified and commissioned in 2023.
- In April 2023, PNE launched a US Department of Energy $12MM R&D grant to expand and enhance PNE's battery recycling production processes through 'up-cycling' of legacy spent cathode chemistries into newer formulations, scaling processes for direct recycling of anode materials, and enhancing recycling/reuse of all other battery components.106
- In April 2023, ZETA member Redwood Materials announced a pair of partnerships to collect EOL battery feedstocks. Rad Power Bikes will provide Redwood with e-bike batteries when they reach the end of their lifespan.107 Redwood and Volkswagen of America expanded their partnership to collect more EOL batteries from consumer electronics.108 Both announcements come following a historic announcement of a $2 billion conditional loan from the Department of Energy to support Redwood's McCarran, NV recycling facility.109 At full production capacity, the McCarran project's anode copper foil and cathode active material output is anticipated to support the production of more than 1 million EVs per year.
- In May 2023, ZETA member Li-Cycle announced a partnership with Glencore to build a battery recycling hub in Portovesme, Italy, with construction expected to commence between late 2026 and early 2 Once completed, the Portovesme Hub is expected to have a processing capacity of up to 50,000 to 70,000 tons of black mass annually, or the equivalent of up to 36 GWh of lithium-ion batteries.110 [EPA-HQ-OAR-2022-0985-2429-A1, pp. 26 - 27]

105 "Update: Princeton NuEnergy launches end-to-end LIB recycling production line," RecyclingToday, (October 25, 2022) https://www.recyclingtoday.com/news/princeton-nuenergy-launching-end-to-end-lib-recycling-production-line/

109 “LPO Offers Conditional Commitment to Redwood Materials to Produce Critical Electric Vehicle Battery Components From Recycled Materials,” Department of Energy, (February 9, 2023) https://www.energy.gov/lpo/articles/lpo-offers-conditional-commitment-redwood-materials-produce-critical-electricvehicle

110 “Li-Cycle and Glencore unveil plans for recycling hub in Italy,” Reuters, (May 9, 2023) https://www.reuters.com/business/sustainable-business/li-cycle-glencore-unveil-plans-recycling-hub-italy-2023-05-09/

There is also a substantial effort to construct new copper recycling facilities, which often require different sources of feedstocks beyond EOL batteries, as demand for copper is expected to increase with increased deployment of EVs. A complete list of existing recycling projects can be found in Appendix Figure A.2. [EPA-HQ-OAR-2022-0985-2429-A1, p. 27.] [See Docket Number EPA-HQ-OAR-2022-0985-2429-A1, page 58, for Figure A.2]

EPA Summary and Response:

Summary:

Some commenters stated that recycling will not be a substantial source of critical materials in the near term due to lack of available supply of spent batteries (e.g. too few batteries, batteries being repurposed rather than scrapped), difficulties posed by a wide variety of cathode types (the source of the recoverable metals), and sorting difficulties. The commenters stated that the result of these issues is that lithium and other critical metal recycling from spent Li-ion batteries has not yet been demonstrated at commercial scale and is presently uneconomic and might remain so past MY 2032. (Chamber of Commerce, API (although API notes that it is presently economic to recover cobalt). Chevron questions the technical feasibility of recovering metals other than lithium.

Commenters including AFPM, API, Delek and TRALA indicated that only 5% of lithium-ion batteries are recycled today, compared to 99% of lead acid batteries. Furthermore, commenters say it will be a long time until the transportation batteries reach their end-of-life (10 years+) and it will take time for there to be a sufficient supply of spent lithium-ion batteries for these to be a major source of recycling supply.

American Fuel and Petroleum Manufacturers and API noted that most of the recoverable metals are found in the cathode, but that there are so many different cathode chemistries that sorting and analytic difficulties impede the viability of the recycling process.

Some commenters (Valero, AFPM, API) contend that EPA has ignored safety issues posed by management and disposal of spent lithium-ion batteries. In addition, they state that mining of raw critical materials poses environmental risks, and has led to degradation and worker abuses, such as in mining of cobalt in the Democratic Republic of the Congo.

Response:

For our response on recycling lithium-ion batteries and associated l issues relating to their management (including applicable EPA regulatory standards), see Preamble II.D.2.ii.c and RTC 17.2. The issue is also addressed (in less detail) in the following section 4.8.

4.8 Safety

Comments by Organizations

Organization: American Bus Association

We also note from the current unified agenda published by the Administration (https://www.reginfo.gov/public/do/eAgendaMain), that standards are not yet fully formed for safe hydrogen battery technology and are still under development (RIN 2127-AM40). Similarly, safety standards are still being developed and adopted for heavy-duty electric batteries as well (RIN 2127-AM43). Between a lack of safe or reliable technology development or operational standards, a lack of existing infrastructure, unreliable projections for future infrastructure, it seems prudent to delay a selection of any particular low or zero-emission technology strategy and any fleet requirements or projections should be set aside. [EPA-HQ-OAR-2022-0985-1634-A1, p. 3]

Organization: American Free Enterprise Chamber of Commerce (AmFree) et al.

d. Serious Safety Concerns Remain Unresolved

Finally, battery-electric and fuel-cell vehicles implicate significant, well-documented safety concerns that could materially impede deployment of heavy-duty electric vehicles. [EPA-HQ-OAR-2022-0985-1660-A1, p. 50]

To begin, spontaneous fires involving battery-electric vehicles have been reported across the country, and major manufacturers have reported battery defects and issued recalls due to fire-related risks. See Joce Sterman et al., Ignition: Spontaneous Electric Vehicle Fires Prompt Recalls, But Some Owners Stalled Waiting on Repairs, WBTV (Sept. 26, 2022), https://tinyurl.com/bddjbbw6. In addition, the National Transportation Safety Board conducted an investigation of electric-vehicle crashes and found that, "[i]n each case, emergency responders faced safety risks related to electric shock, thermal runaway, battery ignition and reignition, and stranded energy." Safety Risks to Emergency Responders from Lithium-Ion Battery Fires in Electric Vehicles, Nat'l Transp. Safety Bd. (Nov. 13, 2020), https://tinyurl.com/4b9bw869. Electric vehicles also are frequently heavier than conventional vehicles, and their greater weight could exacerbate injuries in the case of an accident. See Raul Arbelaez, As Heavy EVs Proliferate, Their Weight May Be a Drag on Safety, Ins. Inst. for Highway Safety (Mar. 9, 2023), https://tinyurl.com/txwb5wtn. [EPA-HQ-OAR-2022-0985-1660-A1, pp. 50 - 51]

EPA must consider these safety concerns as part of its feasibility analysis. See Sierra Club v. EPA, 325 F.3d 374, 378 (D.C. Cir. 2003) ("The statute also intends the agency to consider many factors other than pure technological capability, such as costs, lead time, safety, noise and energy."). But in the proposed rule, it simply brushed them aside. With respect to battery-electric vehicles, the agency merely stated that "standards have already been developed by the industry and are in place for manufacturers to use today to develop current and future products." 88 Fed. Reg. at 25,962; see also Draft RIA at 36–39. Those existing "standards" provide little assurance given the safety problems that have arisen already, and the likely increase in similar incidents if use of electric vehicles substantially increases, as the proposed rule not only anticipates but affirmatively intends. And with respect to fuel-cell vehicles, the agency notes only that "[h]ydrogen has been handled, used, stored, and moved in industrial settings for more than 50 years," and that there are "established methods," "federal oversight and regulation," and "standards" in place to ensure safe use. 88 Fed. Reg. at 25,972; Draft RIA at 75–76. These existing protocols, like those for battery-electric vehicles, are plainly inadequate in light of the documented disasters that have occurred in the United States and elsewhere. Even EPA acknowledges that "[a]s hydrogen demand increases, additional codes and standards at all levels of government are likely going to be needed to accommodate heavy-duty FCEVs and fueling station development." Draft RIA at 76. Those codes and standards must be established and proven effective before the agency adopts a rule that would require manufacturers to produce, and consumers to use, fuel-cell vehicles, not after. EPA cannot—and should not—put the American public in danger to advance its agenda on electric vehicles. [EPA-HQ-OAR-2022-0985-1660-A1, pp. 52 - 53.]

Organization: American Fuel and Petrochemical Manufacturers (AFPM)

Notably, EPA does not consider that ZEVs—particularly BEVs—are heavier than equivalent ICEVs and, therefore, may result in more severe accidents given the additional mass of the battery. As recognized by National Highway Transportation Safety Authority ("NHTSA") Administrator Ann Carlson, "[b]igger is safer if you don't look at the communities surrounding you and you don't look at the other vehicles on the road . . . [i]t actually turns out to be a very complex interaction."50 Yet EPA has not considered this interaction, on safety directly or the associated increase in insurance costs,51 which is all the more critical to the Proposed Rule as commercial trucks are involved in 13 percent of all fatal crashes on U.S. roadways and these trucks will be heavier and faster under the Proposed Rule.52 [EPA-HQ-OAR-2022-0985-1659-A2, p. 14]

50 Reuters, "U.S. NTSB chair raises safety concerns about heavy electric vehicles," David Shepardson (January 11, 2023) available at https://www.reuters.com/business/autos-transportation/us-ntsb-chair-raises-safety-concerns-about-heavy-electric-vehicles-2023-01-11/.

51 Jason Metz & Michelle Megna, Electric Car Insurance: Why It Costs More (Jan. 4, 2023), https://www.forbes.com/advisor/car-insurance/electric-vehicle/ (explaining that electric vehicles are costlier to insure)

52 U.S. DOT, Federal Motor Carrier Safety Administration, "2020 Pocket Guide to Large Truck and Bus Statistics," available at https://www.fmcsa.dot.gov/sites/fmcsa.dot.gov/files/2020-10/FMCSA%20Pocket%20Guide%202020-v8-FINAL-10-29-2020.pdf.

The greater prevalence of heavy-duty batteries will also pose additional risks to first and second responders as battery fires burn hotter and longer than similar fires in ICEVs. As documented by the National Transportation Safety Board, these responders face two major risks: (1) shock from damaged high-voltage electrical components and (2) battery reignition after initial fire suppression due to uncontrolled increases in temperature and pressure retained in the battery.53 Moreover, insufficient information exists from manufacturers on procedures for mitigating the risks of stranded energy to emergency responders. Additionally, storing an EV with a damaged high-voltage lithium-ion battery inside the recommended 50-foot-radius clear area may be infeasible at tow or storage yards.54 And beyond safety concerns, fighting a battery fire demands 30–40 times more water than a fire from an ICEVs.55 The Proposed Rule fails to even acknowledge these issues. [EPA-HQ-OAR-2022-0985-1659-A2, p. 14]

53 NTSB, “Risk to Emergency Responders from High-Voltage, Lithium-Ion Battery Fires Addressed in Safety Report,” (Jan. 13, 2021), available at https://www.ntsb.gov/news/press-releases/Pages/NR20210113.aspx. (See also Watch This Severe Electric Car Fire And Explosion At A Charging Station (insideevs.com)).

Organization: American Highway Users Alliance

Concerns of Truck Dealers

The American Truck Dealers Division (ATD) of the National Automobile Dealers Association also presented testimony at EPA’s May 3 public hearing on the proposed rule. Key points presented include the following.[EPA-HQ-OAR-2022-0985-1550-A1, p. 7]

Repair and servicing of the EV was reported as costly because ‘danger’ in servicing the EV requires two technicians rather than one. [EPA-HQ-OAR-2022-0985-1550-A1, p. 7]

Organization: Arizona State Legislature

The proposed rule is arbitrary and capricious because it fails to consider safety issues. [EPA-HQ-OAR-2022-0985-1621-A1, p. 24]

EPA understands that when acting under Section 202(a) it should consider relevant factors such as impacts on safety. 88 Fed. Reg. 25,949. EPA devotes just two paragraphs of the preamble to assessing the safety of heavy-duty battery electric vehicles, which largely consist of summarizing general design standards. Id. at 25,962. EPA devotes only one paragraph to address the safety risks posed by hydrogen in fuel-cell electric vehicles. Id. at 25,972. [EPA-HQ-OAR-2022-0985-1621-A1, p. 24]

EPA’s preamble does not consider or respond to serious safety issues presented by electric trucks. The National Transportation Safety Board has warned that ‘[f]ires in electric vehicles powered by high-voltage lithium-ion batteries pose the risk of electric shock to emergency responders from exposure to the high-voltage components of a damaged lithium-ion battery.’30 The National Transportation Safety Board also found that ‘[t]hermal runaway and multiple battery reignitions after initial fire suppression are safety risks in high-voltage lithium-ion battery fires.’31 [EPA-HQ-OAR-2022-0985-1621-A1, p. 24]

30 National Transportation Safety Board, Safety Risks to Emergency Responders from Lithium-Ion Battery Fires in Electric Vehicles, NTSB/SR-20/01, Nov. 13, 2020, viii, available at https://www.ntsb.gov/safety/safetystudies/Documents/SR2001.pdf.

31 Id. at 63.

EPA's draft regulatory impact analysis hints at this fire risk. EPA notes that first responders need 'large amounts of water'—2,600 gallons for a 600-pound lithium-ion battery—'to cool the batteries and eliminate the risk of fire.' Draft Regulatory Impact Analysis, 38. EPA also suggests that fire remains a risk days after a crash: 'Safe storage of crashed vehicles is critical as internal battery failure reactions may occur days after the crash and reignite.' Id. EPA recommends standard maintenance and safety training to mitigate these risks. Id. EPA does not estimate the cost or timetable for the safety training or the potential cost from fires and other damage. [EPA-HQ-OAR-2022-0985-1621-A1, p. 25]

Increased weight is another safety concern. The head of the National Transportation Safety Board has expressed concern about the increased weight of electric vehicles: 'I'm concerned about the increased risk of severe injury and death for all road users from heavier curb weights and increasing size, power, and performance of vehicles on our roads, including electric vehicles.'33 The executive director of the Center for Auto Safety warned, 'These bigger, heavier batteries are going to cause more damage. It's a simple matter of mass and speed.'34 [EPA-HQ-OAR-2022-0985-1621-A1, p. 25]

33 NTSB head warns of risks posed by heavy electric vehicles colliding with lighter cars, THE ASSOCIATED PRESS, Jan. 11, 2023, available at https://www.npr.org/2023/01/11/1148483758/ntsb-heavy-electric-vehicles-safety-risks.

34 Id.

Heavier electric trucks increase the risk of fatal crashes. A 2011 study by the National Bureau of Economic Research found that 'a 1,000-pound increase in striking vehicle weight raises the probability of a fatality in the struck vehicle by 47%.'35 Converting this increased fatality risks into external costs, 'total external costs of vehicle weight from fatalities alone are estimated at $93 billion per year.'36 A study by the University of California – Davis estimated that by 2030, heavyduty long haul trucks will have 5,328 extra pounds of weight.37 EPA does not estimate the cost from the increased fatalities or more severe injuries from crashes caused by electric trucks. [EPA-HQ-OAR-2022-0985-1621-A1, p. 25]

35 Michael Anderson and Maximilian Auffhammer, Pounds That Kill: The External Costs of Vehicle Weight, National Bureau of Economic Research Working Paper 17170, June 2011, 3, available at https://www.nber.org/system/files/working_papers/w17170/w17170.pdf.

37 John Harvey et al., Effects of Increased Weights of Alternative Fuel Trucks on Pavement and Bridges, University of California – Davis Institute of Transportation Studies, Nov. 2020, 10, available at https://aboutblaw.com/Xa7.

EPA's failure to adequately consider safety issues is arbitrary and capricious. [EPA-HQ-OAR-2022-0985-1621-A1, p. 25]

The proposed rule is arbitrary and capricious because it fails to adequately consider weight limit issues. [EPA-HQ-OAR-2022-0985-1621-A1, p. 26]

EPA acknowledges that commenters on a previous proposal raised concerns about 'the weight impact of batteries.' 88 Fed. Reg. 25,955. EPA does not identify what those concerns were, however. EPA implicitly acknowledges that the weight of electric batteries limits payload capacity. Id. at 25,969 (‘This allows FCEVs to perform periods of service between fueling events that batteries currently cannot achieve without affecting vehicle weight and limiting payload capacity.’). EPA later acknowledges that ‘heavy-duty vehicles are sensitive to increases in vehicle weight and carrying volume.’ Id. at 25,978. EPA found that extra battery weight in ‘coach buses and tractors that travel long distances could have an impact on operations of these vehicles as [battery electric vehicles].’ Id. If battery weight impacted payload capacity by more than 30%, then EPA assessed fuel cell technology instead. Id. [EPA-HQ-OAR-2022-0985-1621-A1, p. 26]

Organization: Bradbury, Steven G.

- Increasing the costs and burdens of first responders. There is no mention in EPA’s NPRMs or in the accompanying DRIAs of the impact these rules would have on first responders. If EVs come to comprise a greatly increased percentage of the nation’s auto fleet, as EPA’s proposals are intended to achieve, state and local first responders will inevitably incur significantly higher costs and burdens in the form of specialized fire-suppression chemicals and equipment and additional hazardous response training requirements. Lithium-ion battery fires are a common occurrence with EVs, and these fires generate intense heat and toxic fluoride gas emissions, making them more difficult to extinguish than conventional vehicle fires and increasing the costs and management challenges of maintaining effective first responder capabilities.56 [EPA-HQ-OAR-2022-0985-2427-A2, pp. 19-20]

56 See Fredrik Larsson, et al., “Toxic fluoride gas emissions from lithium-ion battery fires,” Scientific Reports, Nature, August 30, 2017, https://www.nature.com/articles/s41598-017-09784-z (corrected March 22, 2018) (also available at https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5577247/).

Organization: California Air Resources Board (CARB)

Regarding the safety of ZEV technologies, CARB staff is not aware of any studies indicating ZEVs are more dangerous than ICE vehicles. To the contrary, the data available suggests for LDVs, ZEVs are significantly less likely to catch on fire than gasoline-powered vehicles or hybrids.79 Per the data, ZEVs catch fire at a rate of 25.1 instances per 100,000 ZEVs sold versus 1,529 instances per 100,000 gasoline vehicles and 3,474 instances per 100,000 hybrid vehicles. Manufacturers have a strong incentive to produce safe vehicles, and ZEVs are no different in this regard. [EPA-HQ-OAR-2022-0985-1591-A1, p.31]

Organization: Clean Air Task Force et al.

d. BEV safety should not be a constraining factor in this rulemaking.

We agree with EPA’s assessment that “HD BEVs can be designed to maintain safety.” 88 Fed. Reg. at 25962. While some have put forward misguided arguments about the safety of BEVs as a reason for EPA to set weak standards in this rulemaking, those claims miss the mark for many reasons. BEVs have been on the road in appreciable numbers for more than a decade already, and BEV sales will continue to grow due to market forces alone. Original equipment manufacturers (OEMs), trade and professional associations, and safety authorities at all levels have long been studying, planning for, and responding to BEV safety matters.252 With or without the Phase 3 rulemaking, the number of BEVs will continue to grow, and safety research, planning, and design efforts will continue apace. Thus, safety should not act as a constraining factor in this rulemaking. [EPA-HQ-OAR-2022-0985-1640-A1, p. 59]

252 Indeed, these efforts began more than a decade ago. For example, in 2010, the National Fire Protection Association and SAE International hosted a summit on EV safety standards. Am. Nat'l Standards Inst. (ANSI), U.S. National Electric Vehicle Safety Standards Summit Report Released (Jan. 5, 2011), https://www.ansi.org/news/standards-news/all-news/2011/01/us-national-electric-vehicle-safety-standards-summit-report-released-05. And in 2011, ANSI convened a workshop on behalf of the U.S. DOE "to consider current and future U.S. domestic, regional, and international standards, codes, and conformity assessment activities needed to facilitate the introduction and widespread deployment of grid-connected electric vehicles." ANSI, ANSI Workshop: Standards and Codes for Electric Drive Vehicles (Apr. 5-6, 2011),
https://share.ansi.org/Shared%20Documents/Meetings%20and%20Events/EDV%20Workshop/EDVSponsorship.pdf

As EPA notes, numerous standards and codes govern BEV safety. 88 Fed. Reg. at 25962; DRIA Ch. 1.5.2. BEVs must meet the same federal safety requirements and undergo the same safety testing as combustion vehicles.253 In the light-duty sector (where BEVs have been on the road in greater numbers and for a longer period of time), evidence shows that BEVs "are at least as safe" as combustion vehicles in terms of crashworthiness test performance, while "injury claims are substantially less frequent" for BEVs than for combustion vehicles.254 And on some safety metrics, BEVs perform substantially better than combustion vehicles. Due to their battery architecture, for example, BEVs typically have a lower center of gravity than combustion vehicles, which increases stability and reduces the risk of rollovers255 (the cause of up to 35 percent of accident deaths).256 [EPA-HQ-OAR-2022-0985-1640-A1, pp. 59 - 60]

Fire risk and emergency response can also be managed effectively. BEVs are significantly less likely to catch fire than combustion vehicles in the first place.260 While BEVs can behave differently in fires than combustion vehicles, emergency responders have been gaining experience in BEV fire response as the number of BEVs on the road has grown. Numerous agencies and associations, including the National Transportation Safety Board,261 National Highway Traffic Safety Administration,262 and National Fire Protection Association,263 have established fire safety and emergency response recommendations for BEVs. The National Fire Protection Association and other organizations offer BEV fire response trainings,264 as do OEMs, which also produce emergency response guides for their vehicles.265 Volvo Trucks has even released an augmented reality safety app that allows first responders "to observe the scene of the emergency through an iPad or tablet camera, and which will then overlay graphics and instructions that enable … a full, detailed view of where potentially dangerous components are located, as well as the steps required to make them safe."266 The National Institute for Automotive Service has also developed safety-related standards and a testing and certification program for automotive technicians who service BEVs.267 Expected future use of solid state batteries will further reduce BEV fire risk.268 Other research efforts have identified battery designs that can improve thermal management,269 as well as improved methods of extinguishing battery fires.270 [EPA-HQ-OAR-2022-0985-1640-A1, pp. 60 - 61]

In sum, the public and private sectors have been working diligently to address BEV safety considerations, and those efforts will continue as the number of BEVs on the road grows. Heavy-duty BEVs can be designed and operated safely and EPA is correct in not treating safety as a constraining factor in this rulemaking. [EPA-HQ-OAR-2022-0985-1640-A1, p. 61]

Organization: Daimler Truck North America LLC (DTNA)

EPA Request for Comment, Request #13: We request comment on our assessment that HD BEVs can be designed to maintain safety.

- DTNA Response: Based upon DTNA's extensive experience in ZEV product development, there is no question that HD BEVs can be designed to maintain safety. [EPA-HQ-OAR-2022-0985-1555-A1, p. 160]

Organization: Owner-Operator Independent Drivers Association (OOIDA)

BEV fires are another safety concern. Lithium-battery fires can be unpredictable, difficult to extinguish, and can inflict a tragic toll. According to experts, BEV fires require different firefighting techniques. The biggest difference is that an BEV fire cannot be put out with the type of firefighting foam used to smother other fires. Instead, the battery must be cooled to stop the fire and end thermal runaway.8 Currently, there is insufficient training for consumers, first responders, and certainly professional truck drivers about how to protect themselves and the public should a fire occur. BEV fires involving commercial vehicles could be particularly dangerous given the weight of the batteries and/or if the fire occurs on or near highway infrastructure. [EPA-HQ-OAR-2022-0985-1632-A1, p. 4]

8 https://www.usatoday.com/story/money/cars/2022/10/26/electric-vehicle-fires-florida-flooding-what-happened/10553207002/

Organization: The Sulphur Institute (TSI)

One key concern not addressed in this NPRM and one from TSI, is how refineries and gas plants will adapt, or can adapt, to having electric vehicles operate "inside the fence line" (i.e., is it safe to operate an electric battery or hydrogen vehicle in such a highly flammable environment). The National Transportation Safety Board has documented (2) the safety risks to emergency responders from lithium-ion battery fires. While occurrence of a fire may be low, there could be catastrophic consequences of such an incident inside a refinery, for example. To date, TSI has not seen a process hazard analysis (PHA) conducted in accordance with EPA's risk management plan (RMP) or OHSA's process safety management (PSM) standards that supports the use of EV or hydrogen vehicles in a highly flammable environment. TSI encourages the EPA to engage energy industry stakeholders to research and conclude if it is safe to operate these vehicles in refineries before a mandate from this NPRM takes effect. Safety Concerns

Safety advocates have raised concerns over the increased weight of ZEVs. The National Transportation Safety Board (NTSB) has also expressed concern about the safety risks that heavy EVs pose if they collide with lighter vehicles.14 Little research has been done on the safety risks of increasing vehicle weights and the interfacing between lighter vehicles with heavier trucks. In 2011, the National Bureau of Economic Research published a paper that said being hit by a vehicle with an added 1,000 pounds increases by 47% the probability of being killed in a crash.15 [EPA-HQ-OAR-2022-0985-1577-A1, p. 12]

14 'NTSB head warns of risks posed by heavy electric vehicles colliding with lighter cars,' The Associated Press (January 11, 2023).

15 'Why the 'significant' weight of electric vehicles is sparking new safety fears,' Global News (April 12, 2023).

Increased weight is not the only issue of concern for safety advocates. ZEVs also afford drivers unprecedented engine power and acceleration if not governed. [EPA-HQ-OAR-2022-0985-1577-A1, p. 12]

ZEVs may also increase road congestion as more vehicles may be needed to fulfill hauling needs due to reductions in drive times (See Hours-of-Service discussion below) and reduced payloads resulting from the thousands of pounds of added weight to trucks from ZEV technologies (See Weight Exemption discussion below). More truck-to-car interactions will increase the potential for more highway accidents. [EPA-HQ-OAR-2022-0985-1577-A1, p. 12]

The national shortage of truck parking spaces has reached historic levels. The increasing number of trucks parked on the shoulders of highways, in retail parking lots, and along on- and off-ramps are the consequence of inadequate rest areas for truckers. Parked trucks in undesignated or unauthorized areas jeopardize the safety for both drivers and the public alike. (See Truck Parking discussion below). Unless the nation's truck parking shortage is addressed, ZEVs stand to potentially exacerbate the current situation. [EPA-HQ-OAR-2022-0985-1577-A1, p. 12]

Emergency responders anticipate the need to prepare for fires in crashes and incidents from lithium-ion battery-powered trucks. EVs present new challenges for first responders and safety concerns from energy stored in battery packs. Proper EV towing is critical and the ignition/reignition of fires several weeks into BEVs being stored in tow yards needs to be carefully monitored and assessed. While much experience is being gained from incidences involving light-duty vehicles, the same cannot be said for EV vehicles at the other end of the spectrum. [EPA-HQ-OAR-2022-0985-1577-A1, p. 12]

Organization: Valero Energy Corporation

Conversely, EPA should consider whether the increased costs resulting from the proposed rule cause shippers to turn to rail. Rural communities with limited highway access are already experiencing unreasonable delays for emergency responders to reach patients due to extremely long trains that may take hours to clear; in some cases, these delays have resulted in fatalities.155 [EPA-HQ-OAR-2022-0985-1566-A2, p. 32]

155 https://www.washingtonpost.com/nation/interactive/2023/long-trains-block-intersections-paramedics/

2. EPA fails to consider threats to human health and safety created by transition to heavy-duty ZEV.

The proposed rule fails to address the real-world safety implications of increasing the number of heavy-duty trucks on America's roadways by as much as 33 to 50 percent. In fact, the head of the National Transportation Safety Board recently warned that the heavier weight of electric vehicles poses increased risk of severe injury or death to passengers in lighter vehicles.156 While her comments were centered on the multi-thousand pound weight differential between battery electric LDVs and their much lighter conventional ICE LDV counterparts, the HDV proposal carries the same risk, but at a much higher HDV to LDV weight differential of tens of thousands of pounds, compounded by the need to increase the sheer number of HDV on U.S. roadways to meet EPA's proposed standards and the cargo demands of the country. In work performed by the National Bureau of Economic Research, Pounds that Kill: The External Cost of Vehicle Weight, showed that "controlling for own-vehicle weight, being hit by a vehicle that is 1,000 pounds heavier results in a 47% increase in the baseline fatality probability."157 EPA's proposal fails to account for the resulting increase in the number of heavier heavy-duty vehicles on U.S. roads and the associated increase in risk of fatalities. [EPA-HQ-OAR-2022-0985-1566-A2, p. 32]

156 See Id.

157 National Bureau of Economic Research, Pounds That Kill: The external costs of Vehicle Weight, June 2011

Further, EPA's proposal lacks coordination with the National Transportation Safety Board and the U.S. Department of Transportation (DOT) to address safety issues created directly from EPA's proposed rule. "The DOT has a responsibility to research and ensure vehicle and roadway design and safety standards meet the challenges and demands of our future transportation system. This Administration continues to push policies that will result in more BEVs on our roadways, but has failed to plan from a safety and infrastructure perspective. The sequence of proposals is misguided; vehicle and roadway design and safety standards should have been under development and deployed well before the EPA proposed a rule to force consumer adoption of heavier EVs. This type of research and development, including vehicle, roadway lifespan, and guardrail and work zone safety equipment testing all will require years to undertake. If these proposals move forward without the appropriate safeguards in place, backed by sound science, the vehicle and infrastructure investments being made today may miss the mark on safety and longevity in the years to come."158 [EPA-HQ-OAR-2022-0985-1566-A2, p. 32]

158 Letter from the United States Senate to EPA Administrator, May 25, 2023

Moreover, EPA fails to address the increase in fire hazards posed by lithium-ion batteries. On May 24, 2023, EPA's Office of Resource Conservation and Recovery issued a memo clarifying applicability of the Resource Conservation and Recovery Act ("RCRA") universal waste and recycling requirements to lithium-ion batteries, stating that these batteries "are likely hazardous waste at end of life."159 A FAQ appended to the memorandum stated that "Given the number of fires from lithium batteries, EPA is evaluating universal waste battery management standards."160 Until this analysis is complete and any necessary regulatory changes are made, these risks likely will remain. Further, since RCRA does not apply to products that are in use and have not been deemed a waste, any standard EPA may develop to mitigate risks from used batteries will not apply to batteries that are in use or have not yet been deemed a waste. EPA therefore should, but to date has not, consider the increased fire hazard presented by additional heavy-duty vehicles with large batteries. [EPA-HQ-OAR-2022-0985-1566-A2, p. 33]

Organization: Volvo Group

Packaging Challenges

The proposed rulemaking requests comment on stringency adjustments based on the suitability of electrification/alternative fuels for various duty cycles. The Volvo Group would presumably register vehicles among 16 of the 101 vehicle categories listed. As we shift our platforms toward more CO2-neutral products, greater packaging challenges will drive new initiatives to ensure we remain compliant with the Code of Federal Regulations (CFR) and Federal Motor Vehicle Safety Standards (FMVSS). [EPA-HQ-OAR-2022-0985-1606-A1, p. 12]

EPA Summary and Response:

EPA discusses the issue of BEV safety considerations extensively in RIA Chapter 1.5.2. In addition to the detailed discussion there, we add the following summary of comments and response thereto.

Summary:

The American Highway Users Alliance claims that EV servicing danger drives the need for two technicians rather than one. NADA-ATD shared that dealerships would require workplace safety and emergency response training to safely work with and around high voltage systems.

The Arizona State Legislature asserted that the "proposed rule is arbitrary and capricious because it fails to consider safety issues," and continues that EPA's discussion of safety issues in the preamble was cursory, even as it acknowledged and also stated that EPA is obliged to consider safety issues "under Section 202 (a)." The Clean Fuel Development Coalition asserts (in a footnote) that "the proposal also arbitrarily ignores the underdeveloped industry standards and safety protocols that exist today for heavy-duty BEVs and FCEVs that it must consider under Section 202(a)(4)(A) that specifically prohibits the use of an emission control device, system or element of design that will cause or contribute to an unreasonable risk to public health, welfare, or safety."

The Arizona State Legislature also stated that the preamble to the proposed rule failed to "consider or respond to serious safety issues presented by electric trucks." The commenter quotes materials from the National Transportation Safety Board which warn that "'[f]ires in electric vehicles powered by high-voltage lithium-ion batteries pose the risk of electric shock to emergency responders from exposure to the high-voltage components of a damaged lithium-ion battery".' and that "'[t]hermal runaway and multiple battery reignitions after initial fire suppression are safety risks in high-voltage lithium-ion battery fires."' Other commenters raising similar concerns were AmFree, AFPM, Steven Bradbury, DTNA, Owner Operator Independent Drivers Ass'n (OOIDA), TRALA, and Valero. DTNA also commented that there is insufficient training on fire protection for first responders and HD BEV users. CARB shared LD data showing that the ZEV rate of fire occurrence is much lower than that of gasoline vehicles. The Clean Air Task Force shared the same fire incidence trend. They also noted the many agencies that provide fire and emergency response recommendations and training. NADA commented that some dealers were educating first responders on proper battery safety when responding to crashes. Steven Bradbury and the Arizona State Legislature shared concern that first responders would have higher operational costs. Also concerning fire risk, TSI raised concern with HD BEV operating "within the fence line" of a refinery.

The American Free Enterprise arm of the Chamber of Commerce maintains that "existing 'standards' provide little assurance given the safety problems that have arisen already, and the likely increase in similar incidents if use of electric vehicles substantially increases, as the proposed rule not only anticipates but affirmatively intends." Similarly, The American Bus Association and Valero claim that there is currently insufficient safe operational standards. Volvo shared that they would have packaging challenges to meet existing Code of Federal Regulations (CFR) and Federal Motor Vehicle Safety Standards (FMVSS) that would drive initiatives to remain compliant.

The Arizona State Legislature, as well as AmFree, TRALA, National Ass'n of Chemical Distributors, AFPM, and Valero, claim that there will be increased fatalities resulting from crashes between HD BEVs and lighter weight ICE vehicles due to the extra weight attributable to the battery. Some of these comments cited a 2011 study for the proposition that "'a 1,000-pound increase in striking vehicle weight raises the probability of a fatality in the struck vehicle by 47%.'" The Arizona legislature comment states that EPA should monetize these additional fatalities as a cost of the rule. AFPM adds that the increased speed of the BEV will be a safety issue while TRALA suggests a risk due to ZEV providing "unprecedented engine power and acceleration."

Valero indicates states that spent lithium-ion batteries are hazardous wastes under federal law and that their recycling and other management could therefore pose risks for which EPA has failed to adequately account.

Commenters like Valero and TRALA maintained that BEVs would lead to additional traffic congestion due to a 33 to 50% increase in HD trucks. Certain commenters (including Valero, National Ass'n of Chemical Distributors and the Sulphur institute) maintained that ZEVs would contribute to increased traffic, the assumption being that due to limited range, more trips would be required. TRALA expanded the concern of additional trucks to theorize that parking could become such an issue that it would cause safety concerns. TRALA also shared that the increased power of HD BEVs could cause safety concerns.

Valero maintains that EPA failed to coordinate with relevant federal safety agencies in issuing its proposed rule.

<u>Response:</u>

EPA's assessment at proposal was that HD BEV systems must be, and are, designed "to always maintain safe operation." 88 FR at 25962. EPA reiterates that conclusion here. As EPA explained at proposal, and as noted by certain commenters, there are industry codes and standards for the safe design and operation of HD BEVs. The operation of BEV extends to service as well as to emergency response. In addition, HD BEVs are subject to, and necessarily comply with, the same federal safety standards and the same safety testing as ICE heavy-duty vehicles. Commenters challenging the safety of HD BEVs failed to address the existence of these protocols and federal standards.

For HD BEVs to uphold battery/electrical safety during and after a crash, they are designed to maintain high voltage isolation, prevent leakage of electrolyte and volatile gases, maintain internal battery integrity, and withstand external fire that could come from the BEV or other vehicle(s) involved in a crash. The internal battery integrity is important to prevent fire risk from developing within the battery over time. Standards driving design and process for optimizing crash and post-crash safety have been completed by IEC and ISO as well as:

- National Highway Traffic Safety Administration (NHTSA) FMVSS 305, electrolyte spillage and electrical shock protection
- NHTSA DOT HS 812 789, post-crash stranded energy tools and procedures
- SAE J1766, crash integrity testing
- SAE J2990, first and second responder recommended practice

Moreover, empirical evidence from the light-duty sector (where BEVs have been on the road in greater numbers and for a longer period of time), shows that BEVs “are at least as safe” as combustion vehicles in terms of crashworthiness test performance, and “injury claims are substantially less frequent” for BEVs than for combustion vehicles.[366] On some safety metrics, BEVs perform substantially better than ICE vehicles. Due to their battery architecture, for example, BEVs typically have a lower center of gravity than combustion vehicles, which increases stability and reduces the risk of rollovers (the cause of up to 35 percent of accident deaths).[367]

Similarly, the record for NHTSA’s 2023 proposal to revise Corporate Average Fuel Economy standards for all light passenger vehicles includes estimates of the safety impacts of EV weight and found that, “Change in vehicle mass affects the prevalence of injuries and fatalities on roadways. Increases in vehicle mass might confer additional safety to vehicle occupants while also reducing safety for pedestrians, cyclists, and other vulnerable road users, as well as for road users with lower mass vehicles.” But this light passenger vehicle Preliminary RIA goes on to say, “Across all alternatives, mass changes relative to the baseline result in small reductions in overall fatalities, injuries, and property damage. These results may seem counterintuitive given the agency’s previous analyses. This outcome amounts to noise around zero.”[368]

---

[366] See Insurance Inst. for Highway Safety, “With More Electric Vehicles Comes More Proof of Safety” (Apr. 22, 2021), https://www.iihs.org/news/detail/with-more-electric-vehicles-comes-more-proof-of-safety.
[367] DOE, “Maintenance and Safety of Electric Vehicles,” https://afdc.energy.gov/vehicles/electric_maintenance.html.
[368] US Department of Transportation, National Highway Traffic Safety Administration. “Preliminary Regulatory Impact Analysis. Corporate Average Fuel Economy Standards for Passenger Cars and Light Trucks for Model Years

Fire risk and emergency response can also be managed effectively. There is evidence (discussed more fully below) that EVs are less likely to catch fire than internal combustion engine vehicles. Although BEVs can behave differently in fires than ICE vehicles, emergency responders have been gaining experience in BEV fire response as the number of BEVs on the road has grown, and there are protocols and guidance at the federal and private levels in support of first responders. See individual response below.

In sum, the public and private sectors have been working diligently to address BEV safety considerations, and those efforts will continue as the number of BEVs on the road grows. Heavy-duty BEVs can be, and are designed and operated safely and EPA, after study and consideration, is therefore not considering safety as a constraining factor in this rulemaking.

In regards to the comment that ZEVs would need two technicians rather than one, requiring two technicians for BEV servicing should not be and is not the preferred or even acceptable safety methodology for BEV. The two-technician proposal suggests one should be an observer. Observing and reacting to an accident after harm is done is much less desirable than preventing the accident altogether. Creating service procedures that require two technicians is not acceptable safety practice and is not seen in service procedure articles.[369] Per these articles, safety is accomplished with proper personnel protective equipment (PPE) and proper procedures, many of which involve deactivating or disconnecting high voltage systems. Proper PPE procedures, and training are all currently required for ICEV just as they are for BEV. Also consistent in the literature is the expectation that BEV will require less maintenance.[370]

Comments that EPA failed to properly consider issues of safety in regards to ZEVs are unfounded. Issues of safety are certainly proper for EPA to consider under section 202(a)(1) and (2), and EPA has done so since the inception of its motor vehicle emission control programs. See, e.g., 81 FR at 73512/2 (Oct. 25, 2016). CAA Section 202(a)(4) indeed mandates EPA to consider whether emission control devices, systems, or design elements pose an “unreasonable risk to public … safety.” EPA also considers issues of safety when determining whether to issue a vehicle a certificate of conformity. See section 206(a)(3)(A). EPA thus discussed and assessed potential safety issues associated with BEV and FCEV at length in the DRIA as well as in the proposed rule preamble, noting potential safety issues and means of securely managing those issues. See DRIA at pp. 37-39 (BEVs), 69 (depot charger installation), and 74-76 (FCEVs). See also RIA Chapter 1.5.2 and 1.7.4. Nor does EPA consider the multiple binding federal safety standards, and industry protocols to be ineffective. The commenters’ claim that EPA arbitrarily failed to consider safety issues is consequently incorrect.

Commenters are also incorrect in their assertion that the EPA did not consider the potential risk of fires in electric vehicles. First, as the commenter Arizona State legislature acknowledges, EPA did discuss these issues in the DRIA. DRIA at 38. EPA stated, and reiterates, that large

amounts of water can be needed to put out fires which may result from large batteries, and that first responders can and should be trained to deal with fires of electrical origin (as they are trained to deal with fires from other chemical, ignitable, or flammable origins). Empirical studies in fact indicate that fire rates from BEVs are lower than fire rates from ICEs or hybrid vehicles. While some aspects of suppressing BEV fires may increase first responder costs, lower fire incidence will keep operational costs down. See AutoinsuranceEZ: Gas vs. Electric Car Fires [2024 Findings], Dec. 19, 2023 (rate of fires from BEV light duty vehicles is one-and-a-half to over two orders of magnitude less than rate for gasoline or hybrid vehicles). Fire-related recalls for BEVs are likewise considerably lower than for their ICE or hybrid counterparts. Id. The same source and AFPM note, as EPA did at proposal, that battery fires are of a different character, can pose different and more difficult challenges to extinguish, and the vehicles may have stranded electrical power, such that first responder training is desirable. Numerous agencies and associations, including the National Transportation Safety Board, National Highway Traffic Safety Administration, and National Fire Protection Association, have established fire safety and emergency response recommendations for BEVs. See Rachel Bodine, Gas vs. Electric Car Fires [2023 Findings], AutoinsuranceEZ (Nov. 11, 2022), https://www.autoinsuranceez.com/gas-vs-electric-car-fires/ (calculating rate of car fires using National Transportation Safety Board data); see, e.g., NTSB, Risks to Emergency Responders from High-Voltage, Lithium-Ion Battery Fires Addressed in Safety Report (Jan. 13, 2021)[371]. See also Comments of Clean Air Task Force, summarizing additional actions of public and private entities regarding emergency preparedness. Although these data are from light duty vehicles, EPA's assessment is that it is appropriate to give weight to them in its consideration of battery safety issues (and, in addition, we note the absence of data from HD BEV applications).

Although HD BEVs are seen as safe with respect to fire risk, operation within a refinery as posed by TSI could be a special case. EPA does not claim to have the knowledge to address refinery risk and safe operating procedures. As not all HD vehicles are projected to be ZEVs in EPA's modeled potential compliance pathway, refineries, like other purchasers, will have choices regarding what vehicle type is best for their special circumstances.

EPA thus has considered the issue of HD and FCEV battery fire safety, and accounted for potential risks and means to mitigate them.

As noted above, BEV fire rates have been historically less than for ICE and hybrid vehicle types. And many of the "standards" (commenter's air quotes) are the same federally applicable safety standards to which ICE vehicles likewise are subject. EPA thus does not accept the commenters' contention that existing standards serve as no guarantee of safety. RIN: 2127-AM43 adds safety requirements for propulsion batteries in electric-powered vehicles and extends the applicability of FMVSS No. 305 to heavy vehicles (vehicles with a gross vehicle weight rating greater than 10,000 pounds) to align the standard with global technical regulation (GTR) No. 20, Electric vehicle safety. The proposed additional FCEV requirements (RIN: 2127-AM40) align with those specified in global technical regulation (GTR) No. 13, Hydrogen and fuel cell vehicles. Both AM40 and AM43 are planned for publication in early 2024. EPA notes further that the heavy-duty manufacturing industry is investing enormous amounts of capital into

[371] https://www.ntsb.gov/news/press-releases/Pages/NR20210113.aspx.; see 262 See, e.g., NHTSA, Interim Guidance for Electric and Hybrid-Electric Vehicles Equipped With High Voltage Batteries (2012), https://www.nhtsa.gov/sites/nhtsa.gov/files/interimguide_emergencyresponse_012012_v3.pdf.

developing and marketing HD BEVs, and it is obviously in their interest that these vehicles be safe in operation. See Comments of Daimler at 160 stating unequivocally that HD BEVs do not pose a safety risk, as well as Volvo's comment that it adheres strictly to all applicable safety standards in designing its HD BEVs.

The comments claiming increased fatalities due to crashes between HD BEVs and lighter weight ICE vehicles due to extra weight are overstated given that the weight of Class 8 BEVs is capped by law at 82,000 lbs, which is only 2,000 pounds (2.5%) more than the maximum weight of a Class 8 ICE vehicle. See, e.g., Comments of Clean Air Task Force at 60; 23 USC section 127s. For other weight classes, the vehicle weight is restricted to the same maximum GVWR for BEV and ICE. In addition, our HD TRUCS analysis took a close look at weight and payload (as further described in RIA Chapter 2.9.1), and there are a number of applications (per HD TRUCS) where the optimized vehicle weight is less than that of the comparable ICE vehicle. Also, per our HD TRUCS analysis, almost 50% of the 101 vehicle types studied had a 2% or less weight gain for BEVs versus a comparable ICE vehicle. We also note that this final rule does not mandate use of ZEVs. The modeled potential compliance pathway is but one example of how manufacturers may choose to meet the standards at reasonable cost within the lead time afforded. See generally our responses in RTC section 2.1 above. As such, certain applications for vehicle types requiring the largest batteries and possibly increasing weight the most will be the most expensive and least likely to improve TCO and the correspondingly manufacturers are most likely to use ICEVs for those applications as a compliance strategy. Moreover, there is every incentive for OEMs to reduce weight of BEV vehicles in order to improve BEV efficiency and vehicle range. Llighter weight battery alternatives are readily available and battery weight can decrease as specific energy increases as expected by ANL/DOE[372]. DRIA at 40; see generally Sebastian Blanco, The Future of Solid-State Batteries, J.D. Power (Apr. 3, 2023).[373] Finally, the comment by AFPM that the HD BEV will have increased speed is not substantiated nor is there reason to think (TRALA) that the acceleration performance of ZEV is a safety concern. Vehicle speeds are governed on our roadways and there is no reason for BEV to be moving faster.

EPA disagrees with the commenter's assertion that spent lithium-ion batteries pose risks that the EPA has not accounted for. The fact that spent lithium-ion batteries may be hazardous wastes is a factor favoring their safe management, not the reverse. As the commenter indicated, most lithium-ion batteries are likely to be hazardous waste when discarded due to potential ignitability (D001) and reactivity (D003) characteristics, which are two of four hazardous waste characteristics that identify any given waste as hazardous. See 40 CFR Part 261 subpart C. Persons who generate wastes that are defined as hazardous under Resource Conservation and Recovery Act (RCRA) are referred to as "hazardous waste generators." While EPA has determined that most lithium-ion batteries on the market today are likely to be hazardous waste when they are disposed of, it is the responsibility of the generators (persons who generate wastes) to make an accurate hazardous waste determination per 40 CFR 262.11. If the battery is a hazardous waste, then the battery must be managed properly from point of generation to point of final disposition under various EPA regulations implementing subtitle C of RCRA.

---

[372] https://publications.anl.gov/anlpubs/2024/01/187177.pdf. Cost Analysis and Projections for U.S.-Manufactured Automotive Lithium-ion Batteries

[373] https://www.jdpower.com/cars/shopping-guides/the-future-of-solid-state-batteries; Chris Teague, What You Need To Know About Solid-State Batteries, Autoweek, https://www.autoweek.com/news/technology/a36189339/solid-state-batteries/ (last visited June 15, 2023).

Spent electric vehicle batteries are likely to be recycled, as the commenter seems to acknowledge. See RTC 17.2. Safe recycling of hazardous waste batteries is encouraged under the RCRA hazardous waste regulations. Hazardous waste batteries of all chemistries may be managed under the Universal Waste battery regulations found in 40 CFR Part 273. These regulations are designed to encourage resource recovery while ensuring adequate protection of human health and the environment. See 60 FR at 25501-02 (May 11, 1995). Requirements for battery handlers (defined in 40 CFR section 273.9) include but are not limited to: notification to EPA and obtaining an EPA identification number, labeling of containers of batteries, employee training, limits on battery accumulation time, plus recordkeeping and record retention. Ultimately the universal waste batteries must go to a destination facility that has a RCRA subtitle C permit if it stores batteries that are hazardous waste, or otherwise satisfies conditions set out in 40 CFR section 261.6(c) for certain recyclers. These regulatory provisions are intended ensure proper management at end-of-life for lithium-ion batteries. In addition, EPA has further clarified how hazardous lithium batteries are regulated when recycled at end of life in the memorandum from Carolyn Hoskinson, Director, Office of Resource Conservation and Recovery, “Lithium Battery Recycling Regulatory Status and Frequently Asked Questions” (EPA Office of Land and Emergency Management, May 24, 2023) (cited by the commenter). Should hazardous waste batteries be disposed rather than recycled, their management is comprehensively regulated from point of generation to point of final disposition under the RCRA subtitle C regulations (40 CFR Parts 261-265 and 267). Among the requirements are a prohibition on land disposal of the batteries until they are pretreated so as to minimize any threats to human health and the environment posed by their land disposal. RCRA section 3004 (m) and 40 CFR Part 267 (treatment standards).

In addition, the Department of Transportation regulates end-of-life batteries under its Hazardous Material Regulations. Manufacturers are required to meet requirements related to altitude, thermal test, overcharge, and shock. Upon passing this test, batteries can be transported but are subject to additional safety requirements, such as being placed in outer packaging that can resist atmospheric pressure, loadings, and shocks that typically occur during transportation. See generally 49 CFR Parts 171-180 generally and 49 CFR section 173.185 for hazardous material regulation for lithium batteries.

EPA consequently does not accept the commenter’s assertion that EPA is unaware of potential issues relating to management of spent lithium-ion batteries, or that management of these batteries poses risks for which EPA has not accounted for in this rulemaking.

EPA’s responses to issues of BEV range and payload are found at RTC Section 4.4, RIA Chapter 2.9.1, and sources there cited. For the reasons there stated, EPA does not accept the premise that traffic congestion or parking problems will increase as a result of the final standards. Moreover, as stated previously, this final rule is not a ZEV mandate, and considers ZEVs in one modeled potential compliance pathway for meeting the standards to support the feasibility of the final standards. Other methods of compliance are available. See, e.g., preamble Section II.F.4; see also our responses in RTC section 2.1. Under our modeled potential compliance pathway, fleet owners are not expected to utilize BEVs, nor manufacturers to produce them, for applications (to the extent there are any) that would require more than one HD ZEV to replace a comparable ICE vehicle. As explained throughout this response, EPA does not accept the assertion that HD BEV power will cause safety concerns. Moreover, RMI notes in its comments that HD drivers have commented that "driving in traffic seems easier and safer" in a BEV due to superior torque, better visibility, and smoother ride.

EPA has a long history of coordinating safety issues with the National Highway Traffic Safety Administration (NHTSA) and did so prior to the proposal and throughout the rulemaking process for the final rule here. See Memorandum from Michael Landgraf "Summary of NHTSA Safety Communications During LD and HD GHG Rulemaking" (February 14, 2024). EPA has also met extensively with the Joint Office of Energy and Transportation, of which NHTSA is a member, throughout this entire rulemaking process. Information included by EPA in EPA's rulemaking record on pending NHTSA rulemakings pertaining to BEVs and FCEVs, as well as documentation of existing NHTSA research pertaining to electrified vehicles, is a product of that consultation.

4.9 BEV Mounting Systems and Tires

Comments by Organizations

Organization: Lynden Incorporated

Batteries and electric motors on rubber mountings are not robust enough to handle the impact of gravel roads, which would make transporting critical supplies and supporting the remote Alaskan and rural agricultural communities in the Pacific Northwest unreliable, if not impossible. [EPA-HQ-OAR-2022-0985-1470-A1, p. 2]

Organization: Truck Renting and Leasing Association (TRALA)

Tires, tubes, liners, and valves for truck businesses are the number one repair and maintenance expense comprising 43% of all such costs. 13 (See Figure 3). [Refer to Figure 3 on p. 11 of docket number EPA-HQ-OAR-2022-0985-1577-A1] ZEV tires will cost even more as the added weight and extra torque of a ZEV will cause greater and quicker tire wear. It also remains unclear whether the new generation of tires for ZEVs will maintain the same tire and casing integrity for retread purposes – a must for today's truck maintenance shops and a key strategy for maximizing tire recovery and reuse. TRALA asks EPA to address increased ZEV tire costs and performance in the final rule. [EPA-HQ-OAR-2022-0985-1577-A1, p. 10]

> 13 'Transportation Fleets Lowering Tire Costs Through Data, Business Intelligence and Lifecycle Management,' Waste Advantage Magazine (November 30, 2019).

Organization: U.S. Tire Manufacturers Association (USTMA)

Additionally, as electric commercial vehicles continue to be introduced into the marketplace, their heavier weight and negative impact on tire wear merits careful consideration. Ensuring tires can handle the increased load of the vehicle can mitigate any unintended consequences impacting driver safety and tire performance. [EPA-HQ-OAR-2022-0985-1635-A1, p. 4]

EPA Summary and Response:

Summary:

EPA received a comment from Lynden Inc. that the mounting systems for electric motors and batteries are not robust enough for extended use on gravel roads and this makes delivering critical supplies in harsh conditions unreliable.

TRALA and USTMA expressed concern over tire performance due to heavier weight EVs and the potential for increased tire wear. TRALA suggested that EPA should consider the cost of any increased maintenance for tires and USTMA noted a need for tires to "handle the increase load" to ensure driver safety.

Response:

We expect that manufacturers will build ZEVs to meet or exceed the reliability requirements of manufacturers' current ICE vehicle portfolio. Moreover, as noted above when considering similar comments regarding ZEV suitability for operation in extreme weather conditions, we expect that fleets operating in extreme conditions (be it ambient temperature or unpaved highways) will adopt ZEVs more slowly than in less harsh areas and, as explained further in our response in RTC Section 4.3.2, there would be ample opportunities under these standards for ICE vehicles to be utilized in those conditions.

We do not have data to suggest tires are underperforming for current EV customers in the heavy-duty sector as explained in Section 13 of RTC. Furthermore, heavy-duty vehicles, regardless of their propulsion technology or tare weight, are limited by their gross vehicle weight rating (GVWR) and tire manufacturers currently offer a wide selection of tires for the entire range of weights legally permissible for heavy-duty vehicles. We expect tire manufacturers will continue to research vehicle trends and design tires that meet the durability and performance needs of their customers. Commenters did not provide data or references from which we could update our analysis for the final rule. See Section 13 of this RTC document, for a description of how heavy-duty vehicle tire wear was factored into our emission impacts analysis for this rule.

4.10 Fuel Operated Heaters

Comments by Organizations

Organization: California Air Resources Board (CARB)

d. Fuel Operated Heaters

Affected page: DRIA 43

In the DRIA, U.S. EPA suggests fuel operated heaters (FOH) may be needed in ZEV applications to provide for cabin heating in extreme cold temperatures, or where a reduction in driving range is unacceptable. [EPA-HQ-OAR-2022-0985-1591-A1, p.38]

FOHs use diesel or gasoline fuel to provide heat and have associated criteria pollutant as well as GHG emissions. They are widely used in HDVs with ICEs to provide cab heating during idling and for pre-heating the engine block during cold start in cold ambient conditions. As a result, since 2008, CARB has been regulating emissions from FOHs installed in HDVs equipped with aftertreatment systems such that emissions from FOHs do not exceed emissions from idling diesel fueled HDVs equipped with aftertreatment systems.115 [EPA-HQ-OAR-2022-0985-1591-A1, p..38]

115 Title 13, California Code of Regulations, section 2485.

Recent studies raise concern about FOH emissions. One study has shown that PM emissions from unregulated FOHs can be up to a thousand times higher than the particulate emissions of idling gasoline vehicles.116 Another study of 64 buses across eight types and five FOH manufacturers reports that FOHs exceeded Euro VI standards for PM on 11 percent of units tested and particle number standards for 54 percent of units tested.117 The same study found higher emitter examples without correlation between high CO and high PM that may suggest multiple mechanisms for creating high emissions conditions. A report on FOH emissions measurement methods reports their observation of PM emissions that appeared driven by cold combustion chamber conditions which are often and recurrently associated with the start of each “fired” period in the on/off duty-cycle of the FOH.118 This can cause emissions rates to be uncorrelated with average FOH power drawn, but instead affected by vehicle/FOH implementation details affecting cycling event frequency that determines the number of start of firing emissions bursts. These results indicate that the use of FOHs in otherwise HD ZEVs can have a significant impact on air quality and would significantly undermine the emissions benefits expected from these vehicles. The high values reported for in-use unregulated FOHs contrast with emissions data submitted for CARB certification of FOHs and some recently reported emissions data U.S. EPA has received from FOH manufacturers. These high levels together with anecdotal reports of frequent required FOH maintenance and user reported run-to-failure maintenance practices119 raise questions about in-use emissions durability, the ability of the FOH industry to self-policy in the absence of U.S. EPA emissions standards and enforcement, and the variability of emissions rates across manufacturers and FOH models. [EPA-HQ-OAR-2022-0985-1591-A1, pp.38-39]

School buses are often cited as an example in support of FOHs as a ‘cost effective’ means to extend battery range. CARB staff point out that PM “self-pollution” is a documented serious issue with conventional diesel buses.120,121,122,123 U.S. EPA has recognized school buses as a target sector for turnover to ZE technologies and Congress has allocated an additional $5 billion for direct funding incentives to replace existing school buses with ZE and low emission models to reduce the exposure to harmful pollutants experienced by school children.124 The addition of FOHs to otherwise ZE school buses would be anticipated to be subject to these same cabin penetrating exhaust re-entrainment physical processes delivering PM and any other FOH exhaust pollutants to the passengers, counteracting the purpose of the program. The discussion above of FOH emission rate issues further underscores the potential harms from such an ill-conceived configuration. [EPA-HQ-OAR-2022-0985-1591-A1, p.39]

As discussed in the NPRM and DRIA, alternative technologies such as positive temperature coefficient electric resistance heater or a full heat pump system can be used to provide cabin heating. A wide array of technologies are available to reduce the vehicle heating load, thus lessening the perceived need for FOHs. Passive means of heating load reduction include design choices for passenger compartment insulation, battery pack insulation and vehicle glazing, as well as active means including shore power pre-heat, and directing heat more efficiently to the occupants via the use of heated seats, steering wheels, interior surfaces and floors.125,126 The energy cost of the remaining heat delivery itself can be reduced using heat pumps that have become increasingly capable at low temperatures. CO2 based R744 heat pump systems maintain efficiency as low as -20 degrees Celsius.127 Already 60 percent of German electric buses are equipped with heat pumps.128 Most major mobile air conditioning (A/C) system suppliers already have a passenger bus heat pump offering, with the low temperature capable R744 systems being quite common among them.129,130,131,132,133 A number of these commercial vehicle oriented heat pump systems already simultaneously incorporate both outside air heat sourcing and liquid coolant heat sourcing to flexibly optimize integration with the powertrain thermal management and maximize waste heat recovery for use in cabin heating. While CARB does not ban FOHs and has emissions standards for FOHs installed on diesel HDVs set 18 years ago,134 CARB also has since taken actions that have had a limiting effect on certain types of FOH deployment in California. For example, CARB's ICT regulation does not recognize FOH equipped buses as ZE buses for credit toward transit agencies obligations.135 On the incentive side, CARB's Implementation Manual for the HVIP states its Zero Emission Vehicle definition "means a vehicle that itself produces no emissions of pollutants (including carbon dioxide, carbon monoxide, hydrocarbons, oxides of nitrogen (NOx), and particulates) when stationary or operating" in determining funding amounts for purchase vouchers.136 [EPA-HQ-OAR-2022-0985-1591-A1, pp.40-41]

Therefore, CARB staff believes that FOH use in HD ZEVs is not justified. To mitigate the driving range reduction in extreme cold temperatures, a combination of the above technologies and sizing batteries to meet anticipated remaining loads could be used to meet the need for cab and battery heating. FCEVs as well could both utilize waste heat137,138 as well as size hydrogen storage to account for the remaining heat energy that may be needed for cabin heating. [EPA-HQ-OAR-2022-0985-1591-A1, p.41]

137 New Approach To Increasing The Range And Comfort In Fuel Cell-Powered Rail Transport. https://fuelcellsworks.com/news/new-approach-to-increasing-the-range-and-comfort-in-fuel-cellpowered-rail-transport/

138 Technical-note---bus-cold-weather-operation. https://www.ballard.com/docs/default-source/motive-modules-documents/technical-note---bus-coldweather-operation---final.pdf?sfvrsn=4&sfvrsn=4

CARB staff regards as overly optimistic the U.S. EPA's expectation that buyer preferences and OEM sustainability goals will make "unlikely FOH will be the primary solution for cabin heat." That stated expectation does not appear to be borne out in the current North American market. FOHs are typically chosen as a 'least expensive option' to lower the purchase cost of vehicles. There are perverse motivations to bid the lowest purchase cost vehicle to capture solicitations even if the resulting vehicle increases operating costs, GHG and criteria emissions. If the ready option remains FOH, there is little motivation to design additional insulation, direct heat delivery, heat pumps and install sufficient energy storage all at a first cost premium over a competitor's FOH upfitted off-the-shelf vehicle. Especially so long as public solicitations remain "least cost" driven—the better designed and integrated vehicle would go unpurchased without a much more sophisticated solicitation spec that values emissions and TCO considerations. U.S.

EPA has the jurisdiction, technical ability and responsibility for FOHs which should not be punted to myriad purchasing entities in the vain hope that each might reach the same sustainability conclusion in each of their series of procurement decisions to avoid a cheaper/dirtier tradeoff merely on the basis of sustainability goals. CARB staff is already aware of industry floated ideas pushing for allowing FOHs to emit higher than the 18 year old CARB standard due to high emissions of current offerings at higher power ratings, as well as proposing ‘workaround’ strategies to effectively double or triple the existing CARB FOH standard by dividing a vehicle’s FOH demand across multiple separate FOH units each with an individual CARB certification. These dubious suggestions seem diametrically opposite of an industry on the verge of abandoning FOHs as a primary means of cabin heat as U.S. EPA statements in the DRIA appear to suggest. [EPA-HQ-OAR-2022-0985-1591-A1, p.41]

CARB staff recommends that U.S. EPA carefully evaluate the emission rates of in-use FOHs including continued collaboration with and incorporation of data from ongoing studies of in-use FOHs underway in neighboring jurisdictions. CARB staff recommends U.S. EPA evaluate the ZE alternatives to FOHs and encourage these alternatives use in lieu of FOHs everywhere possible. CARB staff recommends U.S. EPA to restrict the use of FOHs in HD ZEVs for heating from being the default approach to passenger space heating on electrified vehicles and only allow their use in those narrow range of applications U.S. EPA may deem them actually necessary, since combustion FOHs undermine the purpose of the Phase 3 GHG regulation and confound U.S. EPA’s other efforts to control direct and regional exposure to criteria pollutant emissions. U.S. EPA could also consider issuing requirements that FOHs not be used above the ambient temperatures that necessitate their use in well system integrated ZE vehicles. CARB staff further recommends U.S. EPA act on their own existing efforts to quantify the harmful criteria pollutant and GHG emissions from FOHs by setting stringent emissions standards regulating FOH emissions. CARB staff recommends that U.S. EPA clearly define their FOH standard as also applying to the vehicle level, i.e., that stacking multiple units to game the FOH standard is not appropriate. [EPA-HQ-OAR-2022-0985-1591-A1, p.42]

Organization: ROUSH CleanTech

OMISSIONS OBSERVED IN PROPOSED RULE

We believe that the EPA proposed rule fails to address a significant regulatory gap related to national deployment of heavy-duty BEV/FCEV’s, specifically, the anticipated widespread use of fuel-fired heaters in buses and other large cabin vehicles in the Midwest and northern states. EPA touches on this problem a bit in the discussion of battery sizing and energy use in Section II. The Basma study cited on page 160 is excellent, but by design it only focused on Paris, France, and thus assumed a minimum temperature of -10C (14ºF), which is a far warmer minimum temperature than is found in large parts of the US. Moreover, the proposed dual heat pump system becomes ineffective as temperatures drop, resulting in significantly worse heat energy requirements. In practice, if BEV/FCEV deployment is desired, the buses must be able to support their routes every day—we don’t think it is acceptable to ever cancel school because the buses were only designed for 90th percentile use. Practically, these buses will have to be equipped with a supplementary heating device (typically, a fuel-fired heater, as has been used to supplement diesel engine heat output for years). We suggest that EPA should include specific guidance in the Phase 3 rule allowing the use of manufacturer-installed fuel systems and heaters, including requirements and guidance for refueling, evaporative, and tailpipe emissions, as well as a method for accounting for the carbon emissions expected over the vehicle life. We believe existing vehicle refueling and evaporative standards are sufficient, but tailpipe standards would need to be defined. This will help ensure that these systems are certified, subject to emissions warranties, and integrated into the vehicle, and that gross polluting systems are not used in the aftermarket. We believe that anticipating and including this key enabling technology in the rule will prove highly valuable, especially as a contributing basis for future rules that are likely to focus more on the efficiency and climate impact of BEV's and FCEV's (where the small carbon emissions from a fuel-fired heater are likely far less than the carbon emissions associated with excessive battery sizing). [EPA-HQ-OAR-2022-0985-1655-A1, p.5]

EPA Summary and Response:

Summary:

EPA received two comments that expressed concern about the use of Fuel Operated Heaters (FOH) and the lack of federal regulation on them. Both commenters suggested ways to regulate FOHs and were concerned that the use of FOHs would be more widespread than was predicted in the proposal. (Roush and CARB)

Response:

EPA did not propose to include standards or requirements for FOHs in the NPRM and therefore is not taking final action to address emissions from FOHs in the FRM. We understand that our current 40 CFR part 1037 regulations address FOH in the context of extended-idle only (see 40 CFR 1037.520(j)(4)). EPA understands that FOHs are emitters of both GHG and non-GHG pollutants and we intend to further assess the level of potential emissions from FOHs and may address them in a future rulemaking. We note that non-GHG emission standards for HD vehicles are outside the scope of this current rulemaking. We also note that EPA incentive and grant programs are outside the scope of this current rulemaking.

We note further that these types of heating devices are already in operation on HDVs (including in existing HD ICE vehicles) to aid in cabin heating and engine block warming in low ambient temperature operating conditions, and to heat cabins during overnight hoteling. In our assessment for BEVs, we were able to size the battery with extreme temperature (very hot or very cold) considerations. For discussion on the temperature effects on battery sizing and how this phenomenon was taken into account in our analysis, see RTC 3. We recognize that the temperatures used for our assessment are temperature-vehicle mile weighted, therefore the battery size may not be feasible at extreme temperatures. However, the limited number of vehicle miles traveled indicates that these miles are driven less compared to more moderate temperatures. Therefore, while there will be occasions of high energy consumptions from the battery for HVAC and battery conditioning purpose, the batteries are as oversized for durability, depth of discharge, and high daily milage vehicles. We also recognize that there is limited number of studies available to understand the prevalence and impact of emissions from FOH. We are aware that studies are being conducted on FOHs, especially with respect to FOHs as supplemental heat in ZEVs, and this data may inform our future analysis.[374]

We also recognize that there may be conditions where these conservative approaches for battery sizing are still not sufficient for some applications, therefore we limited ZEV technology

[374] Pettinen, R., Anttila, J., et al. "Testing Method for Electric Bus Auxiliary Heater Emissions." Energies, 2023.

adoption to 70% adoption in MY 2032 and we therefore expect ICE vehicles to continue to meet the needs of such applications under the modeled potential compliance pathway. See RIA Chapter 2.7 for further discussion. We stand by our assertions that FOHs will likely only be used in environments with extremely low temperatures or where a reduction in driving range is unacceptable, and that adoption of this technology will likely be kept to a minimum because FOHs do not meet the sustainability goals of fleets and OEMs.

5 FCEV Technologies

Comments by Organizations:

Organization: Manufacturers of Emission Controls Association (MECA)

Future BEV/FCEV Powertrain Efficiency Standards

Today, vehicle manufacturers are deploying the first generation of electric and fuel cell commercial vehicles. On the other hand, suppliers are already looking ahead and developing the next generation of advanced efficient powertrain components such as batteries, power electronics, transmissions, e-motors and integrated drive units. Technology innovation has strived for greater efficiency and power for the past 50 years of combustion engines and similarly, electric component suppliers continue to innovate electric technology. Some of these innovations will be revealed in the five funded projects under the DOE's SuperTruck III program. [EPA-HQ-OAR-2022-0985-1521-A1, pp. 12 - 13.]

As such, it is important that EPA begins to consider ways to incentivize and reward more efficient vehicles just as it has for combustion engine technology. In the light-duty sector, where EVs have been around for much longer, we are already seeing significant differences in the energy efficiency of similarly sized vehicles. This is a result of some manufacturers deploying more advanced technology and investing in efficient powertrain integration which reduces the impact on the environment across the vehicle life-cycle from manufacturing to recycling and disposal. [EPA-HQ-OAR-2022-0985-1521-A1, p. 13.]

Organization: Truck Renting and Leasing Association (TRALA)

Securing National Weight Exemptions for BEVs and FCEVs Will be Difficult

Battery electric or fuel cell trucks will incur a substantial weight penalty that can put truck gross vehicle weights over their allotted federal limits. Roughly 10-15% of truckloads hit their maximum federal weight limits due to the types of payloads they carry. Federal legislation passed in 2019 allows a 2,000-pound weight exemption for battery powered heavy-duty trucks. The problem is the additional battery weight for a Class 8 BEV could add up to16,000 pounds depending on the battery configuration. This is one of the primary reasons why Class 8 trucks will rely upon the development and advancement of Fuel Cell Electric Vehicles (FCEVs). Fuel cell vehicles will also experience additional weight issues but not to the extent of BEVs. OEMs estimate the additional weight of an FCEV compared to a comparable ICE vehicle will be somewhere in the range of 8,000 pounds. The longer the vehicle range the more battery cells or fuel cell modules required which in turn has a direct correlation to overall added vehicle weight. [EPA-HQ-OAR-2022-0985-1577-A1, p. 15.]

Federal legislation was introduced in May to secure a 2,000-pound weight exemption for hydrogen-powered trucks. However, a 2,000-pound weight allowance for either BEVs or FCEVs is a mere drop in the bucket. Federal legislation to acquire additional weight exemptions to offset added ZEV technology weight will be extremely difficult given strong opposition from select industry, safety, and infrastructure interests. [EPA-HQ-OAR-2022-0985-1577-A1, p. 15.]

With respect to infrastructure concerns, the American Society of Civil Engineers' (ASCE) 2021 Infrastructure Report Card gave the nation's roads a 'D' grade and its bridges a 'C' grade.22 Roads and bridges need continual repair, rebuilding, and investment. Added vehicle weights and the high torque rates of ZEVs has the potential to accelerate the degradation of our nation's road networks. TRALA requests further analysis be undertaken to ensure that the increased use of all on-road ZEVs will not result in any detrimental impacts and unanticipated costs related to maintaining our nation's existing highway infrastructure. [EPA-HQ-OAR-2022-0985-1577-A1, pp. 15-16]

EPA Summary and Response:

Summary:

MEMA acknowledged that the first generation of FCEVs are being deployed and that next generation components are under development, including through DOE's SuperTruck 3 program. They called for incentives for the use of more energy-efficient ZEVs, as EPA has done for ICE vehicles.

TRALA, on the other hand, commented on weight penalties associated with BEV and FCEV technology. They said that weight is one reason why Class 8 trucks may be FCEVs—because a FCEV has about half the weight penalty of a BEV. They stressed that impact of the additional weight of ZEVs on road networks should be further analyzed, asserting that it has the potential to accelerate the degradation of our nation's road networks.

Response:

Please also refer to the additional summary and response to the same comments in RTC Section 4.1.2 (MEMA) and Sections 4.6 and 3.10.1 (TRALA).

With respect to FCEV weight concerns, we recognize that the weight of hydrogen tanks is a mass driver—the more tanks onboard a FCEV to store fuel for longer ranges, the heavier the vehicle. However, we did not find a compelling reason to evaluate the weight of FCEVs in HD TRUCS, as our review of existing literature did not identify weight as a potential constraint.

Basma et. al relied on a teardown analysis by Ricardo to evaluate truck weights. They found a similar payload capacity for HD FCEVs relative to diesel counterparts for current (2022) and future (2035) technologies.[375,376] Also, DOE conducted preliminary analysis to determine the payload capacity of Class 8 long-haul FCEVs relative to a comparable diesel truck and determined there is no loss in payload capacity, even without factoring in exemptions available for alternative fuels and engines.[377,378] RIA Chapter 2.9.1 explains how FCEVs were included in the modeled potential compliance pathway for limited vehicle applications where the volume or

376 Ricardo. "E-Truck Virtual Teardown Study: Final Report". ICCT. June 11, 2021. Available online: https://theicct.org/wp-content/uploads/2022/01/Final-Report-eTruck-Virtual-Teardown-Public-Version.pdf.

377 The analysis is specific to trucks using hybrid platforms with 175- and 275-kW fuel cell systems.

378 U.S. Department of Energy. "The #H2IQ Hour. Today's Topic: Heavy-Duty Vehicle Decarbonization". September 21, 2023. Available online: https://www.energy.gov/sites/default/files/2023-10/h2iqhour-09212023.pdf.

weight of a BEV battery may adversely impact payload for a BEV, given that payload concerns associated with larger and heavier batteries are more notable in the literature.

In general, if a ZEV resulted in a battery that was too large or heavy, it was not included in the modeled potential compliance pathway for that vehicle application's technology package because of its potential impact on payload. Thus, we did not find a need to evaluate potential impacts of added vehicle weights on road degradation.

5.1 FCEV Technology Readiness

Comments by Organizations:

Organization: American Petroleum Institute (API)

While still in the early stages of development and prove out, hydrogen-based vehicles (FCEVs and H2-ICE) are a promising technology that many stakeholders are considering. API members are engaged in hydrogen projects to support development of hydrogen focused technology. Companies are partnering with HD OEMs to explore commercial business opportunities to build demand for commercial vehicles and industrial applications powered by hydrogen. Demonstration projects target hard-to-abate applications like rail and marine, with a goal to develop viable large-scale businesses and advance a thriving hydrogen economy. [EPA-HQ-OAR-2022-0985-1617-A1, p. 8.]

As noted by the American Trucking Associations (ATA), in testimony before the U.S. Senate Committee on Environment and Public Works8:

When battery electric vehicles are not the answer, federal support should refrain from playing favorites, and instead assist in the buildout of alternative fuel facilities. Proposals for hydrogen infrastructure for trucks need to ensure that the infrastructure is in place where that technology best fits in supply chains. Where lifecycle emissions can be reduced by deploying renewable diesel and renewable natural gas, those fuel stocks need to be available for trucking. [EPA-HQ-OAR-2022-0985-1617-A1, p. 8.]

8 U.S. Senate Committee on Environment and Public Works, hearing on "The Future of Low Carbon Transportation Fuels and Considerations for a National Clean Fuels Program", February 15, 2023 (https://www.epw.senate.gov/public/index.cfm/2023/2/the-future-of-low-carbon-transportation-fuels-and-considerations-for-a-national-clean-fuels-program).

d. Technical Feasibility

i. Vehicle readiness

1. Technology readiness

The proposed rule identified various HD ZEVs available in the marketplace or in production, as well as select manufacturer goals and commitments to producing HD ZEVs by a certain timeframe. However, given the nascent technology, there is significant uncertainty regarding EPA's expectation for rapid availability of ZEV powertrains. Further, it should be noted that these vehicles are small in number, some are not able to perform the work that a comparable ICEV would perform (due to charging, range, and duty-cycle constraints), and all are for localized operations; long-haul ZEVs are in the pilot stage and have significant challenges. OEM goals and commitments, coupled with IRA/BIL funding may help to increase the availability of HD ZEVs; however, it will be extremely challenging to meet the proposal's implementation schedule. We have concerns that vehicles may not be available at the rates that EPA is projecting for the 2027-2032 timeframe. [EPA-HQ-OAR-2022-0985-1617-A1, p. 10.]

Even with a fully stocked HD ZEV market, key barriers to entry include customer uptake, capital costs to purchase vehicles, and infrastructure readiness. [EPA-HQ-OAR-2022-0985-1617-A1, p. 10.]

Organization: California Air Resources Board (CARB)

Currently, there are a number of MD and HD FCEVs being demonstrated in the class 6 and 8 weight classes.63,64,65,66,67 Class 8 fuel cell tractors produced by Hyzon Motors, Hyundai, and Nikola are currently commercially available with warranty and service support, as evidenced by CARB eligibility determinations for the Hybrid and Zero- Emission Truck and Bus Voucher Incentive Project (HVIP) catalog.68 Several other manufacturers including Volvo, Cummins with Daimler, Daimler, Paccar, Hino with Toyota, Isuzu with Honda, Navistar with GM, Navistar's fellow Traton company Scania with Cummins, and Quantron are in the process of developing class 8 fuel cell trucks or have announced plans and partnerships to do so.69,70,71,72,73,74,75,76,77 [EPA-HQ-OAR-2022-0985-1591-A1, pp.29-30]

CARB staff has received detailed fleet and vehicle usage information from nearly 2,000 fleets representing 400,000 vehicles in California. Based on data collected, 90 percent of non-tractor vehicles travel below 150 miles per day, and 60 percent of day cab tractors travel below 200 miles per day, indicating typical operation of a large fraction of non-tractor vehicles and day cab tractors can be readily electrified with the existing range performance of vehicles available on the market today.78 This data is presented in more detail in Figure 1. [EPA-HQ-OAR-2022-0985-1591-A1,p.30] [Figure 1 can be found on pg. 31 of docket number EPA-HQ-OAR-2022-0985-1591-A1]

Organization: Clean Air Task Force et al.

a. EPA’s projected penetration of FCEVs into fleets is conservative.

EPA’s proposal does not consider the availability of FCEV technology for fleets until MY 2030. 88 Fed. Reg. at 25973. EPA cites the need for “additional lead time to allow manufacturers to design, develop, and manufacture HD FCEV models.” Id. Yet the FCEV market is expected to grow rapidly over the next several years, heralded by several announcements that, in aggregate, support a growing FCEV fleet before 2030. Given the many announced plans to incorporate FCEVs into fleets earlier than 2030, EPA should consider even modest inclusion of FCEVs in its technology packages starting in MY 2027 and should tighten its overall standards accordingly. [EPA-HQ-OAR-2022-0985-1640-A1, p. 62]

First, FCEVs have already been successfully deployed as transit buses. For example, a long-running FCEV deployment program in the Alameda-Contra Costa Transit District (AC Transit) has shown that FCEV transit buses meet durability, reliability, and performance requirements, making them well-positioned for accelerated deployment in transit fleets. A report released in December of last year shows that during the January–June 2022 period, a total of 122,721 miles were covered by fuel cell buses within the AC Transit service area.272 This number nearly matched the diesel and hybrid bus workload (146,788 miles). During the most recent month in the report, June 2022, the newest FCEVs achieved the second highest uptime at 89 percent, coming in just behind the 96 percent uptime achieved by the diesel drivetrain. Looking at the manufacturing date of the earliest fuel cell buses (2010), recent uptime, and total miles driven, FCEVs are already a viable drivetrain for this transit bus fleet in 2023. [EPA-HQ-OAR-2022-0985-1640-A1, p. 62]

272 Jimmy Chen et al., AC Transit & Stanford Pecourt Inst. for Energy, Zero Emission Transit Bus Technology Analysis 10 fig. 7, 14 fig. 15 (2022), https://www.actransit.org/sites/default/files/2023-01/0430-22%20Report-ZEBTA%20v4_FNL_012423.pdf

There are other examples of hydrogen fuel cell transit bus adoption as well. In California, thirteen transit agencies have committed to initiate or expand fuel cell bus deployments with a goal of deploying at least 1,000 fuel cell electric buses. Known as the "1,000 Bus Initiative,"273 the program looks to establish a market to help commercialize FCEV technology for the entire transit industry. The Center for Transportation and the Environment is heavily involved in this effort and is also looking to aid with the deployment of thousands of Class 8 fuel cell trucks and supporting infrastructure as part of hydrogen hub development in the state.274 [EPA-HQ-OAR-2022-0985-1640-A1, p. 62]

273 Kate Mason, CTE Supports ARCHES: California Hydrogen Hub, Ctr. for Transp. & Env't (May 15, 2023), https://cte.tv/cte-supports-arches-california-hydrogen-hub/

274 Id.

In addition to growing adoption of FCEV transit buses, there are a number of examples of recent announcements for FCEV heavy-duty trucks. The Alberta Motor Transport Association is set to receive two Nikola trucks as part of its Hydrogen Commercial Vehicle Demonstrations Project.275 There will be one BEV and FCEV delivered, with the goal of validating these trucks on real-world load and duty cycles. In a press release, Nikola Energy president Carey Mendes announced "plans for 300 metric-tons of hydrogen supply, with 60 hydrogen stations planned for across North America by 2026." [EPA-HQ-OAR-2022-0985-1640-A1, p. 63]

275 Today's Trucking, AMTA orders Nikola Tre battery-electric, and hydrogen fuel cell trucks for demonstrations, AMTA, Truck News (Apr. 25, 2023), https://www.trucknews.com/sustainability/amta-orders-nikola-tre-battery-electric-and-hydrogen-fuel-cell-trucks-fordemonstrations/1003174531/.

Furthermore, in December 2022, Houston, Air Liquide, Hyzon Motors, and the TALKE Group began a demonstration of a hydrogen fuel cell electric truck in the Port of Houston.276 The article outlining this demonstration notes the importance of having the option of hydrogen as it allows for an acceleration toward clean fuel, especially for heavy-duty vehicles. [EPA-HQ-OAR-2022-0985-1640-A1, p. 63]

276 Air Liquide, Air Liquide fuels first hydrogen fuel cell truck demonstration at Port of Houston (Jan. 12, 2023), https://usa.airliquide.com/hyzon-port-of-houston.

In early May 2023, Hyundai Motor Company premiered its new XCIENT fuel cell tractor for commercial Class 8 vehicles at the Advanced Clean Transportation Expo.277 The vehicle is capable of over 450 miles of range when fully loaded, making it ideal for long-haul operations. Ken Ramirez, Executive Vice President and Head of Global Commercial Vehicle and Hydrogen Fuel Cell Business at Hyundai Motor, said, "We firmly believe that hydrogen is one of the most powerful and pragmatic solutions for achieving our vision of 'Progress for Humanity' with emission-free mobility as a fundamental pillar for a sustainable society." [EPA-HQ-OAR-2022-0985-1640-A1, p. 63]

277 Hyundai Motor Co., Hyundai Motor Premieres Commercialized Model of Its XCIENT Fuel Cell Tractor and Vision for Hydrogen Mobility in US, PR Newswire (May 2, 2023), https://www.prnewswire.com/news-releases/hyundai-motor-premieres-commercialized-model-of-its-xcient-fuel-cell-tractor-and-vision-for-hydrogen-mobility-in-us-301812728.html.

In late May 2023, Volvo Trucks, working together with Daimler Truck, reported successes they have seen testing FCEVs in arctic conditions.278 “Trucks are operating seven days a week and in all types of weather,” said Helena Alsiö, VP of powertrain product management at Volvo Trucks. “The harsh conditions on public roads in northern Sweden, with ice, wind, and lots of snow, make an ideal testing environment. I am pleased to say that the tests are going well.” Volvo is looking to have hydrogen fuel cell trucks in production for long-haul freight applications later this decade. [EPA-HQ-OAR-2022-0985-1640-A1, p. 63]

278 Josh Fisher, Volvo finding fuel cell success in Arctic conditions, Fleet Owner (May 30, 2023), https://www.fleetowner.com/emissions-efficiency/article/21266721/volvo-testing-fuel-cell-tech-in-arctic-conditions.

At the ACT Expo transportation conference in 2023, several other OEMs announced plans for expansion of their FCEV offerings.279 Kenworth and Peterbilt are now planning to offer fuel cell trucks in 2025. Kenworth is of particular note, as it collaborated with Toyota on a successful demonstration pilot in the Port of Los Angeles involving 10 FCEVs. Now that the project has ended, Kenworth is planning to introduce a commercial T680 FCEV that will travel more than 450 miles between fill-ups. Kevin Baney, Kenworth general manager stated, “With quick refueling, this broadens our zero-emission product offering to include round-the-clock operations in regional haul and demonstrates FCEV potential for long haul.” [EPA-HQ-OAR-2022-0985-1640-A1, pp. 63 - 64]

279 Alan Adler, ACT Expo a coming of age for hydrogen-powered trucking, Freight Waves (May 3, 2023), https://www.freightwaves.com/news/act-expo-a-coming-of-age-for-hydrogen-powered-trucking.

Finally, announcements of HDV FCEVs sales well before 2030 continue to pour in. For example, Performance Food Group announced in June 2023 that it agreed to buy at least five FCEV trucks from Hyzon Motors, and that it “could be up to 50.”280 The first five trucks “are expected to be delivered in 2023 and 2024.” Parker Meeks, Hyzon’s chief executive officer, noted of the agreement of Performance Food Group: “This agreement for up to 50 hydrogen-powered trucks demonstrates how Hyzon intends to build customer familiarity with a new technology as the hydrogen infrastructure accelerates.”281 [EPA-HQ-OAR-2022-0985-1640-A1, p. 64]

280 Truckinginfo, Performance Food Group Plans to Buy Hyzon Fuel Cell Trucks (June 9, 2023), https://www.truckinginfo.com/10200499/performance-food-group-to-purchase-hyzon-fuel-cell-trucks.

281 Id.

These recent FCEV-related announcements and demonstrations show the early successes of the drivetrain, both for heavy-duty trucks and transit buses. In addition, the enthusiastic statements from those in the industry show that there is a real push from relevant OEMs to get the technology ready to provide another zero-emission technology option, alongside BEVs. Based on these examples, we expect continued growth in FCEV technology for the HDV market before MY 2030. Rather than underestimating the presence of FCEVs in fleets (again, EPA incorporates no FCEVs into technology packages until MY 2030), EPA’s standards should go beyond what is already occurring in the industry. [EPA-HQ-OAR-2022-0985-1640-A1, p. 64]

In addition to on-the-ground announcements that suggest short-term FCEV market growth, recently released studies model the growth of the FCEV market over a longer time frame. One such report published by the University of California at Davis in April 2023 ("the UC Davis report") projects the number of FCEVs that will be on the road by 2030.282 The report is focused exclusively on California, but given that California is currently the only state with a functioning hydrogen economy, using the rich data sets from that state is one of the best ways to project future growth nationwide. The three paragraphs below focus on the HDV-related sections, but the report is comprehensive, modeling multiple end use sectors and providing a detailed analysis of renewable electricity systems in a hydrogen-oriented context. [EPA-HQ-OAR-2022-0985-1640-A1, p. 64]

282 Lewis Fulton et al., UC Davis, Inst. Transp. Stud. (ITS), California Hydrogen Analysis Project: The Future Role of Hydrogen in a Carbon-Neutral California: Final Synthesis Modeling Report, at fig. 19 (2023), https://escholarship.org/uc/item/27m7g841. See also id. at Executive Summary figs. 5, 19, 45.

The UC Davis report takes advantage of three tools. Two are in-house tools from UC Davis, GOOD (Grid Optimized Operation and Dispatch Model)283 and STIEVE (Spatial Transportation Infrastructure, Energy, Vehicle and Emissions).284 In addition, the study uses a tool from the NREL, known as SERA (Scenario Evaluation and Regionalization Analysis).285 STIEVE was used to project potential FCEV sales, stocks, hydrogen demand, and the number of hydrogen stations, sizes, and locations out to 2050. GOOD is an economic dispatch electric grid model that was used to model the electricity system with higher renewable penetration and with electrolytic hydrogen production. Lastly, SERA is a hydrogen supply chain model that was used to optimize the siting of hydrogen supply locations to meet future demand and to estimate cost along the supply chain, resulting in hydrogen prices at the pump. All three tools were calibrated with California data, some of which were from prior surveys and analyses.286 The result of the UC Davis report's modeling was a characterization of a growing hydrogen system, starting today and projecting out to 2050, for the state of California. These results include a "base" and "high" projection for FCEV penetration, in terms of stocks, which is depicted in Figure 19 of the report. [EPA-HQ-OAR-2022-0985-1640-A1, pp. 64 - 65]

Baker et al., Lawrence Livermore Nat'l Lab'y, Getting to Neutral: Options for Negative Carbon Emissions in California (2020), https://doi.org/10.2172/1597217; CARB, Hydrogen Station Self-Sufficiency Report (2021), https://ww2.arb.ca.gov/sites/default/files/2021-10/hydrogen_self_sufficiency_report.pdf.

For purposes of these comments, we have extrapolated the California hydrogen market growth projections to the rest of the country, differentiating among states that have adopted the ACT Rule287 under Section 177 of the Clean Air Act ("Other ACT States"), states that have yet to adopt the ACT but have adopted other California vehicle regulations ("Non-ACT Section 177

States), states that have signed on to the NESCAUM multi-state MOU, and state-specific heavy duty vehicle registration numbers288 from the U.S. Department of Transportation (see Table 6). The specific assumptions used for the nationwide FCEV penetration analysis are shown in the table below in terms of a fraction of FCEV adoption relative to California in 2030. Note that the UC Davis report assumes 100 percent ZEV sales by 2040 in California, a standard that is more stringent than ACT. While this is reasonable for California considering other recently passed regulations like the ACF, it is more aggressive than regulations other states have adopted to date. For this reason, "Other ACT States" are assumed to move more slowly than California in the table below. In addition, the FCEV penetration analysis was scaled by the number of registered trucks and buses in each state relative to California. [EPA-HQ-OAR-2022-0985-1640-A1, p. 65.] [See Docket Number EPA-HQ-OAR-2022-0985-1640-A1, pages 65-66, for Table 6]

287 CARB, States that have Adopted California's Vehicle Standards under Section 177 of the Federal Clean Air Act, (Aug. 19, 2019), https://ww2.arb.ca.gov/sites/default/files/2019-03/177-states.pdf.

288 Highway Statistics 2021, U.S. DOT (Mar. 2023), https://www.fhwa.dot.gov/policyinformation/statistics/2021/mv1.cfm.

For HDVs, this calculation results in a "base" scenario where 29,927 FCEVs are on the road nationwide by 2030 and a "high" scenario where 87,783 FCEV are part of U.S. fleets. This is a small percentage of overall stocks across the country (roughly 0.2–0.6 percent); however, it represents a notable increase compared to today and shows that FCEVs are likely to benefit from rapid market growth, signaled by the announcements and company pledges described earlier and backed by this modeling, such that we will likely see tens of thousands of HDVs with FCEV technology on the road by 2030. FCEV technology is viable, and widespread availability is expected before 2030 due to baseline market forces, IRA incentives, and state regulations alone. As a result, EPA should incorporate FCEVs into its technology packages beginning in MY 2027 and strengthen its proposed rule accordingly. [EPA-HQ-OAR-2022-0985-1640-A1, p. 66]

Organization: Daimler Truck North America LLC (DTNA)

EPA Request for Comment, Request #15: We request comment on our assessment and data to support our assessment of FCEV technology for the final rule.

- DTNA Response: FCEV technologies are one part of the roadmap to reducing GHG emissions, and DTNA is actively involved in developing this technology. FCEV technology has not, however, matured sufficiently for EPA to predict its price, range, or operational characteristics. Most importantly, there is little basis for accurately projecting infrastructure availability for FCEVs in MY 2030+. DTNA discusses this issue in more detail in Section II.B.3 of these comments. [EPA-HQ-OAR-2022-0985-1555-A1, pp. 160-161]

EPA Request for Comment, Request #19: We request comment on our approach that focuses primarily on BEVs, which currently are more prevalent in the HD vehicle market, and whether there are additional vehicle types that should be evaluated as FCEVs along with BEVs.

- DTNA Response: DTNA agrees in principle with EPA's primary focus on BEVs at this time, as these vehicles are more prevalent in the market. EPA should not consider FCEVs until at least MY 2032, due to the current state of the technology and refueling infrastructure. EPA also should not project ZEV uptake for any vehicle types outside of

> the BEV and FCEV categories included in the Proposed Rule. [EPA-HQ-OAR-2022-0985-1555-A1, p. 161]

Organization: Lubrizol Corporation (Lubrizol)

Lubrizol believes that vehicle owners and fleets in the heavy-duty vehicle sector will use a range of fuels and technologies to meet their future operational and environmental needs. Thus, we are pleased to see EPA acknowledge that it expects to see Original Engine Manufacturers ("OEMs") use an array of technologies to meet the requirements of the Final Rule. Lubrizol strongly encourages EPA to promulgate a Final Rule that will advance all three strategies highlighted in the Biden administration's Transportation Decarbonization Blueprint (the "Blueprint"), i.e., Sustainable Liquid Fuels ("SLFs"), Battery-Electric Vehicles ("BEVs"), and Hydrogen.2 While there is exciting progress being made to develop heavy-duty engines and vehicles that will operate on electricity and hydrogen, the majority of new heavy-duty vehicles will continue to use internal combustion engines ("ICE") for many years to come. This will be especially true in the heavier vehicle classes in the heavy-duty vehicle market.3 [EPA-HQ-OAR-2022-0985-1651-A2, p. 2.]

> 2 The U.S. National Blueprint for Transportation Decarbonization: A Joint Strategy to Transform Transportation (the "Blueprint"). Accessed on June 11, 2023 at The U.S. National Blueprint for Transportation Decarbonization: A Joint Strategy to Transform Transportation | Department of Energy. See, e.g., page 5, Figure B and similar references elsewhere in the Blueprint.

> 3 Lubrizol notes that, even in California and the other states that adopt California's Advanced Clean Transportation ("ACT") rule (collectively, the "ACT States"), most new trucks sold in 2035 will still be ICE vehicles fueled by petroleum diesel fuel, absent any further changes in state or federal fuel policy. More specifically, manufacturers who certify Class 2b-8 chassis or complete vehicles with combustion engines will be required to sell zero-emission trucks as an increasing percentage of their annual sales in the ACT States from 2024 to 2035. By 2035, zero-emission truck/chassis sales will need to be 55% of Class 2b – 3 truck sales, 75% of Class 4 – 8 straight truck sales, and 40% of truck tractor sales in the ACT States.

Organization: Valero Energy Corporation

E. ZEVs are not fit for purpose as HDVs.

EPA's presumptions regarding consumer acceptance of ZEVs overlook these vehicles' unsuitability for the purpose of long-haul freight transport. Factors EPA has not fully considered that are material to HD ZEV feasibility include, among other things: reduced payload capacity; battery weight requirements; range; impacts to trucking industry jobs; charging/re-fueling infrastructure availability; the rate of infrastructure buildout; permitting challenges; upstream environmental impacts inherent to ZEV production; upfront ZEV costs; the HD payback period; electricity price projections; and battery efficiency in different climate conditions. [EPA-HQ-OAR-2022-0985-1566-A2, p. 23.]

Regarding "fitness for purpose," while ZEVs may provide options to help reduce GHG emissions, neither BEV nor FCEV technology is compatible with the full range of use, duty and demand required by the HD transportation sector, and therefore neither one is suitable to replace the ICEV and adequately serve the nation's freight and transit needs. [EPA-HQ-OAR-2022-0985-1566-A2, pp. 23 - 24.]

Current FCEV technology facilitates larger and heavier vehicles due to its higher energy storage capacity than BEVs, and it offers drivers a refueling experience much like conventional vehicles, with the fuel tank capable of being refilled in a matter of minutes. However, adoption of the technology and particularly commitment to developing fueling infrastructure has been limited within the U.S.—currently the nation has 72 active public and private FCEV hydrogen fueling stations, with all but one of these being located in California.112 [EPA-HQ-OAR-2022-0985-1566-A2, p. 25]

112 U.S. DOE Alternative Fuels Data Center, Hydrogen Fueling Station Locations, https://afdc.energy.gov/fuels/hydrogen_locations.html#/analyze?region=US-CA&fuel=HY&country=US, accessed March 21, 2023.

EPA Summary and Response:

Summary:

The commenters offered a range of opinions about the readiness of FCEV technology. Most commenters agreed that hydrogen-based technologies are promising and offer business opportunity. API pointed to American Trucking Association testimony that expressed concern about considering only hydrogen for sectors where BEVs are not the answer—stating that there may be other renewable fuel options that can limit lifecycle emissions, and Federal support should focus on ensuring that alternative fuel infrastructure and feedstocks are available where a given technology or fuel fits best.

At least two commenters support EPA's assertion that FCEVs are technologically feasible now. Both CARB and CATF listed several examples of FCEV demonstrations, announcements and partnerships, and active transit bus and truck deployments that demonstrate early success and market growth potential. CARB noted that three OEMs are producing Class 8 fuel cell trucks in California. CATF cited OEM plans to expand FCEV offerings before 2030. CATF said that additional lead time for FCEVs is not necessary, and that EPA's projected adoption rates are too conservative. They extrapolated the results of a UC Davis study that projected the number of FCEVs on the road in 2030 to the rest of the country and found there could be a notable increase in FCEV stocks nationwide compared to today. To strengthen the proposed rule, they believe that EPA should incorporate FCEV adoption into technology packages beginning in MY 2027 (and include a corresponding increase in stringency in the standards).

At least three commenters were less optimistic about FCEV readiness in the timeframe of the rule. Daimler agreed that BEV technologies are more prevalent now, which justifies the rule's current focus on BEVs in the technology packages for the modeled potential compliance pathway. They contend that FCEV technology is still nascent and should not be considered until at least MY 2032 due to the current state of the technology and infrastructure readiness. Daimler stated that the number of FCEVs in the marketplace is small. They say that long-haul ZEVs still have significant challenges, and they are hesitant to make projections about future FCEV-related costs or characteristics. Lubrizol believes that most vehicles will continue to use internal combustion engines for years to come, particularly in heavier use cases. Valero stated that while the technology can work, adoption has been limited in the U.S. and there has not been sufficient commitment to developing refueling infrastructure. They question the "fitness" of ZEV technologies to meet the full range of needs in the HD transportation sector.

Response:

As described in the preamble and RIA, we continue to find that FCEV technologies can be ready for select vehicle applications in early market volumes by MY 2030. We used the HD TRUCS tool (see RIA Chapter 2) as part of our analysis to evaluate numerous operational characteristics and costs to estimate HD technology feasibility and suitability, and the analysis for the final rule shows that a diverse range of HD vehicle technologies, including but not limited to BEV and FCEV technologies, are feasible and may be used to comply with the final standards to reduce GHG emissions. This flexibility in the nature of performance-based standards offers opportunity to identify where each technology fits best so that emissions can be reduced efficiently and effectively.

With respect to FCEV technologies specifically, our analysis evaluates FCEV technology costs considering early market volumes that correspond to our adoption rates that include roughly 10,000 HD FCEVs by MY 2032. This approach is reasonable because FCEV component costs tend to vary based on manufacturing volumes, as described further in RTC Section 3.4.3.

We agree with commenters who noted that HD FCEV demonstrations and deployments are underway today, suggesting there is sufficient lead time to develop the necessary technologies for the MY 2030 to MY 2032 timeframe. As indicated in RIA Chapter 1.7.5 and 1.7.6, for example, Nikola produced 42 Class 8 FCEVs in 2023.[379] They have a production capacity in their Arizona facility of 2400 BEV or FCEV trucks, with about 200 HD FCEVs on order.[380] Meanwhile, Toyota is starting to develop 160 kW fuel cell modules for Class 8 trucks. They have business offers to support the production of about 100,000 fuel cell systems in 2030, including about 35 percent for heavy-duty trucks.[381,382] And there are projects under DOE's SuperTruck 3 program through 2028 to further develop Class 8 FCEV technologies. Fleets are already purchasing HD FCEVs such as Performance Food Group, for example, who received four Class 8 FCEVs at a facility in Fontana, CA, in February 2024.[383]

Though some FCEV models may be available by MY 2027, as suggested by CATF, we are also balancing other factors like timing to accommodate initial hydrogen infrastructure buildout for HD FCEVs. Likewise, we do not believe that it is necessary to wait until MY 2032, as Daimler asserts, to project utilization of FCEV technologies for select vehicle applications in early market volumes in our HD TRUCS analysis, given that the hydrogen market is heavily incentivized to make initial progress on clean hydrogen production starting by MY 2030. Please see preamble Section II and RIA Chapter 2 for more discussion on our inclusion of FCEV

technology for select vehicle applications in early market volumes starting in MY 2030 in our HD TRUCS analysis. Hydrogen infrastructure readiness and lead time are addressed in RTC Section 8.

Please see RTC Section 9 for a discussion about the use of other alternative fuels. We emphasize that this final rule does not require use of any particular technology or technology mix, and the final standards are performance-based standards. We include FCEVs in a modeled potential compliance pathway to support the feasibility of the final standards, but there are numerous potential compliance pathways for the final standards, including ones that do not include FCEVs or ZEVs (see preamble Section II.F for further discussion and additional example potential compliance pathways, as well as RIA Chapter 2.11). See RTC Section 2 for additional response to comments on the final standards and the final standards' stringency.

5.2 FCEV & Hydrogen Safety

Comments by Organizations:

Organization: American Bus Association

We also note from the current unified agenda published by the Administration (https://www.reginfo.gov/public/do/eAgendaMain), that standards are not yet fully formed for safe hydrogen battery technology and are still under development (RIN 2127-AM40). Similarly, safety standards are still being developed and adopted for heavy-duty electric batteries as well (RIN 2127-AM43). Between a lack of safe or reliable technology development or operational standards, a lack of existing infrastructure, unreliable projections for future infrastructure, it seems prudent to delay a selection of any particular low or zero-emission technology strategy and any fleet requirements or projections should be set aside. [EPA-HQ-OAR-2022-0985-1634-A1, p. 3]

Organization: American Free Enterprise Chamber of Commerce (AmFree) et al.

In addition, the hydrogen used in fuel-cell vehicles presents serious safety risks. As EPA acknowledges, hydrogen molecules are small and "challenging to contain," which means that "[e]ven with properly designed systems, small leaks are common." Draft RIA at 75. Leaks, in turn, lead to dangerous—even fatal—accidents. If hydrogen escapes, "it can form a combustible mixture with air," and ultimately, an "explosion[]." Id.; see also Hao Li et al., Safety of Hydrogen Storage and Transportation, 8 Energy Reports 6258, 6259 (May 2022) ("Hydrogen can easily cause material failure, which in turn can lead to leakage. Hydrogen leakage is followed by a mixture of air in a certain space to form a gas cloud; if it encounters an ignition source at this time, hydrogen cloud explosions easily occur. Even without ignition sources, high-pressure hydrogen leakage may cause spontaneous combustion and explosion."). This risk is greater with hydrogen than with "other common fuels" because hydrogen has a "much greater" flammability range and "will ignite more easily." Draft RIA at 75. And to make matters worse, "[h]ydrogen is colorless, odorless, and tasteless," so detecting leaked hydrogen—and therefore the risk of an explosion—"is difficult." Id. [EPA-HQ-OAR-2022-0985-1660-A1, p. 51]

The inherent danger of hydrogen has already resulted in catastrophic accidents. In 2019, "there were several hydrogen explosions in Norway, the United States and South Korea." Li et al., Safety of Hydrogen Storage, supra, at 6259. In Norway, an "assembly error" involving a hydrogen tank caused an explosion at a fueling station near Oslo, injuring three people. Norway Fines Nel Units $3 Million over 2019 Blast at Hydrogen Fuel Station, Reuters (Feb. 16, 2021), https://tinyurl.com/3twp99k4. In the United States, leaking hydrogen at a silicone products plant led to a "massive explosion and fire that fatally injured four workers and seriously injured another." CSB Releases AB Specialty Silicones Factual Update, U.S. Chem. Safety Bd. (Dec. 18, 2019), https://tinyurl.com/yc4pyz4c. The Chemical Safety Board reported that "[t]he force from the explosion was felt up to 20 miles away in neighboring communities and damaged surrounding businesses." Id. The same year, there was also an explosion at a chemical plant in Santa Clara, California, that "shook buildings and residents at least five miles away" and resulted in evacuations and shelter-in- place orders for residents and businesses in the area. Luz Pena, Hydrogen Explosion Shakes Santa Clara Neighborhood, ABC7 NEWS (June 2, 2019), https://tinyurl.com/mr3r3yxe. The explosion injured two plant employees and caused "extensive damage." Report on the June 2019 Hydrogen Explosion and Fire Incident in Santa Clara, California, H2 Hydrogen Safety Panel, at 7 (June 2021), https://tinyurl.com/yeyu28bj. In South Korea, a hydrogen storage tank at a government research project exploded, "destroy[ing] a complex about half the size of a soccer field, killing two and injuring six." Hyunjoo Jin & Jane Chung, Hydrogen Hurdles: A Deadly Blast Hampers South Korea's Big Fuel Cell Car Bet, Reuters (Sept. 24, 2019), https://tinyurl.com/yx93d5c9. "One victim was blown away by pressure and then killed after being hit by rock." Id. (internal quotation marks omitted). And just this year, there have already been two road accidents in the United States involving the transportation of hydrogen. Agnete Klevstrand, "Explosion After Explosion," Hydrogen Insight (Feb. 7, 2023), https://tinyurl.com/ypea2at8. In one of the accidents, a pickup and trailer, belonging to a domestic hydrogen fuel manufacturer and distributor, collided with a passenger vehicle, caught fire, and led to a "wave of explosions" that sent "balls of flames" ten meters into the air. Id. (internal quotation marks omitted). A witness reported that there was "[e]xplosion after explosion after explosion and it just didn't stop." Id. (internal quotation marks omitted). "The two occupants of the truck and the driver of the Toyota were taken to [the] hospital with minor injuries" and "traffic lights and utility lines were damaged by the flames." Id. [EPA-HQ-OAR-2022-0985-1660-A1, pp. 51 - 52]

EPA must consider these safety concerns as part of its feasibility analysis. See Sierra Club v. EPA, 325 F.3d 374, 378 (D.C. Cir. 2003) ("The statute also intends the agency to consider many factors other than pure technological capability, such as costs, lead time, safety, noise and energy."). But in the proposed rule, it simply brushed them aside. With respect to battery-electric vehicles, the agency merely stated that "standards have already been developed by the industry and are in place for manufacturers to use today to develop current and future products." 88 Fed. Reg. at 25,962; see also Draft RIA at 36–39. Those existing "standards" provide little assurance given the safety problems that have arisen already, and the likely increase in similar incidents if use of electric vehicles substantially increases, as the proposed rule not only anticipates but affirmatively intends. And with respect to fuel-cell vehicles, the agency notes only that "[h]ydrogen has been handled, used, stored, and moved in industrial settings for more than 50 years," and that there are "established methods," "federal oversight and regulation," and "standards" in place to ensure safe use. 88 Fed. Reg. at 25,972; Draft RIA at 75–76. These existing protocols, like those for battery-electric vehicles, are plainly inadequate in light of the documented disasters that have occurred in the United States and elsewhere. Even EPA acknowledges that "[a]s hydrogen demand increases, additional codes and standards at all levels of government are likely going to be needed to accommodate heavy-duty FCEVs and fueling station development." Draft RIA at 76. Those codes and standards must be established and proven effective before the agency adopts a rule that would require manufacturers to produce, and consumers to use, fuel-cell vehicles, not after. EPA cannot—and should not—put the American public in danger to advance its agenda on electric vehicles. [EPA-HQ-OAR-2022-0985-1660-A1, pp. 52 - 53.]

Organization: American Trucking Associations (ATA)

EPA further notes that hydrogen-related fuel cell vehicles carry additional risks that can be mitigated through:30

- proper no/low leak designs for infrastructure, hydrogen fill equipment, vehicle connectors, and vehicle storage and supply;
- ambient hydrogen concentration monitoring and alarm;
- hydrogen pressure monitoring in the vehicle and infrastructure to indicate leaks;
- proper ventilation in and around hydrogen fueling equipment and fuel cell vehicles;
- vehicle controls to ensure the vehicle cannot be driven while fueling equipment is attached; and
- vehicle controls that isolate hydrogen storage in the case of an accident. [EPA-HQ-OAR-2022-0985-1535-A1, p. 20-21]

30 Ibid, pg. 76

Fleets will need to expand existing technician safety training and education to manage these potential risks. Maintenance facilities upgrades will also be needed to accommodate BEV and FCEV vehicles. For example, because hydrogen is lighter than air, shop ventilation and monitoring will be needed for fleets servicing FCEVs. For BEVs, isolating high-voltage service bays has been mentioned as a potential maintenance strategy. Fleets are in the initial stages of understanding how to adapt existing maintenance shops to accommodate BEVs and/or FCEVs. As many fleets conduct in-house maintenance on their vehicles, EPA should further investigate the proposed rule's impact on maintenance practices and facilities. [EPA-HQ-OAR-2022-0985-1535-A1, p. 21]

Organization: Arizona State Legislature

EPA does not estimate the cost or timetable for the safety training or the potential cost from fires and other damage.

The risk is greater for hydrogen-powered vehicles. EPA recommends flame detectors since hydrogen flames are "almost invisible"; ventilation for vehicles stored indoors or under a roof to avoid hydrogen accumulation; safety training for first responders to turning the vehicle off or physically interrupting the power supply; and storage in "an isolated area" after a crash. *Id.* at 74-75. One study simulating a vehicle's hydrogen tank explosion in an underground parking garage and road tunnel found fatality distances from 1-3.2 meters and 3-9.5 meters, respectively, depending on the size of the tank.32 Again, EPA does not estimate the cost or timetable for the safety training or the potential cost from fires, explosions, and other damage. [EPA-HQ-OAR-2022-0985-1621-A1, p. 25]

32 Jinouk Park et al., Study on the Explosion of the Hydrogen Fuel Tank of Fuel Cell Electric Vehicles in Semi-Enclosed Spaces, ENERGIES 2023 16(1), 241 (Dec. 2022), available at https://www.mdpi.com/1996-1073/16/1/241; see also Shaoqi Cui et al., Analysis of the fire hazard and leakage explosion simulation of hydrogen fuel cell vehicles, 41 THERMAL SCIENCE AND ENGINEERING PROGRESS 101754 (June 2023).

Organization: Daimler Truck North America LLC (DTNA)

EPA Request for Comment, Request #17: We request comment on our assessment that HD FCEVs can be designed to maintain safety.

- DTNA Response: Based upon DTNA's extensive experience in ZEV product development, there is no question that HD FCEVs can be designed to maintain safety. [EPA-HQ-OAR-2022-0985-1555-A1, p. 161]

EPA Summary and Response:

Summary:

Comments were received on the safety of FCEVs and hydrogen. American Bus Association shared concern that there are planned additional federal safety standards yet unpromulgated and stated that FCEV implementation should not happen until such standards exist. The American Trucking Association noted that training will need to be expanded to manage risks and facilities will need to be upgraded to maintain HD FCEVs. The Arizona State Legislature commented that the fire and damage risk is greater with hydrogen powered vehicles than with BEV. They discussed explosion risk in enclosed areas such as underground parking garages and tunnels. Arizona State Legislature stated that EPA should estimate the costs and timing for safety training and the potential costs of fires and explosions. AmFree expressed concern about "serious safety risks" and said that leaks are common due to the nature of a hydrogen molecule and are difficult to detect. They cited several examples of accidents: two accidents were tank explosions, one at a fueling station in Oslo; two massive explosions at industrial facilities; and two incidents related to road accidents involving the transportation of hydrogen. AmFree insisted that EPA must consider safety concerns as part of its feasibility analysis. They asserted that existing codes and standards are inadequate and must be established and proven effective before the Phase 3 rule drives the use of FCEVs.

Daimler, a manufacturer working to develop FCEVs, stated that there is no question that the technology can be designed to maintain safety.

Response:

EPA is required to consider safety when establishing motor vehicle emission standards. CAA section 202(a)(4). EPA has done so, as further described in Preamble II.D.3.iv and RIA Chapter 1.7.4. EPA found at proposal that HD FCEV systems must be, and are, designed to always maintain safe operation. EPA reiterates that conclusion here. See RIC Chapter 1.7.4. As EPA explained there, and as noted by DTNA, there are industry codes and standards for the safe design and operation of HD FCEVs. The Hydrogen Industry Panel on Codes, International Code Council, and National Fire Protection Association work together to develop stringent standards for hydrogen systems and fuel cells.[384] The FCEV codes and standards extend to service as well as emergency response. In addition, HD FCEVs are subject to, and necessarily comply with, the same federal safety standards and the same safety testing as ICE heavy-duty vehicles. Commenters challenging the safety of HD FCEVs failed to address the existence of these protocols and federal standards. EPA does not consider the multiple binding federal safety standards, and industry protocols to be ineffective and considers them to support the conclusion that HD FCEV can be utilized safely. When considering safety for the NPRM, EPA coordinated with the National Highway Traffic Safety Administration (NHTSA) on safety regarding comments and updates for the final rulemaking.[385]

This is not to say that there is no room for further investigation and potential strengthening of safety measures. The concern with hydrogen transport in tunnels, for example, is in the process of additional evaluation. In the interim, safety is maintained by existing restrictions. For example, DOT Federal Highway Administration (FHWA)'s Technical Manual for Road Tunnels states, "Road tunnels, especially those in urban areas, often have cargo restrictions. These may include hazardous materials, flammable gases and liquids, and over-height or wide vehicles. Provisions should be made in the approaches to the tunnels for detection and removal of such vehicles."[386] DOE/Sandia National Laboratories is working with other authorities to evaluate safety in tunnels, as described further in RIA Chapter 1.7.4. Additionally, FCEVs including their storage systems, like ICE vehicles, are required to meet the Federal Motor Vehicle Safety Standards (FMVSS) for crash safety so that the systems will maintain their integrity after the specified crash conditions.

Most if not all fuels, due to their nature of transporting energy, can do harm or be unsafe if not handled properly. Although hydrogen incidents (not with FCEVs) were noted in AmFree's comment, it is important to note that there has not been a FCEV accident due to leaking hydrogen.[387] Although smaller in output than a HD FCEV, the Toyota Mirai has similar components. Retail US sales started in late 2015. When compared to other fuels, hydrogen is nontoxic and lighter than air, so it quickly disperses upwards unlike gas vapors that stay at ground level, and has a lower radiant heat so surrounding material is less likely to ignite.[388] Thus, we reasonably have taken into consideration that further steps are being taken and by 2030 these processes will have moved forward to continue to ensure safety in operation.

Two commenters noted additional training needs. One stated that EPA should estimate the cost and timing for safety training and the potential costs of fires and explosions. Safety training

occurs for a variety of reasons for all HD vehicle types. A review of possible safety training for technicians and mechanics as well as safety training for first responders shows appropriate training to be eight hours or less.[389,390] This time is seen as appropriate for ongoing training required of technicians, mechanics, and first responders and does not merit the addition of costs in our analysis. As noted in RIA 2.3.4, after consideration of comments stating that ZEV technicians may initially require additional training, EPA has phased in the ZEV maintenance and repair scaling factors to address this potential transition period. One commenter also noted a potential need to upgrade maintenance facilities to accommodate FCEVs. Please refer to RTC Section 3.7 for a response to comments such as this one regarding maintenance and repair.

We do not agree that costs associated with unfortunate accidents such as fires or explosions are a necessary consideration for our analysis.

5.3 H2 Storage Tank Packaging

Comments by Organizations:

Organization: Daimler Truck North America LLC (DTNA)

EPA Request for Comment, Request #16: We request comment and data related to packaging space availability associated with FCEVs and projections for the development and application of liquid hydrogen in the HD transportation sector over the next decade.

- DTNA Response: To enable FCEV range comparable to that of a conventional vehicle today, HD transportation must rely on liquid hydrogen due to the volume required to achieve the desired ~500 mile range. There is no liquid hydrogen infrastructure suitable for HD vehicles (HDVs) today, and very little suitable gaseous hydrogen infrastructure available. It is unclear how much infrastructure will be developed over the next decade. [EPA-HQ-OAR-2022-0985-1555-A1, p. 161]

EPA Summary and Response:

Summary:

DTNA believes that onboard liquid hydrogen is required for long-range HD FCEVs (e.g., to achieve a desired ~500-mile range). They note that little gaseous hydrogen infrastructure is suitable for HD FCEVs today, and no liquid hydrogen infrastructure, and they point to uncertainty about infrastructure development over the next decade.

Response:

Please see RTC Section 8 for more response to comments about hydrogen infrastructure. We note that, regarding uncertainty about infrastructure development over the next decade, this rule offers some degree of certainty, as it provides a signal supporting industry development of the technology and supporting infrastructure for manufacturers utilizing this technology to comply.

---

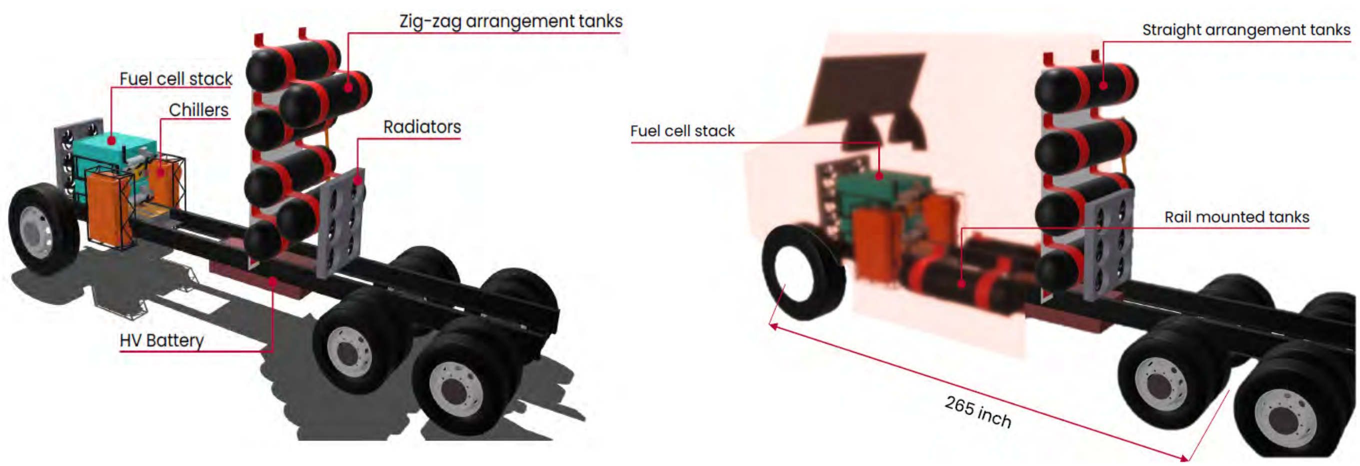
[389] AIChE Institute for Learning & Innovation. “Fundamental Hydrogen Safety Credential”. Available online: https://www.aiche.org/ili/academy/courses/elp200/fundamental-hydrogen-safety-credential.

[390] Redwood Coast Energy Authority. “FCEV Resources for Emergency Responders”. Available online: https://redwoodenergy.org/fcev-resources-for-emergency-responders/.

As DTNA suggests, liquid hydrogen technology may prove beneficial in the longer-term. However, gaseous hydrogen is predominantly used today, including for light-duty vehicles, forklifts, and buses. As explained in RIA Chapter 1.7.3, the readiness of liquid storage and refueling technologies is still relatively low compared to compressed gas technologies, so onboard liquid storage tanks are not included as part of the technology package under the modeled potential compliance pathway that supports our rule.

For the final rule, we contracted FEV to independently conduct a packaging analysis for Class 8 long-haul FCEVs that store 700-bar gaseous hydrogen onboard to see if space would be sufficient to accommodate hydrogen fuel for longer-range travel. EPA conducted an external peer review of the final FEV report.[391] FEV found ways to package six hydrogen tanks (77 kg of hydrogen) to deliver up to a 500-mile range with a sleeper cab using a common 265-inch wheelbase. All of the tanks could be at the back of the cab in a zig-zag arrangement and the batteries inside the frame rails, or four of the tanks could be behind the cab with two tanks mounted to the outside of the frame rails under the cab and the batteries inside the frame rails.

Figure 1 FEV High-Level FCEV Packaging Concept[392]



The FEV analysis was based on the use of high-power lithium titanium oxide (LTO) batteries, which are long-lasting cells that are currently more expensive than the FCEV battery estimates in the rule. Lithium iron phosphate (LFP) batteries could be used instead of LTOs but would require a battery pack with higher energy capacity. LFPs have a lower c-rate rating (i.e., a slower charge or discharge rate) compared to LTOs: LFPs are expected to have 3C c-rate whereas LTOs have a 10C c-rate.[393]. However, one could accomplish similar power output during discharge or power input from regenerative braking using either a smaller LTO or a larger LFP battery. Since we limit our motor power output to 400 kW for tractors, we find LFP batteries sufficient to capture the required regenerative braking. The volumetric energy density of a LFP battery pack

[391] FEV Consulting. "Heavy Duty Commercial Vehicles Class 4 to 8: Technology and Cost Evaluation for Electrified Powertrains—Final Report". Prepared for EPA. March 2024.
[392] FEV's CAD images are based on volumetric energy density of key powertrain components. All engineering aspects of feasibility were not verified.
[393] Toshiba. "High-power type cells". Available online: https://www.global.toshiba/ww/products-solutions/battery/scib/product/cell/high-power.html.

is about 1.8 times higher than a LTO pack, so the packaging study with LTO packs can be used as a surrogate for the LFP pack.[394] In addition, the analysts found that batteries can be packaged along the side rails, which could provide two or three times the packaging volume for the battery pack, as shown in Figure 2.

Figure 2 FEV High-Level FCEV Packaging Concept[395]

The potential to store six onboard hydrogen storage tanks would allow a long-haul tractor to meet a daily operational VMT requirement of at least 420 miles. Daimler shared data based on 18 days of telematics data from their fleet, and they identified a 90th percentile VMT of 484 miles for Class 8 day cabs and 724 miles for Class 8 sleeper cabs. If a HD FCEV refuels once en-route, then it could cover a 90th percentile VMT requirement of at least as far as 724 miles in a day. A refueling event during the day should not be an unreasonable burden, given that refueling times are as short as 20 minutes or less and are considered a key benefit of HD FCEVs.[396]

Based on our review of the literature for the NPRM and after consideration of the comments received and additional information, our assessment is that most HD vehicles have sufficient physical space to package hydrogen storage tanks onboard.[397] This remains the case for long-haul sleeper cabs if they refuel en-route. See also RIA Chapter 2.9.1.2.

---

[394] Figure 1 shows that a 58 kWh LTO battery could fit between the rails. This means that a 110 kWh LFP battery could also fit between the rails.

[395] FEV's CAD images are based on volumetric energy density of key powertrain components. All engineering aspects of feasibility were not verified.

6 Electric Charging Infrastructure

6.1 Charging Infrastructure Availability

Comments by Organizations

Organization: Advanced Energy United

IV. Conclusion

By providing a predictable business and regulatory environment, EPA's proposed vehicle rules can help not only decarbonize US transportation, but also bolster a critical segment of the American economy: automakers. EVs present a critical lifeline for the U.S. automotive industry, as total car sales have declined since 2017. As industry analysts have noted, "[EVs] are the only growth area in the automotive market."12 The EPA's rule can simultaneously sustain this growth and accelerate EV adoption, revitalizing automakers and creating good paying, high-skilled jobs in the process. As such, EPA's proposed rules complement key parts of the Inflation Reduction Act (IRA) - namely the 30D and 45W tax credits that incentivize the purchase of electric vehicles, and the host of industry incentives, such as the manufacturing tax credit (45X) that support the buildout of a domestic EV industry. [EPA-HQ-OAR-2022-0985-1652-A2, p. 6]

12 Carreon, A. (5 May, 2023). The EV Battery Supply Chain Explained. Rocky Mountain Institute. https://rmi.org/the-ev-battery-supply-chain-explained/

However, it is crucial to build the EVSE infrastructure to meet this changing automotive landscape. Simply put, consumers and businesses can only take advantage of the 30D and 45W tax credits if the infrastructure is there to satisfy demand. Ensuring this infrastructure buildout will enable effective implementation of the EPA's rule and accelerate the transition to 100% electrified transportation. Fortunately, the IRA's companion legislation – the Infrastructure Investment and Jobs Act (IIJA) - can help in this effort. IIJA included $7.5 billion in funding as a part of the National Electric Vehicle Infrastructure (NEVI) formula program, which provides states with resources to deploy charging stations. The pieces are in place to make the transition from the internal combustion engine to EVs, we just need to put them together. [EPA-HQ-OAR-2022-0985-1652-A2, p. 6]

Organization: Alliance for Vehicle Efficiency (AVE)

We are concerned that the lack of charging and refueling infrastructure will undermine ZEV adoption by fleet owners. In support of the Proposal, EPA states that it expects most BEV heavy-duty trucks to travel an estimated daily range of about 200 miles, allowing fleet owners to rely on private charging infrastructure and not depend on public charging stations. [EPA-HQ-OAR-2022-0985-1571-A1, p. 7]

Meanwhile, the IRA does not provide fleet owners with any incentives to install charging stations. The timeline for publicly-available stations along major interstate corridors, typically used by heavy-duty trucks, is unclear. In other words, fleet owners investing in BEV trucks will also need to assume the cost of charging on their own or risk that public charging will be available in the future. As a result, it will be challenging for fleet owners to use BEV trucks for longer haul transport. [EPA-HQ-OAR-2022-0985-1571-A1, p. 7]

A recent study by the Environmental Defense Fund, found:

"…when including the cost of charging infrastructure, only one of the five fleets [in the State of New Jersey] was able to maintain fuel cost savings. Without financial support for private fleet infrastructure, these additional costs make it difficult to break even for most use cases. This is especially true for smaller fleets. Fleets of less than 10 trucks are particularly vulnerable to charging infrastructure costs and will require greater support to realize fuel cost savings." 19 [EPA-HQ-OAR-2022-0985-1571-A1, p. 7]

19 https://blogs.edf.org/energyexchange/2022/10/14/charging-infrastructure-is-key-for-new-jersey-fleets-to-electrify/

Organization: American Free Enterprise Chamber of Commerce (AmFree) et al.

Charging Infrastructure. If the proposed rule were adopted, commercial fleets in many segments of the heavy-duty industry would need access to a "robust and accessible network of highway stations that provides on-route fast-charging." Electric Highways at 1; Sam Pournazeri, Criteria to Consider When Siting EV Charging Infrastructure for Medium- and Heavy-Duty Vehicles, ICF (Apr. 28, 2022), https://tinyurl.com/4z7k6z29 ("Criteria for EV Charging"). Vehicles that travel long distances or carry heavy loads, such as long-haul trucks and transit buses, need to charge during their shift or on the way to their next location. See Draft RIA at 63; Medium- and Heavy-Duty Vehicle Electrification at 11. And almost half of all heavy-duty vehicles are purchased by independent owner-operators "who will be more likely to recharge on route than install an expensive charging station at home." Medium- and Heavy-Duty Vehicle Electrification at 11. To date, however, "little attention has been paid to how and where these trucks will charge their batteries, and it's no small problem." Emily Ayshford, Calculating the Cost of E-Trucking, Univ. of Chi. Off. of Sci., Innovation, Nat'l Lab'ys & Glob. Initiatives, https://tinyurl.com/yckmpkd5 ("Calculating the Cost of ETrucking"). [EPA-HQ-OAR-2022-0985-1660-A1, pp. 42 - 43]

According to the Department of Energy, today there are only approximately 54,000 public charging stations nationwide, offering just under 140,000 ports. See Dep't of Energy, Alternative Fuels Data Ctr., Alternative Fueling Station Counts by State (Public), https://tinyurl.com/385e5nk2 ("Alternative Fueling Station Counts – Public") (last accessed June 14, 2023).5 The available data do not identify how many of those stations can accommodate heavy-duty vehicles, but when taking into account charging speed, interoperability, and site design, the number appears to be miniscule. [EPA-HQ-OAR-2022-0985-1660-A1, p. 43]

5 There are also approximately 3,700 private en-route stations. See Dep't of Energy, Alternative Fuels Data Ctr., Alternative Fueling Station Counts by State (Private), https://tinyurl.com/4xc8jfcs (last accessed June 14, 2023). They are not generally accessible to the public.

Charging stations can offer up to three kinds of equipment, all of which provide different ranges and speeds. Level 1 charging provides approximately five miles of range per hour; Level 2 charging provides approximately 25 miles of range per hour; and "direct-current" or "DC" fast charging provides approximately 100 to 200 or more miles of range per thirty minutes. See Dep't of Energy, Alternative Fuels Data Ctr., Developing Infrastructure to Charge Electric Vehicles, https://tinyurl.com/3buv474m ("Developing Infrastructure"); see also Draft RIA at 61. Unless a heavy-duty vehicle can stop for overnight charging, its operator will typically need DC fast charging to stay on schedule. See Dep't of Energy, Alternative Fuels Data Ctr., Electric Vehicles for Fleets, https://tinyurl.com/msv8va9d ("All-electric vehicles that drive more than 100 miles in a day may require DCFC for in-shift recharging."); Marie Rajon Bernard et al., Deploying Charging Infrastructure to Support an Accelerated Transition to Zero-Emission Vehicles, ZEV Transition Council, at 6 (Sept. 2022) ("Deploying Charging Infrastructure"). But only a small fraction of public charging stations offer that capability. Nationwide, there are a mere 7,406 stations with DC fast charging ports. See Dep't of Energy, Alternative Fuels Data Ctr., Alternative Fueling Station Locator, https://tinyurl.com/4xjsc3x6 (last accessed June 14, 2023). That amounts to roughly 14 percent of public stations. Id. [EPA-HQ-OAR-2022-0985-1660-A1, p. 43]

Even among that small group of stations, there are three different types of DC fast charging connectors (the equipment that is "plugged into a vehicle"). Developing Infrastructure. As EPA acknowledges, that "may limit the EVSE ports and stations a particular vehicle may use," which in turn "may pose a challenge for . . . drivers who may need to travel longer distances to find a station with the right connector type." Draft RIA at 68. And "[p]hysical connectors are only one aspect of interoperability." Id. at 69. There are also "[c]ommunication protocols between the network and chargers and between the charger and vehicle [that] facilitate the flow of key information important for charging and billing." Id. Without standardization, heavy-duty vehicle operators may pull up to a DC fast charging port only to realize that they cannot use it. [EPA-HQ-OAR-2022-0985-1660-A1, pp. 43 - 44]

Finally, even if a station has charging capabilities and equipment compatible with a particular heavy-duty vehicle, the site design may not be able to accommodate that vehicle's size. Many stations are constructed with light-duty passenger cars in mind, and as a result, will not have enough space for large vehicles to enter and exit, high enough canopies or roofs, or long enough charging cords. See Draft RIA at 63. [EPA-HQ-OAR-2022-0985-1660-A1, p. 44]

Given these numerous obstacles, recent studies conclude that public charging stations for heavy-duty vehicles today are scarce at best or even practically nonexistent. See Medium- and Heavy-Duty Vehicle Electrification at 19 ("Public charging stations set up for MHEDVs, however, are scarce today."); Deploying Charging Infrastructure at 6 ("There is essentially no public charging infrastructure in place for HDVs right now."). [EPA-HQ-OAR-2022-0985-1660-A1, p. 44]

Both the lack of adequate charging infrastructure and potential electric-vehicle owners' concerns about whether adequate stations would be available where and when needed have already impeded the uptake of heavy-duty electric vehicles. The American Trucking Associations, for example, recently explained in a Senate hearing that, "[w]ithout the required infrastructure, motor carriers cannot properly plan and invest in battery-electric trucks." A Heavy Dose of Reality. The president of one transportation service in Pennsylvania submitted a comment in this rulemaking to emphasize that "[t]he infrastructure required to support the widespread adoption of charging of EV Coaches is nonexistent." John Bailey, President of Bailey Coach, Dkt. No. EPA-HQ-OAR- 2022-0985 (May 2023). And Volvo Group North America testified that customers have delayed and even canceled electric truck purchases in California "because of delayed infrastructure." Volvo Grp. N. Am., Dkt. No. EPA-HQOAR-

2022-0985 (May 2, 2023). According to that manufacturer, its customer base "will not purchase zero emission trucks unless both the vehicles and the fuels are cost-effective and readily available so as not to negatively impact their business operations." Id. [EPA-HQ-OAR-2022-0985-1660-A1, pp. 44 - 45]

These concerns show that the Nation's charging infrastructure must substantially improve before fleet owners would consider replacing their conventional vehicles with electric ones. EPA does not attempt to estimate the number of new public charging stations that would be needed, but available studies— including some that the agency discusses—suggest that this would be an enormous endeavor. Atlas Public Policy, for example, projects that there would need to be between $100 and $166 billion in cumulative infrastructure investments to support a 2030 fleet of over one million battery-electric heavy-duty vehicles and begin building infrastructure for future years. See Draft RIA at 67. That estimate includes $30 billion for depot charging ports, "with most of the remaining investment supporting on-road charging." Id. Attaining even a fraction of that investment is likely impossible under the proposed rule's compressed timeline. [EPA-HQ-OAR-2022-0985-1660-A1, p. 45]

EPA concludes otherwise based primarily on the availability of tax incentives, federal funding, and plans that manufacturers, charging network providers, and energy companies have announced. See 88 Fed. Reg. at 25,933. But the agency overstates the contribution that each of those sources will make. First, the tax incentive that the agency relies on—called the "Alternative Fuel Refueling Property Credit"—provides a credit of up to 30 percent of the cost of charging equipment, but only when the charging equipment is located within low-income or non-urban area census tracts, and only up to $100,000. See Draft RIA at 19–20, 65. Considering that "installing one charging site [that] could supply 100 e-trucks at a time . . . could run costs higher than $21 million," this $100,000 credit will provide little incentive to construct charging stations throughout the country. Calculating the Cost of E-Trucking. [EPA-HQ-OAR-2022-0985-1660-A1, p. 45]

Second, although the Bipartisan Infrastructure Law ("BIL") provides $7.5 billion in federal funding to build out a national network for charging infrastructure, jurisdictions are "not required" to use any of that money "to build stations specifically for heavy-duty vehicles." 88 Fed. Reg. at 25,930, 25,944; Draft RIA at 16, 65. And even if all of those funds were used for heavy-duty charging infrastructure, it still would not be enough. As explained above, developing sufficient charging infrastructure will cost tens of billions of dollars. Indeed, one study found that the BIL funding would not even cover the cost of the infrastructure needed in California alone, which only has "15% of the U.S. MD/HD vehicle market." Criteria for EV Charging ("In California alone, which has 15% of the U.S. MD/HD vehicle market, there will be a need for more than 157,000 DCFCs by 2030 to support the upcoming wave of electric MD/HD vehicles. According to our estimates, such a network of charging infrastructure could cost more than $15 billion over the next 10 years. That is twice the amount of funding the federal government allocated through the [BIL]."). [EPA-HQ-OAR-2022-0985-1660-A1, pp. 45 - 46]

Third, the private investments that EPA identifies are small, and their effects are uncertain. According to the agency, there has been "over a billion dollars for recently announced projects to support electric truck or other commercial vehicle charging in the United States and Europe." 88 Fed. Reg. at 25,934. The source it cites shows that almost half that amount is entirely for Europe. See Zero-Emission Vehicles Factbook. And the domestic projects that the agency discusses are so preliminary that it is unclear how many stations they will actually provide. For example, EPA asserts that Daimler Truck North America is partnering with NextEra Energy Resources and Blackrock Renewable Power to invest $650 million in a nationwide charging network for commercial vehicles. 88 Fed. Reg. at 25,934; Draft RIA at 65. But less than two months ago, the companies had only announced the name of their joint venture and unveiled renderings of the site layout. See Introducing Greenlane: Daimler Truck North America, NextEra Energy Resources and BlackRock Forge Ahead with Public Charging Infrastructure Joint Venture, NextEra Energy (Apr. 28, 2023), https://tinyurl.com/ms2xm43k. It remains to be seen how many charging stations they will be able to construct by the time the proposed rule takes effect. EPA also states that "Volvo Group and Pilot recently announced their intent to offer public charging for medium- and heavy-duty BEVs at over 750 Pilot and Flying J North American truck stops and travel plazas." 88 Fed. Reg. at 25,934; Draft RIA at 65. But those companies have not announced a plan to construct "over 750" public charging stations; instead, the companies announced a plan to install stations "at selected Pilot and Flying J travel centers across the U.S." Volvo and Pilot Company Partner to Build a National Public Heavy Duty Charging Network, Volvo Trucks USA (Nov. 15, 2022), https://tinyurl.com/hcfw35cp (emphasis added). Here too, it is not yet clear how many stations these companies will develop. And finally, many of the other projects EPA points to are based solely in California, see Draft RIA at 65–66, which already has the most public charging stations in the country, see Alternative Fueling Station Counts – Public. [EPA-HQ-OAR-2022-0985-1660-A1, p. 46]

In sum, the Nation's charging infrastructure cannot even support the existing, small customer base for heavy-duty electric vehicles. The number of available stations would need to increase exponentially to service the hundreds of thousands of new electric vehicles that EPA anticipates will be sold—and that would need to be in use to achieve EPA's proposed emission standards. The agency has not provided a reasonable basis for assuming that such an expansion is possible, let alone plausible, within less than a decade. [EPA-HQ-OAR-2022-0985-1660-A1, p. 47]

Organization: American Fuel and Petrochemical Manufacturers (AFPM)

While a significant percentage of the charging installations deployed today are Level 2 EVSEs, dual charging installations to enable the flexibility of light-duty as well as medium-duty and HDV charging will become increasingly important. Direct current fast charging equipment ("DCFCs") will enable broader market coverage, even for LDVs used in applications where they cannot sit for 6 hours and charge during off-peak, lower-cost electricity periods. As utility companies gear up to provide infrastructure installations, EPA should not minimize the impact of supply chain shortages/strains on the cost of materials necessary for installing supporting charging infrastructure in the short time ahead to 2032. Beyond EVSE chargers, the cost of grid upgrade projects needed to support the incremental electricity demand growth from transportation is not insignificant and can be quite variable. A particular case study of Southern California illustrated in IOPscience notes: "the total cost of these upgrades will be at least $1 billion and potentially more than $10 billion." These costs need to be taken into consideration with expected demand growth, within detailed rate base calculations, and in concert with appliance upgrade costs to fully understand their ultimate impacts on annual ratepayer expenditures." 81 We agree with and support the Proposed Rule's acknowledgement that "a recent study found power needs as low as 200 kW could trigger a requirement to install a distribution transformer." Other anecdotal evidence discussed within an RMI report highlights the expensive mistakes that can emerge from insufficient planning and engagement in details.82 Demand charges can be particularly punishing, and in some cases make or break the business case for transition from ICEVs to BEVs, particularly for fleets and vehicles that require DCFC charging. Other considerations for high-reliability use cases should include provisional back-up power system considerations, which likely depend upon back-up generators or expensive stationary energy storage batteries. Absent comprehensive understanding of the dynamics between increased ZEV use and charging infrastructure needs, vehicle manufacturers—as well as consumers—are left in a vulnerable position. Regardless of whether manufacturers even could comply with the Proposed Rule, they would likely be left in a position where there is no consumer demand, and fleet turnover declines because the infrastructure necessary to support the new ZEVs is either at capacity or nonexistent. Indeed, at least one study to date has concluded that, upon ZEVs becoming the norm in California, it could push the total demand for electricity beyond the existing capacity of the state's grid—turning ZEVs into zero electricity vehicles.83 Even more important, meeting the demand in California would likely require construction of new power plants, or electricity purchases from neighboring states—further adding to the infrastructure needs with increased transmission and distribution capabilities.84 Or, in the short term, electricity may come from generators, in which case it makes more sense to leave the ICE in the truck rather than beside it. [EPA-HQ-OAR-2022-0985-1659-A2, pp. 22 - 23]

84 Id.

Despite the potential for increased demands on domestic energy generation and generation capacity,85 EPA offers little to no support that these demands will be sufficiently met. Similarly, EPA's draft Regulatory Impact Analysis86 provides little to no analysis regarding the costs associated with meeting these increased infrastructure and energy generation/capacity needs beyond the flawed reliance on various legislative actions, such as the BIL and IRA.87 Consequently, EPA is pushing a technology at a pace that cannot be adopted within the timeframe of its own proposal. [EPA-HQ-OAR-2022-0985-1659-A2, p. 23]

85 See, e.g., U.S. DRIVE, "Summary Report on EVs at Scale and the U.S. Electric Power System" (Nov. 2019), available at https://www.energy.gov/eere/vehicles/articles/summary-report-evs-scale-and-us-electric-power-system-2019 (summarizing impacts of light-duty vehicles on energy generation and generation capacity alone and acknowledging several potential challenges without including analysis of medium- and heavy-duty ZEVs).

86 DRIA at 15–17, 20–21.

87 See, e.g., Salma Elmallah et al., Can distribution grid infrastructure accommodate residential electrification and electric vehicle adoption in Northern California? (Nov. 9, 2022), available at https://iopscience.iop.org/article/10.1088/2634-4505/ac949c (projecting upgrades needed solely for the PG&E service area in Northern California, which serves 4.8 million electricity customers and is subject to

aggressive targets for both EV adoption and electrification of residential space and water heating will add at least $1 billion and potentially $10 billion to PG&E’s rate base).

Organization: American Trucking Associations (ATA)

5. Infrastructure Will Be a Key Driver Towards the Adoption of ZEV Technology

EPA recognizes that infrastructure availability will be a key enabler to adopting ZEVs. The agency’s proposed GHG 3 regulation includes BEV and FCEV vehicles, each with different infrastructure requirements and investment costs. While EPA estimates the additional cost of providing electrical infrastructure to charge BEVs, this does not ensure that infrastructure is available or suitable for most heavy-duty applications. Without adequate infrastructure, increasing percentages of ZEV sales, both BEVs and FCEVs, will be unachievable, and the industry will not hit the annual milestone targets in EPA’s ZEV adoption table. [EPA-HQ-OAR-2022-0985-1535-A1, p. 15]

EPA cites the Department of Energy’s Alternative Fuels Data Center Station Locator for providing the number of chargers available for publicly and privately held locations to justify the expansion of battery electric vehicles throughout the United States. The agency acknowledges that the station counts of over 53,000 are not broken out by light- or heavy-duty capable charging capacities or site configurations. In our discussions with fleets, ATA is aware that a small number of heavy-duty accessible public charging stations are available nationwide. EPA cites the federal funds available to states to support the construction of charging networks under the Infrastructure Investment and Jobs Act (IIJA) and the Inflation Reduction Act (IRA), but the programs included in the legislation do not robustly support commercial vehicle electrification. [EPA-HQ-OAR-2022-0985-1535-A1, p. 15]

The National Electric Vehicle Infrastructure (NEVI) grant program, included in IIJA, provides federal funds to states to begin to build a nationwide charging network to support transportation electrification in all highway segments. The authorizing legislation qualified medium duty commercial charging as eligible projects, but initial guidance from the Federal Highway Administration (FHWA) in February 2022 discouraged states from providing truck charging capacity and did not require specific design requirements that would co-locate medium- and heavy-duty charging infrastructure support. ATA commented on the NEVI program and pushed FHWA to provide funds to immediately support commercial-scale electrification projects.19 We were pleased to see the agency issue new guidance clarifying the eligibility of medium- and heavy-duty charging infrastructure, but unfortunately, ATA is unaware of any state directing their NEVI state block grant funds toward it. California, Oregon, and Washington provided a competitive grant submission to fund a portion of their joint I-5 charging network, which would include heavy-duty charging stations and are awaiting an award announcement. [EPA-HQ-OAR-2022-0985-1535-A1, p. 15]

19 American Trucking Associations, Comments on the National Electric Vehicle Infrastructure Formula Program, FHWA-2022-0008-0339, August 23, 2022

Organization: BorgWarner Inc.

BorgWarner appreciates the Administration’s support for EV charging and hydrogen infrastructure.

BorgWarner applauds the Administration's support for EV charging and hydrogen infrastructure. More infrastructure support is needed, however, for the HD, MD, and other commercial vehicles to help these segment's shift to an electrified and hydrogen-powered future. We urge federal agencies to align resources and goals to leverage the shared endeavors to decarbonize the transportation sector. [EPA-HQ-OAR-2022-0985-1578-A1, p. 4.]

A key factor for expanding infrastructure is private sector charging support. Fleet owners will need to not only bear higher costs for new ZEV vehicles, but also the charging and refueling equipment as well. More support for these commercial facilities is crucial. Many products are available to help fleet owners navigate this transition and we hope more federal and state incentives will be forthcoming. BorgWarner is currently working with customers to install needed charging stations. [EPA-HQ-OAR-2022-0985-1578-A1, p. 4.]

Organization: California Air Resources Board (CARB)

The NPRM provides several excellent examples of times the nation has adapted to new electrical load including the adoption of A/C and the rapid growth of data centers. The implementation of fleet charging infrastructure is much the same and, it should be noted, not expected to happen overnight. The phase in schedule proposed by U.S. EPA provides ample time for fleets and utilities to plan for and implement charging solutions that meet truck electrification needs. [EPA-HQ-OAR-2022-0985-1591-A1, p.45]

The NPRM requests comment on time considerations for all levels of HD charging infrastructure, including Level 2 up to 350-kilowatt direct current fast charger (DCFC) systems. NPRM states that 2027 provides adequate timing to establish initial levels of depot charging with the expectation that charging capacity will grow over the remainder of the decade. With current CEC MD/HD infrastructure projects, staff are seeing projects take about two to three years from inception to operations. Equipment shipping delays have made up a significant portion of the delays. Those can be expected to improve over time, and, in any event, even with permitting process requirements in California, there is sufficient time to meet U.S. EPA's 2027 and beyond timeframe. With planning, the lead times identified here should be sufficient to support the stringency of the proposed standard and more stringent alternative i.e., values that would reflect the level of ZEV adoption in CARB's ACT regulation. A number of truck OEMs and private companies are already working to provide both depot charging solutions as well as corridor infrastructure solutions. Daimler is leading the Greenlane $650 million investment in West Coast, Southeast Coast and Texas corridors.149 Volvo has a truck-stop agreement150 and is also working on a dealership-based California corridor.151 Hyundai is working to establish a San Pedro ports to Texas southwest hydrogen corridor.152 TerraWatt is working on a similar fast charging network along I-10 from California to Texas.153 Nikola has an agreement with Voltera to build 50 hydrogen stations.154 Voltera,155 Zeem,156 Electrify America,157 Forum Mobility,158 WattEV,159 and TerraWatt160 among others are developing depot charging projects. Private companies dependent on transportation services have announced both electrification plans as well as vehicle and infrastructure projects moving them toward those goals. USPS has announced 66,000 BEV delivery vehicles by 2028 with all electric purchases from 2026 and an initial order of 14,000 chargers.161,162 Walmart has announced its own network of DCFCs aimed at lighter vehicles,163 an order of 4,500 delivery vehicles164 and a fleetwide 100 percent electrification.165 Amazon has ordered 100,000 BEV delivery vehicles166 with "thousands" of chargers already installed167 including reports of sizable charging depot installations.168,169 Amazon is backing class 8 drayage truck charging depots170,171 and has ordered 329 BEV terminal tractors.172 FedEx has committed to ZE delivery vehicles reaching 50 percent by 2025 and 100 percent by 2030 with a 100 percent ZE full delivery fleet by 2040.173,174 UPS has a 10,000 BEV delivery vehicle order175 and has participated in showcasing innovative charging technologies. DHL Supply Chain has cancelled further orders of diesel terminal tractors, ordered 50 BEV terminal tractors toward a 100 percent ZE fleet by 2025 and ordered BEV semi tractors on their way to a 30 percent ZE on-road fleet by 2030.176 [EPA-HQ-OAR-2022-0985-1591-A1, pp.45-48]

Organization: CALSTART

Infrastructure Considerations

One of the major concerns EPA cites as possibly limiting faster ZE-MHDV adoption is the pace of electric charging and hydrogen fueling infrastructure moving to the scale required. Specifically, EPA raises concerns about fleets being able to install sufficient charging at their depots to meet their deployment rate and asks for comment. We believe the approach EPA takes to address infrastructure seriously limits the assumed penetration of key vehicle segments, including regional tractors and an initial percentage of long-haul operations. Addressing these assumptions is critical. [EPA-HQ-OAR-2022-0985-1656-A1, p. 16]

In terms of infrastructure needed and the availability to meet this faster rate, several studies have investigated the ability to meet the pace of change needed. ICCT performed a strong analysis that looked at infrastructure needed to meet a national ACT-based timeline. 35 CALSTART has also performed an infrastructure needs assessment based on the Drive to Zero market penetration projections (which exceed ACT). This assessment has been structured to build on and further detail the implementation roadmap Drive to Zero developed to reach 100 percent ZE-MHDVs by 2040. The 2040 roadmap's core strategy breaks up the activity needed to reach full sales penetration into six overlapping stages, with smart infrastructure phasing as a critical enabling component of five of the stages (Figure 8).35F36 [EPA-HQ-OAR-2022-0985-1656-A1, pp. 16 - 17.] [See Docket Number EPA-HQ-OAR-2022-0985-1656-A1, page 17, for Figure 8]

35 https://theicct.org/publication/infrastructure-deployment-mhdv-may23/

36 https://globaldrivetozero.org/publication/global-roadmap-for-reaching-100-zero-emission-medium-and-heavy-duty-vehicles-by-2040/

Phased approach: Building the next level of implementation detail into this strategy, the infrastructure needs assessment illustrates that infrastructure, while a near-term challenge, will not be the limiting factor on meeting steeper penetration rates. This is due to the unique phased and geographically targeted way infrastructure is most likely to deploy. Indeed, CALSTART's findings show the network benefits of this clustered and phased rollout, which matches ZE-MHDV penetration volumes with first-launch regions, will create charging network efficiencies in deployment volume and utilization that can support more ZE-MHDVs than EPA's approach assumes.37 [EPA-HQ-OAR-2022-0985-1656-A1, p. 18.]

37 Phasing In U.S. Charging Infrastructure, CALSTART, June 2023

The analysis considers that deployment will first occur where it makes sense, not everywhere.38 That is, priority areas will be a focus of most private investment in the near term, and prioritization will inform the coordination of several of the factors critical in reducing lead times for the installation of infrastructure, developing the grid, and making costs more predictable. [EPA-HQ-OAR-2022-0985-1656-A1, p. 18.]

38 https://nacfe.org/research/electric-trucks/#electric-trucks-where-they-make-sensehigh-poten..al-regions-for-electric-truck-deployments

The assessment first identified the critical metrics to determine where focused and phased infrastructure clusters will first grow. This is based on four primary priority factors in Table 1: [EPA-HQ-OAR-2022-0985-1656-A1, p. 19.] [See Docket Number EPA-HQ-OAR-2022-0985-1656-A1, page 19, for Table 1]

These priorities—generally acknowledged by industry as important and serving as a framework where infrastructure development has been coordinated—identify and generate the needs and opportunity "heatmap" matching the first deployment locations satisfying vehicle use needs, infrastructure capability, and investment profiles. By assigning vehicle penetration pacing to these regions, the assessment generated required charger volumes and power levels and projected how they would grow over the ramp-up period to create the hubs, corridors, and networks that can match faster penetration timing. These locations deeply align with where project development, placement, investment, and industry transition toward zero-emission freight movement is already underway. [EPA-HQ-OAR-2022-0985-1656-A1, p. 19]

The analysis does not consider deployment as a uniform process, where charging infrastructure is used irrespective of its general priority for fleets. Rather, it considers utilization in terms of the deployment prioritization of each location, which would introduce effects of the clustering of investment and the acceleration of infrastructure availability (Figures 9–11). Areas identified as priorities for rapid and concentrated deployment can focus investment and shift forward in time. There are multiple co-benefits to not treating deployment as spatially uniform and linearly increasing with a relatively simple vehicle penetration. This infrastructure has the potential to be utilized more in the near term and possibly more efficiently overall than if deployed sporadically. [EPA-HQ-OAR-2022-0985-1656-A1, p. 19.] [See Docket Number EPA-HQ-OAR-2022-0985-1656-A1, pages 20-21, for Figures 9-11]

Phased infrastructure deployment exceeds EPA penetration rate needs: This stage-based, phased implementation model matches a much faster rate of ZE-MHDV penetration than either the EPA preferred option or even the ACT-aligned option. It matches a pace closer to that set by the Advanced Clean Fleet (ACF) rule combined with ACT, and specifically aligns with the pace needed to match 100 percent sales by 2040. What it clearly illustrates is that the implementation of national infrastructure deployment will occur at a regionally differentiated rate where priority geographies support the earlier use of vehicles and installation of infrastructure ecosystems. Notably, the locations in CALSTART's assessment and ICCT's analysis show very strong regional alignment on timing and rate. [EPA-HQ-OAR-2022-0985-1656-A1, p. 21]

Among other considerations, the assessment factors in charger utilization as a consideration, whereas the EPA assessment limits its assumptions primarily to one charger per vehicle and a charging rate limited to an assumed duty-cycle. This limitation has serious implications for restricting capabilities—such as longer-haul operations—that do not match the assumptions. [EPA-HQ-OAR-2022-0985-1656-A1, p. 21]

For example, by assuming that certain bat ery pack sizing and associated weight penalties are needed to achieve EPA's definition of long haul, EPA then projects that no long haul is possible until much later in the rule timeline. However, by adjusting bat ery sizing to the opportunities for using regional charging hubs and early corridor charge locations, critical segments of priority long-haul operations can be achieved much earlier than is assumed. This is a critical—and we believe unintended—flaw. These assumptions do not match the real-world plans already underway for depots by several carriers, manufacturers, and infrastructure service providers. The prioritization of key areas reflects real-world strategy and coordinated investment trends by major industries around high-potential regions. [EPA-HQ-OAR-2022-0985-1656-A1, p. 21]

Highly instructive announcements have been made by major companies increasing the electrification of their facilities/operational territories or signaling investments in targeted areas. Corridor investment examples include:

- Blackrock, Daimler, and NextEra have announced GreenLane, a $650 million joint venture to build out key corridors breaking ground this year.39
- TeraWatt announced that it would use $1 billion in seed funding to build charging stations from Los Angeles to Texas.40
- BP Pulse has made commitments and investments of over $1 billion to move toward its goal of installing and operating 100,000 sites globally.
- Voltera has committed several billions to developing sites in the United States.41 [EPA-HQ-OAR-2022-0985-1656-A1, pp. 21 - 22]

39 https://newsroom.nexteraenergy.com/news-releases?item=123840

40 https://terawattinfrastructure.com/ideas/i-10-electric-corridor/

41 https://www.globenewswire.com/news-release/2022/08/09/2495043/0/en/Voltera-Launches-as-Turnkey-Charging-Infrastructure-Solution-for-Companies-Operating-EVs-With-Plans-for-Multibillion-Dollar-Investment.html

Recent state and federal government funding has also assisted, and many industry players are leveraging the funding to realize the next stage in their charging infrastructure buildout strategy. [EPA-HQ-OAR-2022-0985-1656-A1, p. 22]

This strategy also aligns broadly with utility strategies for investments to support charging infrastructure. Research shows that efficiencies within energy infrastructure investment beyond the site are possible in areas where playbooks are created and new service processes emerge. The models developed by Lawrence Berkeley National Lab for the California Energy Commission's Charging Infrastructure Assessment shows remarkably different overall load profiles given deployment scenarios in which managed charging takes place at sites, or in which charging takes place in short distance travel patterns that can be operationally coordinated for opportunity charging.42 Other studies by NREL show that managed charging can even create, at the grid scale, megawatt-scale resources using aggregated electric vehicle behavior.43 Managed load profiles are reflected in our analysis. We assume the overall load profile on the utility can change drastically if deployment supports these trips clusters, leading to possible charge management scenarios and also larger grid management opportunities. [EPA-HQ-OAR-2022-0985-1656-A1, p. 22]

42 https://www.energy.ca.gov/programs-and-topics/programs/electric-vehicle-charging-infrastructure-assessment-ab-2127

43 https://www.nrel.gov/docs/fy22osti/83404.pdf

The major takeaway from the prioritization of areas is twofold:

- First, by shifting investment into priority regions, more ZE-MHDVs can be supported earlier and more economically.

- Second, by prioritizing key areas and regions, those areas come to be integrated and can realize connected utilization efficiencies. Relatedly, this provides an opportunity to streamline workforce development (e.g., engineers, construction), utility make-ready programs, etc., which have the potential to reduce costs. [EPA-HQ-OAR-2022-0985-1656-A1, p. 22]

This overall network effect and its benefits are fully missing from the EPA assumptions, which primarily consist of linear, one-to-one vehicle to charger relationships and therefore limits pacing and efficiency. [EPA-HQ-OAR-2022-0985-1656-A1, p. 22]

Organization: Clean Air Task Force et al.

b. Charging and grid infrastructure is capable of supporting HD BEVs in volumes aligned with and in excess of EPA's proposed standards.

Deployment of BEVs is well underway across the U.S. and is already requiring the electric power sector to make plans to reliably and safely integrate these vehicles. The electric power industry is well situated to maintain safe and reliable service that can power an increasing deployment of HD BEVs; utilities, aided significantly through investments from the BIL and IRA, are making important upgrades to the system to integrate higher penetrations of BEVs. Additional third party private investments and public investments are also already committed to building a robust HD BEV charging network. [EPA-HQ-OAR-2022-0985-1640-A1, p. 45.]

When considering infrastructure buildout, it is important to remember that HD ZEVs will enter the total on-road HD fleet gradually and in volumes that pale in comparison to in-use HD combustion vehicles. Modeling using HD TRUCS and MOVeS3.R3188 shows that EPA's proposal, if finalized, would likely result in ZEVs comprising just 1 percent of the total on-road HD fleet by 2027, gradually reaching 8 percent in 2032 and 23 percent in 2040. See Table 4, infra. In other words, a relatively small portion of the HD fleet will be tapping into charging and grid infrastructure over the next decade, and even by 2040, HD ZEVs would comprise less than a quarter of the on-road fleet under this proposal. Infrastructure needs for HD ZEVs will accordingly grow gradually over time. [EPA-HQ-OAR-2022-0985-1640-A1, p. 45. See Docket Number EPA-HQ-OAR-2022-0985-1640-A1, pages 45-46, for Table 4.]

> 188 HD TRUCS was used to develop ZEV adoption rates (by vehicle classification). MOVES3.R3 was used to translate HD TRUCS-derived ZEV adoption rates to ZEV sales and in-use curves.

For the final rule, we urge EPA to model how the Phase 3 standards will likely affect the composition of the entire on-road HD fleet, not just HD ZEVs' share of new sales. That information would better help the Agency and the public consider infrastructure issues related to this rulemaking. [EPA-HQ-OAR-2022-0985-1640-A1, p. 46.]

i. Economic theory and historical precedent show that infrastructure buildout will occur at the pace and scale needed to support vehicle electrification.

EPA should reject arguments that the buildout of charging and grid infrastructure cannot occur at the pace and scale needed to support expanded vehicle electrification, which are unreasonably pessimistic and inconsistent with both economic theory and historical precedent. These arguments rely on the classic "chicken-and-egg" scenario said to be presented by ZEV sales and charging infrastructure, where each side of the market waits for the other. But EPA need not and should not wait for infrastructure to fully mature before finalizing strong Phase 3 standards. Instead, EPA's standards themselves will send a strong signal to the market to undertake the infrastructure investments needed to accommodate a gradual rise in vehicle electrification,189 such that increased ZEV sales and infrastructure buildout will occur in relative tandem and reinforce each other. As one analyst sums it up: "The chicken-and-egg conundrum is being solved. Investments in the space and the adoption of EVs [a]re happening much faster than many analysts expected, and this is also accelerating the build-out of the charging network."190 [EPA-HQ-OAR-2022-0985-1640-A1, pp. 46 - 47.]

189 Environmental regulation itself, of course, can lead to technology innovation and market development. See generally Jaegul Lee et al., Forcing Technological Change: A Case of Automobile Emissions Control Technology Development in the US, 30 Technovation 249 (2010); Margaret R. Taylor, Edward S. Rubin, & David A. Hounshell, Regulation as the Mother of Innovation: The Case of SO2 Control, 27 Law & Policy 348 (2005); James Lents et al., Chapter II: The regulation of automobile emission: A case study, in Environmental Regulation and Technology Innovation: Controlling Mercury Emissions from Coal-Fired Boilers (Marika Tatsutani & Praveen Amar eds., 2000) https://www.nescaum.org/documents/rpt000906mercury_innovative-technology.pdf.

190 Gabriela Herculano, Chicken-and-Egg Problem: EV Adoption and Buildout of Charging Networks, Nasdaq (Apr. 18, 2022), https://www.nasdaq.com/articles/chicken-and-egg-problem%3A-ev-adoption-and-buildout-of-charging-networks.

The economic literature on indirect network effects and two-sided markets shows that an increase in BEV sales—a likely effect of the Phase 3 standards, particularly if they are strengthened in the final rule—can be expected to stimulate associated infrastructure development. In a study on flex-fuel vehicles fueled by E85 (85 percent ethanol), Corts (2010) found that growth in sales of flex-fuel vehicles due to government fleet acquisition programs led to an increase in the number of retail E85 stations.191 That relationship held true across all six Midwestern states analyzed, despite differences in those states' E85 subsidies and tax credits.192 The author concluded that the results "confirm the basic validity" of the theory underlying government fleet purchase requirements: that increasing the "base of alternative fuel vehicles can spur the development of a retail alternative fuel distribution infrastructure."193 [EPA-HQ-OAR-2022-0985-1640-A1, p. 47.]

191 Kenneth S. Corts, Building out alternative fuel retail infrastructure: Government fleet spillovers in E85, 59 J. Env't Econ. & Mgmt. 219, 219-20 (2009).

192 Id.

193 Id. at 231.

Recent economic research has confirmed this relationship in the context of ZEVs and charging infrastructure specifically. An influential study by Li et al. (2017) found that "EV demand and charging station deployment give rise to feedback loops" and that "subsidizing either side of the market will result in an increase in both EV sales and charging stations."194 Similarly, Springel (2021) found "evidence of positive feedback effects on both sides of the market, suggesting that cumulative EV sales affect charging station entry and that public charging availability has an impact on consumers' vehicle choice."195 The BIL and IRA subsidize both sides of the market, offering significant incentives for both HD ZEV purchases and the construction of charging infrastructure. Economic theory therefore supports the proposition that strengthened Phase 3 standards, particularly in combination with the BIL and

IRA's large financial incentives, will facilitate expansion of charging and grid infrastructure.196 [EPA-HQ-OAR-2022-0985-1640-A1, p. 47.]

194 Shanjun Li et al., The market for electric vehicles: indirect network effects and policy design, 4 J. Ass'n Env't. & Resources Econ. 89, 128 (2017).

195 Katalin Springel, Network Externality and Subsidy Structure in Two-Sided Markets: Evidence from Electric Vehicle Incentives, 13 Am. Econ. J.: Econ. Pol'y 393, 426 (2021).

196 See id. at 394 (noting that "the presence of positive feedback amplifies the impact of both types of subsidies"), 415 ("positive feedback loops between the charging station network and total all-electric vehicle sales amplify the impact of both types of subsidy").

Economic theory has in fact played out in Norway, where ZEV sales and infrastructure both expanded rapidly over the span of about a decade. There, the "path to charging point saturation started by stimulating more demand for EVs."197 In other words, Norway did not wait for infrastructure to fully mature before beginning its transition to cleaner cars. Rather, rising ZEV sales themselves "helped trigger a spike in demand for charging stations."198 [EPA-HQ-OAR-2022-0985-1640-A1, p. 48.]

The concept that charging infrastructure will adequately scale up over time also finds support in an analogous historical example: the buildout of roads and gasoline refueling infrastructure in the early 20th century to serve the United States' growing fleet of automobiles. The country's exponential growth in automobile sales—first exceeding 1,000 in 1899 and growing to 1 million by 1916199—preceded the establishment of an extensive network of both suitable roads200 and filling stations.201 Instead, the buildout of road and refueling infrastructure unfolded over long time horizons and in a variety of ways, adapting to the needs of the automobile fleet as it changed and grew. Paving and other road improvement efforts began on a small scale in cities, where automobiles were initially concentrated; efforts to improve rural roads and construct highways happened a decade or more later, as motorists began to expand their driving beyond cities.202 Similarly, in the case of refueling infrastructure, a network of modern filling stations did not spring up until well after automobiles had grown in popularity.203 Before that, refueling needs were met through varied and dispersed "non-station" methods such as cans of gasoline sold at general stores, barrels at repair garages, mobile fuel carts, curb pumps, and home refueling pumps, which emerged at various times as the demand for gasoline increased.204 Road and refueling infrastructure therefore exhibited a "long-term, adaptive and portfolio approach"205 that, over the span of several decades, satisfied the shifting needs of the growing ranks of automobile owners. [EPA-HQ-OAR-2022-0985-1640-A1, p. 48

Melaina, Turn of the century refueling: A review of innovations in early gasoline refueling methods and analogies for hydrogen, 35 Energy Pol'y 4919, 4922 (2007) (noting that "the takeoff period for gasoline stations occurred between 1915 and 1925, but exponential growth in vehicles began around 1910, so the rise of gasoline filling stations followed rather than preceded the rise of gasoline vehicles").

202 Geels, at 467-68.

203 Melaina, at 4922.

204 Id. at 4924-27.

205 Id. at 4932 (discussing refueling infrastructure).

That approach holds important lessons for this rulemaking. As detailed above, the introduction of HD ZEVs into the total on-road fleet will occur gradually and, for the first decade or more, in relatively low volumes. As explored in a recent white paper by ICCT,206 successfully meeting the needs of this gradually expanding fleet of heavy-duty ZEVs will not require the overnight nationwide buildout of infrastructure that some have misleadingly claimed. Instead, economic theory and historical precedent show that growth in heavy-duty ZEV sales and infrastructure buildout will occur in relative tandem, with infrastructure responding over time commensurate with the evolving needs of the ZEV fleet. And in finalizing its Phase 3 standards, EPA will send a strong market signal that will facilitate infrastructure development at the pace and scale needed to support compliance with the standards. As explained in the sections below, the nation's infrastructure is already well-positioned to adapt to increased vehicle electrification. EPA must reject unfounded chicken-and-egg arguments questioning whether infrastructure will respond to rising demand. [EPA-HQ-OAR-2022-0985-1640-A1, pp. 48 - 49

206 See generally Pierre-Louis Ragon et al., ICCT, Near-Term Infrastructure Deployment to Support Zero-Emission Medium- and Heavy-Duty Vehicles in the United States (2023), https://theicct.org/wp-content/uploads/2023/05/infrastructure-deployment-mhdv-may23.pdf.

iii. Charging infrastructure development is in line with needs to support higher deployment of HD BEVs.

EPA also correctly identifies that there has been "rapid growth in the broader market for charging infrastructure serving cars or other electric vehicles." 88 Fed. Reg. at 25934. New charging infrastructure announcements are occurring every week, showing the public and private sectors' commitment to building out infrastructure to support vehicle electrification. An analysis of announced but not yet deployed charging infrastructure investments compiled by Atlas Public Policy found that over $29.5 billion of funding has been committed specifically to medium- and heavy-duty vehicle charging, with another $4.3 billion available to medium- and heavy-duty vehicle charging as well as light-duty vehicle charging (see Table 5).232 These totals include public sector (e.g., Charging and Fueling Infrastructure Discretionary Grant funding, state funding commitments, and modeled estimates of 26 U.S. Code § 30C tax credit payments), private sector (e.g., automaker and charging service provider), and utility program investments. [EPA-HQ-OAR-2022-0985-1640-A1, p. 55.] [See Docket Number EPA-HQ-OAR-2022-0985-1640-A1, pages 55-56, for Table 5]

232 Atlas Pub. Pol'y, Announced EV Infrastructure Funding (June 15, 2023).

These totals are likely a significant underestimate of total investment, particularly of private sector commitments. A few recent announcements on investments and technological advancements include:

- Daimler, NextEra, and BlackRock announced the Greenlane joint venture to design, develop, install, and operate a US-wide, BEV public charging and hydrogen fueling network for medium- and heavy-duty BEVs and hydrogen FCEVs.233
- DOE announced the award of $7.4 million to seven projects to develop medium and HD BEV charging and hydrogen corridor infrastructure plans that will benefit millions of drivers across 23 states.234
- Cummins and Heliox announced a deal to bring two innovative fleet charging solutions to market.235
- Scania successfully tested a megawatt charging system from ABB E-Mobility with a next-generation electric truck; ABB intends to launch the next version of that charging technology in late 2024 or early 2025.236 [EPA-HQ-OAR-2022-0985-1640-A1, p. 56]

233 Michelle Lewis, Daimler just announced a $650M US-wide EV charging network for trucks, electrek (Apr. 27, 2023), https://electrek.co/2023/04/27/daimler-just-announced-a-650m-us-wide-ev-charging-network-for-trucks/.

234 DOE, Biden-Harris Administration Announces Funding for Zero-Emission Medium- and Heavy-Duty Vehicle Corridors, Expansion of EV Charging in Underserved Communities (Feb. 15, 2023), https://www.energy.gov/articles/biden-harris-administration-announces-funding-zero-emission-medium-and-heavy-duty-vehicle.

235 Cummins, Inc., Cummins and Heliox to Partner On Electric Vehicle Charging Solutions for Fleet Customers, Cummins Newsroom (May 16, 2023), https://www.cummins.com/news/releases/2023/05/16/cummins-and-heliox-partner-electric-vehicle-charging-solutions-fleet.

236 Nora Manthey, Scania tests ABB's megawatt charging system for next-gen electric trucks, Electrive (May 10, 2023), https://www.electrive.com/2023/05/10/scania-tests-abbs-megawatt-charging-system-for-next-gen-electric-trucks/.

Even more private sector announcements and investments should be expected, as private sector actors often do not announce their investment plans and are especially unlikely to do so if they are investing in depot charging (as opposed to public charging), which will constitute a large proportion of heavy-duty charging. Nevertheless, the scale of these announced investments reflects a strong and growing deployment of public and private charging infrastructure that, even in advance of the finalization of the Phase 3 standards, has begun to set the stage for a robust charging network. Additional analyses have emphasized the growing momentum in infrastructure deployment; for example, an International Energy Agency report noted "there has been a substantial upswing in investment in EV charging infrastructure, which has doubled in 2022 compared to the previous year."237 [EPA-HQ-OAR-2022-0985-1640-A1, pp. 56 - 57]

237 IEA, World Energy Investment 2023, at 50 (2023), https://iea.blob.core.windows.net/assets/54a781e5-05ab-4d43-bb7f-752c27495680/WorldEnergyInvestment2023.pd.

Organization: Clean Fuels Development Coalition (CFDC) et al.

F. There will not be enough charging infrastructure to persuade skeptical consumers to adopt battery electric vehicles in the numbers EPA projects.

Another reason the proposal is not feasible is a dearth of charging infrastructure. The proposal acknowledges that a lack of charging infrastructure is one of the "top barriers" customers identify to fleet electrification. 88 Fed. Reg. 25,943. This is unlikely to change anytime soon. [EPA-HQ-OAR-2022-0985-1585-A1, p. 26]

Currently, the general electric vehicle charging infrastructure is "inadequate and plagued with non-functioning stations." Dan Zukowski, EV charging infrastructure is "inadequate and plagued with non-functioning stations": J.D. Power, SmartCitiesDive (Feb. 22, 2023), https://www.smartcitiesdive.com/news/ev-charginginfrastructure- inadequate-non-functioning-stations/643148/. An on-going study by J.D. Power found that charge point unreliability has increased 50% from 2021 to January 2023, from 14% to 21%. Id. This unreliability has led to high rates of dissatisfaction with public charging stations among electric vehicle owners. Id. This dissatisfaction is worse in states with higher numbers of electric vehicles and in large cities with high-density housing. Id. [EPA-HQ-OAR-2022-0985-1585-A1, p. 27]

This is likely to get worse. While light-duty electric vehicle sales are increasing rapidly, "the rate of EV adoption is growing at a rate that is almost double that of charger installation growth rates" and "the construction of new charging stations is not keeping up with the demand." Id. [EPA-HQ-OAR-2022-0985-1585-A1, p. 27]

And if the US electric vehicle charging infrastructure is already not enough for the rapidly increasing number of electric cars being bought and used, it is woefully inadequate for heavy-duty vehicles. Heavy-duty vehicles require much larger and more powerful chargers than their light-duty cousins. This is because heavy-duty vehicles need more power and need to receive it faster than a light-duty vehicle to meet rigorous commercial on-road operating schedules. The majority of nonresidential electric passenger vehicle charging stations have fast charging at around 150 kWs. To charge fast enough, a large heavy-duty vehicle would need nearly 1,000 kW. One recent study from the electricity and gas utility National Grid projects that by 2030, the typical passenger plaza along a highway will demand as much power— with all the wiring, transformer, and substation upgrades that requires—as a sports arena during its busiest times. Electric Highways Study, National Grid (2022), https://www.nationalgrid.com/us/EVhighway. By 2035, a single larger truck stop charging station could need to provide 19 megawatts of peak power, roughly what a small town uses. Id. And by 2045, that kind of truck stop may require 30 megawatts of capacity, approaching the peak usage of a large industrial plant. Id. [EPA-HQ-OAR-2022-0985-1585-A1, p. 27]

Heavy-duty electric vehicle charging stations also need more physical space. Because heavy-duty trucks are large and because electric charging takes longer than refilling with liquid fuel, truck recharging stations will need to be expanded and undergo enormous grid-interconnection processes just so trucks can recharge. [EPA-HQ-OAR-2022-0985-1585-A1, p. 27]

Many heavy-duty electric vehicle manufacturers point to the lack of charging infrastructure as the single biggest limiting factor in deploying electric heavy-duty vehicles. "Daimler, the leading US heavy-duty truck manufacturer, unveiled the Class 8 Freightliner eCascadia, its first fully electric semi-truck, in May of 2022. Its current production capacity is around 2000 trucks per year and it wouldn't be hard to double that number to 4000, [CEO John] O'Leary said in a recent media briefing…. But there are only around 100 electric trucks out on the streets." Bianca Giacobone, Electric Semi-Trucks Are Ready to Be Deployed, But There Aren't Near Enough Plugs to Charge Them, Business Insider (Feb. 4, 2023), https://www.businessinsider.com/electric-trucks-charging-infrastructure-truckingmanufacturer-daimler-ecascadia-2023-2. “Overwhelmingly, infrastructure is slowing us down in terms of EV deployment,” O’Leary explained. [EPA-HQ-OAR-2022-0985-1585-A1, pp. 27 - 28]

The proposal appears to be aware of this fact. Indeed, heavy-duty charging infrastructure is so comically small that the DRIA must point out the obscure fraction of level two chargers with an arrow. See DRIA at 64. [EPA-HQ-OAR-2022-0985-1585-A1, p. 28. See DRIA Chart, Private Fleet EVSE Ports, on page 28 of docket number EPA-HQ-OAR-2022-0985-1585-A1.]

The proposal suggests that if enough money is thrown at the problem, it will go away. 88 Fed. Reg. 25,943. The proposal explains that it expects the BIL to “help build out a national network of EV charging” because it provides “$2.5 billion in discretionary grant programs for charging and fueling infrastructure along designated alternative fuel corridors and in communities (Section 11401) and $5 billion for the National Electric Vehicle Infrastructure (NEVI) Formula Program (under Division J, Title VIII).” Id. at 25,943–94. But these funds are “not required” to be used to “build stations specifically for heavy-duty vehicles.” Id. And in any event, it is not only money that is a problem. “Siting, permitting, construction delays – all that means current lead times [for charging stations] are measured in years, not weeks or months.” John G. Smith, Broad EV rollouts constrained by infrastructure challenges: Daimler Truck CEO, Trucknews.com (Jan 31, 2023), https://www.trucknews.com/sustainability/broad-ev-rollouts-constrained-by-infrastructure-challenges-daimler-truck-ceo/1003172321/. The proposal provides no evidence that this will change anytime soon. [EPA-HQ-OAR-2022-0985-1585-A1, pp. 28 - 29]

Organization: Colorado Department of Transportation et al.

- With respect to EPA’s request for comment on charging infrastructure availability, our state is working hard to analyze, plan for, and fund needed charging infrastructure by leveraging federal, state, and utility resources. Last month, the Colorado Energy Office launched its first round of grants for medium- and heavy-duty fleet vehicle charging, a program that it expects to grow over time. [EPA-HQ-OAR-2022-0985-1530-A1, p. 2]

Organization: Consolidated Edison, Inc. (Con Edison)

Con Edison supports advancing EV charging infrastructure buildout today while planning proactively to meet the fast ramp in future customer needs to achieve emissions reduction targets. [EPA-HQ-OAR-2022-0985-1661-A1, p.4]

Organization: Daimler Truck North America LLC (DTNA)

Electrical infrastructure buildout pace is a barrier to significant ZEV adoption that should be factored in to Phase 3 CO2 standard levels.

The pace of electrical infrastructure buildout remains the biggest barrier for customer adoption of HD BEVs and poses the greatest threat to successful implementation of the Proposed Rule. As EPA observes, BEV infrastructure is critically important for the success of increasing development and adoption of BEV technologies.108 DTNA thus appreciates the opportunity to respond to EPA’s request for comment on the concerns that have already been expressed to EPA regarding the slow growth of ZEV charging and refueling infrastructure. This Proposed Rule is unique in that compliance will rely heavily on the development of infrastructure that manufacturers have no control over, and providers are not obligated to expand infrastructure to support the scope and timing of the Proposed Rule. [EPA-HQ-OAR-2022-0985-1555-A1, p. 45]

108 See Proposed Rule, 88 Fed. Reg. at 26,000.

DTNA—in partnership with Portland General Electric—is proud to have built the first-of-its-kind public charging island for commercial ZEVs in Portland, Oregon. In addition, DTNA's expert eConsulting team is dedicated to supporting fleets on all aspects of the ZEV transition, including site design and interfacing with utilities. Therefore, DTNA is uniquely positioned to offer insight into the challenges associated with commercial ZEV infrastructure development. [EPA-HQ-OAR-2022-0985-1555-A1, p. 45]

DTNA has concerns about EPA's treatment of electric infrastructure in the Proposed Rule, and the Agency's assumptions that all suitable vehicle applications and willing customer adopters will have charging infrastructure available, or that such infrastructure can be made available within the timeframes that EPA assumes and at the costs projected in HD TRUCS. In this section, DTNA highlights the unique challenges with HD charging infrastructure (especially with respect to electricity transmission and distribution); explains why EPA significantly underestimates infrastructure costs; discusses specific timing challenges; and highlights case studies from its customer fleets. Finally, DTNA concludes by recommending that EPA use an electric infrastructure scalar to ensure that infrastructure development pace is adequately factored in to EPA's adoption rate projections, as discussed in more detail on Section II.C of these comments. [EPA-HQ-OAR-2022-0985-1555-A1, p. 45]

EPA projects that modest increases in electric power generation will be required to support the Proposed Rule. Specifically, the Agency estimates that Proposed Rule requirements would increase HD BEV electric power end use by 0.1% over 2021 levels in 2027, increasing to 2.8% over 2021 levels in 2055.109 EPA notes, however, that these figures do not include the electricity increase required to produce hydrogen.110 [EPA-HQ-OAR-2022-0985-1555-A1, pp. 45-46]

109 Id. at 25,983; DRIA at 430, Table 6-1.

110 See DRIA at 431 (noting that EPA's projected electricity consumption increases attributable to the Proposed Rule do 'not include changes in electricity generation to produce hydrogen').

EPA's figures appear to underestimate the increase in electric power generation that will be required to support implementation of the Proposed Rule. As discussed below, according to the Company's calculations, 45 gigawatts of installed charging capacity will be required to support the vehicle volumes in the Proposed Rule from 2027 - 2032. Based on EIA's estimate that there was 1,143,757 megawatts (MW) of total utility-scale electricity generating capacity in the United States at the end of 2021,111 Proposed Rule implementation will require a 3.9% increase in domestic generation capacity (over the 2021 level) by 2032, conflicting with EPA's projection that only a 2.8% increase will be required by 2055. [EPA-HQ-OAR-2022-0985-1555-A1, p. 46]

111 See U.S. Energy Information Administration, 'Electricity explained: Electricity generation, capacity, and sales in the United States,' https://www.eia.gov/energyexplained/electricity/electricity-in-the-us-generation-capacityand-sales.php.

Further, DTNA is concerned that EIA's commercial vehicle forecast does not align with EPA's ZEV market projections in the Proposed Rule. EIA's AEO 2022 commercial vehicle projections are summarized in Table 15 below. EIA projects zero commercial vehicle BEV sales through 2050, and minimal FCEV penetration up to 1,600 vehicles per year per category. It is critical that federal agencies are aligned on these commercial vehicle projections and communicate them clearly to the electric utility industry. Given the misalignment with EIA on ZEV uptake rates, it is likely that EPA underestimates the electricity generation increase needed to support HD BEVs. [EPA-HQ-OAR-2022-0985-1555-A1, p. 46] [Refer to Table 15 on p. 46 of docket number EPA-HQ-OAR-2022-0985-1555-A1]

EPA points to the adoption of residential air conditioners and growth of power-intensive data centers as historical evidence of the electric utility industry's ability to deliver additional power to customers.113 Residential air conditioners provide a reasonable comparison for light-duty vehicle electricity demand levels, as they represent a relatively low load that is evenly distributed across utility service territories. The electricity demands associated with medium- and heavy-duty electrification will, however, be fundamentally different and must be treated as such. [EPA-HQ-OAR-2022-0985-1555-A1, p. 46]

113 See Proposed Rule, 88 Fed. Reg. at 25,983.

Unlike light-duty vehicles, most HD ZEVs cannot charge using existing 120-volt and 240-volt AC electrical infrastructure, and they require dedicated DC infrastructure. HD ZEVs are also disproportionally located in concentrated urban areas, creating highly localized grid capacity addition needs in constrained spaces (see Figure 3 below, showing heat maps of potential future loads). [EPA-HQ-OAR-2022-0985-1555-A1, p. 47] [Refer to Figure 3 on p. 47 of docket number EPA-HQ-OAR-2022-0985-1555-A1]

Power-intensive data centers and server farms were rapidly constructed across the United States in the last 20 years and were largely greenfield projects that had the flexibility to be sited where grid capacity was available or could be made available relatively easily. By contrast, the commercial transportation industry is already entrenched and invested in existing logistics facilities. Most of these are located in or around high density urban population centers, often clustered tightly together, where grid capacity is not available, and the process of acquiring land and rights-of-way for upgrades is complex. The use of data centers and server farms as anecdotal examples of electric utility adaptability suggests that EPA is significantly underestimating the demand presented by commercial transportation charging infrastructure. [EPA-HQ-OAR-2022-0985-1555-A1, p. 47]

DTNA generally agrees with EPA's assertion that scale-up of electric power generation is not likely to significantly limit the development of BEV electric vehicle charging infrastructure. Rather, the challenge for medium- and heavy-duty charging lies in distribution of that power. As ICCT observed in a recent white paper on near-term medium- and heavy-duty ZEV infrastructure development, 'Most uncertainties regarding infrastructure buildout concern the capacity of distribution systems to bring that energy to the right place in a timely manner and accommodate the highly localized power requirements of [medium- and heavy-duty vehicle] charging.'114 Accordingly, DTNA recommends that EPA engage with electric utilities and their trade associations to further understand the unique challenges that HD ZEVs charging will pose for distribution systems, and how those factors should be accounted for in this rulemaking. [EPA-HQ-OAR-2022-0985-1555-A1, p. 47]

114 See ICCT, ‘Near-Term Infrastructure Deployment to Support Zero-Emission Medium- and Heavy-Duty Vehicles in the United States (May 2023) at 1, https://theicct.org/wp-content/uploads/2023/05/infrastructure-deployment-mhdv-may23.pdf (ICCT ZEV Infrastructure White Paper).

Finally, as described in more detail in Sections I.B.3 and II.C. of these comments, EPA should incorporate a scalar to be used in its calculations of appropriate CO2 standard stringency levels, designed (and regularly updated) to reflect actual installed capacity of HD-accessible charging equipment. [EPA-HQ-OAR-2022-0985-1555-A1, p. 58]

EPA Request for Comment, Request #5: EPA requests comment on this concern, both in the Phase 3 rulemaking process, and in consideration of whether EPA should consider undertaking any future actions related to the Phase 3 standards, if finalized, with respect to the future growth of the charging and refueling infrastructure for ZEVs.

- DTNA Response: EPA should factor in heavy-duty (HD) infrastructure availability by applying an infrastructure scalar to its projected ZEV adoption rates, as discussed in Section II.C of DTNA’s comments on the Proposed Rule. DTNA also encourages EPA to pursue the supporting policies outlined in Section I.B.4. of these comments. [EPA-HQ-OAR-2022-0985-1555-A1, p. 159]

EPA Request for Comment, Request #6: EPA requests comment on what, if any, additional information and data EPA should consider collecting and monitoring during the implementation of the Phase 3 standards; we also request comment on whether there are additional stakeholders EPA should work with during implementation of the Phase 3 standards, if finalized, and what measures EPA should consider to help ensure success of the Phase 3 program, including with respect to the important issues of refueling and charging infrastructure for ZEVs.

- DTNA Response: EPA should collect data on available HD ZEV refueling infrastructure to inform stringency increases throughout implementation of the Phase 3 program, including hydrogen fueling stations and installed HD-accessible electric vehicle supply equipment (EVSE) capacity. DTNA also encourages EPA to work proactively with electric utilities to drive the buildout of HD ZEV support infrastructure, and to pursue the supporting policies set forth in Section I.B.4 of these comments. [EPA-HQ-OAR-2022-0985-1555-A1, p.159]

EPA Request for Comment, Request #77: We request comment on data and methods that could be used to estimate the effect of this action on the HD BEV vehicle charging infrastructure industry.

- DTNA Response: HD BEV vehicle charging infrastructure in the U.S. is inadequate to support the ZEV adoption rates that EPA projects as the basis for the CO2 emission standards in the Proposed Rule. Infrastructure is the most significant limiting factor for HD ZEV adoption. DTNA discusses this issue in detail in Section II.B.3 of its comments and proposes a mechanism for adjusting the stringency of the rule to account for the lack of adequate infrastructure in Section II.C.2. [EPA-HQ-OAR-2022-0985-1555-A1, pp. 172-173]

Organization: Edison Electric Institute (EEI)

Electric Company Policies and Programs Can Help Reduce Capital and Operational Costs for Fleet Electrification Customers.

Many EEI members over the last decade have sought regulatory approval from their state regulatory commissions to accelerate transportation electrification by reducing customer barriers to adoption. As of March 2023, and as mentioned supra, electric transportation filings from 62 electric companies in 35 states and Washington, D.C. have totaled more than $4.2 billion. The majority of these investments support the deployment of EV charging infrastructure at customer locations, and a significant portion is targeted to fleet customers. These programs can help reduce the cost that the customer would otherwise pay for the installation of EV charging infrastructure, which is a commonly cited barrier to EV charging infrastructure deployment.25 Further, electric companies can work with fleet customers to help manage their EV charging to occur at non-peak times. This can reduce operational costs for the fleet customer and improve utilization of the electric system, which puts downward pressure on rates for all customers.26 [EPA-HQ-OAR-2022-0985-1509-A2, pp. 16-17]

25 An oft cited barrier to adoption for some customers is the low utilization of EV charging stations. Traditional electric rates for commercial customers include a demand component designed to recover the fixed costs of delivery electricity. With low utilization (such as a public EV charging station or some fleet charging use cases), the effective electric price can be higher than a customer with the same demand but higher utilization. Many electric companies offer or are exploring commercial rates or other programs that reduce some of the demand charge exposure for these low utilization customers. See Cappers, et al., A Snapshot of EV-Specific Rate Designs Among U.S. Investor-Owned Electric Utilities, https://emp.lbl.gov/publications/snapshot-ev-specific-rate-designs.

26 See, e.g., Metz, et al., Distribution System Investments to Enable Medium- and Heavy-Duty Vehicle Electrification – A Case Study of New York, https://www.edf.org/media/worth-investment-report-finds-utilities-fleet-owners-consumers-benefit-when-utilities-cover.

Organization: Electrification Coalition (EC)

We suggest the EPA work collaboratively with the National Labs and the DOE on solutions that speed the installation of EV charging infrastructure, such as with the utility pre-planning for HD charging infrastructure, the energization process and permitting process. [EPA-HQ-OAR-2022-0985-1558-A1, p. 11]

The EPA specifically requests comments on the concerns from HD vehicle manufacturers over slow growth in HD EV charging infrastructure deployment, and asks whether EPA should consider undertaking any future actions related to Phase 3 standards with respect to the future growth of HD EV charging infrastructure.32 While not necessarily in the jurisdiction of EPA, the agency should nonetheless work collaboratively with the National Labs and DOE on solutions that will ensure a timely installation of HD EV charging infrastructure. [EPA-HQ-OAR-2022-0985-1558-A1, p. 11]

32 See page 25934 of the Environmental Protection Agency’s (EPA) proposed rule for Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles-Phase 3 in the Federal Register: https://www.govinfo.gov/content/pkg/FR-2023-04-27/pdf/2023-07955.pdf

The private sector has begun making investments in expanding public and en-route charging for HD vehicles. For example, TeraWatt Infrastructure announced that it will be developing a network of charging centers for HD trucks along the I-10 corridor between the ports of Long Beach and Los Angeles, California and El Paso, Texas. Additionally, The Volvo Group and Pilot Company announced that they have signed a Letter of Intent to build a 'national, public charging network' for heavy duty trucks across the U.S. at Pilot and Flying J travel centers. These stations will be available for all brands of electric heavy-duty trucks. [EPA-HQ-OAR-2022-0985-1558-A1, p. 13]

Organization: Energy Innovation

IV. THE COMBINED IMPACT OF FEDERAL, STATE, AND PRIVATE INVESTMENTS ON INFRASTRUCTURE DEPLOYMENT WILL HELP MEET THE NEEDS OF AN INCREASINGLY ELECTRIFIED HDV FLEET OVER THE NEXT DECADE.

The EPA notes that "[u]ncertainty about ZEV technology, charging infrastructure technology and availability for BEVs, or hydrogen refueling infrastructure for FCEVs, may affect ZEV adoption rates. As ZEVs become increasingly more affordable and ubiquitous, we expect uncertainty related to these technologies will diminish over time."42 We concur with this assessment and recognize that vehicle adoption must occur apace with infrastructure deployment. [EPA-HQ-OAR-2022-0985-1604-A1, p. 19]

42 U.S. EPA, 26072.

Estimates vary on the level of investment needed to support widespread transportation sector electrification, including for HDVs, depending on the timeframe and percentage of BEVs assumed. For example:

- Analysis by Atlas Public Policy suggests the U.S. will need to commit between $100 and $166 billion in charging infrastructure investments this decade to support an acceleration in electric truck adoption (100 percent electric new medium- and heavy-duty truck sales by the end of 2040).43
- The 2035 2.0 study's DRIVE Clean Scenario estimates the U.S. would require approximately 270,000 public charge-points for LDVs and 35,000 MDV/heavy-duty truck charge-points each year for the next 30 years, which would cost approximately $6.5 billion per year between now and 2050.44
- According to the ICCT, the U.S. needs to spend roughly $30 to $35 billion on public charging infrastructure by 2030 to achieve the widespread adoption of light- and heavy-duty ZEVs as described in the ZEV Declaration and the Global Memorandum of Understanding (MOU) on Zero- Emission Medium- and Heavy-Duty Vehicles.45 [EPA-HQ-OAR-2022-0985-1604-A1, pp. 19 - 20]

43 Lucy McKenzie et al., "U.S. Medium- and Heavy-Duty Truck Electrification Infrastructure Assessment" (Atlas Public Policy, November 12, 2021), https://atlaspolicy.com/u-s-medium-and-heavy-duty-truck-electrification-infrastructure-assessment/.

44 "Public Charging for Electric Cars and Trucks Can Be Built Quickly and Cost-Effectively," 2035 2.0, n.d., https://www.2035report.com/transportation/public-charging/.

45 Slowik et al., "Analyzing the Impact of the Inflation Reduction Act on Electric Vehicle Uptake in the United States," 11.

Fortunately, a combination of federal, state, utility, and private investments is already filling the need for HDV charging infrastructure. [EPA-HQ-OAR-2022-0985-1604-A1, p. 20]

At the federal level, the BIL contains $7.5 billion to develop a nationwide EV charging network, targeting rural and underserved areas.46 To date, all 50 states are moving forward with plans to develop over 75,000 miles (as of July 2022) of EV charging corridors, via funding allocated through the National Electric Infrastructure Program. In addition to the BIL, several federal funding opportunities specifically target infrastructure for the HDV sector. For example:

- The Clean School Bus Program offers school districts $5 billion over 5 years to replace existing school buses with clean and zero-emission models, and recipients can use funds for charging infrastructure for up to $13,000 or $20,000 per bus.47
- The Clean Heavy-Duty Vehicle Program will provide $1 billion in funding to replace dirty HDVs with clean ZEVs, support ZEV infrastructure, and train and develop workers.48
- The U.S. Department of Energy (DOE) and U.S. Department of Transportation (DOT) are funding $7 million for new projects to accelerate decarbonization of medium- and heavy-duty freight transportation.49 [EPA-HQ-OAR-2022-0985-1604-A1, p. 20]

46 "UPDATED FACT SHEET: Bipartisan Infrastructure Investment and Jobs Act," The White House Briefing Room, August 2, 2021, https://www.whitehouse.gov/briefing-room/statements-releases/2021/08/02/updated-fact-sheet-bipartisan-infrastructure-investmentand-jobs-act/.

47 "Clean School Bus Program," U.S. EPA, n.d., https://www.epa.gov/cleanschoolbus.

48 "Clean Heavy-Duty Vehicle Program," U.S. EPA, n.d., https://www.epa.gov/inflation-reduction-act/clean-heavy-duty-vehicle-program.

49 "Biden-Harris Administration Announces Funding for Zero-Emission Medium- and Heavy-Duty Vehicle Corridors, Expansion of EV Charging in Underserved Communities," U.S. Department of Energy, February 15, 2023, https://www.energy.gov/articles/biden-harrisadministration-announces-funding-zero-emission-medium-and-heavy-duty-vehicle.

The IRA extended for 10 years the Alternative Fuel Refueling Infrastructure tax credit (30C) for private investments in qualified clean-vehicle infrastructure, with a commercial tax credit of 30 percent up to $100,000 per charger (up from the prior $30,000-per-location cap). This tax credit for EV charging infrastructure will help support private investments in a more robust national HDV charging network. [EPA-HQ-OAR-2022-0985-1604-A1, p. 20]

States are also playing a leading role. According to the State of Sustainable Fleets' 2023 Market Brief, "funding commitments have increased in California and within a handful of other states, thus driving up the average annual funding that will target the clean fuel market to approximately $32 billion on average per year during the next four to five years,"50 far exceeding expectations of funding before BIL and IRA. See Figure 13. [EPA-HQ-OAR-2022-0985-1604-A1, p. 20.] [See Figure 13, Annual Funding for Clean Fuel and Vehicle Technologies, on page 21 of docket number EPA-HQ-OAR-2022-0985-1604-A1.]

50 "The State of Sustainable Fleets: 2023 Market Brief" (Gladstein, Neandross & Associates (GNA), May 2023), https://cdn.stateofsustainablefleets.com/2023/state-of-sustainable-fleets-2023-market-brief.pdf, 15-16.

State-funded programs aimed at EV charging deployment, including among the largest state ZEV markets (many of which are ACT states), are well on their way to meeting future charging infrastructure demand. [EPA-HQ-OAR-2022-0985-1604-A1, p. 21.] [See Figure 14, State-Funded Programs, on page 21 of docket number EPA-HQ-OAR-2022-0985-1604-A1.]

The private sector and charging companies are also moving quickly to take advantage of new incentives and funding. According to Atlas Public Policy, private investment in public EV charging has increased considerably in the last 5 years, rising from under $200 million in 2017 to nearly $13 billion by early 2023.51 For example:

- Pilot Company and Volvo Group signed a letter of intent to co-develop a charging network across Pilot and Flying J travel centers, catered specifically toward medium- and heavy-duty EVs. Pilot has more than 750 locations across 44 states and six Canadian provinces.52
- A $400 million investment by Forum Mobility, CBRE Investment Management, and Homecoming Capital will help build EV charging infrastructure to support the drayage industry, and a $650 million investment by BlackRock will build chargers along freight routes.53
- Cumulative private investments in EV charging by different infrastructure providers, including the auto industry, totaled just over $13 billion as of March 2023.54 [EPA-HQ-OAR-2022-0985-1604-A1, p. 22]

51 Nick Nigro, "Investment in Publicly Accessible EV Charging in the United States (2023)" (Atlas Public Policy, May 2023), https://atlaspolicy.com/wp-content/uploads/2023/05/Investment-in-Publicly-Accessible-EV-Charging.pdf.6.

53 Lisa Baertlein, "California's Port Truck-Charging Plan Gets a Jolt from Big Investors," Reuters, April 17, 2023, https://www.reuters.com/business/autos-transportation/big-investors-amp-up-californias-port-truck-charging-plan-2023-04-17/.

54 Nigro, "Investment in Publicly Accessible EV Charging in the United States (2023)," 24

Utilities are also investing in EV charging at scale, and more states are authorizing utility investments to support widespread and equitable access to more customers. Total approved utility investments for transportation electrification totaled $5.230 billion as of December 2022. See Figure 15. [EPA-HQ-OAR-2022-0985-1604-A1, p. 22. See Figure 15, States with Approved Utility Investments in Public Charging, on page 22 of docket number EPA-HQ-OAR-2022-0985-1604-A1.]

In summary, national trends combined with historic investments are poised to fill the charging gap and meet the need for increased HDV adoption resulting from more stringent EPA tailpipe rules. In addition, the sizable investment needed will be shared across federal, state, and local governments, the private sector, and utilities, ensuring a more cost-effective charging network for future HDV drivers and fleet owners. [EPA-HQ-OAR-2022-0985-1604-A1, p. 22]

Organization: Environmental Defense Fund (EDF)

IV. Sufficient infrastructure, electric grid capacity, and policies exist to support strong standards.

EPA reasonably considered additional factors, including ZEV infrastructure, in projecting ZEV deployment in its proposal. Recent analyses indicate that buildout of EV infrastructure and the electric grid distribution capacity are sufficient to support even more protective standards. Significant federal, state, and private investments are already being made to grow the HDV infrastructure. States and utilities are initiating processes to ensure adequate infrastructure to meet demand. [EPA-HQ-OAR-2022-0985-1644-A1, p. 61]

a) Federal, state, local and private investments support fast-growing infrastructure

Investment in the infrastructure required to support rapid medium- and heavy-duty ZEV proliferation has already begun. Federal, state, and private parties have directed substantial resources into developing widespread charging networks and driving technological innovation. Together, these investments are laying the groundwork for protective standards. [EPA-HQ-OAR-2022-0985-1644-A1, p. 61]

The federal government has made significant investments towards building the infrastructure necessary for a ZEV future with The Inflation Reduction Act (IRA) and Bipartisan Infrastructure Law (BIL). Both laws are putting billions of dollars towards building out charging networks and updating the grid to support the transition to light-, medium- and heavy-duty ZEVs. [EPA-HQ-OAR-2022-0985-1644-A1, p. 61]

Multiple provisions of the IRA will boost the development of infrastructure to support medium- and heavy-duty ZEVs. The Alternative Fuel Refueling Property Credit will directly fund charging infrastructure in low-income and rural areas. Qualifying businesses and individuals can be reimbursed for up to 30 percent of the cost of installing charging equipment in these areas, substantially reducing the costs of this equipment.146 The Congressional Joint Committee on Taxation estimates this credit will cost almost $2 billion over its lifetime, demonstrating the sizeable impact it will make in driving additional investments from private parties.147 The Advanced Energy Project Credit allocates $10 billion for facilities manufacturing advanced energy technologies, which includes manufacturing of charging and refueling infrastructure for ZEVs as well as grid modernization components.148 Other provisions allocate funding that can help build infrastructure at ports,149 fund grants for infrastructure buildout in nonattainment areas,150 and fund improvements to electricity generation and transmission.151 [EPA-HQ-OAR-2022-0985-1644-A1, p. 62]

146 Inflation Reduction Act of 2022, P.L. 117-169, § 13404.

147 Joint Committee on Taxation, Estimated Budget Effects of the Revenue Provisions of Tile I—Committee on Finance, of an Amendment in the Nature of a Substitute to H.R. 5376, “An Act to Provide for Reconciliation Pursuant to Tile II of S. Con. Res. 14,” as Passed by the Senate on August 7.2-22, and Scheduled for Consideration by the House of Representative on August 12, 2022, JCX-18-22, https://www.jct.gov/publications/2022/jcx-18-22/.

148 Inflation Reduction Act of 2022, P.L. 117-169, § 13501.

149 Inflation Reduction Act of 2022, P.L. 117-169, § 60102.

150 Inflation Reduction Act of 2022, P.L. 117-169, § 60101.

151 Inflation Reduction Act of 2022, P.L. 117-169, § 50144, 50145, 50151, 50152.

The BIL is another source of considerable federal investment in infrastructure development. Through its National Electric Vehicle Infrastructure (NEVI) and Charging and Fueling

Infrastructure (CFI) discretionary grant programs, the law allocates $7.5 billion in funding explicitly towards building out ZEV charging and refueling infrastructure.152 The NEVI program directs the Federal Highway Administration (FHWA) to provide funding to states to deploy EV charging stations to build an interconnected and reliable charging network. The FHWA has already announced its first set of plans under the program, which includes investment in all 50 states plus the District of Columbia and Puerto Rico.153 This first round of NEVI investment is set to bring EV charging to 75,000 miles of highway across the country.154 The CFI program provides additional funding for FHWA administered grants to state and local authorities for development of publicly accessible charging infrastructure.155 [EPA-HQ-OAR-2022-0985-1644-A1, p. 62-63]

On top of these programs, an additional $2.5 billion each year through FY 2026 could be allocated towards charging infrastructure through the Congestion Mitigation and Air Quality Management (CMAQ) program, which the BIL amended to include the purchase of medium- and heavy-duty ZEV charging equipment.156 Additional funding from the BIL is directed towards reducing truck emissions at ports157 and funding grants to states and local governments for reducing transportation carbon pollution,158 both of which will fund additional infrastructure investments. [EPA-HQ-OAR-2022-0985-1644-A1, p. 63]

156 Infrastructure, Investment and Jobs Act, P.L. 117-58, § 1115.

157 Infrastructure, Investment and Jobs Act, P.L. 117-58, § 11402, 11403.

158 Infrastructure, Investment and Jobs Act, P.L. 117-58, § 114023.

The ambition of these federal investments is being matched by infrastructure funding in many states, especially in states that have adopted, or are planning to adopt, California's Advanced Clean Trucks (ACT) rule. [EPA-HQ-OAR-2022-0985-1644-A1, p. 63]

For example, in California, the California Energy Commission's (CEC) Clean Transportation Program announced a $2.9 billion investment plan to accelerate ZEV charging and refueling availability that includes $1.7 billion of funding for medium-and heavy-duty ZEV infrastructure.159 The CEC estimates the plan will result in 90,000 new EV chargers across the state.160 The state has also approved its three major-investor owned utilities to invest $686 million over five years in medium- and heavy-duty infrastructure projects to support electrification.161 [EPA-HQ-OAR-2022-0985-1644-A1, p. 63-64]

159 California Energy Commission, CEC Approves $2.9 Billion Investment for Zero-Emission Transportation Infrastructure (Dec. 14, 2022), https://www.energy.ca.gov/news/2022-12/cec-approves-29-billion-investment-zero-emission-transportation-infrastructure.

160 California Energy Commission, CEC Approves $2.9 Billion Investment for Zero-Emission Transportation Infrastructure (Dec. 14, 2022), https://www.energy.ca.gov/news/2022-12/cec-approves-29-billion-investment-zero-emission-transportation-infrastructure.

Colorado has likewise made significant investments in preparing for a transition to ZEVs. The state's Community Access Enterprise provides funding and support to operators of medium- and heavy-duty fleets by installing charging infrastructure and providing public fast charging capable of supporting medium- and heavy-duty vehicles. The Community Access Enterprise is expected to receive approximately $310 million in its first decade.162 Colorado also has the Clean Transit Enterprise, which includes grant programs towards purchase and installation of charging infrastructure.163 [EPA-HQ-OAR-2022-0985-1644-A1, p. 64]

162 Colorado Energy Office, Community Access Enterprise, https://energyoffice.colorado.gov/about-us/boards-commissions/community-access-enterprise.

Investments by state and local governments are being matched and exceeded by private investments. Multiple companies have announced expansive plans for developing charging networks for medium- and heavy-duty vehicles. For example, Greenlane is a joint venture between Daimler, NextEra Energy Resources, and BlackRock Alternatives, which will put $650 million towards designing, developing, and installing, charging and hydrogen-fueling infrastructure along various freight routes.164 Volvo and Pilot Group have also announced an intent to offer public charging for medium- and heavy-duty BEVs at over 750 Pilot and Flying J travel center locations.165 [EPA-HQ-OAR-2022-0985-1644-A1, p. 64-65]

164 Electrek, Daimler Just Announced a $650M US-Wide EV Charging Network for Trucks, https://electrek.co/2023/04/27/daimler-just-announced-a-650m-us-wide-ev-charging-network-for-trucks/ (Apr. 27, 2023).

i. Utilities and states have already begun to implement programs to support HD ZEV charging

Using data provided by Atlas that tracks public utility commission filings, 29 investor-owned utilities (IOUs) in 17 states have already gotten programs approved to support HDV charging infrastructure build out which account for $1.6 billion in investment.168 These utilities account for 34% of IOU electricity sold in the U.S. and 40% of IOU customers. Since municipally owned and cooperative utilities are not subject to the same rate making processes that IOUs go through, this represents a conservative estimate of the investment by utilities that is already underway. [EPA-HQ-OAR-2022-0985-1644-A1, p. 67-68]

168 Database of approved utility programs tagged with "MHDV Charging" from Atlas Public Policy's EVHub provided by Atlas Public Policy on June 2, 2023.

Additionally, states have begun implementing HD charging infrastructure funding programs. Six states, California, Oregon, Pennsylvania, Colorado, New York, and New Jersey, all have statewide funding programs for HD charging infrastructure, with all except California and New York being finalized in the last year.169 170 171 172 173 174 Five of these states have adopted the Advanced Clean Trucks Rule. And both New York and New Jersey have ongoing proceedings to further address barriers to HDV electrification.175 176 [EPA-HQ-OAR-2022-0985-1644-A1, p. 68]

c) EPA must design the final rule to limit infrastructure related off-ramps

EPA has sought comment on whether the agency "should consider undertaking any future actions related to the Phase 3 standards, if finalized, with respect to the future growth of the charging and refueling infrastructure for ZEVs"195 [EPA-HQ-OAR-2022-0985-1644-A1, p. 75]

195 88 Fed. Reg. 25934.

As discussed above and shown in EPA's own assessment in the proposal and supporting technical documents, the record supports the feasibility of standards that will result in significant ZEV deployment. Indeed, as these standards provide a clear market signal of future infrastructure needs and as ZEV deployment ramps up over a period of five years beginning in 2027, so too will the necessary charging infrastructure and the foregoing discussion and separate report from the Analysis Group both demonstrate that generation and transmission do not pose challenges for heavy-duty ZEV deployment and solutions related to distribution enhancements either already are or are being developed.196 [EPA-HQ-OAR-2022-0985-1644-A1, p. 75]

196 See supra note 166

Including an offramp in the rule is inconsistent with this record evidence and would frustrate the important pollution reductions outcomes the rule will deliver. EPA has regularly considered issues related to the success of its standards on an ongoing basis, including, for example, periodic technical progress reviews. EPA could similarly here consider the development of infrastructure at future intervals to ensure it is continuing to develop at a pace and scale consistent with EPA's projections. However, we strongly encourage EPA not to attempt to directly integrate infrastructure related reviews in its standards setting. [EPA-HQ-OAR-2022-0985-1644-A1, p. 75-76]

Organization: Environmental Protection Network (EPN)

Sufficient Infrastructure Should Not Be A Problem

A recent paper by ICCT assessed the near-term charging and refueling infrastructure needs for Class 4-8 HDV at the national and sub-national levels. Charger needs in 2025 and 2030 are projected based on ZEV market growth, and priority locations for the deployment of charging and refueling infrastructure are identified in key areas.8 [EPA-HQ-OAR-2022-0985-1523-A1, p. 4]

8 'Near-Term Infrastructure Deployment To Support Zero-Emission Medium- And Heavy-Duty Vehicles In The United States', Pierre-Louis Ragon et al. (May 11, 2023).

Building the charging and refueling infrastructure required to support an accelerated transition to zero-emission HDVs requires timely investments and policy support. A full network of charging infrastructure covering the entire United States is not needed in the near term. To best manage resources, infrastructure deployment in the near term should be prioritized in areas that are expected to see the highest energy needs from HDV traffic flows in 2025 and 2030. The ICCT analysis finds that, in the near term, a few U.S. states are expected to experience the highest energy needs from medium- and heavy-duty vehicle charging. Those include states that have adopted California's Advanced Clean Trucks (ACT) rule, as well as states with the largest industrial activity. Industrial areas in the largest metropolitan areas—including Boston, Chicago, Dallas, Houston, Los Angeles, New York, and Phoenix—are expected to require most of the charging needs, driven first by the energy needs of short- and regional-haul trucks and buses. California and Texas are standout priorities, accounting for a combined 19% of the projected nationwide charging needs in 2030. Seven of the top ten counties by absolute charging needs in 2030 will be in these two states. [EPA-HQ-OAR-2022-0985-1523-A1, p. 4]

As the zero-emission HDV market develops, charging needs are expected to expand along freight corridors that connect those industrial nodes. Deploying charging infrastructure along National Highway Freight Network (NHFN) corridors can accommodate up to 85% of the charging needs from long-haul trucks by 2030. Those charging needs can be satisfied by setting traffic-based targets for the deployment of charging stations every 50 miles, in line with the Federal Highway Administration's Alternative Fuel Corridors, as well as introducing additional criteria for HDV compatibility, including pull-through lanes and wide ingress and egress requirements. [EPA-HQ-OAR-2022-0985-1523-A1, p. 4]

Projections of the total energy consumption of the electric HDV fleet in 2030 represent less than 1% of the national electricity retail market in 2021, suggesting that HDV electrification will not be limited by electric power generation capacity. There are immediately actionable options to optimize the use of existing grid capacity, including smart charging, load rebalancing, and making use of non-firm capacity. In parallel, modifications to existing policy frameworks are needed to enable utilities to incorporate projections of future charging load when planning for near- and long-term grid capacity building. [EPA-HQ-OAR-2022-0985-1523-A1, p. 4]

The Private Sector Is Stepping Up On Infrastructure Daimler Truck North America (DTNA), NextEra Energy Resources and BlackRock Alternatives, through a fund managed by its Climate

Infrastructure business (BlackRock), announced Greenlane, a more than $650-million joint venture to design, develop, install, and operate a nationwide, high-performance, zero-emission public charging and hydrogen fueling network for medium- and heavy-duty battery-electric and hydrogen fuel cell vehicles.9Greenlane's initial focus will be on battery-electric medium- and HDV, followed by hydrogen fueling stations for fuel cell trucks, with plans to expand access to light-duty vehicles in the future to serve the greater goal of electrifying mobility. [EPA-HQ-OAR-2022-0985-1523-A1, pp. 4-5]

9 'Daimler Truck North America and partners move ahead with public charging infrastructure', JV: Greenlane, Green Car Congress (April 28, 2023).

Greenlane addresses the need for a publicly available, nationwide electric charging infrastructure for commercial vehicles, especially for long-haul freight operations, and is a major step toward developing a sustainable ZEV ecosystem across North America. The network of charging sites will be built on critical freight routes along the east and west coasts and in Texas. Where synergistic, Greenlane will leverage existing infrastructure and amenities while also adding complementary greenfield sites to fulfill anticipated customer demand. [EPA-HQ-OAR-2022-0985-1523-A1, p. 5]

Organization: International Council on Clean Transportation (ICCT)

We support the agency's conclusions regarding infrastructure lead time for battery-powered vehicles. Our research shows a very strong business case exists for investment in charging infrastructure to enable these trucks, especially tractor-trucks that consume the most fuel. According to Atlas Public Policy, $20 billion in announced and awarded investments in publicly accessible charging infrastructure for all on-road vehicles have been made through 2023. As soon as 2027, battery-powered tractor-trucks will be cheaper to own and operate than diesel-powered trucks, according to our own published analysis. Billions of dollars are already being deployed to establish a multi-state network of electric truck charging depots and long-distance fast charging corridors. The strong business case for these investments is reflected in companies such as GreenLane, Terrawatt Infrastructure, Forum Mobility, WattEV, Voltera, Tesla, and many others. [EPA-HQ-OAR-2022-0985-1553-A1, p. 3]

PRIVATE SECTOR INVESTMENTS IN CHARGING INFRASTRUCTURE This section responds to the EPA's request for comment on whether development in ZEV charging infrastructure will hinder the adoption of ZEVs and the ability to meet the proposed GHG standards. According to Atlas Public Policy, $20 billion in announced and awarded investments in publicly accessible charging infrastructure for all on-road vehicles have been made through 2023 (Gabriel, 2023). Vehicle manufacturers, charging-as-a-service companies, and utilities, together with public sector agencies, are together investing in this space. In support of the EPA's proposed standards, the ICCT has compiled below selected information on private and utility investments into charging infrastructure. [EPA-HQ-OAR-2022-0985-1553-A1, p. 9]

Gabriel, N. (2023, January 12). $210 Billion of Announced Investments in Electric Vehicle Manufacturing Headed for the U.S. Atlas EV Hub. https://www.atlasevhub.com/data_story/210-billion-ofannounced-investments-in-electric-vehicle-manufacturing-headed-for-the-u-s/

Truck manufacturers are among the leading investors in charging infrastructure. Daimler Trucks, together with NextEra Energy and Blackrock Renewable Power, announced a $650M joint venture in January 2022 to construct a nationwide network for powering battery electric and hydrogen fuel cell vehicles (Daimler Truck North America, 2022). Greenlane, the company established under this joint venture (Nextera Energy, 2023), will initially focus on battery electric trucks and will build a network of publicly accessible charging sites along critical freight routes on the west and east coasts of the U.S., and in Texas. Navistar plans to offer full infrastructure design and construction services for its customers. Navistar is partnering with Quanta Solutions, one of the largest electric grid infrastructure companies in North America, who will provide site selection, engineering, and construction services. (Navistar, 2023). Tesla, who delivered its first electric semitrucks in December 2022, currently owns the nation's largest network of publicly accessible charging stations, albeit serving primarily passenger vehicles. Its existing V3 architecture uses 1MW power cabinets that support up to 250kW of charging per vehicle (Tesla, 2019). GM and Ford have announced plans to adopt Tesla's charging standard, giving their vehicles access to the Tesla Supercharger Network and benefitting trucks in the lighter weight classes (Shepardson & White, 2023). Ford already offers its Ford Pro depot charging service, which will build, operate, and maintain a charging depot for a fleet (Depot-Charging-Brochure.Pdf, n.d.). Based on publicly available information, we expect Tesla to release a V4 architecture with megawatt charging capability to support the Tesla Semi (Kane, 2022). Reports from the first Tesla Semi deployment in Modesto, CA suggest the capacity of installed dispensers is 750kW (Seabaugh, 2023). These investments and partnership illustrate the extent to which vehicle manufacturers are investing capital and establishing strategic partnerships to deliver the necessary charging infrastructure. [EPA-HQ-OAR-2022-0985-1553-A1, p. 9]

Charging-as-a-service companies finance, design, construct, operate, and maintain publicly accessible charging depots. Forum Mobility recently announced a $415 million investment, including funds from the Amazon Climate Pledge and commercial real estate company CBRE, to construct electric truck depot charging to support zero-emission port trucks (CBRE Investment Managament, 2023). Terawatt infrastructure has secured at least $1billion in investment capital to construct a multi-state charging network for medium- and heavy-duty vehicles, beginning with an 800-mile corridor that extends from the Port of Long Beach to El Paso at 150-mile intervals (TeraWatt Developing I-10 Electric Corridor, the First Network of Electric Heavy-Duty Charging Centers, 2022). The investments come from Vision Ridge Partners, Keyframe Capital, and Cyrus Capital (Terawatt Infrastructure, 2022). WattEV is constructing a 200-vehicle truck charging depot in Bakersfield, CA as part of a network of charging depots along the I-5 corridor in California (WattEV, 2021). The company recently opened the first of four charging depots in Southern California at the Port of Long Beach, capable of serving 26 trucks with CCS chargers capable of 360kW (WattEV to Open Charging Depot at Port of Long Beach, 2023) The power cabinets are rated at 1.2 MW and CEO Salim Youssefzadeh tells ICCT these will be converted to megawatt charging once a megawatt charging standard is finalized in 2025. Voltera Power, launched in 2022, builds, identifies and acquires real estate, procures power, designs and constructs charging facilities, and deploys operates and maintains charging infrastructure. The company draws experience from data center siting, design and construction through a partnership with EdgeConneX (EdgeconneX, 2022). And Amply Power, whose fleet solutions include charging equipment procurement, installation, operation, maintenance, and smart charging, will also provide mobile and nonpermanent charging solutions to overcome temporary physical and operational constraints to accessing charging infrastructure (‘Products and Services,’ n.d.). Fleet owners and operators are also investing in charging infrastructure at their facilities. Schneider, which will have a fleet of 92 battery-electric class 8 tractors in operation by the end of this year, recently opened a 32-vehicle charging depot in South El Monte to support its fleet of Freightliner eCascadias operating in Southern California. The site includes 16 350 kW dual-corded dispensers (Schneider Opens Large- Scale Zero Emission Electric Charging Depot in Southern California, 2023). Sysco, who has announced plans to take delivery of up to 800 battery-electric tractors by 2026, is investing in charging infrastructure in their Riverside, CA facility (Daimler Truck North America, 2022b). And FedEx, who has purchased 150 electric delivery vehicles from BrightDrop, a subsidiary of GM, has invested in a network of 500 chargers in California with additional purchases planned (FedEx, 2022). [EPA-HQ-OAR-2022-0985-1553-A1, p. 10]

Recent announcements by major retailers demonstrate that significant investments in charging infrastructure are underway at their facilities. As part of its planned deployment of 100,000 electric delivery vehicles by 2030, Amazon has added thousands of charging stations at its delivery stations across the country and will continue to build out charging infrastructure (Amazon, 2022). Recognizing the need to make charging infrastructure smaller, cheaper, and more flexible, Amazon has invested in Resilient Power, who is developing solid state transformers that can significantly reduce the cost and space requirements of distribution infrastructure of high-capacity charging depots (St. John, 2021). IKEA, whose goal is to achieve zero-emission home deliveries by 2025, has partnered with Electrify America and Electrify Commercial to install delivery vehicle charging to 25 IKEA retail locations, including 225 chargers with up to 350kW capacity across locations in 18 states (Sickels, 2022). WalMart, whose goal is to achieve zero emissions across their global operations by 2040, has announced plans to construct its own fast charging network at thousands of WalMart and Sam's club locations where delivery vehicles will have the opportunity to charge (Kapadia, 2023). [EPA-HQ-OAR-2022-0985-1553-A1, p. 10]

Utilities are also making significant investments in charging infrastructure. In 2022, The California Public Utilities Commission approved $1 billion in transportation electrification infrastructure investments by utilities over the period 2025-2029, with 70 percent earmarked for medium- and heavy-duty charging infrastructure (California Public Utilities Commission, 2022). Up to $750 million has already been made available through the period 2020-2024 (California Public Utilities Commission). The California Energy Commission has made an additional $1.7 billion available for medium-and heavy-duty infrastructure for the period 2022-2026 (California Energy Commission, 2022). California Public Utilities Commission. (2022, November 17). CPUC Adopts Transportation Electrification Program To Help Accelerate Electric Vehicle Adoption. https://www.cpuc.ca.gov/news-and-updates/all

Based on this review, we find there is considerable ongoing activity and investment to address both present and future charging infrastructure demand. We support EPA’s conclusion that charging infrastructure can be made available to nearly all trucks that need it in the next decade. We also take the view that the proposed rule further strengthens the market signal for private sector investment. In addition, we encourage EPA’s active participation in infrastructure planning with federal, state, and tribal agency partners. [EPA-HQ-OAR-2022-0985-1553-A1, p. 10]

SCOPE OF CHARGING INFRASTRUCTURE NEEDS ICCT analysis supports the view taken in the ‘Lead time assessment’ of the proposal preamble that there is sufficient time for charging infrastructure to gradually increase over the remainder of this decade to levels that support the stringency of the proposed standards for the timeframe they would apply. [EPA-HQ-OAR-2022-0985-1553-A1, p. 10]

In May 2023, ICCT published an assessment of where, when, and how much charging infrastructure needs to be available to support the deployment of zero-emission class 4-8 vehicles in the contiguous United States (Ragon, Kelly, et al., 2023). We conclude that charging infrastructure needs this decade will be concentrated in a sub-set of states and counties where freight activity is concentrated. This pattern of infrastructure development limits the geographic scale of infrastructure needs during this period and reinforces the business opportunity in the most active freight zones. [EPA-HQ-OAR-2022-0985-1553-A1, p. 10]

Ragon, P.-L., Kelly, S., Egerstrom, N., Brito, J., Sharpe, B., Allcock, C., Minjares, R., & Rodríguez, F. (2023). Near-term infrastructure deployment to support zero-emission medium- and heavy-duty vehicles in the United States. International Council on Clean Transportation. https://theicct.org/publication/infrastructuredeployment-mhdv-may23/

The study finds total energy demand from all Class 4-8 vehicles will be approximately 139,865 MWh. This amount of energy is equivalent to around 1 percent of national electric retail sales in 2021, and we do not expect this share to significantly change in light of the ongoing electrification of other sectors. This relatively small share of national electricity demand suggests to us that the availability of new generating capacity will not be a significant constraint on electrification of this sector. [EPA-HQ-OAR-2022-0985-1553-A1, pp. 10-11]

The overriding infrastructure needs of zero emission class 4-8 vehicles will be concentrated in a subset of U.S. states and major metro areas. This leads us to conclude that the nation's deployment of charging infrastructure will be constructed in stages and not all at once. (See Figure 4.) [Refer to Figure 4, Projected Daily Energy Needs, on p. 11 of docket number EPA-HQ-OAR-2022-0985-1553-A1].The study estimates that 49% of national charging needs in 2030 will exist in ten states led first by Texas and second by California. Texas and California alone will account for 19% of national charging needs in 2030. The study also finds that out of more than 3,079 counties, the top 1% will account for 15% of national charging needs. Among the top ten counties, four of these are located in Southern California (led by Los Angeles then by San Bernardino, San Diego, and Riverside counties) and three are in the Texas triangle (led by Harris and then Dallas and Bexar counties). Other prominent counties that make the top ten include Maricopa, AZ, Salta Lake, UT, and Cook, IL. [EPA-HQ-OAR-2022-0985-1553-A1, p. 11]

While these counties will experience the largest aggregate energy demand, it is also important for planning purposes to consider counties with the largest concentration of energy demand per unit area. From this perspective, nine of the top ten counties are located in the Northeast, including five counties in New York State (the Bronx, New York, Queens, Kings, and Richmond), Suffolk, MA, Philadelphia, PA, and Hudson, NJ. These projections suggest that the infrastructure does not need to be deployed everywhere all at once. A sub-set of states governing these counties and a sub-set of utilities serving them will be responsible for critical charging infrastructure delivery through 2030. [EPA-HQ-OAR-2022-0985-1553-A1, p. 11]

Organization: International Union, United Automobile, Aerospace and Agricultural Implement Workers of America (UAW)

B. Charging Infrastructure

Adequate charging infrastructure is crucial to support electrification and the heavy-duty truck industry presents a unique set of challenges. The EPA must incorporate a more realistic projection of charging infrastructure build-out in the proposed standards. We are concerned that the EPA relies too heavily on the projected federal investment that is intended to support ZEV infrastructure18, and instead, should take the sentiment of heavy-duty manufacturers into greater consideration. At least one OEM with a union workforce has expressed concerns about charging infrastructure availability being insufficient under the proposed standards' ZEV adoption rates.19 According to the DOE's most recent report on EV charging infrastructure trends, there are only 166 private fleet heavy-duty EV charging ports in the country.20 The report also found that the rate of charging infrastructure deployment is not paced to meet the Biden Administration's goal of 500,000 charging ports by 2030.21 This uncertainty highlights the need for flexibility. For example, in response to challenges in the pace of infrastructure development, CARB's Advanced Clean Fleet program includes and has expanded infrastructure delay extensions for fleet owners if ZEV infrastructure is impacted by construction or utility delays.22 [EPA-HQ-OAR-2022-0985-1596-A1, p. 7]

18 See id. at 65 (“While dedicated HD charging infrastructure may be limited today, we expect it to expand significantly over the next decade”).

22 California Air Resources Boards. April 26, 2023. “ACF Proposed Changes”: https://ww2.arb.ca.gov/resources/fact-sheets/acf-proposed-changes

The proposed standards should better reflect that federal investment and incentives will take time to reach maturity and that the market and consumer demand will lag further behind. This is particularly important in larger truck segments, as well as truck segments used in long-haul applications or requiring mid-shift charging. To put it simply, commercial customers of heavy trucks will not purchase BEV trucks unless infrastructure and energy costs fit their business models, no matter what vehicles manufacturers offer customers. Given this uncertainty, GHG standards could also incorporate flexibilities for manufacturers should national charging infrastructure and grid capacity for heavy-duty trucks not meet the necessary levels to support compliance. We strongly encourage the EPA to modify the standards to better reflect the availability of charging infrastructure. [EPA-HQ-OAR-2022-0985-1596-A1, p. 8] [See Figure 19 on p. 8 of Docket Number EPA-HQ-OAR-2022-0985-1596-A1]

Organization: Morales, Jorge

Where will the recharge stations be? And will those be from green energy, such as wind/solar/water, or will it be through coal?

Organization: MEMA

Infrastructure Success is Critical

While MEMA urges EPA to consider other propulsion systems, we believe it is imperative to address infrastructure challenges that will limit the success of a zero-emission vehicle fleet. [EPA-HQ-OAR-2022-0985-1570-A1, p. 8.]

There is currently insufficient infrastructure for EV charging and refueling of MHDV vehicles. While government incentives exist for consumer vehicle systems, there are few comparable programs for heavy and medium-duty trucks. Similar to passenger cars, heavy duty and fleet vehicle EV adoption success will be dependent on positive operator experiences with the EV Charging infrastructure. The government needs to incentive and partner with fleet owners to establish this infrastructure. Without significant federal incentives to expand the MHDV charging and refueling infrastructure, a reliable network with sufficient access to energy and fuels will not be available through the numerous transit corridors along U.S. roads. Likewise, urban, industrial centers will need focused buildout while rural areas will need thoughtful rollouts to achieve sustainable GHG reductions. [EPA-HQ-OAR-2022-0985-1570-A1, p. 8]

MEMA applauds the EPA's leadership on its Clean School Bus program. Federal programs such as the FTA grant programs for Transit bus and IRA Grants to Reduce Air Pollution at Ports are also critical to building better, more future-proofed EVSE that can later support a higher quantity of ZEV vehicle deployment during GHG Phase 3 MY2028+. [EPA-HQ-OAR-2022-0985-1570-A1, p. 9]

Although the recommended EVSE outlay is a significant investment upfront, public funds used for high capacity EVSE will offer the highest return on investment by futureproofing this public investment. Publicly funded DC fast charging will also provide useful lessons to the Joint Office of Energy and Transport on the challenges and opportunities for MHDV applications, including building sufficient ZEV infrastructure in both urban and rural environments, which can prioritize Justice40 communities. [EPA-HQ-OAR-2022-0985-1570-A1, p. 10]

Additionally, we propose EPA purchase ACT Research8 reports for these early adopter segments because upon checking EPA's projection based on MOVES MY 2019 data, we note a significant >30% difference in EPA's projected volume for school bus compared to forecasts for MY 2027 based on market sizing from ACT Research, and an even larger difference >75% in market sizing for other bus (Coach, transit, and shuttle). A specific segmentation report of CL5-7 bus markets can be purchased at this link to inform EPA HD TRUCS projections for these ZEV early adopter segments for better alignment with industry and modeling of emissions benefits for the final GHG Phase 3 rule. ACT Research is a trusted industry information source. [EPA-HQ-OAR-2022-0985-1570-A1, p. 10]

8 Example: https://www.actresearch.net/reports-data/state-of-the-industry-reports/north-americaclasses-5-7-bus-market.

Recommendations:

1) EPA futureproof EVSE purchased with public funds, to enable DCFC and vehicle-togrid interactions like bi-directional charging.

2) EPA pursues other sources of useful information for the regulatory impact analyses, to include ACT Research reports. [EPA-HQ-OAR-2022-0985-1570-A1, p. 10]

To provide helpful feedback to the EPA's question about stakeholders that must be involved and metrics that should be tracked to ensure the success of GHG Phase 3 targets, MEMA recommends EPA work with industry, end-customers, and other sources to understand MHDV unique charging requirements and require the Joint Office of Energy and Transportation to develop a dashboard for transparent reporting for the public to track the maturity of infrastructure needed for net-neutral transportation technology. MEMA has prepared a few charts and high-level takeaways from MHDV infrastructure needs in the U.S., Cybersecurity risks for Fast Charging stations, emerging EU Alternative Fuel Infrastructure Regulations, and a comparison of California State vs. U.S. federal actions to coordinate infrastructure readiness. [EPA-HQ-OAR-2022-0985-1570-A1, p. 10]

A smooth transition will require that infrastructure coverage mature along with projected advanced technology vehicle adoption. Otherwise, payback assumptions on capital are in question. Without sufficient charging availability and capacity, EV cannot reach operational parity with Diesel ICE. Without sufficient renewable fuels infrastructure and supply, advanced ICE vehicles cannot be deployed at scale and existing fleets cannot reduce their carbon footprint in operation. [EPA-HQ-OAR-2022-0985-1570-A1, pp. 10 - 11]

Recommendations:

1) Federal government coordinate infrastructure action with state and local stakeholders specifically to address commercial vehicle needs in metro areas and along interstate corridors.

2) Due to long-lead times for capital improvements, utilities are compelled to begin building out capability ahead of demand from transportation.

3) Workforce development and incentives be aligned with capital planning for MHDV end-users to accelerate advanced vehicle adoption.

4) Coordinate standardization efforts to deliver national standards for the installation, operation, and maintenance of EV charging stations.

5) Standards EV and EVSE Cybersecurity policies, especially for areas of the grid where high peak load events need to be addressed for grid reliability. [EPA-HQ-OAR-2022-0985-1570-A1, p. 11]

A recent International Council on Clean Transportation (ICCT) white paper9 reveals that MD and HD vehicles have different infrastructure requirements than light duty and passenger car, which will need to be addressed for end-users to be willing to adopt net-neutral technology such as ZEV and H2ICE. These include:

a) Energy and higher peak load requirements are concentrated in certain areas and states.

(i) 10 counties in metro areas will have the highest peak load, up to 132MW.

(ii) California and Texas are expected to represent 19% of load requirements for MHDV charging by 2030.

(iii) The states with the highest energy demands are expected to come from a mix of CARB Advanced Clean Truck (ACT) adopting and non-ACT adopting states. Texas, Illinois, and Florida have high industrial activity, but are not ACT adopting states.

b) Local and state legislation and coordination of utilities are needed to support MHDV charging needs.

c) Utilities need to be compelled to begin building out for future demand.

d) Rural areas have other unique charging difficulties.

e) Incentives are difficult to stack and align with capital planning needs.

f) The report assumes that end-users will choose to follow minimum charging protocols to support typical daily energy needs at 19-50KW for most vehicles. Based on our anecdotal experience we disagree with this assumption and think more MHDV end-users will plan for higher DC charging needs to maintain productivity and futureproof on-site infrastructure.

g) Hydrogen needs support to reach Total Cost of Ownership (TCO) parity with conventional technology. Hydrogen is not expected to have good TCO unless it gets to $5/gal and then it will need deployment at stations.

h) Cybersecurity risks of fast charging stations10. [EPA-HQ-OAR-2022-0985-1570-A1, pp. 11 - 12]

9 https://theicct.org/publication/infrastructure-deployment-mhdv-may23/

10 https://www.osti.gov/servlets/purl/1607113

The European Union Alternative Infrastructure Regulation has made significant requirements on member states in making the necessary infrastructure investment. [EPA-HQ-OAR-2022-0985-1570-A1, p. 12]

As an example of how EPA might compel State and Regional infrastructure buildout, we note below how the European Union has approached this challenge:

1) European Union Alternative Fuel Infrastructure Regulation (AFIR) as part of EU's "Fit for 55" package the EU has agreed on a direction forward March 2023 that ensures fast charging availability at distance-based intervals along the trans-European transport network (TENT).

1) Member States will be required to ensure publicly available chargers with power output capable to support BEV deployment;

2) The AFIR established targets for urban nodes for trucks and busses.

3) Member States will be required to ensure installation of a fast-charging pool every 60km in each direction along the TEN-T (Trans-European Transport Network) with milestones for completion in 2025, 2027, and 2030. [EPA-HQ-OAR-2022-0985-1570-A1, p. 12]

Additionally, we refer the reader to Appendix 2, in which MEMA has prepared a chart that reviews current CA state and federal actions to support ZEV transition. [EPA-HQ-OAR-2022-0985-1570-A1, p. 12.] [See Docket Number EPA-HQ-OAR-2022-0985-1570-A1, pages 24-26, for Appendix 2.]

Organization: Moving Forward Network (MFN) et al.

12.2. A More Complete Inventory Reveals $67 billion in Announced Investments in Charging Infrastructure, Including $30 Billion Dedicated to Medium and Heavy-Duty Vehicles and $4 Billion that Could Support Medium and Heavy-Duty Vehicles

The Proposed Rule's description of recently announced investments in charging infrastructure underscores the fact that significant progress is being made. 233 However, this narrative should be supplemented by a more comprehensive inventory of the public, private, and utility sectors. As of March 31, 2023, Atlas Public Policy (Atlas) estimates $67 billion dollars in charging infrastructure investments that have been announced by the public, private, and utility sectors but not yet installed as charging ports in the ground. Table 14 provides a summary of tallied investment amounts, which include:

- $33 billion in announced, unspent investments for light-duty vehicle (LDV) charging,

- $30 billion in announced, unspent investments for medium- and heavy-duty (MDHD) vehicle charging, and
- $4 billion in announced, unspent investments for use across any vehicle class. [EPA-HQ-OAR-2022-0985-1608-A1, p. 105.] [See Table 14 Estimated U.S. Charging Infrastructure Investments Announced but Not Yet In the Ground, as of March 31 2023 located on p. 105 of docket number EPA-HQ-OAR-2022-0985-1608-A1.]

233 U.S. EPA. Draft Regulatory Impact Analysis: RFS Standards for 2023-2025 and Other Changes. (November 2022). Chapter 1.6.2. https://www.epa.gov/system/files/documents/2022-12/420d22003.pdf

Public funding programs included are those that cover only EV charging infrastructure, or for which EV charging infrastructure is expected to comprise the vast majority of funding. This includes the federal National Electric Vehicle Infrastructure (NEVI) formula and Charging and Fueling Infrastructure (CFI) Discretionary Grant funding, state funding commitments, and modeled estimates of 26 U.S.C. § 30C tax credit payments consistent with an EV adoption trajectory that meets President Biden's goal of 50 percent ZEV sales share by 2030 (for LDVs) and an electric vehicles sales trajectory matching EPA's proposed emissions regulations for medium- and heavy-duty vehicles. 234 [EPA-HQ-OAR-2022-0985-1608-A1, p. 106]

234 Note that these figures do not include any funding amounts for hydrogen fuel cell vehicles. Regarding the 30C tax credit, Atlas assumes that 1) all qualifying projects receive the tax credit, 2) on average, qualifying projects will receive tax credits worth 18% of covered costs, and 3) that the U.S. Department of the Treasury will classify a census tract as not urban if more than 10% of the blocks within the census tract are designated as rural census blocks (as recommended by Natural Resources Defense Council (NRDC), Alliance for Automotive Innovation, American Council on Renewable Energy (ACORE), Ample, CALSTART, ChargePoint, Clean Energy Works, Earthjustice, Elders Climate Action, Electrification Coalition, Environmental Defense Fund (EDF), EV Charging for All, EVBox, Forth Mobility, Green Latinos, International Brotherhood of Electrical Workers (IBEW), International Parking & Mobility Institute, Itselectric, League of Conservation Voters, National Association of Convenience Stores (NACS), National Consumer Law Center, NATSO, Navistar, Plug in America, Representing America's Travel Plazas and Truck Stops, Rivian, Sierra Club, SIGMA: America's Leading Fuel Marketers, TeraWatt, Transportation for America, Union of Concerned Scientists (UCS), Volvo Group North America). The estimated Low Carbon Fuel Standard value is based on modeling from Dean Taylor Consulting for California, Oregon, and Washington and does not include capacity credits. It uses a 2023 – 2032 EV adoption trajectory for those three states that meets President Biden's LDV goal of 50% ZEV sales share by 2030 (which is lower than the trajectory modeled in the EPA's proposed vehicle emission standards), an MDHD EV adoption curves modeled on the EPA's proposed emissions regulations for MD and HD vehicles, and modeling from Atlas's INSITE tool of MWh demanded by MDHD vehicles. Utility program investments include approved investor-owned utility programs with an EV charging element. Amounts are unspent program dollars as of the most recent program report available as of March 31, 2023. If no program report was available, Atlas used the percentage of time remaining in the approved program schedule to estimate the unspent proportion of program funding.

Even Atlas's tally of private sector commitments is likely incomplete. Private sector actors often do not announce their investment plans, and are especially unlikely to do so if they are investing in home, depot, or workplace charging. Investments here include announced commitments to public charging network developments made after January 1, 2022, by companies including Tesla, Electrify America, BP, General Motors, Daimler, and Mercedes. For MDHD vehicles, private sector commitments are taken largely from Environmental Defense Fund's Electric Fleet Deployment & Commitment List. 235 Tallied private sector commitments exclude an estimated $3.0 billion in capital raised by charging companies (including ChargePoint, EVgo, Blink, and Volta), some percentage of which is expected still to be invested in charging hardware and installation. In sum, there are $34 billion in announced infrastructure investments not yet in the ground that could support strong HDV standards. [EPA-HQ-OAR-2022-0985-1608-A1, p. 107]

235 Available at: https://docs.google.com/spreadsheets/d/1l0m2Do1mjSemrb_DT40YNGou4o2m2Ee-KLSvHC-5vAc/edit#gid=2049738669. MDHD fleet vehicle counts are multiplied by charging ports per vehicle and costs per port modeled in Atlas's Investment Needs of State Infrastructure for Transportation Electrification (INSITE) tool

12.3. Barriers to the installation of charging infrastructure identified in the Rule are being actively addressed

The Proposed Rule identifies significant investments in charging infrastructure:

… we expect significant increases in HD charging infrastructure due to a combination of public and private investments. This includes Federal funding available through the BIL and the IRA. As discussed in DRIA Chapter 1.6.2.2, states, OEMs, utilities, EVSE providers and others are also investing in and supporting the deployment of charging infrastructure. For example, Daimler Trucks North America, Volvo Trucks, Navistar, and PACCAR are a few of the HD manufacturers investing in EVSE, sometimes packaging the sale of EVSE with the vehicle. Because of these projected increases and the funding available through the BIL and IRA, and as we are proposing more stringent standards that begin in MY 2027, our assessment supports that there is sufficient time for the infrastructure, especially for depot charging, to gradually increase over the remainder of this decade to levels that support the stringency of the proposed standards for the timeframe they would apply. 236 [EPA-HQ-OAR-2022-0985-1608-A1, pp. 107 - 108]

236 U.S. EPA. Proposed Rule: Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles – Phase 3. 88 Fed. Reg. 25926, 26074 (Apr. 27, 2023). p. 228. https://www.epa.gov/regulations-emissions-vehicles-and-engines/proposed-rule-greenhouse-gas-emissions-standards-heavy

The Proposed Rule also states:

EPA has heard from some representatives from the heavy-duty vehicle manufacturing industry both optimism regarding the heavy-duty industry's ability to produce ZEV technologies in future years at high volume, but also concern that a slow growth in ZEV charging and refueling infrastructure can slow the growth of heavy-duty ZEV adoption, and that this may present challenges for vehicle manufacturers ability to comply with future EPA GHG standards. 237 [EPA-HQ-OAR-2022-0985-1608-A1, p. 108]

237 U.S. EPA. Proposed Rule: Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles – Phase 3. 88 Fed. Reg. 25926, 26074 (Apr. 27, 2023). p. 28-29. https://www.epa.gov/regulations-emissions-vehicles-and-engines/proposed-rule-greenhouse-gas-emissions-standards-heavy.

Both the statement that identified significant investments warrants more stringent standards and the statement that the pace of installing charging infrastructure needs to accelerate are true. There are barriers to the timely installation of charging infrastructure that need to be removed to allow investments to be made at an even greater pace and scale, but those challenges are already being actively addressed. [EPA-HQ-OAR-2022-0985-1608-A1, p. 108]

Most of the challenges that vehicle manufacturers have raised associated with energizing charging infrastructure for HDVs in a timely manner are being faced in California, where most electric HDVs are currently being deployed. Thankfully, a state law enacted in 2022 provides

California’s investor- and publicly-owned utilities with data necessary to inform grid planning to accommodate high levels of EV charging, requires those utilities to propose proactive grid investments in their General Rate Cases to comply with ZEV regulations (as well as a long list of other laws, standards, and requirements), and directs the California Public Utilities Commission (CPUC) and local utility governing boards to ensure the proposed investments are consistent with achieving the state’s goals and regulations. 238 In May 2023, Southern California Edison (SCE) filed its General Rate Case, which includes such proactive investments. 239 And the CPUC recently launched a “Zero-Emission Freight Infrastructure Planning” initiative designed to address the mid- to long-term challenges associated with constructing necessary supporting grid infrastructure in a timely manner to accommodate electric HDVs. 240 [EPA-HQ-OAR-2022-0985-1608-A1, pp. 108 - 109]

238 California Assembly Bill 2700 Transportation electrification: electrical distribution grid upgrades. (2021-2022). https://leginfo.legislature.ca.gov/faces/billNavClient.xhtml?bill_id=202120220AB2700

239 Southern California Edison. 2025 General Rate Case, WP SCE-02. V. 07. Bk. A, TEGR Forecast Development Workpaper.

240 California Public Utilities Commission. Draft Staff Proposal: Zero-Emissions Freight Infrastructure Planning. (2023). https://www.cpuc.ca.gov/industries-and-topics/electrical-energy/infrastructure/transportation-electrification/freight-infrastructure-planning

Fundamentally, the charging infrastructure challenges identified by vehicle manufacturers that caused EPA to solicit comment on this issue can be overcome, as evidenced by the progress described above. We are not starting from scratch and do not need to replicate the gas and diesel refueling network to electrify vehicles. The electric grid is already nearly ubiquitous; it only needs to be extended at the fringes. And because it benefits utility shareholders and customers alike to remove barriers to investment in charging infrastructure, we have reason to be optimistic. America’s utilities have a long history of accommodating significant growth. [EPA-HQ-OAR-2022-0985-1608-A1, p. 110]

In sum, the private and federal infrastructure investments EPA has identified justify strong standards, and the challenges it has identified are being addressed. Furthermore, as noted above, the EPA’s inventory of federal, public, and private investments that already justifies increasingly stringent vehicle standards is incomplete. Critical to the implementation of the infrastructure is the coordination with frontline/fenceline communities to ensure that infrastructure does not increase the burden in these communities. 244 [EPA-HQ-OAR-2022-0985-1608-A1, p. 110]

244 Moving Forward Network. Letter to Administrator Regan. (Oct 2021). https://www.movingforwardnetwork.com/wp-content/uploads/2021/11/MFN-Zero-Emission-in-Freight-Letter-to-EPA-10_26_21.pdf “Decisions on siting the new electricity infrastructure must be coordinated with environmental justice leaders, address cumulative impacts and support mandatory emissions reductions.”

Organization: National Association of Clean Air Agencies (NACAA)

EPA also requests comment on the readiness of ZEV charging and refueling infrastructure. Specifically, EPA writes in the proposal that ‘. . .important early actions and market indicators suggest strong growth in charging and refueling ZEV infrastructure in the coming years. Furthermore, as described in Section II of this document, our analysis of charging infrastructure needs and costs supports the feasibility of the future growth of ZEV technology of the magnitude

EPA is projecting in this proposal's technology package. EPA has heard from some representatives from the heavy-duty vehicle manufacturing industry both optimism regarding the heavy-duty industry's ability to produce ZEV technologies in future years at high volume, but also concern that a slow growth in ZEV charging and refueling infrastructure can slow the growth of heavy-duty ZEV adoption, and that this may present challenges for vehicle manufacturers ability to comply with future EPA GHG standards. Several heavy-duty vehicle manufacturers have encouraged EPA to consider ways to address this concern both in the development of the Phase 3 program, and in the structure of the Phase 3 program itself. EPA requests comment on this concern, both in the Phase 3 rulemaking process, and in consideration of whether EPA should consider undertaking any future actions related to the Phase 3 standards, if finalized, with respect to the future growth of the charging and refueling infrastructure for ZEVs.'16 [EPA-HQ-OAR-2022-0985-1499-A1, p. 6]

16 Supra note 1, at 25,934

For reasons we explain earlier in these comments, NACAA does not share the concerns expressed by some representatives of the heavy-duty vehicle manufacturing industry about the ability of electric utilities and/or charging equipment and service providers to continuously meet the incremental rollout needs for ZEV charging and refueling infrastructure. NACAA firmly opposes an 'off-ramp' from the standards or any similar measure. Likewise, anything akin to a mid-term evaluation is unnecessary and inappropriate given the program will begin in just a few years, span the course of only five years and starts from a demonstrated baseline of vehicle and charging technology. NACAA strongly urges EPA to reject any such provisions. [EPA-HQ-OAR-2022-0985-1499-A1, p. 6]

There is a great deal of evidence, including what NACAA provides at the beginning of this section on our comments and recommendations, that points to the coming readiness of the charging and fueling infrastructure needed to support strong Phase 3 standards. The federal government has demonstrated its deep commitment to accelerating the transition to ZEVs by providing historic levels of funding and monetary incentives including for timely infrastructure. NACAA notes that given the importance of this federal funding to achieving meaningful nationwide reductions in GHG emissions, including from heavy-duty vehicles and engines, EPA should ensure that these funds are allocated equitably across the country. In addition to federal action, states and local areas are demonstrating leadership by undertaking their own infrastructure initiatives. These are helping to drive private investment to capitalize on these opportunities. The following a few examples. [EPA-HQ-OAR-2022-0985-1499-A1, pp. 6-7]

Organization: National Association of Convenience Stores (NACS), NATSO, and SIGMA

Robust Charging Infrastructure is Necessary to Support Heavy-Duty Electrification

The Proposed Rule would result in electrifying 50% of new vocational trucks, 35% of new short-haul tractors, and 25% of new long-haul tractors by 2032.5 These estimates are divorced from the reality of the current ZEV market: for MY21, only 0.2% of all HD vehicles certified by the Agency were electric.6 The extraordinary pace of HD electrification that is effectively mandated under this rulemaking is incompatible with the reality of long-haul trucking in the United States. [EPA-HQ-OAR-2022-0985-1603-A1, p. 4]

5 Proposed Rule at 25,932 (Table ES–3).

6 Id. at 25,940.

These comments focus primarily on long-haul HD trucks, which are the vehicles typically serviced by our members. The challenges to electrifying the HD sector cannot be overstated and will require a gradual and unprecedented effort irrespective of regulatory mandates. One major challenge is a lack of HD charging infrastructure. Currently, there is no U.S. network where over-the-road trucks can stop for rest breaks and recharging at the same time. In fact, recent estimates indicate there are fewer than 3,000 HD truck chargers across the entire United States.7 Such chargers are expensive and specialized, as long-haul trucks require two 8,000-pound batteries to operate.8 Given the size of their batteries, HD trucks cannot use light-duty charging infrastructure. It could take up to ten hours to charge those trucks and that would only provide them with a few hundred miles of range.9 By contrast, a diesel truck can refuel in about 15 minutes and get 1,200 miles of range. Dwell times will increase significantly as a result of recharging needs, which will impact scheduling and have implications for Hours-of-Service limits. Prolonged recharging periods will also further exacerbate challenges related to truck parking availability and capacity. [EPA-HQ-OAR-2022-0985-1603-A1, pp. 4-5]

Organization: National Automobile Dealers Association (NADA)

3. Projections suggest that there will not be enough public charging infrastructure available to support EPA forecasted adoption rates.

Several studies have assessed the scale of the refueling infrastructure that will be needed to meet projected ZEV adoption rates. A 2022 utility industry estimate on the charging infrastructure needed to support the projected 2030 EV marketplace points to an alarming and growing infrastructure gap. According to the report from the Edison Electric Institute (EEI), more than 2.6 million charge ports in workplaces and public locations will be needed by 2030.20 EEI states: "The significant difference between the current availability of charging infrastructure and the expected charging infrastructure needed suggests a growing "infrastructure gap" that must be addressed."21 EEI goes on to state that "the number of DCFC ports needed in 2030 to meet demand is more than double the planned DCFC ports."22 The DCFC planned investments include those investments planned by state and federal governments under relevant incentive programs, automakers, electric companies, and the National Electric Highway Coalition. [EPA-HQ-OAR-2022-0985-1592-A1, p. 11.] [See Docket Number EPA-HQ-OAR-2022-0985-1592-A1, page 11, for figure.]

20 Charles Satterfield et al., Electric Vehicle Sales and the Charging Infrastructure Required Through 2030, EDISON ELECTRIC INSTITUTE (June 2022).

21 Id. at 12.

22 Id. at 15.

Even more alarming is that EEI's conclusions are based solely on an estimated 32 percent of total light-duty vehicle sales in 2030.23 Since then, the EPA has issued sweeping regulatory proposals that together estimate that by MY 2032 new vehicle sales will include:

- Nearly 70 percent ZEV penetration across the light-duty sector;
- Nearly 40 percent ZEV penetration across the combined medium-duty van and pickup truck categories;
- Some 50 percent ZEV penetration for vocational vehicles;
- Some 34 percent ZEV penetration for day cab tractors; and
- Some 25 percent ZEVs for sleeper cab tractors. [EPA-HQ-OAR-2022-0985-1592-A1, p. 12]

23 Government and private support of EV charging has traditionally been focused on light -duty charging as light-duty EVs were introduced to the market first. Medium- and heavy-duty EV charging woes are compounded by the fact that most publicly available EV chargers are not physically accessible to larger vehicles. Chargers are often located in parking lots designed only to accommodate light-duty EVs excluding most medium- and heavy-duty buses and trucks from accessing the growing network of public chargers.

On May 11, 2023, the ICCT released a report entitled, "Near-Term Infrastructure Deployment to Support Zero-Emission Medium- and Heavy-Duty Vehicles in the United States" (ICCT Report). This report directly addresses commercial infrastructure predictions and confirms industry infrastructure concerns. The ICCT Report states that by 2030, 522,000 overnight chargers, 20,500 fast chargers, and 9,540 ultrafast chargers will be needed to support the estimated 1.1 million ZEV trucks.24 These numbers are over and above those necessary for light duty ZEVs. Further, the ICCT Report states that the "most recent TCO analysis for the United States shows no case of positive TCO for hydrogen trucks relative to battery-electric trucks."25 [EPA-HQ-OAR-2022-0985-1592-A1, p. 12]

24 Pierre-Louis Ragon et al., Near-Term Infrastructure Deployment to Support Zero-Emission Medium-And Heavy- Duty Vehicles in The United States, ICCT (May 2023).

25 Id. at 3.

New investments in charging infrastructure are being announced daily26 and ATD is hopeful EPA's GHG proposals and other government incentive programs will provide investors with the reassurance they need to build necessary infrastructure. Reliable refueling infrastructure is critical to the successful adoption of ZEV HDVs and must be accounted for by EPA. [EPA-HQ-OAR-2022-0985-1592-A1, p. 12]

26 See e.g., Michelle Lewis, Daimler just announced a $650M US-wide EV charging network for trucks, ELECTREK (April 27, 2023) and Vishal Kapadia, Leading the Charge: Walmart Announces Plan To Expand Electric Vehicle Charging Network, Walmart (April 6, 2023).

4. Recommendations

Dealerships are doing their part to sell and service commercial ZEVs. However, without adequate assurances that the appropriate infrastructure will be in place in time, customers will simply not purchase ZEV HDVs. Infrastructure represents the most complex, expensive, and longest lead time challenge to transition our industry. For a Phase 3 GHG rule to be successful, an "all-in" approach by the government is required. Consequently, ATD recommends the following:

- That EPA work with purchaser stakeholders to ensure that that purchaser costs and lead time associated with EVSE equipment and charging are accurate.
- That EPA work with other agencies to establish clear data and related benchmarks for assessing the deployment of essential ZEV HDV refueling infrastructure.

That EPA ensure that forecasted adoption rates are supported by available infrastructure. EPA must monitor necessary infrastructure investments and modifications to the Phase 3 rule should be made if they fall short. [EPA-HQ-OAR-2022-0985-1592-A1, pp. 12 - 13]

Organization: National Rural Electric Cooperative Association (NRECA)

Critical Role of Electric Cooperatives as Heavy-Duty Highway Vehicles are Electrified

Electrification of the transportation sector creates both opportunities and challenges for the electric sector, and electric cooperatives will play a critical role in the success of the transformation now underway. As such, electric cooperatives welcome the opportunity to partner with state and local entities on implementing the programs dedicated to building out the nation's electric vehicle (EV) charging network in the bipartisan infrastructure law (BIL) and through other opportunities. The funding in the BIL is an important down payment in the federal support required to electrify the transportation sector, particularly in rural areas that could otherwise be left behind. [EPA-HQ-OAR-2022-0985-1515-A1, pp. 1-2]

To support the electrification of heavy-duty highway vehicles as laid out in EPA's proposed rule, electric cooperatives and other utilities must be involved from the very beginning of planning for the charging infrastructure these vehicles will require. There are already examples of 1 MW charging stations being built to support these fleets. Electric cooperatives and other utilities need to be integrated at the very beginning of planning for such facilities by the project developers, or other relevant planning authorities where applicable, to avoid unintended consequences. [EPA-HQ-OAR-2022-0985-1515-A1, p. 2]

Organization: Navistar, Inc.

Navistar's ability to meet its stated ZEV goals is dependent on the buildout of necessary public and depot charging infrastructure.

Navistar stated its ambition to have 50% of its US-directed new vehicle sales be zero emission vehicles by 2030 and 100% of its US-directed new vehicle sales by 2040. With the proper support of public policy, state and local governments and other industries, these ambitions are possible. One key requirement is that the current infrastructure and vehicle incentives remain in place. The provisions of the Inflation Reduction Act and Bipartisan Infrastructure Law are important in supporting this transition. The second requirement is that, overall, infrastructure develops in a way to support a national ZEV fleet of 50% by 2030 and 100% by 2040. There are well-known challenges that operators face in building out their own charging infrastructure for depot charging as well as the public charging infrastructure that is important for long-haul applications. Current and future assistance for operators to help with this transition is required for our goals. [EPA-HQ-OAR-2022-0985-1527-A1, p. 2]

The transition to commercial ZEVs is a paradigm shift. That is Navistar's path in the coming years. The move toward zero emissions mobility cannot, however, happen without the successful buildout of charging infrastructure. Navistar's ZEV goals are dependent on the continued expansion of charging infrastructure sufficient to support public and depot charging of at least 50% of the national commercial trucking fleet by 2030. [EPA-HQ-OAR-2022-0985-1527-A1, p. 3]

Diesel-powered vehicles will continue to serve specific applications in our transportation system for some time. The key is to find the right balance that allows diesel technology to become cleaner in a way that is affordable for customers, while simultaneously encouraging ZEV development and charging infrastructure buildout. Charging and refueling infrastructure will serve as an early proof point for our customers that investment in an electric vehicle is possible. A robust charging network will be needed to support the various applications of commercial vehicles due to their significant duty cycles. [EPA-HQ-OAR-2022-0985-1527-A1, p. 3]

Importantly, much of the infrastructure funding to date, such as the NEVI funding, is largely focused on light-duty infrastructure. It is imperative that, as we go forward, heavy-duty needs are explicitly incorporated. There are considerable differences between commercial heavy-duty and light duty infrastructure needs in the amount of energy required, the space required for parking vehicles while they are charged, the locations in which charging will occur, among others. [EPA-HQ-OAR-2022-0985-1527-A1, p. 3]

Recognition of the headwinds associated with creating an entire new vehicle market and infrastructure support must be understood to bring a zero-emission future a reality. It is necessary to ensure that supply chain issues are smoothed, utilities are nimble enough to respond to customer requests for build-out of charging capabilities and resiliency issues are addressed for future needs. Navistar supports the federal and state governments rapidly developing and implementing a national charging master plan that identifies dedicated corridors and areas for future charging and needs. These plans will need to include both lightduty and commercial heavy-duty vehicle operations, with the deep understanding of the unique use cases for commercial vehicles on location, charging downtime allowed and electricity needs to support commercial vehicle operations. [EPA-HQ-OAR-2022-0985-1527-A1, p. 3]

Simply stated, commercial vehicle manufacturers will not be able to sell an increasing number of ZEVs on an economically viable basis unless a robust ZEV infrastructure is assured and in place. For this rule, and the industry, to succeed in this effort we need a reasonable, flexible rule and the right incentives in place to allow the ZEV ecosystem to grow. As provided below, because this kind of transition is unprecedented in the transportation space in living memory, we need the kind of flexibility that will allow for success. [EPA-HQ-OAR-2022-0985-1527-A1, p. 3]

EPA should link the phase-in of the Phase 3 GHG standards to the availability of sufficient infrastructure. Navistar recommends that EPA revise the proposed rule to include appropriate regulatory mechanisms to monitor and correct for infrastructure availability to support ZEVs. Specifically, EPA should add regulatory language that would temporarily extend the proposed rule's compliance determination requirements in advance of their respective deadlines if adequate ZEV infrastructure installations are not forecasted to be in place by 2027. [EPA-HQ-OAR-2022-0985-1527-A1, p. 5]

EPA's proposed rule is predicated on several assumptions regarding infrastructure costs, as further described in the Draft Regulatory Impact Analysis (RIA) (Document EPA-HQOAR-2022-0985-1428). EPA acknowledges that more infrastructure will be needed as ZEV adoption grows. For example, EPA cites an Atlas analysis, which estimates that it will cost $100 to $166 billion by the end of 2030 to install the necessary infrastructure to support 1 million Class 3 through 8 vehicles and future expansion. That would cover 500,000 depot-charging ports, and over 100,000 public en-route DCFC ports for long-haul trucks. See Draft RIA, p. 67.1 [EPA-HQ-OAR-2022-0985-1527-A1, p. 5]

1 Navistar has previously estimated that the minimum investment required to develop a focused public charging network just to support long haul operations on key major freight corridors alone would likely exceed $20 billion.

EPA further acknowledges that the timeline to complete both permitting and utility interconnection will likely be longer for larger, more complex, and/or higher-power charging stations. EPA stated that '[i]f upgrades to the electricity distribution system are required, this could further extend the timeline.' On that point, EPA notes that new charging loads of several megawatts or higher 'could take months to several years to implement.' Draft RIA, pp. 69-70. [EPA-HQ-OAR-2022-0985-1527-A1, p. 5]

Based on the foregoing, EPA should include a regulatory mechanism in the rule to monitor the progress of the development of the necessary ZEV infrastructure against annual benchmarks. Based on that monitoring, if it is determined by EPA that sufficient infrastructure development has not occurred, EPA would temporarily extend the rule's compliance determination requirements in advance of their respective deadlines. [EPA-HQ-OAR-2022-0985-1527-A1, p. 5]

Organization: Owner-Operator Independent Drivers Association (OOIDA)

BATTERY EMISSION/ZERO-EMISSION VEHICLE TECHNOLOGIES

We oppose EPA's proposal to implement Phase 3 beginning in Model year 2028 given the lack of necessary infrastructure necessary to support BEVs for the long-haul trucking sector. EPA notes, "the potential for the application of zero-emission vehicle (ZEV) technologies in the heavy-duty sector presents an opportunity for significant reductions in heavy-duty GHG emissions over the long term," and that, "Major trucking fleets, HD vehicle and engine manufacturers, and U.S. states have announced plans to increase the use of heavy-duty zero-emissions technologies in the coming years." However, our members are skeptical about the effectiveness of BEV mileage capabilities as well as access to commercial BEV charging stations. [EPA-HQ-OAR-2022-0985-1632-A1, p. 5]

OOIDA members routinely make trips over 1,000 miles and can rely upon a nationwide network of truck stops and other locations to fill up on gas whenever and wherever they need to refuel their tank. There are numerous unanswered questions about how a nationwide BEV charging network will be implemented and it's difficult to estimate when such a network would be readily accessible for CMV drivers. Therefore, we question EPA's proposed BEV production timelines without a reliable charging infrastructure in place. [EPA-HQ-OAR-2022-0985-1632-A1, p. 5] [Refer to table 4 on page 5 of docket number EPA-HQ-OAR-2022-0985-1632-A1]

For comparison, a truck parking crisis has existed for decades. DOT has found that the truck parking shortage is a major problem in every state and region of the country, and these shortages exist at all times of the day, week, and year. Unfortunately, the parking shortage continues to worsen with only 1 parking spot available for every 11 trucks on the road, resulting in drivers wasting an average of one hour every day trying to secure parking. States and local communities across the U.S. are struggling to maintain existing capacity, let alone keep pace with increasing demand. While Congress and DOT have prioritized funding for expanding truck parking capacity, drivers have yet to see tangible results that would help address the parking shortage. [EPA-HQ-OAR-2022-0985-1632-A1, p. 5]

EPA relies upon the confidence that recently enacted legislation will expedite BEV development. The proposed rule states, "the 2021 Infrastructure Investment and Jobs Act (commonly referred to as the "Bipartisan Infrastructure Law" or BIL) and the Inflation Reduction Act of 2022 ("Inflation Reduction Act" or IRA) together include many incentives for the development, production, and sale of ZEVs, electric charging infrastructure, and hydrogen, which are expected to spur significant innovation in the heavy-duty sector." We anticipate there will be a number of legislative, regulatory, and economic/market factors that will impact ZEV production and sales along with other challenges before the completion of a fully deploy a reliable nationwide commercial ZEV infrastructure. [EPA-HQ-OAR-2022-0985-1632-A1, p. 5]

Organization: PACCAR, Inc.

PACCAR is working diligently to develop ZEVs for the future, but the necessary supporting infrastructure must be in place before widespread ZEV market penetration and adoption. Planning, developing, and implementing the charging infrastructure required to support battery electric trucks is a major initiative. The hydrogen refueling infrastructure is also not well developed. EPA's proposed standards are premised on the infrastructure being established and functional. EPA should facilitate the feasibility of the regulation by including a mechanism to adjust the applicable standards to correlate with the progress of the necessary infrastructure development and readiness. [EPA-HQ-OAR-2022-0985-1607-A1, p. 2]

Organization: State of California et al. (2)

2. Significant Investments Are Being Made in Charging Infrastructure and Grid Reliability

There is substantial financial support to build out medium- and heavy-duty truck charging stations at both the national level and in our States and Cities. On the federal level, the Infrastructure Investment and Jobs Act includes $7.5 billion for grant programs administered by U.S. Department of Transportation ("DOT") for EV charging infrastructure to expand Alternative Fuel Corridors and a National Electric Vehicle formula grant program at the DOT to provide additional funding to states to support EV charging infrastructure.199 The National Electric Vehicle Infrastructure ("NEVI") Formula Program is expected to help build EV chargers covering approximately 75,000 miles of highway across the country.200 Many of the State Plans submitted through the NEVI Program address infrastructure needs for freight specifically.201 Moreover, the INFRA Grants Program has $8 billion to award competitive grants for multimodal freight and highway projects of national or regional significance to improve the safety, efficiency, and reliability of the movement of freight and people in and across rural and urban areas.202 In November 2022, California committed $1 billion of funding to the development of charging infrastructure. [EPA-HQ-OAR-2022-0985-1588-A1, pp.27-28]

202 Global Commercial Vehicle Drive to Zero, Global MOU Policy Tracker Dashboard, https://globaldrivetozero.org/progress-dashboard/ (last accessed June 16, 2023).

There is also substantial private investment in developing charging infrastructure in the United States, including both hydrogen and electric-vehicle charging stations. For example, Daimler, NextEra, and BlackRock announced a joint venture, and $650 million initial investment, to design, develop, install, and operate a nationwide charging network for medium- and heavy-duty battery electric vehicles and hydrogen fuel cell vehicles, construction of which is set for 2023.203 And other private efforts to expand heavy-duty charging infrastructure are already underway.204 [EPA-HQ-OAR-2022-0985-1588-A1, p.28]

Organization: Stellantis

The proposed HD GHG targets are incredibly challenging and will require electrification at an unprecedented level in a market segment that demands payload and towing capability. Stellantis is committed to electrification and plans to have products in place that will meet consumer needs. However, it will take much more than manufacturing HD EVs and aggressive GHG standards in the proposed rule to create a successful HD electric vehicle market. There is concern that the proposed rule seeks such a rapid and transformative nationwide shift to electrification that it exceeds what the HD sector or market can withstand. Meeting the goals of the Phase 3 program will require a very significant build out of infrastructure along with a broad willingness from fleets and other customers to buy electrified HD vehicles. As noted in EMA comments, these HD vehicles have more demanding infrastructure needs than the LD segment because they are primarily work trucks with a vast array of vehicle uses that are essential for their business operations. [EPA-HQ-OAR-2022-0985-1520-A1, p. 2]

Organization: Tesla, Inc. (Tesla)

Moreover, as manufacturers begin deploying their heavy-duty vehicles, they will similarly be deploying charging infrastructure in parallel, as recognized in the Draft RIA. For example, Volvo has announced joining a partnership to build a publicly accessible medium- and heavy-duty electric vehicle charging network that connects several of California's largest metropolitan areas.206 In partnership with the Department of Energy, Cummins is developing extensive plans for battery-electric charging and hydrogen fueling stations along the stretch of I-80 that crosses Illinois, Indiana, and Ohio. The planned network of charging and fueling stations will be focused on transitioning 30% of the region's medium- and heavy-duty fleets to zero-emission technologies by 2035.207 Similarly, National Grid has undertaken a project to examine freight corridors in Maine, Massachusetts, New Hampshire, Vermont, Rhode Island, Connecticut, New York, Pennsylvania, and New Jersey, with a goal of informing a blueprint for future commercial EV charging.208 Intensive planning is also ongoing to develop infrastructure deployment plans for zero-emission medium- and heavy-duty vehicles along the I-95 freight corridor, which stretches from Savannah, Georgia, to Newark, New Jersey.209 [EPA-HQ-OAR-2022-0985-1505-A1, p. 28]

206 Volvo, Volvo Trucks Constructing California Electrified Charging Corridor for Medium- and Heavy-Duty Electric Vehicles (July 14, 2022) available at https://www.volvotrucks.us/news-and-stories/press-releases/2022/july/constructing-california-electrified-chargingcorridor- for-medium-and-heavy-duty-electric-vehicles/

Likewise, Daimler Trucks North America partnered with NextEra Energy Resources and BlackRock Alternatives in a joint venture called Greenlane to design, develop, install, and operate a U.S. nationwide, high-performance zero-emission public charging and hydrogen fueling network for medium- and heavy-duty battery-electric and hydrogen fuel cell vehicles.210 [EPA-HQ-OAR-2022-0985-1505-A1, pp. 28-29]

210 Commercial Carrier Journal, Establishing heavy-duty EV charging infrastructure was a key theme at ACT Expo (May 11, 2023) available at https://www.ccjdigital.com/alternative-power/article/15447477/heavyduty-ev-charginginfrastructure-key-theme-at-act-expo?utm_source=Sailthru&utm_medium=email&utm_campaign=Issue%3A+2023-05-11+Transport+Dive+%5Bissue%3A50409%5D&utm_term=Transport+Dive

All of these projects are indicative that manufacturers, utilities, and other investors are bringing to bear an extensive investment in this area and will rapidly develop medium and heavy-duty charging capacity commensurate with the level of BEV deployment stimulated by the Phase 3 rulemaking. [EPA-HQ-OAR-2022-0985-1505-A1, p. 29]

Further, recent analysis has confirmed that heavy-duty charging infrastructure does not all need to be built at once and that focused deployment can support rapid electrification of the sector. For instance, ICCT has found that the corridors of the National Highway Freight Network are projected to comprise 85% of the charging needs from long-haul trucks by 2030.211 [EPA-HQ-OAR-2022-0985-1505-A1, p. 29]

211 ICCT, Near-Term Infrastructure Deployment To Support Zero-Emission Medium- And Heavy-Duty Vehicles In The United States (May 11, 2023) available at https://theicct.org/publication/infrastructure-deployment-mhdv-may23/

Rapid and Expansive Investment in Charging Infrastructure Supports Stringent Phase 3 Emission Standards

s EPA notes, a number of new Congressionally enacted policies will also facilitate greater and rapid deployment of charging infrastructure sufficient to support more robust Phase 3 standards.212 The Bipartisan Infrastructure Law (IIJA) created the Charging and Fueling Infrastructure Discretionary Grant Program to deploy publicly accessible charging and fueling infrastructure and provides for $2.5 billion over five years for the program.213 At the end of March 2023, FHWA issued a notice of funding opportunity to solicit applications for grants totaling up to $700 million to deploy charging and alternative fueling infrastructure projects. Half of the $700 million is allocated for electric vehicle and other infrastructure located on public roads or in other publicly accessible locations, while the other half is allocated for charging and alternative fueling infrastructure located along designated alternative fuel corridors. These funds can be used to build charging infrastructure for medium- and heavy-duty trucks. [EPA-HQ-OAR-2022-0985-1505-A1, p. 29]

212 88 Fed. Reg. at 25928.

213 Infrastructure Investment and Jobs Act, P.L 117-58 (Nov. 15, 2021), Section 11401.

In addition to the federal investments in charging facilitated by the IIJA, the Inflation Reduction Act Section 30C provides significant tax incentives for the deployment of private capital into charging infrastructure for both light and heavy-duty vehicles.214 It allows for up to $100,000 for each charger with no limit on how many chargers a fleet can purchase and install at one site; this can help fleets commit to larger investments in heavy duty BEVs. [EPA-HQ-OAR-2022-0985-1505-A1, p. 29]

214 Id. at Section 13404.

Additionally, utility investment in charging infrastructure will accrue over the next several years as evidenced by active proceedings in many jurisdictions.215 Investment in charging infrastructure will be further enhanced by state rebates and incentive programs. Numerous incentives that will also facilitate MHDV infrastructure have been established and enacted.216 [EPA-HQ-OAR-2022-0985-1505-A1, p. 29]

215 See e.g., New York State Department of Public Service, Proceeding on Motion of the Commission to Address Barriers to Medium- and Heavy-Duty Electric Vehicle Charging Infrastructure, Case No. 23-E-0070 available at https://documents.dps.ny.gov/public/MatterManagement/CaseMaster.aspx?MatterSeq=69967&MNO=23-E-0070E

216 See generally, N.C. Clean Energy Technology Center (NCCETC), The 50 States of Electric Vehicles: State ZEV Targets, Managed Charging, & LMI Access Prioritized in 2022 (Feb. 8, 2023) available at https://nccleantech.ncsu.edu/2023/02/08/the-50-states-of-electric-vehicles-state-zev-targets-managed-charging-lmiaccess- prioritized-in-2022/

Recent estimates already peg that the heavy-duty charging segment investment is expected to reach over $534.7 million, while the other type, AC Charger, is projected to be worth more than $237.6 million by 2024.217 The combination of the IIJA funding, federal IRA incentives, state incentives, private and utility investments, and a robust Phase 3 standard will push an exponential growth in this investment leading up to MY 2027. [EPA-HQ-OAR-2022-0985-1505-A1, p. 30]

217 Statista, Projected heavy-duty electric vehicle charging infrastructure market size in the United States between 2018 and 2024, by type (May 11, 2023) available at https://www.statista.com/statistics/1282171/us-heavy-duty-electric-vehiclecharging-infrastructure-market-size-forecast-type/

Organization: Texas Public Policy Foundation (TPPF)

Moreover, the availability of charging stations for electric trucks is currently poor and still developing. It is certainly not as extensive as refueling stations for diesel trucks, and retrofitting existing truck stops for electric charging will place immense strain on electrical infrastructure and the national grid, especially in rural communities often frequented by truckers traveling the nation’s highways, causing prices to skyrocket for average Americans. [EPA-HQ-OAR-2022-0985-1488-A1, p. 5]

The resulting chaos will limit the range and flexibility of electric trucks for long-haul journeys. Electric trucks already have limited range compared to diesel trucks, particularly when fully loaded. This will mean more frequent charging, adjustment to trucking routes, and overall shipping delays, negatively affecting operational efficiency. And even if the myriad infrastructure issues involved in getting power to truck refueling stations were solved or mitigated, the electricity used to charge electric trucks would still primarily come from America’s most reliable and abundant power source: fossil fuels. [EPA-HQ-OAR-2022-0985-1488-A1, p. 5]

In effect, the HD Tailpipe Rule will force truckers to spend substantial financial and human resources to comply with ultra vires government regulations that fail to make even a marginal dent in global issue of changing climate. [EPA-HQ-OAR-2022-0985-1488-A1, p. 5]

Organization: Truck and Engine Manufacturers Association (EMA)

v. ICCT and Ricardo have assessed the magnitude of the ZEV-truck infrastructure challenge

Following the release of the Phase 3 NPRM, both the International Council on Clean Transportation (ICCT) and Ricardo LLC (Ricardo) have assessed the scope of the recharging/refueling infrastructure that will need to be installed and made operational on a nationwide basis over the next seven years to support the implicitly (and explicitly) mandated numbers of ZEV trucks. The scope of the HDOH infrastructure challenge is daunting. In fact, the challenges associated with the recharging/refueling infrastructure needed for the envisioned numbers of light-duty vehicles are minor in comparison to those associated with the HDOH infrastructure. Consequently, and as noted, the implicit ZEV-truck sales mandates included in EPA's Phase 3 program will need to be linked to the pace of progress that is made over the next seven years to install the requisite recharging/refueling infrastructure (as assessed by ICCT, Ricardo, and others) for the envisioned numbers and types of ZEV trucks. [EPA-HQ-OAR-2022-0985-2668-A1, p. 11]

On May 11, 2023, ICCT released a report entitled, "Near-Term Infrastructure Deployment to Support Zero-Emission Medium- and Heavy-Duty Vehicles in the United States" (ICCT Report). The ICCT Report is directly on point and includes the following relevant findings and conclusions:

- To support the conversion of long-haul trucks to ZEVs, high-capacity charging stations will need to be sited every 50 miles along the National Highway Freight Network (NHFN) by 2030. Some of those charging stations will need capacities up to 22MW, which will require extensive upgrades to grid interconnections.
- The average minimum charging station size for long-haul vehicles along the NHFN will need to be 10MW, a charging capacity size that is roughly half of what is required to power a small town.
- By 2030, approximately 1.1 million ZEV trucks will be deployed, including approximately 130,000 long-haul combination trucks.
- By 2030, 522,000 overnight chargers, 20,500 fast chargers, and 9,540 ultrafast chargers will be needed to support the estimated 1.1 million ZEV trucks.
- Ten key states will comprise roughly half of the energy needed for the anticipated numbers of ZEV trucks by 2030. Within those 10 states, the top 15 counties will account for 11% of the projected energy needs, meaning that targeted infrastructure deployment plans will be required.
- ICCT does not foresee a case for positive TCO for hydrogen trucks relative to battery-electric trucks.
- Table 3 from the ICCT Report (reproduced below) lists the ZEV-charging infrastructure needs for ZEV trucks in the top 10 counties and for the nation as a whole as of 2030: [EPA-HQ-OAR-2022-0985-2668-A1, pp. 11-12.] [See Table 3 on page 12 of docket number EPA-HQ-OAR-2022-0985-2668-A1]

On June 16, 2023, Ricardo issued its own comprehensive needs assessment report regarding the ZEV-truck infrastructure that will be required by 2032 under EPA's Phase 3 proposal (and under CARB's overlapping ACT regulations). The Ricardo Report (a copy of which is attached as Exhibit "1") includes the following key findings and conclusions:

- More than 1.5 million MHD BEV trucks and more than 120,000 FCEV trucks will be on the road by 2032 if EPA's implicit ZEV-truck mandates, as proposed, (and CARB's express ACT ZEV-truck mandates in California and the Section 177 opt-in states) are fully implemented. By way of comparison, only approximately 600 HD ZEVs and zero (0) HD FCEVs were sold in the U.S. in 2021. Eighty percent (80%) of those HD ZEV sales in 2021 were for public transit, shuttle and school bus applications.
- The envisioned level of deployment of ZEV-trucks under EPA's Phase 3 proposal will require the construction of nearly 1.5 million MHD BEV charging ports by 2032. Of that number, approximately 110,000 charging ports will need to be DCFC rated at 150kW or 350kW. The relatively low number of anticipated DCFC chargers stems from Ricardo's utilization of EPA's assumptions regarding the predominance of depot-charging, and the availability of charging times in excess of 8 hours for all trucks in all BEV applications. More realistic assumptions would yield higher estimates for the necessary numbers of DCFCs rated at 50kW or more.
- In order to have 1.5 million MHD BEV chargers installed by 2032, approximately 187,500 chargers will need to be sited, installed and made operational each year over the next 8 years. That equates to the installation of approximately 15,625 MHD BEV chargers every month. Obviously, that is not happening.
- The aggregate cost to construct the necessary number of MHD BEV charging ports under EPA's NPRM will be approximately $21 billion. By way of comparison, the directly available federal funding for the installation of MHD BEV charging ports is approximately $1 billion. The relatively low aggregate cost that Ricardo has calculated stems from utilizing the same EPA assumptions regarding fleets' exclusive reliance on depot-charging and the universal availability of overnight charging. Different assumptions regarding the need for greater numbers of higher-power DCFCs would increase the resultant aggregate cost estimates significantly.
- As a point of reference, the total number of operational DCFS charging stations in California today is approximately 9,200. By 2032, California alone will need more than 60,000 DCFC ports.
- The ZEV-truck infrastructure demands and timelines imposed by the underlying Phase 3 regulatory mandates, as proposed, are likely unworkable. [EPA-HQ-OAR-2022-0985-2668-A1, pp. 12 - 13] [see docket number EPA-HQ-OAR-2022-0985-2668-A2 for Exhibit 1]

5. The Critical Importance of Infrastructure Readiness

Even if the more reasonable outputs from EMA's HD TRUCS are used to frame the final Phase 3 standards, there is no doubt that the infrastructures to power the ZEVs must be in place for any Phase 3 rule to be implementable. For trucking fleets to operate BEVs or FCEVs, whether a few or many, adequate battery-recharging or hydrogen-refueling infrastructures will be needed to power the ZEVs. Without sufficient infrastructures in place in time to meet the needs of the ZEVs implicitly required by EPA's GHG Phase 3 regulation, the rule will be destined to fail. [EPA-HQ-OAR-2022-0985-2668-A1, p. 43]

Based on the data in the NPRM, more than 140,000 battery chargers must be in place by 2027 and 1,400,000 (10-times more) by 2032 to power the MHD BEVs that EPA proposes to indirectly mandate through the Phase 3 rule. More specifically, the following graph depicts the number of chargers needed for the MHD BEVs that manufacturers would be required to sell under the proposed GHG Phase 3 rule: [EPA-HQ-OAR-2022-0985-2668-A1, p. 43] [See the Chargers Needed Table on page 44 of docket number EPA-HQ-OAR-2022-0985-2668-A1.]

To establish more than 1,400,000 battery chargers needed by 2032 to support the mandated MHD BEVs, approximately 15,000 chargers must come online each and every month over the ensuing eight years between now and 2031. Additionally, utilities will have to make extensive upgrades to the distribution capabilities of the electricity grid to provide those chargers with the more than 250 gigawatt-hours of aggregate daily power needs. Needless to state, nothing like that necessary infrastructure transformation is yet underway or even adequately planned for. [EPA-HQ-OAR-2022-0985-2668-A1, p. 44]

Moreover, due to their size and power demands, MHD ZEVs will not be able to utilize the charging infrastructure that is being developed for passenger ZEVs. As envisioned in the NPRM, all of the battery-recharging stations for commercial vehicles will be located at trucking depots and terminals where trucks park overnight. Under that scenario, chargers will need to be concentrated at those locations, requiring significant upgrades to the electricity transmission lines and substations to support the new high electricity demands at each depot location. However, contrary to EPA's core assumption, many experts believe that MHD ZEVs also will need to be recharged en route, at public battery-recharging stations, in addition to depot-charging. But public battery-recharging stations for MHD BEVs are not even considered in EPA's HD TRUCS, and adding that expanded infrastructure demand – which needs to be taken into account - will require changing many of the fundamental assumptions and data inputs to EPA's version of HD TRUCS. [EPA-HQ-OAR-2022-0985-2668-A1, p. 44]

Unlike passenger cars, commercial vehicles are purchased by trucking businesses for the sole purpose of providing a financial return on the investment. If a new MHD BEV cannot perform the work needed by the fleet, at a lifecycle cost equal to or lower than other available technologies, it will not make financial sense for the fleet to invest in purchasing the BEV. Therefore, the charging infrastructure needed to power a new BEV must be in place before the fleet takes delivery of the ZEV-truck. Without that infrastructure in place in time, fleets simply will not purchase ZEVs, making it impossible for manufacturers to sell them. [EPA-HQ-OAR-2022-0985-2668-A1, pp. 44 - 45]

We acknowledge that utilities may be waiting for the electricity demands associated with increasing numbers of MHD ZEVs to materialize before they commit to undertake the needed investments to upgrade the electricity grid. Unfortunately, however, that wait-and-see approach likely will, in effect, doom the GHG Phase 3 rule. If the recharging infrastructure is not in place before a fleet is expected to take delivery of a BEV, the fleet operator will cancel the order to avoid acquiring a stranded asset that is unable to generate revenue. [EPA-HQ-OAR-2022-0985-2668-A1, p. 45]

In light of the foregoing, a whole-of-government initiative is needed to ensure that the necessary battery-recharging infrastructure will be in place in time to power the annually increasing numbers of MHD BEVs implicitly required by the GHG Phase 3 rule. That initiative will need to determine: (i) the sufficiently-sized locations where battery-recharging stations need to be installed, (ii) the needed power ratings of those stations to meet the specific charging demands of the diverse types of commercial vehicles, and (iii) the "behind the meter" grid upgrades needed to deliver sufficient power to each location. Most importantly, that coordinated initiative must include mechanisms to ensure that the necessary battery-recharging infrastructure will be in place in time to meet the needs of the MHD ZEVs required by the GHG Phase 3 rule. Ricardo's need assessment report provides a useful overview of what will be required, and at what cost. [EPA-HQ-OAR-2022-0985-2668-A1, p. 45]

Regarding the types of battery-recharging station that will be needed, below is our estimate of the minimum power ratings and typical daily energy needs of different types of commercial BEVs. Please note that the estimates assume some BEVs will need to be recharged en route, something the NPRM and EPA's HD TRUCS assume will not be the case. Among other crucial issues, the required whole-of-government initiative should assess which MHD ZEVs are likely to be exclusively depot-charged, which may need to be recharged en route, and which will need to utilize both options. [EPA-HQ-OAR-2022-0985-2668-A1, p. 45.] [See the Estimate of Minimum Power Ratings Table on page 45 of docket number EPA-HQ-OAR-2022-0985-2668-A1.]

The NPRM and HD TRUCS incorrectly assume that all commercial BEVs will be depot-charged at night, and that any commercial ZEVs that need to operate further from home will be FCEVs. The NPRM also assumes that trucking fleets will be able to devote up to 30% of each vehicle's cargo carrying capacity for batteries large enough to provide enough power for the vehicle's entire daily work. If a commercial vehicle cannot carry enough batteries to complete its daily work, or if it must travel too far from its home terminal, the NPRM assumes that a FCEV will be used instead of a BEV. Of course, those FCEVs will require an entirely separate infrastructure of hydrogen-refueling stations, which still needs to be designed and developed. [EPA-HQ-OAR-2022-0985-2668-A1, pp. 45 - 46]

EPA has established as a foundational premise of the NPRM that the necessary battery-recharging and hydrogen-refueling infrastructures will be developed in time to meet the needs of the MHD ZEVs that the GHG Phase 3 rule will require manufactures to sell. However, there is a significant chance that EPA's key premise – what really amounts to little more than a stated aspiration – may prove fundamentally wrong, a prospect that would completely undermine this rulemaking. Accordingly, a massive and focused whole-of-government initiative must come together very quickly to ensure the development of the necessary ZEV-truck infrastructures in time. [EPA-HQ-OAR-2022-0985-2668-A1, p. 46]

The current lack of the much-needed whole-of-government initiative already may be chilling investments in the development of necessary battery-recharging and hydrogen-refueling infrastructures. Without clarity about whether long-distance commercial vehicles will be BEVs or FCEVs, investors may be hesitant to commit capital to develop the infrastructure for one of the technologies. For example, clarity is needed regarding whether the required public stations will deliver electricity or hydrogen. Without a long-term technology path identified, investors may be sitting on the sidelines. Similarly, if hydrogen will be part of the solution, clarity is needed to identify whether it will be a compressed gas or cryogenic liquid. Until that hydrogen infrastructure direction is clear, more investors may stay on the sidelines. [EPA-HQ-OAR-2022-0985-2668-A1, p. 46]

Truck manufacturers are doing their part by developing all of the potential ZEV technologies: BEVs, compressed hydrogen-fueled FCEVs, cryogenic hydrogen-fueled FCEVs, compressed hydrogen-fueled H2-ICEs, and cryogenic hydrogen-fueled H2-ICEs. However, without adequate assurances that the appropriate infrastructures will be in place in time, fleets simply will not purchase any of those types of ZEVs. Thus, developing the necessary infrastructures represents the most complicated, most expensive, and longest lead-time challenge to transition the U.S.

trucking industry to ZEVs. Without an effective whole-of-government initiative focused on understanding, developing and ensuring those infrastructures, there may be little chance that the GHG Phase 3 rule will be successful. Consequently, clear links between the phase-in of the Phase 3 rule and the phase-in of the requisite infrastructure must be established, monitored, and acted on if misalignment among the respective phase-ins is detected. [EPA-HQ-OAR-2022-0985-2668-A1, pp. 46 - 47]

In that regard, EMA recommends that EPA work with other agencies, departments and stakeholders to establish clear annual benchmarks for assessing progress in the deployment of the necessary ZEV-truck infrastructures. For example, using the data developed by ICCT, Ricardo, NREL and others, EPA could determine the top 100 counties across the country where the greatest numbers of ZEV-trucks will be deployed under the Phase 3 and ACT regulations by 2032. For each of those counties, benchmarking assessments could be made of the number of BEV-recharging and FCEV-refueling stations that will need to be installed on an annual basis to support the annually increasing deployment of the anticipated numbers of ZEV-trucks in each of those counties. Each year, evaluations could be made on a county-by-county basis to determine whether and how the actual pace of installation of ZEV-truck recharging/refueling stations is keeping up with the benchmark numbers of necessary recharging/refueling stations. If it is determined that the aggregate actual progress in infrastructure development is falling behind the benchmark rates of progress by, for example, 20% or more, the phase-in schedule of the Phase 3 standards could be deferred by one or more years as deemed appropriate by EPA, perhaps in consultation with other agencies and departments. [EPA-HQ-OAR-2022-0985-2668-A1, p. 47]

The foregoing is just an example of the type of direct linkage that needs to be made between the implementation of the Phase 3 rule and the implementation of the fundamentally necessary ZEV-truck infrastructure. Without that type of linkage, there is no real prospect for the proposed rule to stand. To the contrary, much like a one-legged stool, it will be preordained to collapse. [EPA-HQ-OAR-2022-0985-2668-A1, p. 47]

Organization: Truck Renting and Leasing Association (TRALA)

While Battery Electric Vehicle (BEV) charging infrastructure is expanding, much of it is not accessible or practical for commercial fleet use. Short-term rental fleets are highly transient and serve many small businesses that may not have access to ZEV charging and fueling infrastructure. Our members also report that many first-generation charging solutions are unreliable and need frequent repairs. Hydrogen fueling infrastructure is virtually non-existent given the laggard in the design and advancement of hydrogen fuel cell trucks. In addition, not all 50 states are created equal in terms of ZEV fueling infrastructure planning and assistance. Since trucks by nature are not bound to local, state, or international borders, ZEV vehicle travel – aside from hub-and-spoke operations – will be limited to the reach of the nation’s fueling infrastructure. [EPA-HQ-OAR-2022-0985-1577-A1, p. 4]

Return-to-Base Operations Without On-Site Charging Will be Placed in a Precarious Predicament

As previously noted, many TRALA members – and other trucking companies – will not have the luxury of on-site charging installation due to tenant improvement restrictions under their facility lease agreements. If depot charging is not an option, trucking companies will be required to use the public charging network or contract with entities that have surplus charging ports to utilize. However, both scenarios pose problems in that company assets would be required to be parked off-site for extended periods of time in potentially unsecured areas. [EPA-HQ-OAR-2022-0985-1577-A1, p. 6]

Contracting with entities to charge fleet equipment on their property raises several issues involving property access as well as insurance, security, and liability concerns. TRALA asks EPA to address these concerns in the final rule. A regulation is only as feasible as the ability to comply with the requirements. [EPA-HQ-OAR-2022-0985-1577-A1, pp. 6-7]

TRALA requests EPA conduct annual reviews to ascertain whether charging infrastructure, power demands, and hydrogen fuel (when/if available), will satisfy the needs for all ZEVs in every state to meet trucking's charging and hydrogen needs. If the status of charging or hydrogen fueling infrastructure identifies significant gaps that would impede truck mobility in any state, EPA should not implement subsequent milestone year requirements until identified fueling gaps are operational in keeping pace with vehicle needs. [EPA-HQ-OAR-2022-0985-1577-A1, p. 8]

Incentive Use Overestimates ZEV Market Penetration Rates for Trucks

The Bipartisan Infrastructure Law (BIL)25 included a total of $7.5 billion for EV chargers and other alternative fueling facilities. Five billion of that was assigned to the National Electric Vehicle Infrastructure (NEVI) Formula Program. Under the NEVI program, states can receive funding from the Federal Highway Administration (FHWA) for up to 80% of eligible project costs. NEVI requires charging stations receiving assistance be publicly available or available to commercial drivers from more than one company and be installed along designated FHWA Alternative Fuel Corridors (AFCs). [EPA-HQ-OAR-2022-0985-1577-A1, p. 18]

5 Infrastructure Investment and Jobs Act (P.L. 117-58).

The freight industry needs dedicated charging capabilities for both Medium-Duty (MD) and Heavy-Duty (HD) trucks near or within the properties of major warehouses, ports, rail yards, and industrial facilities. These sites can serve multiple companies through an agreement with the site operator but won't necessarily allow 'public' access. In comments filed on behalf of the trucking industry to FHWA on its National Electric Vehicle Infrastructure Formula Program Notice of Proposed Rulemaking (Federal Register, June 22, 2022), FHWA was asked to direct states to dedicate specific funding levels towards the build-out charging infrastructure for the trucking sector. [EPA-HQ-OAR-2022-0985-1577-A1, p. 18]

In its final rule, the FHWA addressed this request as follows:

'FHWA understands that the MD/HD charging industry is very nascent and rapidly evolving; as such, FHWA has not modified the language in this final rule to specifically accommodate MD/HD needs so as not to preempt the pace of the technological innovation. The rule does not preclude MD/HD charging infrastructure and FHWA strongly encourages project sponsors to consider future MD/HD needs. The FHWA will continue to monitor the technological advancements in the MD/HD industry for consideration as to whether further regulation is needed to provide applicable minimum standards and requirements at a future date.' 26 [EPA-HQ-OAR-2022-0985-1577-A1, p. 19]

26 Federal Register, Vol. 88, No. 39, Page 12731 (February 28, 2023).

Given the fact that truck charging infrastructure under NEVI was and remains an afterthought, TRALA is less optimistic than EPA in assuming the BIL will address the tremendous financial needs for powering truck ZEVs. [EPA-HQ-OAR-2022-0985-1577-A1, p. 19]

Organization: Valero Energy Corporation

C. EPA's consideration of HD ZEV infrastructure is inadequate and insufficient.

In order to evaluate HD ZEV infrastructure readiness, EPA relies on projections as evidence-in-fact to support the proposed rulemaking while ignoring the material conditions and limitations disclosed in EPA's own sources. By way of example, EPA states that "[i]n the United States, there was $200 million or more in mergers and acquisition activity in 2022 according to the capital market data provider Pitchbook, indicating strong interest in the future of the charging industry."161 But EPA's source material further provides as follows:

Yet charging companies face plenty of challenges. Even with funding, building EV-charging infrastructure remains extremely costly and time-consuming.

Because of these struggles, not every company will make it — some smaller companies are betting that larger ones will gobble them up and take on their assets through mergers and acquisitions. Global M&A activity in the charging space this year hit at least $900 million across 25 deals as of this week, according to PitchBook. That includes at least $200 million across seven deals in the US.

"For the smaller companies, it's hard to scale up on their own. They really need larger partners," Steve Hilfinger, a partner and senior business counselor with the law firm Foley & Lardner, said. "This is going to take a lot of capital." 162 [EPA-HQ-OAR-2022-0985-1566-A2, p. 33]

161 EPA's HD Phase 3 GHG Proposal at 25934 (citing to St. John, Alexa, and Nora Naughton. "Automakers need way more plug-in stations to make their EV plans work. That has sparked a buyer frenzy as big charging players gobble up smaller ones.'' Insider, November 24, 2022. Available online: https://www.businessinsider.com/evcharging-industry-merger-acquisition-meet-electricvehicle-demand-2022-1).

162 Id.

The above excerpt suggests that much of the mergers and acquisitions is related to smaller companies being absorbed by larger ones, not an overall growth in the marketplace for charging infrastructure. [EPA-HQ-OAR-2022-0985-1566-A2, p. 34]

EPA also states that "[r]ecent findings from Phadke et al. suggest that BEV TCO [total cost of ownership] could be 13 percent less than that of a comparable diesel ICE vehicle if electricity pricing is optimized."163 But the Phadke article also cautions that "major barriers need to be addressed to fully realize [the] potential" of electric trucks.164 These include "[e]lectricity prices, especially demand charges" as well as "higher cost of new [electric HD] vehicles and slow return on charging infrastructure".165 [EPA-HQ-OAR-2022-0985-1566-A2, p. 34]

163 EPA's HD Phase 3 GHG Proposal at 25942 (emphasis added).

164 Phadke, A., et. al. (2021) ''Why Regional and Long-Haul Trucks are Primed for Electrification Now''. https://eta-publications.lbl.gov/sites/default/files/updated_5_final_ehdv_report_033121.pdf

165 Id. at 6.

Additionally, per EPA, "[t]he Rocky Mountain Institute found that because of the [Inflation Reduction Act] IRA, the TCO of electric trucks will be lower than the TCO of comparable diesel trucks about five years faster than without the IRA".166 The Rocky Mountain Institute, however, also provides that:

"[E]-truck manufacturers will have to ramp up production by a factor of 20 by 2035 while meeting new North American final assembly requirements, both of which will be challenging. Utilities and regulators will have to prepare for an unprecedented amount new electric load that can range from as large as a skyscraper to greater than a central business district. By 2035 our grid must be prepared to add 230 TWh of new truck electricity demand, including power for nearly 150,000 fast public chargers and 860,000 depot chargers."167 [EPA-HQ-OAR-2022-0985-1566-A2, p. 34]

166 EPA's HD Phase 3 GHG Proposal at 25942.

167 Kahn, Ari, et. al. ''The Inflation Reduction Act Will Help Electrify Heavy-Duty Trucking''. Rocky Mountain Institute. August 25, 2022. https://rmi.org/inflation-reduction-act-will-help-electrify-heavy-duty-trucking/

EPA also cites to an article detailing DC Metro's plans to shift to a ZEV bus fleets over the next 20 years.168 Yet EPA ignores comments made by a federal representative on DC Metro's Board in the same article:

"[V]ehicle procurements, [are] easy to understand, but it's much less sexy to talk about the infrastructure and what needs to happen behind the scenes…[W]ithout the infrastructure for charging, Metro would have vehicles on their hands that they couldn't run." He cited concerns about load capacity during a hot summer day trying to charge dozens of buses while everyone is also running air conditioners in their homes. "A Metro garage would need 9 megawatts of high-capacity electric connection to support 150 buses in a garage — and so far no garage has that. That amount of electricity is the equivalent needed to power 6,000 homes." [Further,] "Metro would also have to retrain a maintenance workforce to work on electric buses. 'The goals are certainly something we need to establish, but we need to figure out how we're going to execute them,' he said.169 [EPA-HQ-OAR-2022-0985-1566-A2, pp. 34 - 35]

168 EPA's HD Phase 3 GHG Proposal at 25943.

169 Pascale, Jordan. "Metro Approves Plans For Fully Electric Bus Fleet By 2045". DCist. June 10, 2021. https://dcist.com/story/21/06/10/metro-goal-entirely-electric-bus-fleet-2045/

EPA argues that ZEV obstacles can be overcome through "federal incentive programs like those in the BIL and IRA to offset ZEV purchase costs, as well as state and local incentives and investments…with improvements in BEV and FCEV component costs playing an increasing role in reducing costs in the longer term."170 But EPA ignores factors outside the control of regulators and OEMs alike that will be material to the feasibility of EPA's proposal and are highlighted in one of the very sources EPA cites to in support of its assertion.171 EPA glosses over and obfuscates these obstacles in FN 148, stating "[o]ther barriers that fleet managers prioritized for fleet electrification included: [i]nadequate charging infrastructure—our facilities, inadequate product availability, inadequate charging infrastructure—public" etc.172 Indeed, the American Council for an Energy-Efficient Economy White Paper that EPA cites to discusses challenges facing electric truck deployment in-depth, including model availability, greater upfront cost, range, charging, and other challenges. Yet these discussions are absent from EPA's analysis, including the white paper's proposition that "in some cases, EVs may not be the solution."173 Further, the White Paper provides:

"Existing infrastructure at these sites may not be capable of serving such [fleet] loads. Meeting this demand could require upgrades to or the build-out of new infrastructure, often at considerable cost. For example, a Southern California facility had to install a $470,000 transformer after the meter to meet the demand of deploying 20 electric trucks. Installing several chargers at a depot, truck stop, or filling station involves many players to obtain permits, undertake construction, and work with the utility to ensure that adequate power is available when and where needed."174 [EPA-HQ-OAR-2022-0985-1566-A2, p. 35]

170 EPA's HD Phase 3 GHG Proposal at 25943.

174 Id. at 27 (internal citations omitted).

Collectively, these issues illustrate the neglected assumptions underpinning EPA's central trajectory for HD ZEV sales and supporting infrastructure. These issues are central to EPA's proposal and make EPA's proposal unreasonable, arbitrary and contrary to law. [EPA-HQ-OAR-2022-0985-1566-A2, p. 35]

Organization: Volvo Group

Infrastructure Implications

Because of these complications customers have been reluctant to take truck deliveries, leading to extension requests for many of our Hybrid and Zero-Emission Truck and Bus Voucher Incentive Project (HVIP) vouchers in California. While supply chain challenges have contributed to some delivery delays, 70% of the extension requests are due to problems with infrastructure projects and site planning. [EPA-HQ-OAR-2022-0985-1606-A1, p. 8]

Commercial vehicle owners engaged in freight hauling for profit are very different from passenger car owners. Uptime is critical to maximize miles traveled and minimize Total Cost of Ownership (TCO). Commercial trucks are capital assets that customers buy or lease to do a certain job and provide a return on investment. Fleet owners need flexibility in their operations and stability in the availability and cost of electricity to keep their customers satisfied. Fleets can face significant variability in the cost of charging based on the season and the time of day, not to mention the threat of complete unavailability in the case of extreme weather or blackouts. This complicates the ZEV transition experience for fleets, impacting dealership business, and negatively affecting sales. [EPA-HQ-OAR-2022-0985-1606-A1, p. 8-9]

Organization: Zero Emission Transportation Association (ZETA)

d. HDEV Charging Infrastructure

A commonly cited barrier to HDEV adoption is the lack of available charging infrastructure. It is important to note that charging needs for fleet-owned HDEVs can be much different than consumer-owned LMDEVs. HDEVs tend to have higher capacity batteries requiring faster charging rates or longer charge times, or a combination of both. While most electric HD fleet vehicles have shorter, scheduled routes and can rely primarily on depot charging overnight, some fleets may require on-route charging to supplement longer trips. While a public HDEV charging network is still in the early stages of deployment, electric vehicle supply equipment (EVSE) manufacturers and operators are already investing the necessary resources to ensure multiple methods of charging are available and reliable for the 2027-2032 model years affected by these emissions standards. [EPA-HQ-OAR-2022-0985-2429-A1, p. 47]

75% of fleet owners surveyed cite concerns about the cost of installing HDEV-specific charging as one of the greatest barriers to adoption.143 Indeed, an ultra-fast charger capable of 350kW can cost up to $140,000.144 However, the amount of power needed is not the same across all classes of vehicles and smart charging software can optimize power distribution among vehicles according to their charging capabilities and needs. To ensure upfront capital is spent on the appropriate equipment, installation projects will benefit from a customized analysis of a fleet's charging needs based on fleet size and type, average VMT, duty cycles, and time of charging. While the investment in charging infrastructure will be returned via lower lifetime operating costs associated with EV ownership, the upfront investment presents a real but surmountable barrier. [EPA-HQ-OAR-2022-0985-2429-A1, p. 47]

143 Id. at Page 10

144 Michael Nicholas, "Estimating Electric Vehicle Charging Infrastructure Costs across Major U.S. Metropolitan Areas," The International Council on Clean Transportation (August 2019) https://theicct.org/sites/default/files/publications/ICCT_EV_Charging_Cost_20190813.pdf

As discussed previously, the need for increased HDEV charging also creates significant economic opportunities. The charging infrastructure necessary to accommodate the transition to an electrified HD fleet has the potential to create more than 29,000 jobs.145 Considering the Bipartisan Infrastructure Law's Buy America Build America requirements for light-duty charging infrastructure under the NEVI Formula Program146 and CFI Discretionary Grant Program,147 it is reasonable to expect that many of the high-quality jobs in HD EVSE manufacturing will be domestic as manufacturers build increasingly robust domestic supply chains. [EPA-HQ-OAR-2022-0985-2429-A1, pp. 47 - 48]

While the buildout of HDEV charging infrastructure is still in the nascent stages, so too is HDEV deployment. It is also important to remember that just as HDEV deployment will not occur all at once, neither will HD EVSE deployment. Initial strategic buildout of depot-based charging in high-priority areas will help ensure EVSE manufacturing capacity can scale while continuing to support a more rapid HDEV transition. This is already under way at certain locations148, 149 and HD EVSE product offerings are increasing rapidly.150,151,152 [EPA-HQ-OAR-2022-0985-2429-A1, p. 48]

i. EVSE operator statements on EPA emissions standards

As discussed previously, EPA’s proposed rule setting GHG emissions standards for heavy-duty vehicles provides much needed certainty throughout the supply chain, including EVSE manufacturers and operators. A clearer picture of future EVSE demand enables manufacturers and operators to plan and allocate capital accordingly. The statements mentioned below by ZETA’s EVSE manufacturers and operators in response to EPA’s announcement of these standards indicate as much:

- “EVgo applauds the EPA for proposing ambitious tailpipe emissions standards. These standards would accelerate the transition to electric vehicles and result in cleaner air, healthier communities, and create jobs across the country. More EVs demands more EV charging and we will continue to expand our fast charging network to provide the infrastructure to support the growing EV market.”153
- “ChargePoint is pleased to see USEPA’s tailpipe emission proposal, which will shift the electric mobility revolution into high gear. These rules will undoubtedly lead to more investment in heavy-duty EVs. We are actively building a national network of charging infrastructure to support the increased adoption of EVs, including heavy-duty vehicles, and deploying the hardware and software needed to effectively support heavy-duty vehicle charging in depots. Over our 15 year history, we have ensured charging infrastructure deployment kept pace with EV adoption, and we are well-positioned to meet the increased demand these standards will generate.”154 [EPA-HQ-OAR-2022-0985-2429-A1, pp. 48 - 49]

ii. Depot-based applications will satisfy the majority of HDEV charging needs

As studied by the International Council on Clean Transportation, the majority of class 4-8 HDEV charging will occur at depots, with the exception of single unit long-haul trucks.155 Depot charging is ideal for minimizing cost and maximizing battery health, whereas on-route charging prioritizes convenience. [EPA-HQ-OAR-2022-0985-2429-A1, p. 49]

155 Near-Term Infrastructure Deployment to Support Zero-Emission Medium- and Heavy-Duty Vehicles in the United States, International Council on Clean Transportation, (May 2023) https://theicct.org/wp-content/uploads/2023/05/infrastructure-deployment-mhdv-may23.pdf

Depot charging stations are structures where charging infrastructure is co-located with off-duty HDEV storage facilities. Often located at warehouses, logistic hubs, or public stations in industrial areas, fleet owners and operators typically own the charging infrastructure and can use it for overnight charging of vehicles.156 Deploying this method saves fleet operators money: they install the chargers at a pre-existing facility, charge their vehicles during scheduled downtime (which means they do not have to stop during typical hours spent on the road), and pay less for the electricity that they use (per-mile public charging rates are often higher).157 [EPA-HQ-OAR-2022-0985-2429-A1, p. 49]

156 Alana Aamodt, Karlynn Cory, & Kamyria Coney, “Electrifying Transit: A Guidebook for Implementing Battery Electric Buses,” National Renewable Energy Laboratory (April 2021) https://www.nrel.gov/docs/fy21osti/76932.pdf

157 Charles Satterfield and Nick Nigro, “Assessing Financial Barriers to Adoption of Electric Trucks,” Atlas Public Policy (February 2020) http://atlaspolicy.com/wp-content/uploads/2020/02/Assessing-Financial-Barriers-to-Adoption-of-Electric-Trucks.pdf

Given its centralized nature, depot charging is also well-suited for electricity load management. Depots can allow for easier coordination with grid operators to distribute charging activity to off-peak load times and facilitate tracking up-time fleet charging metrics. In an analysis conducted by Atlas Public Policy, more than 98% of cost-competitive scenarios for HDEV fleets included depot charging.158 [EPA-HQ-OAR-2022-0985-2429-A1, p. 49]

158 Id.

Companies may also look into bulk charging negotiations through purchase agreements. Fleets that traditionally run short-haul delivery operations may be attuned to applied charging strategies to flatten the load profile and save money through off-peak charging incentives. Further opportunities for cost-savings may overlap with retail energy designs and could align charging with cheaper renewable energy sources.159 [EPA-HQ-OAR-2022-0985-2429-A1, p. 50]

159 Brennan Borlaug, et al. “Heavy-duty truck electrification and the impacts of depot charging on electricity distribution systems,” Natural Energy (June 21, 2021) https://doi.org/10.1038/s41560-021-00855-0

iii. Ensuring strategic HD EVSE buildout

While depot charging will be suitable for most HDEV applications, a national highway freight network (NHFN) will be necessary to ensure adequate charging access for long-haul trucking applications. A typical highway site will eventually need more than 20 fast-chargers to serve expected traffic.160 [EPA-HQ-OAR-2022-0985-2429-A1, p. 50]

160 “Electric Highways: Accelerating and Optimizing Fast-Charging Deployment for Carbon-Free Transportation,” National Grid, (November 2022) https://www.nationalgrid.com/document/148616/download

Setting targets for charging station deployment along key NHFN corridors can accommodate up to 85% of long-haul charging needs by 2030.161 As discussed in ICCT’s May 2023 white paper on MHDV infrastructure deployment, 844 charging stations will be needed along the Federal Highway Administration’s Alternative Fuel Corridors to accommodate 50-mile spacing intervals between chargers along the entire length of the NHFN.162 [EPA-HQ-OAR-2022-0985-2429-A1, p. 50]

161 Id. at Page 45

162 Id. at Page 45

Under federal regulations, the number of hours drivers can travel per day is limited, with drivers required to take a 30-minute break within an eight-hour driving period and restricting drivers to a limit of 11 hours of driving per day, after which they are required a 10-hour rest break.163 During these mandatory rest times, drivers may be able to charge at individual stations or charging depots. [EPA-HQ-OAR-2022-0985-2429-A1, p. 50]

163 Id. at Page 8

Work is already underway to install HD EVSE at high-traffic freight locations,164,165 and NREL is working to electrify four key freight corridors across the United States:166

- In collaboration with CALSTART, NREL researchers will launch an intensive planning effort to develop infrastructure deployment plans for zero-emission medium- and heavy-duty vehicles along the I-95 freight corridor, which stretches from Savannah, Georgia, to Newark, New Jersey.
- Led by a Cummins Inc. team, NREL researchers will help develop extensive plans for battery-electric charging and hydrogen fueling stations along the stretch of I-80 that crosses Illinois, Indiana, and Ohio.
- In collaboration with a Utah State University team, NREL researchers will assist in developing a community-, state-, and industry-supported action plan for corridor electrification along Utah’s Wasatch Front.
- Led by a National Grid team, NREL researchers will help create a detailed model of truck operations along New England’s freight corridors and then use that data to simulate future electric truck operations, ideal charging locations, and the amount of energy those charging stations will use. The project will examine freight corridors in Maine, Massachusetts, New Hampshire, Vermont, Rhode Island, Connecticut, New York, Pennsylvania, and New Jersey, with a goal of informing a blueprint for future commercial EV charging. Despite both the public and private sector investments to build out HDEV charging capacity, more support will be needed in the coming years to ensure the expected growth of HDEVs is complemented with adequate charging infrastructure. Policies such as EPA's proposed GHG emissions standards for heavy-duty vehicles provide the regulatory certainty needed to support those investments by creating more clarity on expected HD EVSE demand. The lead time provided by the standards' MY 2027-2032 time frame also aids in ensuring HDEV charging infrastructure manufacturers and operators can make the investments necessary today to meet anticipated charging needs of tomorrow. [EPA-HQ-OAR-2022-0985-2429-A1, p. 51]

EPA Summary and Response:

Summary:

Vehicle manufacturers and others raised concerns about the lack of charging infrastructure, asserting that it is inadequate today and that the pace of deployment is not on track to meet levels needed if the standards are finalized. Commenters cited a variety of recent studies that estimate future heavy-duty infrastructure needs. For example, EMA cited a Ricardo study (submitted as Exhibit 1 of EMA's comments), which found that by 2032 about 1.5 million EVSE ports would be needed to support the approximately 1.5 million BEVs it estimates will be on the road if the proposed standards are finalized (along with CARB's ACT program and its adoption by Section 177 states). EMA notes this is equivalent to over 15,000 new ports deployed each month over the next 8 years, which it characterizes as infeasible. Multiple commenters (e.g., EMA, NADA) cited a recent ICCT paper (Ragon et al. 2023), which found a mix of over 550,000 chargers serving medium- and heavy-duty vehicles would be needed in 2030. EMA also highlighted ICCT's modeling of long-haul BEV charging needs in 2030, noting that high-power public charging stations would be needed on the National Highway Freight Network (National Highway Freight Network) at 50-mile intervals and that the stations would need to have high charging capacities that may necessitate some grid upgrades.

Some commenters highlighted what they claim are the high cost of future infrastructure needs estimated in the literature, asserting that current funding streams for heavy-duty charging are far short of what will be needed. For example, citing the same Ricardo study noted above, EMA said, "The aggregate cost to construct the necessary number of MHD BEV charging ports under EPA's NPRM will be approximately $21 billion. By way of comparison, the directly available federal funding for the installation of MHD BEV charging ports is approximately $1 billion." NADA referenced a 2022 EEI report that examined 2030 charging infrastructure needs (focused on LD vehicles) and found that the amount of DCFC ports from planned investments will be under half of those estimated as needed in the study. NADA further noted that the study failed to account for charging demand associated with EPA's proposed rulemakings for light-, medium, and heavy-duty vehicles, implying the actual gap between investments and needs would be even higher. Navistar noted that in the NPRM, EPA cited an ATLAS study, which estimated that between $100 and $166 billion in cumulative investments in charging infrastructure would be needed by 2030 to support HD BEVs. Am Free et al. referenced the same study, to support its conclusion that a public charging network of sufficient scope cannot be completed within the timeframe of a Phase 3 rule.

Multiple commenters (e.g., AmFree et al., ATA, CFDC et al., EMA, and NACS, NATSO, and SIGMA) emphasized the different charging needs of heavy-duty vehicles relative to light-duty vehicles, for example that HD vehicles may need higher power DCFC ports and that charging sites must be designed to accommodate larger vehicles and be located to meet freight needs. Several commenters noted that very few public charging stations that can accommodate heavy-duty vehicles are available today. UAW made a similar point about private stations, citing a recent DOE report that listed 166 private EVSE ports serving HD fleet vehicles. In its comments, CFDC et al. described reliability as an additional barrier to infrastructure availability citing a recent news article about work by J.D. Power on non-functioning public stations and consumer dissatisfaction. A variety of commenters (e.g., AmFree et al., AVE, EMA, Navistar, and UAW) asserted that either fleets will not buy, or customers will cancel orders for, BEVs if infrastructure is not available.

Several commenters asserted the EPA overestimated the impact of BIL and IRA investments. For example, while Navistar noted the importance of these laws to support infrastructure, it stated that so far funding has had a light-duty focus. Other commenters had a similar concern, noting the lack of requirement that any of the $7.5 billion in dedicated infrastructure funding in BIL be used for heavy-duty charging, with AmFree et al. also noting that even if it were, the total would still be insufficient. TRALA commented that FHWA had failed to provide specific guidance to States to dedicate some of the funding received through the National Electric Vehicle Infrastructure (NEVI) program to heavy-duty infrastructure. ATA wrote that it's not aware of states using NEVI funds for heavy-duty charging though it did note that CA, OR, and WA applied for a competitive grant to support heavy-duty charging buildout on I-5. Appendix B to the DTNA comments summarizes each State's infrastructure plan submitted to FHWA for 2022–2023, noting that few had specific commitments regarding using BIL funds for HD BEV infrastructure, and that some failed to mention HD BEV infrastructure.

AVE cited an EDF study noting that small fleets may have a particular difficulty absorbing the cost of charging infrastructure without support, and separately stated, "the IRA does not provide fleet owners with any incentives to install charging stations." AmFree et al. said EPA overstates the potential benefit of the IRA tax credit, given that it is capped at $100,000, far less than the cost of a large-scale charging site intended to serve many vehicles. TRALA noted that many of their customers may not be eligible for IRA tax credit due to census tract restrictions and other requirements (see RTC Chapter 6.3.2).

In its comments, AmFree et al. stated that the private investments cited in the NPRM are uncertain as it's unclear how many announced stations will actually be built. The commenter also noted that private investment amounts are small compared to the amount needed.

DTNA expressed concern that infrastructure availability is largely out of the control of manufacturers but will be critical to complying with proposed standards if finalized. Manufacturers (DTNA, EMA, PACCAR, Navistar) along with NADA, and UAW all requested that EPA monitor infrastructure deployment after the final rulemaking and adjust the stringency or timeline of the standards if it is not keeping pace with needs. EMA suggested that EPA develop annual infrastructure benchmarks in collaboration with other agencies and stakeholders. DTNA recommended that EPA directly incorporate a scalar reflecting installed infrastructure compared to infrastructure needs in its estimates of CO_2 stringency levels whereas Navistar suggested that EPA extend the compliance determination for 2027 standards if sufficient infrastructure is not available.

Several commenters pointed to other regulations as positive examples of how EPA could address infrastructure availability concerns. For example, MEMA noted that EU's "Alternative Fuel Infrastructure Regulation" requires member states to deploy public heavy-duty charging stations at designated intervals along a specified transit network. UAW pointed to provisions in CARB's Advanced Clean Fleet program that allows compliance extensions for fleets if infrastructure is delayed.

We also received comments from non-governmental organizations electrification groups, electric vehicle manufacturers, States and utilities (e.g., CARB, CALSTART, Colorado Department of Transportation et al., Con Edison, DTNA, EEI, Electrification Coalition, Energy Innovation, the EDF, EPN, ICCT, MFN et al., State of California et al., Tesla, and ZETA) highlighting the many public and private investments and plans in charging infrastructure that have been announced or are underway. The Clean Air Task Force (CATF) et al. and Moving Forward Network et al. said that almost $30 billion specifically for medium-and heavy-duty charging infrastructure has been committed according to Atlas Public Policy, noting that actual totals could be higher in light of recent announcements, and given that private depot charging investments may not be fully captured. Some commenters (e.g., ICCT, and CALSTART as shown in RTC Chapter 6.2) also flagged innovative charging solutions such as charging-as-a-service and mobile charging that can help meet the needs of fleets that experience delays installing EVSE or for which there are other barriers to depot charging.

Citing their own recent studies, CALSTART and ICCT noted that public charging needs will be geographically concentrated in early years, allowing for a phased approach for public infrastructure deployment starting with areas likely to have the most initial demand. The Clean Air Task Force et al. also noted that infrastructure could phase in gradually over time, pointing to estimates in EPA's NPRM analysis that ZEVs may represent only one percent of the entire on-road HD fleet in 2027 and eight percent in 2032 if the proposal is finalized, and still less than 25 percent in 2040.

Some commenters noted that EPA finalizing stringent standards would provide certainty to manufacturers, EVSE providers and others and spur further investments in charging infrastructure. For example, the Clean Air Task Force et al. addressed the 'chicken-and-egg conundrum' (i.e., that EVSE providers will not build out infrastructure without having assurance of demand, but vehicle purchasers will not buy without initial assurance of adequate supporting charging infrastructure) saying EPA should not wait on finalizing standards. CATF et al. cited historical precedent in other areas (e.g., E85 stations to support flex-fuel vehicles) and economic theory to support the point that sufficient charging infrastructure will be built to meet demand. Several commenters—EDF and NACAA– explicitly recommended that EPA reject any "off-ramps" to the stringency of the rule based on infrastructure availability.

Response:

EPA agrees that expanding charging infrastructure is important for enabling greater BEV adoption. How much infrastructure will be needed in future years will depend on a number of factors, including not just the number and distribution of BEVs on the road, but also vehicles' duty cycles and daily energy needs, as well as the charging preferences and behaviors of owners.

Indeed, the significant differences in estimates for how many EVSE ports will be needed to support HD vehicles among the studies highlighted by commenters underscores this point. As discussed in RIA Chapter 2.6 and RTC 6.3.1, we project that the majority of BEVs in the modeled potential compliance pathway for the final rule will charge at depots. However, we have updated our final rulemaking analysis to account for the public charging needs for certain vehicle types, such as long-haul trucks, starting in MY 2030. We discuss infrastructure needs for depot and public charging below.

As discussed in RIA Chapter 2.10.3, EPA estimates that about 520,000 EVSE ports will be needed at depots to support MY2027–MY2032 depot-charged BEVs. This is similar to estimates of depot or overnight charging needs from several studies highlighted by commenters. For example, the ICCT study (Ragon et al. 2023)[398] estimated that 522,000 EVSE ports could meet overnight charging needs of Class 4 to 8 BEVs in 2030 (along with about 38,0000 ports for opportunity charging)[399] while the ATLAS study (McKenzie et al. 2021)[400] estimated that between 470,000 and 564,000 EVSE ports would be needed at depots in the same timeframe (along with significant on-road charging infrastructure). A CRC study[401] published after the close of the comment period estimated that 432,000 EVSE ports would be needed at depots to support medium- and heavy-duty BEVs in 2030, growing to just over 700,000 depot ports in 2032 (along with 46,000 and 92,000 public charging ports, respectively). It is important to note that the scope of these studies, including the years covered and number and types of battery electric vehicles, varies significantly. However, the assumed number of BEVs—one of the biggest factors driving charging needs—for the estimates shown in these studies was generally at least as high or higher[402] than the number of BEVs underlying our estimates of the number of EVSE ports needed at depots (see RIA Chapter 1.6 for more information on these studies.)

The Ricardo study (Kuhn et al. 2023)[403] submitted with EMA's comment estimated that about 1.5 million depot ports would be needed through 2032, almost three times higher than EPA's estimate. There are several reasons for this difference.[404] The largest is that Kuhn et al. projected significantly more depot-charged BEVs (about 1.5 million) by 2032 compared to the approximately 630,000 depot-charged BEVs in EPA's FRM analysis. Part of this difference is

[398] Ragon, Pierre-Louis et al. "Near-term Infrastructure Deployment to Support Zero-Emission Medium- and Heavy-Duty Vehicles in the United States." May 2023. Available online: https://theicct.org/wp-content/uploads/2023/05/infrastructure-deployment-mhdv-may23.pdf.

[399] For this discussion, we present ICCT's estimates of overnight and opportunity chargers. However, ICCT notes some opportunity charging may take place at depots while overnight charging for long-haul vehicles is expected at public charging stations.

[402] The number of 2030 BEVs in the Atlas study was estimated from a graph on p.13 of McKenzie et al. 2021.

[403] Kuhn, Mark et. al. "Feasibility study of EPA NPRM Phase 3 GHG standards for Medium Heavy-Duty Vehicles, Prepared for: Truck and Engine Manufacturers Associations." Ricardo. June 16, 2023. (Submitted with "Comments of the Truck and Engine Manufacturers Association." June 16, 2023.)

[404] We summarize a few key differences, but it is not intended to be a comprehensive list.

that EPA's estimates are for BEVs sold in MY 2027 to MY 2032 only while the Ricardo study also includes estimates for BEVs in 2022 to 2026, though BEVs in these earlier years are a small share (under 10%) of the estimated 2032 on-road fleet. For 2027 and later, Kuhn et al. cites EPA's estimated ZEV sales from the NPRM. However, as discussed in RIA Chapter 2.2.3, the number of Class 2b-3 vehicles included in the NPRM version of HD TRUCS was much higher than the number anticipated to be engine certified and within the scope of this rulemaking. Chassis certified Class 2b-3 vehicles are included in the LMDV rulemaking. We project that these Class 2b-3 vehicles have the greatest BEV adoption rates among vehicles within the scope of this rulemaking and consequently contribute significantly to the total count of depot EVSE ports in the NPRM. This has been updated for the FRM. Additionally, EPA made updates in the final rule analysis that directly impacted EVSE needs. As discussed in RIA Chapter 2.6 and RTC 6.3.1, we have updated our analysis to model some long-range day cab tractors as relying on public charging instead of depot charging starting in MY 2030, which reduces the overall number of depot EVSE ports needed.[405] We also adjusted other assumptions related to dwell times and how many vehicles can share a port, for example, in response to comments and updated information (see RIA Chapter 2.6). For these reasons, we do not think the estimates of EVSE ports that will need to be deployed each year over the next 8 years cited by EMA based on Ricardo's study are an appropriate reflection of the final rule.

As seen in comments, and discussed in RIA Chapter 1.6, estimates of future public charging needs for HD BEVs also vary among studies. We did not directly estimate the number of public EVSE ports that would be needed to support the BEVs that we project to use public charging in our FRM analysis, but rather assumed (in agreement with some commenters, as noted in RTC 6.3.1) that hardware and installation costs for public charging infrastructure would typically be passed onto BEV owners through the charging price. As such, we expect that public EVSE stations will be built to meet demand, though we projected public charging in our FRM analysis to begin with MY 2030 in order to allow several additional years for it to develop (see discussion of lead time in RTC 7 (Distribution). We agree with commenters who said that finalizing strong standards will itself spur investments in charging infrastructure to meet the coming demand—both by fleet owners installing EVSE at depots and by OEMs, utilities, EVSE providers, and others installing public charging stations. As noted in many of the public comments, such an effect is well supported in the literature. See e.g., Comments of Clean Air Task Force at pp. 46-47 and n.189; and Comments of CARB (summarized in RTC Chapter 2.4).

We agree with ICCT and CALSTART that public charging infrastructure can be phased in over time, starting with geographic areas that are likely to have the most BEV demand, and we agree with ICCT that freight corridors are likely candidates within the standard's timeframe. As EMA noted, ICCT's study (Ragon et al. 2023)[406] projects that as much as 85% of the charging needs for long-haul BEVs could be covered by building stations every 50 miles along the National Highway Freight Network (NHFN) for a total of just 844 stations. In a supplemental

[405] We also model sleeper cabs and coach buses as using public charging, but they were not modeled as using depot charging in the NPRM and thus would not have contributed to the depot EVSE port count in the Ricardo study.
[406] Ragon, Pierre-Louis et al. "Near-term Infrastructure Deployment to Support Zero-Emission Medium- and Heavy-Duty Vehicles in the United States." May 2023. Available online: https://theicct.org/wp-content/uploads/2023/05/infrastructure-deployment-mhdv-may23.pdf.

analysis submitted to EPA[407] that assumed 100-mile intervals between stations, ICCT estimated that only between 100 and 210 electrified truck stops on priority corridors may be needed by 2030. See RTC 7 (Distribution) for a discussion on estimating increased demand on the grid in certain high freight corridors.

While dedicated HD charging infrastructure may be limited today, we expect it to expand significantly over the next decade. We appreciate the many comments we received highlighting already announced plans and commitments for both depot and public infrastructure and we have updated our summaries of public and private infrastructure investments in RIA Chapters 1.3 and 1.6, respectively. As commenters noted, Atlas Public Policy estimates that about $30 billion in public and private investments has been committed specifically for charging infrastructure for medium- and heavy-duty BEVs.[408] The U.S. government is making large investments in charging infrastructure through the BIL and the IRA. This includes extending and modifying a tax credit (I.R.C. §30C) that could cover up to 30 percent of the costs for procuring and installing charging infrastructure (subject to a $100,000 per item cap) in eligible census tracts, reducing costs for both HD depot and HD public charging. We acknowledge the point made by TRALA that not all fleets will be able to use or maximize the tax credit due to eligibility restrictions including limitations to certain census tracts. However, a map developed by Argonne National Laboratory shows that eligible census tracts cover a large majority of the U.S.[409] In addition, DOE conducted an analysis to assess the average value of this tax credit for charging equipment that supports heavy-duty BEVs. It estimated that approximately 60 percent of depots and 90 percent of public EVSE may be located in qualifying census tracts.[410] (See RIA Chapter 2.6.2.1.2 for a discussion of DOE's analysis and how we accounted for the tax credit in our analysis of depot EVSE costs.)

In addition, there are billions of dollars in funding programs that could support HD charging infrastructure either on its own or alongside the purchase of a HD BEV. As discussed in RIA Chapter 1.3, this includes dedicated HD programs like the EPA-administered Clean School Bus program, Clean Heavy-Duty Vehicle and Clean Ports programs, and DOT-administered Low or No Emission Vehicle program. It also includes programs for which LD and HD charging are eligible investments such as the NEVI and Charging and Fueling Infrastructure (CFI) programs established under the BIL. In the first awards issued under CFI, there were at least five programs that will explicitly support HD BEV charging, as indicated in Table 1.[411] It is possible that other CFI projects along designated Alternative Fuel Corridors may also have stations that accommodate larger vehicles.

WA: Catalyzing Zero–Emission Drayage Trucking Infrastructure & Opportunities in the Seattle–Tacoma Region	$12,000,000

* Programs that indicate support for both LD and HD BEVs

Although we agree with commenters that states are not required to use NEVI funds for deploying HD charging stations, as they note, FHWA's guidance encourages states to consider station designs and power levels that could support heavy-duty vehicles.[413] In particular, the guidance states that, "Station designs should consider the potential for future expansions needed to support the electrification and charging demands of medium- and heavy-duty trucks, including station size and power levels."[414] We also note that there are multiple rounds of NEVI formula funding. The summary Daimler submitted in Appendix B of its comments, which it characterizes as showing a lack of firm State commitments for HD charging in NEVI plans, only covered FY2022 and 2023 funds. This represents about $1.5 billion of the total $5 billion to be distributed.[415] DOE has funded HD charging infrastructure plans that can help guide phased investment.[416] Significant utility investments of up to $1.7 billion in HD charging infrastructure

have been approved by state regulators.[417] Additionally in March 2024, the Joint Office of Energy and Transportation released the National Zero-Emission Freight Corridor Strategy which aims to target public investment to amplify private sector funding and focus utility and regulatory energy planning and align industry activity in order to prioritize deployment over four phases encompassing infrastructure deployment 2024-2040.[418]

We agree with commenters who state that public charging needs for HD vehicles are different than those for light- and medium-duty vehicles in certain respects. RIA Chapter 1.6.3.2 describes some of the reasons that heavy-duty charging stations may differ from light-duty charging stations; for example: stations that serve heavy-duty vehicles may require more ingress and egress, higher canopies or roofs, and longer charging cords. That said, we also note that some stations designed for light-duty vehicles may be able to accommodate (or be modified in the future to accommodate) medium-duty or heavy-duty vehicles. See RIA Chapter 2.6 for a description of our FRM analysis of charging infrastructure, including the EVSE power levels we considered.

We agree with commenters that it's important for charging stations to be reliable. Our HD TRUCS analysis considers EVSE maintenance costs at both depots and public stations (see RIA Chapter 2.4.4.2). Separately, as described in RIA Chapter 1.3, there are many efforts underway to advance infrastructure reliability in advance of the timeframe of this rule. In January 2024, the first round of grants under FHWA's Electric Vehicle Charger Reliability and Accessibility Accelerator Program were awarded, providing nearly $150 million for repairs or replacements of non-operational BEV charging ports.[419] This will complement efforts of the National Charging Experience Consortium (ChargeX Consortium). Launched in May 2023 by the Joint Office of Energy and Transportation (JOET) and led by U.S. DOE labs, the ChargeX Consortium will develop solutions and identify best practices for common problems related to the consumer experience, e.g., payment processing and user interface, vehicle-charger communication, and diagnostic data sharing.[420] Relatedly, in January 2024, JOET announced $46.5 million in federal funding to support 30 projects to increase charging access, reliability, resiliency, and workforce development.[421]

In their comments, manufacturers suggested that EPA establish mechanisms to reduce the stringency of the CO_2 standards if the infrastructure deployment falls short of the amount necessary to support the rule while other stakeholders opposed this suggestion. After carefully

assessing infrastructure needed for the modeled potential compliance pathway, we conclude that the Phase 3 standards are feasible and appropriate. As described in Preamble II.B.2, EPA commits to actively engaging with stakeholders and monitoring heavy-duty BEV infrastructure deployment. In consultation with other agencies, EPA will issue periodic reports on infrastructure buildout throughout the lead up to the Phase 3 standards in MYs 2027 through 2032. Based on these reports, as appropriate and consistent with CAA section 202(a) authority, EPA may decide to issue guidance documents, initiate a rulemaking to consider modifications to the Phase 3 rule, or make no changes to the Phase 3 rule program.

6.2 Charging Infrastructure Lead Time and Deployment

Comments by Organizations

Organization: Advanced Energy United

To fully unlock these investments, the U.S. will need to undertake permitting reform, to streamline transmission projects and free up interconnection queues. [EPA-HQ-OAR-2022-0985-1652-A2, p. 5]

Digital permitting processes could also alleviate bottlenecks in EVSE infrastructure. The Department of Energy’s SolarApp+ is a model program that has saved customers and contractor valuable time and money on solar installations by standardizing and streamlining permitting processes in localities across the U.S. Policymakers across the country should consider a similar approach to slash soft costs for the permitting of EV charging infrastructure. Investment alone cannot satisfy new demand. We must enable streamlined permitting processes if we are to meet the Biden Administration’s goal of building 500,000 new charging stations. [EPA-HQ-OAR-2022-0985-1652-A2, p. 6]

Organization: American Highway Users Alliance

With the two large-scale rules being advanced at the same time, the feasibility of the proposals is more challenging. It is not as if manufacturing charging stations for heavy-duty, light-duty, and medium-duty vehicles is unrelated. At least some supplies and components are relevant to all; some manufacturers will try to manufacture for heavy-duty, light-duty and medium-duty needs; the critical minerals and related processing are needed for all. But suppliers and electric utilities can only gear up so quickly. This confluence of proposed regulations (further combined with separate and significant regulatory actions by the California Air Resources Board) compounds the challenges for relevant industries to comply. It makes it harder to make favorable assumptions on how quickly changes can be made to facilitate marketplace acceptance of heavy-duty EVs.4 [EPA-HQ-OAR-2022-0985-1550-A1, p. 3]

> 4 Given such complexity, we support the request of the American Petroleum Institute and the American Fuel & Petrochemical Manufacturers for a 90-day extension of the comment deadline in this docket.

Set forth below are concerns of key stakeholders. [EPA-HQ-OAR-2022-0985-1550-A1, p. 5]

Concerns of An Original Equipment Manufacturer

The Volvo Group North America presented at EPA's May 3 hearing on the proposed rule and that May 3 statement is in the docket for this NPRM. Volvo made clear that, with respect to the proposed rule, Original Equipment Manufacturers (OEMs) --

- cannot do their part without assurance that charging station providers and utilities as well as federal, state and local governments can deploy electric and hydrogen fueling infrastructure at scale in a timeline that matches the regulation's requirements. [EPA-HQ-OAR-2022-0985-1550-A1, p. 5]

The statement explains that --

- Our customers will not purchase zero emission trucks unless both the vehicles and the fuels are cost-effective and readily available so as not to negatively impact their business operations (emphasis in original). [EPA-HQ-OAR-2022-0985-1550-A1, p. 5]

Noting that EPA had referenced Volvo in the NPRM for having strong goals for manufacture of heavy-duty EVs, Volvo nonetheless found that it could not support the rule as proposed, stating that it --

- look[ed] forward to working with EPA to develop a final rule that it could support which addresses the interdependence of vehicle and infrastructure availability, and alleviates the sole risk of noncompliance being borne by manufacturers. [EPA-HQ-OAR-2022-0985-1550-A1, p. 5]

Testimony presented to the House Transportation and Infrastructure Committee on May 10, 2023 by the Owner-Operator Independent Drivers Association (OOIDA) strongly made very similar points:

- In April, the agency [EPA] released its Phase 3 greenhouse gas (GHG) proposal. ... With these moves, our members are again facing higher projected costs for new vehicles and insufficient lead-up time to properly implement manufacturing standards. The Phase 3 rule is also a blatant attempt to force consumers into purchasing electric vehicles while a national charging infrastructure network remains absent for heavy-duty commercial trucks. Professional drivers are skeptical of EV costs, mileage range, battery weight and safety, charging time, and availability. It's baffling that the EPA is pushing forward with more impractical emissions timelines without first addressing these overwhelming concerns with electric CMVs.[EPA-HQ-OAR-2022-0985-1550-A1,[p. 7]

Organization: American Petroleum Institute (API)

ii. Infrastructure

1. Leadtime and deployment

API, and many other stakeholders, are concerned about the lack of infrastructure for the HD ZEV market. Even coupled with significant tax credits and incentives, fleet operators and vehicle owners will not purchase new HD ZEVs without a reliable charging infrastructure. For the small number of HD ZEVs that are currently available15, it appears most are utilizing depot charging and the vehicles are largely being used for shorter trips. [EPA-HQ-OAR-2022-0985-1617-A1, p. 11]

15 https://ww2.arb.ca.gov/news/california-approves-groundbreaking-regulation-accelerates-deployment-heavy-duty-zevs-protect#:~:text=There%20are%20already%20about%20150%20existing%20medium-%20and,that%20are%20commercially%20available%20in%20the%20U.S.%20today

EPA notes in the proposal various partnerships and plans to build battery manufacturing plants in the U.S., taking advantage of incentives such as the IRA, one must view these as highly complex projects – in addition to siting and construction, it will take time for these new battery manufacturing facilities to ramp up to full production. Further, there is the probability that not all announced projects will materialize. [EPA-HQ-OAR-2022-0985-1617-A1, p. 11]

Organization: American Trucking Associations (ATA)

Lead times are long

Onsite power availability limits the number of BEVs a site can charge. Regardless of location, all fleets surveyed had similar feedback regarding conversations with utilities. Usually, these conversations can begin years before an order is placed for a BEV. Among surveyed fleets, 40 percent indicated a lead time of 12 to 14 months, and 30 percent received quotes of over 36 months for additional electricity. As a fleet looks to acquire one electric vehicle, they begin to assess the available power capacity available from the utility and on their physical site. Site-level analysis, land use configuration, and long-term power usage planning and facility modifications are all outside the typical competencies of most fleets, require learning by doing, and invariably increase the amount of time it takes to adopt ZEV technologies. [EPA-HQ-OAR-2022-0985-1535-A1, p. 15] [See Docket Number EPA-HQ-OAR-2022-0985-1535-A1, p. 15, for Figure 3]

Organization: California Air Resources Board (CARB)

The NPRM provides several excellent examples of times the nation has adapted to new electrical load including the adoption of A/C and the rapid growth of data centers. The implementation of fleet charging infrastructure is much the same and, it should be noted, not expected to happen overnight. The phase in schedule proposed by U.S. EPA provides ample time for fleets and utilities to plan for and implement charging solutions that meet truck electrification needs. [EPA-HQ-OAR-2022-0985-1591-A1, p.45]

The NPRM requests comment on time considerations for all levels of HD charging infrastructure, including Level 2 up to 350-kilowatt direct current fast charger (DCFC) systems. NPRM states that 2027 provides adequate timing to establish initial levels of depot charging with the expectation that charging capacity will grow over the remainder of the decade. With current CEC MD/HD infrastructure projects, staff are seeing projects take about two to three years from inception to operations. Equipment shipping delays have made up a significant portion of the delays. Those can be expected to improve over time, and, in any event, even with permitting process requirements in California, there is sufficient time to meet U.S. EPA's 2027 and beyond timeframe. With planning, the lead times identified here should be sufficient to support the stringency of the proposed standard and more stringent alternative i.e., values that would reflect the level of ZEV adoption in CARB's ACT regulation. A number of truck OEMs and private companies are already working to provide both depot charging solutions as well as corridor infrastructure solutions. Daimler is leading the Greenlane $650 million investment in West Coast, Southeast Coast and Texas corridors.149 Volvo has a truck-stop agreement150 and is also working on a dealership-based California corridor.151 Hyundai is working to establish a San

Pedro ports to Texas southwest hydrogen corridor.152 TerraWatt is working on a similar fast charging network along I-10 from California to Texas.153 Nikola has an agreement with Voltera to build 50 hydrogen stations.154 Voltera,155 Zeem,156 Electrify America,157 Forum Mobility,158 WattEV,159 and TerraWatt160 among others are developing depot charging projects. Private companies dependent on transportation services have announced both electrification plans as well as vehicle and infrastructure projects moving them toward those goals. USPS has announced 66,000 BEV delivery vehicles by 2028 with all electric purchases from 2026 and an initial order of 14,000 chargers.161,162 Walmart has announced its own network of DCFCs aimed at lighter vehicles,163 an order of 4,500 delivery vehicles164 and a fleetwide 100 percent electrification.165 Amazon has ordered 100,000 BEV delivery vehicles166 with "thousands" of chargers already installed167 including reports of sizable charging depot installations.168,169 Amazon is backing class 8 drayage truck charging depots170,171 and has ordered 329 BEV terminal tractors.172 FedEx has committed to ZE delivery vehicles reaching 50 percent by 2025 and 100 percent by 2030 with a 100 percent ZE full delivery fleet by 2040.173,174 UPS has a 10,000 BEV delivery vehicle order175 and has participated in showcasing innovative charging technologies. DHL Supply Chain has cancelled further orders of diesel terminal tractors, ordered 50 BEV terminal tractors toward a 100 percent ZE fleet by 2025 and ordered BEV semi tractors on their way to a 30 percent ZE on-road fleet by 2030.176 [EPA-HQ-OAR-2022-0985-1591-A1, pp.45-48]

Organization: CALSTART

There are several other important considerations in this rapidly evolving infrastructure build out that we believe is imperative that EPA consider. [EPA-HQ-OAR-2022-0985-1656-A1, p. 22]

Transitional and mobile infrastructure: EPA assumes that depot charging implementation will be limited based on capacity expansion delays from utilities. While utility distribution capacity is a limiting factor in today’s early market, it is showing signs of improvement as utilities gain experience and develop installation templates and frameworks. In the near term, the market has created innovative solutions to these constraints in the form of mobile, temporary, and transitional infrastructure options. CALSTART has recently assembled an inventory of transitional infrastructure solutions which could assist in the deployment of vehicles. Some vehicle manufacturers are coupling this mobile infrastructure with sales of new ZE-MHDVs to bridge the gap between when vehicles are available for delivery and when energy supply system upgrades can be performed, enabling vehicle deployment before permanent infrastructure is fully deployed. Temporary and mobile charging solutions can usually be installed and inspected in less than one month, currently cost under $200,000, and generally can be leased rather than owned. The option saves fleet permitting and installation costs in the short term and enables vehicle deployments to stay on pace. FreeWire, Dannar, Eaton, BP Pulse, Proterra, Veloce Energy, Beam, GM, Lightning, XOS, and Voltera all manufacture systems. [EPA-HQ-OAR-2022-0985-1656-A1, pp. 22 - 23]

Infrastructure services: Additional strategies not being considered in EPA’s scenarios are Trucks-(or Transport)-as-a-Service (TaaS), Charging-as-a-Service (CaaS), and smart charging and load management systems which can manage charging timing, sequencing, and facility loads. At the depot level, several efforts are also underway to aggregate demand among multiple fleets at a co-located site, or to coordinate one fleet across multiple locations. CaaS strategies are expanding around freight facility clusters. Vendors have adopted reservation systems or per-charge solutions which can be built out to supply a co-located set of fleets and, in many ways, can be integrated into new facility design and construction, especially in the logistics and warehousing space, shortening timelines and giving predictable coordination to utilities.44 In our analysis, we find that even conservative estimates of the total amount of shared charging arrangement in key areas can reduce the overall cost of total deployment compared to a maximum deployment scenario. Multiple companies offer these solutions, including but not limited to BP Pulse, Forum Mobility, TeraWatt, WattEV, and Zeem Solutions. [EPA-HQ-OAR-2022-0985-1656-A1, p. 23]

44 https://globaldrivetozero.org/site/wp-content/uploads/2021/03/Taking-Commercial-Fleet-Electrification-to-Scale-White-Paper.pdf

Organization: Daimler Truck North America LLC (DTNA)

- Streamlined Authorization Process for EVSE Installation. DTNA recommends that EPA work with stakeholders to develop model building codes that can be adopted by state and local governments to streamline authorizations for EVSE installation projects. Model codes should address zoning reviews, standardize permit review and inspection processes, run these processes in parallel, and make the processes transparent for fleets. EPA should consider encouraging state and local governments to adopt these model codes as a critical enabler for the rapid build-out of EVSE infrastructure that will be needed to support implementation of the Proposed Rule. [EPA-HQ-OAR-2022-0985-1555-A1, p. 15]
- Educational and Training Programs for Municipal Governments. DTNA recommends that EPA and DOE jointly develop educational and training programs for state and municipal governments to prepare reviewers and inspectors who are unfamiliar with the processes for EVSE project development (including direct current fast charging (DCFC) projects), to ensure that state and local governments are adequately prepared to handle project reviews and authorizations. [EPA-HQ-OAR-2022-0985-1555-A1, p. 15]

Timing for Infrastructure Development

EPA implies that in the next five years, electric infrastructure will be sufficiently built out to support the BEVs required by the Proposed Rule, and that buildout will continue to support substantially higher fleet adoption rates by 2032. Without major regulatory and/or legislative action, DTNA does not believe the infrastructure needed will materialize on the timeline required to enable compliance with the Phase 3 CO2 standards as proposed. New interconnection requests are processed on a first-come-first-serve basis, and transportation electrification competes with all other utility priorities, including decarbonization mandates, resiliency, and other residential and commercial interconnection requests. [EPA-HQ-OAR-2022-0985-1555-A1, p. 50]

Utilities are noting extended timelines for installing critical hardware, both in front of and behind the meter, due to supply chain and other constraints. During the ACF rulemaking process, for example, one electric utility commented to CARB that the lead time for transformers was 40 weeks, and that the lead time customer side meter panels/switchgears was 70 weeks.118 In the Company’s experience, utilities will wait for this hardware to be received to perform other upgrades, and these types of sequential gating events can add significant time to transportation electrification projects. [EPA-HQ-OAR-2022-0985-1555-A1, p. 50]

118 See Comments of Pacific Gas and Electric Company, Proposed Advanced Clean Fleets Regulation (Oct. 17, 2022), https://www.arb.ca.gov/lists/com-attach/370-acf2022-AXEFZFUxUFxRY1Bl.pdf.

In a recent joint presentation by Southern California Edison (SCE), Pacific Gas & Electric (PG&E), and San Diego Gas & Electric (SDG&E) at a California Energy Commission (CEC) workshop, the following table was presented reflecting the utilities’ estimations of typical timelines for distribution capacity improvements: [EPA-HQ-OAR-2022-0985-1555-A1, p. 50] [Refer to Table 17 on p. 50 of docket number EPA-HQ-OAR-2022-0985-1555-A1]

As the scope of the necessary distribution capacity improvements is often unknown until detailed site planning is underway, predicting how long fleets will wait for interconnection requests is challenging. DTNA believes many depot electrification projects may require increases in substation capacity, sub-transmission improvements, or new substations to serve the concentrated power demands. One of DTNA's customers cancelled a BEV deployment because their utility returned a 5-8 year lead time for a new substation. Another fleet's initial ZEV deployment at scale required construction of a 6 MW facility, able to charge 32 Class 8 drayage tractors simultaneously.120 Providing these capacities to many sites clustered together, as will be required to support concentrated freight hubs and logistics centers, is likely to require substantial grid upgrades. [EPA-HQ-OAR-2022-0985-1555-A1, pp. 50-51]

120 See 'Schneider's Electric Heavy-Duty Trucks Start Off on Regional Routes' (June 8, 2023) https://www.truckinginfo.com/10200304/new-electric-heavy-duty-trucks-start-off-on-regional-routes.

Because of California's climate policies, including Executive Order N-79-20 requiring all new passenger car and truck sales to be zero emission by 2035, and CARB's ACT and ACF regulations, a number of transportation electrification planning procedures and make-ready programs have already been implemented or have begun to develop in California. Thus, it is important to keep in mind that electric utilities in other states may generally be less prepared to respond to transportation electrification requests. [EPA-HQ-OAR-2022-0985-1555-A1, p. 51]

In the Company's experience, fleets typically purchase their vehicles 6 - 12 months ahead of need, and often utilities require proof of purchase to show the fleet is committed to move forward with infrastructure development. DTNA has experienced fleet customers cancelling BEV orders when utilities respond to interconnection requests with multi-year lead times. Many of these cancellations include the return of incentive program funds, such as HVIP or Clean School Bus Program vouchers. Purchasers who apply for and are granted HVIP funds for example, must redeem the voucher within 90 days, or apply for three-month extensions up to 540 total days.121 It is not uncommon for infrastructure projects to exceed the 540 day timeline, which would require the fleet to take delivery of BEVs with no charging infrastructure, resulting in a stranded capital investment and no air quality improvements. One of DTNA's customers cancelled an order and returned HVIP funding for 20 Class 8 tractors when their utility estimated their site would take 3 years (1,095 days) to energize. [EPA-HQ-OAR-2022-0985-1555-A1, p. 51]

121 See Implementation Manual for the Hybrid and Zero-Emission Truck and Bus Voucher Incentive Project (HVIP) (March 15, 2022) at 20, https://californiahvip.org/wp-content/uploads/2022/03/HVIP-FY21-22-Implementation-Manual-03.15.22.pdf.

Furthermore, it is unlikely that fleets will make major investments in long-term infrastructure that require commitments longer than the vehicle trade cycle. For example, if a fleet plans for a 4-year vehicle product cycle, but the infrastructure lead time is 4 years for an increase in substation capacity, by the time the infrastructure is available, the fleet will be working with the next generation of vehicles, which may or may not have the same power needs. Similarly, where utilities have made capital investments in infrastructure, fleets may be required to commit to a certain utilization rates for 5 to 10 years. Fleets working with shorter trade cycles, contracted routes, or leased properties are likely to see operational changes well before they are released from their utilization obligations. Committing to minimum utilization rates may be a major financial risk for fleets, which is unaccounted for in the cost estimates in the Proposed Rule. [EPA-HQ-OAR-2022-0985-1555-A1, p. 51]

Fleets have also cited the lack of firm interconnection dates as a major deterrent to committing to long-term infrastructure projects. DTNA appreciates that infrastructure buildout projects are difficult to project, and may encounter unanticipated delays, but fleets are unable to make fleet transition plans, place orders for electric vehicles, or apply for funding without firm interconnection timelines. Some of DTNA's fleet customers committed to ZEV deployment have sought temporary power solutions to address these timeline issues. However, temporary power solutions incur additional costs and generally must be paid up front by the fleet. For instance, SDG&E Rule 13 ('Temporary Service') provides that an applicant for temporary service 'shall pay, in advance or otherwise as required by the utility, the estimated cost installed plus the estimated cost of removal, less the estimated salvage of the facilities necessary for furnishing service.'122 [EPA-HQ-OAR-2022-0985-1555-A1, pp. 51-52]

122 See SDG&E Rule 13, https://www.sdge.com/sites/default/files/elec_elec-rules_erule13.pdf.

In addition to electrical interconnection complexities, fleets must navigate their local building codes and permitting processes. As noted by the Northeast States for Coordinated Air Use Management (NESCAUM) in a 2019 paper on DCFC deployment, 'the permitting process for DCFC stations is sometimes lengthy and fraught with delays due to unfamiliarity with the technology, protracted zoning reviews, and undefined requirements for permitting DCFC. As a result, the DCFC permitting process can be resource-intensive for both applicants and [authorities having jurisdiction (AHJs)].'123 Since the NESCAUM paper was published, DTNA's eConsulting team has encountered many AHJs that lack defined processes for DCFC installation projects and the expertise needed to move projects along quickly. [EPA-HQ-OAR-2022-0985-1555-A1, p. 52]

123 NESCAUM, 'Preparing Our Communities for Electric Vehicles: Facilitating Deployment of DC Fast Chargers' (May 2019), https://www.nescaum.org/documents/dcfc-permit-streamlining-whitepaper-final-5-14-19.pdf.

Fleets may encounter additional complications related to EVSE installation that impact BEV technology adoption rates. For example, when converting vehicles to BEVs, the infrastructure needed for charging equipment takes up physical space that could otherwise be occupied by additional trucks. Figure 4 below illustrates the components needed for combined charging systems (CCS). Megawatt Charging Systems (MCS) require additional space for installation as well. [EPA-HQ-OAR-2022-0985-1555-A1, p. 52] [Refer to Figure 4 on p. 53 of docket number EPA-HQ-OAR-2022-0985-1555-A1]

Figure 5 below shows an overhead view of one such fleet operation in Southern California where physical space will limit the number of BEVs that can be deployed. This site will require additional power poles, new transformers, and new switchgears to support only a fraction of the fleet. To convert additional tractors to BEVs, fleets working with constrained spaces like the site shown below will likely be required to purchase additional real estate. Recently, Denver's Regional Transportation District (RTD) announced the cancellation of an $18 million deal for new electric buses, citing space constraints for charging and EVSE equipment.124 RTD officials estimated they would need an additional $85 million to construct a new building to support this deployment. Space constraint issues of this type—and the associated costs—are not accounted for in EPA’s cost estimates for the Proposed Rule. [EPA-HQ-OAR-2022-0985-1555-A1, p. 53] [Refer to Figure 5 on p. 53 of docket number EPA-HQ-OAR-2022-0985-1555-A1]

124 See Denver Post, ‘RTD cancels purchase of 17 electric buses it doesn’t have space to maintain—and orders fleet transition strategy’ (April 26, 2023), https://www.denverpost.com/2023/04/26/regional-transportation-district-battery-electric-buses-contract/.

DTNA’s fleet customers have faced a number of similar challenges, which have resulted in order cancellations or reductions, revealing the following issues :

- Fleet customers have been quoted 1.5 - 8 years for depot site electrification for deployments that are modest compared to the scale of those discussed in the Proposed Rule.
- Depot installation projects are complex and resource intensive for fleets, utilities, and AHJs. DTNA often observes differing views of roles and responsibilities in transportation electrification projects and a lack of expertise in this developing space.
- Infrastructure lead time is not synchronized with funding program lead time, leading fleets to return vouchers they spent resources securing, highlighting that available funding and the calculated TCO is only part of the adoption equation.
- Utilities and fleets sometimes cannot come to agreement on contractual terms, including load restrictions, managed charging, and guaranteed utilization time periods. It is unlikely these issues will be resolved without significant regulatory or legislative changes.
- State and municipal building codes and processes lack transparency and add significant time to depot electrification projects. [EPA-HQ-OAR-2022-0985-1555-A1, p. 54]

EPA Request for Comment, Request #59: Because of these projected increases and the funding available through the BIL and IRA, and as we are proposing more stringent standards that begin in MY 2027, our assessment supports that there is sufficient time for the infrastructure, especially for depot charging, to gradually increase over the remainder of this decade to levels that support the stringency of the proposed standards for the timeframe they would apply. We request comment on time considerations for all levels of HD charging infrastructure, including Level 2 up to 350 kW DCFC systems.

- DTNA Response: As discussed in Section II.B.3 of these comments, DTNA is concerned the BIL and IRA may not have as significant of an impact on the HD ZEV market and infrastructure development as EPA is projecting. With respect to available electrical grid distribution capacity, there is little transparency to understand what size projects will trigger major distribution system upgrades, and how long these upgrades will take. In working with early adopters, DTNA has had fleet customers with relatively modest initial deployments quoted 5-8 years for the required grid upgrades. Other fleet customers have been quoted 8-12 years for initial deployments that require major distribution system upgrades. Further, EPA should consider the need for charging speeds up to 2 MW to enable use in applications with short dwell times and high energy usage, and the buildout of public charging infrastructure that is required to support small businesses and fleets where depots cannot be constructed, as discussed in Section II.B.3 of these comments. [EPA-HQ-OAR-2022-0985-1555-A1, p. 169]

Organization: Dana Incorporated

Charging Infrastructure and Grid Capacity

Another key issue in the success of the proposed rule is whether charging infrastructure, power demands, and hydrogen fuel (when/if available) will satisfy the needs for all ZEVs in every state to meet trucking's charging needs and vehicle adoption rates. A number of recent studies have raised concerns about increased demand on the electricity grid driven by vehicle electrification. EPA should conduct annual reviews to determine whether charging infrastructure and grid capacity are expanding to meet growing needs in those states (such as California) where electrification is likely to proceed most quickly. EPA should also conduct studies to analyze the impact of new federal incentives on the cost of producing hydrogen, which could play an important role for long-haul trucks. [EPA-HQ-OAR-2022-0985-1610-A1, p. 2.]

Charging Infrastructure for Fleet Operations

Charging infrastructure will remain an issue for several reasons and Dana, like many firms in the automotive industry, remains concerned that the charging infrastructure will not develop quickly enough to support the projected ZEV adoption rates. First, there are backlogs of suppliers to provide DC charging terminals for use in public applications, and much of the current public-sector funding focuses more heavily on developing charging infrastructure for light-duty vehicles rather than heavy-duty trucks. Second, the level of power needed at a service center to adequately charge 30-50 HD BEVs would require investment beyond what a typical fuel supplier can provide today. In addition, according to a study from the utility, National Grid, a large service station designed to provide charging for both cars and trucks would need to provide 19 megawatts of peak power by 2035 or 30 megawatts by 2045 — putting significant strain on the grid and creating the potential for peak-demand surcharges. A 2022 study by the American Transportation Research Institute found that electrification of the trucking sector would put a heavy strain on the generating capacity of U.S. utilities. Additionally, HD BEV battery packs will be significantly larger than what is required on light and medium duty applications, which further presents a challenge for charging time required to make them useful fleet vehicles with minimum downtime. A final complication is the potential need for hydrogen fueling infrastructure for long-haul applications. The European Union, for example, has set a target of having a network of hydrogen fueling stations along key European trunk routes by 2031. From Dana's viewpoint the pace of infrastructure development will have a significant impact on the development pipeline and adoption rate of ZEVs. [EPA-HQ-OAR-2022-0985-1610-A1, p. 2]

Organization: National Association of Chemical Distributors (NACD)

Current Electric Vehicle Infrastructure

A significant aspect of the proposed rule is the need for heavy-duty truck manufacturers to adopt additional ZEVs into their fleets in order to meet emission requirements. While NACD supports the adoption of new zero emission technologies to reduce the carbon footprint of the trucking industry, the United States' charging infrastructure makes the mandating of rapid adoption impractical. [EPA-HQ-OAR-2022-0985-1564-A1, p. 4]

When examining the expected number of ZEVs on the road, S&P Global Mobility estimated that the number of chargers will need to be increased four-fold by 2025 and eight-fold by 2030.7 Also, these estimates were made before the EPA's Phase 3 GHG emission proposals, meaning the true need for additional charging stations will likely be much higher if the rules move forward as written. [EPA-HQ-OAR-2022-0985-1564-A1, p. 4]

7 S&P Global Mobility, "EV Chargers: How many do we need?," spglobal.com, S&P Global Mobility, https://www.spglobal.com/mobility/en/research-analysis/ev-chargers-how-many-do-we-need.html

It is not practical to expect the necessary charging stations to be built in time to handle the increase in ZEV heavy-duty vehicles that would be required under this proposal. Constructing these stations can take months or even longer when taking into account the necessary electrical fittings. The California Air Resources Board acknowledged this in their Advanced Clean Fleets rule, allowing for extensions of up to five years for certain truck carriers that have electrification issues when building ZEV charging stations. It is not realistic to expect charging infrastructure to accommodate the increase in heavy-duty ZEVs by Model Year 2027; more time is needed. [EPA-HQ-OAR-2022-0985-1564-A1, p. 4]

This complicated issue requires significant lead-time due to the amount of coordination among states, those responsible for construction, and other stakeholders. NACD urges the EPA to adopt less strict emission standards that adopt ZEVs more gradually in order to allow for the United States charging infrastructure to develop the required capacity. [EPA-HQ-OAR-2022-0985-1564-A1, p. 4]

Organization: National Automobile Dealers Association (NADA)

1. HDV dealer and purchaser infrastructure costs and lead times.

As mentioned, dealerships are investing billions in the infrastructure and equipment to sell and service ZEV HDVs. Customers will also require infrastructure at their facilities and an existing and reliable public refueling infrastructure to support the effective use of ZEV HDVs. A typical CMV dealership would require the following facility and infrastructure upgrades to sell and service ZEV HDVs.:

- Two EV chargers (Level 2 or DCFC) to ensure availability for sales and service;
- Service lifts with higher weight capacity;
- Service bays that can accommodate additional lift heights of approximately six feet to facilitate high-voltage battery maintenance and removal;
- Battery storage and quarantine containers16; and
- Workplace safety and emergency response training to navigate the potential dangers associated with vehicle high-voltage systems and components. [EPA-HQ-OAR-2022-0985-1592-A1, p. 9]

16 EV battery temperature must remain at approximately 70 to 75 degrees, depending on the manufacturer. When a vehicle comes in for repair, a battery may be removed or disconnected from the low-voltage system (12-volt) which maintains the battery temperature. For example, for any body work that requires painting, a battery may need to be removed due to high temperatures achieved within a paint booth, especially during the curing of the paint. Any removed battery requires special storage. The optimal scenario would be a storage/building outside facility that is temperature-controlled and has a ventilation system. Current National Highway Transportation Safety Administration guidelines suggest 50 feet of separation between a stored battery and a building or another vehicle. Ventilation is very important for EV

batteries; there must be ventilation around the battery, including underneath it. When a high-voltage battery is damaged, it can leak fluoride gas, which is heavier than air, causing it to sink and not rise. This gas is highly flammable, and this situation can be created by a chemical reaction in the battery cells before a thermal runaway (or high-voltage battery fire) occurs.

The costs involved in these investments can easily exceed $1,000,000 per dealership. Ultimately, the ability and timeline to make facility upgrades and install chargers will vary significantly by dealership location, the utility upgrades necessary, and permitting lead times. In an initial survey of ATD members, dealership charger installation timelines ranged from less than one year to greater than three years. Some locations will need minimal to no utility upgrades for charger installation, but in most cases, electrical infrastructure (e.g., trenches, distribution transformers, switchboards, and conduit) will need to be upgraded or installed to accept the high-power service necessary to support several chargers. EPA correctly notes power needs as low as 200 kW could trigger a requirement to install a distribution transformer.17 However, EPA fails to acknowledge that the electric sector is facing significant supply chain issues for distribution transformers with the average lead time for transformer delivery at 12- 18 months (which is expected to increase).18 Dealerships requiring distribution transformer upgrades have stated that it has increased their charger installation lead times to between three and five years. In effect, they will be unable to begin selling and servicing ZEV HDVs until these upgrades are completed. Further, dealerships that rent or lease their buildings or property are generally unable to even install chargers due to landlord restrictions on property and building modifications. [EPA-HQ-OAR-2022-0985-1592-A1, pp. 9 - 10]

17 88 Fed. Reg. at 25,983.

18 Robert Walton, Utilities sound alarm over distribution transformer shortage as procurement times surpass 1 year and costs triple, Utility Drive (Dec. 19, 2022). Further, the electric sector anticipating a final rule from the Department of Energy which would increase the distribution transformer efficiency standards, and shift production to an entirely different type of steel, for distribution transformers further exacerbating this issue. See also Paul Ciampoli, Proposed efficiency standards for distribution transformers would worsen shortages, POWER GRID INTERNATIONAL (March 31, 2023).

ZEV HDV fleets and owner/operators will also require facility and infrastructure upgrades. Their needs will vary, but in many cases will meet or exceed those of HDV dealerships. This is particularly true for fleets that perform their own service work or engage in depot charging during off hours. For example, a local transit agency with 15 ZEV school buses may need several ZEV-ready service bays, parking lot upgrades, and several chargers for fleet charging. [EPA-HQ-OAR-2022-0985-1592-A1, p. 10]

It’s worth noting that dealership investments are being made now in preparation for an expected future marketplace. But customers are asking whether ZEV HDVs will be affordable and will meet their needs and expectations. Only when ZEV HDVs and related refueling infrastructure costs “pencil out” will customers begin to adopt them. EPA must strive to accurately assess the costs and timing of necessary ZEV HDV refueling infrastructure. [EPA-HQ-OAR-2022-0985-1592-A1, p. 10]

Organization: NTEA - The Association for the Work Truck Industry

MY 2027 Target - EV Infrastructure Needs

The proposal calls for 20% of vocational trucks be a ZEV by MY 2027. This time frame does not seem possible given the resources needed to achieve such a goal in a compressed amount of time. [EPA-HQ-OAR-2022-0985-1510-A1, p. 4]

As an industry, companies involved in the manufacture and distribution of work trucks (manufacturers of truck chassis, bodies, equipment and final assembly) will require EV charging equipment and power that has not previously been required for their facilities. While these producers of work trucks may not need the recharging capacity of a major truck fleet, they will need to provide charging for all of the EV chassis at their facility for assembly or alteration. [EPA-HQ-OAR-2022-0985-1510-A1, p. 4]

Much like truck dealers who will need EV charging infrastructure, anecdotally, NTEA has been informed that one of the biggest initial challenges is the availability of electricity from local utilities. In some cases, EV charging equipment is available but they can't yet be installed without agreement for power from the utility company, which appears could in some cases be multiple years away. [EPA-HQ-OAR-2022-0985-1510-A1, p. 4]

Based on the current statutory and regulatory landscape, it is assumed that the highest initial energy needs for medium- and heavy-duty vehicle charging is likely to occur in those states that have adopted California's Advanced Clean Trucks rule. While prioritizing charging infrastructure along freight corridors within these states may be a prudent approach, many vocational trucks are not necessarily involved in moving freight but rather accomplishing work tasks at whatever location is required – whether it be along a freight corridor or on a side street or in a rural area. [EPA-HQ-OAR-2022-0985-1510-A1, p. 4]

Given the long lead times involved in building power generation capacity and electric transmission systems, the NTEA questions if the aggressive time frames being mandated for the phase-in of medium and heavy-duty vocational trucks is possible. Will the operators of the wide variety of work trucks have access to charging when and where they will need it in order to complete their vocational missions within the existing timeframe? [EPA-HQ-OAR-2022-0985-1510-A1, p. 4]

Organization: Schneider National Inc.

The EPA Proposed Rule makes no allowance for infrastructure lead time.

- As we experienced in building our first large-scale zero emissions electric charging depot in southern California, lead times for infrastructure enhancements and ZEV charging/filling equipment are long. The project process includes engineering, site design, permitting, construction, installation and testing, all of which can take a significant amount of time. There are also many elements of this process that are outside the control of the party who is installing the infrastructure, all of which can negatively affect the construction time (e.g., out of stock parts, utility improvement timelines, approvals, etc.). Our experience is that the overall process can range from 24-48 months per location for owned sites.
- Motor carriers generally have limited space available at owned and leased facilities. As we have experienced at our southern California location, charging infrastructure takes up a significant amount of space. Adding ZEV charging/filling capabilities will negatively

impact the amount of usable space, requiring carriers to add additional property to their real estate portfolios.

- Lead times for leased sites will likely be longer and add layers of complexity. Additional time will be necessary to seek and obtain formal approvals from property owners to add the infrastructure and equipment.
    - In all likelihood, this could add 6-12 months to the lead time of an individual project. Further, there will certainly be instances where the property owner does not desire to add the infrastructure, thus requiring the carrier to find an alternate location to charge/fill and incur additional real estate costs.
- As the deadline to meet the EPA's requirement comes closer, and as more companies push to meet the deadline, lead times in general will become longer. The ability to meet the deadline will become progressively more challenging due to substantial and increasing competition for limited resources and equipment. [EPA-HQ-OAR-2022-0985-1525-A1, p. 3]

Organization: South Coast Air Quality Management District (South Coast AQMD)

As mentioned in the comment above, zero emissions charging and fueling infrastructure poses the most significant barrier to deployment of zero emissions heavy-duty vehicles at scale. The difficulty in installing this infrastructure varies considerably from site to site. Our early experience has shown that there are many factors that require improvement to speed the transition to zero emissions. Regulations like the proposed Phase 3 rule are helpful, but additional action is needed beyond requirements for vehicle and engine manufacturers. Much of these improvements are best addressed at a local or state level, however the federal government can be a critical partner to speed the transition too. [EPA-HQ-OAR-2022-0985-1575-A1, p. 3]

As a first example, states regulate their own utilities and building codes are often set at the local level. However, most of these regulations and policies were not designed to address the rapid buildout required with zero emission vehicles (e.g., the ability for third party-providers to resell electricity for heavy duty charging stations, the role of demand charges, etc.). There are many potential policy approaches to help streamline infrastructure buildout. At minimum, the federal government can track the innovative solutions that different states and localities are taking to speed the buildout of charging/fueling infrastructure and make the information readily available for consideration in other areas. Key metrics should be tracked to see the effect these policies have, such as the total time needed to install infrastructure for different kinds of sites. [EPA-HQ-OAR-2022-0985-1575-A1, p. 3]

Organization: Tesla, Inc. (Tesla)

Lead Time and Rapid Deployment Mean Other Factors Are Not Barriers to More Stringent Standards

While Section 202(a)(3) directs the agency to give appropriate consideration to cost, energy, and safety factors associated with the application of such technology, these considerations must take place under the same technology forcing context utilized in assessing the vehicle technology. Similarly, the substantial lead time provided to the deployment on new heavy-duty technologies under the statute further favors a similar context for assessment of considerations such as the adequacy of the BEV charging infrastructure. [EPA-HQ-OAR-2022-0985-1505-A1, p. 26]

Assessed under this rubric, any concerns about charging infrastructure adequacy should not dampen the agency's move forward with a stringent heavy-duty rule. Economics dictate that build out of charging infrastructure follows deployment of BEVs, as without adequate vehicles on the road investment in such infrastructure risks becoming a stranded asset. Initial customers will focus on operations that allow heavy-duty BEVs to return to the depot after a shift, thus the focus will be on building out charging infrastructure at truck depots in the near future. [EPA-HQ-OAR-2022-0985-1505-A1, p. 27]

At the outset, nothing in the statute directs EPA to give great weight to infrastructure or similar considerations in evaluating whether a standard can be implemented in a time period the Administrator finds sufficient 'to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such period.'194 This is in contrast to other portions of the statute, which specifically direct the agency to consider, for example, 'the impact of renewable fuels on the infrastructure of the United States, including deliverability of materials, goods, and products other than renewable fuel, and the sufficiency of infrastructure to deliver and use renewable fuel.'195 [EPA-HQ-OAR-2022-0985-1505-A1, p. 27]

194 42 U.S.C. 7521(a)(2).

195 42 U.S.C. 7545(o)(2)(B)(ii)(IV).

In any event, adequate charging infrastructure will be available. EPA's analysis of this issue should focus on when the standards come into effect: to the extent EPA has authority to consider infrastructure issues, it would be under its authority to have the regulation take effect 'after such period as the Administrator finds necessary to permit the development and application of the requisite technology,'196 which necessarily entails a predictive judgment about what the infrastructure capacities would be in the future (including in response to the proposed rule), rather than being limited to the status quo. For example, in the past EPA has considered whether technology would 'would be perfected early enough to allow its mass production and installation.'197 [EPA-HQ-OAR-2022-0985-1505-A1, p. 27]

196 42 U.S.C. 7521(a)(2) (emphasis added).

197 NRDC v. EPA, 655 F.2d 318, 324 (D.C. Cir. 1981).

Organization: Truck Renting and Leasing Association (TRALA)

Charging Infrastructure and Grid Capacity Challenges and Constraints

Fleets wanting to install charging infrastructure are confronted with permitting delays, insufficient power, long installation periods, large monetary outlays, and parking space reductions. TRALA members interested in installing chargers at rented or leased facilities are subject to agreements that depending on the landlord, restrict these types of tenant improvements. If facilities have inadequate power or layouts, real estate acquisition can add one to two years onto many infrastructure development and construction projects. Further illustrating the lengthy lead time to expand charging infrastructure, Pacific Gas and Electric indicated in public comments to the ACF rule that the utility 'strives to interconnect projects in a timely manner, however mid-sized projects such as new distribution circuits or substation modifications can take 2-3 years. Larger projects that require new substations or transmission lines requiring licensing, permitting, or land rights acquisition can take 7 or more years.' 1 [EPA-HQ-OAR-2022-0985-1577-A1, pp. 3-4]

Organization: Volvo Group

Infrastructure

In 2007 and 2010, new Particulate Matter (PM) and NOx regulations required fueling related changes to meet new regulatory standards (availability of Ultra Low Sulfur Diesel and Diesel Exhaust Fluid respectively); however, these cases were far less onerous than requiring the development and adoption of an entirely unfamiliar new fuel with unknown operational implications. [EPA-HQ-OAR-2022-0985-1606-A1, p. 6]

In the case of EPA's Phase 3 proposal, the availability of fuel (and its requisite infrastructure) is the most significant factor influencing the speed of ZEV penetration in the marketplace and thus, OEMs' ability to comply with the regulation. Many factors including supply chain delays, workforce training and high costs will all affect heavy-duty ZEV adoption; but fleets can't use their vehicles if they can't fuel them, and if they can't use them, they won't buy them. Through our Volvo LIGHTS project (Low Impact Green Heavy Transport Solutions) and experience deploying BEVs across 12 different states and provinces, we've experienced a mix of factors contributing to infrastructure delays ranging from permitting delays, incongruence between infrastructure and vehicle funding programs, energization delays, and supply chain challenges for charger and electrical components. These issues must be addressed if OEMs are to be held responsible for meeting ZEV penetration levels on a national level. [EPA-HQ-OAR-2022-0985-1606-A1, p. 6]

Of all states, California is by far the best positioned to achieve its Heavy-Duty (HD) ZEV penetration goals because of its financial and policy inducements. Yet several Volvo fleet customers have had to wait over 18 months to have chargers built and energized at their sites. This experience makes the California Energy Commission's AB2127 report estimate that "an additional 157,000 chargers are needed to support 180,000 medium- and heavy-duty vehicles anticipated for 2030" seem unrealistic. [EPA-HQ-OAR-2022-0985-1606-A1, p. 6]

It is important to note that these challenges can and will be addressed over time. Involvement in the Volvo LIGHTS project and other ZEV deployments in the state have helped California utilities better understand how to service this new market. Likewise, the California Air Resources Board (CARB) and the California Energy Commission (CEC) began working in 2018 to develop a joint project solicitation that packaged incentives for vehicles and infrastructure together to help fleets coordinate public funding needs. [EPA-HQ-OAR-2022-0985-1606-A1, p. 7]

For example, customers are routinely quoted 40 to 50-week lead times for transformers if site upgrades are needed to support fleet electrification. In addition, lead times for electric vehicle supply equipment (EVSEs, or "chargers") are often 30-50 weeks and ensuring everything shows up at the same time is nearly impossible in today's environment.3 Many of the internal components of an EVSE are common with photovoltaic (PV, or solar) inverters, which means that component supplies are further stressed from industries even outside of vehicle and charger manufacturing. [EPA-HQ-OAR-2022-0985-1606-A1, p. 7]

> 3 Smith, G. (2023, May 8). Charging infrastructure delays temper rollouts of battery-electric trucks. Trucknews.com. Accessed on 14 June 2023 at https://www.trucknews.com/sustainability/charging-infrastructure-delays-temper-rollouts-of-battery-electric-trucks/1003174982/?utm_medium=email&utm_source=newcom&utm_campaign=TruckNewsDaily&utm_content=2023050902809&hash=b8dc1bbe8cbdd5dc1fa8f2d3d3026004.

The cost of charging infrastructure for fleets is another issue influencing ZEV penetration. California has established an infrastructure incentive program and several utilities in the state have established make-ready programs to help offset fleet concerns about long term profitability/viability. While most early adopters have installed chargers at their own facilities, many smaller fleets and independent owner-operators will need to rely on the availability of public charging. Over the last two years, a handful of public chargers have been developed; however, their number will likely remain low for some time since concern over long term viability of the business model will continue as long as the utilization level needed to be profitable remains unknown. [EPA-HQ-OAR-2022-0985-1606-A1, p. 7-8]

EPA Summary and Response:

Summary:

Vehicle manufacturers and others raised concerns about ongoing challenges to deploying charging infrastructure and the associated lead times, which commenters said could impede successful adoption of BEVs at levels they believe would be needed under the proposed standards. In particular, they highlighted three ongoing challenges that could extend lead times: permitting, supply chain issues, and utility interconnection. Additional concerns included space constraints and competing demands. Other commenters asserted there is sufficient lead time to deploy charging infrastructure.

Permitting was identified as a potential source of delays by Advanced Energy United, DTNA, TRALA, Schneider and Volvo. Several commenters suggested that permitting reform was needed to standardize and streamline the process. For example, Advanced Energy United suggested digital permitting process could save time and costs, pointing to DOE's SolarAPP+ as a positive example. DTNA suggested that EPA partner with others to help to advance this effort, e.g., by creating model building codes and training programs for state and municipal employees engaged in permitting and inspection. The SCAQMD likewise commented that building codes and other relevant state and local policies should be examined with EVSE deployment in mind, and that the federal government can help track and share best practices.

Several commenters discussed supply chain considerations. For example, CARB stated that delays in shipping EVSE units contributed to an overall lead time of 2 to 3 years for recent California Energy Commission medium- and heavy-duty projects but noted that it expects this issue to improve. Dana Incorporated expressed concerns about supplier backlogs for DCFC equipment while Volvo suggested a 30- to 50-week lead time is typical for EVSE. Commenters also expressed concern about purported supply chain delays for power sector equipment, particularly transformers. For example, NADA stated that current lead times of 12 to 18 months for transformers could increase, while Volvo noted a 40- to 50-week lead times being given as estimates to customers. DTNA commented that in addition to transformers, panels and switchgears may experience long lead times, providing one utility's estimate of 70 weeks as an example.

Many commenters stated that utility interconnection—particularly when upgrades to the distribution system are needed—extend lead times. For example, ATA conducted a survey of fleets finding that, "Among surveyed fleets, 40 percent indicated a lead time of 12 to 14 months, and 30 percent received quotes of over 36 months for additional electricity." TRALA cited a Pacific Gas and Electric comment for a California rulemaking that interconnection times of two to three years may be needed for mid-size projects with 7 or more years for projects involving new transmission lines or substations. NTEA noted that agreements from utility companies to install power can take multiple years in some cases. DTNA provided multiple examples of long lead times experienced by its customers, noting they have been given quotes of 1.5 to 8 years for electrifying depots that "are modest compared to the scale of those discussed in the Proposed Rule." DTNA also discussed challenges connected to the uncertainty in interconnection times, lack of experience among fleets and utilities, and other factors.

In addition, multiple commenters discussed space constraints as a barrier or source of delay for infrastructure deployments as well as unique challenges for fleets that lease property for depots. For example, Schneider National Inc. said it experienced overall lead teams of 2 to 4 years for depot charging station projects but posited that an additional 6-12 months may be needed for projects on leased sites to factor in time to work with the property owner. DTNA cited an announcement by Denver's Regional Transportation District to cancel an electric bus project due to space constraints and related costs, which DTNA said were not accounted for in the proposed rule.

Commenters also said that competing demands could further extend timelines for heavy-duty BEV charging infrastructure buildout. For example, the American Highway Users Alliance noted that both EPA's proposed light- and medium-duty vehicle rule and this heavy-duty proposal would take effect at the same time (while California regulations are also in effect), increasing the overall demand for new infrastructure from manufacturers and utilities.

Several commenters were generally cautious about the charging infrastructure deployment tasks ahead. ATA mentioned there is a learning curve associated with aspects of deployment like site-level analysis and planning for long-term power usage that can increase the time it takes to adopt ZEV technologies. Dana Incorporated noted challenges related to the scale of charging infrastructure and grid needs and suggested that EPA conduct annual reviews to determine whether they are expanding at a sufficient pace, particularly in states where BEV adoption is likely to be concentrated in early years. NACD suggested that it is not practical to build charging stations to handle the proposed adoption levels by MY 2027 due in part to the levels of coordination required among states and other stakeholders. Several commenters noted the high costs of these investments and resources required, which they indicated are new for some stakeholders.

On the other hand, both Tesla and CARB said that lead time for charging infrastructure deployments would be sufficient to support BEVs under the stringency levels in EPA's proposal, with Tesla stating the infrastructure would be available in time and CARB pointing to many ongoing or planned depot charging projects. CALSTART acknowledged that distribution upgrades can be a source of delay, but also stated that utilities are gaining experience and working to reduce lead times. CALSTART also highlighted temporary and mobile solutions that fleets can use to support BEVs while depot charging is being deployed, noting that these can typically be leased and deployed in under a month. They also encouraged EPA to consider alternate business models such as charging-as-a-service, in which charging solutions (and any associated lead times) are provided or handled by a third party or vendor as opposed to the fleet customer and noting that shared charging facilities can also reduce total deployment costs compared to individual depot station buildouts.

Response:

EPA recognizes that it takes time for individual or fleet owners to develop charging site plans for their facility, obtain permits, purchase the EVSE, and have it delivered and installed. We acknowledge, as we had in the NPRM,[422] that the longest lead times will likely be for high-power stations that require significant upgrades to the distribution system (such as to feeders or substations). This is consistent with the comments we received. We also acknowledge comments on supply chain challenges, in particular with respect to lead times for transformers. Lead times associated with distribution system upgrades (including transformers), utility interconnection and other grid topics are covered extensively in RTC Section 7 (Distribution). Here we discuss lead time issues around permitting, EVSE supply, and charging infrastructure more broadly. As further discussed in preamble Section II.D.2.iii and II.F.3, and RIA Chapters 1 and 2, and this response, we assessed these lead time issues and based on that assessment took lead time into account in a balanced and measured approach to setting the Phase 3 final standards.

With respect to permitting, we agree with commenters that streamlining the process and promoting best practices could reduce infrastructure deployment times. As noted in RIA Chapter 1.6.3, permitting generally falls within state and local jurisdictions; specific policies to streamline or standardize it are outside the scope of this rulemaking. While permitting times vary based on applicable state or local jurisdiction, specifics of station sites, and other factors, we note as one example that Electrify America reported that, in 2022, permitting took an average of 13 weeks for its U.S. "ultra-fast" DCFC stations.[423]

Though we recognize permitting is just one step in the deployment process, and that the process could take longer for more complex sites, we don't think permitting times will pose a barrier to the overall pace of infrastructure deployment supporting BEV adoption under the modeled compliance pathway for the final rule. We conclude this for several reasons. The final standards include a lower increase in stringency of standards compared to the proposal for many HD vehicle categories in MY 2027, a slower phase-in of standards through MYs 2028 and 2029, and a phase-in of standards from MYs 2030 through 2032 that, for many of the subcategories, achieves similar levels of stringency in MY 2032 as those proposed. Also, as discussed in RIA Chapter 2.10.3, most (approximately 88%) of our projected depot ports will be Level 2, and as we explain in RTC section 7 (Distribution) we generally do not expect longer lead times being needed for associated buildout for such EVSE ports (which would be an additional lead time consideration to any permitting timelines). In addition, as discussed in RTC 6.3.1, while we determined it was appropriate to incorporate some public charging into our analysis as part of the

[422] DRIA at 70.

[423] Electrify America. "2022 Annual Report to U.S. Environmental Protection Agency." April 2023. Accessed March 11, 2024, at: https://media.electrifyamerica.com/assets/documents/original/1018-2022NationalAnnualReport.pdf.

modeled potential compliance pathway that supports the feasibility of the final standards, we do so starting in MY 2030 to allow time for public infrastructure to develop. Thus, overall the final standards provide greater lead time than proposal and adequate lead time taking into consideration such concerns, among others.

In response to calls to support state and local agencies in the process, we note that federal agencies already offer a variety of resources on charging infrastructure for stakeholders, including information and best practices for permitting,[424] EVSE project planning,[425,426] building codes and standards,[427] and other topics.[428] In addition, EPA, participates in the Electric Vehicle Working Group established under the Bipartisan Infrastructure Law, along with DOE, DOT, and a wide variety of other government, industry, and stakeholders participants.[429] As noted by the Joint Office of Energy and Transportation, the group was formed to make recommendations "regarding the development, adoption, and integration of light-, medium-, and heavy-duty electric vehicles (EVs) into the U.S. transportation and energy systems";[430] its scope includes permitting among other deployment issues.[431]

Another cause of delay identified by commenters was with deliveries of equipment throughout the supply chain. We note generally that there have been disruptions to global supply chains in recent years, and there are ongoing efforts to strengthen and diversify supply chains to improve resiliency.[432] We also acknowledge comments that competing demands for charging infrastructure for light-, medium, and heavy-duty BEVs could extend deployment times. However, as described in RIA Chapters 1.3.2 and 1.6.2, there are many ongoing and planned investments in charging infrastructure through the BIL and IRA and from a wide variety of the private sector participants, and there are indications that the market is already preparing to meet the coming demand for EVSE. DOE estimates that about forty companies have already announced over $500 million of investments in U.S. facilities to construct charging equipment, with planned domestic production capacity of more than 1,000,000 chargers (including 60,000

DCFCs) annually.[433,434] We reasonably predict that this will continue to expand as the market grows. We also note that workforce development is on the rise (e.g., through training and certification programs for those installing EV charging stations); see RIA Chapter 1.6.2 and RTC Section 1.6.4 for additional information on this topic. As previously explained in this response, in part after taking into account lead time considerations, including supply chain and deployment timing, overall the final standards provide greater lead time than proposal. See Preamble Section II.

We acknowledge comments on other implementation challenges for fleets and EVSE developers such as space constraints. We note these and other aspects of station planning, siting, and design considerations in RIA Chapter 1.6.3.2. However, as described in Preamble II.D.2.iii and RIA Chapter 1.6.2, and as noted by commenters (see also comments in RTC Section 6.1), there are a variety of solutions being offered for, and explored by fleets. Manufacturers (e.g., PACCAR, DTNA, Mack Trucks, Navistar, and Nikola) are providing EVSE solutions to their customers either directly or in partnerships with charging providers and other companies. Alternate business models such as transportation- or charging-as-a-service will provide options for fleets that have challenges deploying infrastructure at their depots or otherwise prefer these third-party operated stations. We also agree with CALSTART that mobile chargers (or other transitional charging options) offer a temporary solution for fleets to deploy BEVs while depot charging infrastructure is being installed, and note that some OEMs and fleets are already pursuing this option (see RIA Chapter 1.6.2.).

As described in RIA Chapters 1.3.2 and 1.6.2, there are also many public and private investments to support the buildout of a public charging network that can serve heavy-duty BEVs. As discussed in RTC Section 6.1 and extensively in RTC Section 7 (Distribution), we agree with findings of several recent assessments that charging needs will be geographically concentrated in early years, and that this will allow a phased approach for public charging infrastructure deployment starting with areas likely to have the most initial demand. In March 2024, the U.S. released a National Zero-Emission Freight Corridor Strategy[435] that, "sets an actionable vision and comprehensive approach to accelerating the deployment of a world-class, zero-emission freight network across the United States by 2040. The strategy focuses on advancing the deployment of zero-emission medium- and heavy-duty vehicle (ZE-MHDV) fueling infrastructure by targeting public investment to amplify private sector momentum, focus utility and regulatory energy planning, align industry activity, and mobilize communities for clean transportation."[436] The strategy has four phases. The first phase, from 2024-2027, focuses on establishing freight hubs defined "as a 100-mile to a 150-mile radius zone or geographic area centered around a point with a significant concentration of freight volume (e.g., ports, intermodal

[435] Joint Office of Energy and Transportation. "National Zero-Emission Freight Corridor Strategy." DOE/EE-2816 2024. March 2024. Available at https://driveelectric.gov/files/zef-corridor-strategy.pdf.

[436] Joint Office of Energy and Transportation. "Biden-Harris Administration, Joint Office of Energy and Transportation Release Strategy to Accelerate Zero-Emission Freight Infrastructure Deployment." March 12, 2024. Available online: https://driveelectric.gov/news/decarbonize-freight.

facilities, and truck parking), that supports a broader ecosystem of freight activity throughout that zone."[437] The second phase, from 2027-2030, will connect key ZEV hubs, building out infrastructure along several major highways. The third phase, from 2030-2045, will expand the corridors, "including access to charging and fueling to all coastal ports and their surrounding freight ecosystems for short-haul and regional operations."[438] The fourth phase, from 2035-2040, will complete the freight corridor network. This corridor strategy provides support for the development of HD BEV infrastructure that corresponds to the modeled potential compliance pathway for meeting the final standards.

Taken together, and with conclusions in RTC Section 7 that there is sufficient time for any needed distribution grid upgrades (and solutions available to mitigate the need for such buildout), EPA agrees with CARB and Tesla that there is sufficient lead time for charging infrastructure to be deployed to support the modeled potential compliance pathway for the final rule. In consideration of lead time concerns raised by commenters (on both infrastructure and vehicle developments), and to ensure the necessary infrastructure will be available, EPA applied constraints (in a conservative approach in the earlier model years) such that the final standards include a lower increase in stringency of standards for many HD vehicle categories in MY 2027, a slower phase-in of standards through MYs 2028 and 2029, and a phase-in of standards from MYs 2030 through 2032 that, for many of the subcategories, achieves similar levels of stringency in MY 2032 as those proposed. In addition, as discussed in RTC 6.3.1, while we determined it was appropriate to incorporate some public charging costs into our analysis as part of the modeled potential compliance pathway that supports the feasibility of the final standards, we do so starting in MY 2030 to allow time for public infrastructure to develop.

In sum, our assessment after considering the lead time challenges identified by commenters, is that given the many public and private investments that will support both depot and public charging, along with infrastructure solutions available to fleets, the ability to prioritize initial public charging deployment in discrete freight corridors, and the extra lead time afforded for BEV applications projected to utilize public charging under the modeled potential compliance pathway, we conclude that there is sufficient time to plan and deploy both depot and public charging infrastructure that will support HD BEV adoption in the modeled potential compliance pathway in the MY 2027 to MY 2032 timeframe.

Finally, as noted in RTC 6.1 and described in Preamble II.B.2, EPA commits to actively engaging with stakeholders and monitoring heavy-duty BEV infrastructure deployment. Based on this monitoring, and as appropriate and consistent with CAA section 202(a) authority, EPA may decide to issue guidance documents, initiate a future rulemaking to consider modifications to the Phase 3 rule, or make no changes to the Phase 3 rule program.

6.3 Charging Infrastructure Analysis

6.3.1 General

<u>Comments by Organizations</u>

Organization: American Trucking Associations (ATA)

Public charging will serve as a redundant power supply for fleets

Onsite "behind the fence" depot charging is preferred by early adopters. While public charging could allow for defrayed investment costs for fleets, the unpredictability of electricity prices and uncertain build out of public charging locations are forcing these fleets to invest capital in on-site charging. Today, there is one truck parking space for every 11 drivers in the industry, equating to 313,000 available spaces nationwide. Very few of those spaces have the infrastructure or capacity to charge heavy-duty ZEVs.25 Fleets see public charging stations needing to meet specific requirements to support electrification in the commercial vehicle industry. Public charging stations and sites should be:

- Closely located to where trucks fill up today. Freight corridors are already built out for optimal movement and charging stations will need to be located at or near sites where trucks spend downtime.
- Able to charge trucks at the same rate or faster than the time it takes to refuel a diesel truck today. Even one or two hours of charging downtime requires fleets to reconfigure and reoptimize routes, hours-of-service, scheduled downtime, and delivery schedules.
- Be designed for pull-in-charging to allow for a truck with a trailer to fit properly. [EPA-HQ-OAR-2022-0985-1535-A1, p. 18-19]

25 U.S. Department of Transportation, Jason's Law Commercial Motor Vehicle Parking Survey and Comparative Assessment, December 1, 2022.

Organization: Arizona State Legislature

EPA recognizes that '[m]ore charging infrastructure will be needed to support the growing fleet of HD [battery electric vehicles].' 88 Fed. Reg. 25926, 25978. But in its regulatory impact analysis, EPA only estimates costs for charging depots, not for en-route charging. 'We also do not estimate upfront hardware and installation costs for public or other en-route electric vehicle charging infrastructure because [battery electric vehicle] charging needs are met with depot charging in our analysis.' Draft Regulatory Impact Analysis, 195. EPA also argues that public and private funding 'will help meet future charging infrastructure needs.' Id. at 195-196. [EPA-HQ-OAR-2022-0985-1621-A1, p. 27]

Contrary to EPA's assumptions, en-route charging is critical for long-haul trucking. A diesel truck can travel more than 1,200 miles between refueling, which takes about 15 minutes.43 However, a two-hour charge of an electric battery only allows a truck to travel 200 miles.44 [EPA-HQ-OAR-2022-0985-1621-A1, p. 27]

43 Cleaner Vehicles: Good for Consumers and Public Health: Hearing before the Sen. Comm. On Env't and Public Works Subcomm. On Clean Air, Climate, and Nuclear Safety, 118th Cong. 4 (Apr. 18, 2023) (statement of Andrew Boyle, First Vice Chair of the American Trucking Associations and Co-President,

Boyle Transportation), available at https://www.epw.senate.gov/public/_cache/files/0/d/0d62639d-9821-4f0c-b4f5- 166ab4e7fb06/2DF4F5B6DD996B956650A34F09B92040.04-18-2023-boyle-testimony.pdf.

44 Id.

Chargers en route are required if battery electric vehicles will travel more than 200 miles. Analysis of fleet data indicates that almost 70% of vehicle miles traveled by semis would need to charge at public stations and not at company depots.45 The Department of Energy estimates that 40% of trucks travel between 250 and 750 average miles per workday.46 A study by the International Council on Clean Transportation found that one-third of truck trips leaving Los Angeles went to destinations more than 1,000 miles away.47 [EPA-HQ-OAR-2022-0985-1621-A1, p. 27]

47 Dale Hall and Nic Lutsey, Estimating the Infrastructure Needs and Costs for the Launch of Zero-Emission Trucks, THE INTERNATIONAL COUNCIL ON CLEAN TRANSPORTATION, Aug. 2019, 5, available at https://theicct.org/wpcontent/uploads/2021/06/ICCT_EV_HDVs_Infrastructure_20190809.pdf.

EPA has not considered availability of chargers. As the American Trucking Association noted, diesel fueling stations can serve 4-5 trucks per hour, while charging stations only could serve 2-3 trucks per day.48 The American Transportation Research Institute estimated that 'truck charging needs at a single rural rest area . . . would require enough daily electricity to power more than 5,000 U.S. households.'49 A study by the utility National Grid found that by 2035, the necessary charging capacity for a large passenger and truck stop 'will be roughly equivalent to the electric load of a small town.'50 Electricity loads needed to operate highway charging sites 'will begin to exceed distribution line capacity in the next 5-10 years.'51 [EPA-HQ-OAR-2022-0985-1621-A1, p. 27]

51 Id.

EPA also has not considered the cost of en-route chargers. The American Transportation Research Institute estimates that '[i]nitial equipment and installation costs at the nation's truck parking locations will top $35 billion.'52 [EPA-HQ-OAR-2022-0985-1621-A1, p. 28]

52 American Transportation Research Institute, supra note 42, at 2.

EPA also has not considered the time required by en-route chargers. Even top-of-the-line chargers that cost $100,000 each would still take five hours to achieve the same range as the current 15-minute diesel refueling, assuming a truck could even carry a battery of that size.53

Lost time would impact trucking companies' profitability and dramatically increase costs of shipped goods. [EPA-HQ-OAR-2022-0985-1621-A1, p. 28]

53 Statement of Andrew Boyle, supra note 43, at 4.

Organization: California Air Resources Board (CARB)

U.S. EPA estimates depot charging will fulfill BEV daily charging needs. This approach reflects U.S. EPA's expectation that many HD BEV owners will opt to purchase and install EVSE at depots. Therefore, U.S. EPA does not estimate upfront hardware and installation costs for public and other public electric charging infrastructure. U.S. EPA requests comment on this analytical approach.181 [EPA-HQ-OAR-2022-0985-1591-A1, p.50]

181 U.S. EPA's Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles—Phase 3, Proposed Rules, 88 Fed. Reg., April 27, 2023, page 25978. https://www.govinfo.gov/content/pkg/FR-2023-04-27/pdf/2023-07955.pdf

CARB staff believes this analysis approach is sound but could benefit from also considering that some fleets will want to use pubic fueling. In California, staff are learning that small fleets and independent operators may benefit from access to public overnight charging. Additionally, assuming that all charging needs will be met at the fleet's depot limits the utility of a BEV fleet that may occasionally need to broaden their range beyond the duty cycle that the vehicles and depot charging is designed to handle. [EPA-HQ-OAR-2022-0985-1591-A1, p.50]

The U.S. EPA's analytical approach should include public charging. Given the available information on the relative costs of depot and public charging, it is reasonable to assume that they are similar and that including public charging would not materially affect the analysis. However, the analytical approach would more closely reflect real-world conditions if it were to accommodate public charging. The CEC's analysis shows a ratio of approximately one public charger for every ten depot chargers.182 The installation of depot charging will be less preferred for certain fleets for reasons such as business model preferences, available parking and site footprint, site-level electrical capacity constraints, or others. Public charging, including charging during operational hours, will enable additional vehicles and fleets to electrify. Public charging supports long haul trucking where driving distances exceed range. Public charging will also support equitable access. Smaller independent owner-operators of vehicles such as drayage trucks and goods movement may not have access to depot charging. With that said, under all of EPA's proposed standards (including the most stringent alternative), ZEV penetration rises gradually and never rises above 40/60 percent, which both means there is time to develop public charging and that the fleets that do not need public charging can (if need be) make up the 40/60 percent, thus making public charging supportive but not required for successful implementation. Both hardware and installation costs vary over time. U.S. EPA research indicates that hardware cost would likely decrease over time due to economic scale and manufacturers learning. On the other hand, research indicate installation cost will likely increase due to higher labor and material costs over time. After considering the variation in how costs may change over time, U.S. EPA combined hardware and installation cost into the EVSE. U.S. EPA requests comment on this approach.183 CARB staff agrees with this general approach. There are a range of costs to install at any particular site even with the same hardware. Costs for hardware and some "balance of system" costs are likely to decrease with scale and learning. On the other hand, material and labor costs for installation may increase as they tend to do in general for construction and equipment installation (an effect not unique to EVSE and hydrogen stations), and the lowest-cost sites (with sufficient ground level space and existing electrical capacity) may be occupied first with higher-cost sites being put into use later. Combining these costs shows a cancellation effect allowing costs to remain constant for modeling purposes. It will be important to continue to monitor cost trends. [EPA-HQ-OAR-2022-0985-1591-A1, pp.50-51]

182 Electric Vehicle Charging Infrastructure Assessment - AB 2127, last accessed June 4, 2023. https://www.energy.ca.gov/data-reports/reports/electric-vehicle-charging-infrastructure-assessment-ab-2127

183 U.S. EPA's Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles—Phase 3, Proposed Rules, 88 Fed. Reg., April 27, 2023, page 25982. https://www.govinfo.gov/content/pkg/FR-2023-04-27/pdf/2023-07955.pdf

Organization: Clean Fuels Development Coalition et al.

C. The proposal underestimates the cost for charging infrastructure.

Charging infrastructure is the single largest expense accounted for in the proposal—$47 billion in "electric vehicle supply equipment (EVSE) costs." But this expense only accounts for "depot" charging installation, or the cost to install heavy-duty chargers at an electric vehicle's home base. This completely ignores "upfront hardware and installation costs for public or other en-route electric vehicle charging infrastructure" because it assumes "BEV charging needs are met with depot charging." 88 Fed. Reg. 25,978. This is unrealistic, particularly given the short ranges of heavy-duty batteries and the long travel distances expected of heavy-duty vehicles. To compound this error, the proposal makes unreasonable assumptions about how many of these depot chargers are needed. EPA "assume[s] that up to two vehicles can share one DCFC port if there is sufficient depot dwell time for both vehicles to meet their daily charging needs." DRIA at 200. This allows, as EPA explains, "per-vehicle EVSE costs [to] decline by 50 percent or more." Id. [EPA-HQ-OAR-2022-0985-1585-A1, p. 33]

Organization: Daimler Truck North America LLC (DTNA)

Importance of Public Charging Infrastructure

Because of the costs, complexities, and timelines discussed above, some depot-based fleets will be unable to rely on depot-only charging and will be required to utilize publicly available charging. Small business fleets are less likely to have dedicated depot locations and access to capital for ZEVs and their associated infrastructure, and are more likely to rely on public charging, consistent with today's retail station refueling model. Finally, we predict that some of the vehicle applications and routes modeled in the HD TRUCS tool and assumed to be only depot-charged may in fact require en-route opportunity charging. For example, the Class 8 Regional Day Cab with a 90th percentile daily VMT of 349 miles may exceed the range capabilities of a BEV tractor on a single charge and need to utilize public charging. Estimating the proportion of BEVs that will utilize public versus private charging needs further study as the market develops. Figure 6 below from ICCT's ZEV Infrastructure White Paper may present a reasonable approximation for consideration during this rulemaking process. [EPA-HQ-OAR-2022-0985-1555-A1, p. 55]

Public charging sites will need to be equipped with a range of charging capacities to serve a variety of needs from low-speed overnight charging to ultrafast charging to reenergize large HDV batteries in a short period of time. In its April 2023 white paper on TCO for Class 8 alternative powertrain technologies, ICCT estimates the costs to develop electric infrastructure for dually equipped public charging sites and presents projected public charging rates for select states, as shown in Figure 7 below.126 DTNA recommends that EPA consider incorporating a public charging scenario in HD TRUCS, as the dollar per kilowatt-hour rate is significantly different in this public charging scenario compared to EPA's projection for depot charging on commercial rates. [EPA-HQ-OAR-2022-0985-1555-A1, p. 56] [Refer to Figure 7 on p. 56 of docket number EPA-HQ-OAR-2022-0985-1555-A1]

126 See ICCT, Total Cost of Ownership of Alternative Powertrain Technologies for Class 8 Long-Haul Trucks in the United States (April 2023), https://theicct.org/wp-content/uploads/2023/04/tco-alt-powertrain-long-haul-trucks-us-apr23.pdf (ICCT TCO White Paper).

EPA Request for Comment, Request #30: In draft RIA Chapters 2.6 and 2.7.7 we describe how we accounted for charging infrastructure in our analysis of HD BEV technology feasibility and adoption rates for MYs 2027- 2032. For this analysis, we estimate infrastructure costs associated with depot charging to fulfill each BEV's daily charging needs off-shift with the appropriately sized electrical vehicle supply equipment . . . This approach reflects our expectation that many heavy-duty BEV owners will opt to purchase and install EVSE at depots; accordingly, we explicitly account for all of these upfront costs in our analysis. By contrast, we do not estimate upfront hardware and installation costs for public and other en-route electric charging infrastructure because the BEV charging needs are met with depot charging in our analysis . . .We request comment on this analytical approach.

- DTNA Response: EPA's assumption that all BEVs will rely exclusively on depot charging is mistaken. DTNA believes that many depots will not be able to install adequate charging infrastructure and that many vehicles do not return to depots. DTNA also believes that many vehicles do not have the 12-hour dwell time EPA projects, necessitating much higher power demands for BEV charging. Many vehicles will exceed EPA's projected power demands due to high VMT or accessory loads, and will require opportunity charging that EPA does not account for. Additionally we expect many fleets, especially small businesses, will rely exclusively on public charging. This lack of infrastructure could undermine the feasibility of the Proposed Rule, as discussed in Section II.B.3 and Appendix A to these comments. [EPA-HQ-OAR-2022-0985-1555-A1, p. 163]

Organization: Electrification Coalition (EC)

We concur with EPA that many HD EV owners will opt to utilize depot charging, particularly in the near-term, but en-route charging will also be needed for long-term success in achieving electrification across all HD classes. [EPA-HQ-OAR-2022-0985-1558-A1, p. 13]

The EPA specifically requests comment on their approach to include costs associated with depot charging in the draft RIA Chapters 2.6 and 2.7.7, as their expectation is that many HD EV owners will opt to purchase and install EV charging infrastructure at depots versus utilize en-route charging.36 The EC comments that while depot and en-route public charging will both be needed to scale HD vehicle electrification, we see a trend that depot charging will play a greater role, particularly in the immediate term. [EPA-HQ-OAR-2022-0985-1558-A1, p. 13]

36 See page 25978 of the Environmental Protection Agency's (EPA) proposed rule for Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles-Phase 3 in the Federal Register: https://www.govinfo.gov/content/pkg/FR-2023-04-27/pdf/2023-07955.pdf

During the New York and New Jersey MHDV Fleet Workshop in October 2022 hosted by the Environmental Defense Fund and Atlas Public Policy, speakers representing fleets stated that their preference is depot or at home charging, while noting that there will be an opportunity for en-route public charging in the future. Speakers stated concerns that en-route public charging is too cost prohibitive compared to depot charging, as en-route charging might subject the driver to peak prices if charging during the day, whereas depot charging will likely offer lower overnight rates. In addition, speakers shared concerns of en-route public charging not built out yet to meet the current demands from industry. [EPA-HQ-OAR-2022-0985-1558-A1, p. 13]

We are seeing a trend of companies making investments into HD vehicle depot charging. Prologis, for example, are making investments to provide depot charging for their fleet tenants at their warehouses. Additionally, trucking-as-a-service companies provide customers with access to both electric HD vehicles and depot charging. [EPA-HQ-OAR-2022-0985-1558-A1, p. 13]

To facilitate the long-term adoption of HD electric vehicles, public and en-route charging will be necessary, particularly for long-haul trucking and to charge vehicles that may not have access to depot charging. Where the concertation of depot versus public charging will be installed may be dependent on the use cases for HD vehicles, particularly in the freight sector. The ICCT noted in their report on near-term infrastructure needs of HD vehicle electrification that counties with a greater percentage of urban and regional trucking will require a higher concentration of depot charging whereas counties with a greater percentage of long-haul trucking will require more en-route public charging.37 [EPA-HQ-OAR-2022-0985-1558-A1, pp. 13-14]

Organization: MEMA

BEV early adopter market segments with predictable daily routes and usage: Bus applications, including school bus and transit, are early adopter segments for BEV. Even though Heavy Duty BEV is still in early stages of deployment worldwide, school bus and transit bus have already had more time to validate that BEV technology can be 1:1 with ICE for performing daily missions for a larger percentage of fleets than the adoption currently projected in the HD TRUCS model for these segments (0-32% in MY27 and 35-45% in MY32). [EPA-HQ-OAR-2022-0985-1570-A1, p. 22]

Segments that can reliably charge overnight in depot: School bus, transit bus, and port drayage can take advantage of the flexibilities of overnight depot charging and opportunity charging throughout the day when not in use. Although more costly EVSE is required to maintain the fleet's business model, these three applications also have increased incentive support to overcome initial cost barriers of vehicle and EVSE at the state and federal level. These fleets can also participate in V2G bi-directional charging capabilities. [EPA-HQ-OAR-2022-0985-1570-A1, p. 22]

Port drayage fleets are more likely to require multi-shift operation during peak shipping periods, which will need higher power EVSE to maintain productivity. Multishift operation can challenge 1:1 productivity parity for BEV vs. conventional technology if minimum charging infrastructure is assumed, as is currently reflected in HD TRUCS at 50KW. However, purchasing high power EVSE (350KW+) as noted above can be part of the drayage fleet manager's and port operator's plans for electrifying port operations due to domiciled operations allowing for re-charging during 30-minute lunch breaks. [EPA-HQ-OAR-2022-0985-1570-A1, pp. 22 - 23]

End-users with goals to minimize fuel costs and/or achieve progress towards ESG metrics

Pickup a delivery duty cycles served by Box trucks, Step-Vans, and Regional Haul tractors, especially those purchased by fleets motivated by ESG goals, indicate fleet owner/operators with more willingness to adopt new technology faster. Many of the early orders of BEV included in EPA's GHG Ph 3 preambles come from packaging and consumer package goods fleets who have aligned goals to reducing GHG from operations. [EPA-HQ-OAR-2022-0985-1570-A1, p. 23]

Recommendations:

a) EPA and other Federal agencies consider how incentivized support for infrastructure can be used to 1) future-proof DC charging needs, 2) allow faster ZEV deployment for early adopter segments, 3) provide opportunity to leverage potential benefits in bi-directional charging for school bus and other suitable municipal applications, resulting in 4) improved grid resiliency to maintain critical services in case of casualty. [EPA-HQ-OAR-2022-0985-1570-A1, p. 23]

b) EPA reexamine the readiness for ZEV adoption for the three advanced applications noted above and adjust the TRUCS model accordingly. [EPA-HQ-OAR-2022-0985-1570-A1, p. 23]

Organization: RMI

The EPA projects manufacturers will make a combination of internal combustion engine (ICE) and zero-emission vehicle technologies in order to comply with the rules. Electric heavy-duty trucks are a critical way to reduce transportation emissions and improve environmental health. Electric trucks provide an economic, practical, and environmentally clean solution for our increasing trucking demand. [EPA-HQ-OAR-2022-0985-1529-A1, p. 1]

RMI's analysis of trucking in California and New York found that almost 50% of heavy-duty trucks can complete their routes using electric trucks commercially available today without the need for public charging.2 RMI's partner organization, the North American Council for Freight Efficiency (NACFE), has shown that trucks with routes less than 200 miles a day can be electrified now, with adoption hinging on vehicle economics improving and available depot and on-route charging extending the truck's range.3 [EPA-HQ-OAR-2022-0985-1529-A1, p. 1]

2 Jessie Lund et al., Charting the Course for Early Truck Electrification, RMI, 2022, https://rmi.org/insight/electrify-trucking/.

3 Roeth et al,. Electric Trucks Have Arrived: The Use Case for Heavy-Duty Regional Haul Tractors, NACFE, May 5, 2022, https://nacfe.org/wp-content/uploads/edd/2022/05/HD-Regional-Haul-Report-FINAL.pdf

RMI recently released two reports on the benefits of EVs that the comments below pull from:

- A report, Preventing Electric Truck Gridlock, which provides a background on electric trucks, their market potential, and an overview of the challenges facing rapid electrification of the industry.
- A report, How Policy Actions Can Spur EV Adoption in the United States, which includes analysis on the market transforming Inflation Reduction Act EV incentives [EPA-HQ-OAR-2022-0985-1529-A1, pp. 1-2]

RMI is working to support the North American Council for Freight Efficiency in their 2023 biannual Run On Less – Electric DEPOT Event in September which will focus on fleet scaling considerations such as charging infrastructure, engagement with utilities, total cost of ownership management, driver and technician training, and more. This event will provide useful information for the EPA on the truck industry. Current sponsors include PepsiCo, Cummins, and Shell [EPA-HQ-OAR-2022-0985-1529-A1, p. 2]

Organization: Truck Renting and Leasing Association (TRALA)

EPAs methodology within its Heavy-Duty Technology Resource Use Case Scenario (HD TRUCS) also assumes that all customers will choose minimal on-site charging power to keep capital costs low. 27 The agency's assumption for 19-50KW charging across many vehicle applications in medium heavy-duty vehicles seems fundamentally incorrect based on what TRALA is hearing from end-users about intentions to install 150KW-350KW charging on-site. This assumption does not match many end-users plans to future-proof their charging infrastructure to enable use across more vehicles and opportunity charging for multi-shift or peak operational periods. [EPA-HQ-OAR-2022-0985-1577-A1, p. 19]

27 EPA's Heavy-Duty Technology Resource Use Case Scenario (HD TRUCS) was specifically developed by EPA to evaluate HD ZEV technologies and costs under Phase 3.

Some MD truck applications, such as Class 4-8 box trucks, port drayage tractors, Class 4-7 step vans, and Class 6-7 flatbed trucks are used for routes similar to those of regional haul tractors which are projected in HD TRUCS to need 150-350KW charging. However, in HD TRUCS the applications mentioned above are only assumed to require 19-50KW chargers. TRALA recommends EPA issue a request for information (RFI) to end-users to acquire information on charging power needs for commercial vehicle operations and test these sensitive up-front cost assumptions that are used to project end-user willingness to adopt ZEVs. [EPA-HQ-OAR-2022-0985-1577-A1, p. 19]

To demonstrate the importance of testing this assumed critical input, EPA should run a sensitivity analysis to project the payback for all vehicle applications that are assumed to require 19-50KW charging if they require higher power DC charging. If, as many in industry suspect, most medium heavy-duty end-users require higher power charging in the 150-350KW and beyond range to maintain 1:1 productivity, this will change HD TRUCS model payback and ZEV projections. [EPA-HQ-OAR-2022-0985-1577-A1, p. 19]

The uncertainty within FHWA's guidance for public charging infrastructure for medium heavy-duty vehicles undermines end-user confidence that there will be sufficient public infrastructure to support ZEV technologies. Therefore, it will benefit EPA, and all stakeholders impacted under Phase 3, to define medium heavy-duty charging requirements for 1:1 productivity now so that HD TRUCS has correct Electric Vehicle Supply Equipment (EVSE) costs modeled and FHWA has clear requirements for NEVI planning early in the program to ensure public funding efficiently enables ZEV deployment across all targeted vehicle applications. [EPA-HQ-OAR-2022-0985-1577-A1, p. 20]

Organization: Valero Energy Corporation

5. EPA's analysis inappropriately categorizes all HD EVSE as depot charging.

Regarding HD PEV charging, EPA states "we…do not estimate upfront hardware and installation costs for public or other en-route electric vehicle charging infrastructure because BEV charging needs are met with depot charging in our analysis."53 [EPA-HQ-OAR-2022-0985-1566-A2, p. 12]

53 DRIA at 195.

However, EPA separately acknowledges that "certain vehicles, such as long-haul trucks, may depend on these [en-route] stations for a significant fraction of their daily electricity needs."54 EPA cites to studies by ICCT, Atlas Public Policy, and the Goldman School of Public Policy that project future infrastructure needs and costs for HD EVSE. But these studies do not support EPA's assumption that all BEV charging needs will be met with depot charging – in fact, they directly contradict EPA's assumption:

- A "depot charging approach limits freedom of movement of the vehicle, so additional infrastructure investments will be necessary. Some trips will require more power than one overnight depot charging event can provide." 55
- A "reasonable share of vehicle owners, particularly independent owner-operators, will not have the resources to install a private network of charging points and will depend on chargers installed by others."56
- "In 2030, internal combustion engines will continue to power 96% of tractor-trailers operating in the United States," and while "around 75% of charging points will provide overnight private depot charging, an additional 14% will provide overnight publicly accessible depot charging, and 11% will provide publicly accessible charging speeds of 350 kW or greater."57
- Personally-owned Class 4-8 trucks and all long-haul trucks will use on-road charging exclusively; and personally-owned Class 3 trucks and Class 3-8 fleet vehicles (excluding long-haul) use depot/home charging 75 to 90 percent of the time and on-road charging 10 to 25 percent of the time.58
- For heavy-duty trucks, "the combination of 125-, 350-, and 1,000-kW HDT chargepoints will be spread across about 2,700 truck stops."59 [EPA-HQ-OAR-2022-0985-1566-A2, p. 12]

54 DRIA at 63.

55 ICCT Working Paper 2021-33, "Infrastructure to support a 100% zero-emission tractor-trailer fleet in the United States by 2040" at 2 (September 2021).

56 ICCT Working Paper 2021-33, "Infrastructure to support a 100% zero-emission tractor-trailer fleet in the United States by 2040" at 2 (September 2021).

57 ICCT Working Paper 2021-22, at 9.

58 Atlas Public Policy, “U.S. Vehicle Electrification Infrastructure Assessment: Medium- and Heavy-Duty Truck Charging” at 15, (November 12, 2021).

59 Goldman School of Public Policy, University of California Berkeley, “Plummeting Costs and Dramatic Improvements in Batteries can Accelerate our Clean Transportation Future” at 31 (April 2021).

Despite EPA’s statement that its EVSE and operating costs represent “estimated costs incurred by users and society more generally of MY 2027 and later HD vehicles,”60 EPA fails to account for the hardware and installation costs for en-route PEV charging in its overall program costs. Rather, EPA anticipates “that a variety of public and private funding—including Federal investments under the BIL and the IRA, and funding from states, automakers, charging providers, utilities, and others—will help meet future charging infrastructure needs.”61 EPA must acknowledge in its impact analysis that public and private funding is not “free” – every dollar supported by public funding is ultimately borne by taxpayers, and every dollar invested by private funders is supported by a plan for recouping the investment. [EPA-HQ-OAR-2022-0985-1566-A2, p. 13]

60 DRIA at xiii, emphasis added.

61 DRIA at 195-196.

Even if fleet owners will not bear the direct burden of capital costs for installing the requisite en-route stations, EPA should assume that the station capital costs will be amortized within the price of electricity, consistent with the methodology that EPA has applied for both FCEV and ICEV fueling.62 [EPA-HQ-OAR-2022-0985-1566-A2, p. 13]

62 DRIA at 85.

EPA Summary and Response

Summary:

In the NPRM, EPA estimated infrastructure costs associated with depot charging to fulfill each BEV’s daily charging needs off-shift with appropriately sized EVSE. While we acknowledged some vehicles may use public or other en-route charging, we did not directly estimate these costs since BEV charging needs were met with depot charging in our NPRM analysis (see DRIA at 195). We requested comment on this approach.

Multiple commenters agreed with EPA that depot charging would be preferred and sufficient for many BEVs, particularly in the Phase 3 program’s early years. For example, RMI cited an analysis they conducted of heavy-duty trucks in California and New York, which found that almost half of the vehicles can meet their daily needs without public charging. The Electrification Coalition noted that New York and New Jersey fleet owners participating in a 2022 workshop stated that they currently preferred depot charging, expressing concern that public charging may not yet be available and that electricity costs would be higher due to peak daytime pricing. Likewise, ATA noted that early adopters prefer depot to public charging noting some of the challenges with the latter. MEMA also cited several vocations—school buses, transit buses, and port drayage—for which depot charging can be effective.

However, most commenters on this topic also saw a role for public charging at some point in the Phase 3 rule’s time frame and many recommended that EPA include public charging in its analysis. For example, the Electrification Coalition said that en-route charging would be needed in the longer term both for vehicles without depot charging access and for long-haul applications. CARB stated that EPA's decision to only model depot charging was sound given the ZEV penetration levels and phase-in time in the agency's modeled compliance pathway but noted that the analysis would better reflect the real world if it included some public charging. CARB further noted that it did not anticipate a significant impact on costs based on comparable cost data for depot and public EVSE.

The Arizona State Legislature, Clean Fuels Development Coalition et al., DTNA, and Valero also said that EPA should account for public charging costs. The Arizona State Legislature commented that en-route charging would be needed for long-haul or other vehicles with daily VMT over 200 miles, citing several sources showing significant numbers of vehicles are over that threshold or would otherwise need public charging. DTNA also stated that BEVs with high VMT (e.g., a Class 8 regional cab with 349 miles a day) may need public charging as would other vehicles (e.g., those in small business fleets) for which it's difficult to install depot charging (e.g., due to location or capital costs). DTNA suggested that EPA could use a recent ICCT paper (Ragon et al.) to inform modeling of public infrastructure needs and costs within HD TRUCS.

Valero commented that EPA should include the costs for public charging infrastructure in its impacts analysis regardless of whether it is borne directly by fleet owners or paid for with public or private investments, and suggested amortizing costs of public charging within the estimated electricity price (noting this would be consistent with the approach EPA uses for ICE vehicles and FCEVs). The Arizona State Legislature said EPA did not consider costs of downtime associated with en-route charging.

EPA also received comments about the EVSE power levels in our depot charging analysis, which included L2 charging at 19.2 kW and DCFC at 50 kW, 150 kW, and 350 kW. TRALA commented that EPA's approach to select the lowest cost option is inconsistent with the user preferences and plans to install higher power (150 kW+) charging. TRALA suggested EPA issue a request for information to better understand power needs and to conduct a sensitivity within HD TRUCS to assess impact on payback periods if depot charging is assumed to be 150 kW to 350 kW. MEMA likewise noted that higher power charging than is assumed in HD TRUCS may be needed to serve multi-shift operations for port drayage vehicles (e.g., fleets may opt for 350 kW EVSE to enable charging during operators' lunch breaks.)

Other comments on EVSE costs, charging costs, and dwell times are summarized and addressed in the following sections.

Response:

As discussed above, EPA's NPRM analysis estimated infrastructure costs associated with depot charging to fulfill each BEV's daily charging needs. This reflected our expectation that many heavy-duty BEV owners would opt to purchase and install sufficient EVSE to ensure their vehicle's operational needs are met. Commenters agreed that charging at depots is likely to be preferred over public (or en-route charging) for certain fleets and vehicle types, particularly in the early years of the Phase 3 program. Therefore, we continue to project that most vocational vehicles and certain day cab tractors—those with return-to-base operations—will rely on depot charging and we model them accordingly in our FRM analysis (though we have made updates to that analysis as described in RIA 2.6 and RTC 6.3.2 to 6.3.4 below).

However, we acknowledged in the proposal that some public charging may be needed in future years, and we agree with commenters that it is appropriate to incorporate some public charging costs into our analysis as part of the modeled potential compliance pathway that supports the feasibility of the final standards. In particular, we agree that long-haul and certain other vehicles with long daily ranges or that do not regularly return to base may rely on en-route or public charging. As described in RIA 2.6, starting in MY 2030 in our final rule HD TRUCS analysis we project public charging will be used by certain long-haul vehicles (both sleeper cab and long-range day cab tractors) and coach buses (although we note that the coach bus custom chassis standards are unchanged for the Phase 3 – we assume that if there are electrified coach buses, they would utilize public charging networks). We further agree with the commenters who suggested that the hardware and installation costs for public charging infrastructure would typically be passed onto BEV owners through the charging price. Accordingly, we have incorporated amortized public charging infrastructure costs into a $ per kWh charging cost for vehicles that we project will use public charging. DTNA suggested a public charging cost of $0.196 per kWh sourced from a recent ICCT paper (Basma et al. 2023).[439] We agree that is a reasonable choice and have utilized it in our FRM analysis (while also making adjustments in future years to reflect changes in electricity prices over time as described in RIA 2.4.4.2 and RTC 6.3.3). These public infrastructure costs reflect ICCT's assumed mix of 1 MW and 150 kW EVSE ports to meet long-haul BEV charging needs with each station capable of 20 MW power.[440] See RIA 2.6.3 for a discussion of this topic, including estimated charge times for vehicles that we project will use public charging at 1 MW.

We selected MY 2030 as the year when we project there will be sufficient public charging infrastructure for HD vehicles for the projected utilization of such technologies under the modeled potential compliance pathway (see our discussion of lead time in RTC Chapter 6.2).

For depot charging, we continue to model four EVSE power levels (19.2 kW, 50 kW, 150 kW, and 350 kW) and to select the lowest cost EVSE option for each of the depot-charging vehicle types in HD TRUCS that can meet its needs. However, we agree with TRALA that some fleet owners may opt for higher power and higher cost EVSE options, as we acknowledged in the NPRM (DRIA at 201). TRALA suggested we conduct a sensitivity that restricts depot charging options to 150 kW or higher but did not provide detailed information on the specific scenario EPA should use for such a sensitivity. In particular, we note that per vehicle EVSE costs are impacted not only by the hardware and installation costs of the selected EVSE, but by how many vehicles can share that EVSE port. Fleet owners that opt for higher-power ports may be doing so in order to share those ports across more vehicles (and reduce total installed depot costs) or to future-proof the depot so additional EVSE do not need to be installed as more BEVs are incorporated into the fleet. To illustrate this point, consider a fleet of transit buses that each need to add 350 kWh of energy from charging over the same 8-hour dwell period at a depot. A fleet owner opting for 50 kW EVSEs would need one port per bus at a cost of about $54,000 each

[439] Hussein Basma, Claire Buysee, Yuanrong Zhou, and Felipe Rodriguez. "Total Cost of Ownership of Alternative Powertrain Technologies for Class 8 Long-haul Trucks in the United States." International Council on Clean Transportation. April 2023. Available online: https://theicct.org/wp-content/uploads/2023/04/tco-alt-powertrain-long-haul-trucks-us-apr23.pdf.

[440] Hussein Basma, Claire Buysee, Yuanrong Zhou, and Felipe Rodriguez. "Total Cost of Ownership of Alternative Powertrain Technologies for Class 8 Long-haul Trucks in the United States." International Council on Clean Transportation. April 2023. Available online: https://theicct.org/wp-content/uploads/2023/04/tco-alt-powertrain-long-haul-trucks-us-apr23.pdf.

(using EVSE cost and charging loss assumptions from our FRM analysis) whereas if the fleet owner opts for 350 kW charging, up to seven buses could share the same port at a per vehicle cost of about $28,000 (just over half the costs under 50 kW.) EPA did not conduct a sensitivity in HD TRUCS, but notes that overall costs could be higher or lower (depending on assumptions), and to the extent fleets owners opt for higher power charging in order to share ports among vehicles, EPA's costs could be conservative.

We address the issue of potential need for distribution grid buildout to support public charging stations in RTC 7 (Distribution) below.

6.3.2 EVSE Costs

Comments by Organizations

Organization: American Fuel and Petrochemical Manufacturers (AFPM)

EPA's cost analysis also assumes—without any concrete support—an "upfront" cost for ZEV purchasers of EVSE at or near the time of the vehicle purchase. [EPA-HQ-OAR-2022-0985-1659-A2, p. 30]

Organization: American Trucking Associations (ATA)

The uncertainty of the costs associated with opportunity public charging and the availability of mega charging sites requires fleets to invest in onsite charging. Investment in charging onsite has become a barrier as well. On average, a 180-kW charger with dual ports costs fleets $100,000 each. In consultation with utilities, available power and expected power usage dictate the number of chargers on site. In many cases, the high cost of installation and planning also limits fleets from electrifying a greater number of ZEVs or narrows their electrification plans to just forklifts or yard trucks. [EPA-HQ-OAR-2022-0985-1535-A1, p. 18]

Organization: CALSTART

Technology diffusion and infrastructure costs: EPA's cost scenario assumes no reduction in the cost of infrastructure over time. Both the range of costs used in EPA's assumptions and the lack of reduction do not match market realities. EPA references an ICCT assumption of a 3 percent annual cost reduction but does not include it.53F54 To assume no change in costs over time can cause an incorrect assumption of payback timing and introduce artificial cost/benefit tradeoffs for fleets. Analyses show that capital costs across energy supply infrastructure have shown significant reductions due to technology learning rates, such as in solar technology.54F55 Our analysis considers a technology reduction cost between 4 percent and 7 percent annually, similar to those seen in wind and solar, as reasonable. Using this assumption in our assessment reduces total capital costs of electric vehicle supply equipment in our scenarios by 11 percent. [EPA-HQ-OAR-2022-0985-1656-A1, pp. 24 - 25]

54 https://theicct.org/wp-content/uploads/2021/06/ICCT_EV_Charging_Cost_20190813.pdf

55 https://www.sciencedirect.com/science/ar..cle/pii/S1364032120307747#fig4

Organization: Clean Fuels Development Coalition et al.

And, as will be discussed later in this comment, the proposal's listed costs grossly underestimate the rule's true costs. The proper metric is aggregate cost because the major-questions doctrine asks about the rule's significance to the "national economy." West Virginia v. EPA, 142 S. Ct. at 2609 (2022). These aggregate costs include: [EPA-HQ-OAR-2022-0985-1585-A1, p. 4]

Vehicle fueling infrastructure: Not only the costs to build depot chargers that the proposal contemplates, but also the cost to install and maintain all the DC fast-charging stations necessary for purchasers to use the heavy-duty vehicles when they are out on the road. [EPA-HQ-OAR-2022-0985-1585-A1, p. 5]

Electric power costs: Researchers estimate that the 350 million electric vehicles required to decarbonize the U.S. fleet by 2050 could use as much as half of U.S. national electricity demand. See Thea Riofrancos et al., Achieving Zero Emissions with More Mobility and Less Mining, U.C. Davis Climate + Community Project (Jan. 2023), https://subscriber.politicopro.com/eenews/f/eenews/?id=00000185-e562-de44-a7bf-ed7751a00000. The proposal would hence amount to a complete transformation of the electric power sector, requiring substantially more generation, transmission, and distribution, which in turn would result in higher power prices not just for those using electrified vehicles, but for all users. [EPA-HQ-OAR-2022-0985-1585-A1, p. 5]

Organization: Daimler Truck North America LLC (DTNA)

Infrastructure Costs Electrical infrastructure costs are not adequately accounted for in EPA's HD TRUCS modeling. As a counterpoint to EPA's estimates in the Proposed Rule, the Company presents a summary of the average combined hardware and installation EVSE costs in Table 10 below, based upon DTNA's experience working with fleet customers. EPA assumes all customers will have 12- hour depot dwell times for lower speed overnight charging, however, DTNA believes that a significant portion of the HD fleet sees higher utilization, requiring faster charging times. We would thus expect higher costs for customers where faster charging speeds are required. [EPA-HQ-OAR-2022-0985-1555-A1, p. 30] [Refer to Table 10 on p. 30 of docket number EPA-HQ-OAR-2022-0985-1555-A1]

EPA Request for Comment, Request #75: We request comment on our estimated EVSE costs as well as our proposal to add EVSE costs to each vehicle's purchaser RPE costs in estimating purchaser costs.

> DTNA Response: As EVSE is required for fleets, and heavy-duty public charging networks do not exist, EPA should include EVSE costs in each vehicle purchaser's RPE. DTNA believes that EPA underestimates EVSE costs and is willing to share relevant data confidentially with EPA. As discussed in Section II.C of these comments, EPA should re-evaluate its assumptions on this issue on a regular basis, using the best available data. [EPA-HQ-OAR-2022-0985-1555-A1, p. 172]

EPA Request for Comment, Request #36: After considering the uncertainty on how costs may change over time, we keep the combined hardware and installation costs per EVSE port constant. We request comment on this approach.

- DTNA Response: See DTNA Response to Request # 20, above. In addition, DTNA believes EPA is under-estimating EVSE costs, and is willing to share relevant data confidentially with EPA. [EPA-HQ-OAR-2022-0985-1555-A1, p. 164]

EPA Request for Comment, Request #37: We request comment, including data, on our approach and assessment of current and future costs for charging equipment and installation

DTNA Response: See DTNA Response to Request # 20 and 36, above. [EPA-HQ-OAR-2022-0985-1555-A1, p. 164]

Organization: Environmental Defense Fund (EDF)

1. EPA's underlying component costs are high

While EPA includes the Commercial Clean Vehicle Credit and the production tax credit for batteries, it fails to include the Alternative Fuel Refueling Property Credit in its assessment of cost. The IRS has not published guidance yet on how this credit will be applied, but the language from the IRA indicates that businesses could receive up to a 30% credit on up to $100,000 of EVSE. Roush, in a recent report, showed that this also could save vehicle owners $1,064 for a 25 kW charger to $26,000 for a 100 kW charger.130 [EPA-HQ-OAR-2022-0985-1644-A1, p. 53]

130 H. Saxena, S. Pillai, "Impact of the Inflation Reduction Act of 2022 on Medium- and Heavy-Duty Electrification on MYs 2024 and 2027," 2023. Roush.

In their modeling, EPA has a maximum of two vehicles per charger even if many more vehicles could be charged in the 12 hours of dwell time EPA assumes. This results in a high estimate of number of EVSE ports needed, driving up the EVSE costs and driving down the stringency of the rule. [EPA-HQ-OAR-2022-0985-1644-A1, p. 53]

Organization: MEMA

- The model assumes that end-users will buy the lowest cost, lowest power chargers possible given the vehicle application's daily energy expenditures and overnight dwell time -12 hours. This assumption does not match what we have heard from end-users that indicates commercial vehicle end users want to invest in EVSE at a higher power level than minimum requirements. Because of the need for faster charging time, 150KW-350KW charging rather than 19-50KW charging is more desirable in the commercial vehicle space due to desires to future proof infrastructure investments and have more flexibility in charging options for overnight and opportunity charging. It is believed this higher kW power charging provides a margin of safety that fleet operators will seek to avoid costly vehicle downtime. [EPA-HQ-OAR-2022-0985-1570-A1, p. 16]

Recommendation: EPA run a sensitivity analysis using HD TRUCS to see how payback and adoption analyses would change if the applications currently assumed to use 19- 50 KW in the model instead are projected using 150-350KW. EPA issue a public request for information about vehicle dwell time and intentions to install higher power DC fast charging on site. [EPA-HQ-OAR-2022-0985-1570-A1, p. 16]

Some percentage of the above noted vehicle applications can electrify once suitable charging is available near the job site. We would expect BEV adoption to increase in areas where fast charging (>150-350KW) has been deployed in industrial, metro, and interstate locations. However, we would not recommend full-BEV technology be modeled, recommended or mandated for utility vehicles that restore critical services in emergency situations due to the risk of charging infrastructure downtime impeding the vehicles' missions. [EPA-HQ-OAR-2022-0985-1570-A1, p. 19]

Given sufficient time to gather data, industry can support EPA development of HD TRUCS model with GPS-driven geographical inputs of a variety of vehicle applications to assess the variability of routes/location and assess public infrastructure charging needs. A MEMA member provides an example below of the kind of additional data that could be provided to EPA using telematics, GPS, and elevation maps on a refuse application. [EPA-HQ-OAR-2022-0985-1570-A1, p. 19.] [See Docket Number EPA-HQ-OAR-2022-0985-1570-A1, page. 19, for referenced figure.]

Organization: PACCAR

C. EPA UNDERESTIMATES CHARGER COSTS

TRUCS underestimates the cost of electric vehicle supply equipment (EVSE). EPA assumed a $162,333 cost in 2021 dollars for a 350 kW charger. However, during the Phase 3 timeframe, PACCAR projects that actual per-charger costs will be tens of thousands of dollars more. The TRUCS analysis also fails to consider EVSE maintenance costs, including those for periodic cable replacement, repairs due to operator damage, and filter replacement, each of which can be significant. A recent ICCT paper, for example, estimates that annual maintenance charger costs will be $3,200 annually.4 [EPA-HQ-OAR-2022-0985-1607-A1, p. 6.] [See table 8 on page 7 of EPA-HQ-OAR-2022-0985-1607-A1.]

4. Id.

E. TRUCS DOES NOT ACCOUNT FOR IMPORTANT OPERATING COSTS

TRUCS omits other key considerations that will affect electric vehicle operating costs. For example, only onsite-charging costs are considered in estimating electric vehicle charging cost. Although EPA's Regulatory Impact Analysis recognizes that "public charging price may incorporate the profit margin of the third-party charging provider along with operating expenses, and costs associated with charging equipment depreciation," TRUCS does not factor in such public charging station cost increases.5 It was unrealistic for EPA to assume that all charging will take place onsite, so EPA should have considered higher offsite-charging costs as well. [EPA-HQ-OAR-2022-0985-1607-A1, p. 8]

5 Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles: Phase 3 Draft Regulatory Impact Analysis at 68, EPA-420-D-23-001 April 2023, available at: https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P10178RN.pdf

Organization: Tesla, Inc. (Tesla)

Turning to the record the agency has set forth then, first, the agency's cost estimates for DCFC installation are higher than Tesla's experience. Tesla has established the lowest cost in the industry and shown the costs to be more than 50% below current industry averages.198 Importantly, EPA should recognize that non-utility ownership of BEV charging stations is associated with significantly reduced cost of installation.199 Further, charging technology, like vehicle technology, is also maturing as more suppliers and manufacturing facilities are coming online.200 [EPA-HQ-OAR-2022-0985-1505-A1, p. 27]

Organization: Truck and Engine Manufacturers Association (EMA)

EVSE Costs – The EVSE costs included in EPA's HD TRUCS cover the cost of the EVSE unit (charger) and the installation cost downstream of the electricity meter. The NPRM expects that the vehicle owner will be responsible for those costs. The data for those costs in the EPA tool came from an article published on June 21, 2021 by Nature Energy, as referenced in the Draft RIA. That article is based on a study authored in part by NREL as part of a DOE contract. The EVSE cost data from that study forms the basis of the EPA's EVSE costs, as shown in the Draft RIA Table 2-58 (p. 197), reproduced below. Significantly, EPA uses the low-end in each range of estimated ESVE costs in HD TRUCS. [EPA-HQ-OAR-2022-0985-2668-A1, p.28]

EMA data from OEMs shows that the low-end costs are consistently too low in comparison to what actually is being experienced in the field today and what likely will be experienced in the future. Instead, EMA has determined that the midrange values (average of the high and low values in the table) are far more consistent with OEM experience and with what is reasonably expected in the future for the Level 2, DC-50kW and DC-150kW installations. The high end of the range is more appropriate for the DC-350kW EVSE, even though that is still significantly below the current cost in the field. [EPA-HQ-OAR-2022-0985-2668-A1, p.28]

EMA agrees with EPA that the EVSE costs should be held constant throughout the regulated years. Increased labor costs are expected to offset or even overtake any reductions in the cost of the EVSE units over time. [EPA-HQ-OAR-2022-0985-2668-A1, p.29]

Based on the foregoing, the table below reflects the recommended values for EVSE costs that EMA has used in the EMA HD TRUCS model. [EPA-HQ-OAR-2022-0985-2668-A1, p.29] [See the EMA Recommended Values for EVSE Costs table on page 29 of docket number EPA-HQ-OAR-2022-0985-2668-A1]

EVSE Costs – EMA's recommended EVSE costs, shown in the table below, also were run together. The ensuing table shows the revised projected ZEV adoption rates for 2027 and 2032. [EPA-HQ-OAR-2022-0985-2668-A1, p. 37] [See the Projected ZEV Adoption Rates for MYs 2027 and 2032 Tables on page 37 of docket number EPA-HQ-OAR-2022-0985-2668-A1.]

Organization: Truck Renting and Leasing Association (TRALA)

The maximum 30% tax credit, up to $100,000 per EV charger, also has qualifying conditions including that charging stations must be located in an eligible census tract which by definition requires:

- A poverty rate of at least 20%; OR
- Location in a census tract that is not in a metropolitan area and the medium family income for the tract does not exceed 80% of the applicable statewide median family income; AND
- Laborers employed in the construction of EV charging stations must meet the new prevailing wage and apprenticeship requirements [EPA-HQ-OAR-2022-0985-1577-A1, p. 20]

Many TRALA customers (i.e.., lessees) will not likely be able to maximize this tax credit either since they may not meet the preceding criteria or they will not have permission to install charging ports on leased property under their lease terms. [EPA-HQ-OAR-2022-0985-1577-A1, p. 20]

Organization: Valero Energy Corporation

6. The EVSE installation costs adopted by EPA are unrealistic.

Table 2-58 of the draft RIA summarizes the ranges of costs that EPA considered for EVSE hardware and installation, for Level 2 (19.2 kW), DC-50 kW, DC-150 kW and DC-350 kW power levels.63 [EPA-HQ-OAR-2022-0985-1566-A2, p. 13.] [See Table 2-58 Combined Hardware and Installation Costs, per EVSE Port: ICCT Costs on page 13 of docket number EPA-HQ-OAR-2022-0986-1566-A2.]

63 DRIA at 197.

While EPA details the significant funding opportunities made available for EV charging infrastructure under the Bipartisan Infrastructure Law (BIL) and Inflation Reduction Act (IRA),64 it acknowledges the “complexity of analyzing the combined potential impact of these provisions (including IRA programs for which implementation guidance is not yet available)”65 and clarifies that it did “not directly account[] for these cost savings in our depot charging analysis.”66 Instead, “to reflect our expectation that these programs could significantly reduce the overall infrastructure costs paid by BEV and fleet owners for depot charging, we are using the low end of our hardware and installation cost ranges, as shown in Table 2-60, for each charging type.”67 [EPA-HQ-OAR-2022-0985-1566-A2, p. 13.] [See Table 2-60, Combined Hardware and Installation Costs, per EVSE Port, on page 14 of docket number EPA-HQ-OAR-2022-0986-1566-A2.]

64 DRIA at 15-22.

65 DRIA at 202.

66 DRIA at 202.

67 DRIA at 202.

EPA again regards funding opportunities through the BIL and IRA as being "free," when in reality the funding comes at a very real cost to the U.S. taxpayer. Further, the cost ranges presented by EPA are drawn from sources published between 2017 and June 2021,68 all of which pre-date the adoption of the BIL in November 2021. In contrast to EPA's expectation that the BIL and IRA funding opportunities will reduce the cost of EVSE hardware and installation, industry warns that the "Build America, Buy America" provisions of the BIL will "slow the rollout, drive up costs" of compliant charging infrastructure.69 [EPA-HQ-OAR-2022-0985-1566-A2, p. 14]

69 See https://www.reuters.com/business/autos-transportation/ev-charger-makers-brace-slowdown-new-made-america-rules-kick-2023-03-21/ (accessed May 13, 2023).

In fact, recent estimates by EV charging station vendors and in DOT-approved state EV Infrastructure Deployment Plans project significantly higher EVSE costs than used by EPA in their cost analysis, ranging from $500,000 to $1.2 million in capital expenditures for a minimally-compliant NEVI charging station containing four simultaneously operable 150 kW CCS ports (i.e., $125,000 - $300,000 per DC-150 kW port).70,71,72,73 [EPA-HQ-OAR-2022-0985-1566-A2, p. 14]

EPA Summary and Response

Summary:

Comments on EPA's assumptions about hardware and installation costs for EVSE generally fell into three categories: comments on the EVSE costs themselves, comments on whether and how these should be adjusted based on tax credits, and comments on whether EVSE costs should vary or be kept constant over time.

Vehicle manufacturers including DTNA and PACCAR asserted that EPA underestimated hardware and installation costs. PACCAR stated that costs for 350 kW will be tens of thousands higher than the $162,333 value used in the proposed rulemaking, while DTNA confidentially provided average EVSE cost estimates informed by its experience with fleet customers. EMA commented on EPA's choice to use the low end of a range of EVSE costs presented in the NPRM, stating that this underestimated costs. EMA recommended that EPA use the mid (or average) point of the range for L2 ports and DCFCs at 50 kW and 150 kW. For the highest-power depot charging option of 350 kW, EMA recommended using the high end of the range though noted this was still low compared to today's costs. Valero also stated that EPA underestimated costs and asserted that EPA's assumptions come from older sources published from 2017 to 2021. Valero provided an estimated range of $125,000 to $300,000 per DC-150 kW port drawn from state NEVI plans and EVSE providers as a purported example of current costs.

By contrast, Tesla commented that EPA's EVSE costs for DC fast charging installations in the NPRM are high, noting that Tesla's own costs are half of the average industry costs. More broadly, Tesla stated that installation costs are lower in situations where entities other than utilities own the charging stations. While not directly addressing EPA's EVSE cost assumptions, ATA cited as an example that a dual port 180-kW charger could cost $100,000 in its comment on how high EVSE costs for fleets could impede adoption.

Several commenters addressed the Alternative Fuel Refueling Property tax credit that was extended and modified by the IRA. EDF said that EPA's EVSE costs were too high because the NPRM analysis failed to incorporate the tax credit, and cited a Roush report that found it could save owners as much as $26,000 for a 100-kW charger. TRALA noted the limitation of the tax credit to certain census tracts and the prevailing wage requirements, indicating that its customers may not be eligible for the maximum credit. TRALA also noted that customers with leased property may not be able to install charging infrastructure. Valero disagreed with EPA's approach to account for the potential savings from the tax credit by using the low end of EVSE cost ranges. It noted that costs funded by public sources under IRA or BIL are borne by taxpayers and therefore still must be accounted for in EPA's analysis. Beyond the tax credit, Valero cautioned that due to "Build America, Buy America" provisions, costs for EVSE funded under BIL programs could increase.

Both EMA and CARB thought that EPA's approach of holding combined EVSE hardware and installation costs constant over time was reasonable, noting as EPA did in the proposal, that EVSE unit costs could decline, but installation costs could rise and offset these cost savings. By contrast, CALSTART said that EPA should account for learning rates when assessing EVSE equipment costs and noted that they have considered annual reductions of 4 to 7 percent in their analysis, consistent with reductions from renewable energy generation.

Response:

As described in RIA Chapter 2.6.2.1, we made several changes in how we estimate the EVSE costs incurred for depot charging in the final rule analysis in response to these comments and to account for the most up-to-date information available.

For the NPRM analysis, we developed cost ranges for each of the four EVSE types considered in our depot charging analysis. The DCFC costs were sourced from a 2021 study specific to heavy-duty electrification at charging depots while L2 cost ranges were informed by several sources (as described in RIA Chapter 2.6.2.1). After reviewing new information on EVSE costs provided in comments as well as a new NREL study released since the publication of the NPRM (Wood et al. 2023),[441] we determined it was appropriate to increase the underlying hardware and installation cost ranges we considered for DCFC-150 kW and DCFC-350 kW to those in Wood et al. 2023. As discussed in RIA Chapter 2.6.2.1, hardware and installation costs vary due to differences in equipment, installation sites, labor costs and other factors. We selected

[441] Wood, Eric et al. "The 2030 National Charging Network: Estimating U.S. Light-Duty Demand for Electric Vehicle Charging Infrastructure." 2023. Available online: https://driveelectric.gov/files/2030-charging-network.pdf.

the midpoint of the EVSE cost ranges to use in our cost analysis for the final rule to reflect an average cost for charging infrastructure deployment. We note that this differs from our approach in the NPRM. For that analysis, we used the low end of EVSE cost ranges to reflect typical costs that may be borne by BEV and fleet owners for installing EVSE after accounting for savings from the Alternative Fuel Refueling Property tax credit as well as grants, rebates, or other funding available through the IRA (see DRIA at 202). As described below, and to reflect new and more detailed information on the potential value of the tax credit, we now consider the tax credit in a separate step.

The resulting EVSE costs used in our FRM analysis before accounting for the tax credit for L2 and DC-50 kW ports now match the NPRM midpoint values as recommended by EMA. The updated cost for each DC-150 kW port in our FRM analysis is $154,200, which is within the range Valero provided in its comments as an example, and higher than the value recommended by EMA.[442] For a 350-kW port, the updated EVSE cost in our FRM analysis is $232,700, which is consistent with PACCAR's comment that costs would be "tens of thousands of dollars more" than the approximately $162,000 in the NPRM analysis and similar to the value recommended by EMA of about $228,000.[443] We also acknowledge Tesla's comments reporting significantly lower installed DCFC costs. To the extent that is experienced more widely by the industry in future years, our EVSE costs could be considered conservative.

We agree with EDF that it is appropriate to account for the potential savings to BEV owners from the Alternative Fuel Refueling Property Tax credit, but also with TRALA that it is important to consider eligibility restrictions when assessing the value of the tax credit. As described in RIA Chapter 2.6.1, DOE conducted an analysis of the average value of this tax credit for charging equipment that supports heavy-duty BEVs. DOE estimated that approximately 60 percent of depots will be located in qualifying census tracts and that businesses will generally meet prevailing wage and apprenticeship requirements to utilize the maximum 30 percent tax credit where applicable.[444] Accordingly, we apply an average reduction of 18 percent to the upfront costs we assume BEV owners will incur for EVSE at depots in our HD TRUCS model for the FRM (see RIA 2.6.1 for more information on this assumption.) We also agree with Valero that even though purchasers will pay less for EVSE due to the tax credit, these costs are still borne by taxpayers and represent a societal cost. Therefore, for the FRM analysis, we only include the assumed 18% cost savings as a savings to purchasers. We include the full EVSE costs in our cost benefits calculations as presented in RIA Chapter 8.

For the FRM analysis, we determined it was still appropriate to keep total hardware and installation costs constant over time as both EMA and CARB had affirmed in their comments. However, we agree with CALSTART that EVSE unit costs could decline significantly due to learning or other factors, as we acknowledged in the NPRM. As described in RIA Chapter 2.6, we decided to keep overall EVSE costs constant to reflect that while hardware costs may decline, installation costs could rise over time, particularly if fleet owners choose to install charging

[442] While EPA did not estimate the cost associated with a 180-kW EVSE port, we note that our assumed costs for the lower power 150-kW port are higher than those ATA cited for a 180-kW unit.
[443] As PACCAR noted, the $162,333 in the NPRM was expressed in 2021 dollars and the same is true of the $227,687 value recommend by EMA. We treat the $232,700 value in our FRM analysis as being expressed in 2022 dollars.
[444] Department of Energy. "Estimating Federal Tax Incentives for Heavy Duty Electric Vehicle Infrastructure and for Acquiring Electric Vehicles Weighing Less Than 14,000 Pounds." March 11, 2024.

stations at easier (and lower cost sites) first, and then move onto more challenging sites. To the extent installation costs stay constant or even decline, the combined hardware and installation EVSE costs we utilized for the FRM analysis could be considered conservative for future years.

6.3.3 Charging Costs

Comments by Organizations

Organization: American Fuel and Petrochemical Manufacturers (AFPM)

In addition, EPA underestimates the cost of the electricity to those customers who are not able to install their own charging stations and take advantage of charging at low-cost times, as the EPA's cost analysis uses a commercial rate and does not consider peak power or time of use charges. Notably, the cost to consumer also fails to account for the decreased range and loads for ZEV HDs in accounting for the payback occurring between three and seven years for long-haul tractors. EPA also fails to account for infrastructure impacts from increased operation of heavier ZEVs on the road including road and bridge deterioration and commensurate reduced funding for infrastructure from fuel tax collections as EPA fails to account for the fact that ZEVs do not pay federal and state liquid transportation fuel taxes. [EPA-HQ-OAR-2022-0985-1659-A2, p. 30]

Critically, EPA fails to account for billions of dollars in electric power infrastructure upgrades needed to supply power to the mandated heavy-duty ZEVs, including additional power generation, transmission, substations, transformers, and other distribution equipment. [EPA-HQ-OAR-2022-0985-1659-A2, p. 30]

Organization: Arizona State Legislature

Finally, EPA has not considered other important factors necessary to enable cross-country freight transportation by electric heavy-duty trucks. 'Other barriers include laws preventing commercial charging at public rest areas and the remoteness of many truck parking locations.'54 EPA acknowledges that 'the buildout of public and private charging stations (particularly those with multiple high-powered DC fast charging units) could in some cases require upgrades to local distribution systems.' 88 Fed. Reg. 25,982. EPA also recognizes that '[t]here is considerable uncertainty associated with future distribution upgrade needs, and in many cases, some costs may be borne by utilities rather than directly incurred by [battery electric vehicle] or fleet owners.' Id. at 25,983. But rather than conduct a comprehensive analysis of the cost and technology availability as the statute requires, EPA punted: 'Therefore, we do not model them directly as part of our infrastructure cost analysis.' Id. [EPA-HQ-OAR-2022-0985-1621-A1, p. 28]

54 American Transportation Research Institute, supra note 42, at 2.

Organization: Clean Fuels Development Coalition et al.

This charging infrastructure analysis further ignores the massive increase in electricity infrastructure necessary to supply an additional 110,000 GWh per year the rule says will be needed by 2055. Supplying this load will not only require significant new generation assets, but also additional transmission and distribution equipment including replacement of every transformer between the substation and the "depot." Assuming that this can all be done on EPA's timeline (and it almost certainly can't), these costs will be borne either by the buyers of the electric trucks or by electric ratepayers, many of whom will receive no benefit. EPA unreasonably ignores these costs. [EPA-HQ-OAR-2022-0985-1585-A1, pp. 33 - 34]

Organization: Daimler Truck North America LLC (DTNA)

As discussed in more detail in Section II.B.3.f, grid side updates to support transportation electrification must be included in EPA's payback period calculation, either as a separate input or as a cost per kilowatt-hour addition to the base electricity price. DTNA recommends that the costs set forth in Table 11 be included in EPA's assessment of payback period in HD TRUCS to assess the cost of grid updates as a separate input:56 [EPA-HQ-OAR-2022-0985-1555-A1, pp. 30-31] [Refer to Table 11 on p. 31 of docket number EPA-HQ-OAR-2022-0985-1555-A1]

56 Alternatively, EPA could consider ICCT's approach to estimating public infrastructure costs on a cent per kilowatt-hour basis, which is reflected in Table 7 of the ICCT TCO White Paper. See id. at Table 7 (estimating grid upgrade and connection costs, plus behind-the-meter charger-related cost estimates in cents-per-kWh). The ICCT figures may reasonably estimate the costs of depot site electrification; however, ICCT assumes that new public charging sites will have flexibility in station location selection to reduce the grid connection costs and that there will either be space inside the existing substation to add another substation transformer, or it would be possible to upgrade an existing transformer. Id. at 14. Using these assumptions, the ICCT TCO White Paper does not consider land acquisition costs, nor engineering design or right-of-way acquisition activities. As discussed in Section II.B.3.f, fleet depot locations do not have this flexibility, and therefore ICCT may underestimate grid side costs. Further, there is significant uncertainty in ICCT's grid update cost estimates, as the cost of grid improvements to support transportation electrification will widely vary based on the project scope. DTNA believes that its grid update cost estimates set forth in Table 11 are more accurate than the ICCT figures, but it requests that EPA consider using the ICCT cent-per-KW/h figures if it determines not to use the Company's per-vehicle cost figures in HD TRUCS.

DTNA also recommends that EPA proactively engage with electric utilities to better understand the range of associated grid update costs and that these costs be updated regularly in the HD TRUCS tool as additional data becomes available. [EPA-HQ-OAR-2022-0985-1555-A1, p. 31]

A number of fleet operations will require some charging to occur during peak hours or at public charging infrastructure, both of which will likely have higher associated costs than the commercial electricity end-use rate projection used by EPA in the HD TRUCS tool. These are factors fleets will likely consider when assessing the payback period for a BEV, thus EPA should periodically update electricity costs in the HD TRUCS model to inform its payback periods and adoption rates. To perform this analysis, it may be reasonable for EPA to rely on the 19.6 cents per kilowatt-hour charging cost estimate from the ICCT TCO White Paper as the basis for more accurate cost estimates. [EPA-HQ-OAR-2022-0985-1555-A1, p. 32]

EPA's projected electricity costs are based on the DOE EIA AEO 2022 reference case, but these estimates do not account for the supply-demand relationship, decarbonization mandates in the power generation sector, nor rate increases for large scale utility projects. In a 2022 article exploring the impact of the net-zero transition on a number of sectors, including electricity generation, McKinsey Sustainability projects that electricity costs could rise by about 40% by 2040 over 2020 prices, as power companies must invest in building renewable generation, transmission, and storage capacity—and some fossil fuel-based power assets would continue to incur capital costs, even if underutilized or prematurely retired.58 [EPA-HQ-OAR-2022-0985-1555-A1, p. 32]

58 See McKinsey Sustainability, 'The economic transformation: What would change in the net-zero transition' (Jan. 25, 2022), https://www.mckinsey.com/capabilities/sustainability/our-insights/the-economic-transformation-what-would-change-in-the-net-zero-transition.

A number of fleet operations will require some charging to occur during peak hours or at public charging infrastructure, both of which will likely have higher associated costs than the commercial electricity end-use rate projection used by EPA in the HD TRUCS tool. These are factors fleets will likely consider when assessing the payback period for a BEV, thus EPA should periodically update electricity costs in the HD TRUCS model to inform its payback periods and adoption rates. To perform this analysis, it may be reasonable for EPA to rely on the 19.6 cents per kilowatt-hour charging cost estimate from the ICCT TCO White Paper as the basis for more accurate cost estimates. [EPA-HQ-OAR-2022-0985-1555-A1, p. 32]

There are a number of TCO Inputs that EPA has not accounted for. [EPA-HQ-OAR-2022-0985-1555-A1, p. 34]

There are a number of TCO inputs that EPA has not accounted for in the HD TRUCS tool that should be included to more accurately inform payback periods and adoption rate projections for the Proposed Rule, including:

- Grid Update Costs. As discussed in this section and in Section II.B.3.f of these comments, fleets will pay for the grid updates required to support charging equipment for HD BEVs. EPA should include these costs either as a standalone line item in the HD TRUCS tool (using the per-vehicle costs provided above in Table 11, 'DTNA Proposed Grid Update Cost Inputs for HD TRUCS') or as an increase on its estimated costs per kilowatt hour (potentially using the estimates in Table 7 of the ICCT TCO White Paper). [EPA-HQ-OAR-2022-0985-1555-A1, p. 34]
- Land Acquisition. As discussed in Section II.B.3.f, fleets with space constraints may need to purchase additional land to site charging equipment. As real estate prices are extremely variable, and DTNA does not have information about how many fleets would need to expand their depot locations, we do not offer cost estimates here; however, the Company recommends that EPA consider adding land acquisition cost to HD TRUCS as more data becomes available. [EPA-HQ-OAR-2022-0985-1555-A1, p. 35]

Infrastructure Costs

EPA asserts 'there is considerable uncertainty associated with future distribution upgrade needs, and in many cases, some costs may be borne by utilities rather than directly incurred by BEV or fleet owners. Therefore, we do not model them directly as part of our infrastructure analysis.'115 DTNA appreciates that there is significant complexity and uncertainty in modeling these costs, but believes that omitting front-of-meter costs is a significant error in the TCO calculation that has major implications for EPA's proposed CO2 standard stringency levels. [EPA-HQ-OAR-2022-0985-1555-A1, p. 48]

115 Proposed Rule, 88 Fed. Reg. at 25,983.

How fleet owners pay for infrastructure will depend on a variety of factors, including utility structure (investor-owned, municipal, cooperative), existing available grid capacity, project scale, real estate needs, etc. For fleets in cooperative and municipality service territories, including many in critical urban freight hubs, upgrade costs are likely borne directly by the fleet. For fleets working with investor-owned utilities, the cost mechanism will vary. If infrastructure is needed by more than one utility customer, the utility will typically ask the fleet for a pro-rata share of those costs, or in some cases, increase electricity rates to cover those costs. Where fleets do not meet the minimum utilization rates for the contracted time period (5 to 10 years), fleets may be required to reimburse the utility for infrastructure upgrades, or costs are distributed among all ratepayers. One DTNA customer fleet has cancelled an order for 25 Class 8 tractors because of what they viewed as risky contract terms, including requirements for load management and a 10-year commitment to construct capacity for a 3 MW site. Regardless of the pathway, fleets will bear the cost of infrastructure upgrades to support charging needs, and those costs should be included in the proposed rule. [EPA-HQ-OAR-2022-0985-1555-A1, p. 48]

DTNA relied on a cost study by the Boston Consulting Group (BCG) to estimate an optimized and non-optimized dollar-per-kilowatt cost figure for grid updates.116 To estimate per-vehicle grid update costs for Class 3 - 8 BEVs, we applied the BCG dollar-per-kilowatt cost estimates to an assumed average daily power need for each vehicle class that would be subject to the Phase 3 CO_2 standards, shown in Table 11 (‘DTNA Proposed Grid Update Cost Inputs for HD TRUCS’) presented in Section II.B.3.b. As reflected in Table 11, these costs are non-negligible, significantly impact the TCO proposition, and must be considered in EPA’s HD TRUCS analysis. [EPA-HQ-OAR-2022-0985-1555-A1, p. 48]

116 See Boston Consulting Group, ‘The Costs of Revving Up the Grid for Electric Vehicles’ (Dec. 20, 2019), https://www.bcg.com/publications/2019/costs-revving-up-the-grid-for-electric-vehicles.

Using the same average daily power assumptions, DTNA estimated the additional installed capacity that will be needed to support HD BEVs at the adoption rates projected in the Proposed Rule. The Company calculated a 5-year average of commercial vehicle sales in all 50 states from the Polk Automotive database from 2017-2021, applied EPA’s projected ZEV volumes for 2027-2032, and calculated the total installed charging capacity that will be required by these vehicles in 2027 - 2032 to be approximately 45 gigawatts. In Appendix C to these comments, DTNA estimates the investments in charging infrastructure and grid upgrades, as well as total installed charging capacity, that will be required in each of the 50 states to support implementation of the Proposed Rule.117 DTNA considers installed capacity in this context to mean the total power available as EVSE to charge commercial vehicle batteries. Using installed capacity is a more appropriate metric for evaluating available charging capacity than the number of chargers alone, as installed capacity better reflects the variability in charging speeds needed to support different vehicle dwell times and truck-to-charger ratios. [EPA-HQ-OAR-2022-0985-1555-A1, pp. 48-49]

This installed capacity must be available at a combination of public and private purpose built HD-accessible charging stations. To be HD-accessible, public charging stations must include pull-through charging lanes and accommodate wide ingress and egress to support all vehicle types. Commercial vehicles are often unable to utilize existing passenger car charging infrastructure, due to space constraints that are not compatible with HDVs. [EPA-HQ-OAR-2022-0985-1555-A1, p. 49] [Refer to graphics on p. 49 of docket number EPA-HQ-OAR-2022-0985-1555-A1]

Based on the projected vehicle mix in the Proposed Rule and installed capacity needed to support these vehicles, DTNA estimated the total costs of EVSE charging equipment and necessary supporting grid updates to support Class 3-8 BEVs that would be required under the Proposed Rule. These figures, summarized in Table 16 below, do not include the additional capacities and investments needed to support passenger car electrification. [EPA-HQ-OAR-2022-0985-1555-A1, p. 49] [Refer to Table 16 on p. 49 of docket number EPA-HQ-OAR-2022-0985-1555-A1]

Even with incentive funding available, many fleets are unable to make the capital investments required to add BEVs to their fleets. DTNA is currently working with one school bus fleet that has secured Clean School Bus funds from EPA for 23 buses, as well as a payment plan through their utility's Make Ready program, and is still facing a $500,000 funding gap for site construction that threatens to jeopardize the project. Private fleet deployments are likely to face similar gaps, even where some combination of incentive program funding is available. [EPA-HQ-OAR-2022-0985-1555-A1, p. 50]

EPA Request for Comment, Request #38: However, there is considerable uncertainty associated with future distribution upgrade needs, and in many cases, some costs may be borne by utilities rather than directly incurred by BEV or fleet owners. Therefore, we do not model them directly as part of our infrastructure cost analysis. We welcome comments on this and other aspects of our cost analysis.

- DTNA Response: In using this approach, EPA significantly underestimates the cost of associated infrastructure in the BEV payback period calculation. Fleets will pay for the necessary grid upgrades in a variety of ways, depending on their utility structure and scope of project. EPA should consider these costs in its payback analysis, either as an up-front cost for fleets, or by building in a rate increase, as detailed in Section II.B.3 of these comments. [EPA-HQ-OAR-2022-0985-1555-A1, p. 164]

Organization: Edison Electric Institute (EEI)

EPA notes that 'there is considerable uncertainty associated with future distribution upgrade needs, and in many cases, some costs may be borne by utilities rather than directly incurred by BEV or fleet owners' in explaining why it models these costs as part of the infrastructure cost analysis. 88 Fed. Reg. 25,983. In general, the upgrades to the local electric system needed to bring sufficient power to the site may be known as 'electric company-side make-ready' or 'front-of-the-meter' infrastructure and includes but is not limited to poles, vaults, service drops, transformers, mounting pads, trenching, conduit, wire, cables, meters, other equipment as necessary, and associated engineering and civil construction work. Front-of-the-meter infrastructure is distinct from infrastructure on the customer side of the meter ('behind-the-meter'), which includes the supply infrastructure (conduit and wiring to bring power from the service connection to the charging station, and the associated installation costs, sometimes known as 'customer-side make-ready') and the charging equipment, sometimes known as Electric Vehicle Supply Equipment (EVSE). [EPA-HQ-OAR-2022-0985-1509-A2, p. 17]

Front-of-the-meter infrastructure is generally installed, owned, and operated by the electric company. However, the costs associated with front-of-the-meter infrastructure may be borne by the site host customer in full or in part if the costs exceed an allowance as determined by the electric company's line-extension and/or service extension policy. These costs may also be known as 'contributions in aid of construction.' [EPA-HQ-OAR-2022-0985-1509-A2, pp. 17-18]

Modeling these front-of-the-meter infrastructure costs is inappropriate for the following reasons. First, estimating distribution upgrade costs may be beyond the scope of EPA's analysis, as it is not clear that a similar scope of analysis is applied to traditional liquid fuels. For example, the analogous cost comparison for internal combustion engine vehicle would include cost considerations for fleet operators either 1) installing refueling stations at their own facilities, or 2) the embedded cost of fuel retailers' business operations in the cost of diesel or gasoline. [EPA-HQ-OAR-2022-0985-1509-A2, p. 18]

Second, as described above, distribution upgrades are highly location specific. The costs associated with these upgrades are also highly variable, depending on the upgrade requested by the customer and the local distribution capacity. As stated in EEI's Preparing to Plug In Your Fleet guide, 'the grid can expand as needed to accommodate the needs of any customer, but the time and resources needed to make the required upgrades are highly dependent on the specific facility and the circuit that serves it.'27 [EPA-HQ-OAR-2022-0985-1509-A2, p. 18]

27 See EEI, Preparing To Plug In Your Fleet – 10 Things to Consider, https://www.eei.org/-/media/Project/EEI/Documents/Issues-and-Policy/Electric-Transportation/PreparingToPlugInYourFleet.pdf.

Third, the share of any distribution costs that the customer may bear varies as a matter of policy. Some electric companies have or are seeking approval for line extension allowances to cover some or all of these costs for serving EV charging infrastructure. In California, for example, legislation required electric companies in the state to file tariffs that would authorize them to 'design and deploy all electrical distribution infrastructure on the utility side of the customer's meter for all customers installing separately metered infrastructure to support charging stations, other than those in single-family residences.' This policy prompted tariffs from EEI members Pacific Gas & Electric (PG&E), San Diego Gas & Electric (SDG&E), and SCE that essentially allow electric companies to invest in more of the electric company-side infrastructure costs as part of the standard distribution system investment. [EPA-HQ-OAR-2022-0985-1509-A2, pp. 18-19]

Fourth, EEI expects that the majority of fleets to electrify in the next several years will be those with return-to-base operations, which enables depot charging that is owned and operated by the fleet itself. Public charging, analogous to the existing gas station model, will be needed to serve long-haul electric trucks, but that opportunity will be limited in the near-term by battery capabilities. However, there are many new refueling models emerging, including but not limited to: fleet charging facilities owned by third parties and accessed by fleet operators through a reservation or subscription system; charging-as-a-service companies that disintermediate the fleet operator from the electric company, owning and operating the charging equipment at a customer facility and assessing the fleet operator a fully-bundled, flat charging fee (e.g., $/kWh); and transportation-as-a-service companies that provide the vehicle and charging to a fleet operator, such that the fleet operator pays a fully-bunded, flat service feel (e.g., $/mile). In all of these models, the fleet operator itself is not exposed to the front-of-the-meter infrastructure costs, but rather these costs are borne by a third party that then recoups all of its costs through their charging or service fees. [EPA-HQ-OAR-2022-0985-1509-A2, p. 19]

In conclusion, EPA is justified in not modeling front-of-the meter costs because doing so would result in an apples-to-oranges comparison to liquid fuels, those costs are site-specific and variable, the recovery mechanism of those costs depends upon state-specific policies, and fleet-operators may not always bear those costs. [EPA-HQ-OAR-2022-0985-1509-A2, p. 20]

Organization: Moving Forward Network (MFN) et al.

12.7. EV Charging is Already Putting Downward Pressure on Electric Rates to the Benefit of All Utility Customers

Because much EV charging can be accomplished when there is spare capacity on the grid, charging can spread the costs of maintaining the system over a greater volume of electricity sales, reducing the per-kilowatt-hour price of electricity to the benefit of all customers. This has already been demonstrated in the real-world with light-duty EV charging and is expected to hold true for HD EV charging as well. [EPA-HQ-OAR-2022-0985-1608-A1, p. 117]

In fact, real-world data compiled by Synapse Energy Economics shows EV drivers are not being subsidized by other utility customers and, in fact, they are putting downward pressure on rates. Between 2011 and 2020, EV customers across the United States have contributed more than $1.7 billion in net-revenue to the body of utility customers. 266 [EPA-HQ-OAR-2022-0985-1608-A1, p. 117]

266 Melissa Whited, Tyler Fitch, Jason Frost, Eric Borden, Courtney Lane, Ben Havumaki Sarah Shenstone- Harris, and Elijah Sinclair. Electric Vehicles Are Driving Rates Down. (June 2023). https://www.synapse-energy.com/sites/default/files/Electric%20Vehicles%20Are%20Driving%20Rates%20Down%20Factsheet.pdf

The results shown in Figure 34 compare the new revenue the utilities collected from EV drivers to the cost of the energy, capacity, transmission, and distribution system upgrades required to charge those vehicles, plus the costs of utility EV infrastructure programs that are deploying charging stations for EVs. In total, EV drivers contributed an estimated $1.7 billion more than associated costs. That net-revenue is returned to the body of utility customers in the form of electric bills that are lower than they otherwise would be. [EPA-HQ-OAR-2022-0985-1608-A1, p. 117.] [See Figure 34 Total Utility Revenues vs. Total Costs Associated with EVs (2011-2020) located on p. 118 of docket number EPA-HQ-OAR-2022-0985-1608-A1.]

While the costs associated with serving generally higher-powered HD EV charging could be more significant on a per-vehicle basis, there is still significant potential for HD EV charging (much of which can still be done during off-peak hours when there is plenty of spare grid capacity) to improve the utilization of the electric grid and put downward pressure on utility rates as a result. In fact, analysis conducted by ERM estimates that widespread medium and heavy-duty EV charging could result in $433 million in net-utility-revenue in 2030, rising to $2.4 billion in 2040, and $4.1 billion in 2050. 267 [EPA-HQ-OAR-2022-0985-1608-A1, p. 118]

267 ERM. Federal Clean Trucks Program: An Analysis of the Impacts of Low NOx and Zero-Emission Medium- and Heavy-Duty Trucks on the Environment, Public Health, Industry, and the Economy. ERM. (2022). p. 23. https://www.erm.com/contentassets/f3d6061dd8a04147a3f38b7db256ae44/federal-clean-trucks-report.pdf

12.8. New Utility Rates Designed for EV Charging Increase the Fuel Cost Savings EVs Can Provide

Gasoline, diesel, and electricity prices vary across the country, and electricity prices vary depending upon the particular characteristics of the utility rate on which a customer takes service. And many existing commercial and industrial utility rates have “demand charges” that can reduce fuel cost savings for high-powered/low-utilization applications like some EV charging use-cases. Thankfully, the challenge such demand charges can pose for EV charging has long been recognized and across the nation, many utilities and regulators have already implemented solutions or are in the process of doing so. [EPA-HQ-OAR-2022-0985-1608-A1, pp. 118 - 119]

In fact, the BIL amended the Public Utility Regulatory Policies Act (PURPA) Section 111(d) to require regulators and non-regulated utilities to consider new rates that:

promote affordable and equitable electric vehicle charging options for residential, commercial, and public electric vehicle charging infrastructure; improve the customer experience associated with electric vehicle charging; accelerate third-party investment in electric vehicle charging for light-, medium-, and heavy-duty vehicles; and appropriately recover the marginal costs of delivering electricity to electric vehicles and electric vehicle charging infrastructure. 268 [EPA-HQ-OAR-2022-0985-1608-A1, p. 119]

268 H.R.3684. Infrastructure Investment and Jobs Act. 117th Congress. (2021-2022). Section 40431 www.congress.gov/bill/117th-congress/house-bill/3684/text.

This has spurred new regulatory proceedings across the country. But many utilities, regulators, and state legislatures were already acting to address this issue before the BIL became law. [EPA-HQ-OAR-2022-0985-1608-A1, p. 119]

As detailed in a publication of the National Association of Regulatory Utility Commissioners (NARUC) entitled “Best Practices for Sustainable Commercial EV Rates and PURPA 111(d) Implementation,” rates designed for EV charging can deliver significant fuel cost savings without relying upon cross-subsidies from other utility customers. 269 For example, on a new Pacific Gas & Electric rate designed for commercial EV charging that still recovers all associated marginal costs, the San Joaquin Regional Transit District reduced its overall fuel cost per mile from $2.31 to $0.68 (in a utility service territory that has some of the higher underlying marginal costs in the nation). 270 The paper also details rates that take a similar approach that were approved for Southern California Edison, San Diego Gas & Electric, and Alabama Power. [EPA-HQ-OAR-2022-0985-1608-A1, p. 119]

269 Nancy Ryan, Alissa Burger, Jenifer Bosco, John Howat, and Miles Muller. Best Practices for Sustainable Commercial EV Rates and PURPA 111(d) Implementation. (2022). https://pubs.naruc.org/pub/55C47758-1866-DAAC-99FB-FFA9E6574C2B

270 Id.

Since the publication of that NARUC paper, many other utilities and regulators have either proposed or secured approval of new rates designed for EV charging. And by the time the HDV rule goes into effect in 2027, many more will have followed suit, increasing the fuel cost savings EVs can provide. [EPA-HQ-OAR-2022-0985-1608-A1, p. 119]

Organization: National Automobile Dealers Association (NADA)

D. EPA's proposed rule fails to appropriately consider infrastructure lead times and costs.

EPA has failed to analyze or model the essential and unique refueling infrastructure needs and costs associated with its Phase 3 GHG proposal. ZEV HDVs will have special refueling infrastructure needs versus light-duty ZEVs. Without sufficient infrastructure, the number of ZEV HDVs purchased between 2028 and 2032 will be far lower than EPA forecasts. One of several impediments to widespread charging infrastructure availability is the cost.14 Among other things, the costs associated with EV charging infrastructure include the equipment itself, ongoing operation and maintenance costs, and the back-end equipment, transmission, and installation costs needed to get power to the charging station site. These should be considered as purchaser costs in the HD TRUCS tool as those costs are passed on to HDV purchasers installing infrastructure. In addition to private infrastructure, a massive amount of costly public refueling infrastructure designed for ZEV HDVs must be built out. This will take time.15 [EPA-HQ-OAR-2022-0985-1592-A1, pp. 8 - 9]

14 M. Melaina et al., Consumer Convenience and the Availability of Retail Stations as a Market Barrier for Alternative Fuel Vehicles, NREL (Jan. 2013).

15 Hydrogen Fueling Station Locations, DOE.

2. EPA's infrastructure assumptions must be adjusted to reflect reality.

The infrastructure needed to support ZEV HDVs will require increased electricity generation capacity and a more comprehensive transmission system than exists today. EPA has not considered necessary public charging investments. Apparently, the Phase 3 GHG proposal envisions that all the battery-recharging stations for ZEV HDVs will be located at trucking depots and terminals where trucks park overnight. But depot charging will result in high electricity demands and significant upgrades to transmission lines and substations to support each depot. On-site power availability limits the number of ZEV HDVs a site can charge. The assumption that ZEV HDVs will exclusively charge at night is a fallacy as many will need to be charged on route at public battery-recharging stations, in addition to at depots. Sites acting as electrified truck stops will also concentrate electricity demands and could require the same amount of energy as a small town.19 EPA's final Phase 3 GHG rule must reflect realistic infrastructure timelines and demand considerations. [EPA-HQ-OAR-2022-0985-1592-A1, pp. 10 - 11]

19 High-Voltage Transmission Grid Critical to Meeting Electric Vehicle Charging Demands, First -in-the-Nation Study Finds, NATIONAL GRID (Nov. 14, 2022).

Organization: National Waste & Recycling Association (NWRA)

NWRA also asks that EPA work with the Department of Energy to understand the electrical load that would be needed to electrify the heavy-duty truck fleet. NWRA members are concerned that the electrical infrastructure is not expanding fast enough to support an electrified fleet. [EPA-HQ-OAR-2022-0985-1616-A1, p. 2]

Organization: Schneider National Inc.

The EPA assumes all vehicles will have a 12-hour overnight dwell time for charging.

- A driver break is 10 hours, so a 12-hour dwell for charging requirements would extend the driver's standard break time and would likely negatively impact work time/hours for a driver. Additionally, a 12-hour overnight dwell time would eliminate a motor carrier's ability to slip-seat a truck to be used in multiple shifts in a day (again, affecting productivity and freight transportation capabilities). In the over-the-road trucking industry, a 12- hour overnight dwell time – particularly at a specific location that has charging infrastructure – is not typical.
- Team drivers would be most impacted as they would need to shut down for charging; whereas, today, they trade off sleeper berth time with driving time. As a result, until infrastructure is more prevalent and charging times are faster, forcing team drivers to utilize ZEVs will certainly affect productivity and pay.
- Today, drivers will often take their DOT break and fuel at the same time/location. If a charger is not available (and, to be clear, charging infrastructure certainly is not prevalent), it will negatively impact a driver's ability to pick up, deliver or take his/her mandatory break when needed.
- Driver parking is already very congested and there is limited visibility to locations with available parking spots, especially at third-party fuel locations. Requiring a 12-hour charging shutdown would exacerbate the situation.
- DOT breaks would need to take place where there is the availability to charge the tractor instead of after a driver utilizes his/her full complement of 11 available driving hours and 14 available on-duty hours, thus reducing a driver's productive hours and further increasing the need for additional capacity to perform the same amount of work. [EPA-HQ-OAR-2022-0985-1525-A1, p. 2]

Organization: Tesla, Inc. (Tesla)

Utility Rate Design Reform Will Spur Greater Infrastructure Investment

Addressing utility demand charges will also play a role in facilitating the expansion of heavy-duty charging infrastructure. 218 The combination of low load factors with high demand charges can result in uneconomic operation of charging stations and stymies investment in charging infrastructure in otherwise promising markets where heavy-duty electrification is growing. EPA should recognize that this issue is changing with many utilities now proposing or already having implemented novel approaches to mitigate the impact of demand charges and encourage time of use rates to facilitate higher volume charging.219 Moreover, since BEV charging stations are large upfront investments assessed over a long-time horizon, the longer-term certainty provided in many of these rate reform proceedings will drive greater infrastructure investment. A number of utilities proceedings have already addressed these issues including the following:

- Illinois Commerce Commission Docket No. 20-0170 – In the Matter of Ameren Illinois Company d/b/a Ameren Illinois's Proposed Creation of Rider Optional Vehicle Charging Program ('Rider EVCP').
- Oregon Public Utilities Commission Docket No. UE 374 – In the Matter of Pacificorp d/b/a Pacific Power Request for a General Rate Revision

- New Jersey Board of Public Utilities Docket No. EO18101111 – In the Matter of the Petition of Public Service Electric and Gas Company for Approval of its Clean Energy Future – Electric Vehicle and Energy Storage ('CEF-EVES') Program on a Regulated Basis
- Colorado Public Utilities Commission Proceeding No. 21AL-0494E – In the Matter of Advice No. 1867- Electric Filed by Public Service Company of Colorado to Revise Its PUC No. 8-Electric Tariff and to Add Schedule S-EV-CPP and Implement Changes to Schedules S-EV, EVC, and TEPA, to be Effective on Thirty- Days' Notice
- Massachusetts Department of Public Utilities Docket # 21-90 – Petition of NSTAR Electric Company d/b/a Eversource Energy for approval of its Phase II Electric Vehicle Infrastructure Program and Electric Vehicle Demand Charge Alternative Proposal
- Illinois Commerce Commission Docket No. 22-0432 Petition for Approval of Beneficial Electrification Plan under the Electric Vehicle Act, 20 ILCS 627/45 and New EV Charging Delivery Classes under the Public Utilities Act, Article IX
- New York PSC's Case No. 22-E-0236 Proceeding to Establish Alternatives to Traditional Demand-Based Rate Structures for Commercial Electric Vehicle Charging. [EPA-HQ-OAR-2022-0985-1505-A1, p. 30]

218 See Alliance for Transportation Electrification, Rate Design for EC Fast Charging: Demand Charges (May 2022) available at https://evtransportationalliance.org/wp-content/uploads/2022/06/Rate.Design.TF_.Demand-Charge-Paper-Final- 5.25.22.pdf

219 Utility Dive, With looming EV load spikes, PG&E, Duke, other utilities adopt new rate design and cost recovery strategies (Apr. 18, 2023) available at https://www.utilitydive.com/news/electric-vehicle-load-spikes-pge-duke-sce-entergy-apsdynamic-rate-design-reduced-demandcharges/646603/?utm_source=Sailthru&utm_medium=email&utm_campaign=Issue:%202023-04-21%20Utility%20Dive%20Newsletter%20%5Bissue:49850%5D&utm_term=Utility%20Dive

Additional proceedings addressing these issues will help further facilitate investment and deployment of charging infrastructure that can support a more ambitious Phase 3 standard. [EPA-HQ-OAR-2022-0985-1505-A1, p. 31]

Organization: Truck and Engine Manufacturers Association (EMA)

HD TRUCS calculates BEV charging characteristics using the known losses that occur with the flow of electricity from the grid to the battery. Four unique EVSE (i.e., chargers) are included in the HD TRUCS assessment tool. The AC EVSE and DCFC EVSEs provide a spread of possible recharging equipment that could be used with a given type of BEV truck. [EPA-HQ-OAR-2022-0985-2668-A1, p. 21]

As noted above, EPA chose to assume that all BEV-truck charging will occur at private depot locations at the end of each daily shift. EPA determined that a 12-hour dwell time (downtime) is most appropriate based on its literature search. HD TRUCS assesses the appropriate EVSE, and its associated cost, for the various truck applications using the 12-hour dwell time and calculates the least expensive EVSE unit capable of performing the modeled needed charging. [EPA-HQ-OAR-2022-0985-2668-A1, p. 22]

Annual BEV Electricity Cost in A3a_Cost worksheet – HD TRUCS calculates the annual cost of electricity based on the energy that is consumed by the vehicle from the batteries rather than from the electricity that is used to recharge the batteries. The latter includes the wall-to-battery loss factor for the charging process. The current formula in HD TRUCS underestimates the annual electricity cost by approximately 11%. [EPA-HQ-OAR-2022-0985-2668-A1, p. 23] Annual BEV Electricity Cost in A3a_Cost worksheet – HD TRUCS calculates the annual cost of electricity based on the energy that is consumed by the vehicle from the batteries rather than from the electricity that is used to recharge the batteries. The latter includes the wall-to-battery loss factor for the charging process. The current formula in HD TRUCS underestimates the annual electricity cost by approximately 11%. [EPA-HQ-OAR-2022-0985-2668-A1, p. 23]

Electricity Cost – Electricity cost in HD TRUCS is based on the commercial rate from the AEO 2022 Report, Table 8. The cost starts at 10.63 cents per kilowatt-hour. While that may be a good estimate of the base rate that is paid by large commercial users of electricity, it does not adequately reflect the total cost of electricity that purchasers of BEVs will experience. Three important elements are missing, and a fourth is recommended to be added. The missing elements of the cost of electricity are: peak time-of-use (TOU) electricity rates, monthly peak demand charge, and upfront costs of modifications to the electrical grid upstream of the electric meter. The item to be added is the annual maintenance cost of the EVSE unit, normalized to a cents per kilowatt-hour basis. [EPA-HQ-OAR-2022-0985-2668-A1, p.29]

In ICCT's April 2023 TCO white paper, they report on their study of electricity costs for BEV battery charging. Their study looked at seven states, covering all four corners of the US plus the middle of the country. It shows the spread of electricity costs and provides real-world data for use in determining more complete electricity costs. [EPA-HQ-OAR-2022-0985-2668-A1, p.29]

EMA's research directionally aligns with the data shown in the ICCT white paper. With the limited time for this comment period, a more exhaustive study by EMA could not be accomplished. [EPA-HQ-OAR-2022-0985-2668-A1, p.29]

Using the ICCT data, the average cost of electricity for businesses charging BEVs works out to be 12.26 cents per kilowatt-hour (cents/kWh). That includes 10% of the charging at peak rates and 30% at super off-peak rates. Based on the charging times and vehicles per-charger calculations in HD TRUCS, EMA believes the percent time at peak rates, between 4 PM and 9 PM, is lower than will be seen by fleet owners, but is acceptable until a more comprehensive study can be completed. [EPA-HQ-OAR-2022-0985-2668-A1, p.29]

Also included in the ICCT paper are estimates of the cost of required upstream infrastructure changes, normalized to cents/kWh. Utilities have not shown a willingness to absorb those upfront costs without including them in the electricity rates for the end users. Thus, those costs need to be included in the cost of electricity. [EPA-HQ-OAR-2022-0985-2668-A1, p.29]

The cost to maintain the EVSE units is estimated by ICCT to be $3,200 annually. Normalized, this becomes 0.52 cents/kWh. This maintenance cost needs to be included in the cost of electricity in HD TRUCS as well. [EPA-HQ-OAR-2022-0985-2668-A1, p.30]

With the foregoing in mind, the table below provides a breakdown of all the relevant components of the cost of electricity for BEV battery charging:

EMA has applied this total cost of electricity (14.29 cents/kWh) for each year of the proposed regulation in the EMA HD TRUCS tool. [EPA-HQ-OAR-2022-0985-2668-A1, p.30] [See the Cost of electricity for BEV Battery Charging table on page 30 of docket number EPA-HQ-OAR-2022-0985-2668-A1.]

Electricity Cost – The revised total cost of electricity of 14.29 cents/kWh, as detailed above, was run on its own in EMA HD TRUCS. The table below shows the revised projected ZEV adoption rates for 2027 and 2032 from running that one updated input: [EPA-HQ-OAR-2022-0985-2668-A1, p. 37] [See the Projected ZEV Adoption Rates for MYs 2027 and 2032, Electricity Table on page 37 of docket number EPA-HQ-OAR-2022-0985-2668-A1.]

Organization: Valero Energy Corporation

Beyond the EVSE hardware and installation costs, EPA fails to consider annual operating and maintenance costs for EVSE, estimated by the District of Columbia to run $1,000 per Level 2 charger and $1,400-$2,000 per Level 3 DC fast charger.74 [EPA-HQ-OAR-2022-0985-1566-A2, p. 14]

74 Government of the District of Columbia, "District's Electric Vehicle Infrastructure Deployment Plan" at 13 (2022), https://www.fhwa.dot.gov/environment/nevi/ev_deployment_plans/dc_nevi_plan.pdf.

Although EPA acknowledges that upgrades to electricity distribution systems may be required to meet the charging loads associated with EVSE, it immediately dismisses the costs, explaining that "in many cases, costs for some distribution system upgrades may be borne by utilities rather than directly incurred by BEV or fleet owners whose costs we model in our analysis of depot charging infrastructure; therefore, we do not include these costs in our analysis."75 Regardless of who is paying, upgrades to electrical infrastructure are real impacts associated with EVSE installation and come with real costs. In their EV Infrastructure Deployment Plans, several states quantify the cost of electrical system upgrades needed to accommodate EVSE, including:

- Idaho cites that "charging stations installed with NEVI formula funds must be able to provide a power output of at least 600kW. In Idaho, most NEVI sites will require transformer upgrades. Additional improvements such as installing new feeder lines and completing substation upgrades also may be needed. At the very least, new electrical upgrades for a new transformer cost approximately $20-30,000."76
- Indiana cites that "Utilities estimated investment between $50,000 to $125,000 to serve 600kW per station with locations requiring significant system upgrades totaling greater than $1 million. Upgrades could include new transformers, trenching, concrete/asphalt work, conduit, underground vaults, new conductor, and other miscellaneous equipment to serve the DCFC. Respondents expressed they would not deny an installation from proceeding. However, as expressed above, costs may be prohibitive for the prospective customer at certain locations."77 [EPA-HQ-OAR-2022-0985-1566-A2, pp. 14 - 15]

75 DRIA at 201.

76 Idaho Transportation Department, "2022 State of Idaho Electric Vehicle Infrastructure Baseline Plan" at 38 (August 1, 2022), https://www.fhwa.dot.gov/environment/nevi/ev_deployment_plans/id_nevi_plan.pdf.

77 Indiana Department of Transportation, "Indiana Electric Vehicle Infrastructure Deployment Plan" at 37 (July 29, 2022), https://www.fhwa.dot.gov/environment/nevi/ev_deployment_plans/in_nevi_plan.pdf.

These utility costs may not be borne solely by individual customers; in some cases, these costs will ultimately be passed on to ratepayers. EPA fails to acknowledge these costs, nor to assess the cumulative cost burden resulting from the concurrent increase in electrical demand resulting from implementing the proposed heavy-duty vehicle rule in the same time frame it seeks to force electrification of the light- and medium-duty vehicle fleet. [EPA-HQ-OAR-2022-0985-1566-A2, p. 15]

7. The charging efficiencies adopted by EPA for purposes of this proposed rule are arbitrarily inconsistent with other contemporaneously proposed rules.

EPA adopts the following charging efficiency rates for use in this rulemaking:78 [EPA-HQ-OAR-2022-0985-1566-A2, p. 15.] [See Table 2-68, Charging Efficiency, on page 15 of docket number EPA-HQ-OAR-2022-0986-1566-A2.]

78 DRIA at 227.

Upon examination of the NREL study to which EPA cites,79 these charging efficiencies represent NREL program goals, not projections. Further, the years represent assumptions of when the goals will reach commercial production, which NREL expects to occur 5 years after demonstration in a lab.80 At the time of publication of the NREL report (2021), then, these charging efficiencies had not yet even been demonstrated in a lab, and yet EPA incorporates them as fact and relies upon them for purposes of the proposed rulemaking. [EPA-HQ-OAR-2022-0985-1566-A2, pp. 15 - 16]

79 NREL, "Vehicle Technologies and Hydrogen and Fuel Cell Technologies Research and Development Programs Assessment Report for 2020" (August 2021), https://www.nrel.gov/docs/fy21osti/79617.pdf.

80 NREL, "Vehicle Technologies and Hydrogen and Fuel Cell Technologies Research and Development Programs Assessment Report for 2020" at 26 and v (August 2021), https://www.nrel.gov/docs/fy21osti/79617.pdf.

Further, the EV charging efficiencies used by EPA in this rulemaking are inconsistent with those used in other proposed rulemakings:

- In the "Draft Regulatory Impact Analysis: RFS Standards for 2023-2025 and Other Changes," to support the generation of eRINs, EPA used an EV charging efficiency of 85% and a line loss factor of 5.3%, yielding a total loss rate of 19.5% (p. 329).
- The efficiency and loss factors applied in EPA's Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles81 assume an overall loss rate of 15.9% (i.e., 1 – 0.9*0.935).
- Here, EPA proposes a third distinct charging efficiency, but fails to account for transmission line losses.
- EPA provides no explanation for why the efficiency values should differ among the three proposed rules. [EPA-HQ-OAR-2022-0985-1566-A2, p. 16]

81 88 Fed. Reg. 29303 (May 5, 2023).

EPA Summary and Response

Summary:

EPA received comments both on the electricity prices we used in the NPRM analysis, and on additional categories of costs that commenters said should be included in the FRM analysis either as part of the $ per kWh cost to charge or through other means.

In general, most commenters stated that our assumed electricity costs—based on the commercial rate in the AEO 2022 reference case—were too low and understated the cost to charge. DTNA noted several limitations of AEO's costs, saying they "do not account for the supply-demand relationship, decarbonization mandates in the power generation sector, nor rate increases for large scale utility projects." DTNA pointed to McKinsey work, which suggests that electricity costs could be significantly higher by 2040 given the costs of new generation, transmission, and storage to increase renewable electricity.

AFPM, DTNA, and NADA stated that EPA failed to consider the higher costs associated with public charging, which may happen during peak hours and include higher time of use rates and demand charges (among other costs). EMA likewise noted that the AEO electricity rates do not account for demand charges or peak time of use rates and that EPA should include these costs in its FRM analysis.

Many commenters stated that upgrades to the electric distribution system or, in some cases, to generation or transmission infrastructure, would be needed to meet increased demands from BEV charging. Most—including AFPM, the Arizona State Legislature, CFDC et al., DTNA, EMA, NADA, and Valero—said that EPA should account for the cost of such power sector upgrades in the analysis. Valero provided examples of estimated potential distribution upgrade costs ranging from $20,000 to $125,000 or more per station from two state plans for NEVI-funded stations. DTNA shared estimates of potential distribution costs that it recommended EPA use for this purpose but noted that costs from a 2023 ICCT TCO paper (Basma et al. 2023) may be a reasonable alternative. EMA also pointed to the ICCT paper as a source for distribution upgrade costs.

DTNA, EMA, NADA, and Valero all stated that EPA should include EVSE maintenance costs in its analysis, with several pointing to values in the same ICCT paper of $3200 per port per year, amortized as $0.0052 per kWh. Valero cited cost estimates from the District of Columbia's plan for NEVI-funded stations of $1000 per L2 charger and up to $2000 per DCFC each year. DTNA additionally commented that the costs to purchase or lease land for station deployments should be accounted for in EPA's cost analysis.

As noted above, both EMA and DTNA suggested the ICCT paper (Basma et al. 2023) as a potential source to inform charging costs in EPA's analysis, since it accounts for many of the costs discussed above. EMA suggested that $0.1429 per kWh, which combines ICCT's electricity price, amortized EVSE maintenance costs, and costs associated with distribution system upgrades, is a reasonable choice for depot charging. DTNA suggested ICCT's value of $0.196 per kWh—which includes the aforementioned costs as well as amortized costs of public charging equipment—may be a reasonable source of public charging costs (while noting some limitations).

However, not all commenters agreed with the above points. Whereas DTNA and others suggested that EPA's assumed electricity prices were too low and did not properly account for the impacts of BEV charging demand on the power grid, the Moving Forward Network et al. stated that EV charging can actually reduce electricity prices for all users by taking advantage of unused grid capacity (e.g., at night) and distributing system costs that would be incurred anyway over more electricity sales. The commenter cited data from Synapse Energy Economics showing that EV charging was responsible for $1.7 billion in net revenue that helped lower electricity bills in the 9 years leading up to 2020, and an ERM study, which projected that future medium-heavy-duty charging could also reduce rates.

Both the Moving Forward Network et al. and Tesla acknowledged that demand charges are currently a challenge for EVSE providers and customers. However, both commenters characterized this as a well-known issue that utilities and others are working to address. For example, the Moving Forward Network et al. pointed to an amendment to the Public Utility Regulatory Policies Act (promulgated in the Bipartisan Infrastructure Law) to promote affordable EV charging rates and "appropriately recover the marginal costs of delivering electricity to electric vehicles and electric vehicle charging infrastructure" among other actions. The Moving Forward Network et al. and Tesla also noted utilities and regulators have already been addressing this issue through rate reform or other strategies, with Tesla citing a variety of recent utility proceedings.

EEI commented that EPA was justified in its decision not to model costs of distribution upgrades to fleets in the NPRM as EEI stated that these costs will be site specific, who bears the costs (utilities vs. fleets) will vary, and accounting for these costs would be inconsistent with the approach EPA has taken for liquid fuels, in which comparable upgrades are not directly accounted for in fleet costs. EEI also discussed a variety of emerging market solutions including third-party subscription or bundled services (e.g., charging-as-a-service or transportation-as-a-service), in which fleets would not directly bear the upfront costs for front-of-the meter upgrades.

Separately, Valero commented on EPA's charging efficiency assumption stating that the value is inconsistent with comparable values in other contemporaneous EPA proposed rulemakings and that the underlying source for the charging assumption is an NREL program goal rather than a projection of feasible or demonstrated charging efficiencies. Valero also stated that EPA did not account for transmission line losses.

Response:

For the NPRM analysis, we used the DOE EIA AEO 2022 reference case commercial electricity end-use rate projection for our electricity price. EPA agrees with commenters that this approach likely underestimates charging costs that will be experienced by BEV owners, and we have updated our assumed charging costs for the FRM analysis. For example, in the NPRM, we acknowledged that certain stations, particularly those with many high-power DCFC, may require upgrades to the distribution system; however, we did not include these estimates in our EVSE or charging costs. On further consideration, and taking into account comments received, EPA has included these costs in our FRM analysis.As described in RIA Chapter 2.4.4.2, to estimate charging costs for the final rule analysis, we start by modeling future electricity prices, as charged by utilities, that account for the costs of BEV charging demand and the associated distribution system upgrade costs. We do this in three steps: 1) we model future power generation using the Integrated Planning Model (IPM), 2) we estimate the cost of distribution system upgrades associated with charging demand through the DOE Transportation Electrification Impact Study (TEIS),[445] and 3) we use the Retail Price Model (RPM) to project electricity prices accounting for both (1) and (2).

As described in RIA Chapter 4.2, IPM models the power sector, including changes to power generation based on future demand scenarios. In order to capture the potential future impacts on

[445] National Renewable Energy Laboratory, Lawrence Berkeley National Laboratory, Kevala Inc., and U.S. Department of Energy. "Multi-State Transportation Electrification Impact Study: Preparing the Grid for Light-, Medium-, and Heavy-Duty Electric Vehicles." DOE/EE-2818. U.S. Department of Energy. March 2024. ("TEIS").

the power sector from ZEVs, we ran IPM for a scenario that combined electricity demand from an interim version of the final standards case and EPA's proposed rulemaking "Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles."[446] The same demand scenario was used as the action case for the TEIS. The TEIS research team modeled how many new or upgraded substations, feeders, and transformers would be needed to meet projected electricity demand from transportation, including demand from residential workplace, depot, and public charging to support projected light-, medium-, and heavy-duty plug-in electric vehicles. For all public and workplace charging, vehicles were assumed to charge at full power upon arrival. At homes and depot charging stations—where vehicles have longer dwell times—a managed charging scenario was developed to spread out charging and reduce peak power.

The changes to power generation in our modeled IPM scenario and the distribution cost estimates from TEIS were then input to the Retail Price Model.[447] The RPM developed by ICF generates estimates for average electricity prices over consumer classes accounting for the regional distribution of electricity demand. The resulting national average retail prices, which include distribution upgrade costs, were used as a basis for the charging costs in HD TRUCS.

We agree with commenters that we could model additional costs related to BEV charging that drivers may incur beyond just electricity prices. For the final rule, in HD TRUCS we differentiate between depot charging and public charging when assigning charging costs. We agree with EMA, DTNA, and other commenters that it is appropriate to account for EVSE maintenance costs, and that the estimate from a recent ICCT paper[448] of $0.0052 per kWh is a reasonable choice. Accordingly, we have incorporated this into both our depot and public charging costs.

Our public charging price additionally includes the amortized cost of public charging equipment and land costs for the station; we project that third parties may install and operate these stations and pass costs onto BEV owners via charging costs. For public charging, we use a total charging cost of 19.6 cents per kWh, from the previously mentioned ICCT paper and as recommended by DTNA, for 2027. We adjust it for future years according to the results of the IPM Retail Price Model discussed above. The initial value from the ICCT study reflects costs for public charging at stations designed for long-haul vehicles. Stations are assumed to have seventeen 1 MW EVSE ports and twenty 150 kW EVSE ports for a total peak power capacity of 20 MW. The 19.6 cent per kWh price includes the amortized cost of this charging equipment, land costs, both electricity prices (cents/kWh) and demand charges (cents/kW) associated with high peak power, distribution upgrade costs for substations, feeders, and transformers associated with these public charging stations, and EVSE maintenance costs. Overall, our charging costs

[446] Electricity demand for heavy-duty ZEVs matches that of the interim control case as described in RIA Chapter 4.2.4 while demand from light- and medium-duty vehicles was based on Alternative 3 from EPA's proposed "Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles" (88 FR 29184 et seq.)
[447] ICF. "Documentation of the Retail Price Model: Draft." 2019. Available online: https://www.epa.gov/sites/default/files/2019-06/documents/rpm_documentation_june2019.pdf.
[448] Hussein Basma, Claire Buysee, Yuanrong Zhou, and Felipe Rodriguez. "Total Cost of Ownership of Alternative Powertrain Technologies for Class 8 Long-haul Trucks in the United States." International Council on Clean Transportation. April 2023. Available online: https://theicct.org/wp-content/uploads/2023/04/tco-alt-powertrain-long-haul-trucks-us-apr23.pdf.

used in the final rule analysis for both depot and public charging are higher than those used in the NPRM analysis. See RIA Chapter 2.4.4.2 for a more complete discussion and a summary of depot and public charging costs used in the FRM analysis.

EPA updated the wall-to-battery efficiency for the FRM analysis to a value (89.3 percent) sourced from the EPA MOVES model, as described in RIA Chapter 2.8. Regarding Valero's comment about inconsistent charging efficiencies across EPA analyses, we note that the final RFS rule did not make use of the value noted by the commenter and slightly different efficiencies between values used for rulemakings covering light- and medium-duty vehicles versus heavy-duty vehicles (90 percent versus 89.3 percent) is not inappropriate from our perspective given differences in the light-duty and heavy-duty markets. Valero stated that EPA did not account for transmission losses in the proposal. As described above, EPA's charging costs utilized electricity prices from IPM's Retail Price Model in the FRM analysis; these prices reflect the price to the end user and therefore account for upstream losses, including transmission. More broadly, the power sector modeling conducted in IPM to estimate emissions associated with BEV charging and other electricity demand accounts for transmission losses (see RIA Chapter 4).

6.3.4 Dwell Time & EVSE Sharing

Comments by Organizations

Organization: American Trucking Associations (ATA)

Onsite charging is preferred

As fleets examine battery electric and hydrogen fuel cell trucks, they prefer to charge and refuel onsite. Today, most fleets have diesel refueling onsite for beginning trips, and line-haul fleets manage their refueling and break time for drivers to overlap. As ATA's Vice Chairman Andrew Boyle testified at the Senate Environment and Public Works Committee, today's diesel technology allows a fleet to travel 1,200 miles and refuel in 15 minutes for an additional 1,200 miles. Based on the range for Class 8 battery-electric trucks today, that same truck can travel roughly 250 miles before the need to charge with downtime of up to 3-8 hours, depending on the charging equipment available.24 [EPA-HQ-OAR-2022-0985-1535-A1, p. 18]

24 Boyle, Andrew, Testimony at Hearing: Cleaner Vehicles: Good for Consumers and Public Health, Senate Environment and Public Works Committee, April 18, 2023.

EPA assumes that battery electric trucks can accommodate eight hours of charging downtime. While this could work for certain truck applications that return to base each night, constantly moving regional and line-haul trucks will require more energy for shorter charge times. The agency's assumption is based on electricity pricing, where overnight charging would be more cost-effective than daytime charging. While this is true for electricity costs, truck operators have already found the most optimal time for them to operate. For example, line-haul fleets prefer to run at night due to less congestion on the road. In addition, many line-haul fleets "slip seat" their drivers to meet federal hours-of-service regulations and ensure that their investment, the truck, operates 24 hours a day. Many regional fleets begin their days in the pre-dawn hours to stage before sites open to begin their routes for the day's pickup and delivery routes. [EPA-HQ-OAR-2022-0985-1535-A1, p. 18]

Organization: California Air Resources Board (CARB)

The EVSE cost estimates include both direct and indirect costs also referred to as EVSE retail price equivalent costs. U.S. EPA assume that up to two vehicles can share one DCFC port if there is sufficient dwell time for both vehicles to meet their daily charging needs. While fleet owners may also choose to share Level 2 chargers across vehicles, U.S. EPA is conservatively assigning one Level 2 charger per vehicle. They assume that EVSE costs are incurred by purchasers/ fleet owner.184 Assigning two vehicles per fast charger and one vehicle per Level 2 is reasonable on a cost basis given current information. There will be variation on a site-by-site basis on power and number of depot chargers and it is not clear the proportion of Level 2 assigned to vehicles to estimate costs. Level 2 is suitable in a limited number of cases. Also, the model could be improved by explicitly including public charging. However, the assumption that depot and public charging will be approximately the same cost is reasonable considering the available information. The cost estimation in NPRM Table IV-6: EVSE Costs for the Proposed Option Relative to the Reference Case, Millions 2021 Dollars is reasonable without an explicit accounting for public chargers. [EPA-HQ-OAR-2022-0985-1591-A1, p.51]

184 Ibid. Page 26030

Organization: Clean Fuels Development Coalition et al.

C. The proposal underestimates the cost for charging infrastructure.

Charging infrastructure is the single largest expense accounted for in the proposal—$47 billion in “electric vehicle supply equipment (EVSE) costs.” But this expense only accounts for “depot” charging installation, or the cost to install heavy-duty chargers at an electric vehicle’s home base. This completely ignores “upfront hardware and installation costs for public or other en-route electric vehicle charging infrastructure” because it assumes “BEV charging needs are met with depot charging.” 88 Fed. Reg. 25,978. This is unrealistic, particularly given the short ranges of heavy-duty batteries and the long travel distances expected of heavy-duty vehicles. To compound this error, the proposal makes unreasonable assumptions about how many of these depot chargers are needed. EPA “assume[s] that up to two vehicles can share one DCFC port if there is sufficient depot dwell time for both vehicles to meet their daily charging needs.” DRIA at 200. This allows, as EPA explains, “per-vehicle EVSE costs [to] decline by 50 percent or more.” Id. [EPA-HQ-OAR-2022-0985-1585-A1, p. 33]

Organization: Daimler Truck North America LLC (DTNA)

DTNA also evaluated the average stop duration for this population of vehicles to assess EPA’s 12-hour charging dwell time assumption, and found that the median average stop time for day cabs in this population to be 5.9 hours for day cab tractors and 7.4 hours for sleeper cab tractors, as reflected in Appendix A. DTNA believes only approximately 25% of the tractor population meets or exceeds EPA’s estimate of 12-hour charging dwell time. The need for shorter dwell times can be addressed by high speed charging; however, higher charging speeds require additional installed capacity for EVSE and the grid, which is not widely available given the associated higher costs and complexities. EPA should account for these costs and complexities, or reduce ZEV suitability to better reflect fleet operational needs. [EPA-HQ-OAR-2022-0985-1555-A1, p. 22]

> Using this same data snapshot, DTNA assessed where these tractors end their work days. In doing so, the Company considered vehicles to have "returned-to-base" if during the 18 day evaluation period, the tractor ended its day of operation repeatedly in the same location. On average, we found that day cabs returned to base 21% of the time, with sleeper cabs returning only 9% of the time. DTNA evaluated 90th percentile daily VMT, charging dwell time, and return-to-base as independent variables, consistent with EPA's approach. *See* Appendix A. However, we note that fleets will only deem a ZEV suitable if it meets *all* daily operational criteria, including VMT, dwell time, and return-to-base operation. Neither DTNA's nor EPA's data determines if the return-to-base VINs dwell greater than 12 hours and have suitable daily VMTs. It is possible return-to-base vehicles dwell for significantly shorter periods of time and/or exceed the daily VMT. [EPA-HQ-OAR-2022-0985-1555-A1, pp. 22-23]

The 12-hour dwell time that EPA assumes for recharging for modeling purposes is not realistic for many routes and operations, including some daily VMTs assumed in the HD TRUCS tool. NACFE states regional haul accounts for 30% of tractor applications, and typically include long dwell times that could be suitable for BEVs.50 Vocational applications and long haul applications need further study to understand what proportion of operations have significant dwell times that can support charging. As discussed above, DTNA's telematics data suggests approximately 5.9 hours and 7.4 hours are more reasonable assumptions for day cabs and sleeper cabs, respectively. Shortening the dwell time may be possible with high speed charging and allow BEV penetration in more applications, but charging at higher speeds adds significant cost that must be considered in the TCO calculation and additional infrastructure challenges. [EPA-HQ-OAR-2022-0985-1555-A1, p. 27]

50 Id. at 127.

There are a number of TCO inputs that EPA has not accounted for in the HD TRUCS tool that should be included to more accurately inform payback periods and adoption rate projections for the Proposed Rule, including:

- Charging Downtime. EPA assumes all HD BEVs will have 12-hour depot dwell times for overnight charging. While DTNA believes this may be true in some applications, many fleets run two-shift operations, and any charging time that exceeds today's diesel refueling time is likely to be viewed as downtime, as the asset is unusable. EPA should collect additional data on fleet operating characteristics, and either constrain suitability to single-shift operations or somehow account for downtime in HD TRUCS. [EPA-HQ-OAR-2022-0985-1555-A1, p. 35]

EPA Request for Comment, Request #50: Our request for comment includes a request for data to inform an assessment of the distribution of daily miles traveled and the distribution of the number of hours available daily to charge for each of the vehicle types that we could use to update a constraint like this in the final rulemaking analysis.

- DTNA Response: Based upon DTNA's analysis, EPA significantly underestimates daily VMT in the tractor categories and over-estimates dwell time available for vehicles to charge, as reflected in Section II.B.3 and Appendix A to these comments. An accurate estimate is critical to the feasibility of HD ZEVs to replace conventional vehicles, thus EPA should reevaluate VMT using the best available data, including the data DTNA provides for certain vehicle categories in Section II.B.3 and Appendix A to these comments. [EPA-HQ-OAR-2022-0985-1555-A1, p. 167]

Organization: Delek US Holdings, Inc.

b. BEV charging consumes significantly more time than refueling ICE-powered vehicles.

The Proposed Rule fails to consider the impact that increased HD BEV charging times will have on consumer adoption rates and whether end users will be willing to accept disruptions to fleet usage in addition to the increased purchase price of HD BEVs. According to DOT, Level 1 EV chargers can take 40-50 hours to fully charge a BEV from empty, Level 2 chargers can take 4-10 hours to fully charge a BEV from empty, and Direct Current Fast Charging Technology chargers can take up to an hour to fully charge a BEV from empty. But under any scenario, HD BEVs will incur additional downtime for more frequent, and longer, charging times as compared to the equivalent ICE. For example, a 3,000 mile cross-country freight journey taking 54 hours by ICE would take 71 hours by BEV.37 Yet the Proposed Rule fails to consider whether, in light of these impacts, consumers will purchase HD BEVs at the rate necessary to meet EPA's targets. [EPA-HQ-OAR-2022-0985-1561-A1, p. 8]

Organization: Environmental Defense Fund (EDF)

1. EPA's underlying component costs are high

While EPA includes the Commercial Clean Vehicle Credit and the production tax credit for batteries, it fails to include the Alternative Fuel Refueling Property Credit in its assessment of cost. The IRS has not published guidance yet on how this credit will be applied, but the language from the IRA indicates that businesses could receive up to a 30% credit on up to $100,000 of EVSE. Roush, in a recent report, showed that this also could save vehicle owners $1,064 for a 25 kW charger to $26,000 for a 100 kW charger.130 [EPA-HQ-OAR-2022-0985-1644-A1, p. 53]

130 H. Saxena, S. Pillai, "Impact of the Inflation Reduction Act of 2022 on Medium- and Heavy-Duty Electrification on MYs 2024 and 2027," 2023. Roush.

In their modeling, EPA has a maximum of two vehicles per charger even if many more vehicles could be charged in the 12 hours of dwell time EPA assumes. This results in a high estimate of number of EVSE ports needed, driving up the EVSE costs and driving down the stringency of the rule. [EPA-HQ-OAR-2022-0985-1644-A1, p. 53]

Organization: International Council on Clean Transportation (ICCT)

SENSITIVITY OF ZEV ADOPTION RATES OF VOCATIONAL VEHICLES TO LEVEL 2 CHARGING ASSUMPTIONS EPA assumes that each Level 2 charging station (AC charging up to 19.2 kW in this context) will not be shared by more than one truck. EPA explicitly states that this is a conservative assumption. Level 2 charging is considered the main charging technology for step vans, box trucks, shuttle and school buses, and utility trucks. Given the long dwell times of these vehicles and their relatively smaller battery sizes, it is technically possible to share charging ports between at least two trucks, and fleets will take advantage of port sharing among several trucks to reduce their capital investment. ICCT modified this assumption in the HD TRUCS model to investigate the impact on the payback period and adoption rates. The total ZEV adoption rate of vocational vehicles increased by 6% in 2027 and 4% in 2032 under this new assumption. [EPA-HQ-OAR-2022-0985-1553-A1, p. 8]

Organization: Schneider National Inc.

The EPA assumes all vehicles will have a 12-hour overnight dwell time for charging.

- A driver break is 10 hours, so a 12-hour dwell for charging requirements would extend the driver's standard break time and would likely negatively impact work time/hours for a driver. Additionally, a 12-hour overnight dwell time would eliminate a motor carrier's ability to slip-seat a truck to be used in multiple shifts in a day (again, affecting productivity and freight transportation capabilities). In the over-the-road trucking industry, a 12- hour overnight dwell time – particularly at a specific location that has charging infrastructure – is not typical.
- Team drivers would be most impacted as they would need to shut down for charging; whereas, today, they trade off sleeper berth time with driving time. As a result, until infrastructure is more prevalent and charging times are faster, forcing team drivers to utilize ZEVs will certainly affect productivity and pay.
- Today, drivers will often take their DOT break and fuel at the same time/location. If a charger is not available (and, to be clear, charging infrastructure certainly is not prevalent), it will negatively impact a driver's ability to pick up, deliver or take his/her mandatory break when needed.
- Driver parking is already very congested and there is limited visibility to locations with available parking spots, especially at third-party fuel locations. Requiring a 12-hour charging shutdown would exacerbate the situation.
- DOT breaks would need to take place where there is the availability to charge the tractor instead of after a driver utilizes his/her full complement of 11 available driving hours and 14 available on-duty hours, thus reducing a driver's productive hours and further increasing the need for additional capacity to perform the same amount of work. [EPA-HQ-OAR-2022-0985-1525-A1, p. 2]

Organization: Tesla, Inc. (Tesla)

Second, Tesla believes that more than two vehicles can use high powered DCFC as is suggested in the Draft RIA.201 Depending on the driving use case, battery sizes and charging power levels, when fast charging, one could have more than five vehicles per charger. This higher utilization rate can vitiate many concerns about the volume of charging ports needed to be deployed at the outset of the Phase 3 program. [EPA-HQ-OAR-2022-0985-1505-A1, p. 27]

201 Draft RIA at 202 (Table 2-60).

Third, regulations that mandate rest periods can also provide a time window for mid-shift charging if fast or ultra-fast charging options are available in route, allowing for a greater number of vehicles to utilize individual chargers.202 Recent studies of power requirements for regional and long-haul truck operations in the U.S. and Europe find that charging power higher than 350 kW, and as high as 1 MW, may be required to fully recharge electric trucks during a 30- to 45-minute break.203 In Tesla's case, it is deploying 750 kW chargers (using a version of a megawatt charging standard) at depots utilizing Tesla Semi's. Like Tesla, others are already deploying depot charging for the tractor class.204 Moreover, a number of analyses have found that that the total cost of ownership for depot-charging electric trucks, including charging infrastructure, will be cost-competitive with diesel in the near future without incentives.205 [EPA-HQ-OAR-2022-0985-1505-A1, p. 28]

205 Atlas Public Policy, U.S. Medium- and Heavy-Duty Truck Electrification Infrastructure Assessment available at https://atlaspolicy.com/u-s-medium-and-heavy-duty-truck-electrification-infrastructure-assessment/

Organization: Truck Renting and Leasing Association (TRALA)

Increased ZEV Use Will Impact Federally Mandated Hours-of-Service Requirements

Federal Hours-of-Service (HOS) regulations require drivers to take a 30-minute break after driving for eight hours and a 10-hour break after 14 hours. (See Figure 4). [Refer to Figure 4 on p. 13 of docket number EPA-HQ-OAR-2022-0985-1577-A1] Driver break times will not likely align with where chargers are physically located or available for immediate use. While rapid charging using megawatt ports will evolve over time and allow greater range for trucks and faster charging intervals, every minute of not driving reduces the period that drivers can legally operate their trucks on the road. [EPA-HQ-OAR-2022-0985-1577-A1, pp. 12-13]

Driver dwell times at shipper and receiver facilities are already severely impacting driver HOS windows and adding a layer of inefficiency into the supply chain. According to the American Transportation Research Institute (ATRI), in 2021, drivers rated dwell time as their second-highest concern.16 In its report, ATRI summarizes its current dwell time findings as follows:17

- The average dwell time at facilities for all fleets was 1 hour and 54 minutes per stop.
- Refrigerated carriers had an average dwell time of 3 hours and 16 minutes.
- LTL carriers averaged dwell times was 1 hour.
- Fleets with 25 or fewer trucks experienced the highest dwell time averaging 2 hours and 23 minutes per stop.

- At 1 hour and 37 minutes per stop, fleets with more than 1,000 trucks had the lowest average dwell time. [EPA-HQ-OAR-2022-0985-1577-A1, p. 13]

16 An Analysis of the Operational Costs of Trucking, American Transportation Research Institute (August 2022).

17 Id. at 40.

In addition, truck drivers often park prior to exhausting available drive time and drivers surrender an average of 56 minutes of available drive time per day.18 [EPA-HQ-OAR-2022-0985-1577-A1, p. 14]

18 Managing Critical Truck Parking Case Study: Real World Insights From Truck Parking Diaries, American Transportation Research Institute (December 2016).

Route planning will become critical to account for EV operational range limitations, needed charging infrastructure on travel routes, and charger types (i.e., slow versus fast charging). While EV and fleet software continues to evolve, the best route planning involving an EV can be thrown a curveball based upon congestion, temperature extremes, charging time, charger up-times, charger availability, battery health, and driver behavior. [EPA-HQ-OAR-2022-0985-1577-A1, p. 14]

High energy needs and big battery packs present challenges for truck EV dwell times. Direct current fast chargers (DCFCs) are the fastest chargers available today. A 600-kWh electric truck would require six hours to charge using a 100 kW DCFC. More powerful DCFCs will of course greatly reduce charge and dwell times. When it comes to EV charger ratings and speed, size matters. [EPA-HQ-OAR-2022-0985-1577-A1, p. 14]

Given the uncertainties as to how EVs may impact federal HOS requirements, TRALA requests EPA coordinate with DOT to conduct on-going analysis and reporting on how driver HOS requirements are being impacted by the increased use of ZEV vehicles. [EPA-HQ-OAR-2022-0985-1577-A1, p. 14]

EPA Summary and Response

Summary:

Multiple commenters said that EPA's assumed dwell time in the NPRM is too long or may not be applicable for some vehicles, particularly long-haul vehicles or those with multi-shift operations. DTNA conducted its own analysis of tractors' dwell times from telematics data, estimating that only one-quarter of tractors had a dwell time of 12 hours or longer and instead finding a median dwell time for day cabs of under 6 hours and for sleeper cabs just above 7 hours. DTNA further found that the large majority of the time, day cabs and sleeper cabs sampled did not return to base. ATA, which incorrectly noted that EPA assumed an 8-hour dwell time, cautioned that this would not work for line-haul or other vehicles that operate at night or those that "slip-seat" (change drivers so the truck can operate for the full 24-hour day). Schneider raised similar concerns.

Tesla stated that drivers' mandatory rest periods present an opportunity for en-route charging, though it also noted that higher charging powers (up to 1 MW) may be needed to deliver the electricity required during these breaks. (Tesla noted it is installing 750 kW DCFC ports at its depots.) TRALA also discussed the mandatory driver rest periods in its comments, noting that charging may not be available in locations where drivers have these 30-minute breaks so that significant route planning would be needed. TRALA asked that EPA coordinate with DOT to better understand the impact of if ZEV adoption on federal hours-of-service regulations. TRALA expressed concern about added downtime for charging, and cited an ATRI report that found average downtime at shipping and receiving facilities was just under two hours a stop.

Delek US Holdings and DTNA also commented on cost of additional downtime for charging. While Delek's comments primarily concerned the potential impact on BEV adoption, DTNA recommended that EPA account for charging downtime in its analysis, or alternately limit BEV feasibility in HD TRUCS to vehicles with single-shift operations. DTNA also suggested EPA gather data to better understand dwell times and other aspects of fleet operations.

EPA also received comments on how many vehicles can share EVSE ports. CARB found our assumption that up to two vehicles could share a DCFC port and one for L2, to be reasonable, whereas Clean Fuels Development Coalition et al. thought allowing two vehicles to share a DCFC port (and therefore halving the EVSE costs in those cases) to be unreasonable.

Tesla commented that our assumed limits on DCFC sharing were too restrictive, stating that 5 or more vehicles could share a DCFC in some circumstances. EDF stated that EPA overestimated EVSE costs by assuming only up to two vehicles could share a charger, noting that in some cases, many more could charge. ICCT commented that multiple vehicles could also share L2 ports and that fleets are likely to do to save costs.

Response:

How long a vehicle is off-shift and parked at a depot, warehouse, or other home base each day is a key factor for determining which charging type(s) could meet its needs. We refer to this as dwell time. In the NPRM, we assumed all vehicle types would have at least 12 hours of available time to charge at a depot or other location the vehicle is parked off-shift. However, we acknowledged that the amount of time available at the depot for charging will depend on a vehicle's duty cycle and other factors (88 FR at 25979). We requested comment on this approach. EPA further assumed that up to two vehicles could share a DCFC port if both vehicles could meet their charging needs within this dwell time, while each vehicle using L2 charging would have its own port (see DRIA Chapters 2.6.4.1 and 2.6.4.2).

Commenters on this topic generally thought the 12-hour dwell time assumption is too long, particularly for regional or long-haul applications in which vehicles may not return to their home base. As discussed in RTC 6.3.1, EPA agrees that it is appropriate to model long-haul vehicles, certain other long-range tractors, and coach buses as relying on public rather than depot charging and we have updated our FRM analysis accordingly. Given that, we no longer estimate a depot dwell time for these vehicles.

To better understand how dwell times might vary by vehicle application and class for vehicles that we assume will use depot charging in our FRM analysis, we supported new data analysis by NREL through an interagency agreement between EPA and the U.S. Department of Energy. NREL analyzed several data sets for this effort: General Transit Feed Specification (GTFS) data for about 21,700 transit buses, operating data for nearly 300 school buses from NREL's Fleet DNA database, and a set of fleet telematics data from Geotab's Altitude platform covering about

13,600 medium- and heavy-duty trucks. As described in the report Bruchon et al. 2024,[449] NREL separately analyzed data for 18 unique combinations of vocations and class types. We mapped the resulting dwell times to the applicable BEV type in our HD TRUCS model, as described in Chapter 2.6.2.1.4 of the RIA. As shown in Table 2-78 of RIA, Chapter 2.6.2.2, the updated dwells times in HD TRUCS range from 7.4 hours (for a class 8 regional vehicle) to 14.5 hours (for school buses). For the large majority of depot-charged BEV types in HD TRUCS, dwell times used are under 12 hours.

For the NPRM, we assumed that each vehicle using Level 2 charging would have its own EVSE port, while up to two vehicles could share DCFC if charging needs could be met within the assumed dwell time. We agree with comments received by EDF, ICCT, and Tesla that these limits were conservative as fleet owners have a strong financial incentive to share EVSE ports among vehicles if it could decrease their costs while still ensuring operational needs are met. Accordingly, and in consideration of more robust dwell time assumptions, in our final rule analysis we allow up to two vocational vehicles to share one EVSE port if there is sufficient depot dwell time for all vehicles to meet their daily charging needs. For tractors, which tend to be part of larger fleets, we allow up to four vehicles to share one EVSE port if there is sufficient daily depot dwell time for each vehicle to meet its charging needs. To the extent higher numbers of BEVs can share EVSE ports and still meet their daily electricity consumption needs, these limits should still be considered conservative. See RIA Chapter 2.6.2.1.5.

In response to the comments about the impact of charging time on slip seating operations, if slip seating is utilized, then this would be an instance when ICE vehicles would be appropriate. As noted, EPA's modeled compliance pathway allows for ICE vehicles, and the majority of sleeper cabs would remain ICE vehicles in that modeled compliance pathway. See also RTC Section 4.3.3.

6.4 Charging Infrastructure (Miscellaneous)

Comments by Organizations

Organization: Daimler Truck North America LLC (DTNA)

- Mandatory Transportation Electrification Infrastructure Reporting. DTNA is not aware of any existing tool where fleets, manufacturers, or regulators can find information about public or private charging stations that can accommodate HD BEVs with pull-through charging and ingress/egress appropriate for commercial vehicles. DOE's Alternative Fueling Station Locator could serve as one such tool by adding fields to indicate whether or not the charging site can support medium heavy-duty (MHD)18 and/or heavy heavy-duty (HHD) vehicles.19 Collecting this data is critical to inform the Agency of the development of HD electric vehicle supply equipment (EVSE) and should be used to inform and enable increased CO2 stringencies throughout the GHG Phase 3 program. This data is also critical information for fleets utilizing BEVs that may need en route access to public charging. DTNA also recommends that EPA work with FHWA to

[449] Bruchon, Matthew, Brennan Borlaug, Bo Liu, Tim Jonas, Jiayun Sun, Nhat Le, and Eric Wood. "Depot-based Vehicle Data for National Analysis of Medium- and Heavy-Duty Electric Vehicle Charging." NREL/TP-5400-88241. February 2024. Available online: https://www.nrel.gov/docs/fy24osti/88241.pdf.

reconsider the designations of Alternative Fuel Corridors (AFCs), in particular to ensure that the ‘ready’ corridor designation is reserved for AFCs that have HD-accessible BEV and hydrogen infrastructure spaced at regular intervals. Even where an AFC has stations 50-100 miles apart, if the stations cannot accommodate HDVs, then the corridor is not HD-ready. [EPA-HQ-OAR-2022-0985-1555-A1, p. 14]

18 DTNA uses the term ‘Medium Heavy Duty’ (MHD) to refer to Class 5 and Class 6 vehicles and the term ‘Heavy Heavy-Duty’ (HHD) to refer to Class 7 and 8 vehicles.

19 See DOE, Alternative Fueling Station Locator, available at https://afdc.energy.gov/stations/#/analyze.

- National Electric Vehicle Infrastructure (NEVI) Formula Program Funding. DTNA recommends that 15% of NEVI funding be set aside for charging stations that can accommodate HD BEVs with at least one pull-through charging lane. To be eligible for the set-aside, station owners should be required to build at least one dual-use (HDV and light-duty vehicle capable) pull-through charging lane with a charging level above 150 kilowatts (kW). Station owners located near known fleet operating routes or major distribution hubs should be given priority for funding applications to encourage fleet owners to integrate electric HD BEVs into their fleets. Site proposals that include future-proofing measures to increase charging speeds for HDVs, up to 1.5 MW, should also receive additional consideration. Other site design considerations for station owners to accommodate HD charging include: (1) cable lengths and management systems; (2) vehicle turning radius; and (3) charger locations. DTNA recommends that EPA work with FHWA to issue additional HD guidance and direct state departments of transportation to include the above in next year’s NEVI plans. [EPA-HQ-OAR-2022-0985-1555-A1, pp. 14-15]

Organization: Daimler Truck North America LLC (DTNA)

Recommendations to Facilitate ZEV Infrastructure Buildout and CO2 Standard Feasibility

While EPA does not have regulatory authority over many of the factors that currently pose challenges to ZEV infrastructure development, the Agency could help to mitigate these challenges by supporting the policies, legislation, and regulatory initiatives that are detailed in Section I.B.4 of these comments, including:

- Align with EIA vehicle uptake estimates, to ensure accurate estimates of real power demand by MHD and HHD ZEVs and net CO2 emissions.
- Work with FERC to direct utilities to incorporate demand projects into both a system-wide transportation electrification electricity forecast and a utility distribution grid capacity requirement forecast, to serve these medium- and heavy-duty transportation electrification loads on a geographic basis.
- Assume financial liability as a demand guarantor for infrastructure buildout that is undertaken based upon EPA’s ZEV penetration forecasts.
- Work with FERC to identify high traffic freight hubs that are likely to see rapid increase in BEVs, and direct utilities to proactively upgrade this infrastructure.
- Encourage state utility regulatory commissions to adopt PBRs to incentivize faster interconnection timelines for charging infrastructure projects. [EPA-HQ-OAR-2022-0985-1555-A1, p. 57]

- Work with stakeholders to develop model building codes that can be adopted by state and local governments to streamline authorizations for EVSE installation projects and encourage state and local adoption of these model codes.
- Require reporting of medium- and heavy-duty ZEV infrastructure and make this information available to fleets.
- Work with FHWA to revise the NEVI formula program to more actively encourage states to provide HD-accessible public charging infrastructure. [EPA-HQ-OAR-2022-0985-1555-A1, p. 58]

Organization: Fermata Energy

There are numerous reasons for the EPA to encourage the adoption of V2G technology and support our detailed recommendations below. We feel strongly that the EPA has a unique opportunity to make a major difference in the commercialization of V2X technology. If the EPA were to provide incentives or regulations on V2X, as we are recommending, it could provide market confidence for vehicle manufacturers and V2X charging equipment providers, and accelerate V2X by providing a positive value to consumers, including low- and moderate-income consumers. EPA action to unlock the full potential of V2X could help mitigate the emerging generation shortage because with V2X, EVs become grid assets.3 For example, PG&E CEO Patti Poppe recently noted that EVs on the road in “PG&E’s service area today have 6,700 MW of capacity,” which equals “three Diablo Canyon nuclear power plants. It’s on the road today, and we are not using it as a power source. We’re only using it as a power draw.”4 EPA action on V2X could also help address the duck curve, evening ramp, and summertime “needle” peaks in many generation and distribution grids. More importantly V2G, as a storage asset, unlocks and enables the large GHG benefits of the on-going, large-scale transition to intermittant renewable energy. EPA action to help commercialize V2X could create a low-cost, cleaner alternative to the zero-emission portable gensets required by California Air Resources Board’s (CARB) recent Small Off-Road Engines (SORE) regulation and replace dirty portable gensets in other states. Finally, Fermata Energy encourages the EPA to support all connectors, protocols, and EVSE sizes in any V2X recommendations for incentives or regulation in order to foster competition and encourage lower cost solutions. [EPA-HQ-OAR-2022-0985-1662-A2, p.3]

3 Decommissioning of Diablo Canyon and lack of hydropower in drought years. https://www.utilitydive.com/news/california-drought-could-halve-summer-hydropower-share-leading-to-more-nat/624489/
https://www.utilitydive.com/news/california-grid-reliability-2022-2023-summer/609261/

4 https://www.latimes.com/environment/newsletter/2021-10-14/as-california-fires-burn-pge-ceo-promises-fixes-boiling-point

BNEF data (Figures 1 and 2) show over 10 million battery-powered EVs on the road globally at the end of 2020, with a combined 296-gigawatt hours of lithium-ion batteries installed in them. That’s a lot of batteries driving around – 8 times more than the number of stationary grid-scale batteries installed globally.5,6 While these figures are mostly for light duty EVs and electric buses, they illustrate what will soon be happening with heavy duty vehicles in a few years as a result of EPA’s final rule. [EPA-HQ-OAR-2022-0985-1662-A2, p.3] [[See Docket Number EPA-HQ-OAR-2022-0985-1662-A2, page 4, for Figures 1 and 2]]

5 More EVs Are Being Designed to Push Power to The Electrical Grid - Bloomberg

6 https://news.bloomberglaw.com/environment-and-energy/electric-vehicles-to-drive-massive-battery-demand-bnef-chart

7 Electric Vehicles to Drive Massive Battery Demand, BNEF, 2021 [[Reference for Figures 1 and 2]]

In addition, a May 2022 presentation by the World Resources Institute using Bloomberg NEF and Energy Information Administration data found the power capacity in 2030 for EVs to be 10 to 20 times more than the 2030 power capacity of stationary storage.8 While these numbers are for light-duty EVs, electrified trucks can also contribute and some fleets (e.g., school buses, municipal trucks, trucks in one-shift operations) are expected to be early adopters. [EPA-HQ-OAR-2022-0985-1662-A2, p.4]

8 See slide 5 at https://www.slideshare.net/emmaline742/building-resiliency-with-v2g-in-residential-homes-by-camrongorguinpour

V2X bidirectional charging is a win-win-win investment: many benefits accrue:

- Achieves EPA's environmental goals. Just like stationary storage, V2X bidirectional charging platforms can reduce carbon and criteria pollutant emissions from generators by shifting electricity consumption to the cleanest hours of the day and removing the need for dirty thermal peaker electricity generation. However, V2X is more cost-effective than stationary storage, as ratepayers don't have to pay for purchase of the EV battery and can accelerate the renewable transition.
- Provides grid services. With V2X bidirectional charging, utilities gain a low-cost energy storage resource to help integrate renewable energy into the electric grid by shifting energy, providing resource adequacy, and ancillary services (Figure 3). For example, modeling by the CPUC currently projects 14,700 MW of new energy storage is needed in CA by 2032 to support the integration of renewables but only 2,185 MW is operational today.9,10 V2X, with supportive policies, can provide many thousands of MW by 2030.
- Lower vehicle ownership costs. EV owners can earn money by selling electricity back to the grid, significantly cutting the cost of vehicle ownership. Offsetting the cost of owning and maintaining an EV supports equitable access to EVs, particularly those EVs in the used car market, such as the low-income EV driving community.
- Increased resiliency. Unidirectional charging is a grid load. V2X bidirectional charging cost-effectively supports grid resilience. During black outs and public safety power shut offs, EV owners can power their homes, businesses, and critical infrastructure.
- Ratepayer benefits. EV adoption has already been shown to significantly benefit utility ratepayers and V2X technology can further those benefits.12 For example, a 2018 CEC study projects $1 Billion in annual ratepayer benefits if 50% of chargers were V2X capable.13 V2X technology also improves driver economics which would likely drive further EV adoption and even greater ratepayer benefits. [EPA-HQ-OAR-2022-0985-1662-A2, pp.4-6] [[See Docket Number EPA-HQ-OAR-2022-0985-1662-A2, page 5, for Figure 3]]

Charger Infrastructure and Standards

The prioritization of building forward-looking vehicle charging infrastructure is critical to the penetration of electric commercial vehicles. Furthermore, analogous to vehicle electronic designs and material selection impacts electric vehicle efficiency, similar approaches can be used to improve charger efficiency in delivering the maximum power to the vehicle. For this reason, we believe that EPA should work with other agencies, like the Joint Office on Energy and Transportation, in setting minimum charger efficiency standards to ensure that infrastructure funds are spent on chargers with the best utilization of electric power. [EPA-HQ-OAR-2022-0985-1521-A1, p. 11]

While overnight charging at lower power may be appropriate for certain vehicle applications and fleets on a regimented schedule, we recommend the EPA prioritize the planning and building of direct current fast chargers (DCFC). The planning of public DCFCs is indispensable to allow in-service electric vehicles to address unforeseen day-to-day vehicle use variables (i.e., weather, traffic conditions, needed route changes, etc.). The availability of strategically placed, publicly accessible DCFCs prevents vehicles becoming inoperable due to these use variables, allowing vehicles to be rapidly charged and quickly placed back into service while minimizing interruptions to vehicle operations, traffic disruptions from vehicle strandings and maximizing the utilization of available space for heavy-duty vehicle recharging. [EPA-HQ-OAR-2022-0985-1521-A1, p. 11]

DCFC is also crucial to address long-term heavy-duty vehicle charging needs. Many commercial EVs will need to achieve fast charging times to encourage fleet owners to transition to e-mobility. This is particularly true for those vehicle operators who do not have access to charging at their own facilities. EV fleet adopters with slower rate overnight charging should also diversify their charging assets with DCFCs to have more flexibility as their fleets grow and unforeseen needs arise to charge vehicles and return them to service. [EPA-HQ-OAR-2022-0985-1521-A1, p. 12]

Additionally, DCFCs futureproof infrastructure investments by allowing fleet operators to immediately convert and deploy BEVs while also allowing them to remain up to date with advancements in battery technology. Vehicle batteries are quickly improving in size, chemistry, energy density, and efficiency resulting in increased vehicle range. This range improvement will, however, require faster charging capabilities. While HD BEV vehicles typically require large batteries with increasing power density, DCFCs enable quicker and more efficient charging of these vehicles. In addition, site and infrastructure owners maximize their investment because DCFCs enable site-readiness for future DCFC expansions while allowing the best utilization of available space and higher turnover of serviced vehicles. [EPA-HQ-OAR-2022-0985-1521-A1, p. 12]

DCFCs also allow for bidirectional charging which futureproofs infrastructure investment further by providing support for increasing electricity demand. Vehicle-to-Grid ("V2G") technology can help address energy use and manage peak demand times and costs, as well as serve as backup power during an outage. As EV adoption increases, this technology becomes more critical to enable sustainable grid management, grid resilience, utilization, and national security protection. [EPA-HQ-OAR-2022-0985-1521-A1, p. 12]

MECA also recommends the EPA consider national certification, such as UL Certification, for EV supply equipment to provide consistency, quality, safety, efficiency and compliance. A Certificate of Compliance will mean the product has passed a series of rigorous tests to demonstrate performance, safety, quality, and serviceability, while enhancing sustainability, strengthening security, and managing risk. National certification also supports local permitting efficiency, therefore, helps fast track deployment of charging stations. [EPA-HQ-OAR-2022-0985-1521-A1, p. 12]

For these reasons, MECA urges EPA to work with other government agencies, such as the Joint Office for Transportation and Energy, and industry to develop national standards for minimum charger efficiency which will ensure the efficient energy utilization and lowest operating cost for electric vehicles. With regards to technology, several suppliers of vehicle power electronics are applying similar electric efficiency technology innovation to the development of more efficient chargers to minimize switching losses and deliver maximum power to the battery. This is important to fleets as charging losses increase their operating cost and it is important to the environment because these loses represent electricity that is generated but never used. The difference in electric efficiency between the first generation of chargers, that are deployed in the field today, and the advanced second generation chargers can be as much as 10-20%. This becomes significant given the magnitude of battery energy in conventional vehicles. [EPA-HQ-OAR-2022-0985-1521-A1, p. 12]

Organization: MEMA

EVSE that has higher DC charging capacity (i.e., DC fast charging, or DCFC) than the minimum requirements modeled in the HD TRUCS tool will enable opportunity charging and help future-proof charging infrastructure, which is especially important to further encourage EV rollouts. School bus and other applications suited to bi-directional charging can also offer a layer of grid resiliency that will address stakeholder concerns about increasing dependency on electrical grids and also improve local and national security. Likewise, significantly more investment is needed to address fleet operator confidence and reliability for EVs. For medium- and heavy-duty EV, DCFC is critical. [EPA-HQ-OAR-2022-0985-1570-A1, pp. 9 - 10]

Organization: Nuvve Holding Corporation

EVs equipped with V2G technology can help further reduce GHG emissions in multiple ways beyond the emissions reductions that EVs alone can achieve, and enhance infrastructure resilience and national security. For example, EVs equipped with V2G technology can help reduce GHG emissions and help avoid harmful health effects from diesel generators, when used to provide emergency backup power as a substitute for diesel. V2G also supports the integration of variable clean generation resources, such as solar and wind energy, into the grid and can enhance the management thereof. These benefits can be realized across all types of EVs, from

HD to light-duty EVs (both battery-only and plug-in hybrids). [EPA-HQ-OAR-2022-0985-1572-A1, p. 2]

In addition, V2G technology can provide valuable grid flexibility, e.g., to regional power grids, by leveraging V2G as a grid resource during periods of extreme grid strain, thereby helping to avoid local, state, or regional power outages. An Electric Power Resources Institute ("EPRI") study found that implementing V2G capability can provide two-to-three times the value that unidirectional, managed charging (otherwise known as "V1G") from the grid to a vehicle can provide.2 EPRI estimates that V2G could generate $1 billion in annual grid benefits to California ratepayers under an aggressive EV adoption scenario of 5 million EVs by 2030 with 50 percent of the vehicles being V2G-enabled. Another study of light-duty bidirectional EVs in California estimated an annual V2G value of $2,850 per vehicle.3 [EPA-HQ-OAR-2022-0985-1572-A1, p. 2]

Organization: South Coast Air Quality Management District (South Coast AQMD)

The workforce needed to install this infrastructure also can present a key challenge. In California, our Energy Commission estimated that 157,000 fast charging stations (>50 kW) would be needed by 2030 to support zero emissions heavy-duty on-road vehicles.1 This equates to more than 400 charging stations per week that need to be installed. This is in addition to those needed for light duty vehicles. A significant workforce is needed to do the site work, the upstream utility distribution, transmission, and generation work, as well as the manufacturing of electrical equipment (e.g., transformers, etc.). The federal government has a key role in developing programs across the nation to first estimate the workforce needed and in which key sectors and regions, and then to provide resources to ensure that workforce is trained and available. [EPA-HQ-OAR-2022-0985-1575-A1, pp. 3-4]

1 https://www.energy.ca.gov/data-reports/reports/electric-vehicle-charging-infrastructure-assessment-ab-2127

Finally, while most sites installing infrastructure are focused on their local needs (e.g., site installation, local utility distribution infrastructure, etc.), when implemented at scale, additional generation/production and transmission/transportation of electricity and hydrogen will be needed, in many cases across state lines. The federal government can continue to facilitate these interstate connections to ensure a streamlined market that will encourage the rapid growth of zero emissions vehicles. Key factors in the adoption of zero emissions vehicles is the actual price that end consumers will pay for electricity and hydrogen as well as a reliable supply of both, especially in comparison to conventional fossil fuels. The federal government can play a role in driving down the cost to consumers as well as ensuring stable and reliable fuel supplies to the extent that they cross state lines. [EPA-HQ-OAR-2022-0985-1575-A1, p. 4]

Organization: Truck Renting and Leasing Association (TRALA)

ZEVs Will Exacerbate the Nation's Shortage of Truck Parking Spaces

TRALA is concerned over how the build-out of a national truck charging network will impact the nation's truck parking space shortage. Truck drivers count on safe parking spaces to comply with trucking regulations and to get a good night's sleep. Parking has been in short supply for years, over 300,000 spaces to be more precise. For every 11 drivers in the U.S., there is one truck parking space.19 Drivers spend, on average, one hour each day searching for truck parking.20 The DOTs 2019 Jason's Law Report found that approximately 98% of drivers have trouble finding parking compared to 75% in 2015 – a 23% increase. Admittedly 70% of commercial motor vehicle drivers were forced to violate HOS regulations seeking safe, legal parking.21 DOT also found that the truck parking shortages exist in every state and region and is most acute along major freight corridors – the very same corridors targeted to install truck EV charging. [EPA-HQ-OAR-2022-0985-1577-A1, p. 14]

19 'Truck Parking Shortage: A Heavy Load for Truck Drivers to Bear,' Driver Safety (July 5, 2022).

20 Id.

21 'Trucking Groups Urge Secretary Buttigieg to Address Safe Parking Shortage,' Safety+Health (March 1, 2022).

Diesel remains the predominant fuel in trucking and will continue to be over the near-term future. With that being the case, as truck parking facilities add or expand charging infrastructure, it will likely take away valuable parking spaces for diesel-powered trucks that – at this point in time – are more likely to need limited parking spaces. What is more troublesome are areas having few parking spaces, little land for parking expansion, or under-utilized truck parking spaces reserved for truck charging, will result in spill-over parking along roadways and in surrounding neighborhoods.[EPA-HQ-OAR-2022-0985-1577-A1, pp. 14-15]

One has to go no further than rest areas along the interstate to see trucks parked on interstate entry and exit ramps due to lack of parking. Rural areas may have better opportunities to purchase land for expanding parking and adding charging spaces but they may also be less inclined to do so until sufficient ZEV product lines are available and in use. Even electrified parking spaces can compound parking shortages depending on vehicle dwell times, wait periods for electrified spaces to become available, charger downtimes, speed of charging, fire code spacing requirements, and the numbers of chargers. TRALA recommends the agency coordinate with DOT to conduct periodic reviews, assessments, and define solutions regarding any truck parking impacts created from electrifying current truck parking locations. [EPA-HQ-OAR-2022-0985-1577-A1, p. 15]

Organization: Volvo Group

Even other seemingly unrelated issues could influence the availability of charging, such as parking concerns. Parking for Class 8 vehicles is a significant problem today and many truck stop operators are understandably nervous about converting existing parking stalls for EV charging for fear of having those spaces blocked by internal combustion engine (ICE) trucks. This parking problem has been exacerbated by state decisions to close existing, and limit future development of interstate rest stop parking. More state and federal dollars for parking along with amendments to the Federal-Aid Highway Act currently restricting EV charging at rest areas will help. [EPA-HQ-OAR-2022-0985-1606-A1, p. 8]

EPA Summary and Response:

Summary:

At least one commenter requested better public information and resources to support HD BEV charging. For example, DTNA suggested that mandatory reporting could help resolve the lack of public information for fleets, manufacturers, and regulators about charging stations for HD BEVs. They noted that stations for HD BEVs have special requirements that need to be accounted for (e.g., along designated Alternative Fuel Corridors and in NEVI plans). DTNA stated that DOE's AFDC could be supplemented to share additional data relevant to HD vehicles, which could also be useful to EPA for tracking purposes. They suggested working with agencies like FHWA, EIA, FERC, the NEVI program, and others to align data, encourage programs that accommodate and support BEV charging for HD vehicles, and help mitigate challenges to ZEV infrastructure deployment.

Others commented on the value of encouraging vehicle-to-grid (V2G) and vehicle-to-X (V2X) technologies. Fermata, MECA, MEMA, and Nuvve noted the benefits of future-proofing BEV infrastructure to address long-term needs. Fermata and Nuuve encouraged the use of V2G and V2X technologies to enhance infrastructure resilience. Fermata said the technology could provide a potential revenue stream for charging equipment owners, and with proper implementation can act as a grid asset that would benefit ratepayers at large. Fermata commented that V2X could provide a "positive value to consumers and low- and moderate-income consumers." They recommend that EPA provide incentives or regulations on V2X to increase confidence in the technology, and to help commercialize V2X. They also encourage EPA to "support all connectors, protocols, and EVSE sizes in any V2X recommendations for incentives or regulations in order to foster competition and encourage lower cost solutions." Nuvve pointed to V2G as an alternative to diesel generators, which offers emissions benefits. They noted that V2G can work across vehicle types and pointed to a few studies on the financial benefits of V2G. Nuvve and MECA also highlighted the national security benefits of V2G.

Also as a means of future-proofing infrastructure, MECA and MEMA wrote about the importance of improving charger efficiency and setting minimum charger efficiency standards to ensure the efficient use of energy and to lower operating costs. MECA stated that EPA should prioritize the planning and building of public DCFCs. They described many reasons including the fact that DCFC allows for bidirectional charging, which can support increasing electricity demand. They suggested that EPA work with other government agencies such as JOET to develop national standards and certification requirements to ensure reliability. MEMA noted that higher-power chargers like DCFC are critical for HD BEVs. For example, DCFCs can enable opportunity charging, and bidirectional charging can offer additional benefits. They suggested that more investment is needed to improve reliability and promote confidence in these technologies.

At least one commenter expressed concerns about workforce requirements. South Coast AQMD focused on the workforce needed in California to install charging infrastructure. They said the federal government has a key role to play in creating programs to develop the skills and training needed to ramp up the deployment of charging stations. The rapid scaling of infrastructure for ZEVs, they note, will require interstate connections, and the federal government is in a good position to help facilitate the market, create stability and reliable fuel supplies, and drive down costs.

Finally, TRALA and Volvo commented on an existing truck parking station shortage that they say could be impacted by the buildout of a national HD BEV charging network. TRALA explained issues that commercial vehicle drivers must deal with to find safe, legal parking and expressed concerns about converting limited spaces for diesel trucks to spaces for BEV charging. They recommend that EPA coordinate with DOT to monitor and assess conditions as the market evolves and develop solutions. Volvo suggested that additional state and federal funding for parking and restrictions on BEV charging at rest stops could help.

Response:

In response to DTNA's comment suggesting that EPA work with other agencies to improve public information about HD BEV charging infrastructure, EPA has worked closely with the Joint Office of Energy and Transportation (JOET) and other federal agencies on a range of BEV charging infrastructure issues and challenges. For example, EPA works with DOE and DOT (along with other government, industry, and other stakeholders participants) on the Electric Vehicle Working Group, which, as described by JOET, was formed to make recommendations "regarding the development, adoption, and integration of light-, medium-, and heavy-duty electric vehicles (EVs) into the U.S. transportation and energy systems."[450] EPA collaborated with other agencies in development of a National Zero-Emission Freight Corridor Strategy,[451] released in March 2024, that, "sets an actionable vision and comprehensive approach to accelerating the deployment of a world-class, zero-emission freight network across the United States by 2040. The strategy focuses on advancing the deployment of zero-emission medium- and heavy-duty vehicle (ZE-MHDV) fueling infrastructure by targeting public investment to amplify private sector momentum, focus utility and regulatory energy planning, align industry activity, and mobilize communities for clean transportation."[452] The strategy has four phases. The first phase, from 2024-2027, focuses on establishing freight hubs defined "as a 100-mile to a 150-mile radius zone or geographic area centered around a point with a significant concentration of freight volume (e.g., ports, intermodal facilities, and truck parking), that supports a broader ecosystem of freight activity throughout that zone."[453] The second phase, from 2027-2030, will connect key ZEV hubs, building out infrastructure along several major highways. The third phase, from 2030-2045, will expand the corridors, "including access to charging and fueling to all coastal ports and their surrounding freight ecosystems for short-haul and regional operations."[454] The fourth phase, from 2035-2040, will complete the freight corridor network. This corridor strategy provides support for the development of HD ZEV infrastructure that

[453] Joint Office of Energy and Transportation. "National Zero-Emission Freight Corridor Strategy" DOE/EE-2816 2024. March 2024. Available at https://driveelectric.gov/files/zef-corridor-strategy.pdf. See page 3.

[454] Joint Office of Energy and Transportation. "National Zero-Emission Freight Corridor Strategy" DOE/EE-2816 2024. March 2024. Available at https://driveelectric.gov/files/zef-corridor-strategy.pdf. See page 8.

corresponds to the modeled potential compliance pathway for meeting the final standards. In addition, EPA has announced several funding opportunities through BIL and IRA focused on HD sectors that allow for spending on HD BEV charging infrastructure, as discussed in RIA Chapter 1.3.2, and we offer information on our website to inform the public about implementation of these funding programs. As discussed in RTC Section 2.10, we are committed to continuing our engagement with federal partners and with multiple stakeholders and to monitoring build-out of major elements of the HD ZEV infrastructure. We may in the future request additional information, as appropriate, and as consistent with our Clean Air Act and other authorities, but we do not agree with the commenter that mandatory reporting about infrastructure deployment is warranted at this time.

The commenter suggested that DOE's Alternative Fuels Data Center (AFDC), for example, could be a tool for providing public information about HD BEV charging stations. We agree the AFDC Station Locator is a useful resource for finding stations and further note that it is possible to identify stations with access for HD BEVs through advanced filters.[455] We encourage industry to also partner with DOE to ensure that accurate and useful information is made publicly available in a timely manner, given that the AFDC Station Locator data collection methods include "collaborating with infrastructure equipment and fuel providers, original equipment manufacturers (OEMs), and industry groups".[456] We also note that many utilities publish hosting capacity maps, and there is a Department of Energy publication compiles all of these maps' locations in a central registry. See RTC Section 7 (Distribution) below.

We agree with the commenters that V2G and related technologies may offer numerous benefits and potentially save money for fleets, as discussed further in RIA Chapter 1.6.4 and RTC Section 7. We did not quantitatively include these benefits in our analysis for the rule so to the extent that fleets monetize such benefits, our costs analysis may be considered conservative.

In response to comments about charger efficiency, we note that DOT's Federal Highway Administration 2023 rule sets minimum charging infrastructure standards and requirements for infrastructure projects funded under the NEVI program, including DCFCs. The rule "does not specifically accommodate" HD BEV charging, but FHWA explicitly and strongly encourages the consideration of future HD charging needs and notes that they will continue to monitor technological advancements.[457] In January 2024, DOT's FHWA awarded the first EV Charger Reliability and Accessibility Accelerator Program grants to address charger reliability.[458] We agree that the efficiency of technologies can help lower costs, and that higher power chargers like DCFCs make sense for some HD BEV charging scenarios that require faster charging times, such as en-route charging. EPA encourages the use of energy efficient chargers through our

voluntary EnergyStar program, which certifies AC-Output and DC-Output charger models with power levels of up to 350 kW.[459]

Please see RTC Section 19.2 for a detailed response to comments regarding employment, including some discussion related to workforce and training needs to install charging infrastructure. There are many programs to support the training of technicians supporting ZEV infrastructure, including through federal agencies. For example, both EPA and JOET identify resources related to workforce development and training on their websites.[460,461] In January 2024, DOE announced $46.5 million for BEV charging that is intended in part to grow the clean energy workforce.[462] In November 2023, the National Governors Association and the National League of Cities launched a State and Local Collaborative to Support an Inclusive Workforce for the Electric Vehicle Charging Sector to develop career pathways, supported by the Siemens Foundation's EVeryone Charging Forward initiative that has a similar focus.[463] We expect that programs like the many that are listed throughout RTC Section 19.2 and this rulemaking, as well as other efforts not included, will increase with the increasing buildout of charging infrastructure.

We acknowledge concerns about the availability of parking for commercial trucks and potential impacts due to public charging, particularly along major freight corridors where the shortages may be most acute according to TRALA. We note that DOT released a truck parking handbook for state and local planners that mentions designing facilities for future freight vehicles, including electric vehicles. They recognize that parking will continue to play a significant role in trucking and that as vehicle technologies evolve, activity at a site may change over time. DOT also updated guidance on funding eligibility for commercial vehicle parking projects that recognizes truck parking shortages as a national concern.[464,465] We thus note that this issue is being addressed as part of the federal government's response to promoting successful deployment of needed HD ZEV infrastructure, as discussed further in RTC Section 2.10.

Comments by Organizations

Organization: Advanced Energy United

Transportation is the largest source of domestic [GHG] emissions. In 2021, 28% of emissions came from the transportation sector, 23% of which came from HDVs1. We have a unique opportunity to not only decarbonize this sector, but improve public health, create good paying jobs, and produce technologically advanced vehicles for consumers and businesses in the process. The EPA's promulgation of the new emissions reductions rule on heavy-duty vehicles provides a pathway to meet emissions reductions targets and expand the adoption of zero-emissions vehicles on our roads. [EPA-HQ-OAR-2022-0985-1652-A2, p. 1]

1 EPA. (28 April, 2023). Sources of Greenhouse Gas Emissions. https://www.epa.gov/ghgemissions/sources-greenhouse-gas-emissions

A large percentage of emissions reductions from the transportation sector will be accomplished by replacing gas- and diesel-powered buses, trucks and vans with EV models. EVs are not only much more energy efficient than gas-powered cars but are also less expensive to fuel and maintain over their lifetimes. Thus, the EPA's proposed rule presents an opportunity to decarbonize the largest source of emissions in the American economy while scaling up an emerging domestic market. Electrified transportation reduces our reliance on fossil fuels, strengthens America's energy independence, and produces economic benefits across the value chain of the automotive industry. [EPA-HQ-OAR-2022-0985-1652-A2, pp. 1 - 2]

However, in order to fully realize the benefits of this new fuel source, we must consider innovative approaches that will effectively manage that electric load and mitigate potential grid impacts. In the draft regulatory impact assessment for the Phase 3 rule, the EPA rightly recognized that grid constraints will be a challenge, and the likely necessity of a variety of approaches to reduce the need or scale of upgrades.2 While some solutions to this challenge will require the engagement of state and federal policymakers, others are already being deployed by innovative companies across the advanced energy industry. [EPA-HQ-OAR-2022-0985-1652-A2, p. 2]

2 Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles: Phase 3 Draft Regulatory Impact Analysis p 70 https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P10178RN.pdf

Building out a decarbonized electric grid with advanced energy technologies—and the infrastructure necessary to ensure its stability—will require the innovation and speed demonstrated by President Roosevelt's Arsenal of Democracy. In response to the need for tanks, weapons, and planes, American companies like Ford, GM, and Boeing ramped up manufacturing production and began making the technologies, equipment, and parts necessary to bolster Allied efforts. That is the kind of American innovation that we will need—and have begun to see—from leading automakers and new market entrants as they increase their share of EVs. For instance, Ford and Sunrun have teamed up to pair the energy storage capabilities of the all-electric F-150 Lightening with rooftop solar. In a similar vein, Rivian has indicated an interest in implementing bi-directional charging—vehicle-to-load—software into their vehicles which would alleviate grid constraints and improve resiliency. This technology turns an EV into a mobile battery. Heavy-duty vehicles in particular have larger battery capacity than light-duty vehicles, and can provide even more power in times of need. This could yield immense benefits to grid resiliency and provide helpful energy storage for commercial buildings and homes. [EPA-HQ-OAR-2022-0985-1652-A2, p. 2]

In addition to hardware solutions to manage grid impacts from electric HDVs, software-based managed charging solutions (sometimes called automated load management or power control systems) serve a similar role to mitigate the need for electrical distribution system upgrades. Fleets comprised of HDVs are well-suited to such managed charging technologies. Fleet vehicle routes and deployment schedules are often fairly predictable, with fleet operators closely monitoring schedules for operational and economic optimization. At the same time, many vehicles often have long dwell times which can help to shift and shape load, thereby reducing impact on the grid. [EPA-HQ-OAR-2022-0985-1652-A2, p. 2]

II. Case Studies

Below are three brief case studies that show how these proven technologies have helped to alleviate grid constraints and benefit consumers. [EPA-HQ-OAR-2022-0985-1652-A2, pp. 2 - 3]

Case Study 1:

Dedicated EVSE companies like FreeWire Technologies are an example of American innovation, which has shown repeatedly that it can keep pace with the demands of the moment. Free Wire's battery-integrated charging technology "solves grid constraints by packaging charging infrastructure, grid infrastructure, and energy storage into a fully-integrated compact solution These ultrafast chargers provide enhanced grid resiliency options during peak demand and can support critical facilities during outages and charge vehicles at 200kW in 15 minutes.4 [EPA-HQ-OAR-2022-0985-1652-A2, p. 3]

3 FreeWire Technologies. (27 April, 2022). FreeWire Technologies Announces $125 Million Series D Financing to Accelerate Deployment and Development of Next-Gen EV Charging Technology and Energy Management Services. https://freewiretech.com/freewire-technologies-announces-125-million-series-d-financing/

4 FreeWire Technologies. (2023). FAQ. https://freewiretech.com/faq/#:~:text=Visit%20the%20Boost%20Charger%20web,200%20miles%20in%2015%20minutes.

Case Study 2:

Octopus Energy has employed a demand response program in the United Kingdom called Intelligent Octopus, which demonstrates the potential for managed charging to reduce grid pressures and the costs associated with overbuilding the distribution system. A customer simply sets their preferences in an app (specifying when they need the EV charged and the state of charge that is needed) and the platform will automatically charge the cars at times where there is abundant, low-cost energy, helping to balance out demand and supply on the grid while saving customers money. Intelligent Octopus enrollment has grown from 600 EVs since it was launched in January 2022 to over 45,000 EVs today, providing 250 MW in shiftable load resources. Intelligent Octopus was launched for EV drivers in Texas in February. [EPA-HQ-OAR-2022-0985-1652-A2, p. 3]

Case Study 3:

Irish Post issued an RFP to electrify 100 parking sites across the country for its mail fleet of trucks, vans, and cars. Understanding that they were working with constrained grid conditions, Irish Post included load management capability as a requirement so as to avoid the cost and time delays of extensive local grid upgrades.

A general contractor and The Mobility House (TMH) won the RFP and deployed 2800 22 kW AC chargers and 180 DC chargers ranging from 22-50 kW while avoiding an estimated 50 MW of utility upgrades across all sites. At a subset of 31 sites using exclusively 32 Amp chargers, TMH's load management technology enabled the team to safely install and operate EVSE nameplate capacity exceeding the main site panel capability by an average of 200-300%. This allowed an average of eight extra EVSEs per site to be installed without upgrading service, saving Irish Post time and money as they electrified their fleet while allowing all EVSEs access to their full nameplate capacity when needed and serving their mobility needs with no adjustments in driver behavior. [EPA-HQ-OAR-2022-0985-1652-A2, pp. 3 - 4]

Case Study 4:

Vehicle-to-grid (V2G) technology allows an electric vehicle (EV) to draw energy from the grid (typically during periods of low cost & low demand) and discharge energy back to the grid (during periods of high cost & high demand). V2G technology also helps reduce energy costs associated with owning and operating EV fleets. An increasing number of electric utilities, like National Grid in Massachusetts, support programs that pay electric fleets and other battery storage resources to discharge energy, turning them into revenue-generating assets without disrupting normal operations. In the summers of 2021 & 2022, Highland Electric Fleets piloted V2G technology in battery storage from electric school buses. 10+ MWh was discharged to the Massachusetts grid across 158 hours, generating $2,300. [EPA-HQ-OAR-2022-0985-1652-A2, p. 4]

Case Study 5:

The San Diego-based company Nuvve is a global leader in vehicle-to-grid (V2G) technology with deployments on five continents. In the US, Nuvve is focused on the school bus market. Electrified school bus fleets represent an excellent candidate for V2G given the large batteries and the long dwell times. School buses are often idle for months at a time during the summer when additional grid capacity is at a premium. The U.S. Environmental Protection Agency (EPA) acknowledges the potential of electrified school bus fleets to provide V2G services.5 [EPA-HQ-OAR-2022-0985-1652-A2, p. 4]

5 See U.S. EPA, What if Electric School Buses Could be Used to Supply Power When Off Duty? Available at https://www.epa.gov/greenvehicles/what-if-electric-school-buses-could-be-used-supply-power-when-duty.

Nuvve is the only company, working collaboratively with San Diego Gas & Electric (SDG&E), to have successfully developed an electric school bus (ESB) V2G pilot program in California. Six 60 kW bidirectional chargers and six V2G capable Lion Electric school buses were deployed at Cajon Valley Union School District. Using Nuvve's GIVe software platform, these buses participated in 10 Emergency Load Reduction Program (ELRP) events from August 17th through September 9th through SDG&E.6 The host school district was paid $2/kWh for V2G exports helping to reduce the total cost of ownership of its ESB fleet. Nuvve has additional V2G deployments totaling over 1 MW under development in California. In addition, Nuvve has multiple projects under development in other states including Oregon, Utah, Nevada, Colorado, Texas, Illinois, Florida, and Rhode Island. [EPA-HQ-OAR-2022-0985-1652-A2, p. 4]

6 See SDG&E and Cajon Valley Union School District Flip the Switch on Region's First Vehicle-to-Grid Project Featuring Local Electric School Buses Capable of Sending Power to the Grid available at https://www.businesswire.com/news/home/20220726006137/en/SDGE-and-Cajon-Valley-Union-School-District-Flip-the-Switch-on-Region%E2%80%99s-First-Vehicle-to-Grid-Project-Featuring-Local-Electric-School-Buses-Capable-of-Sending-Power-to-the-Grid.

III. Technology Impacts

Managed charging with both hardware- and software-based solutions is an essential strategy to reduce infrastructure costs for fleet charging depots. Depot charging is likely to account for nearly 90% of fleet operating needs, with vehicles on average having 14 hours of downtime per day.7 Managing these vehicles' charging load to avoid peak periods can substantially reduce the need to upgrade both the facility's infrastructure and the utility-side infrastructure, compared to an unmanaged charging scenario in which vehicles charge simultaneously during peak periods. A recent NREL study found that managed charging in the MHD sector can reduce distribution system investment costs by up to $1,090 per EV per year.8 [EPA-HQ-OAR-2022-0985-1652-A2, pp. 4 - 5]

7 Perspectives on Charging Medium- and Heavy-Duty Electric Vehicles, NREL, December 2021. https://www.nrel.gov/docs/fy22osti/81656.pdf

8 Electric Vehicle Grid Integration, NREL. https://www.nrel.gov/transportation/project-ev-grid-integration.html

In 2021 testimony filed at the California Public Utilities Commission, Pacific Gas & Electric stated that utilizing these load management technologies could reduce the originally requested capacity by more than 50%, which resulted in cost savings ranging from $30,000 to $200,000 per project.9 [EPA-HQ-OAR-2022-0985-1652-A2, p. 5]

9 PGE testimony 2-9-210 https://docs.cpuc.ca.gov/PublishedDocs/SupDoc/A2110010/4240/417398449.pdf

Modeling based on New York's existing medium- and heavy-duty electrification indicates that managed charging will yield cost savings that will accrue to all ratepayers. A 2023 report from Synapse Energy Economics, leveraging data and tariffs from ConEd and National Grid, found that managed charging reduced site peak load by 15% and 5% respectively.10 This data reflects the more rigid charging needs and schedules of fleet vehicles, but is significant, nonetheless. The cost savings associated with managed charging are also likely to lead to faster economic return on investment for fleets in the process of electrification. [EPA-HQ-OAR-2022-0985-1652-A2, p. 5]

10 MHDV Integration Costs Report, Synapse, April 2023. https://acrobat.adobe.com/link/track?uri=urn%3Aaaid%3Ascds%3AUS%3Ab0fd0780-9882-3a25-9ef2-f8c73bd80c92&viewer%21megaVerb=group-discover

The implimentation of managed charging policies are a critical factor to speed overall adoption of medium- and heavy-duty electric vehicles in line with the EPA's rulemaking. As emissions standards steadily increase and EVs proliferate on our roads, it is likely that demand for electricity will rise beyond what managed charging can save. This new demand will call for added transmission capacity and resiliency measures, vehicle-grid integration, smart charging, and bidirectional charging/ V2G, and other innovative solutions. Without proactive planning and buildout of charging infrastructure, the U.S. is at risk of failing to meet its ambitious, and laudable, goals for transportation emissions reductions. A 2021 study by the Brattle Group estimated that investments in transmission would have to reach $25 billion in order to charge 20 million EVs11. To fully unlock these investments, the U.S. will need to undertake permitting reform, to streamline transmission projects and free up interconnection queues. [EPA-HQ-OAR-2022-0985-1652-A2, p. 5]

> 11 Sergici, S., Hagerty, M., & Long, L. (1 June, 2020). Electric Power Sector Investments of $75-125 Billion Needed to Support Projected 20 Million EVs by 2030, According to Brattle Economists. Brattle Group. https://www.brattle.com/insights-events/publications/electric-power-sector-investments-of-75-125-billion-needed-to-support-projected-20-million-evs-by-2030-according-to-brattle-economists/

American innovation has shown repeatedly that it can keep pace with the demands of the moment. There will be stumbling blocks on the road to electrification, but we have the tools to mitigate them. Innovative approaches like bidirectional charging/V2G technology can support the grid when supply is needed. Managed charging and demand response technologies and battery-integrated charging stations help ease peak demand. These types of approaches can facilitate the transition to 100% clean energy, while transmission and distribution capacity are built out. These comments reflect industry concerns, priorities, and above all, solutions. [EPA-HQ-OAR-2022-0985-1652-A2, p. 6.]

Advanced Energy United and its member-companies believe that these recommendations will bolster the effectiveness of the EPA's implementation of this rule and we look forward to further collaboration. [EPA-HQ-OAR-2022-0985-1652-A2, p. 7.]

Organization: Alliance for Vehicle Efficiency (AVE)

According to a recent study, "… the electric grid does not have 'sufficient delivery headroom' for highway charging to meet projected demand and policy targets… Sites with significant charging loads will need 'considerable' electric distribution system upgrades and, in many cases, high-voltage transmission-level interconnection." 23 [EPA-HQ-OAR-2022-0985-1571-A1, p. 8]

c. Electricity Grids Will Need Substantial Upgrades Before They Can Support Commercial Fleets

Even if adequate charging stations could be established in the numbers and at the locations needed across the United States, providing those stations with the massive amounts of electricity required to charge heavy-duty vehicles would pose another likely insuperable obstacle on the proposed rule's timeline. Heavy-duty electric vehicles require especially large batteries and charging them will raise electricity demand across the country. See Medium- and Heavy- Duty Vehicle Electrification at 16. For example, a modest-sized fleet of Class 7 and 8 vehicles could consume more than four gigawatt hours of electricity per year and could reach peaks that rival outdoor sports stadiums. Id. [EPA-HQ-OAR-2022-0985-1660-A1, pp. 48 - 49]

Today's electricity grids do not have capacity for such a dramatic increase in demand. See Medium- and Heavy-Duty Vehicle Electrification at 18; Hauke Engel et al., The Potential Impact of Electric Vehicles on Global Energy Systems, McKinsey & Co. (July 2018) ("Potential Impact"). Researchers have emphasized that heavy-duty charging stations "wouldn't be like the charging stations you see around now for cars"; instead, they would "require much more power" that "existing grid connections would not be able to handle." Calculating the Cost of E-Trucking. Others have similarly warned that the integration of electric heavy-duty vehicles "could bring challenges to power systems, such as increased peak load, power quality issues, increased power losses, and shortened life of transformers." Mingzhi Zhang et al., Location Selection of Fast-Charging Stations for Heavy-Duty EVs Using GIS and Grid Analysis, NREL, at 1 (Feb. 2021) (footnotes omitted). [EPA-HQ-OAR-2022-0985-1660-A1, p. 49]

Indeed, one recent study found that electrification of even 11 percent of trucks and buses "could destabilize the transmission grid." Medium- and Heavy- Duty Vehicle Electrification at 18. And local officials and utilities have reportedly halted company plans for electrification over these concerns. See A Heavy Dose of Reality. For example, "[a]fter one trucking company tried to electrify just 30 trucks at a terminal in Joliet, Illinois, local officials shut those plans down, saying they would draw more electricity than is needed to power the entire city," and when "[a] California company tried to electrify 12 forklifts"—not trucks, but forklifts—"[l]ocal power utilities told them that's not possible." Id. Thus, before manufacturers can comply with the proposed rule, there will need to be major upgrades to the nation's electricity grids. [EPA-HQ-OAR-2022-0985-1660-A1, p. 49]

Those upgrades would be expensive—and would take time. Modifications to local electricity-distribution systems can cost between $30,000 (to produce and install electric-vehicle supply equipment) and $35 million (to install a new substation) and can take between three months and four years. See Medium- and Heavy-Duty Vehicle Electrification at 17. In places with highway charging stations, there would also likely be a need for transmission interconnection. See Electric Highways at 6; Potential Impact ("[A] single fast-charging station can quickly exceed the peak-load capacity of a typical feeder-circuit transformer."). That project can take as long as eight years to complete—if it can even be done at all. See Electric Highways at 4, 34 ("It may not be feasible to extend the transmission network to every site, particularly in locations where there would be impacts to local residents and the environment."). Given these long lead times, even if fleet owners, utilities, and others began work on grid improvements today, necessary upgrades might not be completed in time to support the surging demand for electricity distributed across the grid that EPA's proposed rule would require. [EPA-HQ-OAR-2022-0985-1660-A1, pp. 49 - 50]

EPA observed that the precise extent and nature of improvements to the grid that ultimately would be necessary is difficult to predict years in advance— and on that basis declined to model those changes directly. See 88 Fed. Reg. at 25,983 ("[T]here is considerable uncertainty associated with future distribution upgrade needs, and in many cases, some costs may be borne by utilities rather than directly incurred by BEV or fleet owners. Therefore, we do not model them directly as part of our infrastructure cost analysis."). That regulate-first, confront-practical-impediments-later approach is backwards. It is irrational to press forward without robust analysis of the changes that are likely to be necessary; if EPA concludes that reliable analysis is impossible, it should stay its hand or pursue a different approach. At a minimum, the acknowledged uncertainty about the potentially massive burdens that grid improvements might necessitate provides further doubt on the proposed rule's feasibility and more reason for caution.7 [EPA-HQ-OAR-2022-0985-1660-A1, p. 50]

7 Relying on other forms of energy would also be infeasible. Researchers have found that “[t]he initial cost for a solar-powered charging site would be between $82 million and $139 million,” “[a] nuclear reactor station would initially cost $141 million,” and “[a] wind power station would initially cost up to $75 million.” Calculating the Cost of E-Trucking. And even if those options were not prohibitively expensive, “[e]ach alternative also comes with its own issues,” making them ill suited for a widespread shift away from internal-combustion-engine vehicles. Id.

Organization: American Fuel and Petrochemical Manufacturers (AFPM)

Critically important to increased ZEV adoption is the infrastructure necessary to operate such vehicles. EPA overlooks this issue in the Proposed Rule. Notably absent from EPA’s analysis is any demonstration that sufficient charging stations, utilities, and other infrastructure needed to support accelerated ZEV implementation will be available by MY27. As engine manufacturers have acknowledged, even as new ZEVs are ready to enter into production, the necessary infrastructure for both electric vehicles and hydrogen vehicles continue to lag, especially when multiple facilities are needed to support the multiple fuel and powertrain technologies EPA contemplates.72 Focusing solely on electric vehicles themselves, EPA has not adequately evaluated or grasped the time and resources required to permit, construct, and operate the necessary infrastructure to power these vehicles. This is particularly concerning in light of the very real risk that the electric grid will not be able to meet the increased demand anticipated by the Proposed Rule.73 [EPA-HQ-OAR-2022-0985-1659-A2, pp. 17 - 18]

72 See Jack Roberts, Truck Tech, “5 Takeaways from ACT Expo 2020,” (May 20, 2022), available at https://www.truckinginfo.com/10172184/5-take-aways-from-act-expo-2022 (citing Cummins CEO Tom Linebarger as warning ACT Expo attendees that the undertaking will cost multiple trillions of dollars to accomplish).

73 North American Electric Reliability Corporation, 2022 Long-Term Reliability Assessment (Dec. 2022), 21, available at https://www.nerc.com/pa/RAPA/ra/Reliability%20Assessments%20DL/NERC_LTRA_2022.pdf. (indicating that increased demand projections may lead to reliability concerns for the electric grid, especially as dual-peaking or seasonal peaking times change with increased electrification)

While a significant percentage of the charging installations deployed today are Level 2 EVSEs, dual charging installations to enable the flexibility of light-duty as well as medium-duty and HDV charging will become increasingly important. Direct current fast charging equipment (“DCFCs”) will enable broader market coverage, even for LDVs used in applications where they cannot sit for 6 hours and charge during off-peak, lower-cost electricity periods. As utility companies gear up to provide infrastructure installations, EPA should not minimize the impact of supply chain shortages/strains on the cost of materials necessary for installing supporting charging infrastructure in the short time ahead to 2032. Beyond EVSE chargers, the cost of grid upgrade projects needed to support the incremental electricity demand growth from transportation is not insignificant and can be quite variable. A particular case study of Southern California illustrated in IOPscience notes: “the total cost of these upgrades will be at least $1 billion and potentially more than $10 billion.” These costs need to be taken into consideration with expected demand growth, within detailed rate base calculations, and in concert with appliance upgrade costs to fully understand their ultimate impacts on annual ratepayer expenditures.” 81 We agree with and support the Proposed Rule’s acknowledgement that “a recent study found power needs as low as 200 kW could trigger a requirement to install a distribution transformer.” Other anecdotal evidence discussed within an RMI report highlights the expensive mistakes that can emerge from insufficient planning and engagement in details.82 Demand charges can be particularly punishing, and in some cases make or break the business case for transition from ICEVs to BEVs, particularly for fleets and vehicles that require DCFC charging. Other considerations for high-reliability use cases should include provisional back-up power system considerations, which likely depend upon back-up generators or expensive stationary energy storage batteries. Absent comprehensive understanding of the dynamics between increased ZEV use and charging infrastructure needs, vehicle manufacturers—as well as consumers—are left in a vulnerable position. Regardless of whether manufacturers even could comply with the Proposed Rule, they would likely be left in a position where there is no consumer demand, and fleet turnover declines because the infrastructure necessary to support the new ZEVs is either at capacity or nonexistent. Indeed, at least one study to date has concluded that, upon ZEVs becoming the norm in California, it could push the total demand for electricity beyond the existing capacity of the state's grid—turning ZEVs into zero electricity vehicles.83 Even more important, meeting the demand in California would likely require construction of new power plants, or electricity purchases from neighboring states—further adding to the infrastructure needs with increased transmission and distribution capabilities.84 Or, in the short term, electricity may come from generators, in which case it makes more sense to leave the ICE in the truck rather than beside it. [EPA-HQ-OAR-2022-0985-1659-A2, pp. 22 – 23]

Despite the potential for increased demands on domestic energy generation and generation capacity,85 EPA offers little to no support that these demands will be sufficiently met. Similarly, EPA's draft Regulatory Impact Analysis86 provides little to no analysis regarding the costs associated with meeting these increased infrastructure and energy generation/capacity needs beyond the flawed reliance on various legislative actions, such as the BIL and IRA.87 Consequently, EPA is pushing a technology at a pace that cannot be adopted within the timeframe of its own proposal. [EPA-HQ-OAR-2022-0985-1659-A2, p. 23]

85 See, e.g., U.S. DRIVE, "Summary Report on Evs at Scale and the U.S. Electric Power System" (Nov. 2019), available at https://www.energy.gov/eere/vehicles/articles/summary-report-evs-scale-and-us-electric-power-system-2019 (summarizing impacts of light-duty vehicles on energy generation and generation capacity alone and acknowledging several potential challenges without including analysis of medium- and heavy-duty ZEVs).

(Nov. 9, 2022), available at https://iopscience.iop.org/article/10.1088/2634-4505/ac949c (projecting upgrades needed solely for the PG&E service area in Northern California, which serves 4.8 million electricity customers and is subject to

aggressive targets for both EV adoption and electrification of residential space and water heating will add at least $1 billion and potentially $10 billion to PG&E's rate base).

Organization: American Highway Users Alliance

Significantly, at the same time that EPA has issued this NPRM, it has also issued a major proposal calling for reduced tailpipe emissions of CO2, other GHGs, and other substances from light-duty and medium-duty vehicles. See 88 Fed. Reg. 29184 (May 5, 2023). That proposed rule, similar to the one in this docket, assumes astronomical growth in EVs as a percentage of new light-duty and medium-duty vehicles. That rule faces similar questions regarding feasibility due to, among other uncertainties, the availability of charging infrastructure that is sufficiently fast, the ability of the electric grid to provide electricity to support the growth in light-duty EVs, the ability of the electric utilities to provide connections from the grid to charging facilities, and the availability of critical minerals, processing and related battery components. [EPA-HQ-OAR-2022-0985-1550-A1, p. 3]

Organization: American Petroleum Institute (API)

iv. Stakeholders missing from the discussion – utilities

EPA requested comment on stakeholders that may be missing from the discussion. As noted during the public hearing testimony, of the various stakeholders who testified, representation from the utilities was lacking. We implore the agency to fully engage the utilities in discussion prior to finalizing the Phase 3 rule. Because infrastructure is such an important piece of the program, the main stakeholder group needs to be included in the design of the program to provide EPA guidance. For example, a set of truck chargers of sufficient size to charge a fleet of fully electric trucks requires power enough for a small town.10 If there are National Electric Vehicle Infrastructure (NEVI) charging facilities (i.e., four direct current fast chargers (DCFCs) with the capability to deliver 150 kW simultaneously) located on the same grid, there could be significant challenges to delivering the power without impacting other residential, commercial, and industrial customers. Further, a guidance report by the North American Council for Freight Efficiency (NACFE) and RMI highlights that "[c]harging infrastructure includes not only the chargers themselves, but the interrelated system of vehicles, duty cycles, chargers, and electric utilities."11 [EPA-HQ-OAR-2022-0985-1617-A1, p. 9]

ii. Infrastructure

2. Grid and charging

A robust analysis of the potential for the development and application of ZEV technologies in the HD sector must be conducted by EPA. We have concerns that EPA is overly optimistic about the technology readiness of ZEVs across the HD vehicle classes. Even with the low numbers of vehicles available on which to provide data, numerous studies and reports have been issued noting important concerns regarding ZEV readiness of the HD fleet. For example, a 2022 report by ATRI identified three overarching challenges in the deployment of HD ZEVs: electricity needs, battery materials and technology sourcing, and truck charging and parking infrastructure.16 The report cites the need for up to a 40 percent increase (based on HD vehicle class) in the nation's present electricity generation to fully electrify the U.S. vehicle fleet, and individual states would need 28 to 63 percent to meet vehicle travel needs. ATRI quantified that the truck charging needs at a single rural rest area would be equal to the amount of daily electricity required to power more than 5,000 U.S. households. [EPA-HQ-OAR-2022-0985-1617-A1, pp. 11 - 12]

16 "Charging Infrastructure Challenges for the U.S. Electric Vehicle Fleet", American Transportation Research Institute, December 2022.

EPA requested comment on whether certain HD sectors may need alternate standards or timing due to the energy content required for charging. The ATRI study, as well as a study prepared for the Diesel Technology Forum, indicate significant electricity demand and costs associated with HD ZEV charging for larger vehicles as well as for fleets with multiple vehicles. HD vehicle charging may require megawatt-levels of charging, which will require significant buildout of electricity distribution that does not exist today.17 [EPA-HQ-OAR-2022-0985-1617-A1, p. 12]

17 "Environmental Benefits of Medium- and Heavy-Duty Zero Emission Vehicles Compared with Clean Bio- & Renewable-Fueled Vehicles 2022-2032," prepared for Diesel Technology Forum by Stillwater Associates LLC, July 19, 2022.

Organization: American Trucking Associations (ATA)

Grid Availability

Charging sites for depots or large public charging stations for commercial vehicles will require significant energy. The American Transportation Research Institute (ATRI) estimates full commercial vehicle electrification would require a 14 percent increase in energy generation from today's standards.20 In many cases, remote or densely populated areas do not have available power to direct toward commercial vehicle charging sites. The International Council on Clean Transportation (ICCT) recognizes that the electrification of commercial vehicles will significantly burden the current electrical grid and challenge the centralization of where and how charging accommodates trucks in operation today.21 [EPA-HQ-OAR-2022-0985-1535-A1, p. 15-16]

20 American Transportation Research Institute, Charging Infrastructure Challenges for the U.S. Electric Vehicle Fleet, pg. 17, December 2022.

21 The International Council on Clean Transportation, Near Term Infrastructure Deployment to Support Zero-Emission Medium-and Heavy-Duty Vehicles in the United States, May 2023.

"We find that near-term energy needs will be concentrated in industrial areas in the largest metropolitan areas in the country, including Los Angeles, Phoenix, Houston, Chicago, and Dallas. 1% of U.S. counties will account for 15% of nationwide MHDV charging energy needs in 2030, constituting high-priority areas in which to concentrate near-term deployment of charging and refueling infrastructure of MHDVs." [EPA-HQ-OAR-2022-0985-1535-A1, p.16]

Early adopting fleets are being forced to quickly learn electricity demands and generation requirements as an important external factor that impacts their operations and TCO calculation. One fleet interviewed provided an example of their desire to electrify forklifts. In their mind, it would serve as an early use case to understand electric technology as they explored BEVs for their operations. However, in their discussions with the local utility, they were only allowed to electrify a small percentage of the originally desired forklifts due to limited onsite power. ATA asked fleets about their experiences with local utilities. More than two-thirds of respondents said they had not begun conversations with them. [EPA-HQ-OAR-2022-0985-1535-A1, p. 16]

The multi-state patchwork of energy generation and transmission regulatory bodies has made investment and modernization of the U.S grid even more challenging. Fleets are left with the reality of wading through local utility politics to receive approval for a permit to install minimal chargers on their site today. Addressing these site-specific challenges to build out charging infrastructure is essential to achieving the proposed rule's adoption rates and should begin immediately to accommodate large-scale transportation electrification. Yet, most states have not begun this process. With 168 investor-owned utilities, 1,958 publicly owned utilities and 812 cooperatives providing electricity to customers in the U.S., the scale of this undertaking will be significant and time consuming.22 The planning and oversight associated with hydrogen infrastructure is especially so. EPA should not propose a ZEV-dependent rule prior to ensuring the needed electric and hydrogen infrastructure will be available, including initiating state-wide planning and deployment assessments prior to establishing proposed ZEV adoption rates and timelines. [EPA-HQ-OAR-2022-0985-1535-A1, p. 16]

22 Energy Information Administration, Investor-owned utilities served 72% of U.S. electricity customers in 2017, August 15, 2019, available at http://www.eia.gov/todayinenergy/detail.php?id=40913.

For example, recently the California Public Utilities Commission (CPUC) developed a "Draft Staff Proposal: Zero-Emissions Freight Infrastructure Planning" that addresses the need for proactive planning of long lead time utility-side electric infrastructure (i.e., distribution and transmission) needed to support the acceleration of transportation electrification.23 [EPA-HQ-OAR-2022-0985-1535-A1, p. 16]

23 California Public Utilities Commission, Freight Infrastructure Planning, May 22, 2023, available at: http://www.cpucc.ca.gov/industries-and-topics/electricial-energy/infrastructure/transportation-electrification/freight-infrastructure-planning.

CPUC identified several challenges through this process, including:

- Approximately three years of required time to sequence statewide planning efforts and complete infrastructure authorizations. This does not include the time for cost recovery approval.
- Significant market and technology uncertainty affects the state's ability to proactively authorize infrastructure solutions.
- Risks and uncertainties regarding electricity grid load that are dependent on large-scale infrastructure buildout. These have not been adequately quantified within the state's existing planning and forecasting processes.
- The lack of an existing source of information on future fleet charger locations, and the need for long-term grid infrastructure planning to account for fleets' current flexible and economical routes.
- The lack of a coherent planning framework to optimize fleet business needs with electricity sector goals and requirements (i.e., how to cost-effectively upgrade the distribution and transmission system).

- The lack of a process for identifying long-term substation land acquisition needs. [EPA-HQ-OAR-2022-0985-1535-A1, p. 17]

Organization: CALSTART

One interesting example of successful load management strategies comes from EO Charging, a UK company that is expanding its presence in North America. EO currently manages the charging operations for several large fleets, including more than 5,000 Amazon commercial electric vehicles in Europe, primarily delivery vans but including medium-duty trucks. Their site design and operation enable accelerated truck deployments and manage utility capacity delays via smart managed charging and a mix of flexible charging rates to meet fleet operational requirements, site capacity limits, energy storage, and pricing considerations.45 In conversations, the group noted the system has been delivering consistent 99+ percent reliability/uptime. [EPA-HQ-OAR-2022-0985-1656-A1, p. 23]

45 https://www.eocharging.com/stories/eo-unveils-complete-electric-vehicle-fleet-charging-ecosystem

In our study, we assume a wide availability and strategic use of on-site battery storage for managed charging purposes and consider it a near-standard component of sites within certain geographies in the study, and estimate additional average costs per vehicle at a fraction of total charger cost based on industry data and project information available to CALSTART.46 Our assessment shows that significant total cost decreases of deployment compared to a baseline maximum deployment scenario are possible by on-site storage unlocking managed charging and making it available to deployments. Other studies show that managed charging reduces grid operating costs in general.47 [EPA-HQ-OAR-2022-0985-1656-A1, p. 23]

46 https://www.ostigov/pages/servlets/purl/1507680

47 https://www.sciencedirect.com/science/article/pii/S030142151930638X?via%3Dihub

Energy services and markets: CALSTART has witnessed utilities implementing a variety of new strategies to speed interconnection and find optimal places for it within their business, as distribution upgrade costs in general will make up a fraction of the overall annual utility annual revenue requirements.48 Many utilities now plan to work with shared charging service providers since they can create a new market for energy services at the edge of the grid and address the economics of increasing amounts of distributed loads.49 This may allow utilities to support aggregated loads and address interconnection queues more proactively. Others are looking into ways both increasing transactive coordination of services across a more distributed load can provide a hybridized energy resource platform.50 Interconnect queues are therefore managed not just through overcoming physical barriers in capacity and reliability but by developing new business models that realize cost efficiencies. EPA does not factor this growing market for services—critical to the future of the energy market—into its analysis. [EPA-HQ-OAR-2022-0985-1656-A1, pp. 23 - 24]

Grid integration: Fleet deployments are often integrated within comprehensive and long-term facility development plans, which afford a managed and phased-in approach to interconnection issues and close coordination with utilities. This approach also allows fleets to integrate electrification within larger sustainability planning efforts in cooperation with utility capabilities to aggregate demand. In addition, supportive public sustainability strategy frameworks and regional emissions regulations increasingly anticipate grid integration and the utilization of these facility-based integration measures as a means for fleet compliance with emissions reduction targets. The California Sustainable Goods Movement Action Plan,51 California's ACF rule regarding drayage vehicles and their traffic near ports,52 and the South Coast Air Quality Management District's Warehouse Indirect Source Rule53 all focus on the phase-in of new infrastructure from a holistic facility approach to managing emissions. Many of these strategies are already being replicated in ACT states. Emerging vehicle-to-grid (V2G) technologies offer methods for integrating fleet, facilities, and the grid directly, and managing demand in real-time and even in advance with utilities through advanced demand response technologies and charging-discharging scheduling. This capability will be a factor during the timeline of EPA's proposed rule. However, assuming infrastructure deployment is a sporadic, unplanned process which is initiated only with the purchase of a new vehicle ignores and possibly undermines these technologies and approaches. [EPA-HQ-OAR-2022-0985-1656-A1, p. 24]

51 https://ww2.arb.ca.gov/our-work/programs/california-sustainable-freight-action-plan

52 https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2022/acf22/acffroa3.pdf

53 http://www.aqmd.gov/home/air-quality/clean-air-plans/air-quality-mgt-plan/facility-based-mobile-source-measures/warehs-distr-wkng-grp

Interconnect planning services: An array of established service providers enables planned and cost-effective phase-in of infrastructure upgrades. These provide advanced simulation of grid needs for medium-duty fleets as well as many other commercial vehicle applications. In the course of their analyses, they identify and flag grid reliability needs and grid upgrades necessary for a fleet's electrification. Comparable services are now being offered by major firms, including but not limited to Arup, Black and Veatch, Edison Energy, ICF, Microgrid Labs, Siemens, and Parsons. This allows transitions to pace themselves at a rate responsive to the grid's upgrade timelines and fleet needs—and still at a pace that can accommodate many more vehicles than proposed in EPA's stringency assumption. [EPA-HQ-OAR-2022-0985-1656-A1, p. 24]

Organization: Clean Air Task Force et al.

b. Charging and grid infrastructure is capable of supporting HD BEVs in volumes aligned with and in excess of EPA's proposed standards.

Deployment of BEVs is well underway across the U.S. and is already requiring the electric power sector to make plans to reliably and safely integrate these vehicles. The electric power industry is well situated to maintain safe and reliable service that can power an increasing deployment of HD BEVs; utilities, aided significantly through investments from the BIL and IRA, are making important upgrades to the system to integrate higher penetrations of BEVs. Additional third party private investments and public investments are also already committed to building a robust HD BEV charging network. [EPA-HQ-OAR-2022-0985-1640-A1, p. 45.]

When considering infrastructure buildout, it is important to remember that HD ZEVs will enter the total on-road HD fleet gradually and in volumes that pale in comparison to in-use HD combustion vehicles. Modeling using HD TRUCS and MOVeS3.R3188 shows that EPA's proposal, if finalized, would likely result in ZEVs comprising just 1 percent of the total on-road HD fleet by 2027, gradually reaching 8 percent in 2032 and 23 percent in 2040. See Table 4, infra. In other words, a relatively small portion of the HD fleet will be tapping into charging and grid infrastructure over the next decade, and even by 2040, HD ZEVs would comprise less than a quarter of the on-road fleet under this proposal. Infrastructure needs for HD ZEVs will accordingly grow gradually over time. [EPA-HQ-OAR-2022-0985-1640-A1, p. 45. See Docket Number EPA-HQ-OAR-2022-0985-1640-A1, pages 45-46, for Table 4.]

188 HD TRUCS was used to develop ZEV adoption rates (by vehicle classification). MOVES3.R3 was used to translate HD TRUCS-derived ZEV adoption rates to ZEV sales and in-use curves.

For the final rule, we urge EPA to model how the Phase 3 standards will likely affect the composition of the entire on-road HD fleet, not just HD ZEVs' share of new sales. That information would better help the Agency and the public consider infrastructure issues related to this rulemaking. [EPA-HQ-OAR-2022-0985-1640-A1, p. 46.]

i. Economic theory and historical precedent show that infrastructure buildout will occur at the pace and scale needed to support vehicle electrification.

EPA should reject arguments that the buildout of charging and grid infrastructure cannot occur at the pace and scale needed to support expanded vehicle electrification, which are unreasonably pessimistic and inconsistent with both economic theory and historical precedent. These arguments rely on the classic "chicken-and-egg" scenario said to be presented by ZEV sales and charging infrastructure, where each side of the market waits for the other. But EPA need not and should not wait for infrastructure to fully mature before finalizing strong Phase 3 standards. Instead, EPA's standards themselves will send a strong signal to the market to undertake the infrastructure investments needed to accommodate a gradual rise in vehicle electrification,189 such that increased ZEV sales and infrastructure buildout will occur in relative tandem and reinforce each other. As one analyst sums it up: "The chicken-and-egg conundrum is being solved. Investments in the space and the adoption of EVs [a]re happening much faster than many analysts expected, and this is also accelerating the build-out of the charging network."190 [EPA-HQ-OAR-2022-0985-1640-A1, pp. 46 - 47.]

189 Environmental regulation itself, of course, can lead to technology innovation and market development. See generally Jaegul Lee et al., Forcing Technological Change: A Case of Automobile Emissions Control Technology Development in the US, 30 Technovation 249 (2010); Margaret R. Taylor, Edward S. Rubin, & David A. Hounshell, Regulation as the Mother of Innovation: The Case of SO2 Control, 27 Law & Policy 348 (2005); James Lents et al., Chapter II: The regulation of automobile emission: A case study, in Environmental Regulation and Technology Innovation: Controlling Mercury Emissions from Coal-Fired Boilers (Marika Tatsutani & Praveen Amar eds., 2000) https://www.nescaum.org/documents/rpt000906mercury_innovative-technology.pdf.

190 Gabriela Herculano, Chicken-and-Egg Problem: EV Adoption and Buildout of Charging Networks, Nasdaq (Apr. 18, 2022), https://www.nasdaq.com/articles/chicken-and-egg-problem%3A-ev-adoption-and-buildout-of-charging-networks.

The economic literature on indirect network effects and two-sided markets shows that an increase in BEV sales—a likely effect of the Phase 3 standards, particularly if they are strengthened in the final rule—can be expected to stimulate associated infrastructure development. In a study on flex-fuel vehicles fueled by E85 (85 percent ethanol), Corts (2010) found that growth in sales of flex-fuel vehicles due to government fleet acquisition programs led to an increase in the number of retail E85 stations.191 That relationship held true across all six

Midwestern states analyzed, despite differences in those states' E85 subsidies and tax credits.192 The author concluded that the results "confirm the basic validity" of the theory underlying government fleet purchase requirements: that increasing the "base of alternative fuel vehicles can spur the development of a retail alternative fuel distribution infrastructure."193 [EPA-HQ-OAR-2022-0985-1640-A1, p. 47.]

191 Kenneth S. Corts, Building out alternative fuel retail infrastructure: Government fleet spillovers in E85, 59 J. Env't Econ. & Mgmt. 219, 219-20 (2009).

192 Id.

193 Id. at 231.

Recent economic research has confirmed this relationship in the context of ZEVs and charging infrastructure specifically. An influential study by Li et al. (2017) found that "EV demand and charging station deployment give rise to feedback loops" and that "subsidizing either side of the market will result in an increase in both EV sales and charging stations."194 Similarly, Springel (2021) found "evidence of positive feedback effects on both sides of the market, suggesting that cumulative EV sales affect charging station entry and that public charging availability has an impact on consumers' vehicle choice."195 The BIL and IRA subsidize both sides of the market, offering significant incentives for both HD ZEV purchases and the construction of charging infrastructure. Economic theory therefore supports the proposition that strengthened Phase 3 standards, particularly in combination with the BIL and IRA's large financial incentives, will facilitate expansion of charging and grid infrastructure.196 [EPA-HQ-OAR-2022-0985-1640-A1, p. 47.]

195 Katalin Springel, Network Externality and Subsidy Structure in Two-Sided Markets: Evidence from Electric Vehicle Incentives, 13 Am. Econ. J.: Econ. Pol'y 393, 426 (2021).

196 See id. at 394 (noting that "the presence of positive feedback amplifies the impact of both types of subsidies"), 415 ("positive feedback loops between the charging station network and total all-electric vehicle sales amplify the impact of both types of subsidy").

Economic theory has in fact played out in Norway, where ZEV sales and infrastructure both expanded rapidly over the span of about a decade. There, the "path to charging point saturation started by stimulating more demand for EVs."197 In other words, Norway did not wait for infrastructure to fully mature before beginning its transition to cleaner cars. Rather, rising ZEV sales themselves "helped trigger a spike in demand for charging stations."198 [EPA-HQ-OAR-2022-0985-1640-A1, p. 48.]

The concept that charging infrastructure will adequately scale up over time also finds support in an analogous historical example: the buildout of roads and gasoline refueling infrastructure in the early 20th century to serve the United States' growing fleet of automobiles. The country's exponential growth in automobile sales—first exceeding 1,000 in 1899 and growing to 1 million by 1916199—preceded the establishment of an extensive network of both suitable roads200 and filling stations.201 Instead, the buildout of road and refueling infrastructure unfolded over long time horizons and in a variety of ways, adapting to the needs of the automobile fleet as it changed and grew. Paving and other road improvement efforts began on a small scale in cities, where automobiles were initially concentrated; efforts to improve rural roads and construct highways happened a decade or more later, as motorists began to expand their driving beyond cities.202 Similarly, in the case of refueling infrastructure, a network of modern filling stations did not spring up until well after automobiles had grown in popularity.203 Before that, refueling needs were met through varied and dispersed “non-station” methods such as cans of gasoline sold at general stores, barrels at repair garages, mobile fuel carts, curb pumps, and home refueling pumps, which emerged at various times as the demand for gasoline increased.204 Road and refueling infrastructure therefore exhibited a “long-term, adaptive and portfolio approach”205 that, over the span of several decades, satisfied the shifting needs of the growing ranks of automobile owners. [EPA-HQ-OAR-2022-0985-1640-A1, p. 48.]

204 Id. at 4924-27.

205 Id. at 4932 (discussing refueling infrastructure).

That approach holds important lessons for this rulemaking. As detailed above, the introduction of HD ZEVs into the total on-road fleet will occur gradually and, for the first decade or more, in relatively low volumes. As explored in a recent white paper by ICCT,206 successfully meeting the needs of this gradually expanding fleet of heavy-duty ZEVs will not require the overnight nationwide buildout of infrastructure that some have misleadingly claimed. Instead, economic theory and historical precedent show that growth in heavy-duty ZEV sales and infrastructure buildout will occur in relative tandem, with infrastructure responding over time commensurate with the evolving needs of the ZEV fleet. And in finalizing its Phase 3 standards, EPA will send a strong market signal that will facilitate infrastructure development at the pace and scale needed to support compliance with the standards. As explained in the sections below, the nation’s infrastructure is already well-positioned to adapt to increased vehicle electrification. EPA must reject unfounded chicken-and-egg arguments questioning whether infrastructure will respond to rising demand. [EPA-HQ-OAR-2022-0985-1640-A1, pp. 48 - 49.]

206 See generally Pierre-Louis Ragon et al., ICCT, Near-Term Infrastructure Deployment to Support Zero-Emission Medium- and Heavy-Duty Vehicles in the United States (2023), https://theicct.org/wp-content/uploads/2023/05/infrastructure-deployment-mhdv-may23.pdf.

ii. The grid can reliably support significantly increased loads.

The electric industry is well situated to maintain safe and reliable service that can power the increasing deployment of HD BEVs. As detailed below, the projected growth in electricity demand over the coming years, including demand related to BEV deployment in line with strengthened Phase 3 standards as well as additional economy-wide load growth, is well within the range of past historical load growth. Additionally, the industry is already responding to and preparing for increased electrification as more fleets and individuals adopt BEVs and has a wide range of tools, practices, and partnerships in place to continue to maintain a strong and reliable grid. [EPA-HQ-OAR-2022-0985-1640-A1, p. 49]

EPA conducted modeling within the Integrated Planning Model (IPM) to assess the electric sector and emissions impact of the proposal. In this modeling, the Agency utilized baseline projections of electricity demand and generation growth from the Annual Energy Outlook 2021 (AEO2021). DRIA at 321. EPA notes that this forecast "does not include the full forecasted ZEV adoption in the [proposal] reference case," and so it developed further incremental demand estimates to include "the demand of electric vehicles not captured by IPM's defaults," which EPA "calculated from the output of national MOVES runs." Id. While these files are not available to us, we are able to approximate this projected demand growth under the proposal by similarly calculating electric demand utilizing the proposal case in MOVES3.R3. This output reflects demand from all HD BEVs, including those HD BEVs that would be deployed in absence of this rule. In order to combine this with AEO2021 generation values, we converted this demand value to generation using a charging efficiency factor of 95 percent and transmission line loss factor of 5 percent. We then are able to combine this incremental generation calculation with projected generation from AEO2021 Reference Case (net available to grid).207 [EPA-HQ-OAR-2022-0985-1640-A1, p. 49]

207 U.S. Energy Information Administration, Annual Energy Outlook 2021, at Table 8 (Electricity Supply, Disposition, Prices, and Emissions), https://www.eia.gov/outlooks/aeo/data/browser (last accessed, June 13, 2023).

This analysis finds that system-wide increases in generation to meet demand growth, including both increased demand from the proposed Phase 3 standards (assuming EPA finalizes the stringency levels it has proposed) and projected economy-wide load growth, is projected to average 1.2 percent per year between 2028 and 2040. Importantly, this methodology is likely to overestimate generation growth, as the AEO2021 Reference Case already includes some level of transportation electrification.208 Isolating the impact of HD BEVs alone shows load average growth of 0.5 percent per year between 2028 and 2040. Further isolating only the incremental HD BEV generation projected under MOVES3.R3 associated with this proposal (as compared to the baseline) shows average generation growth of 0.4 percent per year between 2028 and 2040. [EPA-HQ-OAR-2022-0985-1640-A1, pp. 49 - 50]

208 U.S. Energy Information Administration, Annual Energy Outlook 2021: Narrative, at 13 (2021), https://www.eia.gov/outlooks/aeo/pdf/AEO_Narrative_2021.pdf.

Maintaining reliable and safe electric power delivery through this level of demand growth, as well as higher levels of growth resulting from more stringent Phase 3 standards, is within electric utility standard practice as demonstrated through the electric power sector's strong track record of reliability and resiliency. These annual generation increases are well within the range of contemporary, normal operations for the U.S. electric sector (see Figure 1 below). According to data reported to the Energy Information Administration in Form 861, in the 31 years from 1990 to 2021, average annual national growth in electricity sales was 1.1 percent.209 In 15 of those years, growth was 1.5 percent or higher, and in ten years it exceeded 2 percent. The U.S. has also seen previous periods of sustained high demand growth across most states; for example, 1995 to 2007 saw average nationwide growth of approximately 1.9 percent per year. [EPA-HQ-OAR-2022-0985-1640-A1, p. 50.] [See Docket Number EPA-HQ-OAR-2022-0985-1640-A1, page 51, for Figure 1]

209 Note that these data are for statewide demand, not generation. State level demand figures are more meaningful to show local variations in electricity usage as compared to state-level generation, which does not necessarily (or even usually) serve in-state customers. While absolute generation and demand figures (TWh) should not be compared, growth rates between the two, as shown here, should track proportionally. U.S. Energy Information Administration, Historical State Data, EIA-861, Annual Electric Power Industry Report (Mar. 8, 2023), https://www.eia.gov/electricity/data/state/.

Many states saw much higher, sustained levels of growth. In the two decades from 1999 to 2018, North Dakota electric sales more than doubled. Year over year growth averaged nearly 5 percent, and in 2014 electric sales were 14 percent higher than the previous year alone. In Nevada between 1992 and 2007, annual electric sales growth averaged 4.9 percent and fell below 1.5 percent only once. More recently, Virginia has seen strong annual sales growth, with sales increasing 12.3 percent in the five years from 2016 to 2021, or 3 percent on average per year, even accounting for a pandemic dip. [EPA-HQ-OAR-2022-0985-1640-A1, p. 50]

This analysis draws similar conclusions to those of the researchers at the Electrification Futures Study, a multi-year research project to explore potential widespread electrification in the future energy system of the United States. In a report developing an integrated understanding of how the potential for electrification might impact the demand side in all major sectors of the U.S. energy system—transportation, residential and commercial buildings, and industry—this study concluded that "[e]lectrification has the potential to significantly increase overall demand for electricity, although even in the High scenario, compound annual electricity consumption growth rates are below long-term historical growth rates."210 [EPA-HQ-OAR-2022-0985-1640-A1, p. 50]

210 Trieu Mai et al., NREL, Electrification Futures Study: Scenarios of Electric Technology Adoption and Power Consumption for the United States (2018), https://www.nrel.gov/docs/fy18osti/71500.pdf.

We further recognize that many parties will nevertheless need to take important steps to manage increased electrification demand. Utilities, public utility commissions and other state regulators, grid operators, charging providers, and others can and have already begun to coordinate and plan for increased vehicle electrification. Examples include:

- The West Coast Clean Transit Corridor Initiative is an ongoing, collaborative effort among 16 utilities to support the development of BEV charging facilities along I-5, from San Diego to British Columbia, for heavy- and medium-duty freight haulers and delivery trucks.211
- The National Charging Experience Consortium (ChargeX) is a collaborative effort between Argonne National Laboratory, Idaho National Laboratory, NREL, BEV charging

industry experts, consumer advocates, and other stakeholders whose mission is "to work together as BEV industry stakeholders to measure and significantly improve public charging reliability and usability by June 2025."212

- The National BEV Charging Initiative brings together automakers, power providers, BEV and charging industry leaders, labor, and public interest groups to "develop a national charging network for light, medium, and heavy-duty vehicles and inspire deeper commitments from state leaders, the administration and each other."213
- The National Association of State Energy Officials and the American Association of State Highway and Transportation Officials partnered with the U.S. Joint Office of Energy and Transportation to hold a series of convenings to coordinate on a range of topics, including ZEV infrastructure and utility planning needs.214 These convenings brought together State Departments of Transportation officials, State Energy Offices, and other key partners.
- PG&E and BMW of North America are testing a "vehicle-to-everything technology that will improve grid reliability and help EV customers lower their electric bills by exporting power back to the grid during peak demand periods." PG&E notes that "[t]he utility and automotive industries are creating a transformative clean energy future together."215
- NREL and Volvo collaborated on a research paper regarding challenges and opportunities of HD and commercial ZEVs, noting: Coordination between disparate and historically unconnected stakeholders, including state agencies, local governments, automotive manufacturers, fleets, energy infrastructure and utility companies, and research and academia will be required to ensure a smooth and timely transition to ZEVs. This paper, a joint research and industry perspective, is one such example of cross-sectoral collaboration.216 [EPA-HQ-OAR-2022-0985-1640-A1, pp. 52 - 53]

Finally, ICCT has highlighted myriad actions that utilities, local and state agencies and regulators, fleet operators, and property owners can take to help reduce barriers to infrastructure deployment and aid "timely planning and construction to ensure transmission and distribution systems can accommodate the needs of [medium- and heavy-duty vehicle] electrification."217 These examples show that the relevant stakeholders are already stepping up to plan for and accommodate the charging and grid needs associated with greater vehicle electrification. [EPA-HQ-OAR-2022-0985-1640-A1, p. 53]

217 Ragon et al., at 25.

Utilities in particular are also already planning for and deploying solutions to address increased vehicle electrification as their customers adopt BEVs to improve fleet economics and performance. For example, executives at Southern California Edison, which is one of the largest electric utilities in the U.S. and is facing industry-leading levels of electrification, have recently voiced strong support for the ability of the grid to manage, respond to, and benefit from BEVs. Caroline Choi, Edison International and Southern California Edison senior vice president of corporate affairs, noted that “the electric grid is really going to be the backbone of the whole system” for electrified transit, and that “[w]hat we’re seeing are the investments necessary to ensure that the grid is available.”218 Utilities and their customers will benefit from the ability to plan ahead for any significant infrastructure requirements. The regulatory certainty provided by Phase 3 standards can aid this planning. [EPA-HQ-OAR-2022-0985-1640-A1, p. 53]

218 Casey Wian, Transportation Electrification Gains Momentum: Edison International and SCE outline plans to seize the “huge opportunity” of preparing the grid for exponential EV growth, Energized, (Feb. 1, 2023), https://energized.edison.com/stories/transportation-electrification-gains-momentum.

Regulatory certainty can also help ensure that investments not only maintain strong electric service, but improve it while at the same time lowering costs. Southern California Edison President and CEO Steve Powell noted: “if we leverage the electric vehicle load and have that work for consumers as well, that whole idea of vehicle-to-grid, there can be real value in helping alleviate a lot of the infrastructure investments that need to happen,” ultimately lowering overall energy bills for customers.219 Similarly, Seattle City Light, in its Transportation Electrification Strategic Investment Plan, found that the utility received a net benefit of roughly $120,500 per bus or other heavy-duty ZEVs through an increase in new revenue, placing downward pressure on rates.220 It stated that “[w]hile there are system costs associated with increased transportation electrification (e.g., distribution and transmission infrastructure upgrades), with proactive utility planning and intervention, the system benefits (e.g., new revenue) are estimated to outweigh the costs, spreading the economic benefits of transportation electrification to all customers.”221 This will require action from regulators as well to help shape and approve these proactive and critical investments. As RMI recommended, “regulators can fulfil [sic] their responsibility for ensuring prudent and least-cost grid investments while proactively planning by using new information.”222 [EPA-HQ-OAR-2022-0985-1640-A1, pp. 53 - 54]

222 Ari Kahn et al., RMI, Preventing Electric Truck Gridlock: Meeting the Urgent Need for a Stronger Grid 16 (2023), https://rmi.org/insight/preventing-electric-truck-gridlock/.

Third-party analyses have bolstered these statements from utilities that BEVs, if deployed strategically, can improve grid operations. For example, Lawrence Berkeley National Laboratory estimated that enabling “vehicle-to-grid” technology,223 which allows ZEVs to serve as electricity storage and provide power back to the grid during periods of high demand, would save

California utility customers $13-15 billion in stationary battery costs.224 An analysis conducted by Gladstein, Neandross & Associates on behalf of EDF found that managed charging of class 8 trucks combined with strategic deployment of distributed energy resources could provide significant cost savings for fleet operators and "result in significant savings to utilities through avoided grid buildout costs."225 Yet another analysis found that BEVs can "contribute significantly to grid stability" and provide value to the grid through "deferred or avoided capital expenditure on additional stationary storage, power electronic infrastructure, transmission build-out, and more."226 Additionally, utilities can deploy proven and emerging rate designs that ensure utilities recover costs, reliably serve BEV charging load, improve BEV owner experience, and take advantage of grid strengthening services from these vehicles.227 [EPA-HQ-OAR-2022-0985-1640-A1, p. 54]

In addition, the historic investments of the BIL and IRA are helping utilities build a stronger, cleaner grid and prepare for advanced electrification while minimizing customer costs. Duke Energy, for example, has stated that "[the BIL] provides an important down payment on the infrastructure and incentives that are needed to electrify transportation and secure the grid," and "[the IRA] can create significant cost savings for our customers."228 New York utilities have indicated that they will be applying for $900 million in grants from the BIL and IRA to advance grid resilience.229 National Grid in particular notes that "EV charging make-ready infrastructure is identical to electric infrastructure that serves other purposes, this is the kind of work electric utilities do every day,"230 and that "areas of the [BIL] funding are enabling increased investment."231 [EPA-HQ-OAR-2022-0985-1640-A1, pp. 54 - 55]

Organization: Consolidated Edison, Inc. (Con Edison)

Con Edison recommends that the Agency identify utility proactive planning as a best practice to support the buildout of grid infrastructure to prepare the grid for the ramp up in EV charging. [EPA-HQ-OAR-2022-0985-1661-A1, p.4]

Organization: Daimler Truck North America LLC (DTNA)

Policies to Promote ZEV Infrastructure Development

- Utility Grid Planning and Identification of High-Priority Charging Sites. To support achievement of ZEV sales targets and climate goals, electric utilities should be required to conduct detailed grid planning and assessments for transportation electrification. Legislation proposed and currently being considered in New York (AB 5052/SB 4830), for example, would require utilities to establish a highway and depot charging action plan, and addresses identification of high priority medium- and heavy-duty vehicle charging sites that are likely to see high traffic from commercial vehicles.15 EPA should consider advocating for legislation of this type in all 50 states to encourage advanced planning to develop the infrastructure needed to support feasibility of the Phase 3 standards. [EPA-HQ-OAR-2022-0985-1555-A1, p. 12]

  15 See New York Assembly Bill A5052 (2023-2024 Legislative Session), available at https://www.nysenate.gov/legislation/bills/2023/A5052; Senate Bill 4830 (2023-2024 Legislative Session), https://legiscan.com/NY/bill/S04830/2023.

- Proactive Grid Upgrades at HD High Priority Sites. Going beyond NY AB 5052/SB 4830, utilities should be required to proactively upgrade the electric grid to support the high priority HD BEV sites identified in the grid planning exercise described above. These proactive grid upgrades are required to bring interconnection timelines in line with the pace that EPA proposes. EPA should consider working with the Federal Energy Regulatory Commission (FERC) and other stakeholders to craft model legislation that requires grid upgrades at the identified high-priority sites and initiation of infrastructure build-outs as needed to support implementation of the Proposed Rule. [EPA-HQ-OAR-2022-0985-1555-A1, p. 12]
- Align EPA and EIA ZEV Forecasts to Facilitate Utility Demand Planning. Utilities need detailed fleet transition plans in order to update their 5-10 year demand forecasts, and demand must be guaranteed to prompt investment in improved infrastructure. Fleets are unlikely to have detailed transition plans until there is sufficient experience with the use cases, technology maturity, and confidence in the infrastructure. In order to solve this

chicken-and-egg scenario, EPA's ZEV forecast should be aligned with the Energy Information Administration's (EIA) ZEV projections in its Annual Energy Outlook (AEO), and these forecasts should further project ZEV adoption on a geographic basis. Utilities should be required to treat EPA and EIA's aligned ZEV forecasts as sufficient evidence of demand to start the build out of infrastructure. [EPA-HQ-OAR-2022-0985-1555-A1, pp. 12-13]

- Demand Guarantors for Infrastructure Utilization. When fleets submit interconnection applications to their utility for charging capacity, and the utility makes investments to build up that infrastructure, the applicants (fleets) are responsible for using power at the requested levels in the interconnection application for a minimum of 5 years, or sometimes up to 10 years. If the applicant does not meet the required utilization rate, the applicant and/or ratepayers may be financially responsible for bearing the costs of those infrastructure upgrades. Fleets are not required to take on this type of financial risk in the conventional vehicle market, and DTNA believes it to be a major disadvantage for BEVs. In order to reduce the risk for fleets, utilities, and ratepayers, EPA and/or the Department of Energy (DOE) should consider assuming a portion of the financial liability in the event infrastructure utilization is not met. [EPA-HQ-OAR-2022-0985-1555-A1, p. 13]
- Performance-Based Regulations to Incentivize Faster Interconnection Timelines. The California Public Utilities Commission (CPUC) Resolution E-5247 establishes an interim average service energization timeline of 125 business days for certain EV infrastructure projects, excluding projects with a capacity exceeding two megawatts (MW), projects that need distribution line upgrades, and projects requiring substation upgrades.16 Many fleet charging infrastructure projects will meet these exclusion criteria, however, thus EPA should encourage state utility regulatory commissions to adopt similar resolutions that address depot charging interconnection requests on a standard timeline but that apply to a broader array of projects. We also recommend that EPA encourage state utility regulatory commissions to adopt performance-based regulations (PBRs) to incentivize faster interconnection timelines for commercial vehicle charging needs. Hawaii Public Utilities Commission (HPUC) Decision and Order No. 37787, for example, established new performance mechanisms to incentivize faster interconnection timelines for certain infrastructure projects undertaken by the Hawaiian Electric companies and may serve as a model for similar PBRs that could be established in other states.17 [EPA-HQ-OAR-2022-0985-1555-A1, p. 13]

16 See CPUC, Resolution E-5247 (Dec. 16, 2022), https://docs.cpuc.ca.gov/PublishedDocs/Published/G000/M500/K043/500043680.PDF.

17 See HPUC, In re Instituting a Proceeding to Investigate Performance-Based Regulation, Decision and Order No. 37787 (May 17, 2021), https://dms.puc.hawaii.gov/dms/DocumentViewer?pid=A1001001A21E17B53226E00118.

- Standardized Processes and Commitments for Interconnection Timing. With more than 3,000 electric utilities in the United States, navigating new service requests poses challenges for fleets. Utilities cite incomplete or inaccurate information on applications from fleets as contributors to transportation electrification delays. Fleets cite lack of communication and firm interconnection timing commitments from utilities as a deterrents to adopting ZEVs, as they are unable to properly plan their fleet operations and vehicle delivery timelines. To mitigate these concerns, EPA could work with DOE and

FERC to standardize the application and review processes for interconnection requests. [EPA-HQ-OAR-2022-0985-1555-A1, p. 13]

- Single Application Requests for Site Projects. Today, fleets interested in installing on-site solar and energy storage as part of a depot charging infrastructure project must often submit separate applications to their utility service provider for these project components, in addition to their interconnection request. These three requests are often handled by different teams on different timelines, which do not serve the needs of the fleet's depot site development and deter fleets from incorporating on-site storage and solar to offset peak loads and manage charging. EPA should consider working with FERC to encourage utilities to bundle fleet depot projects so that they may be considered as a single request. [EPA-HQ-OAR-2022-0985-1555-A1, pp. 13-14]
- Clear Track for Third Parties to Support Infrastructure Development. Where utilities are unable to make the infrastructure investments needed for fleet electrification, a clear process should be in place to allow for third-party companies to step in and build out necessary infrastructure capacity, which could be leased or sold back to the utility at a future date. EPA should consider working with FERC to find pathways for third-party infrastructure funding and development, to enable buildout at the pace needed to support implementation of the Proposed Rule. [EPA-HQ-OAR-2022-0985-1555-A1, p. 14]

Electrical infrastructure buildout pace is a barrier to significant ZEV adoption that should be factored in to Phase 3 CO2 standard levels.

The pace of electrical infrastructure buildout remains the biggest barrier for customer adoption of HD BEVs and poses the greatest threat to successful implementation of the Proposed Rule. As EPA observes, BEV infrastructure is critically important for the success of increasing development and adoption of BEV technologies.108 DTNA thus appreciates the opportunity to respond to EPA's request for comment on the concerns that have already been expressed to EPA regarding the slow growth of ZEV charging and refueling infrastructure. This Proposed Rule is unique in that compliance will rely heavily on the development of infrastructure that manufacturers have no control over, and providers are not obligated to expand infrastructure to support the scope and timing of the Proposed Rule. [EPA-HQ-OAR-2022-0985-1555-A1, p. 45]

108 See Proposed Rule, 88 Fed. Reg. at 26,000.

DTNA—in partnership with Portland General Electric—is proud to have built the first-of-its-kind public charging island for commercial ZEVs in Portland, Oregon. In addition, DTNA's expert eConsulting team is dedicated to supporting fleets on all aspects of the ZEV transition, including site design and interfacing with utilities. Therefore, DTNA is uniquely positioned to offer insight into the challenges associated with commercial ZEV infrastructure development. [EPA-HQ-OAR-2022-0985-1555-A1, p. 45]

DTNA has concerns about EPA's treatment of electric infrastructure in the Proposed Rule, and the Agency's assumptions that all suitable vehicle applications and willing customer adopters will have charging infrastructure available, or that such infrastructure can be made available within the timeframes that EPA assumes and at the costs projected in HD TRUCS. In this section, DTNA highlights the unique challenges with HD charging infrastructure (especially with respect to electricity transmission and distribution); explains why EPA significantly underestimates infrastructure costs; discusses specific timing challenges; and highlights case studies from its customer fleets. Finally, DTNA concludes by recommending that EPA use an electric infrastructure scalar to ensure that infrastructure development pace is adequately factored in to EPA's adoption rate projections, as discussed in more detail on Section II.C of these comments. [EPA-HQ-OAR-2022-0985-1555-A1, p. 45]

EPA projects that modest increases in electric power generation will be required to support the Proposed Rule. Specifically, the Agency estimates that Proposed Rule requirements would increase HD BEV electric power end use by 0.1% over 2021 levels in 2027, increasing to 2.8% over 2021 levels in 2055.109 EPA notes, however, that these figures do not include the electricity increase required to produce hydrogen.110 [EPA-HQ-OAR-2022-0985-1555-A1, pp. 45-46]

109 Id. at 25,983; DRIA at 430, Table 6-1.

110 See DRIA at 431 (noting that EPA's projected electricity consumption increases attributable to the Proposed Rule do 'not include changes in electricity generation to produce hydrogen').

EPA's figures appear to underestimate the increase in electric power generation that will be required to support implementation of the Proposed Rule. As discussed below, according to the Company's calculations, 45 gigawatts of installed charging capacity will be required to support the vehicle volumes in the Proposed Rule from 2027 - 2032. Based on EIA's estimate that there was 1,143,757 megawatts (MW) of total utility-scale electricity generating capacity in the United States at the end of 2021,111 Proposed Rule implementation will require a 3.9% increase in domestic generation capacity (over the 2021 level) by 2032, conflicting with EPA's projection that only a 2.8% increase will be required by 2055. [EPA-HQ-OAR-2022-0985-1555-A1, p. 46]

111 See U.S. Energy Information Administration, 'Electricity explained: Electricity generation, capacity, and sales in the United States,' https://www.eia.gov/energyexplained/electricity/electricity-in-the-us-generation-capacityand-sales.php.

Further, DTNA is concerned that EIA's commercial vehicle forecast does not align with EPA's ZEV market projections in the Proposed Rule. EIA's AEO 2022 commercial vehicle projections are summarized in Table 15 below EIA projects zero commercial vehicle BEV sales through 2050, and minimal FCEV penetration up to 1,600 vehicles per year per category. It is critical that federal agencies are aligned on these commercial vehicle projections and communicate them clearly to the electric utility industry. Given the misalignment with EIA on ZEV uptake rates, it is likely that EPA underestimates the electricity generation increase needed to support HD BEVs.[EPA-HQ-OAR-2022-0985-1555-A1, p. 46] [Refer to Table 15 on p. 46 of docket number EPA-HQ-OAR-2022-0985-1555-A1].

EPA points to the adoption of residential air conditioners and growth of power-intensive data centers as historical evidence of the electric utility industry's ability to deliver additional power to customers.113 Residential air conditioners provide a reasonable comparison for light-duty vehicle electricity demand levels, as they represent a relatively low load that is evenly distributed across utility service territories. The electricity demands associated with medium- and heavy-duty electrification will, however, be fundamentally different and must be treated as such. [EPA-HQ-OAR-2022-0985-1555-A1, p. 46]

113 See Proposed Rule, 88 Fed. Reg. at 25,983.

Unlike light-duty vehicles, most HD ZEVs cannot charge using existing 120-volt and 240-volt AC electrical infrastructure, and they require dedicated DC infrastructure. HD ZEVs are also disproportionally located in concentrated urban areas, creating highly localized grid capacity addition needs in constrained spaces (see Figure 3 below, showing heat maps of potential future loads). [EPA-HQ-OAR-2022-0985-1555-A1, p. 47] [Refer to Figure 3 on p. 47 of docket number EPA-HQ-OAR-2022-0985-1555-A1]

Power-intensive data centers and server farms were rapidly constructed across the United States in the last 20 years and were largely greenfield projects that had the flexibility to be sited where grid capacity was available or could be made available relatively easily. By contrast, the commercial transportation industry is already entrenched and invested in existing logistics facilities. Most of these are located in or around high density urban population centers, often clustered tightly together, where grid capacity is not available, and the process of acquiring land and rights-of-way for upgrades is complex. The use of data centers and server farms as anecdotal examples of electric utility adaptability suggests that EPA is significantly underestimating the demand presented by commercial transportation charging infrastructure. [EPA-HQ-OAR-2022-0985-1555-A1, p. 47]

DTNA generally agrees with EPA's assertion that scale-up of electric power generation is not likely to significantly limit the development of BEV electric vehicle charging infrastructure. Rather, the challenge for medium- and heavy-duty charging lies in distribution of that power. As ICCT observed in a recent white paper on near-term medium- and heavy-duty ZEV infrastructure development, 'Most uncertainties regarding infrastructure buildout concern the capacity of distribution systems to bring that energy to the right place in a timely manner and accommodate the highly localized power requirements of [medium- and heavy-duty vehicle] charging.'114 Accordingly, DTNA recommends that EPA engage with electric utilities and their trade associations to further understand the unique challenges that HD ZEVs charging will pose for distribution systems, and how those factors should be accounted for in this rulemaking. [EPA-HQ-OAR-2022-0985-1555-A1, p. 47]

114 See ICCT, 'Near-Term Infrastructure Deployment to Support Zero-Emission Medium- and Heavy-Duty Vehicles in the United States (May 2023) at 1, https://theicct.org/wp-content/uploads/2023/05/infrastructure-deployment-mhdv-may23.pdf (ICCT ZEV Infrastructure White Paper).

Infrastructure Costs

EPA asserts 'there is considerable uncertainty associated with future distribution upgrade needs, and in many cases, some costs may be borne by utilities rather than directly incurred by BEV or fleet owners. Therefore, we do not model them directly as part of our infrastructure analysis.'115 DTNA appreciates that there is significant complexity and uncertainty in modeling these costs, but believes that omitting front-of-meter costs is a significant error in the TCO calculation that has major implications for EPA's proposed CO2 standard stringency levels. [EPA-HQ-OAR-2022-0985-1555-A1, p. 48]

115 Proposed Rule, 88 Fed. Reg. at 25,983.

How fleet owners pay for infrastructure will depend on a variety of factors, including utility structure (investor-owned, municipal, cooperative), existing available grid capacity, project scale, real estate needs, etc. For fleets in cooperative and municipality service territories, including many in critical urban freight hubs, upgrade costs are likely borne directly by the fleet. For fleets working with investor-owned utilities, the cost mechanism will vary. If infrastructure is needed by more than one utility customer, the utility will typically ask the fleet for a pro-rata share of those costs, or in some cases, increase electricity rates to cover those costs. Where fleets do not meet the minimum utilization rates for the contracted time period (5 to 10 years), fleets may be required to reimburse the utility for infrastructure upgrades, or costs are distributed among all ratepayers. One DTNA customer fleet has cancelled an order for 25 Class 8 tractors because of what they viewed as risky contract terms, including requirements for load management and a 10-year commitment to construct capacity for a 3 MW site. Regardless of the pathway, fleets will bear the cost of infrastructure upgrades to support charging needs, and those costs should be included in the proposed rule. [EPA-HQ-OAR-2022-0985-1555-A1, p. 48]

DTNA relied on a cost study by the Boston Consulting Group (BCG) to estimate an optimized and non-optimized dollar-per-kilowatt cost figure for grid updates.116 To estimate per-vehicle grid update costs for Class 3 - 8 BEVs, we applied the BCG dollar-per-kilowatt cost estimates to an assumed average daily power need for each vehicle class that would be subject to the Phase 3 CO2 standards, shown in Table 11 ('DTNA Proposed Grid Update Cost Inputs for HD TRUCS') presented in Section II.B.3.b. As reflected in Table 11, these costs are non-negligible, significantly impact the TCO proposition, and must be considered in EPA's HD TRUCS analysis. [EPA-HQ-OAR-2022-0985-1555-A1, p. 48]

116 See Boston Consulting Group, 'The Costs of Revving Up the Grid for Electric Vehicles' (Dec. 20, 2019), https://www.bcg.com/publications/2019/costs-revving-up-the-grid-for-electric-vehicles.

Using the same average daily power assumptions, DTNA estimated the additional installed capacity that will be needed to support HD BEVs at the adoption rates projected in the Proposed Rule. The Company calculated a 5-year average of commercial vehicle sales in all 50 states from the Polk Automotive database from 2017-2021, applied EPA's projected ZEV volumes for 2027-2032, and calculated the total installed charging capacity that will be required by these vehicles in 2027 - 2032 to be approximately 45 gigawatts. In Appendix C to these comments, DTNA estimates the investments in charging infrastructure and grid upgrades, as well as total installed charging capacity, that will be required in each of the 50 states to support implementation of the Proposed Rule.117 DTNA considers installed capacity in this context to mean the total power available as EVSE to charge commercial vehicle batteries. Using installed capacity is a more appropriate metric for evaluating available charging capacity than the number of chargers alone, as installed capacity better reflects the variability in charging speeds needed to support different vehicle dwell times and truck-to-charger ratios. [EPA-HQ-OAR-2022-0985-1555-A1, pp. 48-49]

This installed capacity must be available at a combination of public and private purpose-built HD-accessible charging stations. To be HD-accessible, public charging stations must include pull-through charging lanes and accommodate wide ingress and egress to support all vehicle types. Commercial vehicles are often unable to utilize existing passenger car charging infrastructure, due to space constraints that are not compatible with HDVs. [EPA-HQ-OAR-2022-0985-1555-A1, p. 49] [Refer to graphics on p. 49 of docket number EPA-HQ-OAR-2022-0985-1555-A1]

Based on the projected vehicle mix in the Proposed Rule and installed capacity needed to support these vehicles, DTNA estimated the total costs of EVSE charging equipment and necessary supporting grid updates to support Class 3-8 BEVs that would be required under the Proposed Rule. These figures, summarized in Table 16 below, do not include the additional capacities and investments needed to support passenger car electrification. [EPA-HQ-OAR-2022-0985-1555-A1, p. 49] [Refer to Table 16 on p. 49 of docket number EPA-HQ-OAR-2022-0985-1555-A1]

Even with incentive funding available, many fleets are unable to make the capital investments required to add BEVs to their fleets. DTNA is currently working with one school bus fleet that has secured Clean School Bus funds from EPA for 23 buses, as well as a payment plan through their utility's Make Ready program, and is still facing a $500,000 funding gap for site construction that threatens to jeopardize the project. Private fleet deployments are likely to face similar gaps, even where some combination of incentive program funding is available. [EPA-HQ-OAR-2022-0985-1555-A1, p. 50]

Timing for Infrastructure Development

EPA implies that in the next five years, electric infrastructure will be sufficiently built out to support the BEVs required by the Proposed Rule, and that buildout will continue to support substantially higher fleet adoption rates by 2032. Without major regulatory and/or legislative action, DTNA does not believe the infrastructure needed will materialize on the timeline required to enable compliance with the Phase 3 CO2 standards as proposed. New interconnection requests are processed on a first-come-first-serve basis, and transportation electrification competes with all other utility priorities, including decarbonization mandates, resiliency, and other residential and commercial interconnection requests. [EPA-HQ-OAR-2022-0985-1555-A1, p. 50]

Utilities are noting extended timelines for installing critical hardware, both in front of and behind the meter, due to supply chain and other constraints. During the ACF rulemaking process, for example, one electric utility commented to CARB that the lead time for transformers was 40 weeks, and that the lead time customer side meter panels/switchgears was 70 weeks.118 In the Company's experience, utilities will wait for this hardware to be received to perform other upgrades, and these types of sequential gating events can add significant time to transportation electrification projects. [EPA-HQ-OAR-2022-0985-1555-A1, p. 50]

118 See Comments of Pacific Gas and Electric Company, Proposed Advanced Clean Fleets Regulation (Oct. 17, 2022), https://www.arb.ca.gov/lists/com-attach/370-acf2022-AXEFZFUxUFxRY1Bl.pdf.

In a recent joint presentation by Southern California Edison (SCE), Pacific Gas & Electric (PG&E), and San Diego Gas & Electric (SDG&E) at a California Energy Commission (CEC) workshop, the following table was presented reflecting the utilities' estimations of typical timelines for distribution capacity improvements: [EPA-HQ-OAR-2022-0985-1555-A1, p. 50] [Refer to Table 17 on p. 50 of docket number EPA-HQ-OAR-2022-0985-1555-A1]

As the scope of the necessary distribution capacity improvements is often unknown until detailed site planning is underway, predicting how long fleets will wait for interconnection requests is challenging. DTNA believes many depot electrification projects may require increases in substation capacity, sub-transmission improvements, or new substations to serve the concentrated power demands. One of DTNA's customers cancelled a BEV deployment because their utility returned a 5-8 year lead time for a new substation. Another fleet's initial ZEV deployment at scale required construction of a 6 MW facility, able to charge 32 Class 8 drayage tractors simultaneously.120 Providing these capacities to many sites clustered together, as will be required to support concentrated freight hubs and logistics centers, is likely to require substantial grid upgrades. [EPA-HQ-OAR-2022-0985-1555-A1, pp. 50-51]

120 See ‘Schneider’s Electric Heavy-Duty Trucks Start Off on Regional Routes’ (June 8, 2023) https://www.truckinginfo.com/10200304/new-electric-heavy-duty-trucks-start-off-on-regional-routes.

Because of California’s climate policies, including Executive Order N-79-20 requiring all new passenger car and truck sales to be zero emission by 2035, and CARB’s ACT and ACF regulations, a number of transportation electrification planning procedures and make-ready programs have already been implemented or have begun to develop in California. Thus, it is important to keep in mind that electric utilities in other states may generally be less prepared to respond to transportation electrification requests. [EPA-HQ-OAR-2022-0985-1555-A1, p. 51]

In the Company’s experience, fleets typically purchase their vehicles 6 - 12 months ahead of need, and often utilities require proof of purchase to show the fleet is committed to move forward with infrastructure development. DTNA has experienced fleet customers cancelling BEV orders when utilities respond to interconnection requests with multi-year lead times. Many of these cancellations include the return of incentive program funds, such as HVIP or Clean School Bus Program vouchers. Purchasers who apply for and are granted HVIP funds for example, must redeem the voucher within 90 days, or apply for three-month extensions up to 540 total days.121 It is not uncommon for infrastructure projects to exceed the 540 day timeline, which would require the fleet to take delivery of BEVs with no charging infrastructure, resulting in a stranded capital investment and no air quality improvements. One of DTNA’s customers cancelled an order and returned HVIP funding for 20 Class 8 tractors when their utility estimated their site would take 3 years (1,095 days) to energize. [EPA-HQ-OAR-2022-0985-1555-A1, p. 51]

121 See Implementation Manual for the Hybrid and Zero-Emission Truck and Bus Voucher Incentive Project (HVIP) (March 15, 2022) at 20, https://californiahvip.org/wp-content/uploads/2022/03/HVIP-FY21-22-Implementation-Manual-03.15.22.pdf.

Furthermore, it is unlikely that fleets will make major investments in long-term infrastructure that require commitments longer than the vehicle trade cycle. For example, if a fleet plans for a 4-year vehicle product cycle, but the infrastructure lead time is 4 years for an increase in substation capacity, by the time the infrastructure is available, the fleet will be working with the next generation of vehicles, which may or may not have the same power needs. Similarly, where utilities have made capital investments in infrastructure, fleets may be required to commit to a certain utilization rates for 5 to 10 years. Fleets working with shorter trade cycles, contracted routes, or leased properties are likely to see operational changes well before they are released from their utilization obligations. Committing to minimum utilization rates may be a major financial risk for fleets, which is unaccounted for in the cost estimates in the Proposed Rule. [EPA-HQ-OAR-2022-0985-1555-A1, p. 51]

Fleets have also cited the lack of firm interconnection dates as a major deterrent to committing to long-term infrastructure projects. DTNA appreciates that infrastructure buildout projects are difficult to project, and may encounter unanticipated delays, but fleets are unable to make fleet transition plans, place orders for electric vehicles, or apply for funding without firm interconnection timelines. Some of DTNA’s fleet customers committed to ZEV deployment have sought temporary power solutions to address these timeline issues. However, temporary power solutions incur additional costs and generally must be paid up front by the fleet. For instance, SDG&E Rule 13 (‘Temporary Service’) provides that an applicant for temporary service ‘shall pay, in advance or otherwise as required by the utility, the estimated cost installed plus the estimated cost of removal, less the estimated salvage of the facilities necessary for furnishing service.'122 [EPA-HQ-OAR-2022-0985-1555-A1, pp. 51-52]

122 See SDG&E Rule 13, https://www.sdge.com/sites/default/files/elec_elec-rules_erule13.pdf.

In addition to electrical interconnection complexities, fleets must navigate their local building codes and permitting processes. As noted by the Northeast States for Coordinated Air Use Management (NESCAUM) in a 2019 paper on DCFC deployment, 'the permitting process for DCFC stations is sometimes lengthy and fraught with delays due to unfamiliarity with the technology, protracted zoning reviews, and undefined requirements for permitting DCFC. As a result, the DCFC permitting process can be resource-intensive for both applicants and [authorities having jurisdiction (AHJs)].'123 Since the NESCAUM paper was published, DTNA's eConsulting team has encountered many AHJs that lack defined processes for DCFC installation projects and the expertise needed to move projects along quickly. [EPA-HQ-OAR-2022-0985-1555-A1, p. 52]

123 NESCAUM, 'Preparing Our Communities for Electric Vehicles: Facilitating Deployment of DC Fast Chargers' (May 2019), https://www.nescaum.org/documents/dcfc-permit-streamlining-whitepaper-final-5-14-19.pdf.

Fleets may encounter additional complications related to EVSE installation that impact BEV technology adoption rates. For example, when converting vehicles to BEVs, the infrastructure needed for charging equipment takes up physical space that could otherwise be occupied by additional trucks. Figure 4 below illustrates the components needed for combined charging systems (CCS). Megawatt Charging Systems (MCS) require additional space for installation as well. [EPA-HQ-OAR-2022-0985-1555-A1, p. 52] [Refer to Figure 4 on p. 53 of docket number EPA-HQ-OAR-2022-0985-1555-A1]

Figure 5 below shows an overhead view of one such fleet operation in Southern California where physical space will limit the number of BEVs that can be deployed. This site will require additional power poles, new transformers, and new switchgears to support only a fraction of the fleet. To convert additional tractors to BEVs, fleets working with constrained spaces like the site shown below will likely be required to purchase additional real estate. Recently, Denver's Regional Transportation District (RTD) announced the cancellation of an $18 million deal for new electric buses, citing space constraints for charging and EVSE equipment.124 RTD officials estimated they would need an additional $85 million to construct a new building to support this deployment. Space constraint issues of this type—and the associated costs—are not accounted for in EPA's cost estimates for the Proposed Rule. [EPA-HQ-OAR-2022-0985-1555-A1, p. 53] [Refer to Figure 5 on p. 53 of docket number EPA-HQ-OAR-2022-0985-1555-A1]

124 See Denver Post, 'RTD cancels purchase of 17 electric buses it doesn't have space to maintain—and orders fleet transition strategy' (April 26, 2023), https://www.denverpost.com/2023/04/26/regional-transportation-district-battery-electric-buses-contract/.

DTNA's fleet customers have faced a number of similar challenges, which have resulted in order cancellations or reductions, revealing the following issues :

- Fleet customers have been quoted 1.5 - 8 years for depot site electrification for deployments that are modest compared to the scale of those discussed in the Proposed Rule.

- Depot installation projects are complex and resource intensive for fleets, utilities, and AHJs. DTNA often observes differing views of roles and responsibilities in transportation electrification projects and a lack of expertise in this developing space.
- Infrastructure lead time is not synchronized with funding program lead time, leading fleets to return vouchers they spent resources securing, highlighting that available funding and the calculated TCO is only part of the adoption equation.
- Utilities and fleets sometimes cannot come to agreement on contractual terms, including load restrictions, managed charging, and guaranteed utilization time periods. It is unlikely these issues will be resolved without significant regulatory or legislative changes.
- State and municipal building codes and processes lack transparency and add significant time to depot electrification projects. [EPA-HQ-OAR-2022-0985-1555-A1, p. 54]

Utility Long Range Planning vs. Fleet Planning

Utilities today rely on long-range forecasts in the 5 - 10 year timeframe to plan investment and system upgrades. During CARB's ACF rulemaking process, a number of electric utilities submitted comments recommending that CARB facilitate the ongoing sharing of data with utilities about fleet customers' detailed near-term and long-term charging infrastructure needs, including fleet transition plans by year, whether the fleet would need to charge full-time or on peak, what percentage of time fleets would charge on peak and at what level, and if fleets anticipated seasonal peaks. [EPA-HQ-OAR-2022-0985-1555-A1, p. 55]

As discussed above, fleets typically order their vehicles 6 - 12 months in advance, and it is unlikely fleets are able to make accurate predictions of what the future fleets' energy needs might be, as fleet operations are subject to change with changes in contracted routes, technology maturity, etc. Some fleets rent their depot facilities, and short term leases will prevent the tenant fleet from making long range plans. Where long term leases are in place, the fleet tenant often cannot make substantial changes to the property without the landlord's permission. Even with the landlord's permission, fleets are unlikely to make a long-term investment in sites that they do not own. Landlords could choose to install EVSE if they anticipated a positive business case, but are similarly unable to provide detailed long range forecasts. [EPA-HQ-OAR-2022-0985-1555-A1, p. 55]

DTNA has made vehicle telematics data available for interested utilities to predict where future loads may occur, but this dataset only represents a subset of the Company's products, and not the market as a whole. Without substantive regulatory and/or legislative intervention to prompt utilities to plan for and buildout for transportation electrification, DTNA does not believe significant buildout of electrical infrastructure will occur on the timeline required to support EPA's proposed CO2 stringency levels. [EPA-HQ-OAR-2022-0985-1555-A1, p. 55]

Recommendations to Facilitate ZEV Infrastructure Buildout and CO2 Standard Feasibility

While EPA does not have regulatory authority over many of the factors that currently pose challenges to ZEV infrastructure development, the Agency could help to mitigate these challenges by supporting the policies, legislation, and regulatory initiatives that are detailed in Section I.B.4 of these comments, including:

- Align with EIA vehicle uptake estimates, to ensure accurate estimates of real power demand by MHD and HHD ZEVs and net CO2 emissions.

- Work with FERC to direct utilities to incorporate demand projects into both a system-wide transportation electrification electricity forecast and a utility distribution grid capacity requirement forecast, to serve these medium- and heavy-duty transportation electrification loads on a geographic basis.
- Assume financial liability as a demand guarantor for infrastructure buildout that is undertaken based upon EPA's ZEV penetration forecasts.
- Work with FERC to identify high traffic freight hubs that are likely to see rapid increase in BEVs, and direct utilities to proactively upgrade this infrastructure.
- Encourage state utility regulatory commissions to adopt PBRs to incentivize faster interconnection timelines for charging infrastructure projects. [EPA-HQ-OAR-2022-0985-1555-A1, p. 57]
- Work with stakeholders to develop model building codes that can be adopted by state and local governments to streamline authorizations for EVSE installation projects and encourage state and local adoption of these model codes.
- Require reporting of medium- and heavy-duty ZEV infrastructure and make this information available to fleets.
- Work with FHWA to revise the NEVI formula program to more actively encourage states to provide HD-accessible public charging infrastructure. [EPA-HQ-OAR-2022-0985-1555-A1, p. 58]

Finally, as described in more detail in Sections I.B.3 and II.C. of these comments, EPA should incorporate a scalar to be used in its calculations of appropriate CO_2 standard stringency levels, designed (and regularly updated) to reflect actual installed capacity of HD-accessible charging equipment. [EPA-HQ-OAR-2022-0985-1555-A1, p. 58]

Organization: Edison Electric Institute (EEI)

EPA notes that several stakeholders have raised concerns that 'slow growth in ZEV charging and refueling infrastructure can slow the growth of heavy-duty ZEV adoption, and that this may present challenges for vehicle manufacturers ability to comply with future EPA GHG standards.' 88 Fed. Reg. 25,934. EEI member companies have addressed similar infrastructure build out issues in the past. Like those issues, these concerns can be addressed through deliberate effort and collaboration among electric companies, fleet operators, and stakeholders, including planning for increased demand, customer engagement, and fleet electrification. [EPA-HQ-OAR-2022-0985-1509-A2, p. 7]

Electric companies can accommodate increased energy demand.

As EPA notes, the electric power sector has a long history of accommodating growth in electricity demand from the adoption of new technologies, including electric home appliances, residential and commercial air conditioning, and data centers. See id. At 25,983. Electricity use from EVs today is modest. Argonne National Lab estimates the approximately 2.3 million EVs on the road as of the end of 2021 consumed 6.1 terawatt-hours of electricity in that year, or about 0.16 percent of the total electric sales to U.S. customers in that year.18 As EPA also notes, the increase in electricity use resulting from the Proposed Rule also will be modest, increasing electricity end-use by less than 3 percent in 2055. See id. On a macro-level, meeting the increased energy usage from electric truck adoption as contemplated in the Proposed Rule will not be a significant challenge for the electric power sector. Meeting the location-specific power needs of large electric vehicle (EV) charging facilities can be a more pressing challenge. However, this is a challenge that can be addressed with deliberate effort and collaboration among electric companies, fleet operators, and stakeholders. [EPA-HQ-OAR-2022-0985-1509-A2, pp. 7-8]

18 See Gohlke, et al., Assessment of Light-Duty Plug-in Electric Vehicles in the United States, 2010 – 2021, https://publications.anl.gov/anlpubs/2022/11/178584.pdf and U.S. Energy Information Administration, Electric Power Monthly

Electric companies can accommodate localized power needs at the pace of customer demand, provided appropriate customer engagement and enabling policies are in place. The power required by a customer is essential when considering the infrastructure needed at the facility level, because the capacity of the local distribution circuit is sized to meet the peak power requirements of customers on that circuit. Some large EV charging facilities have power requirements in the tens of megawatts (MW). Electric companies are well accustomed to serving facilities with those types of power needs, but large fleet customers differ from traditional electric customers (e.g., commercial or industrial buildings) in several important aspects. These aspects include, but are not limited to:

- Construction timelines: A new, large commercial building with a multi-MW power demand, for example, will typically have a multi-year construction timeline, giving the local electric company time to plan and make appropriate upgrades to the electric distribution system serving that customer. A fleet operator, in contrast, may be able to procure vehicles and complete construction on a multi-MW charging facility in a matter of months. This creates a potential misalignment between the fleet operators' timeline to procure vehicles and charging equipment and the electric company's timeline for making the necessary system upgrades to provide power to that facility. [EPA-HQ-OAR-2022-0985-1509-A2, p. 8]
- Customer familiarity with procuring electric power: Commercial and industrial electric customers are used to working with electric companies for the operation of their facilities as part of their normal course of business, including working with electric companies as part of the construction process for launching new facilities. In particular, national corporate customers often have long-standing relationships with the electric companies that serve them. Electric companies typically assign these customers an account manager, given their scale and complexity. A fleet operator, in contrast, is used to procuring diesel to operate its vehicles, and may consider procuring electricity in the same paradigm. Fleet operators may be small electricity users today and thus that division may not yet be considered a managed account for the electric company. However, EEI members have identified this issue and are expanding their working relationship with these customers. [EPA-HQ-OAR-2022-0985-1509-A2, pp. 8-9]
- Uncertain and dynamic load profiles: The power usage throughout the day, known as the 'load profile,' of typical commercial and industrial buildings is well understood (e.g., large retail store, data center, or manufacturing facility). Typical load profiles for electric fleet customers are not yet well understood and often hypothetical given the early stage of electric truck commercialization. A fleet charging load profile is the product of many factors, including the routes of the vehicles, the state of charge of the EV when returning to the facility, the number of operating shifts, etc. Unlike a typical commercial building, the load profile of a fleet facility could also drastically change with a change in vehicle

operations (e.g., changing from a one-shift to two-shift operation). This uncertainty adds complexity for electric companies when determining how best to serve the power requirements of a fleet customer. [EPA-HQ-OAR-2022-0985-1509-A2, p. 9]

These factors could result in misalignment between expectations and reality regarding the timing, cost, and complexity of procuring electric power for fleet charging. Electric companies are taking a multi-pronged approach to remedy this potential misalignment, as discussed in the following sections. [EPA-HQ-OAR-2022-0985-1509-A2, p. 9]

Earlier customer engagement through education and coordination will alleviate infrastructure delays.

Early engagement between the relevant fleet customer and electric company is important as it allows planning for the infrastructure to support EV charging to occur much earlier and accommodate longer lead-times. In 2020, EEI began a collaboration with a large, national corporate customer that was planning to electrify a significant portion of its fleet operation. EEI facilitated meetings for this customer to share its conceptual plans with EEI's members and establish points of contact at the customer and each electric company. Over the course of more than a year, the customer identified the locations within each member's territory where it planned to deploy EVs and developed a five-year forecast to inform the electric company how the power demand would increase at each location over time. This unprecedented level of collaboration has resulted in this customer deploying thousands of electric vehicles to date. This includes alternative locations that were identified by the electric company after consulting with the customer. [EPA-HQ-OAR-2022-0985-1509-A2, pp. 9-10]

The extent of collaboration described in this example may not be feasible, or necessary, for every fleet customer. But it does provide a helpful template for how early engagement and planning can streamline fleet electrification. The Electric Power Research Institute (EPRI) is developing a data-sharing platform as part of its EVs2Scale2030 initiative that will formalize and expand this model by allowing fleet customers to upload their forward-looking fleet electrification plans to a common database.19 Electric companies will then be able to access this data to visualize where on its system upgrades will be needed to accommodate growing power needs from fleet customers. [EPA-HQ-OAR-2022-0985-1509-A2, p. 10]

19 See Electric Power Research Institute, EVs2Scale2030, https://www.epri.com/research/products/000000003002025622.

Many electric companies are developing tools and resources to assist fleet customers. These include, but are not limited to:

- Grid capacity evaluation tools: Several electric companies have launched capacity hosting maps that are available on public websites that illustrate local grid capacity in their service territory.20 These maps can be helpful early indicators for fleet customers when considering the level of upgrades that may be required at a particular facility. These maps have limitations, as they are a snapshot in time and do not substitute for a formal engineering study. Even if they have not published such a capacity map, many electric companies have the ability to assist fleet customers by providing an early screen for local grid capacity by location directly. In either case, the outcome is the same: for customers that have the ability to consider multiple locations for their EV deployment plans, pre-screening the local distribution system capacity at these locations allows the fleet to factor grid upgrade timelines into their deployment plans. [EPA-HQ-OAR-2022-0985-1509-A2, pp. 10-11]

20 Examples include: AVANGRID (United Illuminating, NYSEG, Rochester Gas & Electric), Ameren Illinois, Con Edison, Dominion Energy, Eversource, Exelon (Atlantic City Electric, Delmarva Power, Pepco, Comed, PECO), Jersey Central Power & Light, National Grid, Orange & Rockland, Public Service Electric & Gas, San Diego Gas & Electric, and Southern California Edison.

- Fleet assessments and advisory services: Many electric companies have launched programs to provide in-depth consulting services to fleets that are considering electrification, including elements like feasibility studies based on total cost of ownership.21 These programs also may include dedicated staff resources to guide customers through the fleet electrification journey, including choosing the appropriate charging strategy and charging infrastructure to meet their operational needs. These programs help to educate fleet customers about the nuances of procuring power for their fleet operations and allow electric companies to learn more about the expected operations of electric fleets. [EPA-HQ-OAR-2022-0985-1509-A2, p. 11]

21 See Alliance for Transportation Electrification, Fleet Advisory Services (FAS) for Fleet Electrification: Meet Customer Needs and Provide Grid Benefits, https://evtransportationalliance.org/wp-content/uploads/2023/02/PRESS-ATE-EC-White-Paper.pdf, which includes case studies from DTE Energy, Exelon, Portland General Electric, Southern California Edison, and Xcel Energy.

These and other resources being developed and deployed today by electric companies are essential to ensuring that infrastructure plans and efforts are matched to forthcoming electrification efforts from fleets and other operators. [EPA-HQ-OAR-2022-0985-1509-A2, p. 11]

Electric companies are planning for fleet electrification.

Investor-owned electric companies are regulated by state commissions, which approve electric company capital plans to maintain and upgrade the electric grid. While policies vary by state commission, two generally applicable principles have important implications for fleet electrification. First, the ‘used and useful’ standard means that regulators will only approve the electric company to build infrastructure that will be utilized and provide value. The onus is on electric companies to provide evidence that their capital plans will meet this standard. Second is the principle that the customer that incurs the cost must pay for the cost. Typically, a customer seeking new or upgraded electric service must submit a formal service request to the electric company, which prompts the electric company to perform an engineering study to determine the cost of the upgrades needed to provide that service. [EPA-HQ-OAR-2022-0985-1509-A2, pp. 11-12]

The implication for fleet electrification, a potentially fast-growing source of significant new demand on the electric system, is that electric companies are not authorized to upgrade the electric system in anticipation of new demand without robust evidence that those upgrades will be ‘used and useful.’ Only when a fleet customer submits a service request is the electric company permitted to make the upgrades necessary to serve that customer. Electric company forecasts for load growth, including that due to electrification, are typically at a system level, not the local distribution system level for individual fleet facilities. Given the nascent commercialization of fleet electrification, there is a lack of visibility into how, where, and when fleet electrification will appear on the system sufficient evidence to give electric companies (and their regulators) confidence to build for it. [EPA-HQ-OAR-2022-0985-1509-A2, p. 12]

Importantly, electric companies are recognizing the risks of this approach and are getting ahead of the need. Given the long lead times to make distribution upgrades, particularly if the upgrades are significant to extend further upstream to the substation and transmission level, it will increasingly be unacceptable to customers to wait for the customer service request-driven process. There is a risk that fleet customers, facing increased regulatory pressure to electrify their fleets, will be unable to plan their businesses around these infrastructure lead times and fail to meet their electrification goals. Electric companies must find mechanisms to plan and build for these increased loads now, so that the power is available when the customer needs them. [EPA-HQ-OAR-2022-0985-1509-A2, pp. 12-13]

In California, the investor-owned electric companies use the California Energy Commission's Integrated Energy Policy Report (IEPR) as their base forecast. Southern California Edison (SCE) in its recent General Rate Case found a significant gap between the electric transportation load growth in the IEPR forecast and that expected due to the state's policies, specifically the California Air Resources Board's Advanced Clean Cars II, Advanced Clean Trucks, and Advanced Clean Fleets rules.22 SCE developed a Transportation Electrification Grid Readiness (TEGR) analysis to account for this gap in its General Rate Case that will set the electric company's grid investments for the next several years. SCE used a top-down methodology to apply this higher forecast to the circuit level for electric transportation loads, as well as a bottom-up methodology for certain high growth areas. [EPA-HQ-OAR-2022-0985-1509-A2, p. 13]

22 See Southern California Edison, 2025 General Rate Case, WP SCE-02, Vol. 07 Bk. A, TEGR Forecast Development Workpaper.

SCE has deployed a variety of new methods to account for HDV development and deployment, including the Power Service Availability (PSA) initiative to support transportation electrification. The PSA initiative, working in concert with the TEGR analysis, focuses on improving SCE's internal processes to streamline interconnection, engaging fleet operators to better understand their plans for electrification, improving their ability to forecast and assess the impacts of load growth from electrification, and leveraging new technologies as grid infrastructure solutions. Because some projects will require more time than others to build, SCE actively encourages fleet owners to engage with them early in the process so that SCE can better understand and plan for their needs. For grid upgrades that require a longer construction schedule, SCE is developing temporary solutions that can deploy quickly while those upgrades are being built. These solutions may include mobile battery storage or a mobile substation brought in on a semi tractor-trailer. [EPA-HQ-OAR-2022-0985-1509-A2, pp. 13-14]

In New York, the Public Service Commission opened a proceeding in April to address barriers to medium-and heavy-duty electric vehicle infrastructure. In particular, the order recognizes that 'proactive planning for the grid infrastructure needed to serve future electrification load must anticipate the location and magnitude of future demand' and notes an analogy to previous policies in which the commission directed the electric companies in New York to 'develop proactive planning processes to anticipate the need for local transmission and distribution system upgrades to enable the renewable interconnections required to achieve the State's renewable energy goals.' 23 [EPA-HQ-OAR-2022-0985-1509-A2, p. 14]

23 State of New York Public Service Commission, Case 23-E-0070, Proceeding on Motion of the Commission to Address Barriers to Medium- and Heavy-Duty Electric Vehicle Charging Infrastructure.

EPA's assessment that 'there is sufficient time for the infrastructure, especially for depot charging, to gradually increase over the remainder of this decade to levels that support the stringency of the proposed standards for the timeframe they would apply' is accurate. 88 Fed. Reg. 25,999. As seen above, EEI members actively are planning for and deploying infrastructure today. However, the increased deployment of this infrastructure over the next decade and beyond will not happen on its own. Proactive planning processes, whether initiated by the relevant electric company or state regulatory commission, will be critical to accommodate fleet electrification to meet customer expectations and planning requirements, while also providing affordable and reliable service. [EPA-HQ-OAR-2022-0985-1509-A2, pp. 14-15]

EPA specifically requests comment on 'whether there are additional stakeholders EPA should work with during implementation of the Phase 3 standards.' 88 Fed. Reg. 26,000. EPA, states, engine and truck manufacturers, and fleet operators should work with electric companies on a regional or state level to glean additional insight into their planning processes and help bolster proactive planning and infrastructure investments. As discussed above, electric companies and their regulators benefit from the confidence that fleet electrification load will materialize through additional forward planning and outreach, which also provides visibility into where and when that load will materialize on the system. Final adoption of the Proposed Rule will help provide confidence that fleet electrification will occur through the period of the rule, but at a national level. [EPA-HQ-OAR-2022-0985-1509-A2, p. 15]

Additionally, the States, Congress, EPA, and other federal partners should work with the electric power industry to ensure policies are aligned across the federal government to reduce the cost and timelines associated with building infrastructure to support increased electrification. This includes but is not limited to:

- Investing in domestic manufacturing of critical electrical infrastructure, including efforts to alleviate the labor pool shortage limiting domestic manufacturing of critical electrical infrastructure and provide loan or purchase guarantees to manufacturers. [EPA-HQ-OAR-2022-0985-1509-A2, p. 15]
- Not exacerbating the supply shortage of distribution transformers with unsupported efficiency rules. The U.S. Department of Energy should choose an efficiency standard for transformers that does not require switching to a new type of steel or make a determination that no new standard is needed.24 [EPA-HQ-OAR-2022-0985-1509-A2, pp. 15-16]

24 EEI's comments are attached as Appendix A.

- Reforming permitting, both at the bulk power level with respect to building electricity generation and transmission, and at the state and local levels with respect to building distribution infrastructure. [EPA-HQ-OAR-2022-0985-1509-A2, p. 16]

EEI and its members stand ready to work with our regulatory and legislative partners to ensure these challenges are appropriately addressed. [EPA-HQ-OAR-2022-0985-1509-A2, p. 16]

EPA notes that 'there is considerable uncertainty associated with future distribution upgrade needs, and in many cases, some costs may be borne by utilities rather than directly incurred by

BEV or fleet owners' in explaining why it models these costs as part of the infrastructure cost analysis. 88 Fed. Reg. 25,983. In general, the upgrades to the local electric system needed to bring sufficient power to the site may be known as 'electric company-side make-ready' or 'front-of-the-meter' infrastructure and includes but is not limited to poles, vaults, service drops, transformers, mounting pads, trenching, conduit, wire, cables, meters, other equipment as necessary, and associated engineering and civil construction work. Front-of-the-meter infrastructure is distinct from infrastructure on the customer side of the meter ('behind-the-meter'), which includes the supply infrastructure (conduit and wiring to bring power from the service connection to the charging station, and the associated installation costs, sometimes known as 'customer-side make-ready') and the charging equipment, sometimes known as Electric Vehicle Supply Equipment (EVSE). [EPA-HQ-OAR-2022-0985-1509-A2, p. 17]

Front-of-the-meter infrastructure is generally installed, owned, and operated by the electric company. However, the costs associated with front-of-the-meter infrastructure may be borne by the site host customer in full or in part if the costs exceed an allowance as determined by the electric company's line-extension and/or service extension policy. These costs may also be known as 'contributions in aid of construction.' [EPA-HQ-OAR-2022-0985-1509-A2, pp. 17-18]

Modeling these front-of-the-meter infrastructure costs is inappropriate for the following reasons. First, estimating distribution upgrade costs may be beyond the scope of EPA's analysis, as it is not clear that a similar scope of analysis is applied to traditional liquid fuels. For example, the analogous cost comparison for internal combustion engine vehicle would include cost considerations for fleet operators either 1) installing refueling stations at their own facilities, or 2) the embedded cost of fuel retailers' business operations in the cost of diesel or gasoline. [EPA-HQ-OAR-2022-0985-1509-A2, p. 18]

Second, as described above, distribution upgrades are highly location specific. The costs associated with these upgrades are also highly variable, depending on the upgrade requested by the customer and the local distribution capacity. As stated in EEI's Preparing to Plug In Your Fleet guide, 'the grid can expand as needed to accommodate the needs of any customer, but the time and resources needed to make the required upgrades are highly dependent on the specific facility and the circuit that serves it.'27 [EPA-HQ-OAR-2022-0985-1509-A2, p. 18]

27 See EEI, Preparing To Plug In Your Fleet – 10 Things to Consider, https://www.eei.org/-/media/Project/EEI/Documents/Issues-and-Policy/Electric-Transportation/PreparingToPlugInYourFleet.pdf.

Third, the share of any distribution costs that the customer may bear varies as a matter of policy. Some electric companies have or are seeking approval for line extension allowances to cover some or all of these costs for serving EV charging infrastructure. In California, for example, legislation required electric companies in the state to file tariffs that would authorize them to 'design and deploy all electrical distribution infrastructure on the utility side of the customer's meter for all customers installing separately metered infrastructure to support charging stations, other than those in single-family residences.' This policy prompted tariffs from EEI members Pacific Gas & Electric (PG&E), San Diego Gas & Electric (SDG&E), and SCE that essentially allow electric companies to invest in more of the electric company-side infrastructure costs as part of the standard distribution system investment. [EPA-HQ-OAR-2022-0985-1509-A2, pp. 18-19]

Organization: Electrification Coalition (EC)

With continued planning efforts, the electric grid can manage the additional load from mass EV adoption, including the EPA forecasted 35-57% of HD EVs, depending on vehicle type, by 2032, in the proposed rule. [EPA-HQ-OAR-2022-0985-1558-A1, p. 9]

The EPA states,

As discussed in Section V, we model changes to power generation due to the increased electricity demand anticipated in the proposal as part of our upstream analysis. We project the additional generation needed to meet the demand of the heavy-duty BEVs in the proposal to be relatively modest (as shown in DRIA Chapter 6.5). As the proposal is estimated to increase electric power end use by heavy-duty electric vehicles by 0.1 percent in 2027 and increasing to 2.8 percent in 2055. The U.S. electricity end use between the years 1992 and 2021, a similar number of years included in our proposal analysis, increased by around 25 percent 449 without any adverse effects on electric grid reliability or electricity generation capacity shortages. Grid reliability is not expected to be adversely affected by the modest increase in electricity demand associated with HD BEV charging.'27 [EPA-HQ-OAR-2022-0985-1558-A1, p. 9]

27 See page 25983 of the Environmental Protection Agency's (EPA) proposed rule for Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles-Phase 3 in the Federal Register: https://www.govinfo.gov/content/pkg/FR-2023-04-27/pdf/2023-07955.pdf

The EC notes the following additional information for consideration, and overall agrees with the EPA's assessment in terms of the HD EV adoption impact to the electric grid. The May 2023 report from the International Council on Clean Transportation (ICCT), 'Near-Term MHDV Infrastructure Deployment in the United States,' projected an increase in total electricity consumption resulting in MHD electrification by 2030 to be 1 percent.28 A significant share of this projected energy consumption will be concentrated in several states, for example, as well as along key freight corridors, such as the National Highway Freight Network. As such, while MHD electrification may not be constrained by electricity generation, investments will be required at the regional level in additional generation capacity, transmission, and distribution to meet peak electricity loads for electric truck charging along these freight corridors. [EPA-HQ-OAR-2022-0985-1558-A1, pp. 9-10]

28 https://theicct.org/wp-content/uploads/2023/05/infrastructure-deployment-mhdv-may23.pdf

In addition, there are many planning efforts underway with utilities, regulators and additional EV stakeholders to prepare for the impending adoption of EVs in the HD sector. For example, in March 2023, the Nevada Public Utilities Commission approved $70 million of NV Energy's proposed $348 million transportation electrification plan (TEP). Of the nearly 20 programs included in the TEP proposal, three programs were approved: the Interstate Corridor Depot Program, the Electric School Bus Vehicle to Grid Trial, and the Inflation Reduction Act Innovation Demonstration Program. All of these programs involve the HD EV sector. [EPA-HQ-OAR-2022-0985-1558-A1, p. 10]

Another example is Pennsylvania. For the past few years, the Pennsylvania General Assembly has considered transportation electrification planning legislation – similar to laws passed in Nevada and New Mexico. This year, new TEP legislation was introduced (HB 1240) that would establish a robust, holistic planning process for electric utilities in the state for EV charging station deployment. The development of TEPs by electric utilities, overseen by the Public Utility Commission, would ensure the electric grid is prepared for future EV adoption by requiring load forecasting, evaluation of the transmission and distribution networks, rates charged to customers, and providing an implementation plan today so we are prepared for tomorrow. Depot charging and large public charging sites would also be a part of the utility's analysis. This analysis will prepare the utilities for added load capacity requests reaching into the in the 2 to 5 MWh range- or for more, depending on the size of the EV charging depot. The TEP legislation would allow utilities to identify where upgrades are needed now, begin installation, and prepare for the impending greater adoption of EVs in the HD sector. [EPA-HQ-OAR-2022-0985-1558-A1, p. 10]

Utilities are also preparing reports and studies that will help with the planning and timely installation of HD EV charging infrastructure. For example, National Grid commissioned a report, "Electric Highways Study," to examine the planning considerations for alternative-fueled corridors with the freight and goods movement in mind.29 This first of its kind study examined the traffic patterns and infrastructure needed to support the transportation decarbonization mandates in NY and MA, the service territories for National Grid. The report looked at 71 sites in both states, with results showing that by 2030, over a quarter of the sites would need more than 5 MW of capacity to meet peak charging demand. National Grid was able to share the results of the whitepaper with MA DOT and NY DOT to help them be aware of the advanced planning that will be required for enabling highway charging for the light-duty and MHD sectors. While some sites may need electric grid upgrades, the planning occurring now will ease any bottlenecks in the future, particularly as future-proofing 'no-regrets' sites/zones will limit the need for retroactive upgrades. Planning ensures that costs are kept low, EV charging station deployment is timely, generation is available, and distribution lines are not strained. [EPA-HQ-OAR-2022-0985-1558-A1, pp. 10-11]

29 https://www.nationalgrid.com/us/EVhighway

Utilities are also planning for the adoption of EVs in the HD sector with fleet advisory services. An issue brief by the Alliance for Transportation Electrification and the Electrification Coalition examined several utilities' fleet advisory services programs.30 These programs are comprised of dedicated utility staff with a suite of tools and assistance offered by the electric company that is designed to educate and enable fleet managers to make informed choices. Ultimately, the programs help the utilities and fleets to work together and begin to think through the best sites for any depot charging, allowing for any grid issues or concerns to be addressed ahead of time. [EPA-HQ-OAR-2022-0985-1558-A1, p. 11]

30 https://electrificationcoalition.org/wp-content/uploads/2023/02/FAS.White-Paper.E.O.task_.force_.FINAL_.2.23.23.pdf

Finally, it should be noted that HD EVs can also be used to enhance grid resiliency and reliability. In January 2023, the EC released a V2X Implementation Guide and Mutual Aid Agreement Template that would encourage V2X-enabled EBS to be used as mobile power units to enhance resilience during emergency response and disaster relief efforts.31 As ESB adoption grows, it is highly likely we will see ESBs deployed in this manner. The report also outlines reasons as to why ESBs represent a great use case for any grid resiliency efforts. [EPA-HQ-OAR-2022-0985-1558-A1, p. 11]

31 https://electrificationcoalition.org/resource/v2x/

The ATE Interconnection brief outlines some of the current challenges and opportunities with the installation of HD EV charging infrastructure, including the three aspects of pre-planning, energization and permitting.33 In terms of the pre-planning, using existing data and considering states that have adopted the Advanced Clean Truck (ACT) rule, utilities should be approved to move forward with the build out of HD EV charging infrastructure, and not need to wait for a lengthy regulatory approval process. For example, the ICCT projects that 85% of the charging needs for long-haul trucking in 2030 will be along the corridors of the National Highway Freight Network.34 Of course, ratepayer advocate concerns must be taken into consideration but balanced with the need for swift deployment of HD EV charging infrastructure if climate targets and public health goals are to be achieved. The EC is also currently developing a set of practical tools and policy solutions as well to speed the installation of HD EV charging infrastructure that we would eagerly share in a meeting with EPA and DOE staff, when completed. [EPA-HQ-OAR-2022-0985-1558-A1, p. 12]

34 https://theicct.org/publication/infrastructure-deployment-mhdv-may23/

Organization: Energy Strategy Coalition

III. Coalition members are investing in EV charging infrastructure

Members of this Coalition have begun making significant investments in the charging infrastructure needed to support a growing number of electric heavy-duty trucks, vans, and passenger cars. For example, NextEra Energy is pursuing a $650 million joint venture called Greenlane with BlackRock Alternatives and Daimler Truck North America to design, develop, install, and operate a nationwide charging and hydrogen fueling network for medium- and heavy-duty vehicles.19 Coalition members are also making significant investments in the charging infrastructure for electric passenger cars and trucks:

- National Grid recently received approval for a $206 million initiative to enable up to 32,000 additional charging ports in Massachusetts.20
- The New York Power Authority will have up to 400 fast chargers installed or in construction through its EVolve NY program by the end of 2025.21
- The Pacific Gas and Electric Company ("PG&E") has successfully installed through March 2023 over 5,700 charging ports through its EV Charge Network, EV Fleet, EV Fast Charge and EV Schools programs.22
- Austin Energy provides rebates of up to $1,200 and $4,000 for customers installing Level 2 charging stations at their homes and workplaces respectively.23
- The Sacramento Municipal Utility District ("SMUD") offers up to $1,000 toward residential charging equipment and installation costs through its Charge@Home program.24
- Constellation Energy Corporation's venture arm (Constellation Technology Ventures, or "CTV") has invested in portfolio companies focused on EV and charging infrastructure.25 [EPA-HQ-OAR-2022-0985-1626-A1, pp. 4 - 5]

25 For instance, CTV invested in Qnovo, which offers a solution suite that uses advanced computation to optimize the chemical reactions within lithium-ion batteries, resulting in faster charging, increased daily run times, and longer battery lifetimes. See Constellation Technology Ventures, https://www.constellationenergy.com/our-work/innovation-and-advancement/technology-ventures.html.

Coalition members are making these investments in part because of the benefits that EVs can provide to grid reliability. EVs' primary near-term grid benefits stem from their enablement of load shifting—whether from periods of higher load demand to periods of lower load demand, or from periods of more carbon-intensive power generation to periods where more renewable energy is available.26 Load shifting can involve both deferral (to avoid charging during periods of peak load) and more targeted scheduling (to take advantage of periods of excess energy supply).27 In addition to enhancing grid reliability, load shifting can also reduce customer electricity rates, increase the value of renewable energy investments (by maximizing usage of excess solar energy produced during the day), and mitigate the need for equipment upgrades (e.g., increased storage capacity to accommodate excess solar energy).28 [EPA-HQ-OAR-2022-0985-1626-A1, pp. 5 - 6]

For example, PG&E has partnered with the BMW Group to explore ways to incentivize EV drivers to shift their charging times to support grid reliability.29 This program—called ChargeForward—first kicked off in 2015 and moved into its third phase in 2021.30 Building on the success of the first two phases, phase three expanded the program's scope to 3,000 EV drivers (from prior pilots of 100 and 400 drivers in phases one and two).31 Phase two of ChargeForward demonstrated the ability to shift nearly 20% of charging from a particular hour to another time and to shift up to 30% of charging to a particular hour.32 SMUD is also engaged in a managed charging pilot program with BMW, Ford, and GM, and is planning to add Tesla vehicles to the pilot as well, targeting participation of around 2,000 vehicles through 2024.33 [EPA-HQ-OAR-2022-0985-1626-A1, p. 6]

Coalition members are also exploring Vehicle-to-Grid (“V2G”) technology, through which EVs can send power back to load sources (e.g., homes) and the grid from their batteries. While still in the early stages of development, V2G technology can offer reliability benefits by serving as a grid resource during periods of peak demand.34 PG&E and BMW recently extended their ChargeForward partnership until March 2026 and, as part of that program, will conduct a field trial of V2G-enabled vehicles in order to explore their potential to increase grid reliability.35 In addition, PG&E has announced vehicle-grid integration (“VGI”) pilot programs with Ford36 and General Motors to test the ability of EVs to provide backup power to homes.37 SMUD is also in the process of conducting an electric school bus V2G demonstration project with the Twin Rivers Unified School District.38 SMUD is planning to expand the program to additional school districts and is also pursuing other projects to explore V2G capabilities for light-duty EVs.39 [EPA-HQ-OAR-2022-0985-1626-A1, pp. 6 - 7]

IV. EPA should work closely with state and local partners to ensure deployment of the resources and infrastructure needed to accelerate transportation electrification while maintaining grid reliability

EPA's HDV Proposal will help support deployment of the charging and generation resources needed to meet anticipated demand from vehicle electrification. Yet effective and efficient deployment of these resources will require coordination among electric utilities, state public utility commissions, and local governments to ensure loads from EVs are factored into long-range resource planning and to permit distribution and transmission system upgrades and siting of new generation and storage resources. To ensure these resources are deployed on the pace and scale needed to support vehicle electrification and grid reliability, EPA should play a leadership role in ensuring coordination occurs among relevant federal, state and local agenices to remove barriers, emphasizing the benefits to the electricity grid, public health, and climate that will be achieved as a result. [EPA-HQ-OAR-2022-0985-1626-A1, p. 7]

Organization: Environmental Defense Fund (EDF)

4. The benefits of bi-directional charging from buses should also be considered

EPA's rulemaking should consider the potential benefits of using school buses for bi-directional charging. Electric school buses can function as large batteries to support the power grid, providing energy to municipalities through the use of vehicle-to-grid (V2G) technologies. According to WRI, at least 15 utilities across 14 states have committed to pilot electric school bus V2G programs, which allow electricity to be stored in the bus batteries and later discharged onto the grid.128 The bus batteries' stored power "can help stabilize fluctuating energy conditions, alleviate the need to start up additional power generation sources by shaving peak energy needs and provide mobile emergency power to shelters and other essential facilities. Because school buses operate on set daily schedules and often sit idle in the summer and during portions of the school day when electricity demand is high, they are ideal for this purpose. The power they can provide to the grid or buildings could offer revenue to help pay for the buses, a win-win for schools and the utility or other entity using the electricity."129 [EPA-HQ-OAR-2022-0985-1644-A1, p. 52]

128 Norma Hutchinson and Greggory Kresge, "3 Design Considerations for Electric School Bus Vehicle-to-Grid Programs," World Resources Institute (February 14, 2022). https://www.wri.org/insights/electric-school-bus-vehicle-grid-programs

129 Id.

b) The electric grid can support widespread HD ZEV adoption

The U.S. electric grid has provided reliable, cheap, instantaneous power to millions of homes and businesses every second of every day for well over a century. For so many end uses, electrification represents the cheapest and most attainable decarbonization pathway. [EPA-HQ-OAR-2022-0985-1644-A1, p. 65]

Growing the electric grid to meet increased demand is nothing new. Since 1960, about a third of the year over year increases in state electricity sales have been higher than 5% with 7% of those years having increases higher than 10% annual growth.166 The compound annual growth rate for the entire grid since 1960 is 2.8%. The total increase in electricity consumption as a result of the proposed rule is expected to be 1.3%, less than half of the average annual increase that has occurred since 1960. Research shows that, with planning, utilities will meet the demand for additional electricity needed to charge our nation's fleet of heavy-duty vehicles, and those vehicles may improve the reliability of the grid. [EPA-HQ-OAR-2022-0985-1644-A1, p. 65] [See Figure 11 on p. 66 of Docket Number EPA-HQ-OAR-2022-0985-1644-A1]

166 U.S. Energy Information Administration, EIA-861: Annual Electric Power Industry Report, 1960-2021, https://www.eia.gov/electricity/data/state/

EDF commissioned a report by Analysis Group to understand how the expected growth in HDV charging will impact the grid and what processes are in place or need to be added to enable the grid to meet the increased demand.167 Their main findings include:

1. The overall magnitude of growth in demand that would result from EPA's proposed rule is very small relative to historic periods of growth in the electric industry, and will not pose a challenge from the perspectives of power system generation or transmission infrastructure needs.
2. Charging station needs that may result from EPA's proposed rule range greatly in size and location; most counties and utilities in the U.S. analyzed in ICCT's report will likely not face new distribution system infrastructure needs due to charging load different from past experience.
3. Some utilities will need to plan for the development of new distribution system infrastructure to accommodate fairly large point sources of new charging station demand.
4. Adding significant new distribution system infrastructure is not a new experience for states, public utility commissions, or electric companies, and there are long-standing policies and practices in place to process development of infrastructure needed to ensure system reliability.
5. The need for a high level of certainty around the timely integration of charging stations and associated distribution system infrastructure at the scale and speed needed for HDV electrification warrants – and has already prompted – proactive action on behalf of some states and utilities to engage and expand planning and regulatory practices at the scale necessary to ensure timely readiness of the power system.
6. There are many emerging technologies, ratemaking practices, and distributed resource solutions that have the potential to significantly and efficiently reduce the expected impacts on distribution systems associated with vehicle electrification. [EPA-HQ-OAR-2022-0985-1644-A1, p. 66-67]

167 Paul Hibbard et al. Heavy Duty Vehicle Electrification: Planning for and Development of Needed Power System Infrastructure. 2023. Analysis Group, https://blogs.edf.org/climate411/wp-content/blogs.dir/7/files//Analysis-Group-HDV-Charging-Impacts-Report.pdf. Analysis Group, https://blogs.edf.org/climate411/wp-content/blogs.dir/7/files//Analysis-Group-HDV-Charging-Impacts-Report.pdf. (Attachment W).

Evolution of distribution systems to meet the potential increase in charging station demand associated with EPA’s proposed Phase 3 rule for HDVs is eminently achievable. [EPA-HQ-OAR-2022-0985-1644-A1, p. 67]

Additionally, they found that 83% of utility service territories would not see more than 5 MW of increased load from HDV charging based on a study done by ICCT. The localized nature of the expected growth of HDV charging demand presents unique challenges but also allows for focused action. [EPA-HQ-OAR-2022-0985-1644-A1, p. 67]

ii. Robust solutions exist and are being implemented to ensure rapid interconnection and widespread vehicle electrification

The main concern that has been raised by OEMs and other parties related to the grid is the ability to build out infrastructure quickly enough to meet demand.177 In addition to the existing policies and practices around upgrading distribution systems that have served to build things like data centers which have high load requirements, additional practices have been developed and are being implemented in some areas to address specific challenges around HD ZEV charging. [EPA-HQ-OAR-2022-0985-1644-A1, p. 68]

177 https://documents.dps.ny.gov/public/Common/ViewDoc.aspx?DocRefId={D05A8E88-0000-CE16-8EA2-97D9432AAEE9}

These include practices and policies that maximize the existing grid capacity, proactively building the grid, and updating planning procedures. [EPA-HQ-OAR-2022-0985-1644-A1, p. 69]

By maximizing the existing grid capacity, fleet owners can transition to ZEVs without requiring immediate grid upgrades allowing more time for utilities to build out infrastructures. Techniques such as leveraging non-wires alternatives (managed charging, onsite storage and generation, and energy efficiency programs) have had great success in minimizing the upgrades required, and allowing for continued load growth while waiting for a necessary upstream grid upgrade. One clear example of this is Con Edison’ BQDM program which resulted in a 7-year grid upgrade deferral.178 A report by the Smart Electric Power Alliance (SEPA) found a wide range of non-wires alternatives succeeded at enabling rapid interconnection and HDV electrification.179 [EPA-HQ-OAR-2022-0985-1644-A1, p. 69]

178 Coley Girouard. BQDM program demonstrates benefits of non-traditional utility investments. 2019. Utility Dive, https://www.utilitydive.com/news/bqdm-program-demonstrates-benefits-of-non-traditional-utility-investments/550110/

179 Brenda Chew et al. Non-Wires Alternatives: Case studies from leading U.S. projects. 2018, Smart Electric Power Alliance, https://sepapower.org/resource/non-wires-alternatives-case-studies-from-leading-u-s-projects/

Where fleets install managed charging software and/or onsite storage and solar generation to minimize charging costs including demand charges, their net load can be significantly lower than the utility-assigned capacity requirements for the site. To connect to the grid, they may be required to undergo site and utility upgrades to provide significantly higher capacity than what is actually needed and in some cases these solutions result in some sites never exceeding the existing capacity on their site making the upgrades unnecessary. Flexible interconnection, where customers agree to limit their peak load to a specified level below that of the cumulative nameplate capacity of their equipment, is one solution to energize chargers while those grid upgrades are ongoing. This mitigates any site and upstream grid upgrades in the short term in exchange for early energization of their charging equipment, and can even lower long-term upgrade needs. EPRI has shown the benefits of flexible interconnections for broader grid decarbonization.180 [EPA-HQ-OAR-2022-0985-1644-A1, p. 69]

180 Chris Warren. Can allowing curtailment speedup DER growth? EPRI Journal, https://eprijournal.com/getting-flexible-about-interconnection/

States are working towards allowing utilities, with guardrails in place to protect ratepayers, to proactively build the grid to need ahead of interconnection requests for new load, such as EV charging. [EPA-HQ-OAR-2022-0985-1644-A1, p. 70]

There are legislative efforts that are paving the way for this solution. California's AB 2700, which in addition calls for the collection of fleet electric vehicle deployment plans, also allows for utilities to submit pro-active grid expansion proposals to the utility commission in areas with identified future congestion using fleet deployment data.181 SB 410 in California would take this a step further, setting requirements for utilities to have their grid ready for interconnection requests and calls for utilities to plan and evaluate potential grid impact of Advanced Clean Fleets (ACF) and Advanced Clean Trucks (ACT) rules as well as submit plans to address potential areas of congestion to meet energization timelines. This bill also requires utilities to report interconnection requests and delays to better track progress and hold utilities accountable.182 [EPA-HQ-OAR-2022-0985-1644-A1, p. 70]

181 Transportation electrification: electricial distribution grid upgrades. AB2700. 2021-2022 Regular Session, (California 2022) https://legiscan.com/CA/bill/AB2700/2021

182 Powering Up Californians Act, SB410, 2023-2024 Regular Session, (California, 2023) https://legiscan.com/CA/text/SB410/id/2813946

Other states have also taken steps to ensure utilities are able to proactively build infrastructure. New York senate bill S4830, which recently passed both houses of the New York legislature, directs the New York State Energy Research and Development Authority (NYSERDA) to identify the number and location of fleet charging zones and highway charging hubs where significant demand from EV charging, including electric HDVs, is expected in line with meeting state and federal transportation sector emissions regulations, and the associated grid impact of that charging.183 [EPA-HQ-OAR-2022-0985-1644-A1, p. 70]

183 Establishing a highway and depot charging action plan, Senate Bill S4830A, 2023-2024 Legislative Session. (New York, 2023) https://www.nysenate.gov/legislation/bills/2023/S4830

Efforts to update planning processes have also improved the ability for the grid to meet demand from HDV charging. If utilities have accurate forecasts well in advance of when grid needs arise, they can complete needed upgrades without as great of a need for mitigating solutions like grid deferment and flexible interconnection. In a recent article, Southern California Edison (SCE) emphasized the importance of planning for utilities: "On the forecasting and planning side, utilities and energy system planners must adapt planning efforts to reflect expected EV growth, including impacts from proposed and adopted policies and incentives. For example, to account for the new developing needs of the Advanced Clean Cars II and Advanced Clean Fleets policies in California, SCE and the other California investor-owned utilities were recently approved to use higher forecasts for transportation electrification than previously used."184 [EPA-HQ-OAR-2022-0985-1644-A1, p. 70-71]

184 Pamela MacDougall and Katie Sloan, As the electric truck transition shifts into high gear, utilities must lead the charge. 2022. Utility Dive, https://www.utilitydive.com/news/electric-truck-bus-ev-utilities-sce-edison-edf/634214/

The New York Joint Utilities' Coordinated Grid Planning Process and California PUC's Freight Infrastructure Planning Framework, both currently under development, also represent examples of improved planning processes to enable accelerated HDV electrification and grid interconnection.185 186 [EPA-HQ-OAR-2022-0985-1644-A1, p. 71]

185 https://documents.dps.ny.gov/public/MatterManagement/CaseMaster.aspx?MatterCaseNo=20-e-0197&CaseSearch=Search

186 Zero-Emissions Freight Infrastrucutre Planning. California Public Utilities Commission, https://www.cpuc.ca.gov/industries-and-topics/electrical-energy/infrastructure/transportation-electrification/freight-infrastructure-planning

iii. Upgrade costs for charging HD ZEVs can help more efficiently use the grid and drive down costs

Large-scale electrification of medium- and heavy-duty vehicles will require grid upgrades, largely at the distribution grid level, to support the added load from charging. But, research shows that EVs can help strengthen the grid, and the costs of the needed upgrades can be covered by the additional revenue from fleets charging without raising consumers' electricity rates.187 [EPA-HQ-OAR-2022-0985-1644-A1, p. 71]

187 Lucy Metz, Melissa Whited, Paul Rhodes and Ellen Carlson. Distribution System Investments to Enable Medium- and Heavy-Duty Vehicle Electrification: A Case Study of New York, Synapse Energy Economics, Inc., prepared for EDF. (April 2023). (Attachment X) https://acrobat.adobe.com/link/track?uri=urn%3Aaaid%3Ascds%3AUS%3Ab0fd0780-9882-3a25-9ef2-f8c73bd80c92&viewer%21megaVerb=group-discover

According to electricity company executives, EVs can boost grid reliability.188 EVs are schedulable loads that typically charge off peak (at night). Utilities can encourage EV owners to charge when and where they want, leading to more efficient use of existing grid infrastructure.189 [EPA-HQ-OAR-2022-0985-1644-A1, p. 72]

188 Tomlinson, Chris. "Will electric vehicles crash the Texas grid? It's not complicated." Houston Chronicle (April 10, 2023). https://www.houstonchronicle.com/business/columnists/tomlinson/article/electric-vehicles-ercot-grid-reliabilty-17880578.php

189 Jennifer Chen. 2023. Leveraging Locational and Temporal Flexibility in Transportation Electrification to Benefit Power Systems. Energy Systems Integration Group. https://www.esig.energy/leveraging-locational-and-temporal-flexibility-in-transportation-electrification-to-benefit-power-systems/

EV charging can also finance and justify needed grid updates. Recent analysis conducted by Synapse Energy Economics for EDF finds that if U.S. utilities rate-base the cost of infrastructure upgrades needed for fleet charging, the utilities will see increased revenue without the need to raise consumers' electricity rates.190 The analysis used two New York State utilities as case studies and found that if utilities cover the "make-ready" cost for both private and municipal medium- and heavy-duty fleets at the pace necessary for 100 percent electrification by 2045, the investment will pay off for utilities and have a positive to neutral impact on ratepayers in both utility service areas. The analysis' findings are applicable beyond New York to states across the country due to the varying grid costs, geography and electricity demand profiles of the utilities studied. Con Edison primarily serves New York City, while National Grid provides electricity to portions of upstate New York. [EPA-HQ-OAR-2022-0985-1644-A1, p. 72]

190 Metz et al Distribution System Investments to Enable Medium- and Heavy-Duty Vehicle Electrification: (April 2023).

The study finds that if fleets are assumed to engage in modest managed charging (shifting charging times by only two hours at night), Con Edison's make-ready program could generate $690 million in net revenue between 2023-2045, while National Grid's program could generate $89 million in the same time period. Even without managed charging, investing in make-ready programs was shown to have a positive to neutral impact on ratepayers in both utility service areas. As more fleets are incentivized to plug in - and therefore spend more of their operating budget on electricity and less on diesel - utilities can invest a portion of that revenue on grid upgrades elsewhere that would have otherwise been paid for by all ratepayers. [EPA-HQ-OAR-2022-0985-1644-A1, p. 72-73]

iv. Managed charging represents an opportunity for fleet owners to reduce their costs and to increase grid benefits from HDV electrification

Medium- and heavy-duty fleets can experience short but high energy demand events that can significantly increase their grid impact and energy bills. When these fleets go beyond merely managing charging to leveraging onsite distributed energy resources (DERs) such as solar and battery storage, they can benefit from an even more powerful lever for reducing charging costs. A GNA study examined two types of clean DERs: on-site solar panels and batteries. When combined with managed charging, DERs produced additional annual electric savings of $625,000 (Schneider) and $835,000 (NFI) for fleets of 40-50 electric HDVs. Moreover, managed charging and DERs together reduced annual on-peak load by 611 kW for the Schneider fleet and 4 MW for the NFI fleet.191 Thus, such techniques would not only reduce costs for the truck companies, but the utility and ratepayers as a whole as well owing to the reduced need for grid buildout. If scaled to all trucks in a utility's territory, these load reductions could drastically decrease the amount of grid upgrades needed to accommodate electric fleets. [EPA-HQ-OAR-2022-0985-1644-A1, p. 73]

191 Gladstein, Neandross & Associates, California Heavy-Duty Fleet Electrification Summary Report, March 2021, http://blogs.edf.org/energyexchange/files/2021/03/EDF-GNA-Final-March-2021.pdf Gladstein, Neandross & Associates, California Heavy-Duty Fleet Electrification Summary Report, March 2021, http://blogs.edf.org/energyexchange/files/2021/03/EDF-GNA-Final-March-2021.pdf. (Attachment Y)

A recent New Jersey study evaluated the statewide grid impact of meeting ACT, as well as the grid savings when implementing managed charging and utilizing on-site solar and storage for all Class 3-7 vehicles in the state. Avoided peak load ranges from ~8,400 MW for managed charging, to ~10,000 MW for managed charging with solar + battery. Total avoided infrastructure costs are between $320 million and $1.80 billion for managed charging, and between $382 million and $2.15 billion for managed charging with solar + battery.192 [EPA-HQ-OAR-2022-0985-1644-A1, p. 73-74]

192 Jeffery Greenblatt. New Jersey Medium Duty Fleet Electrification Infrastructure Summary Report. 2022. Emerging Futures, https://blogs.edf.org/energyexchange/files/2022/05/New_Jersey_Medium_Duty_Fleet_Elecrtification_Infrastructure_Summary_Report.pdf Emerging Futures,

https://blogs.edf.org/energyexchange/files/2022/05/New_Jersey_Medium_Duty_Fleet_Elecrtification_Infrastructure_Summary_Report.pdf (Attachment Z)

Furthermore, these largely avoided infrastructure costs are sure to be an underestimate for HDV electrification as a whole for the state since they do not account for the benefits of electrifying Class 8 vehicles with managed charging or managed charging with solar + battery. [EPA-HQ-OAR-2022-0985-1644-A1, p. 74]

The flexibility associated with vehicle charging is also extremely valuable to the grid operator. A study by the Midwest ISO shows the untapped potential of EV load flexibility as a DER resource in the wholesale markets. This study evaluated the impact of expected electrification of both MHDVs as well as LDVs in the MISO footprint. A key factor in this study was determining the potential flexibility of these vehicles when applying managed and bidirectional charging tactics to mitigate ramp and peak load. It showed that at any given hour this additional load can provide a minimum of 10 GW of combined ramp up capacity and just under 10 GW of ramp down or generation capacity using the flexibility of EV charging alone. To reiterate, this ramp capacity was based on vehicle charging alone and would be even greater if combined with other on-site DERs.193 [EPA-HQ-OAR-2022-0985-1644-A1, p. 74]

193 Greenblatt, Jeff and Margaret McCall, Exploring enhanced load flexibility from grid-connected electric vehicles on the Midcontinent Independent System Operator grid (Feb. 2021), available at https://cdn.misoenergy.org/Exploring%20enhanced%20load%20flexibility%20from%20grid%20connected%20EVs%20on%20MISO%20grid543291

Of critical importance, this load flexibility also comes at a fraction of the cost of traditional fixed battery storage. A study by Lawrence Berkeley National Lab shows that managed charging of EVs—modulating when and at what rate the EVs are charged— can provide reliable storage at approximately a tenth of the cost of equivalent storage provided by single-purpose, stationary batteries. When scaled to California's projected 1.5 million light-duty EVs by 2025, the storage potential of managed charging alone is 1 GW, resulting in savings of approximately $1 billion compared to investments needed for equivalent stationary storage. This number also does not include the thousands of MHDVs such as buses and trucks expected to be electrified in the near future.194 By leveraging the flexibility of newly electrified resources, stakeholders can significantly reduce grid management costs ultimately, resulting in savings for end-customers and mitigating grid upgrade needs, further supporting accelerated HDV electrification. [EPA-HQ-OAR-2022-0985-1644-A1, p. 74-75]

194 Jonathan Coignard et al., Clean vehicles as an enabler for a clean electricity grid, 13 Environmental Research Letters 54031 (2018).

Organization: International Council on Clean Transportation (ICCT)

Utilities have many options to provide timely delivery of grid capacity to support these charging needs. ICCT has identified actions that (1) require no regulatory approval or pre-authorization (2) require regulator consent or notification, or (3) require regulatory approval or state legislation. [EPA-HQ-OAR-2022-0985-1553-A1, p. 12]

Utilities have the greatest flexibility to meet charging infrastructure needs in a timely fashion when actions can be taken without regulator notification or approval. These actions include short-term load rebalancing, the use of non-firm distribution capacity, the incorporation of smart charging into feeder ratings and load forecasting, the deployment of temporary distribution, generation and storage, and public-private partnerships that allow for third-party funding, design, and construction of infrastructure. This list is not comprehensive but demonstrates that options do exist for utilities to meet the most acute needs of fleets. [EPA-HQ-OAR-2022-0985-1553-A1, p. 12]

As the trend toward truck electrification grows, utilities will need to take actions to adapt to a new market environment in their service area. Any adaptation in programs and planning will require the notification, if not consent, of state regulatory agencies. For example, utility regulators can consent to periodic adjustments to transportation electrification programs to better respond to market trends. Utilities can also request consent to explicitly incorporate transportation electrification load forecasts into their distribution system planning and related investments. These modifications to existing programs and planning processes reflect the type of adaptation most utilities serving freight zones will need to perform. [EPA-HQ-OAR-2022-0985-1553-A1, p. 12]

Finally, utilities may need to take certain actions that increase their responsiveness to freight charging needs beyond what state utility regulation permits them to do. For example, authorization to pre-build distribution capacity infrastructure in 'no-regrets' freight zones will require either state legislation or explicit regulation where it does not already exist. Examples of such policies under development in California include SB410 passed by the California State Senate on 25 May 2023.(Powering Up Californians Act, n.d.) Another example includes the Zero-Emissions Freight Infrastructure Planning proposal made by the staff of the California Public Utilities Commission on 22 May 2023. (Gruendling, 2023.) Similar examples exist in New York State, including a new proceeding opened by the New York Public Service Commission to address barriers to Medium- and Heavy-Duty Charging Infrastructure.4 [EPA-HQ-OAR-2022-0985-1553-A1, p. 12]

4 https://documents.dps.ny.gov/public/MatterManagement/CaseMaster.aspx?MatterCaseNo=23-E-0070&CaseSearch=Search

Power Up Californians Act. Retrieved June 15, 2023, from https://legiscan.com/CA/text/SB410/id/2813946

Gruendling, P. (2023). Freight Infrastructure Planning. California Public Utilities Commission. https://www.cpuc.ca.gov/industries-and-topics/electrical-energy/infrastructure/transportationelectrification/freight-infrastructure-planning

In response to EPA's request for comment on how to engage infrastructure stakeholders, we suggest EPA consider infrastructure needs tbroadly, starting from the transmission grid and downstream to the charger that connects to the vehicle. Many players exist in each segment of this chain. [EPA-HQ-OAR-2022-0985-1553-A1, p. 12]

Key stakeholders include electric utilities (IOU, POU, NRECA, EPRI), EVSE manufacturers, CharIN (MCS), CPO (Charge Point Operators/Network Service Providers), Bundled Service Providers (charging-as-a-service, trucking-as-a-service), public charging hub owner/operators (such as the Daimler/NextEra/Blackrock JV, WattEV, Terawatt, bp Pulse, etc), engineering/construction firms (Black & Veatch, Burns MacDonnell, Schneider Electric, etc), fleets (including NACFE) and depot owners. EPA can engage these stakeholders individually and facilitate dialogue across these groups to support the data collection, planning, and coordinated deployment to support the objectives of the greenhouse gas standards. A regular meeting, such as an annual summit, is one strategy EPA could use to gather information on challenges and solutions in the zero-emission vehicle transition. [EPA-HQ-OAR-2022-0985-1553-A1, p. 12]

While EPA does not have jurisdictional authority over electric utilities, interagency collaboration with the Department of Energy, Department of Transportation, and the Joint Office of Energy and Transportation would ensure EPA has a voice in federal infrastructure policy these other agencies may be responsible for developing. [EPA-HQ-OAR-2022-0985-1553-A1, p. 12]

Organization: MEMA

EPA appears to be over optimistic with regard to both electricity generation growth and wide dispersal needed to assure charging across the roads of the U.S. Similarly, many heavy trucks must operate off road away from infrastructure. Today they are capable of doing this, as fuel can be topped-off before leaving the road or brought to the job site. EVs do not have this luxury and would require a large generator to replicate this scenario, which would be counterproductive. Oversizing a fuel tank is a cost-effective way to guarantee sufficient energy for asset flexibility across the full range of applications and locations. Oversizing batteries or pressurized hydrogen tanks is more costly. [EPA-HQ-OAR-2022-0985-1570-A1, p. 8]

Opportunity to Build a Resilient and Sustainable EV Infrastructure

The American Transportation Research Institute (ATRI) has released a study’ on the challenges facing the U.S. infrastructure for EV, which we urge the EPA to incorporate alongside the other ATRI studies noted in the DRIA. It projects significant grid expansion is needed in each state if all vehicle applications are electrified; see Appendix 3. [EPA-HQ-OAR-2022-0985-1570-A1, p. 9]

7 https://truckingresearch.org/2022/12/new-atri-research-evaluates-charging-infrastructure-challenges-for-the-us-electric-vehicle-fleet/

Organization: Missouri Farm Bureau (MOFB)

Further, MOFB is greatly concerned that the proposed rule contains zero language regarding what impact it will have on the severely aged and inadequate electric grid. In 2020, the U.S. experienced 180 major electrical disruptions, up from fewer than two dozen in 2000.9 In this proposed rule, EPA fails to illustrate how electricity will actually be delivered to thousands of new charging stations that will be built in the near future, and what impact this action will have upon every other aspect of our lives, much of which relies on the constant delivery of electricity. [EPA-HQ-OAR-2022-0985-1584-A1, p. 2]

9 America’s Power Grid Is Increasingly Unreliable - WSJ, accessed June 14, 2023.

In addition, but not separable from this conversation, MOFB is especially concerned with the future buildout of electric transmission lines that will be needed to carry the proposed rule’s mandates into fruition. Unfortunately, and all too often, farmers and ranchers hear others say that their land is needed for the ‘public’s benefit.’ Government agencies and renewable energy advocates often forget that farmers and ranchers are part of the ‘public’ as well, and need to be fairly compensated for the continued buildout of transmission lines through their private property which will take away the critical farm and ranch land necessary to run their businesses for generations to come. [EPA-HQ-OAR-2022-0985-1584-A1, p. 3]

Organization: Moving Forward Network (MFN) et al.

7.2. The ability of electric trucks to reduce emissions compared to diesel vehicles

The benefits of an electric drayage truck compared to its diesel-powered equivalent change between today and 2035 based predominantly on the improvement in the electric grid. Figure 4 shows the relative greenhouse gas emissions benefits resulting from the two different timeframes. Figure 5 shows the relative public health impact, as indicated by the Public Health Score defined earlier through aggregated mortality. While today's diesel vehicles are the benchmark for the public health scores, the 2035 diesel truck public health score in Figure 5 reflects a Phase 2 diesel truck meeting the 2027 NO X and PM 2.5 standards finalized last year. [EPA-HQ-OAR-2022-0985-1608-A1, p. 44]

Electric trucks powered by electricity supplied from the U.S. grid production average today would lead to more than a two-thirds reduction in greenhouse gas emissions compared to their diesel counterpart. By 2035, under a scenario consistent with the administration's goals for the power sector and analysis of what is needed to decarbonize by 2050, that achieves a 95 percent reduction compared to diesel. [EPA-HQ-OAR-2022-0985-1608-A1, p. 44]

However, the story is more complicated when it comes to public health impacts. It underscores the tremendous importance of eliminating fossil fuels across the electricity sector and in transportation. 102 On average, an electric drayage truck powered by today's grid would reduce premature deaths by nearly 57 percent compared with current diesel trucks. Nearly all regional electricity grids, covering 97 percent of the U.S. population, result in net benefits today. However, there are some subregions where, if the average grid powered the truck, an electric truck could lead to more net harm as the result of substantial particulate emissions from fossil fuel power: in Alaska, diesel generators continue to be utilized in remote areas, especially as a backup source to hydropower, and make up more than one-quarter of generation in the AKMS subregion and 10 percent of generation in the AKGD subregion; in Hawaii (HIOA and HIMS subregions), while there has been significant growth in both rooftop and utility-scale solar power, more than two-thirds of grid-supplied electricity in the state comes from petroleum power plants; and in rural Missouri/Illinois (SRMW subregion), approximately two-thirds of the grid remains coal-powered. 103 [EPA-HQ-OAR-2022-0985-1608-A1, p. 44] [Refer to Figure 4, Greenhouse gas emissions reductions for an electric drayage truck compared to a diesel drayage truck on p. 45 of docket number EPA-HQ-OAR-202-1608-A1.] [Refer to Figure 5, Public health impact for an electric drayage truck compared to a diesel drayage truck on p. 46 of docket number EPA-HQ-OAR-202-1608-A1.]

102 See footnote 7. An electric truck is not inherently a zero emission vehicle (ZEV) – zero-emission solutions must minimize impacts when accounting for upstream and downstream impacts. If the full lifecycle is not considered, we risk trading pollution for more pollution, and the same frontline and fenceline communities are left to suffer.

103 All current values come from EPA's eGRID 2021 dataset, the most recent available. It is worth noting, however, that this dataset excludes net metered, distributed solar production (i.e. it only reflects utility-delivered electricity).

By 2035, an electric truck would have public health benefits compared to today's diesel everywhere, even when powered by the average grid. In the country's most remote areas, where petroleum and diesel power is expected to remain a significant share of the grid, electric trucks may continue to have unhealthy public health impacts. However, it is unlikely that such a grid would be used to fuel electric trucks given the high cost of fossil power in this instance, so it is more probable that electric trucks would accelerate the adoption of cleaner energy sources to augment the renewable energy in the Alaskan and Hawaiian grids and/or be preferentially charged on more renewable sources than the average grid in such a future. [EPA-HQ-OAR-2022-0985-1608-A1, p. 46]

Importantly, the difference in time for the two grids is short enough to be within the anticipated lifespan of a given truck—any electric truck sold today is still likely to be on the road in 2035. Unlike a combustion vehicle, which gets dirtier over time due to aging of emissions controls, mal-maintenance, and tampering, electric trucks get cleaner over the vehicle's lifespan as the grid continues to incorporate more renewable sources of electricity. [EPA-HQ-OAR-2022-0985-1608-A1, p. 47]

In addition, the California Senate recently voted 32-to-8 to advance new legislation (Senate Bill 410, "Powering Up Californians Act") that builds upon existing law to accelerate short-term energization timelines for EV charging and to ensure timely grid investments needed to electrify "light-duty, medium-duty, and heavy-duty vehicles and off-road vehicles, vessels, trains, and equipment" consistent with state law requiring economy-wide carbon neutrality by 2045, and "federal, state, regional, and local air quality and decarbonization standards, plans, and regulations." 241 The legislation also establishes a balancing account to recover associated costs, which would ensure Pacific Gas & Electric (PG&E) and San Diego Gas & Electric (SDG&E) do not have to wait several years for their next General Rate Cases to propose investments such as those recently proposed by SCE (and it would also allow SCE to propose subsequent investments before its next rate case that could not be predicted when its current rate case was filed). [EPA-HQ-OAR-2022-0985-1608-A1, p. 109]

241 California Senate Bill 410. (2023). https://leginfo.legislature.ca.gov/faces/billTextClient.xhtml?bill_id=202320240SB410

Grid operators around the country are also beginning to incorporate EV planning into existing planning structures. For example, the Minnesota Public Utilities Commission has shifted investor-owned utility transportation electrification planning and reporting requirements to the integrated distribution planning process to account for increasing linkages between EV planning and distribution system planning. 242 Incorporating robust EV planning in existing planning structures can help ensure those processes account for EV adoption, even where the utility business units responsible for those areas of planning may be distinct. Furthermore, combined planning processes can create administrative efficiencies that help expedite time-sensitive planning needs. On the transmission planning side, regional grid operators, such as the Midcontinent Independent System Operator, have already begun to think about how transportation electrification will affect total energy needs and the timing of annual peaks in electricity demand. 243 Strong vehicle standards give grid operators a reliable EV forecast against which to plan in processes that are already underway. [EPA-HQ-OAR-2022-0985-1608-A1, p. 109]

12.4. EPA's Conclusion that HDV Charging Will Not Compromise the Reliability of the Electric Grid is Supported by Empirical Data

EPA observes HDV charging is not anticipated to impact electric grid reliability adversely:

U.S. electric power utilities routinely upgrade the nation's electric power system to improve grid reliability and to meet new electric power demands. For example, when confronted with rapid adoption of air conditioners in the 1960s and 1970s, U.S. electric power utilities successfully met the new demand for electricity by planning and building upgrades to the electric power distribution system. Likewise, U.S. electric power utilities planned and built distribution system upgrades required to service the rapid growth of power-intensive data centers and server farms over the past two decades. U.S. electric power utilities have already successfully designed and built the distribution system infrastructure required for 1.4 million battery electric vehicles. Utilities have also successfully integrated 46.1 GW of new utility-scale electric generating capacity into the grid. 245 [EPA-HQ-OAR-2022-0985-1608-A1, p. 110]

245 88 FR 25983

And:

Our assessment is that grid reliability is not expected to be adversely affected by the modest increase in electricity demand associated with HD BEV charging and thus was not considered to be a constraining consideration. 246 [EPA-HQ-OAR-2022-0985-1608-A1, p. 111]

246 88 FR 26003.

These conclusions are supported by empirical evidence from California, which already has more than 1.3 million EVs on the road. While some pundits have claimed EV charging is already straining the grid, triggering the need for service disruptions, those claims have been debunked. 247 And root cause analysis from the California Independent System Operator (California ISO) showed that EVs are not what has strained the grid. 248 Indeed, empirical evidence shows that EV charging has been accommodated with minimal required grid upgrades and that EV charging can be shifted to hours of the day when there is plenty of spare grid capacity. Since 2011, the California Public Utilities Commission has required the utilities it regulates to report annually on costs associated with accommodating EV charging and on the charging patterns of EVs on different utility rates. 249 While the vast majority of those EVs are passenger vehicles, the real-world data on charging patterns and associated grid impacts gathered by the largest utilities in the state is still relevant, especially considering that the "Level 2" equipment used to charge those passenger vehicles is the same equipment that is used to meet the daily charging needs of most of the categories of vehicles subject to the Proposed Rule. As summarized by Synapse Energy Economics, utility grid upgrades required to accommodate EV charging to this point in those service territories are essentially rounding errors compared to the costs of maintaining the electrical grid:

Even in the service territories with the most EVs of any, the observed costs have been minor. For instance, in California where EV adoption has been markedly higher than other states, EV-related distribution upgrade costs appear minor compared to total distribution costs. Despite the fact EVs are often more concentrated in many neighborhoods and distribution circuits, California utilities collectively spent less than 0.03% of their total distribution-related expenses on distribution system upgrades associated with residential EV adoption. 250 [EPA-HQ-OAR-2022-0985-1608-A1, p. 111 - 112]

(June 2023). https://www.synapse-energy.com/sites/default/files/Electric%20Vehicles%20Are%20Driving%20Rates%20Down%20Factsheet.pdf

And costs associated with integrating both light- and heavy-duty EV charging onto the grid can also be minimized with effective load management programs, as described immediately below. [EPA-HQ-OAR-2022-0985-1608-A1, p. 112]

12.5. Time-of-Use Electric Rates Are Extremely Effective at Pushing EV Charging to Hours of the Day When there is Plenty of Spare Grid Capacity

Real-world data from hundreds of thousands of EVs reveals that time-of-use (TOU) electricity rates work. At the time the data described below was collected, SCE estimated there were 329,940 EVs in its service territory (through December 31, 2021). 251 Figure 32 shows the load profile of households in SCE territory with EVs, with a readily discernible uptick in electricity demand after 9PM (when the on-peak period ends on the time-of-use rates) as a result of EV charging that increases until just before midnight and trails off in the early morning hours as those EVs complete their charging. [EPA-HQ-OAR-2022-0985-1608-A1, p. 112.] [See Figure 32 Load Profile of Households with EVs on a TOU Rate in SCE Territory located on p. 113 of docket number EPA-HQ-OAR-2022-0985-1608-A1.]

251 Joint IOU Electric Vehicle Load Research and Charging Infrastructure Cost Report 10th Report. Filed on March 31, 2022. https://www.cpuc.ca.gov/-/media/cpuc-website/divisions/energy-division/documents/transportation-electrification/10th-joint-iou-ev-load-report-mar-2022.pdf

252 Id.

The impact of TOU rates is even more self-evident in Figure 33, which isolates EVs on separate meters, demonstrating that EVs charge almost exclusively after 9 PM on that TOU rate. [EPA-HQ-OAR-2022-0985-1608-A1. p. 113.] [See Figure 33 Load Profile of EVs on a Separately Metered TOU Rate in SCE Territory located on p. 114 of docket number EPA-HQ-OAR-2022-0985-1608-A1.]

253 Id.

The figures above represent real-world data collected from hundreds of thousands of households with EVs. There is no need to test the proposition that simple TOU rates designed for EVs work. If they work for LDVs parked at home for long periods of time, they should also work for HDVs parked at depots, homes, or other locations for long periods of time. Given EPA expects the vast majority of charging for the HD EVs contemplated in its Proposed Rule will occur at depots and other locations where EVs are typically parked for long periods of time, often overnight, the real-world data described above remains relevant. And TOU rates are often the default option for commercial and industrial customers in the U.S. (whereas residential customers typically need to opt-into a TOU rate), and commercial and industrial customers are generally more sensitive to price signals than residential customers. [EPA-HQ-OAR-2022-0985-1608-A1, p. 114]

The combination of TOU rates and more active means of managing EV charging can yield even greater benefits. Researchers from NRDC, Lawrence Berkeley National Laboratory, and Pacific Gas & Electric found that well-designed TOU rates could allow the utility's system to accommodate universal light-duty EV adoption with minimal associated costs. 254 This peer-reviewed study used real-world data on the distribution grid and EVs to simulate what would happen if every household in a major metro area had an EV and found that, if just 30 percent of light-duty EVs were on TOU rates, the required grid upgrades were reduced by a factor of four and that more comprehensive load management could essentially prevent all otherwise necessary grid upgrades. 255 The potential impacts of generally higher-powered HD EV charging, some of which may need to occur during hours when overall demand for electricity is greater, could be more extensive, but the demonstrated efficacy of TOU rates and other load management strategies is still relevant. [EPA-HQ-OAR-2022-0985-1608-A1, pp. 114 - 115]

255 Id.

12.6. EVs Can Lower the Cost of Managing an Increasingly Dynamic Electric Grid

Researchers from Lawrence Berkeley National Laboratory estimate that using smart charging of light-duty EVs as a means to comply with California's energy storage procurement mandate (designed to facilitate the integration of renewable energy) would save utility customers $1.5 billion because it is cheaper to use batteries customers have already purchased on four wheels than it is to pay private companies to deploy standalone battery storage. 256 The same study also found enabling so-called "vehicle-to-grid" (V2G) technology, allowing EVs to supply power back to the grid during times of stress, could save $13-15 billion in stationary battery costs. 257 "By displacing the need for construction of new stationary grid storage, EVs can provide the dual benefit of decarbonizing transportation while lowering the capital costs for widespread renewables integration," the researchers concluded. 258 [EPA-HQ-OAR-2022-0985-1608-A1, p. 115]

256 Jonathan Coignard, Samveg Saxena, Jeffery Greenblatt, and Dai Wang. Clean Vehicles as an Enabler for a Clean Electricity Grid. Environmental Research Letters. V. 13, No. 5. (May 2018). http://iopscience.iop.org/article/10.1088/1748-9326/aabe97. (last checked September 14, 2022).

257 Id.

258 Id.

Focusing on the Midwest to underscore the point, researchers conclude very high levels of renewable energy penetration in the Midcontinent Independent System Operator (MISO) region could result in “negative valleys” (requiring excess renewable energy to be exported or curtailed) but “[c]ontrolled (EV) charging (both smart charging and smart discharging back onto the grid) is able to reduce these negative valleys, and with sufficient numbers of EVs can eliminate them altogether, obviating the need for either export of excess renewable generation or curtailment.” 259 This would provide both increased environmental benefits by facilitating the integration of high levels of renewable generation and significant customer benefits. [EPA-HQ-OAR-2022-0985-1608-A1, p. 115]

259 Jeffery Greenblatt, Cong Zhang, Samveg Saxena. Quantifying the Potential of Electric Vehicles to Provide Electric Grid Benefits in the MISO Area: Final report to the Midcontinent Independent System Operators. Lawrence Berkeley National Laboratory. https://cdn.misoenergy.org/Quantifying%20the%20Potential%20of%20Electric%20Vehicles%20to%20Provide%20Electric%20Grid%20Benefits%20in%20the%20MISO%20Area354192.pdf. (last checked September 14, 2022).

Put simply, it is cheaper to pay individual utility customers to use batteries on wheels they have already bought-and-paid-for than it is to pay corporations to buy big batteries and park them on the grid. And that simple proposition holds true for both individual passenger vehicle drivers and for fleet managers whose HD EVs have even bigger batteries and higher power intake and output potential (meaning they can potentially both absorb more excess renewable energy when available and put more power back onto the grid when needed). [EPA-HQ-OAR-2022-0985-1608-A1, pp. 115 - 116]

Moreover, the revenues from participating in vehicle-grid integration programs and markets can create value streams that reduce the total cost of ownership of EVs for the driver or fleet operator. HD EVs have a variety of duty cycles and vehicle characteristics, including battery size and charging power. A particular vehicle segment or vocation may be better suited to providing power or other grid services than others. The California Joint Agencies Vehicle-Grid Integration Working Group found that a large number of vehicle use cases could provide value now in a variety of different vehicle-grid integration applications, including V2G applications. 260 [EPA-HQ-OAR-2022-0985-1608-A1, p. 116]

260 Final Report of the California Joint Agencies Vehicle-Grid Integration Working Group. (June 30, 2020). https://gridworks.org/wp-content/uploads/2020/09/GW_VehicleGrid-Integration-Working-Group.pdf

While many types of HD EVs could potentially provide V2G services, school buses are already doing so in the real world. They have defined duty-cycles during the school year that include significant portions of the day when they are sitting idle while solar generation peaks in the afternoon and when wind generation often peaks overnight. In the summer months, they can often be fully dedicated to providing energy storage and grid services. Many V2G school bus demonstration projects have been conducted or are in progress. A pair of early examples in California demonstrates how different approaches to power export can create revenue streams for school districts or school bus operators and support the grid in the process. A project in Torrance Unified School District uses energy stored in two electric school buses to power on-site electrical loads. This behind-the-meter solution saved the school district about $10,000 per year, by reducing power usage and demand charges. 261 A project in Rialto Unified School District is taking a different approach, using a front-of-the-meter grid interconnection to allow eight electric buses to generate revenue by participating as a distributed energy resource in the CAISO market. 262 [EPA-HQ-OAR-2022-0985-1608-A1, p. 116]

Dominion Energy in Virginia has the largest electric school bus V2G program in the country. 263 In 2020, the utility program already had 50 electric school buses on the road. To date, the program has tested and verified V2G functionality on one bus and is deploying and testing firmware capability on the balance of the 50 bus fleet. 264 Over time, the program is designed to scale to 1,000 buses that will be able to provide 105 megawatt-hours of energy storage, enough to power 10,000 homes. 265 [EPA-HQ-OAR-2022-0985-1608-A1, pp. 116 - 117]

Organization: National Association of Clean Air Agencies (NACAA)

EPA also requests comment on the readiness of ZEV charging and refueling infrastructure. Specifically, EPA writes in the proposal that '. . .important early actions and market indicators suggest strong growth in charging and refueling ZEV infrastructure in the coming years. Furthermore, as described in Section II of this document, our analysis of charging infrastructure needs and costs supports the feasibility of the future growth of ZEV technology of the magnitude EPA is projecting in this proposal's technology package. EPA has heard from some representatives from the heavy-duty vehicle manufacturing industry both optimism regarding the heavy-duty industry's ability to produce ZEV technologies in future years at high volume, but also concern that a slow growth in ZEV charging and refueling infrastructure can slow the growth of heavy-duty ZEV adoption, and that this may present challenges for vehicle manufacturers ability to comply with future EPA GHG standards. Several heavy-duty vehicle manufacturers have encouraged EPA to consider ways to address this concern both in the development of the Phase 3 program, and in the structure of the Phase 3 program itself. EPA requests comment on this concern, both in the Phase 3 rulemaking process, and in consideration of whether EPA should consider undertaking any future actions related to the Phase 3 standards, if finalized, with respect to the future growth of the charging and refueling infrastructure for ZEVs.'16 [EPA-HQ-OAR-2022-0985-1499-A1, p. 6]

16 Supra note 1, at 25,934

For reasons we explain earlier in these comments, NACAA does not share the concerns expressed by some representatives of the heavy-duty vehicle manufacturing industry about the ability of electric utilities and/or charging equipment and service providers to continuously meet the incremental rollout needs for ZEV charging and refueling infrastructure. NACAA firmly opposes an 'off-ramp' from the standards or any similar measure. Likewise, anything akin to a mid-term evaluation is unnecessary and inappropriate given the program will begin in just a few years, span the course of only five years and starts from a demonstrated baseline of vehicle and charging technology. NACAA strongly urges EPA to reject any such provisions. [EPA-HQ-OAR-2022-0985-1499-A1, p. 6]

There is a great deal of evidence, including what NACAA provides at the beginning of this section on our comments and recommendations, that points to the coming readiness of the charging and fueling infrastructure needed to support strong Phase 3 standards. The federal government has demonstrated its deep commitment to accelerating the transition to ZEVs by providing historic levels of funding and monetary incentives including for timely infrastructure. NACAA notes that given the importance of this federal funding to achieving meaningful nationwide reductions in GHG emissions, including from heavy-duty vehicles and engines, EPA should ensure that these funds are allocated equitably across the country. In addition to federal action, states and local areas are demonstrating leadership by undertaking their own infrastructure initiatives. These are helping to drive private investment to capitalize on these opportunities. The following a few examples. [EPA-HQ-OAR-2022-0985-1499-A1, pp. 6-7]

Organization: National Association of Convenience Stores (NACS), NATSO, and SIGMA

Another substantial challenge is the generation and supply of electricity to charging stations. Every market participant that our membership communicates with is extraordinarily skeptical that electricity providers will be able to increase generation and transmission activity to service the kind of load necessary to provide charging infrastructure for this volume of HD trucks at scale within ten years. A recent analysis of grid upgrades necessary for HD electrification found that a single highway fast-charging site will require the same amount of electricity as a sports stadium or a small town.10 This will require the development of dedicated substations and significant energy resources behind the meter. EPA's Proposed Rule largely assumes that, with an increase in EV production, there will be a sufficient increase in electricity generation and transmission to meet those EV needs. Even when HD charging sites are financed, more than 50% of fleet operators already operating HD EVs report that building a charging site takes over a year on average.11 [EPA-HQ-OAR-2022-0985-1603-A1, p. 5]

mck&hlkid=cf69cd78c86a42938ccdc7806b06c93d&hctky=14495856&hdpid=4eb1e872-7192-48d7-b6cb-0642d205d4c5.

On top of these challenges, the overarching structure of wholesale and retail electricity markets is not designed for—and is currently incompatible with—the retail diesel market. Currently, electric utilities monopolize both generation and access, and they experience shifts in supply and demand with little to no risk as they are able to pass on costs to ratepayers. These electric utilities routinely impose demand charges on commercial users of electricity added to a monthly utility bill. These charges are not based on the amount of electricity used by that business, but on the highest rate of usage the business has during the two fifteen-minute periods in a month in which the business draws electricity from the grid at the highest pace. EV fast chargers—a must-have for on-the-go charging such as those found at a truck stop or convenience store—draw extensive electricity from the grid to charge an EV quickly. To power HD diesel trucks, this would result in inordinate charges to a refueling location's monthly utility bill that it likely could not recover. There is simply no business case for electric truck charging in the United States. The Associations are actively working with state and federal policymakers to enhance this business case, but until there is a clearer light at the end of that tunnel, it makes little sense to put all of our heavy-duty decarbonization eggs in one basket. [EPA-HQ-OAR-2022-0985-1603-A1, pp. 5-6]

Organization: National Association of Manufacturers

Infrastructure Needed

According to the Department of Energy's draft National Transmission Needs Study released in February 2023, the national electric transmission infrastructure would need to grow 57% by 2035 to reach the administration's clean energy goals as it relates to the growing light-,medium- and heavy-duty vehicle industries.1 Yet at the historical pace of approximately 1% annual growth for these projects,2 the transmission system would require more than half a century to achieve the goals the administration hopes to achieve in little more than a decade. As such, the rulemaking must recognize the realities and limitations of current infrastructure, even as manufacturers urge administration officials and congressional leaders to prioritize policies that would strengthen transmission systems and infrastructure, including critical permitting reforms. [EPA-HQ-OAR-2022-0985-1649-A2, p. 1 - 2]

Organization: National Rural Electric Cooperative Association (NRECA)

EPA Should Account for Grid-side Investments in Proposed Rule's Analysis

Bearing these realities in mind, we write to express our significant concern that EPA has failed to adequately account for the costs associated with serving the new load that will be created via heavy-duty highway vehicle (HDV) electrification as outlined in this proposed rule. While EPA accounts for the cost to purchasers for the hardware and installation of charging equipment, EPA fails to include the electric grid-side upgrades that will likely be needed, if not now, certainly in the future as electrification spreads and this could have serious negative consequences to American consumers. Specifically, within the proposed rule section on

Charging Infrastructure Costs, EPA states:1 "there may be additional infrastructure needs and costs beyond those associated with charging equipment itself. While planning for additional electricity demand is a standard practice for utilities and not specific to BEV charging, the buildout of public and private charging stations (particularly those with multiple high-powered DC fast charging units) could in some cases require upgrades to local distribution systems." [EPA-HQ-OAR-2022-0985-1515-A1, p. 2]

1 Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles – Phase 3, 88 Fed. Reg. 25,982 (April 27, 2023)

It is important for EPA to correct this failure in the proposed rule stage by updating its analysis with inclusion of a range of expected costs associated with serving the new load from the HDV fleet created by EPA's proposal. Failure to do so will likely result in unrealistic expectations on the part of fleet operators and possibly delay plans for electrification as they learn of the full costs that will be required to serve this new load from their electric cooperatives or other electric utilities. Neither these HDV fleet operators, nor the EPA, should expect that electric cooperatives can bear the burden of these new costs alone, particularly when these costs will ultimately need to be passed on to the end of the line consumer-members of the cooperative.[EPA-HQ-OAR-2022-0985-1515-A1, p. 2]

Overall, it is important for EPA to recognize that electrification of the transportation sector, and the increased flexibility of this newly electrified demand, will require substantial distribution infrastructure investment over time to meet increased average local electric demand and to meet increased demand in new locations (e.g., EV charging stations). Significant transmission infrastructure investment may also be required to meet increased average electric demand and changes in the spatial distribution of electric demand among load centers. According to the National Academy of Sciences, to transition the transportation sector through increased electrification, electric utilities will need to increase generation by up to 170% and see a three-fold expansion of the transmission grid by 2050. Over time, electrification of the transportation sector will require additional generation investment to ensure resource and energy adequacy to meet increased average electric demand and changing consumption profiles. Unfortunately, this investment challenge is becoming more complex due to several recent EPA actions that are jeopardizing flexible, dispatchable always available generation resources.2 These actions would require increased reliance on intermittent energy sources. Particular attention will be needed to ensure that generation investment is adequate in amount and in operational characteristics to meet the demands of electrification while ensuring grid stability, security, and reliability. [EPA-HQ-OAR-2022-0985-1515-A1, pp. 2-3]

2 These actions include: Supplemental Effluent Limitations Guidelines and Standards for the Steam Electric Power Generating Point Source Category, 88 FR 18824 (March 29, 2023); National Emission Standards for Hazardous Air Pollutants: Coal- and Oil-Fired Electric Utility Steam Generating Units Review of the Residual Risk and Technology Review, 88 FR 24854 (April 24, 2023); Hazardous and Solid Waste Management System: Disposal of Coal Combustion Residuals From Electric Utilities; Legacy CCR Surface Impoundments, 88 FR 31982 (May 18, 2023; New Source Performance Standards for Greenhouse Gas Emissions From New, Modified, and Reconstructed Fossil Fuel-Fired Electric Generating Units; Emission Guidelines for Greenhouse Gas Emissions From Existing Fossil Fuel-Fired Electric Generating Units; and Repeal of the Affordable Clean Energy Rule, 88 FR 33240 (May 23, 2023); and Federal Good Neighbor Plan for the 2015 Ozone National Ambient Air Quality Standards, 88 FR 36654 (June 5, 2023).

Specific Costs for EPA to Consider Incorporating in the Proposed Rule's Analysis

Again, we urge EPA to update its analysis to account for the costs needed to make updates to the grid to support HDV electrification. Grid upgrade costs for EV charging will vary by region, neighborhood, cooperative, circuit, and feeder. However, to illustrate the types and ranges of costs that EPA should account for, we provide the following costs sourced from four different cooperative regions, broken down by charge level:

- Residential (Level 1 and Level 2): One out of three households will need an expanded electric panel to accommodate 240 V Breakers. If a household purchases two electric vehicles, then four slots on a breaker will be needed to accommodate this load. The average cost will be approximately $4,000 for a Level 2 residential charger with a panel upgrade.
    - Upgrading panel (20% of panels must be upgraded) ¡V can start around $600
    - Transformer upgrades - $2,600 and climbing
    - Service wire gauge upgrades to accommodate higher amperage - $3,000
- Public (Level 2 and DC Fast Charging (DCFC)): For commercial sites, transformer upgrade needs will vary. Most sites will already have three-phase power available; however, in very rural locations single-phase power will need to be upgraded to three-phase. If transformers do need to be upgraded on a three-phase line, then three transformers will need to be upgraded.
    - Level 2 charger including panel - approx. $4,000 on average
    - National EV Infrastructure Program (NEVI)-Compliant DCFC - approx. $25,000-$150,000
        - Transformer - $25,000 - $40,000 (reflects current prices for three transformers)
        - Service entrance - $3,000-$4,000
        - Metering package (including instrumentation, voltage transformers (PT) and current transformers (CT) - $2,000
        - Line extension, if required (site dependent) - $50,000 - $75,000 [EPA-HQ-OAR-2022-0985-1515-A1, pp. 3-4]

Circumstances vary across cooperatives, but some of these costs will be borne directly by the consumer-members and others will be paid for by the cooperative. Regardless, these costs help to illustrate more accurately the investment it will take to implement on EPA’s proposed rule. [EPA-HQ-OAR-2022-0985-1515-A1, p. 4]

We note that these costs reflect a snapshot estimate in time and are likely to increase, particularly due to the significant challenges and delays utilities are facing in their supply chains, which are contributing to an unprecedented shortage of the most basic machinery and components essential to ensure the continued reliability of the electric grid. Electric cooperatives are waiting a year, on average, to receive distribution transformers. Additionally, lead times for large power transformers have grown to more than three years. And orders for electrical conduit have been delayed five-fold to 20 weeks with costs ballooning by 200 percent year-over-year. As a result, new projects are being deferred or canceled, and electric cooperatives are concerned about their ability to respond to major storms due to depleted stockpiles. We expect these supply chain challenges to persist with the increased demand for electrification projects being incentivized by the U.S. federal government. All these delays will likely impact the cost and timing of charging infrastructure buildout needed to support the HDV fleet electrification envisioned in this proposed rule. [EPA-HQ-OAR-2022-0985-1515-A1, p. 4]

Organization: NTEA - The Association for the Work Truck Industry

MY 2027 Target - EV Infrastructure Needs

The proposal calls for 20% of vocational trucks be a ZEV by MY 2027. This time frame does not seem possible given the resources needed to achieve such a goal in a compressed amount of time. [EPA-HQ-OAR-2022-0985-1510-A1, p. 4]

As an industry, companies involved in the manufacture and distribution of work trucks (manufacturers of truck chassis, bodies, equipment and final assembly) will require EV charging equipment and power that has not previously been required for their facilities. While these producers of work trucks may not need the recharging capacity of a major truck fleet, they will need to provide charging for all of the EV chassis at their facility for assembly or alteration. [EPA-HQ-OAR-2022-0985-1510-A1, p. 4]

Much like truck dealers who will need EV charging infrastructure, anecdotally, NTEA has been informed that one of the biggest initial challenges is the availability of electricity from local utilities. In some cases, EV charging equipment is available but they can't yet be installed without agreement for power from the utility company, which appears could in some cases be multiple years away. [EPA-HQ-OAR-2022-0985-1510-A1, p. 4]

Based on the current statutory and regulatory landscape, it is assumed that the highest initial energy needs for medium- and heavy-duty vehicle charging is likely to occur in those states that have adopted California's Advanced Clean Trucks rule. While prioritizing charging infrastructure along freight corridors within these states may be a prudent approach, many vocational trucks are not necessarily involved in moving freight but rather accomplishing work tasks at whatever location is required – whether it be along a freight corridor or on a side street or in a rural area. [EPA-HQ-OAR-2022-0985-1510-A1, p. 4]

Given the long lead times involved in building power generation capacity and electric transmission systems, the NTEA questions if the aggressive time frames being mandated for the phase-in of medium and heavy-duty vocational trucks is possible. Will the operators of the wide variety of work trucks have access to charging when and where they will need it in order to complete their vocational missions within the existing timeframe? [EPA-HQ-OAR-2022-0985-1510-A1, p. 4]

Organization: RMI

Electric Grid

One of the key challenges to truck electrification is about the ability for the grid to meet electric charging infrastructure demand and this is commonly cited as a key concern in electrifying fleets. Fully electrifying trucking would increase current national electricity consumption by almost 10% and create uneven, local impacts. The electric distribution system will require new infrastructure to support electric truck load.19 By 2035 our grid must be prepared to add 230 TWh of new truck electricity demand, including power for nearly 150,000 fast public chargers and 860,000 depot chargers.20 Building this new infrastructure requires time and costs that are or will soon be the limiting factor in truck decarbonization. Forward-looking fleets, utilities, and regulators are beginning to reimagine business practices, infrastructure planning, and building decisions [EPA-HQ-OAR-2022-0985-1529-A1, p. 8]

19 'Use of electricity,' U.S. Energy Information Administration (EIA), Accessed April 27, 2023, https://www.eia.gov/energyexplained/electricity/use-of-electricity.php.

20 Kahn et al., The Inflation Reduction Act Will Help Electrify Heavy-Duty Trucking, RMI, August 25, 2022, https://rmi.org/inflation-reduction-act-will-help-electrify-heavy-duty-trucking/

There are not that many electric trucks compared with the 750,000 electric passenger cars on the road, but adoption of electric trucks does not look the same as the adoption of electric passenger vehicles.21 While utilities generally support and facilitate electric car adoption, e-truck adoption will be more rapid than what utilities have seen so far due to the fleet nature of trucks. Once a fleet is convinced of e-trucks' reliability, capability, and economics, it will be ready to purchase vehicles. Fleet managers, as professional consumers, can act more decisively than consumers hindered by unfamiliarity and range anxiety, if they are not limited by either the grid or vehicle availability.22 [EPA-HQ-OAR-2022-0985-1529-A1, p. 8]

21 Zachary Shahan, 'US Electric Car Sales Increased 65% In 2022,' CleanTechnica, February 25 2022, https://cleantechnica.com/2023/02/25/us-electric-car-sales-increased-65-in-2022/.

22 Kahn et al., Preventing Electric Truck Gridlock, RMI, 2023 https://rmi.org/insight/preventing-electric-truck-gridlock/?utm_medium=email&utm_source=spark&utm_content=spark-a&utm_campaign=2023_06_01

The truck depots need megawatts of power at a scale that utilities aren't yet mobilized to address. And while providing new power in new places is a big challenge for utilities, it is at least an extension of their core business. For fleets, electrifying a depot can be foreign, an additional new requirement on top of understanding how e-trucks operate differently in the field. The economics of procuring power, installing chargers, and managing charging power and time are just some of the new skills fleets need to succeed with electric trucks. [EPA-HQ-OAR-2022-0985-1529-A1, p. 8]

There are some 'no regrets' actions that can make the process better, but there is no getting around the fact that utilities, regulators, and fleets will need to change their business practices to electrify trucking.23

1. Determine where load growth will be to plan accordingly
2. Streamline procedures with updated regulatory requirements
3. Provide utilities with regulatory incentives to update the grid
4. Embrace proactive grid planning [EPA-HQ-OAR-2022-0985-1529-A1, p. 8]

23 Kahn et al., Preventing Electric Truck Gridlock, RMI, 2023 https://rmi.org/insight/preventing-electric-truck-gridlock/?utm_medium=email&utm_source=spark&utm_content=spark-a&utm_campaign=2023_06_01

Organization: Schneider National Inc.

Grid side improvements do not appear to be factored into the Proposed Rule's costs. The EPA's Proposed Rule assumes grid updates are going to be paid by utility.

- The upfront capital costs for the grid improvements may be paid by the utilities; however, the utilities will undoubtedly seek to recoup the costs via rate recovery. As a result, the costs will ultimately be borne by the utility's customers via rate increases and higher utility bills.
- The costs to upgrade infrastructure at the ZEV charging sites will be solely borne by the owner or user of the site, whether it is an owned site or leased site. [EPA-HQ-OAR-2022-0985-1525-A1, pp. 2 - 3]

Organization: State of California et al. (2)

Our States and Cities do not anticipate significant concerns about the electrical grid's ability to support the additional energy needs created by vehicle electrification. A case study shows that in 2040, battery-electric truck energy needs represent 3 percent of electricity production in the United States in 2021; however, the International Council on Clean Transportation notes that a "3 [percent] increase in grid capacity will not necessarily be needed, since the existing infrastructure can be leveraged through demand management and minor distribution network upgrades."205 There are also efforts underway by utilities and transmission organizations to put electrified vehicles to work for the grid. For example, the public power utilities in Austin, Texas conducted a pilot project with the US Department of Energy that incorporated use of electric vehicles as a way to add stability to the power grid via vehicle-to-grid, or V2G, charging,206 as has San Diego Gas and Electric.207 Ultimately, the decisions needed to respond to a modest increase in energy demand required by increasing numbers of electric vehicles will take place at the state public utility commission, grid operator, and utility level, as they are appropriately situated to plan for and respond to those changes in demand. These are routine plans and adjustments that these entities make as a matter of course. Indeed, utilities may be uniquely well situated to make the "distribution level" updates, and "smart charging and pricing schemes" that will respond to the changing energy needs of increasing electric vehicles.208 And, as EPA correctly notes, the power sector and its regulators have responded to much larger changes in demand—including from increased use of electrical equipment—over similar (or smaller) timeframes.209 [EPA-HQ-OAR-2022-0985-1588-A1, pp.28-29]

The annual rate at which U.S. grid infrastructure needs to expand to maximize the potential of the new clean-energy tax breaks under the Inflation Reduction Act (IRA) of 2022 is 2.3%.2 If expansion continues at the current rate of around 1% a year, 80% of the emissions-reduction potential of those incentives will be lost and CO2 emissions will be 800 million tons a year higher in 2030.3 The advancement of transmission infrastructure will make or break America's energy transition for the freight sector. [EPA-HQ-OAR-2022-0985-1577-A1, p. 4]

Organization: Valero Energy Corporation

Significant investments in charging/fueling infrastructure will also be needed. The CEC has projected that an additional 157,000 chargers will be needed to support California's anticipated electric HD population in 2030—all of these will be DCFC, representing 9,100 additional job-years of dedicated workforce requirements, compounding timeline feasibility challenges. CEC further projects that the HDV charging network will see loads "in excess of 2,000 MW around 5 p.m. on a typical workday," further exacerbating the existing gap between net peak energy demand and existing generation. [EPA-HQ-OAR-2022-0985-1566-A2, p. 41.]

195 https://www.nytimes.com/2022/09/01/us/california-heat-wave-flex-alert-ac-ev-charging.html

Twelve states expressed concerns regarding electrical grid and utility impacts in their DOT-approved state EV Infrastructure Deployment Plans, as summarized below. While the plans primarily focus on infrastructure to be installed along designated alternative fuel corridors, the concerns relating to grid and utility impacts are similarly applicable to depot and truck parking stations. EPA has not accounted for these concerns in its analysis. [EPA-HQ-OAR-2022-0985-1566-A2, p. 41.] [See the table of State Concern on page 41 of docket number EPA-HQ-OAR-2022-0985-1566-A2.]

Additionally, within California there are significant challenges to be overcome in order to build the infrastructure necessary to support freight electrification under the CARB Advanced Clean Trucks and Advanced Clean Fleets rules. The California Public Utilities Commission (CPUC) recently identified the need for an accelerated electrical infrastructure deployment as a challenge for forecasting and planning, with approximately three years lead time needed for statewide planning efforts to be completed and infrastructure authorized.208 Indeed, in the six priority corridors alone, which doesn't account for more rural routes, California would need between 556 and 1,832 public BEV charging stations by 2040.209 For comparison, California currently has approximately 5,000 retail diesel stations statewide as of 2021.210 As a result, there are risks that could negatively impact MD and HD adoption including uncertainty regarding long-term electricity rate, delayed construction of distribution/transmission infrastructure, and differences in charging behavior from what was assumed in the planning stages (which would result in an infrastructure buildout that doesn't align with actual charging behavior).211 Clearly, there will be significant shortfall in resources in California alone to meet the needs of the freight electrification push, let alone the entire nation, as contemplated by the instant proposed rule. [EPA-HQ-OAR-2022-0985-1566-A2, p. 43

Organization: Volvo Group

Nevertheless, governance of the electricity industry is exceedingly fractured in terms of geography, purview, and governing entities, with more than 3,000 separate power/electric utilities across the United States. California stakeholders have had years to gain experience and prepare for this transition. Other states with much less experience and more resistant stakeholders will make it virtually impossible to successfully extend the ZEV penetration rates of the Advanced Clean Truck Regulation to a national level. [EPA-HQ-OAR-2022-0985-1606-A1, p. 7]

Finally, utilization of medium and heavy-duty ZEVs, together with the continued growth in electric passenger vehicles will place unprecedented demand on the grid, particularly during peak hours. While all ZEV owners will be sensitive to charging prices, the elasticity of demand for commercial ZEVs is much more sensitive to electricity price and reliability than for light-duty vehicles. Significant expansion of transmission lines and distribution infrastructure (circuits/feeders) will require utility investment; however current industry norms enable utilities to build additional capacity only after increased demand is assured. This process, while logical for meeting residential and commercial building needs, undermines the assurance fleets will demand before ordering more than a couple of pilot trucks. [EPA-HQ-OAR-2022-0985-1606-A1, p. 8]

Organization: Zero Emission Transportation Association (ZETA)

c. Electricity Generation and Grid Readiness

Transitioning to zero-emission transportation offers a unique challenge to the energy companies that will need to ensure they have ample electricity supply to match EV-driven demand. At minimum, this will require investments in the electricity distribution system to enable the deployment of electric vehicle charging equipment. In some instances, this may also require investing in new energy generation sources and associated distribution system infrastructure to accommodate major EV centers like heavy-duty vehicle depots or co-locate other necessary amenities. [EPA-HQ-OAR-2022-0985-2429-A1, p. 29]

However, this is not the first time electricity providers have navigated increases in electricity demand brought on by new technologies: similar spikes accompanied the mass adoption of now-standard appliances like refrigerators and in-home air conditioners. Still, it will be important to ensure that providers and government agencies can work within their regulatory frameworks to test solutions and upgrade the grid to prepare for future demand increases accompanying greater EV adoption. [EPA-HQ-OAR-2022-0985-2429-A1, p. 29]

This section will discuss the growing energy demands of widespread EV adoption and new potential hotspots for energy demand. It will also use case studies to highlight how electricity providers are preparing for this transition. These case studies showcase solutions that have the potential to revolutionize energy consumption and highlight how electricity providers support customer EV adoption through incentive programs, building infrastructure, and other initiatives. [EPA-HQ-OAR-2022-0985-2429-A1, pp. 29 - 30]

The grid's ability to handle millions of additional EVs hinges on utilities' proactive planning capacity. Granting utilities the flexibility to make proactive upgrades to the electrical grid and facilitate transportation electrification will require careful planning and coordination between regulators and stakeholders. [EPA-HQ-OAR-2022-0985-2429-A1, p. 30]

Regulatory certainty will allow utilities to make the investments necessary to facilitate a smooth EV transition. To invest proactively, rather than in response to firm load, energy providers will need clear insight into multi-year schedules for customer electrification, approval from regulators to recover costs, and/or flexibility to serve loads with non-wire alternatives. [EPA-HQ-OAR-2022-0985-2429-A1, p. 30]

Robust EPA emission standards will provide the regulatory certainty needed to not only ensure vehicle manufacturers continue to invest in EV technologies, but that the entire supply chain supporting the transition to electrification will have a clearer picture of how to plan capital expenditures today to meet the increased demand over the coming years. [EPA-HQ-OAR-2022-0985-2429-A1, p. 30]

i. Anticipated impacts to electricity providers from increased EV deployment

In 2021, the U.S. fleet of electric vehicles used 6.1 terawatt hours (TWhs) of electricity to travel 19.1 billion miles.125 That accounted for just 0.15% of the total national energy generation that year.126 In 2022, the United States produced 4,243 TWhs of electricity.127 To meet the demand of transportation electrification, more generation will be needed to service EVs and electrified vehicle technologies. One estimate suggests it would take roughly 800 to 1,900 TWh of electricity to power all vehicles if they were electric.128 It is important to remember, however, that this new demand will not occur all at once but rather more gradually as EVs continue to displace ICEVs. While achievable, meeting this increase in electricity demand will require significant strategy as electric providers transition to renewable, carbon free resources. [EPA-HQ-OAR-2022-0985-2429-A1, p. 30]

128 "How much electricity would it take to power all cars if they were electric?," USAFacts, (May 15, 2023) accessed June 13, 2023 https://usafacts.org/articles/how-much-electricity-would-it-take-to-power-all-cars-if-they-were-electric/

The key to meeting these energy requirements will be the expansion of renewable energy resources but also the addition of new, zero-emission and low-emission load-following resources like advanced nuclear, carbon capture, long-term energy storage, and green hydrogen. In

2022, electricity generated from renewable sources surpassed coal for the first time in U.S. history.129 At the same time, electricity providers are looking at ways to add low-cost energy storage to increase the availability of non-dispatchable renewable generation such as solar and wind. Currently, renewable energy generates about 20% of all electricity production in the U.S, and renewable sources like solar and wind are expected to account for the majority of new utility-scale electricity generation going forward.130,131 Already, available renewable energy resources in the U.S. are estimated to amount to more than 100 times the nation's current electricity needs.132 [EPA-HQ-OAR-2022-0985-2429-A1, pp. 30 - 31]

129 "U.S. renewable electricity surpassed coal in 2022," Associated Press, (March 28, 2023), accessed June 4, 2023 https://apnews.com/article/renewable-energy-coal-nuclear-climate-change-dd4a0b168fe057f430e37398615155a0

132 "Renewable Energy Resource Assessment Information for the United States," Department of Energy, accessed June 4, 2023 https://www.energy.gov/eere/analysis/renewable-energy-resource-assessment-information-united-states

133 "Yes, the grid can handle EV charging, even when demand spikes," Yale Climate Connections, (March 23, 2023) accessed June 4, 2023 https://yaleclimateconnections.org/2023/03/yes-the-grid-can-handle-ev-charging-even-when-demand-spikes/

Power generation is only one of the considerations when preparing for 100% transportation electrification. In particular, the industry needs to develop its ability to precisely manage demand in real time, including by accurately predicting when and where increases in demand will occur. [EPA-HQ-OAR-2022-0985-2429-A1, p. 31]

It is important to note that energy demand is not constant. Instead, it consists of relatively predictable peaks and troughs throughout the day. High demand consistently occurs between 5:00 PM and 8:00 PM each day, as customers return home, turn up their climate control systems, begin cooking dinner, and turn on other devices.133 System demand peak is typically between 5:00-6:00 PM during the summer, and 7:00-8:00 AM in the winter. As such, EV charging poses minimal impacts to the winter peak hours but could increase summer peaks without managed charging. [EPA-HQ-OAR-2022-0985-2429-A1, p. 31]

ii. Utility-specific planning underway

The following collection of case studies demonstrates how electricity providers in ZETA's membership are preparing for the EV transition and highlights some of their groundbreaking initiatives to support EV adoption in the United States. It should be noted that each provider operates within a regulatory framework that is unique to the state in which it serves. The cases outlined below do not represent the entire portfolio of EV-related products and services offered by these providers. [EPA-HQ-OAR-2022-0985-2429-A1, p. 31]

These examples include programs that exist across the EV supply chain, with earlier examples covering infrastructure planning programs and later examples focusing on programs to engage with EV drivers on their charging needs. [EPA-HQ-OAR-2022-0985-2429-A1, p. 32]

1. Pacific Gas & Electric

As California's largest electric provider, PG&E continues to play an important role in advancing electric vehicle adoption in support of the state's broad climate goals. PG&E works in collaboration with the California Energy Commission and California Public Utilities Commission to plan and approve grid infrastructure upgrades to support this shift to zero-emission transportation. [EPA-HQ-OAR-2022-0985-2429-A1, p. 32]

With nearly 500,000 EVs sold in its service area—one in every seven of all EVs on the road throughout the nation—expansion of PG&E's EV charging network in Northern and Central California is critical to support the State's transition to a clean transportation future. Over the last half-decade, the provider has deployed more than 5,000 EV charging ports across its service area. Additionally, it offers a variety of resources to help accelerate EV adoption among customers, and PG&E is working collaboratively with vehicle manufacturers to develop vehicle grid-integration technologies. [EPA-HQ-OAR-2022-0985-2429-A1, p. 32]

Grid planning requires precise forecasts to ensure electric infrastructure is available to support future demand. Pre-existing electricity demand (load) forecasts did not provide the geographical granularity needed to best plan for grid investments. PG&E could allocate the load to residential charging locations; however, larger charging loads that are often not associated with existing service points—such as public charging systems—lacked a methodology to be accounted for in long-term forecasting efforts. Without the ability to identify future EV demand with geographic and temporal accuracy, PG&E was limited in its ability to plan future grid capacity. [EPA-HQ-OAR-2022-0985-2429-A1, p. 32]

Lacking a long-term geospatial forecasting methodology, PG&E was primarily dependent on customer requests for service to inform where EV load would materialize. This reliance on customer requests led PG&E to reactively develop capacity solutions to serve load requests. Given the long lead times often associated with capacity projects and the relatively fast pace at which customers wish to build EV charging infrastructure, there would be instances where energization timelines exceeded the requested energization date from customers. This can occur with large load applications associated with public DCFC charging stations or large fleets, which have the potential to exceed the maximum capacity of existing electrical infrastructure in those areas. [EPA-HQ-OAR-2022-0985-2429-A1, p. 32]

Identifying a need for a more proactive approach, PG&E set out to improve its forecasting abilities to increase the clarity of where and when EV loading is most likely to materialize. This enables PG&E to build capacity in advance of service applications being received. Although research indicates that customer preference for EVs is increasing, and there are many regulations and incentives which further support the transition to EVs, there are still uncertainties around the pace of adoption. This impacts how the EV load will manifest on the electric grid. For this reason, a solution capable of supporting a variety of forecast scenarios was necessary for success. PG&E commissioned a multi-faceted project focused on three common categories of EV charging load: 1) public DCFC & Level 2 charging stations, 2) residential EV charging, and 3) fleet charging. [EPA-HQ-OAR-2022-0985-2429-A1, pp. 32 - 33]

Detailed analysis and machine learning modeling and testing were applied to each of these focus areas to predict where EV charging is most likely to occur. These analyses were performed at the premise level and resulted in over 5 million potential growth points across PG&E's service territory that were integrated into existing distribution planning software. This created a dynamic tool that can adapt to a variety of forecast inputs, such as system-level adoption forecasts, EV charging behaviors, and charging infrastructure assumptions. These scenarios can be integrated into PG&E's distribution planning processes. [EPA-HQ-OAR-2022-0985-2429-A1, p. 33]

Developing a solution that was easily integrated into existing distribution planning processes and software was critical for successful implementation. Involving PG&E forecasting and asset planning teams in the development of the EV forecasting tool, as well as reviewing and approval of the major inputs and assumptions used to develop forecast scenarios, ensured alignment in the scenarios generated. [EPA-HQ-OAR-2022-0985-2429-A1, p. 33]

In figure 7 above, the difference in magnitude of localized EV load in the year 2035 can be seen in a relatively low EV adoption scenario (2020 California Energy Commission (CEC) Integrated Energy Policy Report (IEPR Mid)) and a higher policy-based scenario based on the California Air Resources Board (CARB) Multiple Source Strategy (MSS) forecast. Grid planners can use this tool to investigate and solve for circuit level impacts of EV load growth. [EPA-HQ-OAR-2022-0985-2429-A1, p. 34.] [See Docket Number EPA-HQ-OAR-2022-0985-2429-A1, page 34, for Figure 7. This Figure was redacted]

Using varying EV forecast scenarios, PG&E was able to assess the localized grid impacts from high EV adoption scenarios that are better aligned with state transportation electrification goals and policies. PG&E assessed how various levels of EV adoption, as well as the impacts that changing charging behaviors (such as on vs. off-peak charging), can have on grid needs. Early analysis has indicated that off-peak charging can reduce near-term grid constraints. In the future, this may lead to new circuit peaks and capacity constraints that must be addressed. [EPA-HQ-OAR-2022-0985-2429-A1, p. 34]

Results from these analyses were helpful in advocating for approval of higher transportation electrification forecasts with regulators and the state energy commission, which are ultimately used for electric grid planning. PG&E has also used these forecasts to produce directional assessments of the resources needed to support capacity investments included in their long-term capital planning. PG&E continues to work to improve its forecasting and planning capabilities. Still, the solutions implemented to date have enabled a more robust approach that will allow PG&E to continue to support its customers' electrification transition. [EPA-HQ-OAR-2022-0985-2429-A1, pp. 34 - 35]

2. Vistra

Electricity generators are making the transition to low- and no-carbon-emitting sources of energy as quickly as possible in response to investor, regulator, policymaker, and customer expectations. This transition is backed by a strong business case for doing so, as renewables and battery storage systems are able to compete effectively with fossil fuel generation and provide benefits to the power grid. The International Energy Agency expects renewable energy resources to provide 18% of the world's power by 2030, up from 11.2% in 2019.134 However, certain renewable energy sources—such as solar and offshore/onshore wind—are dependent on weather conditions and the time of day. This means deploying these resources at scale will require accompanying battery technology to ensure electric grid reliability. [EPA-HQ-OAR-2022-0985-2429-A1, p. 35]

134 “Modern renewables,” IEA, accessed June 4, 2023 https://www.iea.org/reports/sdg7-data-and-projections/modern-renewables

Energy storage allows for the integration of more intermittent resources by storing electricity until it is needed. It also augments existing energy generation by allowing excess energy to be produced when low demand is stored until demand peaks. Energy storage can provide benefits beyond emissions reduction, including cost-savings for consumers, reliability, and backup and startup power during extreme events. [EPA-HQ-OAR-2022-0985-2429-A1, p. 35]

Vistra operates the Moss Landing Energy Storage Facility in California, the largest of its kind in the world, and is pursuing an expansion that will bring 750 MW online in the second quarter of 2023.135 This facility is particularly valuable in California, where the swift transition to renewable energy, paired with a constantly growing demand for electricity, illustrates the need for reliability in the electric grid and the role energy storage can play. As of 2021, non-hydroelectric renewables provide approximately 35% of California’s electricity, and electricity demand has increased due to a variety of factors, including severe weather events, widespread electrification, and electric vehicle deployment.136 This combination was put to the test in September 2022, when the state faced its most extreme September heat event in recorded history. This weather event put unprecedented strain on the electric grid and set records for electricity demand. To the surprise of many, the lights stayed on. During that event, batteries, including Vistra’s Moss Landing facility, provided about 4% of supply—over 3,360 MW, more than the Diablo Canyon nuclear power plant (the state’s largest electricity generator)—during the peak demand, averting rolling blackouts. A report from the California Independent System Operation (CAISO) following the September 2022 event specifically highlighted the increase in energy storage resources as a key factor that supported the grid’s reliability.137 As a comparison, the August 2020 heat wave, which occurred when California’s energy storage resources were few and far between, resulted in rolling blackouts over multiple days. [EPA-HQ-OAR-2022-0985-2429-A1, pp. 35 - 36]

135 “Vistra Announces Expansion of World’s Largest Battery Energy Storage Facility,” Vistra, accessed June 4, 2023 https://investor.vistracorp.com/2022-01-24-Vistra-Announces-Expansion-of-Worlds-Largest-Battery-Energy-Storage-Facility

136 “2021 Total System Electric Generation,” California Energy Commission, accessed June 5, 2023 https://www.energy.ca.gov/data-reports/energy-almanac/california-electricity-data/2021-total-system-electric-generation

137 “California ISO posts analysis of September heat wave,” California ISO, accessed June 5, 2023 http://www.caiso.com/Documents/california-iso-posts-analysis-of-september-heat-wave.pdf

Recognizing that the replacement of fossil fuel-powered assets with zero-carbon resources is not a one-to-one exchange, Vistra is working to maintain reliability by using energy storage and installing zero-carbon investments on the sites of retired or soon-to-be-retired fossil fuel plants. This also ensures that communities do not lose key energy supplies or ongoing tax revenue. Vistra is also focused on ensuring that existing zero-carbon generation remains online, such as the Comanche Peak Nuclear Power Plant in Texas, which is currently going through the Nuclear Regulatory Commission’s relicensing process to continue operations through 2053. This high-performing plant is able to produce power—rain, snow, or shine—increasing grid reliability for Texans and making it a keystone generator for the Electric Reliability Council of Texas (ERCOT) grid. Alongside the transition to cleaner generation resources, Vistra has been able to maintain reliability for its consumers and ensure that individuals and businesses are able to keep their lights on, even during extreme weather events. During Winter Storm Uri in Texas in 2021, Vistra's plants produced between 25-30% of the power on the grid during the storm, far beyond its ~18% market share. [EPA-HQ-OAR-2022-0985-2429-A1, p. 36]

As the energy supply mix shifts toward low- and zero-carbon resources, energy storage will fill the reliability gap and allow that mix to evolve more reliably and flexibly. The Inflation Reduction Act provides new tax incentives for investment in energy storage technologies and resources to support the R&D of advanced and long-duration energy storage technologies. These investments will enable the deployment of utility-scale energy storage and add reliability to the grid, no matter what the future energy generation mix looks like. It is crucial that the United States continues to make the transition to a carbon-neutral economy and electric grid in a way that ensures the continued reliability of the grid at a reasonable cost to consumers. [EPA-HQ-OAR-2022-0985-2429-A1, p. 36]

3. Southern California Edison: Preparing the Grid for EV Adoption

About 40% of the nation's electric vehicles, more than 1.3 million, have been sold in the state of California. More than 430,000 of those are in SCE's service area alone. Many have expressed doubts that the grid is ready for the energy demand created by the need to charge so many EVs, but electric power companies, including SCE, are keeping up with increasing levels of adoption. [EPA-HQ-OAR-2022-0985-2429-A1, p. 36] In anticipation of growing EV demand in Southern California, SCE is continuously taking the steps to upgrade the grid and promote customers' transition to electric transportation and proactively solve near-term issues, while also undertaking long-term investments to ensure the grid is ready for all levels of anticipated electrification adoption. [EPA-HQ-OAR-2022-0985-2429-A1, p. 37]

Solving near-term challenges

One way SCE is addressing the near-term issues is its Power Service Availability (PSA) initiative for Transportation Electric service

- SCE is focusing on (1) improving its internal processes to streamline interconnection, (2) engaging fleet operators to better understand their plans for electrification, (3) improving its ability to forecast and assess the impacts of transportation electrification (TE) growth, and (4) leveraging new technologies as grid infrastructure solutions
- Because some projects require more time than others to build, SCE is encouraging fleet owners to engage with the utility early in the process so that SCE can better understand and plan for the fleets' needs [EPA-HQ-OAR-2022-0985-2429-A1, p. 37]

SCE is also improving how we partner with customers to meet their needs.

- This includes streamlining buildout, developing deeper customer engagements that include rate planning and load management education, and right-sizing grid solutions to meet the expected charging demand growth in both the near and long term. These efforts will provide more innovative and customer-focused solutions. [EPA-HQ-OAR-2022-0985-2429-A1, p. 37]

In addition to customer project deployment, SCE has also pushed to accelerate EV adoption through customer-side infrastructure programs such as Charge Ready for light-duty vehicles.

- Through its Charge Ready program, SCE installs, maintains, and covers installation costs for charging infrastructure while participants own, operate, and maintain the charging stations. For those ready to invest in EV charging for medium- and heavy-duty vehicles, SCE's Charge Ready Transport program similarly offers low- to no-cost site upgrades to support the installation. The program provides funding to help electrify semi-trucks, buses, and delivery vehicles, among others. Through its Charge Ready programs, SCE has installed more than 3,000 charging ports throughout its service area and is targeting 30,000 charging ports by 2026. [EPA-HQ-OAR-2022-0985-2429-A1, p. 37]

SCE's Transportation Electrification Advisory Services program is also available for commercial customers considering electric transportation options.

- On top of offering educational webinars and workshops, the program also offers to develop site-specific EV-readiness studies to help determine the feasibility of proposed projects and grant writing assistance to help customers secure zero-emission vehicle grants. [EPA-HQ-OAR-2022-0985-2429-A1, p. 37]

Long-term Planning and investing in the grid for TE

SCE is improving the value of EV adoption forecasts used for grid planning by assessing where, when, and how much EVs are likely to charge.

- SCE led the West Coast Clean Transit Corridor Initiative, composed of nine other electric utilities and two agencies representing more than two dozen municipal utilities, to conduct a multi-phase and multi-year research study to forecast EV truck populations and determine the proper number and size of highway charging sites. Subsequent phases of this initiative are supporting internal planning operations across the participating utilities.
- SCE developed a new forecasting approach for Medium-Duty / Heavy Duty (MDHD) vehicles for the recent General Rate Case (GRC) Application.
    - Because MDHD electrification is still nascent, current forecasting methodologies that are based (in part) on historical adoption are insufficient
    - For the GRC, SCE's new forecasting methodology leverages MDHD fleet industry data to more accurately predict MDHD electrification adoption and corresponding grid needs
    - SCE (and the IOUs) are collaborating with CPUC on a new "Freight Infrastructure Planning" (FIP) Framework to further address planning for MDHD
- SCE is working to expand the current distribution planning forecast window from 10 years to 20 years. Developing and implementing an interagency-sponsored forecast that spans 20 years for distribution will bring benefits, such as:
    - Identifying long lead time projects that are needed beyond the 10-year horizon
    - Identifying important land acquisition needs
    - Informing how the development of infrastructure may need to be levelized to practically achieve the scale of development required by achieving state ZEV policies and GHG targets
- SCE has proposed robust investments in its GRC application to support TE adoption and load growth.
    - The investments proposed are designed to ensure long-lead infrastructure projects (such as new or expanded substations) will be completed when load growth

arrives. The plan especially focuses on high TE locations: freight corridors, fleet hubs, Port of Long Beach, etc.

- Specific TE-focused projects include: [EPA-HQ-OAR-2022-0985-2429-A1, p. 38.] [See Docket Number EPA-HQ-OAR-2022-0985-2429-A1, pages 38-39, for Figure of TE-focused projects]

4. Con Edison

Con Edison is helping to accelerate New York State's transition to clean transportation and EV adoption through grid and customer investments that support buildout of a widespread charging network. The Company's PowerReady Program provides incentives to connect thousands of new public and private charging stations to the electric grid. Authorized by the New York State Public Service Commission's July 2020 Order Establishing Electric Vehicle Infrastructure Make-Ready Program and Other Programs, the program offsets the electric infrastructure costs associated with installing chargers for light-duty EVs, including cars and small vans. To date, nearly 4,000 Level 2 and 175 DCFC chargers have been installed under the program, with the goal of installing 18,539 Level 2 and 457 DCFC chargers by 2025, with the potential for significant expansion of the program budget and goals as recently recommended by the New York State Department of Public Service Staff. The Company provides a similar pilot program for medium- and heavy-duty (MHD) vehicles, and a full-scale program is being considered in the recently launched New York State proceeding to address barriers to MHD charging infrastructure (MHD Proceeding). [EPA-HQ-OAR-2022-0985-2429-A1, p. 39]

Along with these infrastructure incentive programs, Con Edison also offers the SmartCharge New York managed charging program that provides incentives for personal drivers to charge outside of grid peak periods and the Company is launching a commercial managed charging program later this year including eligibility for all fleets, public stations, and multi-unit dwellings. SmartCharge New York is discussed below as an example of how managed charging can help mitigate the impact of EV charging on the grid. [EPA-HQ-OAR-2022-0985-2429-A1, p. 39]

An essential step in EV charger buildout is interconnection with the grid. Con Edison has developed dedicated teams that support the growing number of EV charging interconnections, including those that provide load evaluation, engineering review, project queue management, and incentive deployments. The Company is implementing multiple efforts to improve the customer experience and speed interconnection timelines and will continue to identify and implement efficiencies and improvements. For example, the Company provides pre-application advisory services for fleets and other customers to evaluate site feasibility and understand electric fueling costs, automates internal processes such as service rulings for smaller stations, and is coordinating with permitting agencies to identify and resolve challenges. Con Edison provides load-serving capacity maps to help those seeking to install EV charging infrastructure identify suitable sites with adequate grid capacity. [EPA-HQ-OAR-2022-0985-2429-A1, pp. 39 - 40]

While Con Edison is supporting installation of increasing numbers of EV chargers under its programs today, the Company is also working to evolve its robust planning processes to prepare for the ramp in clean transportation loads. These loads are expected to drive significant grid impacts in New York State and ambitious emissions regulations will further accelerate an already rapidly growing EV market, with the exact timing in the inflection point unknown. The timeline to install EV chargers is relatively short compared to that of other new customer infrastructure, such as a new building, while the buildout of utility-side grid infrastructure to meet the significant increase in demand from EV chargers requires longer timelines, sometimes of 5 to 7 years. A proactive grid planning process to meet near-term needs and build out the grid in advance to support long-term growth in the deployment of EVs is being considered in the New York State MHD Proceeding. Con Edison, along with other NY State Utilities, filed comments proposing a proactive utility infrastructure planning framework to prepare the grid in advance of future transportation electrification needs. [EPA-HQ-OAR-2022-0985-2429-A1, p. 40]

SmartCharge New York Managed Charging Case Study

In 2017, Con Edison launched SmartCharge New York program with the goal of instilling gridbeneficial charging behavior in parallel with the upswing in electric vehicle adoption. The goal was to influence driver behavior at the inflection point of transitioning from combustion-engine fueling to electric battery charging and have drivers default to grid-optimizing charging activity. Program participants received a free cellular-enabled device that plugs into the vehicle's diagnostic port that allowed Con Edison to track time, energy, and power consumed when charging in the utility's service territory. Incentives encourage drivers to 1) avoid charging during the system peak (2 PM to 6 PM) during summer weekdays from June to September, and 2) charge overnight from 12 AM to 8 AM. Incentives were initially paid off-bill through gift cards to the customer's business of choice, such as Amazon, Starbucks, or Home Depot. [EPA-HQ-OAR-2022-0985-2429-A1, p. 40]

As electric vehicle adoption continues to rise, managing charging behavior will grow increasingly important in maintaining a healthy and reliable grid. Since its inception, the SmartCharge New York program has evolved to meet customer needs and program objectives. Starting in 2023 for example, the program was overhauled to allow participation through a mobile application and payments are now issued through Venmo or Paypal, in line with participant feedback. This shift also changed the way the program collects data, favoring more cost-effective vehicle onboard telematics or networked electric vehicle supply equipment such as a Wi-Fi-enabled charger or charging cable. This enables the program to scale efficiently with the market and give a greater number of drivers insight into their behavior and how that activity translates to incentive earnings. [EPA-HQ-OAR-2022-0985-2429-A1, pp. 40 - 41]

In light of the EPA announcement of its heavy-duty and light/medium-duty proposed emissions standards, Con Edison released the following statement:

"Con Edison applauds the Environmental Protection Agency's efforts to rev up the market for electric vehicles, which will improve the air in the communities we serve and help in the fight against climate change. A rapid shift to mass EV adoption looks more achievable all the time, with vehicle options expanding and new charging stations being built across New York City and Westchester County, including locations that serve the needs of disadvantaged communities. Con Edison will continue to support the EV market's development through investment in the grid and by offering a range of programs, from incenting new chargers to managing the grid impact by rewarding drivers for charging overnight."138 [EPA-HQ-OAR-2022-0985-2429-A1, p. 41]

138 "Con Edison Supports Effort to Encourage Electric Vehicle Adoption," Con Edison Media Relations, (April 12, 2023) accessed June 5, 2023 https://www.coned.com/en/about-us/media-center/news/2023/04-12/con-edison-supports-effort-to-encourage-electric-vehicle-adoption

5. SRP

When EVs were still in the early stages of adoption, SRP recognized the importance of exploring ways to identify EV households and analyze their charging behavior in order to help prepare for greater EV uptake in the future. It was also important to begin engaging customers who were EV drivers in order to understand their interests and their charging patterns and assess ways to influence charging behaviors. [EPA-HQ-OAR-2022-0985-2429-A1, p. 41]

In 2014, SRP launched "EV Community" (EVC)—a program that offers customers a $50 bill credit for each EV they register (up to two vehicles per household)—as a means to incentivize EV drivers to identify themselves and engage with SRP. Participants provide basic information about the electric vehicle and the type of charger they use. This provides a way for SRP to learn more about EV customers and their charging behavior and needs while offering them an incentive to help support EV growth in the region. There are currently more than 7,500 customers enrolled in the program. [EPA-HQ-OAR-2022-0985-2429-A1, p. 41]

While EVC members only account for a small number of total EV households, they are a fair overall representation of the EV customer base since all price plans are included, as well as households with one vs. two EVs. The program offers SRP a good platform for analysis, including the type of cars they drive (PHEV, BEV, brand, etc.) and the charge levels they use. In addition, SRP found that EVC members are willing to share information and are eager to participate in future pilot programs. [EPA-HQ-OAR-2022-0985-2429-A1, p. 42]

The EVC program also provides SRP with a method and channel to promote their Electric Vehicle Price Plan, a special time-of-use pricing plan which offers EV drivers the most opportunity to save on EV charging costs by charging during super off-peak times (between 11 PM and 5 AM). Load research has shown that this program has been highly effective at shifting EV charging loads away from peak periods. [EPA-HQ-OAR-2022-0985-2429-A1, p. 42]

The EVC program has helped SRP plan and prepare the grid for widespread EV adoption by enabling them to:

- Anticipate load growth. A pilot study with EVC members that monitors their EV driving and charging behavior through data telematics devices enables SRP to estimate typical consumption and charging load profiles per EV.
- Understand the impacts of EV charging on the grid. EVC data is used to model the impacts of EV charging on the electric grid, identify when transformers and wires may need to be upgraded, and understand when and how customers need to charge.
- Recruit for Managed Charging pilot programs. The EVC program and channel have enabled SRP to recruit participants for additional Managed Charging pilot programs to test other active control technologies to control EV charging load on the grid.
- Survey participants for insights. EVC members are surveyed regularly to get more data on their charging behaviors, including their use of home, workplace, and public charging and their satisfaction with EVs overall.
- Engagement. EVC participants receive regular newsletters and other communications with EV-related information. [EPA-HQ-OAR-2022-0985-2429-A1, p. 42]

6. Duke Energy

Electric fleet commitments are increasing as companies with ambitious sustainability goals work to decarbonize operations. Fleet owners are also seeking ways to take advantage of the cost savings available by transitioning to EVs. However, programs for fleet electrification and managed charging options are still limited to date. [EPA-HQ-OAR-2022-0985-2429-A1, p. 42]

When transitioning to an electric fleet, it is important that fleet managers understand the full scope of charging multiple vehicles while maintaining fleet operations and that larger MHDVs bring with them additional factors to consider. Fleet owners who have electrified fleets without consulting experts or an electric provider have likely been experiencing avoidable operational and technological issues. Long-term energy cost and performance risk are also potential issues for fleets and can hinder mainstream fleet electrification technology development if not managed correctly. [EPA-HQ-OAR-2022-0985-2429-A1, pp. 42 - 43]

Duke Energy's significant experience and large customer base make it well-positioned to design and implement fleet electrification and charging programs. Duke Energy is building a first-of-its-kind performance center that will model and accelerate the development, testing, and deployment of zero-emission light-, medium-, and heavy-duty commercial electric vehicle EV fleets. The site will be located in North Carolina at Duke Energy's Mount Holly Technology and Innovation Center and incorporate microgrid integration. [EPA-HQ-OAR-2022-0985-2429-A1, p. 43]

The fleet electrification center will provide a commercial-grade charging experience for fleet customers evaluating or launching electrification strategies—reinforcing reliability, clean power, and optimization by integrating solar, storage, and microgrid controls software applications. The center will be connected to both the Duke Energy grid—charging from the bulk electric system—and to 100% carbon-free resources through the microgrid located at Mount Holly. This project is the first electric fleet depot to offer a microgrid charging option. [EPA-HQ-OAR-2022-0985-2429-A1, p. 43]

In addition to fleet charging, the site will also function as an innovation hub, allowing Duke Energy to collect data around charger use, performance, management, and energy integration with various generation resources. It will also allow for the development of managed charging algorithms for fleets connected to the bulk power system or integrated with renewables and storage—which can be utilized to minimize the upgrades needed to the distribution system, easing the transition to electrifying fleets. Identifying EV charging technologies and how they may be used to power any type of fleet with vehicles (ranging from class 1) will help develop a model to show the industry a clear, integrated, and cost-effective path to fleet electrification. [EPA-HQ-OAR-2022-0985-2429-A1, p. 43]

Duke Energy is teaming up with Daimler Truck North America and Electrada on this importantwork. Electrada, an electric fuel solutions company, is providing funding for research and demonstration efforts. For fleets seeking to electrify, Electrada invests all required capital "behind the meter" and delivers reliable charging to the fleet's electric vehicles through a performance contract, eliminating the complexity and risk that fleets face in transitioning to this new source of fuel. Electrada's investment in the depot allows Duke Energy to focus on programs that simplify adoption for electric fleet customers and distribution system performance to support the predictable addition of electric load over time. [EPA-HQ-OAR-2022-0985-2429-A1, p. 43]

By the end of 2023, fleet operators will be able to experience a best-in-class, commercial-grade fleet depot integrated with energy storage, solar, and optimization software. Moving to zero-emission vehicles in this sector allows North Carolina to seize the large economic potential of the transition and generate billions in net benefits for the state. Projects like Duke Energy's fleet performance center will be key for fleet owners across the state to take advantage of the cost savings of transitioning to electric vehicles. That said, fleet owners exploring electrification should engage their electricity provider early and often to identify and address site-specific considerations. As fleet electrification accelerates, it will be important for electricity providers and policymakers to identify best practices to proactively plan for fleet electrification, including readying the distribution grid. [EPA-HQ-OAR-2022-0985-2429-A1, pp. 43 - 44]

7. Xcel Energy

Xcel Energy is committed to electrifying all of its light-duty fleet and 30% of its medium and heavy-duty fleet by 2030, equating to over 2,500 EVs. It's part of their vision to be a net-zero energy provider by 2050 and enable one out of five vehicles to be electric in the areas they serve by 2030. This will save customers $1 billion annually on fuel by 2030 and deliver cleaner air for everyone. [EPA-HQ-OAR-2022-0985-2429-A1, p. 44]

With a fleet that includes iconic bucket trucks, all-terrain service vehicles, and a host of pickup trucks and pool cars across eight states, achieving these goals will be no small feat, but an important one. There are notable hurdles, yet evolving technology presents solutions. [EPA-HQ-OAR-2022-0985-2429-A1, p. 44]

Electrifying the Marquee Fleet Vehicle

Xcel Energy is the first electric provider in the nation to add an all-electric bucket truck to its fleet. The truck features two electric sources: one for the drivetrain and one for the lift mechanism. It has a 135-mile driving range and can operate the bucket for an entire workday on a single charge. Crews are collecting data from real working conditions in Minnesota and Colorado that will be used to inform further improvement to the vehicle's technology and operation. [EPA-HQ-OAR-2022-0985-2429-A1, p. 44]

Optimizing Charging to Minimize Grid Impacts

To support a growing electric fleet, over 1,200 EV chargers must be brought into service by 2030, which will result in an electric load increase of 71 megawatts. Charge management techniques enable low-cost charging for this growing electric fleet. It's a sophisticated approach to optimize charging times by using time-of-day and grid demand efficiencies and builds on the expertise Xcel Energy has developed through offering managed charging programs to customers in multiple states. [EPA-HQ-OAR-2022-0985-2429-A1, p. 44]

For fleets, overnight charging schedules make the most sense. Demand and rates are lower, and renewable wind sources are ample at that time. Yet, fast charging outside of these time periods may be required to help larger vehicles make it through a workday. This is when charging schedules need to be customized and highly specific. [EPA-HQ-OAR-2022-0985-2429-A1, p. 45]

Enabling Cleaner Service Calls Through Bucket Truck Technology

Xcel is also taking immediate action on other high-impact emission reduction opportunities, using technologies such as electric power take-off, idle mitigation, and solar systems to power jobsite tools.

- Electric power take-off (ePTO) - An ePTO system is a device that uses battery power. It's similar to an EV, but instead of moving the vehicle down the road, it powers equipment and tools to avoid engine idling at the job site. These devices are recharged by plugging into the same chargers that EVs use.
- Idle mitigation - An idling truck can consume 1.5 gallons of gas each hour. Idle mitigation on Xcel Energy's utility bucket trucks works by automatically shutting down the gas-powered engine when the vehicle is not in use or when the engine is idling for too long. This helps to reduce emissions and conserve fuel. [EPA-HQ-OAR-2022-0985-2429-A1, p. 45]

Fleet Electrification Solutions for Customers

Xcel Energy's experience and expertise with fleet electrification doesn't stop with their own fleet. They have developed a mix of customer programs across service areas to support fleet electrification for businesses and communities. These customer-centric solutions enable sophisticated planning, lower upfront costs with various rebates and incentives, and minimize impacts to the grid. [EPA-HQ-OAR-2022-0985-2429-A1, p. 45]

Xcel's approach for commercial EV fleet development includes:

- Advisory services: Xcel offers a "white-glove service" to meet customers where they are on their electrification journey by guiding them through customized planning for their infrastructure needs. For fleet operators, this includes a free assessment to help them determine the best path to electrify their fleet and advise them on future electric fleet considerations such as charging best practices.
- Infrastructure installation: Xcel designs and builds EV supply infrastructure to support charging station installations at minimal to no cost to customers.
- Equipment recommendations and rental options: Xcel also provides recommendations for charging equipment and offers customers the option to purchase their own qualifying vehicle chargers or rent them at a monthly fee that includes installation and maintenance.
- Grid continuity: Xcel designs long-term clean energy resource and distribution plans to consider the future impact of new EV load to ensure ongoing grid stability, reliability and affordability.
- Equitable opportunities: Xcel supports EV adoption in higher emissions communities and income-qualified neighborhoods through rebates and incentives. This includes facilitating the electrification of carshare, refuse trucks, school buses, paratransit vehicles, and other fleets operating in these disproportionately impacted communities. [EPA-HQ-OAR-2022-0985-2429-A1, pp. 45 - 46]

Fleet electrification is a key component of Xcel Energy's larger vision, which includes enabling zero-carbon transportation by 2050 across our eight-state service footprint. This long-term strategy balances affordability with sustainability across the entire grid. It's why Xcel is dedicated to assisting fleet managers across the ecosystem in providing fleet electrification solutions that empower and inspire a clean energy future while also leading by example. [EPA-HQ-OAR-2022-0985-2429-A1, p. 46]

iii. Transmission

A critical part of ensuring a smooth transition to an electrified heavy-duty sector will be a robust build out of high-voltage transmission lines. Doing so will also enable increased penetration of renewables into the grid mix, helping to further improve the environmental and climate benefits of electric vehicles. While progress in this space has historically been slow and bogged down by procedural delays, there are some signs of progress. In April 2023, the U.S. Bureau of Land Management approved a 732-mile transmission line, which will carry wind energy from Wyoming through to Nevada.139 Also in April 2023, a Maine court granted approval to restart work on the 145-mile New England Clean Energy Connect project, which will carry hydropower from Canada to New England.140 The line is expected to carry up to 1,200 megawatts of power. [EPA-HQ-OAR-2022-0985-2429-A1, p. 46]

139 "US approves $3bn Wyoming-Nevada power line," (April 12, 2023) accessed May 15, 2023 https://www.power-technology.com/news/us-approves-3bn-wyoming-nevada-power-line/#:~:text=The%20US%20BLM%20has%20given,blustery%20Wyoming%20through%20to%20Nevada.&text=US%20officials%20on%20Tuesday%20gave,running%20from%20Wyoming%20to%20Nevada

140 "Maine court greenlights embattled $1B transmission line," (April 17, 2023) accessed May 17, 2023 https://subscriber.politicopro.com/article/eenews/2023/04/21/maine-court-greenlights-embattled-1b-transmission-line-00093087

Electricity transmission is also a key focus of the Biden-Harris Administration. In May 2023, the administration published its plan to decrease permitting timelines for new transmission projects, among other key items.141 Also in May 2023, the U.S. Department of Energy proposed a rule on designating National Interest Electric Transmission Corridors.142 There will also be a role for Congress to play in improving transmission permitting times and this is a policy area where some bipartisan support exists. [EPA-HQ-OAR-2022-0985-2429-A1, pp. 46 - 47]

141 "FACT SHEET: Biden-.Harris Administration Outlines Priorities for Building America's Energy Infrastructure Faster, Safer, and Cleaner," (May 2023) https://www.whitehouse.gov/briefing-room/statements-releases/2023/05/10/fact-sheet-biden-harris-administration-outlines-priorities-for-building-americas-energy-infrastructure-faster-safer-and-cleaner/

142 88 FR 30956

EPA Summary and Response – Feasibility of Timing[466]:

Summary:

EPA received comments regarding the ability of the grid to grow and supply the power needed to charge HD BEV. General concerns with grid capability (based on current hardware or its age) and timely grid build out were voiced by American Free Enterprise Chamber of Commerce (AmFree), American Highway Users Alliance, American Petroleum Institute (API), American Trucking Associations (ATA), Dana Incorporated (Dana), Transfer Flow, Inc., MEMA, and Missouri Farm Bureau (MOFB). American Fuel and Petrochemical Manufacturers (AFPM) and AmFree stated that EPA should analyze the changes required and demonstrate that the grid can grow sufficiently to support this policy. Additionally, Clean Fuels Development Coalition and AFPM state that EPA has not accounted for the time and resources required to permit, site, construct (with usual delays), and operate the grid improvements required for both HD and LD. (We note that AFPM's comments on the LD rule driving level 2 charger load in neighborhoods pertains to a different rulemaking; however, we are addressing here the question

[466] Note that issues relating to timing and adequacy of hydrogen infrastructure are addressed separately in RTC 8.1.

of the combined effect of the HD and LD rules on the grid). Comments by National Association of Manufacturers put the time needed for infrastructure transmission build out at half a century based on their assumption of 57% growth required by 2035. Comments expressing concern regarding location - specific power distribution for HD BEV, such as highways (including alternative fuel corridors), rural areas, remote areas, and densely populated areas, were received from Alliance for Vehicle Efficiency (AVE), American Trucking Associations (ATA), Daimler Truck North America LLC (DTNA), MEMA, RMI, and Valero. These comments stated that more detailed regional information is required to understand the grid distribution build out challenges. Specific concerns were identified with remote areas with minimal power that may not have sufficient excess power available as well as densely populated industrial areas that, although they already have significant power available, they do not have sufficient excess available power. MEMA shares a concern that heavy trucks operating away from infrastructure will require generators on site if they are switched to BEV.

AFPM noted that one supercharger equals the power need of 70 air conditioners which points out how the HD BEV need may drive a grid distribution shortfall. AmFree echoes this concern when they state that a modest fleet of HD BEV would require 4 GWh/year that existing grid connections would not be able to handle. They also point out that high energy stations could require a new substation requiring 4 years to install or they could require a transmission interconnection taking 8 years to complete. Daimler Truck North America LLC (DTNA) calls electrical infrastructure build out the biggest barrier for adoption of HD BEV. Manufacturers like DTNA shared their concern that they don't control the infrastructure buildout and there is nothing that obligates the utilities to deliver. DTNA does not believe the infrastructure build out will happen quickly enough without major regulatory and/or legislative action. One of DTNA's concerns is that utility infrastructure planning is in the 5-10 year timeframe, much farther out than fleets planning on adopting HD BEV, making alignment difficult.

Comments by AVE, Arizona State Legislature, NACS, and Delek US Holdings, Inc., and Valero focused on the challenge of delivering the large amount of power required for any individual charging station. NACS focused concern on charging stations possibly requiring 10 MW of power. ASL shared a similar concern in that a charging station could require the power of a data center or small town. Valero shared concern on the grid capability based on comments by California Energy Commission regarding peak demand at 5 pm and based on input from 12 states in their state EV Infrastructure plans.

Other comments focused concern on the complexity and number of stakeholders required to implement grid buildout. Volvo states that the large number of utilities, compounded with different geography and governing bodies, will make it impossible to extend ACT adoption rates to the nation. API points out the critical nature of the grid infrastructure and that the utilities must be fully engaged. ATA comments that the infrastructure plans should be site and state specific to address the large number and varying types of utilities.[467] ATA shares that having almost 3,000 utilities as well as individual energy regulatory entities will hamper investment and modernization of the grid. They further state that the different utility types (investor owned

[467] We note here that ATA's reference that ICCT, "recognizes that the electrification of commercial vehicles will significantly burden the current electrical grid" is misleading as ICCT stated that the relatively small share of the electricity demand attributable to the Phase 3 proposed rule (which was more stringent than that finally adopted) as not being a constraint. See Comments of ICCT, June, 2023, Comment 1553, at pp. 10-11 (estimating demand from proposed Phase 3 rule at 1% of national electric retail sales in 2021).

(IOU), publicly owned (POU), and cooperatives), will add to these challenges. They reference input from California Public Utility Commission (a state wide planning and development organization) regarding challenges including: time (3 years) to align statewide efforts and complete infrastructure authorizations; market and technology uncertainty making it unclear what infrastructure actions should be supported; the quantity of infrastructure build out needed not having been adequately quantified within the states planning process; lack of detail on fleet charger needs; lack of planning for enroute stations, no coherent planning framework; and, finally, no process for identifying the land needed for substations. The concerns relating to availability of critical minerals raised by American Highway Users Alliance are addressed in RTC 17.2.

Supply chain concerns were mentioned by DTNA such as 40 weeks for transformers and 70 weeks for side meter panels /switch gears. DTNA added that the long lead times could be as much as vehicle cycle time. Plans made for aligning HD BEV vehicles with charging needs could become obsolete as the fleet changes by the time charging infrastructure is finally available. National Rural Electric Cooperative Association (NRECA) states that supply chain issues are causing shortages of basic machinery needed to ensure grid reliability. They also share that cooperative utilities are waiting a year on average for distribution transformers and that the lead time for large transformers is over 3 years. NTEA, The Association for the Work Truck Industry is concerned with their work truck manufacturers getting required power and states that in some cases the equipment required for power delivery is available but the agreement from the utility to supply power has not been received and could be multiple years away. Comments were also received (DTNA) that truck customers had cancelled orders when utility timing for depot supply came in at 5-8 years. Other buildout estimates were shorter (3 years) but were deemed unacceptable as the fleet needs had to be proven through an order such that the HD BEV would be available but would sit idle for 2 years before the grid buildout. EEI recognizes this potential misalignment between the time of obtaining HD BEV and the time required for buildout of supporting infrastructure. EEI also shared the related issue that fleet customers are not familiar enough with the process of obtaining grid buildout. As mentioned before, their investor-owned utility members are strengthening their relationship with fleet customers to address this. Comments by EEI show that utilities are working to deliver power when needed, understand critical detail like load profiles, and share information such as hosting capacity maps. They note that utilities are adding account managers for fleets that will engage early and help plan successful implementation. EEI also shares the utility challenge that many are not authorized to make proactive upgrades but rather must wait until they have a customer request. Energy Innovation commented that more states are authorizing utility investments to support widespread and equitable access.

DTNA shared that some customers looked at temporary power solutions but those would have increased upfront costs borne by their fleet. Related comments by ATA shared that a company wanting to electrify forklifts was only able to change over a small percentage of their original plan due to power availability.

Comments were received from Clean Air Task Force, CalStart, Edison Electric Institute (EEI), Electrification Coalition (EC), Environmental Defense Fund (EDF), and National Association of Clean Air Agencies (NACAA) supporting that the electrical distribution grid and its buildout will be sufficient for the adoption rates analyzed by EPA in its projected compliance pathway. The Edison Electric Institute (EEI), the trade association for all of the nation’s investor-owned utilities supported the proposal, indicating that needed infrastructure buildout can be accommodated within a MY 2027-2032 timeframe. CalStart and EDF commented that even more aggressive standards, posited on a higher ZEV adoption rate, would not be precluded by grid reliability concerns. EDF shared that grid buildout since 1960, as shown by electricity sales, has averaged 2.8%, well above what the proposed Phase 3 rule would necessitate, assuming every OEM chose to comply using the compliance pathway projected by EPA. CalStart and Clean Air Task Force stated that buildout will be possible and HD BEV adoption will be supported since the fleet turnover will happen gradually allowing needed buildout to be phased in over time rather than built all at once. Clean Air Task Force emphasizes that the HD fleet composition, not just annual sales, should be presented to show the small portion of the fleet that will be adding load to the grid (again, assuming that every OEM adopts the projected compliance pathway). CalStart comments that investment in key nodes and then corridors will drive efficient infrastructure implementation and greater availability than EPA assumes. ICCT made the same point and provided quantified analysis of freight corridors that would be the likely candidates for immediate buildout, noting that infrastructure buildout outside of these areas would not be necessitated in the early years of a Phase 3 regime. CATF commented that historical precedent shows that infrastructure buildout will occur as needed (see the further summary in the following paragraph). They specifically reject the 'chicken-egg conundrum' raised in a number of comments whereby utilities require guaranteed demand before building out, but ZEV purchasers require assurance of infrastructure before purchasing a ZEV.

CATF states that utilities are planning and deploying solutions. EDF notes that there are a number of State legislative initiatives to allow or to force proactive buildout by utilities. EDF and EEI agree with the need for states, regulators, and utilities to improve planning and regulatory practices and provide instances of where this process has already commenced. MFN shares positive planning and reporting actions taken by the Minnesota PUC. EEI shares positive actions by SCE and NY PSC. They reiterate that longer term buildout (10 year) will require proactive planning processes between the utilities and regulators. MFN shares that California legislation establishes a balancing account to recover associated costs, which would ensure utilities do not have to wait several years for their next General Rate Cases to propose investments. EDF, ICCT, and MFN share proposed California legislation that would drive or even require utilities to be ready for connection requests. EC shares thoughts on expediting grid buildout but suggests that utilities in ACT States should be approved to move forward with grid buildout without a time-consuming regulatory approval process. DTNA recognizes the need for government, utilities and other industries to work together. They share proposals for grid planning responsibilities, legislation to require key grid updates, aligned adoption plans to properly support utility forecasts, process to protect fleets from financial burden if planned energy use isn't met, encouraging state regulators to adopt performance based regulations regarding buildout, standardized application and review process for upgrade requests, encourage utilities to bundle requests for grid upgrades with DER and stationary battery, process to allow third parties to deliver and profit from infrastructure for HD BEV. ICCT comments that EPA should engage other federal agencies and provide input on federal infrastructure policy. In public comments, and in a contemporaneous May 2023 White Paper, ICCT provided quantified estimates of electricity demand that could be needed for a regulatory program predicated on some electrification, analysis of where demand might be heaviest potentially creating need for some buildout, and means by which the buildout could be effectuated considering actions utilities can take without need for regulatory approval, actions necessitating regulatory approval, and actions requiring authorizing legislation.

RMI recognizes in their comments that the infrastructure build-out time and cost can be limiting factors for ZEV adoption. RMI and ZETA share practical enablers such as identifying where grid growth is needed, streamlining regulatory processes, providing regulatory incentives, and embracing proactive grid planning. Energy Strategy Coalition, CARB, EDF, and ZETA referenced the certainty a federal regulation would provide for needed planning relating to the grid. CATF shares economic theory supporting that an increase in HD BEV sales will spur infrastructure development. Like EDF, CATF notes that BIL and IRA support both HD ZEV and infrastructure such that they will clearly support grid buildout. They use Norway as proof that BEV sales and infrastructure can expand rapidly. They point to our US infrastructure buildout of roads and service stations as automobile use expanded as another example of markets and support infrastructure growing together. Comments supporting that grid reliability and grid distributive buildout would not be impediments to achieving the proposed Phase 3 standards were received from CalStart, CATF, EDF, EEI, the thrust of these comments being that implementation will be supported by federal, state, public entities, utilities, charging providers, and fleets working together proactively on the required plans, policy, and funding. CalStart also identified service providers that simulate grid needs for commercial vehicles and identify required grid upgrades.

Electrification Coalition (EC), EEI, RMI and ICCT made comments that success will require funding and cooperative actions between the transport and utility sectors and provided specific examples of actions required. Consolidated Edison recommends that utility proactive planning should be a best practice. EC comments highlighted studies by utilities that help identify and communicate the issues that require proactive planning,while EDF highlights that NY State has passed statutes requiring such studies. ICCT went into detail regarding what utilities can implement on their own, those that need regulator notification, and those that require approval. They assert that utilities can get started implementing change and do not require approval for every helpful action.

EEI recognized that the grid buildout needs to support large charging stations capable of supplying tens of megawatts. EEI states that “[e]lectric companies can accommodate localized power needs at the pace of customer demand, provided appropriate customer engagement and enabling policies are in place”, that servicing HDV BEV demand posed some new issues for the utility sector – notably rapid construction timelines, reduced customer familiarity with procuring electric power, and uncertainty of load profiles, but went on to explain how the utility sector is addressing these potential challenges.

Many of these comments stated how BEV purchasers could mitigate electricity demand. AEU, State of California, and EDF provided examples of hardware enablers such as DER, V2G, and stationary batteries. AEU, State of California, and EDF also shared software solutions that manage power requested from the grid to optimize charging with grid temporal supply. AEU focuses their input on the cost savings of managed charging, but they make it clear that, “Managing these vehicles’ charging load to avoid peak periods can substantially reduce the need to upgrade both the facility’s infrastructure and the utility-side infrastructure”. EDF shares that these hardware and software enablers can, in some cases, eliminate the need for grid buildout. Another means of mitigating demand mentioned in comments was for users and utilities to agree that demand would remain a given percentage below nameplate capacity (EDF, AEU.). MFN shares evidence that time-of-use rates push electric demand (HD BEV charging) to times when power is plentiful and less expensive.

Other commenters spoke positively to the issue of regional impacts. The Energy Strategy Coalition noted that both Regional Transmission Organizations (RTO) and Independent System operators (ISO) engage in long range planning and are doing so in anticipation of increased demand posed by both light and heavy-duty electrification. Commenter EDF noted the work of its contractor Analysis Group showing that 83% of demand posed by the HD rule would be less than 5MW. MFN cited to a recent study of the Lawrence Berkeley National Laboratory (September 2022) which centered on the MISO (midwest) grid and found the EVs could smooth out the "negative valley" sometimes resulting from difficulties storing excess capacity from renewables. CATF and EC provided multiple examples of regional stakeholders coming together to coordinate and plan for increased electrification.

Comments were received that EPA should monitor and review charging infrastructure and grid capacity. Other comments (NACAA) opposed ongoing evaluation as unnecessary and inappropriate.

Response:

EPA has carefully considered the comments regarding the distribution infrastructure for charging HD BEVs, including issues of feasibility, lead-time, and costs. In this response, we discuss the feasibility and lead-time of distribution infrastructure; subsequent responses discuss costs and other issues related to distribution infrastructure, as well as grid reliability and resiliency. The agency has conducted comprehensive analyses of distribution infrastructure needed to support HD ZEV charging, including in close coordination with the Department of Energy and informed by the extensive public engagement on this issue. We find that there will be sufficient lead-time to develop the necessary distribution infrastructure associated with HD ZEV uptake under the modeled potential compliance pathway for the final standards. We note that the final standards themselves, as discussed in section II of the preamble, provide significant additional lead-time relative to the proposal, which also means additional lead-time to build and connect distribution infrastructure. Our conclusion as to the sufficiency of distribution infrastructure is supported by numerous comments and analyses, including those from the stakeholders most intimately familiar with building and operating distribution infrastructure: the utility industry and state utility and energy regulatory agencies. Below, we highlight several key lines of evidence.

Because the need for distribution infrastructure is associated with increases in electricity demand, EPA evaluated demand increases at the national, regional, and local levels. We found only modest increases in demand associated with the Phase 3 Rule at all of these levels. Assuming manufacturers follow the modeled potential compliance pathway—which focuses on increasing penetrations of HD ZEVs[468]—the Phase 3 rule would account for less than 1%

---

[468] We emphasize that the final rule does not require manufacturers to adopt any particular technological pathway; nor does it force consumers to buy ZEVs, including because we anticipate that a large number of ICE vehicles will continue to be produced and sold during the timeframe of this rule. Whether in response to potential charging infrastructure or other constraints, manufacturers and consumers may choose to adopt a wide range of technologies not dependent on charging infrastructure.

increase in transportation-sector electricity demand in MY 2027, the first year of the program, rising to slightly over 9% in MY 2032. From the perspective of total utility demand for all sectors, the increase by 2035 attributable to the rule is just slightly over 2.5%. These are modest increases and consistent with historical increases in demand, such as accompanying the introduction of refrigerators, air conditioners, and data centers, which the electric utilities have successfully managed.

With respect to regional demand, we concentrated our analysis on the high freight corridor areas identified as the most likely candidates for electrified infrastructure during the Phase 3 rule's timeframe. We found that demand associated with the Phase 3 rule in each of these areas remains low, especially at the commencement of the Phase 3 rule in 2027, when issues of lead time are most critical.

At the local level, our analysis is informed by the recent Department of Energy Transportation Electrification Impact Study (TEIS), which found that only a small amount of new infrastructure would be needed as a result of the rule. The TEIS evaluated five States susceptible to increased infrastructure needs, including due to high concentrations of freight corridors necessitating additional infrastructure, dense urban areas with less space for infrastructure buildout, and rural areas with relatively little existing infrastructure. The study evaluated the combined effects of both the Phase 3 Rule and the Light- and Medium-Duty Multi-Pollutant Rule. It found only minor increases in peak demand associated with the incremental impact of the rule in 2027 and 2032 (+0.1 to +3.0%) and that even those minor increases could be reduced, in some cases to below zero (i.e., decreases in peak demand), through basic, easily implemented, demand management strategies (-1.8% to +0.5%). The study estimated that the peak demand increases could be accommodated by a small volume of additional infrastructure; for example, in 2027 with basic management strategies, it found the need for zero new substations, five new feeders, and 2,400 transformers across the five states evaluated. Based on our assessment of the time needed to build different kinds of infrastructure, EPA determined that the level of buildout identified by the TEIS could be achieved within the timeframe available.

We also carefully evaluated programs and funding to support charging infrastructure, including at the Federal, State, local, and utility levels, for both depot and public charging. The Federal government continues to provide significant funds for developing charging infrastructure, including through the Charging and Fueling Infrastructure Discretionary Grant Program. Many States have also developed programs to support such infrastructure; we anticipate much of the needed charging infrastructure would be developed in States that have adopted the Advanced Clean Trucks program, which mandates increasing levels of HD ZEVs, and that also have especially supportive policies for developing such infrastructure. Many localities and utilities also are actively developing innovative strategies to build and support additional charging infrastructure; for example, Edison Electric Institute, the trade group for the nation's investor owned utilities, identified numerous such strategies and concluded that needed infrastructure could be timely developed. The final rule provides beneficial regulatory certainty to support the development of these programs and of charging infrastructure generally.

Finally, we underscore the potential for numerous innovative strategies to mitigate distribution infrastructure demands. As noted regarding the TEIS study, even basic mitigation strategies for HD BEV charging can significantly ameliorate or even reduce peak demand. A panoply of potential strategies—including short-term load rebalancing, smart charging contracts, flexible interconnections, hosting capacity maps, managed charging software, vehicle-to-grid technologies, distributed energy generation, onsite battery storage, and more—provides many opportunities for mitigating the impacts of additional demand, and in some cases, for providing benefits back to the grid as the volume of BEV charging increases.

The balance of this response details the above factors.

EPA found at proposal that "there is sufficient time for the infrastructure, especially for depot charging, to gradually increase over the remainder of this decade to levels that support the stringency of the proposed standards for the timeframe they would apply." 88 FR at 25999. We reiterate that conclusion here. Addressing the question of availability of supporting electrification infrastructure in the rule's 2027-2032 MY timeframe necessitates a predictive judgment by the agency. In making this type of prediction, EPA follows the same template as in developing emission standards under Title II generally: EPA must identify the steps necessary for deployment of the needed amount of infrastructure, and provide plausible reasons as to how these steps can be effectuated in the lead time provided.[469] In making these projections, EPA has consulted repeatedly with the Department of Energy (DOE), and has benefitted greatly from the Department's expertise.[470] EPA also met with the North American Electric Reliability Corporation (NERC) staff on the two rules for on-highway vehicles, the light- and medium-duty vehicle multipollutant standards proposal, and the heavy-duty vehicle Greenhouse Gas (GHG) emissions standards .[471]

We estimate a modest annual generation increase attributable to the Phase 3 rule.[472] In consideration of lead time concerns raised by commenters (on both infrastructure and vehicle developments), we are finalizing CO2 emission standards for heavy-duty vehicles that include a lower increase in stringency of standards for many HD vehicle categories in MY 2027, a slower phase-in of standards through MYs 2028 and 2029, and a phase-in of standards from MYs 2030 through 2032 that, for many of the subcategories, achieves similar levels of stringency in MY 2032 as proposed

In 2027, the Phase 3 rule is projected to increase demand for electricity posed by the transportation sector by a modest 0.666%.; that is, of the demand for electricity posed by the transportation sector, well less than 1% is attributable to the Phase 3 rule. In 2032, this is projected to increase demand from that sector by 9.232%. [473] We note that the modelling associated with these estimates assumed somewhat higher electricity demand than the demand

[469] NRDC v. EPA, 655 F. 2d 318, 333 (D.C. Cir. 1983).
[470] See *Shafer & Freeman Lakes Env't Conservation Corp. v. FERC*, 992 F.3d 1071, 1090 (D.C. Cir. 2021) (deference to agency determination supported where agency consulted with outside experts regarding that determination). See also *Intelligent Transportation Soc'y of Am. v. Fed. Commc'ns Comm'n*, 45 F.4th 406, 413–14 (D.C. Cir. 2022) (Federal Communications Commission properly rejected challenge relating to its findings involving transportation safety by utilizing analysis from the Department of Transportation).

[472] Murray, Evan "Calculations of the Final Standards at Various Geographic Scales" (February, 2024).

[473] Murray, Evan "Calculations of the Impacts of theFinal Standards at Various Geographic Scales" (February, 2024).(National Demand tab)

ultimately reflected in the final rule.[474] The final rule adoption scenario and associated electricity needs were not finalized when inputs were required for this analysis. Our interim scenario was used for input as it was the most accurate data available when inputs were required. The modelling also includes needed electricity generation for the hydrogen necessary to fuel FCEVs produced using grid electrolysis (as a simplifying assumption). The power supply for electrolysis is assumed to be available or made available while the electrolysis facility is built so the related electricity distribution build out is not a critical factor for timing. EPA thus regards this modeling as conservative.

Furthermore, since this demand is only that portion attributable to the transportation sector, the demand as a percentage of total demand on a utility would be less, since it would be in effect diluted by all other sources of demand. Thus, in 2030 and 2035 (the only years for which we are able to generate these values), increases in generation are only 0.41% and 2.59% of total demand.[475]

Furthermore, there is near consensus that charging infrastructure needed to meet this demand in the time frame of the rule will be centered in a sub-set of states and counties where freight activity is concentrated and where many have supportive ZEV polices. See RTC section 6.1 above. These likely areas of high concentration include Texas (Harris, Dallas, and Bexar counties); southern California (Los Angeles, San Bernadino, San Diego and Riverside counties); New York State (Bronx, New York, Queens, Kings, and Richmond counties); Massachusetts (Suffolk county); Pennsylvania (Philadelphia county); New Jersey (Hudson county); and Florida (Miami-Dade county).[476] These areas are projected to experience either higher aggregate demand or higher energy demand per unit area attributable to HD BEV adoption. The projected increases from baseline transportation sector demand are especially modest in 2027, the initial year of the phase 3 program, when there is the shortest amount of lead time:

- Boston-Cambridge-Newton (Mass/New Hampshire) 0.093%
- Chicago-Napierville-Elgin (Illinois-Indiana-Wisconsin) 0.836%
- Dallas -Fort Worth-Arlington (Texas) 0.866%
- Houston -The Woodlands-Sugar Land (Texas) 0.847%
- Los Angeles-Long Beach-Anaheim (California) 0.002%

[476] Comments of ICCT, July 2023 at 11. These comments reflect Ragon, Kelly, et al., 2023 (“ICCT May 2023 White Paper”). The ICCT May 2023 White Paper combines trucking operational data and route information with locational factors to estimate the types quantity and approximate location of new charging capacity that may be needed due to electrification requirements and growth on HDV BEVs. These estimates reflect BEV adoption in the heavy duty fleet slightly greater than EPA projects in its estimated compliance pathway for MY 2032, and so constitute conservative estimates. See Hibbard et al. “Heavy Duty Vehicle Electrification: Planning for and Development of Needed Power System infrastructure” (Analysis Group, June 2023) at Table 1 (“Analysis Group HDC Electrification Paper”), available at Analysis Group, https://blogs.edf.org/climate411/wp-content/blogs.dir/7/files/Analysis-Group-HDV-Charging-Impacts-Report.pdf.

- Miami-Ft. Lauderdale-West Palm Beach (Florida) 0.830%

- Phoenix-Mesa-Scottsdale (Arizona) 0.878%
- Riverside-San Bernadino-Ontario (California) 0.002%
- San Antonio-New Braunfels (Texas) 0.870%
- San Diego-Carlsbad (California) 0.002%[477]

These estimates are conservative. The projected increases represent increased electricity demand attributable to both the heavy-duty rule and demand from the light duty sector absent the final rule . EPA did not disaggregate these data, and they reflect the aggregate increase demand associated with both rules that utilities would face. However, the portion of electricity demand attributable to the Phase 3 rule as finalized would be less.

We estimate that electricity demand in these critical freight corridors attributable to the transportation sector would increase in 2032, reflecting increased standard stringency, including standards for sleeper cab tractors and heavy heavy-duty vocational vehicles which commence in later years of the program:

- Boston-Cambridge-Newton (Mass/New Hampshire) 1.157%
- Chicago-Napierville-Elgin (Illinois-Indiana-Wisconsin) 10.95%
- Dallas -Fort Worth-Arlington (Texas) 12.285%
- Houston -The Woodlands-Sugar Land (Texas) 11.715%

- San Diego-Carlsbad (California) 0.014%[478]

[477]Murray, Evan "Calculations of the Impacts of the Final Standards at Various Geographic Scales" (February, 2024).(MSA Demand tab). We note that the differences in demand reflect ACT implementation in some of the states

[478] Murray, Evan "Calculations of the Impacts of the Final Standards at Various Geographic Scales" (February 2024).(MSA Demand tab)

EPA regards these projected increases as modest. The projected increases in 2027, when there is the shortest lead time for buildout, are small. As expected, demand is projected to increase in 2032 but there is considerably more available lead time in which buildout can be accommodated. Moreover, these increases are modest compared to total electricity demand on utilities within the States in these freight corridors. Thus, looking at the dominant state in each freight corridor which in 2032 showed incremental transportation sector increases greater than 1.1%, the effect on total in-state demand (in 2035) is low: Arizona is 2.85%, Florida 2.39%; Illinois 0.91%, Pennsylvania 1.04%, and Texas 2.34 %.[479] The National Zero-Emission Freight Corridor Strategy described above identifies many of these areas in its phasing of a national network, which will help focus timely planning for and investment in the deployment of refueling and utility infrastructure in advance of the regulatory period.[480]

The Department of Energy Study, "Transportation Electrification Impact Study" ("TEIS") supports this conclusion.[481] This is a first-of-its-kind study which performs thermal capacity analysis (at the substation, feeder, and service transformer levels) compared to cumulative LMHD vehicle demand (i.e., demand from both the light- and heavy-duty sectors) enabling location-specific estimates of potential buildout capacity needs and costs. This is the first study to be bottom up, comparing parcel level LMHD demand to parcel supply by PV (photo voltaic) and grid capacity at each examined parcel.[482] Previous studies made estimates of how the new demand from BEV might align with the existing grid capacity or studied the parcel level grid needs for a smaller area (as compared to this 5 state analysis). The TEIS is especially valuable, in fact unique, in assessing both a large area (5-State) coupled with parcel-level analysis.[483] The study focuses on five study States (California, Illinois, New York, Oklahoma, and Pennsylvania), and extrapolates those results nationwide. The five states were intentionally chosen to address geographic concerns such as freight corridors, crowded urban areas, and rural areas with widely distributed demand sources. These states represent 30-35% of the costs of the extrapolated results in the TEIS.[484] They also account for nearly 20% of 2021 nationwide utility peak demand and account for 25 % of electricity customers nationwide.[485] The study also incorporates public charging such that the corresponding high power needs are reflected, addressing a concern of

---

[479] Murray, Evan "Calculations of the Impacts of the Final Standards at Various Geographic Scales" (February 2024) (State generation tab). We recognize that generated electricity can cross state lines, so that these corridors could be serviced by multiple states. However, increased total electric demand in states in the freight corridors other than those mentioned in the text above remains low. Incremental impact on Indiana electricity demand, for example, is 1.90 %. Id.

[485] TEIS at 72 .

many comments. . The study estimates overload at the substation level (100% criteria)[486], feeder level (100% criteria), and at the residential service transformer per feeder level (125% criteria). [487] Scenarios examined are no action case (baseline without EPA light-duty or heavy-duty emission standards), and action case with EPA light- and heavy-duty rules), using as an Action case the same case EPA used for its national and regional estimates presented above.), Both action and no action cases are analyzed with and without mitigation resulting in four scenarios generated. The study examines the same four scenarios for both 2027 and 2032.[488] The TEIS unmanaged (without mitigation) case simply distributes the BEV demand over the vehicle dwell time available for charging. The BEV charging is ignorant to non BEV loads. Charging could still occur on top of, and increasing, peak demand. As an example, if the peak load due to existing homes and business occurs at 7 pm and the BEV dwell time runs from 6 pm to 6 am, the unmitigated charging would apply peak power charging at 7 pm, exacerbating peak demand. The mitigated scenario assumes a lower power level and uses the available dwell time -- it lasts until the vehicle leaves the charging venue.[489] The peak power demand increases but at a lower level.

Consistent with the national demand and high freight corridor regional demand estimates above, the TEIS projects minimal increase in demand (energy consumption) and minimal increase in peak demand for the LMHD action case relative to no action for both 2027 and 2032, even without considering any management. In 2027, incremental energy consumption across the five states attributable to the light- and heavy-duty rules ranged from 0.1-0.3%.[490] In 2032, that incremental increase ranged from 1.6% to 2.7%.[491] Incremental impact on 5 state peak demand, again from the unmanaged case, was 0.1-0.2% in 2027 and 0.6-3.0% in 2032.[492]

If ZEV users engage in non-optimized "conservative" management –shifting charging times so that vehicles minimize charging power such that the charging session starts on arrival and finishes when the vehicle departs the charging location[493] – not only do these estimates of peak demand impacts decrease, but in some instances, peak demand is projected to decrease in absolute terms, that is, to be less than in the no action unmanaged case. Just by engaging in easy-to-implement time of day charging adjustments, overall demand to the grid is reduced (demand relative to the no action case), smoothing out overall demand and allowing for more efficient distribution. Thus, for 2027, incremental peak demand is reduced in four of the five states, and unchanged in the fifth.[494] . For 2032, incremental peak demand is positive in two of

[486] Criteria level is showing if the peak loads are directly applicable to the design capacity of the system as is the case for the 100% criteria level. Criteria level of 125% for service transformer shows that many individual noncoincident peaks exist. See TEIS at 47-49 for additional detail.

the states but the increase is only 0.1% and 0.5%, and *reduced* in the other states by 0.5%-1.8% potentially obviating the need for any incremental buildout at all.[495]

These minor increases reflect low numbers of transformers, feeders, and substations estimated to be needed (again, for the five states studied and for both light and heavy-duty rules together). In 2027, the TEIS projects need for only a single incremental substation, and zero in the managed case. In 2032, the TEIS projects that only 8 incremental substations would be needed in the unmanaged case, 4 if conservative mitigative measures are utilized.[496] Of these, all but one would be upgrades to an existing substation.[497] Projections for incremental feeders are 9 in 2027 (5 in the managed case), and 125 in 2032 (75 if managed). In 2027, the TEIS projects an incremental need of 2800 transformers (2,400 if managed), and 30,000 in 2032 (21,000 in the managed case). [498] Compare this to the estimated 1 million transformers sold domestically each year, and the estimated 50 million transformers associated with the U.S. electric grid.[499]. Industry is also responding with actions such as Prolec GE's $30 million expansion at its Shreveport, Louisiana transformer plant, their $85 million new plant in Monterrey, Mexico, and Siemens Energy investing $150 million to build their first transformer production facility in the US in Charlotte, North Carolina.[500].

EPA finds that this projected amount of buildout attributable to the Phase 3 rule can be accommodated in the rule's time frame. Indeed, the TEIS finds that "[n]otably, substation, transformer bank and service transformers built by 2027 mostly cover 2032 needs based off size assumptions for existing and new substations; feeder upgrades are still triggered in 2032." [501] Realistic estimates for time needed to install infrastructure components have been studied and are shared here (and see also RIA Chapter 1.6.5 for further discussion):

[501] TEIS at 74.

		Time to Implement (months)	
Component	**Capacity per Borlaug**	**Borlaug et al. 2021**[502]	**EPRI**[503]
Substation New	3 – 10+ MW	24–48	36–60
Substation Upgrade	3 – 10+ MW	12–18	24–36
Feeder New	5+ MW		12–24
Feeder Upgrade	5+ MW	3–12	6–12
Transformer New	200+ kW	3 - 8	3 - 8

Although new substations are a significant undertaking that can take multiple years as shown in the Table above, as noted, the TEIS finds that, for the 5-state analysis, only 4 substations (incremental to the no action case) are required for the managed scenario and 8 for unmanaged in 2032. In 2027, the TEIS found that only a single additional upgraded substation (or none in the managed case), and, as just noted, finds that substations built by 2027 can "mostly cover 2032 needs". We note further that the estimates in the TEIS Study of the amount of distributive buildout needed are conservative with respect to the Heavy-duty Phase 3 rule – indeed, the estimates are almost certainly overstated. First, the TEIS Study considered both the light/medium duty standards and the Phase 3 heavy-duty emission standards together and did not disaggregate the results. Second, the Action scenario considered was more stringent with respect to electricity demand for Phase 3 than the rule ultimately finalized. In addition as noted above, the "unmanaged" scenario presented above considers no mitigation efforts at all. If conservative, simple charging level adjustments in the TEIS managed scenarios estimated impacts decrease sharply. The action managed case is projected to *reduce* peak loads in all 5 States in 2027, and to reduce peak loads in 3 of the 5 States in 2032.

EPA recognizes that from the standpoint of timing, one may consider not only incremental increases in demand attributable to the Phase 3 rule but also other demand from the transportation sector that might occasion the need for distributive grid buildout. That is, buildout can be needed with respect to HD BEVs in the EPA reference case as well as to those reflected in the analysis supporting the Phase 3 rule. We continue to find that this overall demand can be accommodated within the timeframe of the rule for the following reasons.

As discussed above, buildout need not occur everywhere and all at once. In the rule's time frame, as shown in particular in the ICCT White Paper, it can be centered in a discrete number of high freight corridors.

In the early model years of the program, when lead time is the shortest, projected demand remains low.[504] When accounting for the increase from all vehicles (light-duty and heavy-duty), we find the portion of demand attributable to the entire heavy-duty vehicle sector (including ACT) increases by only 2.6% between 2024 and 2027. [505] That is, the increase in demand

[504] Murray, Evan, "Calculations of the Impacts of the Final Standards at Various Geographic Scales" (February 2024).

[505] Murray, Evan "Calculations of the Impacts of the Final Standards at Various Geographic Scales" (February , 2024) (Demand National tab.)

attributable specifically to electric heavy-duty vehicles (including ACT), and therefore the infrastructure buildout necessary to support those vehicles, is small compared to other factors.

We further project that a substantial majority of these ACT-compliant ZEVs would be light and medium heavy vocational vehicles which would be the least likely to require additional buildout. RIA Chapter 4.2.2. For example, the TEIS projects no need for new and upgraded substations in 2027 nationally, and need for only approximately 24-48 (managed and unmanaged cases) nationally in 2032).[506]

Most of the demand comes from the states which have adopted ACT: California, Oregon, Washington, New Jersey, New York, Massachusetts, and Colorado.[507] In adopting ACT, these States have considered the means to successfully implement the program and in some cases taken additional legislative or regulatory action specifically to support needed infrastructure. This is reflected in the administrative record here. For example, the California Public Utility Commission is developing a Zero-Emission Freight infrastructure planning framework to identify distribution, substation and transmission needs under high transportation electrification scenarios.[508] Similarly, in New York, the State Department of Public Services has ordered seven utilities within the state to develop a Coordinated Grid Planning Process which requires utilities to proactively identify potential barriers to incremental new load, including from HDV charging, and to identify near-term solutions for any such identified barriers.[509] Eversource, New England's largest energy delivery company, has published an Integrative System Planning Approach per the order of the Massachusetts Department of Public Utilities.[510] See also the legislative actions undertaken in California and New York, cited in the comments of the Environmental Defense Fund. CARB, EMA, and the HDV OEMs have also reached agreement to "actively promote further needed infrastructure development."[511]

With respect to non-ACT states, most of the demand in these states is attributable to the Phase 3 rule itself. See RIA Chapter 4.2.2 (sales ratio for HD BEVs in non-ACT states is approximately 0.2). As shown above with respect to high freight corridors in non-ACT states (including Pennsylvania, Texas, Arizona, and Illinois), incremental demand is low, especially in the critical initial year of the program. State-by state results show similar small percentages of increased demand. [512] We note that Florida (a non-ACT state) has experienced a dramatic load growth since 2012 (10 percent overall), but has accommodated that growth, including building

[506] TEIS at 65 and using the TEIS analysis showing that the 5 states analyzed account for approximately one third of national costs (TEIS at 66).
[507] Murray, Evan "Calculations of the Impacts of the Final Standards at Various Geographic Scales" (February 2024) (Demand by State tab.) . At the time we performed the inventory modeling analysis, seven states had adopted ACT in addition to California. Oregon, Washington, New York, New Jersey, and Massachusetts adopted ACT beginning in MY 2025 while Vermont adopted ACT beginning in MY 2026 and Colorado in MY 2027. Three other states, New Mexico, Maryland, and Rhode Island adopted ACT (beginning in MY 2027) in November and December of 2023, but there was not sufficient time for us to incorporate them as ACT states in our modeling.

new substations, feeders (9 percent increase), and transformers, all between 2013 and 2021.[513] This is far more buildout than will be occasioned by heavy-duty BEVs within the Phase 3 rule's timeframe.

We further note the comments of the Edison Electric Institute (trade association of the nation's investor owned utilities) ("EEI") that the degree of anticipated buildout is similar to increases experienced historically by the utility industry, and can be accommodated within the Phase 3 rule's timeframe. EEI Comments at 7, 8. The Analysis Group reached a similar conclusion.[514] Some commenters were concerned that interactions with utilities and their regulatory commissions vary state-by-state, and that this balkanized regime adds to grid buildout deployment timing difficulties.[515] Other commenters, however, persuasively maintained that this localized system is actually a plus. Each potential buildout is a localized decision, best handled by the local utility and grid operator.[516] As discussed in the following section, there are also many mitigative measures which BEV users can utilize to reduce demand, and the localized process provides a ready means to best develop optimized local mitigative measures.

Finally, we expect that the Phase 3 rule itself will serve as a strong signal to the utility industry to make proactive investments and otherwise proactively analyze and plan for potential buildout needs.[517] This is a partial answer to the chicken-egg conundrum voiced in the comments (see discussion in the following section).

Putting this together, EPA finds that the increases in national electricity demand associated with the Phase 3 Rule are very low in 2027 and increase to modest and manageable levels in later years of the program. At a regional and local level, we expect some areas to see small increases in peak demand, while other areas may see small decreases in peak demand associated with basic managed charging strategies. The resulting level of needed infrastructure buildout is small and manageable given the lead-time available. We now consider the specific situations of depot charging and en route (public) charging.

A. Depot Charging

We consider first the situation of a centralized depot accommodating multi-vehicle fleets, the typical situation for most of the HD BEVs considered in our modelled compliance pathway. As noted above, a number of commenters pointed out, accommodating the increased demand for this type of depot is not unprecedented, or even unusual, for utilities to timely accommodate. Charging infrastructure needs for a depot housing a large fleet would be similar to those of a data center or of a large commercial building, which demand even greater power at a centralized

location.[518] Utilities successfully connected more than 1,000 MW of new data center loads in 2023.[519] In Virginia alone, the data center industry's load has increased 500 MW annually for the past three years and been accommodated.[520]

The final standards are structured to minimize demand for electrification infrastructure distributive buildout in the initial years of the program, the critical years for this purpose given the shorter lead time. The standards for MYs 2027-2029 are less stringent than proposed. The standards for the HDVs which pose the highest demand, heavy heavy-duty vocational vehicles and sleeper cab tractors, do not take effect until MYs 2029 and 2030, respectively.

We further have demonstrated a compliance pathway whereby almost all of the HDV BEVs utilize Level 2 or DC-50 kW chargers for depot EVSE, rather than higher rated chargers.[521] These lower rated chargers will not pose the types of electricity demand potentially requiring distributive buildout upgrades as the higher-rated chargers posited by some of the commenters.[522]

We have carefully considered the public comments and see that utilities and fleets have both the means to address issues of timing of buildout and are already utilizing them. EPA recognizes the various comments about leadtime. For example, a commenter states that "at the distribution system level it is not sufficient to simply compare potential charging station demand growth to system capacities."[523] Some commenters pointed to a chicken-egg conundrum, whereby potential fleet purchasers contemplating BEVs will not purchase without an assurance of adequate electrical supply, but utilities cannot build out without having assurance of demand. They say that utilities can be required to demonstrate that any buildout will be utilized in order to obtain regulatory approval for the buildout,[524] and state that infrastructure buildout needs can be heightened by the current practice of establishing capacity to handle nameplate power, the theoretical maximum power delivered when all users demand maximum load at once. Commenters note that related issues can arise from misalignment of timing of purchasing

[523] Analysis Group Heavy Duty Vehicle Electrification at 10.

[524] Comment of EEI at 11:"While policies vary by state commission, two generally applicable principles have important implications for fleet electrification. First, the 'used and useful' standard means that regulatory will only approve the electric company to build infrastructure that will be utilize and provide value." EEI further documents that a number of large utilities are finding ways to move away from this model so as to provide infrastructure readiness in advance of individual applications. EEI comments at 12-14. (described more fully in text above).

decisions and distributive grid buildout, including that utilities need to account for the fact that a BEV purchasing decision is on a shorter timeline than building construction. Commenters also note that a major distributive buildout requiring new substations would require significant lead time; for example, buildouts entailing new substations could take years for construction and for obtaining regulatory approvals.[525]

EPA has thoroughly considered these issues, including in consultation with experts at the Department of Energy. While we acknowledge the leadtime concerns raised by these commenters, the agency believes there is sufficient leadtime. We have identified solutions to each of these issues, many of which are already being implemented. First, as demonstrated above, we have projected a compliance pathway whereby there will be limited need for any grid distributive buildouts. Those buildouts that we project largely involve transformers or feeders, and a small number of expanded substations. Few new substations are projected to be needed , even when considering national demand (i.e. BEVs in EPA's reference case plus those attributable to the Phase 3 rule, in the potential compliance pathway). We emphasize again that this analysis is conservative in that we do not consider ameliorative measures available to utilities to apportion demand (discussed below), and consider only conservative mitigative measures on the part of depot owners (limited time-of-day charging assumptions).

Second, utilities can and are acting proactively to provide added capacity when needed. As stated by EEI, "EPA's assessment that 'there is sufficient time for the infrastructure, especially for depot charging, to gradually increase over the remainder of this decade to levels that support the stringency of the proposed standards for the timeframe they would apply' is accurate. As seen above, EEI members actively are planning for and deploying infrastructure today."[526] EEI documents that a number of large utilities are finding ways to move away from a business model requiring demonstration of concrete demand so as to provide infrastructure readiness in advance of individual applications. EEI comments at 12-14 (actions of California and New York State investor owned utilities, and their respective regulatory bodies); see also Analysis Group Heavy Duty Vehicle Electrification at 31 and n. 75 (rate orders allowing utilities to include adjustment clauses in tariffs, whereby utility buildout expansions need not wait upon the outcome of a full rate case).

There are means for utilities to ameliorate demand which do not require regulatory approval at all. Utilities can engage in short-term load rebalancing by optimizing use of existing distributive infrastructure. This can accommodate new HDV demand while maintaining overall system reliability.[527] In addition, because depot charging often occurs over nighttime hours corresponding to reduced system demand, utilities have the flexibility to use otherwise extra grid capacity for those hours (excess capacity being inherent in constructing to nameplate capacity).[528] Utilities also can reduce needed demand by incorporating so-called smart charging

[527] ICCT White Paper at 18-19.

[528] https://www.forbes.com/sites/bradtempleton/2022/09/12/evs-wont-overload-the-power-grid-in-fact-evs-and-ice-are-its-salvation/?sh=61f3269949c5

into feeder ratings and load forecasting whereby the utility need not provide capacity based on annual peak load, but can differentiate by daily and seasonal times.[529] An available variant of this practice is use of flexible interconnections (discussed in more detail below), whereby customers agree to limit their peak load to a specified level below the cumulative nameplate capacity of their equipment (in this case, their EVSEs).[530]

Many utilities also provide hosting capacity maps. Utilities, developers, and other stakeholders can use these maps to better plan and site energy infrastructure. Hosting capacity maps provide greater transparency about where new loads such as EV chargers, can be readily connected. Specifically, hosting capacity maps identify where power exists and at what level, where distributed energy resources (DERs) can alleviate grid constraints, or where an upgrade may be required. For example, EV charging companies can use the maps to identify new areas to expand their charging station networks more quickly and cost-effectively. While the information in hosting capacity maps does not address all the interconnection questions for individual sites, they can indicate relative levels of investment needed. DOE has identified 39 unique hosting capacity maps currently available covering 24 States and the District of Columbia.[531] Similarly, utilities have developed tools providing detailed information on electrification fueling requirements, site preparation and depot needs, the process of interconnection, total cost of ownership calculation mechanisms, maintenance and operations issues associated with both vehicles and infrastructure.[532] ERCOT (the grid operator for most of Texas) has in place a method and process to forecast EV loads at the substation level, and has commenced using these estimates as part of its near-term transmission planning studies.[533]

Third, there are many mitigative measures open to fleet owners utilizing depots. Readily available practices include use of managed charging software, energy efficiency measures, and onsite battery storage and solar generation.[534] Other solutions include bi-directional charging and V2G (vehicle to grid) whereby vehicles can return electricity to the grid during peak hours while drawing power at low demand times.[535] Solar DER allows on site electricity generation that reduces the energy demand on the grid. As discussed in the RIA, battery-integrated chargers can reduce the need for distribution upgrades by limiting the peak power draw of high-powered charging stations. On-site distributed generation can similarly be deployed to reduce the amount of power needed from the grid, and allow for faster interconnection. Mainspring Energy has deployed its linear generators to accelerate interconnection for heavy-duty EV charging for

Prologis in California.[536] The TEIS captures existing solar energy in its analysis but did not consider the potential for increased future on-site solar generation at charging locations. All of these can reduce demand below what would otherwise be nameplate capacity. See the summaries in the following section on distribution costs further documenting additional mitigative possibilities. We note that EPA's cost estimates do not expressly consider these mitigative measures. However, standard available Level 2 chargers have power/amperage control that would enable basic charge management such as used in the TEIS. Others had features allowing charge start time control which is the next level of charge management to mitigate distribution buildout cost and timing. These chargers have low enough price points that total cost with installation is expected within our cost assumptions.[537] This demonstrates that additional cost for managed charging is not required, and that some measure of managed charging is already encompassed within our cost analysis under the potential compliance pathway. There thus exist multiple available measures to reduce demand and need for distribution buildout, and consequently provide further support for finding that there are reasonable means of providing needed distribution buildout in the rule's timeframe when there is a need to do so. See RIA Chapter 1.6.4 for additional examples.

As many commenters noted, the question of availability of supporting electrification infrastructure is not in the control of the regulated entity here, the OEM, nor is it in the direct control of prospective vehicle purchasers. See, e.g., Comments of EMA summarized above. As all agree, this necessitates some measure of coordination between a range of stakeholders and utilities. Many such means of coordination are described in the comments by utility associations like EEI, [538] and the transportation industry coalition ZETA[539] Additional examples and strategies are set out in RIA Chapter 1.6.4 and in the following discussion of public charging network availability. OEMs and regulators likewise can contribute to this coordination, as in the agreement between CARB, EMA, and OEMs to "promote future infrastructure development" noted earlier in this response.

We note further that this is not an unprecedented situation with CAA section 202 standards. For example, when EPA required the removal of lead from gasoline, an entire new parallel fuel distribution system was developed to dispense the new unleaded gasoline. See Preamble section I. Other examples where new distribution systems arose to ensure delivery of fuels necessary to vehicular pollution control include the infrastructure to supply diesel exhaust fluid (used to support selective catalytic reduction) and ultra-low sulfur diesel fuel (used to support diesel particulate filters). We thus see that there can be successful market responses to demand created by a section 202 standard, including successful responses from unregulated entities.

Utilities, of course, are motivated to continue investment in the distribution system for reasons other than demand from the transportation sector, and so could be building out in some cases for

their own purposes.[540] In addition, as noted at the end of this section, the utility industry has a strong financial incentive to service the HDV sector, and to do so expeditiously. That is to say, the increased demand due to BEV charging presents a significant positive business opportunity for utilities to increase their revenues and profits, and it is reasonable to believe that utilities will successfully capitalize on these opportunities. Utilities are thus themselves pursuing innovative solutions to address the issue of needed buildout. One approach is for utilities to make non-firm capacity available immediately as they construct distribution system upgrades. In California, Southern California Edison (SCE) is running a two-year Automated Load Control Management Systems (LCMS) Pilot. The program would use third-party owned LCMS equipment approved by SCE to accelerate the connection of new loads, including new EVSE, while "SCE completes necessary upgrades in areas with capacity constraints." SCE would use the LCMS to require new customers to limit consumption during periods when the system is more constrained, while providing those customers access to the distribution system sooner than would otherwise be possible. Once SCE completes required grid upgrades, the LCMS limits will be removed, and participating customers will gain unrestricted distribution service. SCE hopes to evaluate the extent to which LCMS can be used to "support distribution reliability and safety, reduce grid upgrade costs, and reduce delays to customers obtaining interconnection and utility power service." .[541]

Plans like SCE's to use LCMS to connect new EV loads faster in constrained sections of the grid will be bolstered by standards for load control technologies. UL, an organization that develops standards for the electronics industry, drafted the UL 3141 Outline of Investigation (OOI) for Power Control Systems (PCS). Once finalized, manufacturers will be able to use this standard for developing devices that utilities can use to limit the energy consumption of BEVs. The OOI identifies five potential functions for PCS. One of these functions is to serve as a Power Import Limit (PIL) or Power Export Limit (PEL). In these use cases, the PCS controls the flow of power between a local electric power system (local EPS, most often the building wiring on a single premises) and a broader area electric power system (area EPS, most often the utility's system). Critically, the standardized PIL function will enable the interconnection of new BEV charging stations faster by leveraging the flexibility of BEVs to charge in coordination with other loads at the premise. With this standard in place and manufacturer completion of conforming products, utilities will have a clear technological framework available to use in load control programs that accelerate charging infrastructure deployment for their customers.[542]

Finally, as a number of commenters noted, the utility industry has a strong financial incentive to service the HDV sector, and to do so expeditiously. For example, the study conducted by Synapse Energy Economics for EDF showed significant financial opportunity. Con Edison's

make ready program could generate net revenue of $690 million and National Grid could generate $89 million over the years of 2023 – 2045.

In sum, we project that distribution systems to meet the potential increase in charging station demand associated with depot charging under the Phase 3 rule will be available in the rule's timeframe. Quantified demand attributable to the rule is relatively modest, and there are ways—many on-going—to accommodate demand. Where buildout might be needed, it can be met for the most part with the least time-intensive forms of infrastructure buildout. We have also considered further potential issues, including the chicken-egg paradigm, and described means that are reasonably available to resolve these issues in the lead time provided by the rule. That the trade association of the investor-owned utility industry agrees provides further support for our finding. Comments of EEI at 14.

B. Public Charging Infrastructure Availability

Commenters from both industry and NGO sectors agreed that EPA's assumption of depot charging as the exclusive charging mode for the 2027-2032 MY standards was inadequate for certain long-haul applications. EPA agrees and has revised its projected compliance pathway accordingly such that sleeper cab tractors and certain day cab tractors are projected to utilize public (en-route) charging networks rather than depot charging. See generally, Preamble section II.D.5. We find here that there will be adequate supporting public charging infrastructure for sleeper cab tractors in the lead time afforded by the rule.

First, as documented in the ICCT White Paper, and as discussed above, there is no need to build out all at once. It is reasonable to project that activity will center on the busiest long-haul freight routes and corridors. The White Paper further finds that in MY 2030, up to 85% of long-haul truck charging needs in the country will concentrate on discrete corridors of the National Highway Freight Network.[543] Assuming an average of 50 miles between stops, this would mean a need for 844 public charging stations. Id. In a supplemental analysis assuming 100 mile intervals between stations, ICCT refined that estimate to needing between 100-210 electrified truck stops, assuming a given level of BEV long-haul tractors. ICCT Supplemental Comment (January 2024.) We note that the ICCT estimates in both the White Paper and the supplemental comment assume more long-haul tractor BEV adoption than in EPA's projected compliance pathway for 2030, and also assume public charging rather than depot charging for some short-haul tractors and vocational vehicles. From that standpoint, the White Paper estimates can be viewed as conservative. [544]

This level of public charging is doable. First, under the final standards, there would be no need for public charging until MY 2030. One reason for the extra lead time in the final rule is to provide more time for the public infrastructure development. See RIA Chapter 2.8.7.3.

Second, manufacturers, charging network providers, energy companies and others are investing in high-power public or other stations that will support en-route charging. See RIA Chapter 1.6.2.2 and 1.6.5. As noted there, a recent assessment by Atlas Public Policy

[543] ICCT White Paper at 14. This estimate reflects total need, not just an increment attributable to Phase 3 standards. Id. at 10.. .

[544] See Analysis Group "Heavy Duty Vehicle Electrification" at Table 1 (showing ICCT long-haul tractor estimates for 2030: 16% (ICCT) v. 6% (EPA final rule potential compliance pathway)).; ICCT White Paper at 10, 23 (showing projections for all MHDVs).

estimated that $30 billion in public and private investments had been committed as of the end of 2023 specifically for charging infrastructure for medium- and heavy-duty BEVs.[545] The U.S. government is making large investments in charging infrastructure through the BIL[546] and the IRA,[547] as discussed in RIA Chapter 1.3.2. This includes extending and modifying a tax credit that could cover up to 30% of the costs for procuring and installing certain charging infrastructure (subject to a $100,000 per item cap) and billions of dollars in funding programs that could support charging infrastructure either on its own or alongside the purchase of a HD BEV. In the past year, for example, the States of California, Colorado, New Mexico, New York, and Washington have received a total of approximately $166 million in grants under the Charging and Fuel Infrastructure federal program for designated alternative fuel corridors. See RTC section 6.1.

Private investments will also play a critical role in meeting future infrastructure needs. Much of this will likely be charging infrastructure purchased by individual BEV or fleet owners for depot charging. This is occurring already. Over a billion dollars have been announced for projects to support electric truck or other commercial vehicle charging in the United States and Europe.[548] For example, Daimler Truck North America is partnering with electric power generation company NextEra Energy Resources and BlackRock Renewable Power to collectively invest $650 million to create a nationwide U.S. charging network for commercial vehicles with a later phase of the project also supporting hydrogen fueling stations.[549] Volvo Group and Pilot recently announced their intent to offer public charging for medium- and heavy-duty BEVs at priority locations throughout the network of 750 Pilot and Flying J North American truck stops and travel plazas[550]. One Energy plans a 30 MW charging facility in Ohio. It is located next to a 138kV transmission line to benefit from reduced connection cost and time needed for development. The size and capacity are such that 90 trucks can charge at 300 kW.[551] This example shows that, with proper planning, even the largest charging facilities can potentially be accommodated without significant new distribution infrastructure buildout. See RIA Chapter 1.6.2.2 describing additional existing and projected efforts among vehicle manufacturers, fleets, charging providers, and other public and private sources to support HDV

BEV public charging. And, of particular import, the TEIS included public charging in its analysis and identified no barriers to implementation.[552]

As described in RIA Chapter 1.6.2.2, states and utilities are also engaged. Seventeen states plus the District of Columbia (and the Canadian province Quebec) developed a "Multi-State Medium- and Heavy-Duty Zero-Emission Vehicle Action Plan," which includes recommendations for planning for, and deploying, charging infrastructure. California is investing $2.9 billion through 2026 in BEV charging and hydrogen fueling infrastructure (and related projects), including $1.7 billion specific to infrastructure for medium- and heavy-duty vehicle applications. Actions such as these are required to address DTNA and similar concerns that utility infrastructure planning is 5-10 year timeframe, much farther out than fleets. This coordination and communication will allow utilities to determine future infrastructure needs, align with regulators on the need and cost, and implement on time. The Edison Electric Institute estimates that electric companies are investing about $4 billion to advance charging infrastructure and fleets. The National Electric Highway Coalition, a group that includes more than 60 electric companies and cooperatives that serve customers in 48 states and D.C. aims to provide fast charging along major highways in their service areas. Other utilities, like the Jacksonville Electric Authority (JEA) are supporting infrastructure through commercial electrification rebates. JEA is offering rebates of up to $30,000 for DCFC stations and up to $5,200 for Level 2 stations. In the west, Nevada Energy is supporting fleets by offering rebates for up to 75% of the project costs for Level 2 ports and up to 50% of the project costs for DCFC stations (subject to caps and restrictions. For supporting citations, please see RIA Chapter 1.6.2.2.

Thus, we see coordinated responses at the federal,[553] state, utility, fleet, and vehicle manufacturer level to meet evident market demand. EPA agrees with commenters that all these entities may play a role in facilitating public charging infrastructure, and that is what we see already happening. We note further that numerous comments by varied stakeholders reinforced that this EPA rule will provide clear direction and help infrastructure plans move forward. See RTC section 2.4 (Theme: Federal standards themselves will provide regulatory certainty for investment in ZEVs, critical materials, and infrastructure). We view the Phase 3 rule as providing the vital regulatory certainty for supporting the development of charging infrastructure.

Putting this together, we believe that there will be adequate public charging infrastructure within the Phase 3 rule's timeframe. The standards are structured to provide extra lead time until 2030 for commencing public charging. Substantial sums are being invested in creating a public charging network for HD BEVs, and there is coordinated activity across the public and private sectors, including the utility sector, to successfully implement a network. EPA's rule will provide regulatory certainty to support further investment. Accordingly, we find that the rule affords adequate lead time for public charging.

We discuss the issue of cost in the following RTC section, but note here the conclusion that costs associated with distributive grid buildouts attributable to the potential compliance pathway

[552] TEIS at 23 (overall methodology) and 73 (incremental number of public charging ports estimated).
[553] As noted above, the National Zero-Emission Freight Corridor Strategy is part of this federal response.

used to support the standard’s feasibility are modest both absolutely and as a percentage of total grid investment.

EPA Summary and Response – Distribution Cost:

Summary:

EPA received many comments regarding the cost needed for upgrading the grid to deliver the power required for HD BEV (AFPM, AmFree, NACS). AmFree states that a new substation can cost $35M and take 4 years to implement. AFPM highlights the cost magnitude by sharing a Southern California case study where the infrastructure upgrades were at least $1B and possibly over $10B. International Union, United Automobile, Aerospace and Agricultural Implement Workers of America (UAW) comments that the standards should better reflect that federal incentives will take time to mature, and that market demand will lag behind that timing. RMI recognizes in their comments that the infrastructure buildout time and cost can be limiting factors for ZEV adoption.

Commenters provided input on various cost aspects driven by or related to Phase 3 standards. Some shared external factors that would drive up electric prices. One (CFDC) expects that new power plant regulations will increase costs as the demand for power from HD BEV increases. Zero Emission Transportation Association (ZETA) provided comment on investments being required for distribution systems and possibly energy generation and associated distribution. Other comments like those from DTNA and EEI focused on the cost of the infrastructure build out and how that cost is passed on to consumers. They share that the HD fleets may cover buildout costs directly when power is supplied by utility coops or by municipal service. NRECA mirrored this thought and added that costs will be region, neighborhood, cooperative, circuit, and feeder dependent and must be passed to their coop members. DTNA and Schneider National similarly stated that, when power is from an investor-owned utility, the costs will be covered by rate increases that impact the fleets or all electric customers. EMA likewise noted that there are different mechanisms for allocating costs of distributive grid buildout, but agreed that it was reasonable to consider that the cost would be reflected in the overall rate base. EMA further suggested what this cost should be, based on analytic work of the ICCT.

DTNA utilized analysis by BCG to estimate an optimized and non-optimized electric rate increase driven by grid infrastructure. DTNA calculated and shared grid build out cost estimates for each of the 50 states. DTNA’s calculation shows a price tag of $36B for grid buildout in support of HD BEV Phase 3 standards. NACS indicated that pricing could be based on peak demand, rather than on actual use, and also shared concern that HD BEV en route charging stations would incur high demand charges as HD BEV at these facilities would require immediate, high power charging.

Clean Air Task Force pointed out that revenue would be generated by additional electricity supply with existing systems such that rates could decrease. This possibility to lower rates for all users, due to the increased revenue from HD BEV, was also found in a study of NY State conducted for EDF. EDF goes on to state that HD BEV users can decrease their own rates by implementing managed charging and save even more with stationary batteries and DER. Valero shares that if fleets add stationary batteries to keep distribution upgrade cost low, the cost of the stationary batteries must go into the analysis. Clean Air Task Force and Moving Forward Network (MFN) comments offered that using V2G technology would provide significant savings such as $13-15 billion in stationary battery costs in CA. Comments on related costs like the charging equipment taking up physical space and possibly adding parking lot size and cost were made by DTNA. Clean Fuels Development Coalition shared that HD BEV charging stations will require more space since the large trucks will remain at the station longer as charging takes longer than filling the tank of an ICE vehicle. If the infrastructure upgrade requires land, MOFB states that land owners need fair compensation for any land they relinquish.

Comments were received that distribution upgrades and their cost can be minimized through load management and Time of Use charging (AEU, CALSTART, MFN). They shared that TOU works for residential customers and they expect HD BEV users to be even more cost sensitive and, for depot charging situations, potentially having more latitude about scheduling off-peak charging times. MFN also shared that LBNL studies showing TOU and load management reduce grid investment needs. Comments by EDF cover a NJ study where grid buildout savings (i.e., avoided costs) were up to $2.15B when managed charging was combined with solar and battery hardware. AEU shared NREL data that managed charging can save a fleet $1,090 per EV per year. They also shared PGE testimony that managed charging can reduce capacity request 50% and save $30,000 to $200,000 per project. CALSTART shared information on EO Charging, a UK company that has made managed charging, energy storage, and flexible rates a way to accelerate BEV deployment and deliver reliable charging while working around grid capacity constraints. CALSTART shared other new business models that, although possibly supporting HD BEV adoption, are outside of the scope of this rule. Energy Strategy Coalition and NACAA noted massive subsidies at the federal and State level supporting grid improvements, including specific instances of funding directed at the heavy-duty sector. Commenter DTNA, however, included an Appendix B documenting that most states have not yet given specific consideration to HD infrastructure needs in their plans for disposition of NEVI subsidies for public charging EVSE. Energy Innovation shared that private investment has grown from $200 million to $13 billion in the 5 years ending in 2023. It was not made clear if this investment was distribution or EVSE or both. This commenter further notes that total approved utility investment for transportation electrification was $5.230 billion as of March 2023.

<u>Response:</u>

EPA recognizes that grid distribution upgrade costs will be present when existing capacity is not sufficient for HD BEV loads. We have considered the costs of distribution buildout in the RIA costs analysis. The below discussion supplements our prior response as well as the analysis in RIA Chapter 2.4.4.2.

In order to better understand potential distribution upgrade costs associated with the combined BEV demand under potential compliance pathways for this rulemaking and for the proposed Multipollutant Emissions Standards for Model Years 2027 and Later Light-Duty Medium-Duty Vehicles, EPA and DOE supported a first of its kind Transportation Electrification Impact Study (TEIS). To reiterate, the TEIS was conducted by a team of researchers at NREL, LBNL, and Kevala. The study focuses on 5 states (California, New York, Illinois, Oklahoma, and Pennsylvania) to capture diversity in population density (urban and rural areas), freight demand, BEV demand, state EV policies, utility type (i.e., investor owned, municipality, or cooperative) and distribution grid composition. The TEIS used these states to extrapolate a national demand for where and when upgrades will be needed to the electricity distribution system—including substations, feeders, and service transformers—due to increased BEV load associated with an approximation of the EPA light- and heavy-duty rules, referred to in the Study as the EPA policy case, and under a no action case. The research team also assessed the potential impact of "conservative " [554]managed EV charging to reduce the needs and associated costs of distribution upgrades. The 5 State portion of the TEIS for the year 2027 shows incremental distribution grid capital investment of $195 million for the unmanaged scenario. When managed, this drops to $82 million.[555] The 5 state portion of the TEIS for the year 2032 shows incremental distribution grid capital investment of $2.3 billion for the unmanaged action scenario. When managed, the $2.3 billion drops to $1.0 billion.[556] The savings is driven by the reduction in peak incremental load achieved by the basic load management applied in this study. More effective load management is expected to be utilized in practice.[557] Incremental distribution grid investment to enable BEV charging ($2.3 billion across five states over 6 years) was found to be approximately 3% of existing utility distribution system investments (2027-2032).[558] In 2027, when there is the least lead time, projected incremental distribution capital investment is only $195 million (82 million managed), an even smaller percentage.[559] The study moreover finds that "[m]anaged charging techniques can decrease incremental distribution grid investment needs by 30%, illustrating the potential for significant cost savings by optimizing PEV charging and other loads at the local level."[560] These values are inclusive of effects for LMHD and so overstate the amount of grid investment associated with the Phase 3 rule.

A 3% increase in distribution system build out correlates to a small increase in manufacturing output so concerns regarding supply chain timing and cost are minimal. The total costs are modest both in and of themselves, as a percentage of grid investment even without considering mitigation strategies. Based on utility reports to the Federal Energy Regulatory Commission, data from electric co-ops, and extrapolation for the remaining utilities, the TEIS estimated that the national investment in distribution systems exceeded $60 billion annually as of 2021.[561] A high-level approach for scaling the national distribution system investment to the five states under study was applied to estimate that $15 billion of distribution system investment occurred in 2021. The TEIS estimated that the incremental investment in distribution networks (to accommodate PEV growth due to EPA's rulemaking) as an additional $2.3 billion of grid investment for PEVs relative to a no action case. Annualizing this between 2027 and 2032 results in an annual cost from the EPA light- and medium duty rule combined with the heavy-duty phase 3 rule of $0.4 billion, or approximately 3% of existing annual distribution investments, across the five states.[562]

---

[554] TEIS at 4.
[555] TEIS Table 26.
[556] TEIS Table 26.
[557] As noted in the previous section, even in 2032, peak demand is projected to decrease in three of the five states, and increase only minimally in the other two. TEIS at 76. . Consistent with the small increase in load and peak load, total costs are modest as well.
[558] TEIS at 75 ..
[559] TEIS at 75.
[560] TEIS at 76. PEV refers to Plug-in electric vehicles. Since the TEIS is considering effects of both rules, it includes plug-in hybrid vehicles as part of its analysis. Breaking this down further, the TEIS finds that "managing charging could substantially reduce incremental grid components needs, including for substations by 50%, feeders by 40%, and service transformers by 30%." Id.
[561] TEIS Executive Summary at ix.
[562] TEIS Executive Summary at ix.

The TEIS grid buildout cost results were extrapolated to all IPM regions in order to estimate impacts on electricity rates using the Retail Price Model. There is no difference in retail electricity prices between the No action/unmanaged and action/mitigated case in 2030 and the difference in 2055, is only 2.5 percent and we estimate that the 2.5 percent difference is primarily due to distribution-level costs. The net cost of distribution-level upgrades are included within our analysis of costs and benefits for the final rule along with other grid-related costs modeled by IPM, and is reflected in electricity rates estimated using the Retail Price Model. EPA thus believes that the costs associated with distributive grid buildout attributable to the Phase 3 rule are reasonable. The relative small cost increases further support our conclusion in the prior response that there is sufficient lead-time to upgrade distribution infrastructure.[563]

As noted, based on utility reports to the Federal Energy Regulatory Commission, data from electric co-ops, and extrapolation for the remaining utilities, the TEIS estimated that the national investment in distribution systems exceeded $60 billion annually as of 2021. A high-level approach for scaling the national distribution system investment to the five states under study was applied to estimate that $15 billion of distribution system investment occurred in 2021. The TEIS estimated that the incremental investment in distribution networks (to accommodate PEV growth due to EPA's rulemakings) as an additional $2.3 billion of grid investment for PEVs relative to a no action case. Annualizing this between 2027 and 2032 results in an annual cost from the EPA light- and medium duty rule combined with the heavy-duty phase 3 rule of $0.4 billion, or approximately 3% of existing annual distribution investments, across the five states. The TEIS results were extrapolated to all IPM regions in order to estimate impacts on electricity rates using the Retail Price Model (see RIA Chapter 2.4.4.2). There is no difference in retail electricity prices between the No action/unmanaged and action/mitigated case in 2030 and the difference in 2055, is only 2.5 percent and we estimate that the 2.5 percent difference is primarily due to distribution-level costs. Note also that this is comparable to the 3% increase in distribution-level investments estimated for the 5 states within the TEIS.[564] The net cost of distribution-level upgrades are included within our analysis of costs and benefits for the final rule along with other grid-related costs modeled by IPM, and is reflected in electricity rates estimated using the Retail Price Model. See RIA Chapter 2.4.4.2.

Land Acquisition Costs

A number of commenters stated that grid distribution buildout would require additional space, sometimes necessitating acquisition of land. They noted that freight depots are often located in densely populated areas where land is either not available, or at a premium. See, e.g. Comments of DTNA at 47. The ATA (at 17) gave the example of when a new substation is a specific situation where more land would be needed. If land is available, there would be a cost which should be reflected in EPA's analysis.

With respect to public charging, EPA agrees that there may be additional costs associated with land acquisition that should be considered in our modeling. In many cases, the public charging stations will be new facilities, see RIA Chapter 1.6.1.5, and so will not be utilizing an existing footprint. Our estimate of electricity rate for public charging includes an amortized cost of land acquisition. RIA Chapter 2.4.4.2. We agree with commenters that HDV public charging

[563] See Preamble section II.D.2.iii.c at n. 452.
[564].TEIS at 74.

will in many cases require more parking and other space, as well as higher rates chargers, than public facilities servicing light duty vehicles. See RIA Chapter 1.6.1.4 noting this concern, and RIA Chapter 1.6.2.2 describing various means of sizing to accommodate HD BEVs. The fact that much of the heavy-duty public charging network will be new facilities allows this extra space to be included in the facility design.

With respect to depot charging, we are not including a cost for land acquisition. First, these are typically not greenfield sites (i.e., new facilities), but will be utilizing existing footprints. Second, we believe that the early targets of electrification will be facilities where it is most cost effective to do so, which would include considerations of available space. In this regard, as noted throughout the Preamble and RIA, the majority of HDV in our potential compliance pathway remain ICE vehicles, leaving fleet owners flexibility as to where to electrify.

In addition, our modeled potential compliance pathway shows that depot charging needs for most HDVs can be met with level 2 chargers. RIA Chapter 2.6.2.2. This type of charger would generally not require power cabinets or other behind-the-meter equipment for which higher-power stations need extra space. In confirmation (and in response to the comment of ATA), the TEIS Study finds that in 2032, only 8 substations would be required in its 5-State study area even in the unmanaged case (i.e. without any mitigation), and only 4 substations would be required if "conservative " mitigation is utilized, of which only 1 would be new, the rest being upgrades to existing substations which would not add to an existing footprint.[565] Nationally, the number of substations in 2032 is projected at from 24-48 (managed and unmanaged) of which most would be upgrades.[566] Moreover, as discussed in the responses above, there are many other mitigative measures readily available to reduce the need for buildout at all, or for the type of buildout that would occasion the need for additional land.

Daimler cites two instances where space constraints have precluded BEV purchases by fleet owners, one in California and one in Denver, Colorado. Daimler Comment at Fig. 4 and 5. These instances both involved situations where grid buildout was needed. It is not clear from the comment if Level 2 or other chargers were being utilized, if any mitigative measures for reducing demand were considered, or otherwise why buildout was involved. Given the lack of specificity provided by the commenter, EPA cannot respond further to this individual instance, which in any case would not be generalizable to national conditions years hence.

Total Cost (DTNA Appendix C)

DTNA estimated the additional installed capacity that will be needed to support HD BEVs at the adoption rates projected in the Proposed Rule. They calculated a 5-year average of commercial vehicle sales in all 50 states from the Polk Automotive database from 2017-2021, applied EPA's projected ZEV volumes for 2027-2032, and calculated the total installed charging capacity that will be required by these vehicles in 2027 - 2032 to be approximately 45 gigawatts. In Appendix C of its comments, DTNA then estimated the investments in charging infrastructure and grid upgrades, as well as total installed charging capacity, that will be required in each of the 50 states, state by state, to support implementation of the Proposed Rule. They project a 50-State cost of $36 billion.

[565] TEIS at 75.
[566] TEIS at 65 , and see text at n. 501 above for further explanation.

First, DTNA used sales estimates and BEV (their analysis assumes no FCEVs) adoption rates reflecting the proposed rule, and so based its estimates on nearly 1,500,000 BEVs.[567] This is almost three times the number of BEVs projected under the final Phase 3 standards; 525,0000.[568] DTNA also used its own cost estimates for charging and installation, which are higher than EPA's. In addition, although they present state-by-state estimates of amount of charging and distributive infrastructure needed, there is no breakdown of either charger type or the nature of the grid buildout. There is also no discussion of mitigation to reduce need for buildout, but as EPA explained above, we think it is very likely that mitigation strategies will be employed, and that even the most rudimentary of such strategies can greatly reduce the need for infrastructure buildout. For all these reasons, it is difficult to evaluate DTNA's estimate, although it is clearly higher than the final rule's costs given the difference between the proposed and final standards.

The TEIS does provide an estimate of 5-State costs for charging ports and charging infrastructure capital investment (for substations, feeders and transformers). The basis for these quantified estimates of individual asset type is well documented in the TEIS.[569] Over 2027-2032 the TEIS estimates a cost of $12 billion (unmitigated), and $10.7 billion (managed). These estimates are for both light and heavy-duty action cases, so the portion attributable to the heavy-duty sector would be less. The five states in the TEIS represent 30-35% of nationally extrapolated costs[570],. This yields extrapolated costs of roughly $33 billion to $39 billion, but these reflect costs from both light duty and heavy duty sectors. We consequently believe that DTNA's cost estimates for the Phase 3 rule are significantly overstated.

<u>IOP study cited by AFPM</u>

AFPM states that "[B]eyond EVSE chargers, the cost of grid upgrade projects needed to support the incremental electricity demand growth from transportation is not insignificant and can be quite variable. A particular case study of Southern California illustrated in IOPscience notes: 'the total cost of these upgrades will be at least $1 billion and potentially more than $10 billion.'" The commenter mischaracterizes the study. It considered electrification not just of heavy-duty vehicles, but of light and medium duty vehicles, and of residential electrification.[571] The study is thus not directly comparable here.

<u>Time for Interconnection</u>

Certain commenters (e.g. AFPM, DTNA) noted that even if no distributive buildout is needed, it can sometimes take two years or longer just to be connected to the grid and that this would dissuade fleets from purchasing BEVs given that purchase decisions are generally made 6-12 months in advance (meaning that timetables of purchase and connection will not synchronize).

As an initial matter, we note that even if we accepted two years or longer as the time for grid connection, there is sufficient lead-time. The standards phase in from MY 2027 through 2032, which is 2-8 years from now.

568 RIA Chapter 10.2.3.
569 TEIS at 16-25 ("Charging Demand for Heavy-Duty Vehicles).
570 TEIS at 66 .
571 "Can distribution grid infrastructure accommodate residential electrification and electric vehicle adoption in Northern California?" https://iopscience.iop.org/article/10.1088/2634-4505/ac949c at Abstract.

More importantly, we do not agree that two or more years is generally representative of the time for interconnection. The timeline for EVSE deployment—even without distribution upgrades—is very site specific and also has considerable variability based on the jurisdiction, but there are certainly documented instances already of connection occurring in considerably less than two years. . As noted in RIA Chapter 1.6.5, an EPRI survey of distribution utilities with 18 respondents from different areas of the country found the typical interconnection time was under six months where no distribution buildout was needed.

Commenters also note the measures being taken by utilities and BEV purchasers to speed the connection process. A report by the Smart Electric Power Alliance (SEPA) found a wide range of non-wires alternatives succeeded at enabling rapid interconnection and HDV electrification.[572] CALSTART cites instances of utilities implementing a variety of new strategies to speed interconnection by planning to work with shared charging service providers since they can create a new market for energy services at the edge of the grid and address the economics of increasing amounts of distributed loads.[573] This may allow utilities to support aggregated loads and address interconnection queues more proactively and rapidly.

Finally, we note FERC Order 2023, which relates to interconnection reforms. Order 2023 requires grid operators to adopt certain interconnection practices with the goal of reducing interconnection delays. These practices include a first-ready, first-served interconnection process that requires new generators to demonstrate commercial readiness to proceed, and a cluster study interconnection process that studies many new generators together.[574]

Reflecting Front-of-the Meter Costs

EPA agrees that it is appropriate to account for distributive grid buildout costs attributable to the Phase 3 rule. There are different ways of assessing this cost. Utilities often spread the cost of buildout over their rate base, and we have chosen this method. See RIA Chapter 2.6.4. Members of both the utility industry and HDV manufacturing industry agreed that this was a reasonable approach. See Comments of EEI and DTNA.

Substation Cost and Lead Time

Commenter AmFree stated that new substations could cost $35 million and take 4 years to install, raising issues of both lead time and cost. The commenter does not provide data or estimates of numbers of substations needed to service demand posed by the Phase 3 rule, however. AmFree's cost estimate is at the very high end of literature estimates for the cost of a new substation, and far higher than literature estimates for substation upgrades. See RIA Chapter 1.6.5. Their estimate of timing for a new substation are similar to other literature values, but again, higher than literature values for an upgraded substation. Id. The TEIS shows that few if any substations (new or upgraded) will be needed in 2027, and only a small number in 2032, almost all of which are upgrades. It further finds, for the 5 States in the study, that "substation

[572] Brenda Chew et al. Non-Wires Alternatives: Case studies from leading U.S. projects. 2018, Smart Electric Power Alliance, https://sepapower.org/resource/non-wires-alternatives-case-studies-from-leading-u-s-projects/

[573] "The Economics Of Load Defection". RMI. https://rmi.org/insight/economics-load-defection/

[574] See generally FERC Order 2023, 184 FERC ¶ 61,054 (July 28, 2023) (Docket No. RM22-14-000).

[and] transformer bank … built by 2027 mostly cover 2032 needs."[575] So we do not believe that the few projected substations not needed until 2032 would pose issues as to reasonableness of cost or adequacy of lead time to install. (Note further that both the comment and this response are referring to the potential compliance pathway supporting the final standards. Alternative available means of compliance involving non-ZEV vehicles would not pose this issue at all.)

AmFree Comment Relating to Total Demand Summary and Response

Commenter AmFree states that "today's electric grids do not have the capacity for such a dramatic increase in demand", referring to demand posed by "a modest-size fleet of Class 7 and 8 vehicles", and further quotes a "recent study" finding that "electrification of even 11 percent of trucks and buses 'could destabilize the transmission grid'", citing Spiller et al. "Medium – and Heavy-Duty Vehicle Electrification: Challenges, Policy Solutions, and Open Research Questions" (Resources for the Future, 2023). (Incidentally, this is a Report, not a Study, and so does not provide references for the statements it makes.)

First, the modelled compliance pathway used to support the Phase 3 standards does not posit anything like electrifying 11 per cent of the nation's trucks and buses. The standard applies to new vehicles only where the overwhelming percentage of vehicles will remain ICE for years to come. Second, depot charging with lower power chargers, as EPA analyzes and costs in its modelled compliance pathway, significantly reduces grid demand. RIA Chapter 2.10.3.

Third, with respect to public charging networks, there is already an instance of a public charging facility accommodating more demand than posited by the commenter without need for buildout. As described above, One Energy plans a 30 MW charging facility in Ohio located next to a 138kV transmission line to benefit connection cost and timing. The size and capacity is such that 90 trucks can charge at 300 kW. This is an example of how public charging networks, being for the most part greenfield sites, can site optimally in relation to available grid capacity. Generally, businesses building public charging facilities have strong incentives to make cost-minimizing decisions that take full advantage of existing infrastructure, and we fully expect them to do so going forward.

Finally, as discussed in RTC section 7.1, total demand on the grid posed by the Phase 3 rule is modest and does not pose issues as to grid reliability, even considered out to 2055 when projected HD BEV utilization would be greatest due to fleet turnover.

Response to Comment of National Rural Electrical Cooperative Association (NRECA)

NRECA states, correctly, that EPA did not assess the need for distributive grid buildout at proposal, and needs to do so. We agree, and have analyzed the issue in detail, informed by the public comments, including this one. See Preamble section II.D.2.iii.c and response above in this section 7.

The commenter also projects the need for additional service transformers in rural area because of the need to convert power to three-phase in very rural locations with only single-phase power. In the rural state analyzed in the TEIS (Oklahoma), transformer costs between the no action and action cases (both unmanaged and managed) are virtually none in 2027, and minimal in 2032.[576]

[575] TEIS at 74.
[576] TEIS at 80 .

Our modeled compliance pathway also projects availability of ICE vehicles for all HDV applications, and we have noted elsewhere that ICE vehicles may remain a norm in rural areas.

The commenter notes current delays in obtaining transformers due to supply chain irregularities, and that these irregularities have led to price spikes. We do not anticipate supply chains to remain disrupted years into the future but have structured the standards to reduce demand in the program's initial years when there is the least lead time. We also address transformer supply chain delays and costs in our earlier response in this RTC 7.

With respect to costs to NRECA member utilities for adding infrastructure, we note that those costs are recoverable via inclusion in the rate base, or by direct recovery from users. See RIA Chapter 2.4.4.2. HDV demand consequently can be a source of income to cooperative utilities, and from that standpoint, can be viewed as a positive development for the utilities.

7.1 Generation and Transmission

Comments by Organizations

Organization: American Fuel and Petrochemical Manufacturers (AFPM)

2. The Proposed Rule Requires Deployment of Technology Not Feasible within the Timeframe Contemplated.

Section 202(a) of the Clean Air Act does not mandate that EPA set standards to drive pollutant emissions down to zero; rather, EPA must balance benefits to health and welfare against costs of compliance to reflect "the greatest degree of emission reduction achievable through the application of technology which the [EPA] determines will be available" during the relevant model year.71 Here, the Proposed Rule forces a transition from ICEVs to ZEVs in the MY27–32 timeframe without demonstrating that such a transition is feasible, let alone necessary. [EPA-HQ-OAR-2022-0985-1659-A2, p. 17]

71 42 U.S.C. § 7521(a)(3)(A)(i).

Critically important to increased ZEV adoption is the infrastructure necessary to operate such vehicles. EPA overlooks this issue in the Proposed Rule. Notably absent from EPA's analysis is any demonstration that sufficient charging stations, utilities, and other infrastructure needed to support accelerated ZEV implementation will be available by MY27. As engine manufacturers have acknowledged, even as new ZEVs are ready to enter into production, the necessary infrastructure for both electric vehicles and hydrogen vehicles continue to lag, especially when multiple facilities are needed to support the multiple fuel and powertrain technologies EPA contemplates.72 Focusing solely on electric vehicles themselves, EPA has not adequately evaluated or grasped the time and resources required to permit, construct, and operate the necessary infrastructure to power these vehicles. This is particularly concerning in light of the very real risk that the electric grid will not be able to meet the increased demand anticipated by the Proposed Rule.73 [EPA-HQ-OAR-2022-0985-1659-A2, pp. 17 - 18]

72 See Jack Roberts, Truck Tech, "5 Takeaways from ACT Expo 2020," (May 20, 2022), available at https://www.truckinginfo.com/10172184/5-take-aways-from-act-expo-2022 (citing Cummins CEO Tom Linebarger as warning ACT Expo attendees that the undertaking will cost multiple trillions of dollars to accomplish).

73 North American Electric Reliability Corporation, 2022 Long-Term Reliability Assessment (Dec. 2022), 21, available at https://www.nerc.com/pa/RAPA/ra/Reliability%20Assessments%20DL/NERC_LTRA_2022.pdf. (indicating that increased demand projections may lead to reliability concerns for the electric grid, especially as dual-peaking or seasonal peaking times change with increased electrification)

Even assuming sufficient ZEVs can be manufactured with the corresponding consumer demand to buy them, EPA has not fully considered the uncertainty around the grid being able to support them. Grid resiliency is at risk of further deterioration due to increasing power demand from electrification, not just in transportation. Combined with other issues, such as a disorderly transformation of the generation base as conventional units are replaced with intermittent resources, increased electrification raises questions about the grid's ability to reliably meet consumer demand on a regional basis. The regional operation of the power grid is managed by entities called Regional Transmission Organizations ("RTO") or Independent System Operators ("ISO"). These authorities are not only responsible for transmission, but also balancing a regional power system to ensure that supply constantly matches demand. The grids in some RTOs are already under various degrees of stress. For example, the North American Electric Reliability Corporation's ("NERC") recent summer assessment shows roughly two-thirds of the U.S. faces increased resource adequacy risk in the summer of 2023.74 [EPA-HQ-OAR-2022-0985-1659-A2, p. 18]

74 North American Electric Reliability Corporation, "2023 Summer Reliability Assessment" (May 2023).

EPA's projections of ZEV sales are on a national basis, but the ability to charge the vehicles is driven by the ability to manage regional or local power grids to supply electricity on demand. EPA's national data thus disguises important problems that increasing EV penetration will cause. By 2022, over 50% of BEVs were concentrated in California, Florida, and Texas. The distribution of the BEV fleet across RTOs can be seen in Figure 1, in which state shares of EV registrations are allocated across RTOs.75 EPA barely pays lip-service to this issue. Even without increased demand on the grid from transportation electrification, today's grid is fragile. EPA should discuss the costs of power outages from weather events that could preclude truck recharging and put fleets out of operation for days at a time. Reduced utilization from grid dependency is an important issue that EPA failed to quantify. [EPA-HQ-OAR-2022-0985-1659-A2, p. 18.] [See Figure 1, EV Registrations by RTO, on page 19 of docket number EPA-HQ-OAR-2022-0985-1659-A2.]

75 There are several states that are covered by more than one RTO. For this high-level assessment, our consultants have allocated the state's EV sales by roughly the geographic footprint of each RTO within the state.

Potential stress on the grid within any given RTO is not just a function of EVs on the road, but also power generation capacity within the region. As seen in Figure 2, the greatest stress is not in California (though the California's stress is significant), but rather in the southwestern U.S. [EPA-HQ-OAR-2022-0985-1659-A2, p. 19. See Figure 2, EV Power Requirement by RTO, on page 20 of docket number EPA-HQ-OAR-2022-0985-1659-A2.]

This figure is based on EPA's estimate of EV electricity demand in 2032, allocated to RTOs, under the assumption that no reserve capacity is added over the next eight years. If an RTO wanted to fill incremental EV electricity demand and keep its reserve margin constant, the required capacity investment depends on the source of generation and that source's availability (i.e., expected load factor) specific to that region. For the U.S., the total investment cost could range from $15 to $100 billion, not including up to an additional $80 billion for storage to improve ratability of intermittent sources. [EPA-HQ-OAR-2022-0985-1659-A2, p. 20]

RTOs face another complication with the times of day likely to see greater EV charging. Sparsely available data suggest most EV charging currently occurs during daytime. However, if a growing EV fleet were to switch to overnight charging, it would put much less stress on a grid. EPA should work with other federal entities to ensure the growth in power demand stemming from an expanding EV fleet in the Proposed Rule can be safely and reliably supplied. Furthermore, EPA should provide a comprehensive analysis on how the light- and medium-duty multipollutant and the HD Phase 3 GHG proposed rules will jointly impact these demands on the grid. [EPA-HQ-OAR-2022-0985-1659-A2, p. 20]

Power generation using traditional fuels has an advantage in the capacity being located near demand centers. Except for nuclear, any low-carbon power generation capacity must be located at the energy source (e.g., where the wind blows, water flows, sun shines). Supplying low-carbon electricity to charge EVs also needs to resolve the transmission of that power to the demand center. Installation of transmission capacity in a timely manner is not a guarantee. The Bureau of Land Management ("BLM") recently issued its record of decision for the SunZia Southwest Transmission Project more than 15 years after the project was proposed.76 Once this incremental power is transmitted from supply location to a load center, there are potentially additional distribution transmission constraints before the electrons reach charging stations and homes. One supercharger equals the launch of 70 air-conditioning units at once. Such an instant change in the power demand profile is a significant problem for the local distribution grid. And EPA's ambitious light-duty proposal compounds this problem as Level 2 EV chargers, typically used in a home, can increase a home's peak load by 40% to 100%, which can stress neighborhood transformers and compromise reliability. [EPA-HQ-OAR-2022-0985-1659-A2, pp. 20 - 21]

76 Emma Peterson, INSIDE CLIMATE NEWS, "SunZia Southwest Transmission Project Receives Final Federal Approval" (May 29, 2023) available at https://insideclimatenews.org/news/29052023/sunzia-transmission-project-approval/.

The intensity is further complicated in that the capacity factor (percentage of time a plant is likely to be available for generation) of solar (28%) and wind (36%) plants is so much lower than dispatchable (typically 90+%) generation capacity. To put the intensity of effective generation capacity in perspective, solar and wind farms require almost three times as much copper to meet the load of a typical (combined cycle gas turbine) natural gas plant. For EPA to achieve its GHG reduction aspirations in the Proposed Rule, all three of these challenges must be met: (1) sufficient materials to manufacture the required EVs, (2) consumer willingness to substitute EVs for incumbent ICEVs currently for sale, and (3) a low-carbon power generation grid capable of reliably supply energy for this mode of transportation. [EPA-HQ-OAR-2022-0985-1659-A2, p. 21]

Relatedly, it is unlikely that the grid can be upgraded quickly enough to overcome the constraints referenced above. A recent DOE-funded study finds that: "[o]nly ~21% of projects (14% of capacity) requesting interconnection from 2000-2017 reached commercial operations by the end of 2022"; "[c]ompletion rates are even lower for wind (20%) and solar (14%); and "[t]he average time projects spent in queues before being built has increased markedly. The typical project built in 2022 took 5 years from the interconnection request to commercial operations."77

Moreover, EPA has failed to account for the direct effect its new carbon dioxide standards for fossil-fuel fired power plants, proposed shortly after the Proposed Rule, will have on the grid including how the increased demand for baseload and peaking power as a result of the Proposed Rule can be met as affordable base-load generators are rapidly phased out.78 Even in California, where renewable energy is a priority, daily evening peak load is still routinely supplied by approximately 70 percent fossil fuels.79 [EPA-HQ-OAR-2022-0985-1659-A2, p. 21]

77 See LAWRENCE BERKELEY NATIONAL LABORATORY, “Queued Up: Characteristics of Power Plants Seeking Transmission Interconnection As of the End of 2022”, available at https://emp.lbl.gov/sites/default/files/queued_up_2022_04-06-2023.pdf.

78 Proposed Rule at 33,240. Notably, EPA’s electric generating unit rule is not referenced in the proposed rule. Nor does the electric generating rule’s mere one-page assessment of grid reliability considerations even address EPA’s parallel efforts to push mass adoption of electric vehicles. Id. at 33,415.

79 See, e.g., CALIFORNIA ISO, “Today’s Outlook” (accessed June 13, 2023), available at https://www.caiso.com/TodaysOutlook/Pages/supply.html#section-supply-trend (showing data from Aug. 4, 2022, indicating more than 70 percent of energy from natural gas, coal, and imports).

Beyond the normal approximately four-year lead time for vehicle manufacturers to make incremental changes to their production, the typical duration of an electricity transmission system capital project timeline would need to be accelerated from approximately ten-years to have a chance to support the proposed ZEV demand, while current large-scale electric generation and storage projects are increasingly backlogged year-on-year due to long lead times for permitting and approvals, supply chain shortages, and shortage of skilled workers. While government programs have recently been put in place to help overcome some of these hurdles, they will take time for the benefits to be realizable.80 [EPA-HQ-OAR-2022-0985-1659-A2, pp. 21 - 22]

Organization: American Trucking Associations (ATA)

Grid AvailabilityCharging sites for depots or large public charging stations for commercial vehicles will require significant energy. The American Transportation Research Institute (ATRI) estimates full commercial vehicle electrification would require a 14 percent increase in energy generation from today’s standards.20 In many cases, remote or densely populated areas do not have available power to direct toward commercial vehicle charging sites. The International Council on Clean Transportation (ICCT) recognizes that the electrification of commercial vehicles will significantly burden the current electrical grid and challenge the centralization of where and how charging accommodates trucks in operation today.21 [EPA-HQ-OAR-2022-0985-1535-A1, p.15-16]

20 American Transportation Research Institute, Charging Infrastructure Challenges for the U.S. Electric Vehicle Fleet, pg. 17, December 2022.

21 The International Council on Clean Transportation, Near Term Infrastructure Deployment to Support Zero-Emission Medium-and Heavy-Duty Vehicles in the United States, May 2023.

“We find that near-term energy needs will be concentrated in industrial areas in the largest metropolitan areas in the country, including Los Angeles, Phoenix, Houston, Chicago, and Dallas. 1% of U.S. counties will account for 15% of nationwide MHDV charging energy needs in 2030, constituting high-priority areas in which to concentrate near-term deployment of charging and refueling infrastructure of MHDVs.” [EPA-HQ-OAR-2022-0985-1535-A1, p.16]

Early adopting fleets are being forced to quickly learn electricity demands and generation requirements as an important external factor that impacts their operations and TCO calculation. One fleet interviewed provided an example of their desire to electrify forklifts. In their mind, it would serve as an early use case to understand electric technology as they explored BEVs for their operations. However, in their discussions with the local utility, they were only allowed to electrify a small percentage of the originally desired forklifts due to limited onsite power. ATA asked fleets about their experiences with local utilities. More than two-thirds of respondents said they had not begun conversations with them. [EPA-HQ-OAR-2022-0985-1535-A1, p. 16]

The multi-state patchwork of energy generation and transmission regulatory bodies has made investment and modernization of the U.S grid even more challenging. Fleets are left with the reality of wading through local utility politics to receive approval for a permit to install minimal chargers on their site today. Addressing these site-specific challenges to build out charging infrastructure is essential to achieving the proposed rule’s adoption rates and should begin immediately to accommodate large-scale transportation electrification. Yet, most states have not begun this process. With 168 investor-owned utilities, 1,958 publicly owned utilities and 812 cooperatives providing electricity to customers in the U.S., the scale of this undertaking will be significant and time consuming.22 The planning and oversight associated with hydrogen infrastructure is especially so. EPA should not propose a ZEV-dependent rule prior to ensuring the needed electric and hydrogen infrastructure will be available, including initiating state-wide planning and deployment assessments prior to establishing proposed ZEV adoption rates and timelines. [EPA-HQ-OAR-2022-0985-1535-A1, p. 16]

22 Energy Information Administration, Investor-owned utilities served 72% of U.S. electricity customers in 2017, August 15, 2019, available at http://www.eia.gov/todayinenergy/detail.php?id=40913.

For example, recently the California Public Utilities Commission (CPUC) developed a “Draft Staff Proposal: Zero-Emissions Freight Infrastructure Planning” that addresses the need for proactive planning of long lead time utility-side electric infrastructure (i.e., distribution and transmission) needed to support the acceleration of transportation electrification.23 [EPA-HQ-OAR-2022-0985-1535-A1, p. 16]

23 California Public Utilities Commission, Freight Infrastructure Planning, May 22, 2023, available at: http://www.cpucc.ca.gov/industries-and-topics/electricial-energy/infrastructure/transportation-electrification/freight-infrastructure-planning.

CPUC identified several challenges through this process, including:Approximately three years of required time to sequence statewide planning efforts and complete infrastructure authorizations. This does not include the time for cost recovery approval.Significant market and technology uncertainty affects the state’s ability to proactively authorize infrastructure solutions.Risks and uncertainties regarding electricity grid load that are dependent on large-scale infrastructure buildout. These have not been adequately quantified within the state’s existing planning and forecasting processes.The lack of an existing source of information on future fleet charger locations, and the need for long-term grid infrastructure planning to account for fleets’ current flexible and economical routes.The lack of a coherent planning framework to optimize fleet business needs with electricity sector goals and requirements (i.e., how to cost-effectively upgrade the distribution and transmission system).The lack of a process for identifying long-term substation land acquisition needs. [EPA-HQ-OAR-2022-0985-1535-A1, p. 17]

Organization: Arizona State Legislature

EPA estimates that the additional electricity generation needed to meet the demand of heavy-duty battery electric vehicles is 'relatively modest.' 88 Fed. Reg. 25,983. According to EPA's estimates, the proposed rule will 'increase electric power end use by heavy-duty electric vehicles by 0.1 percent in 2027 and increase to 2.8 percent in 2055.' Id. EPA argues that the electric grid supported adoption of air conditioners and data processing centers successfully. Id. EPA concludes that '[g]rid reliability is not expected to be adversely affected by the modest increase in electricity demand' from the proposed rule. Id. [EPA-HQ-OAR-2022-0985-1621-A1, p. 28]

The electric grid is already stretched to the breaking point before implementing the proposed rule. According to the North American Electric Reliability Corporation's 2023 Summer Reliability Assessment, numerous sectors of the electric grid face shortfalls during peak demand this summer:

- Midcontinent ISO (MISO): 'MISO can face challenges in meeting above-normal peak demand if wind generator energy output is lower than expected. Furthermore, the need for external (non-firm) supply assistance during more extreme demand levels will depend largely on wind energy output.'55 [EPA-HQ-OAR-2022-0985-1621-A1, pp. 28-29]
- NPCC-New England: 'Operating procedures for obtaining emergency resources or non-firm supplies from neighboring areas are likely to be needed during more extreme demand or low resource conditions.'56
- SERC-Central: 'Compared to the summer of 2022, forecasted peak demand has risen by over 950 MW while growth in anticipated resources has been flat. The assessment area is expected to have sufficient supply for normal peak demand while demand-side management or other operating mitigations can be expected for above-normal demand or high generator-outage conditions.'57
- Southwest Power Pool (SPP): 'Reserve margins have also fallen in SPP as a result of increasing peak demand and declining anticipated resources. Like MISO, the energy output of SPP's wind generators during periods of high demand is a key factor in determining whether there is sufficient electricity supply on the system.'58
- Texas (ERCOT): 'Resources are adequate for peak demand of the average summer; however, dispatchable generation may not be sufficient to meet reserves during an extreme heat-wave that is accompanied by low winds.'59
- U.S. Western Interconnection: 'However, wide-area heat events can expose the WECC assessment areas of California/Mexico (CA/MX), Northwest (NW), and Southwest (SW) to risk of energy supply shortfall as each area relies on regional transfers to meet demand at peak and the late afternoon to evening hours when energy output from the area's vast solar PV resources are diminished.'60 [EPA-HQ-OAR-2022-0985-1621-A1, p. 29]

Almost all of these sectors are projected to have fewer resources than demand during extreme heat conditions.61 Power outages reached an all-time high in 2020, and the average person went seven hours without power in 2021.62 [EPA-HQ-OAR-2022-0985-1621-A1, p. 29]

Other observers recognize significant issues with the current electric grid's reliability. A commissioner to the Federal Energy Regulatory Commission recently testified to a U.S. Senate committee, 'The United States is heading for a reliability crisis.'63 Another commissioner echoed this warning, testifying, 'We know that there is a looming resource adequacy crisis.'64 The commissioner predicted that 'there will be, in time, a catastrophic reliability event.'65 [EPA-HQ-OAR-2022-0985-1621-A1, pp. 29-30]

EPA has only exacerbated the threats to grid reliability by proposing new carbon pollution standards for coal and natural-gas fired power plants in May 2023.66 The National Rural Electric Cooperative Association is 'concerned the proposal could disrupt domestic energy security, force critical, always-available power plants into early retirement and make new natural gas plants exceedingly difficult to permit, site and build.'67 This is consistent with a FERC commissioner's concern that '[t]he problem generally is not the addition of intermittent resources, primarily wind and solar, but the far too rapid subtraction of dispatchable resources, especially coal and gas.'68 As the Electric Power Supply Association observed upon release of the proposed power plant rule, 'For the EPA to issue proposed rules that are likely to drive power plant retirements while simultaneously undertaking separate actions to significantly increase demand for electricity due to electrification of the nation's vehicle fleet creates the conditions for a reliability failure. . . . We are not slow walking into a reliability crisis – if this rule is finalized, we will be choosing to run toward that outcome.'69 [EPA-HQ-OAR-2022-0985-1621-A1, p. 30]

69 Electric Power Supply Association, 'Proposed EPA Power Plant Rules Could Intensify Reliability Challenges,' May 11, 2023, available at https://epsa.org/proposed-epa-power-plant-rule-could-intensify-reliability-challenges/.

Into the face of these EPA-exacerbated grid reliability issues come EPA's electric vehicle rules, and many electricity requirement estimates are far less optimistic than EPA's. Before the electric vehicle rules, the U.S. Energy Information Administration was forecasting that 'electricity consumption by the transportation sector will increase by more than a factor of 12 between 2021 and 2050 (from 12 billion kWh in 2021 to more than 145 billion kWh in 2050).'70 The American Research Transportation Institute estimates that full electrification of the country's freight trucks will require a 14 percent increase in existing electricity generation.71 When combined with the needs for electricity generation for passenger cars and trucks, which EPA is separately proposing, the country needs to increase its existing electricity generation by more than 40%.72 California needs to increase its existing electricity generation by more than 57%.73 [EPA-HQ-OAR-2022-0985-1621-A1, p. 30]

EPA's mandate could require automobile manufacturers to sell 10-12 million electric vehicles in calendar year 2035 alone.74 Millions more would be sold in the years before that. According to a study conducted for the Department of Energy that modeled grid impacts in 2028 from electric vehicles, 'The results indicated that the first issues would occur between 30 and 37 million EVs, at which point load could not be reliably met.'75 [EPA-HQ-OAR-2022-0985-1621-A1, p. 31]

Organization: California Air Resources Board (CARB)

D. ZE Fueling Infrastructure147

Affected pages: 25982-25984, 25996-25998, and 26000-26006

147 CARB staff worked collaboratively with CEC team to provide this comment.

The NPRM states that the projected additional generation needed to meet demand of the HD BEVs in the proposal will be relatively modest. This is consistent with California's finding with regard to energy generation needed to meet MD and HD fleet electrification needs. As modeled by the CEC, California expects that LDV, MDV, and HDV charging will account for less than 5 percent of California's total system electric load during peak hours.148 [EPA-HQ-OAR-2022-0985-1591-A1, p.45]

148 California Energy Commission Revised Staff Report Zero-Emission Vehicle Infrastructure Plan (ZIP), last accessed June 5, 2023. https://www.energy.ca.gov/sites/default/files/2022-12/600-2022-054-REV.pdf

The NPRM points out that the responsibility for delivering reliable electrical service is a shared responsibility between private utilities and government entities. CARB staff agrees with this finding. California works closely with utilities to forecast electrical demand and plan for load growth from all sectors. Working with the Public Utilities Commission, investor-owned utilities develop rate cases and investment plans that consider expected growth of electrical load from all sectors of the economy and take into account needed grid upgrades to account for climate change and maintenance. Planning for further truck electrification can be analyzed and rolled into forecasting even before fleets apply for service upgrades and interconnection associated with specific infrastructure installations, much as that planning occurs for other anticipated changes in demand.

Organization: Clean Air Task Force et al.

b. Charging and grid infrastructure is capable of supporting HD BEVs in volumes aligned with and in excess of EPA's proposed standards.

Deployment of BEVs is well underway across the U.S. and is already requiring the electric power sector to make plans to reliably and safely integrate these vehicles. The electric power industry is well situated to maintain safe and reliable service that can power an increasing deployment of HD BEVs; utilities, aided significantly through investments from the BIL and IRA, are making important upgrades to the system to integrate higher penetrations of BEVs. Additional third party private investments and public investments are also already committed to building a robust HD BEV charging network. [EPA-HQ-OAR-2022-0985-1640-A1, p. 45.]

When considering infrastructure buildout, it is important to remember that HD ZEVs will enter the total on-road HD fleet gradually and in volumes that pale in comparison to in-use HD combustion vehicles. Modeling using HD TRUCS and MOVeS3.R3188 shows that EPA's proposal, if finalized, would likely result in ZEVs comprising just 1 percent of the total on-road HD fleet by 2027, gradually reaching 8 percent in 2032 and 23 percent in 2040. See Table 4, infra. In other words, a relatively small portion of the HD fleet will be tapping into charging and grid infrastructure over the next decade, and even by 2040, HD ZEVs would comprise less than a quarter of the on-road fleet under this proposal. Infrastructure needs for HD ZEVs will accordingly grow gradually over time. [EPA-HQ-OAR-2022-0985-1640-A1, p. 45. See Docket Number EPA-HQ-OAR-2022-0985-1640-A1, pages 45-46, for Table 4.]

188 HD TRUCS was used to develop ZEV adoption rates (by vehicle classification). MOVES3.R3 was used to translate HD TRUCS-derived ZEV adoption rates to ZEV sales and in-use curves.

For the final rule, we urge EPA to model how the Phase 3 standards will likely affect the composition of the entire on-road HD fleet, not just HD ZEVs' share of new sales. That information would better help the Agency and the public consider infrastructure issues related to this rulemaking. [EPA-HQ-OAR-2022-0985-1640-A1, p. 46.]

i. Economic theory and historical precedent show that infrastructure buildout will occur at the pace and scale needed to support vehicle electrification.

EPA should reject arguments that the buildout of charging and grid infrastructure cannot occur at the pace and scale needed to support expanded vehicle electrification, which are unreasonably pessimistic and inconsistent with both economic theory and historical precedent. These arguments rely on the classic “chicken-and-egg” scenario said to be presented by ZEV sales and charging infrastructure, where each side of the market waits for the other. But EPA need not and should not wait for infrastructure to fully mature before finalizing strong Phase 3 standards. Instead, EPA’s standards themselves will send a strong signal to the market to undertake the infrastructure investments needed to accommodate a gradual rise in vehicle electrification,189 such that increased ZEV sales and infrastructure buildout will occur in relative tandem and reinforce each other. As one analyst sums it up: “The chicken-and-egg conundrum is being solved. Investments in the space and the adoption of EVs [a]re happening much faster than many analysts expected, and this is also accelerating the build-out of the charging network.”190 [EPA-HQ-OAR-2022-0985-1640-A1, pp. 46 - 47.]

189 Environmental regulation itself, of course, can lead to technology innovation and market development. See generally Jaegul Lee et al., Forcing Technological Change: A Case of Automobile Emissions Control Technology Development in the US, 30 Technovation 249 (2010); Margaret R. Taylor, Edward S. Rubin, & David A. Hounshell, Regulation as the Mother of Innovation: The Case of SO2 Control, 27 Law & Policy 348 (2005); James Lents et al., Chapter II: The regulation of automobile emission: A case study, in Environmental Regulation and Technology Innovation: Controlling Mercury Emissions from Coal-Fired Boilers (Marika Tatsutani & Praveen Amar eds., 2000) https://www.nescaum.org/documents/rpt000906mercury_innovative-technology.pdf.

190 Gabriela Herculano, Chicken-and-Egg Problem: EV Adoption and Buildout of Charging Networks, Nasdaq (Apr. 18, 2022), https://www.nasdaq.com/articles/chicken-and-egg-problem%3A-ev-adoption-and-buildout-of-charging-networks.

The economic literature on indirect network effects and two-sided markets shows that an increase in BEV sales—a likely effect of the Phase 3 standards, particularly if they are strengthened in the final rule—can be expected to stimulate associated infrastructure development. In a study on flex-fuel vehicles fueled by E85 (85 percent ethanol), Corts (2010) found that growth in sales of flex-fuel vehicles due to government fleet acquisition programs led to an increase in the number of retail E85 stations.191 That relationship held true across all six Midwestern states analyzed, despite differences in those states’ E85 subsidies and tax credits.192 The author concluded that the results “confirm the basic validity” of the theory underlying government fleet purchase requirements: that increasing the “base of alternative fuel vehicles can spur the development of a retail alternative fuel distribution infrastructure.”193 [EPA-HQ-OAR-2022-0985-1640-A1, p. 47.]

191 Kenneth S. Corts, Building out alternative fuel retail infrastructure: Government fleet spillovers in E85, 59 J. Env’t Econ. & Mgmt. 219, 219-20 (2009).

192 Id.

193 Id. at 231.

Recent economic research has confirmed this relationship in the context of ZEVs and charging infrastructure specifically. An influential study by Li et al. (2017) found that “EV demand and charging station deployment give rise to feedback loops” and that “subsidizing either side of the market will result in an increase in both EV sales and charging stations.”194 Similarly, Springel (2021) found “evidence of positive feedback effects on both sides of the market, suggesting that cumulative EV sales affect charging station entry and that public charging availability has an impact on consumers’ vehicle choice.”195 The BIL and IRA subsidize both sides of the market, offering significant incentives for both HD ZEV purchases and the construction of charging infrastructure. Economic theory therefore supports the proposition that strengthened Phase 3 standards, particularly in combination with the BIL and IRA’s large financial incentives, will facilitate expansion of charging and grid infrastructure.196 [EPA-HQ-OAR-2022-0985-1640-A1, p. 47.]

194 Shanjun Li et al., The market for electric vehicles: indirect network effects and policy design, 4 J. Ass’n Env’t. & Resources Econ. 89, 128 (2017).

195 Katalin Springel, Network Externality and Subsidy Structure in Two-Sided Markets: Evidence from Electric Vehicle Incentives, 13 Am. Econ. J.: Econ. Pol’y 393, 426 (2021).

196 See id. at 394 (noting that “the presence of positive feedback amplifies the impact of both types of subsidies”), 415 (“positive feedback loops between the charging station network and total all-electric vehicle sales amplify the impact of both types of subsidy”).

Economic theory has in fact played out in Norway, where ZEV sales and infrastructure both expanded rapidly over the span of about a decade. There, the “path to charging point saturation started by stimulating more demand for EVs.”197 In other words, Norway did not wait for infrastructure to fully mature before beginning its transition to cleaner cars. Rather, rising ZEV sales themselves “helped trigger a spike in demand for charging stations.”198 [EPA-HQ-OAR-2022-0985-1640-A1, p. 48.]

197 Whitney Bauck, How Norway Became the World’s Electric Car Capital, Nexus Media News (Mar. 7, 2023), https://nexusmedianews.com/how-norway-became-the-worlds-electric-car-capital/.

198 McKinsey & Co, What Norway’s Experience Reveals About the EV Charging Market 3 (2023), https://www.mckinsey.com/industries/automotive-and-assembly/our-insights/what-norways-experience-reveals-about-the-ev-charging-market#/.

The concept that charging infrastructure will adequately scale up over time also finds support in an analogous historical example: the buildout of roads and gasoline refueling infrastructure in the early 20th century to serve the United States’ growing fleet of automobiles. The country’s exponential growth in automobile sales—first exceeding 1,000 in 1899 and growing to 1 million by 1916199—preceded the establishment of an extensive network of both suitable roads200 and filling stations.201 Instead, the buildout of road and refueling infrastructure unfolded over long time horizons and in a variety of ways, adapting to the needs of the automobile fleet as it changed and grew. Paving and other road improvement efforts began on a small scale in cities, where automobiles were initially concentrated; efforts to improve rural roads and construct highways happened a decade or more later, as motorists began to expand their driving beyond cities.202 Similarly, in the case of refueling infrastructure, a network of modern filling stations did not spring up until well after automobiles had grown in popularity.203 Before that, refueling needs were met through varied and dispersed “non-station” methods such as cans of gasoline sold at general stores, barrels at repair garages, mobile fuel carts, curb pumps, and home refueling pumps, which emerged at various times as the demand for gasoline increased.204 Road and refueling infrastructure therefore exhibited a "long-term, adaptive and portfolio approach"205 that, over the span of several decades, satisfied the shifting needs of the growing ranks of automobile owners. [EPA-HQ-OAR-2022-0985-1640-A1, p. 48.]

203 Melaina, at 4922.

204 Id. at 4924-27.

205 Id. at 4932 (discussing refueling infrastructure).

That approach holds important lessons for this rulemaking. As detailed above, the introduction of HD ZEVs into the total on-road fleet will occur gradually and, for the first decade or more, in relatively low volumes. As explored in a recent white paper by ICCT,206 successfully meeting the needs of this gradually expanding fleet of heavy-duty ZEVs will not require the overnight nationwide buildout of infrastructure that some have misleadingly claimed. Instead, economic theory and historical precedent show that growth in heavy-duty ZEV sales and infrastructure buildout will occur in relative tandem, with infrastructure responding over time commensurate with the evolving needs of the ZEV fleet. And in finalizing its Phase 3 standards, EPA will send a strong market signal that will facilitate infrastructure development at the pace and scale needed to support compliance with the standards. As explained in the sections below, the nation's infrastructure is already well-positioned to adapt to increased vehicle electrification. EPA must reject unfounded chicken-and-egg arguments questioning whether infrastructure will respond to rising demand. [EPA-HQ-OAR-2022-0985-1640-A1, pp. 48 - 49.]

206 See generally Pierre-Louis Ragon et al., ICCT, Near-Term Infrastructure Deployment to Support Zero-Emission Medium- and Heavy-Duty Vehicles in the United States (2023), https://theicct.org/wp-content/uploads/2023/05/infrastructure-deployment-mhdv-may23.pdf.

ii. The grid can reliably support significantly increased loads.

The electric industry is well situated to maintain safe and reliable service that can power the increasing deployment of HD BEVs. As detailed below, the projected growth in electricity demand over the coming years, including demand related to BEV deployment in line with strengthened Phase 3 standards as well as additional economy-wide load growth, is well within the range of past historical load growth. Additionally, the industry is already responding to and preparing for increased electrification as more fleets and individuals adopt BEVs and has a wide range of tools, practices, and partnerships in place to continue to maintain a strong and reliable grid. [EPA-HQ-OAR-2022-0985-1640-A1, p. 49]

EPA conducted modeling within the Integrated Planning Model (IPM) to assess the electric sector and emissions impact of the proposal. In this modeling, the Agency utilized baseline projections of electricity demand and generation growth from the Annual Energy Outlook 2021 (AEO2021). DRIA at 321. EPA notes that this forecast “does not include the full forecasted ZEV adoption in the [proposal] reference case,” and so it developed further incremental demand estimates to include “the demand of electric vehicles not captured by IPM’s defaults,” which EPA “calculated from the output of national MOVES runs.” Id. While these files are not available to us, we are able to approximate this projected demand growth under the proposal by similarly calculating electric demand utilizing the proposal case in MOVES3.R3. This output reflects demand from all HD BEVs, including those HD BEVs that would be deployed in absence of this rule. In order to combine this with AEO2021 generation values, we converted this demand value to generation using a charging efficiency factor of 95 percent and transmission line loss factor of 5 percent. We then are able to combine this incremental generation calculation with projected generation from AEO2021 Reference Case (net available to grid).207 [EPA-HQ-OAR-2022-0985-1640-A1, p. 49]

207 U.S. Energy Information Administration, Annual Energy Outlook 2021, at Table 8 (Electricity Supply, Disposition, Prices, and Emissions), https://www.eia.gov/outlooks/aeo/data/browser (last accessed, June 13, 2023).

This analysis finds that system-wide increases in generation to meet demand growth, including both increased demand from the proposed Phase 3 standards (assuming EPA finalizes the stringency levels it has proposed) and projected economy-wide load growth, is projected to average 1.2 percent per year between 2028 and 2040. Importantly, this methodology is likely to overestimate generation growth, as the AEO2021 Reference Case already includes some level of transportation electrification.208 Isolating the impact of HD BEVs alone shows load average growth of 0.5 percent per year between 2028 and 2040. Further isolating only the incremental HD BEV generation projected under MOVES3.R3 associated with this proposal (as compared to the baseline) shows average generation growth of 0.4 percent per year between 2028 and 2040. [EPA-HQ-OAR-2022-0985-1640-A1, pp. 49 - 50]

208 U.S. Energy Information Administration, Annual Energy Outlook 2021: Narrative, at 13 (2021), https://www.eia.gov/outlooks/aeo/pdf/AEO_Narrative_2021.pdf.

Maintaining reliable and safe electric power delivery through this level of demand growth, as well as higher levels of growth resulting from more stringent Phase 3 standards, is within electric utility standard practice as demonstrated through the electric power sector’s strong track record of reliability and resiliency. These annual generation increases are well within the range of contemporary, normal operations for the U.S. electric sector (see Figure 1 below). According to data reported to the Energy Information Administration in Form 861, in the 31 years from 1990 to 2021, average annual national growth in electricity sales was 1.1 percent.209 In 15 of those years, growth was 1.5 percent or higher, and in ten years it exceeded 2 percent. The U.S. has also seen previous periods of sustained high demand growth across most states; for example, 1995 to 2007 saw average nationwide growth of approximately 1.9 percent per year. [EPA-HQ-OAR-2022-0985-1640-A1, p. 50.] [See Docket Number EPA-HQ-OAR-2022-0985-1640-A1, page 51, for Figure 1]

209 Note that these data are for statewide demand, not generation. State level demand figures are more meaningful to show local variations in electricity usage as compared to state-level generation, which does not necessarily (or even usually) serve in-state customers. While absolute generation and demand figures (TWh) should not be compared, growth rates between the two, as shown here, should track proportionally. U.S. Energy Information Administration, Historical State Data, EIA-861, Annual Electric Power Industry Report (Mar. 8, 2023), https://www.eia.gov/electricity/data/state/.

Many states saw much higher, sustained levels of growth. In the two decades from 1999 to 2018, North Dakota electric sales more than doubled. Year over year growth averaged nearly 5 percent, and in 2014 electric sales were 14 percent higher than the previous year alone. In Nevada between 1992 and 2007, annual electric sales growth averaged 4.9 percent and fell below 1.5 percent only once. More recently, Virginia has seen strong annual sales growth, with sales increasing 12.3 percent in the five years from 2016 to 2021, or 3 percent on average per year, even accounting for a pandemic dip. [EPA-HQ-OAR-2022-0985-1640-A1, p. 50]

This analysis draws similar conclusions to those of the researchers at the Electrification Futures Study, a multi-year research project to explore potential widespread electrification in the future energy system of the United States. In a report developing an integrated understanding of how the potential for electrification might impact the demand side in all major sectors of the U.S. energy system—transportation, residential and commercial buildings, and industry—this study concluded that "[e]lectrification has the potential to significantly increase overall demand for electricity, although even in the High scenario, compound annual electricity consumption growth rates are below long-term historical growth rates."210 [EPA-HQ-OAR-2022-0985-1640-A1, p. 50]

210 Trieu Mai et al., NREL, Electrification Futures Study: Scenarios of Electric Technology Adoption and Power Consumption for the United States (2018), https://www.nrel.gov/docs/fy18osti/71500.pdf.

We further recognize that many parties will nevertheless need to take important steps to manage increased electrification demand. Utilities, public utility commissions and other state regulators, grid operators, charging providers, and others can and have already begun to coordinate and plan for increased vehicle electrification. Examples include:

- The West Coast Clean Transit Corridor Initiative is an ongoing, collaborative effort among 16 utilities to support the development of BEV charging facilities along I-5, from San Diego to British Columbia, for heavy- and medium-duty freight haulers and delivery trucks.211
- The National Charging Experience Consortium (ChargeX) is a collaborative effort between Argonne National Laboratory, Idaho National Laboratory, NREL, BEV charging industry experts, consumer advocates, and other stakeholders whose mission is "to work together as BEV industry stakeholders to measure and significantly improve public charging reliability and usability by June 2025."212
- The National BEV Charging Initiative brings together automakers, power providers, BEV and charging industry leaders, labor, and public interest groups to "develop a national charging network for light, medium, and heavy-duty vehicles and inspire deeper commitments from state leaders, the administration and each other."213
- The National Association of State Energy Officials and the American Association of State Highway and Transportation Officials partnered with the U.S. Joint Office of Energy and Transportation to hold a series of convenings to coordinate on a range of topics, including ZEV infrastructure and utility planning needs.214 These convenings

brought together State Departments of Transportation officials, State Energy Offices, and other key partners.

- PG&E and BMW of North America are testing a "vehicle-to-everything technology that will improve grid reliability and help EV customers lower their electric bills by exporting power back to the grid during peak demand periods." PG&E notes that "[t]he utility and automotive industries are creating a transformative clean energy future together."215
- NREL and Volvo collaborated on a research paper regarding challenges and opportunities of HD and commercial ZEVs, noting: Coordination between disparate and historically unconnected stakeholders, including state agencies, local governments, automotive manufacturers, fleets, energy infrastructure and utility companies, and research and academia will be required to ensure a smooth and timely transition to ZEVs. This paper, a joint research and industry perspective, is one such example of cross-sectoral collaboration.216 [EPA-HQ-OAR-2022-0985-1640-A1, pp. 52 - 53]

Finally, ICCT has highlighted myriad actions that utilities, local and state agencies and regulators, fleet operators, and property owners can take to help reduce barriers to infrastructure deployment and aid "timely planning and construction to ensure transmission and distribution systems can accommodate the needs of [medium- and heavy-duty vehicle] electrification."217 These examples show that the relevant stakeholders are already stepping up to plan for and accommodate the charging and grid needs associated with greater vehicle electrification. [EPA-HQ-OAR-2022-0985-1640-A1, p. 53]

217 Ragon et al., at 25.

Utilities in particular are also already planning for and deploying solutions to address increased vehicle electrification as their customers adopt BEVs to improve fleet economics and performance. For example, executives at Southern California Edison, which is one of the largest electric utilities in the U.S. and is facing industry-leading levels of electrification, have recently voiced strong support for the ability of the grid to manage, respond to, and benefit from BEVs. Caroline Choi, Edison International and Southern California Edison senior vice president of corporate affairs, noted that "the electric grid is really going to be the backbone of the whole system" for electrified transit, and that "[w]hat we're seeing are the investments necessary to ensure that the grid is available."218 Utilities and their customers will benefit from the ability to plan ahead for any significant infrastructure requirements. The regulatory certainty provided by Phase 3 standards can aid this planning. [EPA-HQ-OAR-2022-0985-1640-A1, p. 53]

218 Casey Wian, Transportation Electrification Gains Momentum: Edison International and SCE outline plans to seize the "huge opportunity" of preparing the grid for exponential EV growth, Energized, (Feb. 1, 2023), https://energized.edison.com/stories/transportation-electrification-gains-momentum.

Regulatory certainty can also help ensure that investments not only maintain strong electric service, but improve it while at the same time lowering costs. Southern California Edison President and CEO Steve Powell noted: "if we leverage the electric vehicle load and have that work for consumers as well, that whole idea of vehicle-to-grid, there can be real value in helping alleviate a lot of the infrastructure investments that need to happen," ultimately lowering overall energy bills for customers.219 Similarly, Seattle City Light, in its Transportation Electrification Strategic Investment Plan, found that the utility received a net benefit of roughly $120,500 per bus or other heavy-duty ZEVs through an increase in new revenue, placing downward pressure on rates.220 It stated that "[w]hile there are system costs associated with increased transportation electrification (e.g., distribution and transmission infrastructure upgrades), with proactive utility planning and intervention, the system benefits (e.g., new revenue) are estimated to outweigh the costs, spreading the economic benefits of transportation electrification to all customers."221 This will require action from regulators as well to help shape and approve these proactive and critical investments. As RMI recommended, "regulators can fulfil [sic] their responsibility for ensuring prudent and least-cost grid investments while proactively planning by using new information."222 [EPA-HQ-OAR-2022-0985-1640-A1, pp. 53 - 54]

221 Id.

222 Ari Kahn et al., RMI, Preventing Electric Truck Gridlock: Meeting the Urgent Need for a Stronger Grid 16 (2023), https://rmi.org/insight/preventing-electric-truck-gridlock/.

Third-party analyses have bolstered these statements from utilities that BEVs, if deployed strategically, can improve grid operations. For example, Lawrence Berkeley National Laboratory estimated that enabling "vehicle-to-grid" technology,223 which allows ZEVs to serve as electricity storage and provide power back to the grid during periods of high demand, would save California utility customers $13-15 billion in stationary battery costs.224 An analysis conducted by Gladstein, Neandross & Associates on behalf of EDF found that managed charging of class 8 trucks combined with strategic deployment of distributed energy resources could provide significant cost savings for fleet operators and "result in significant savings to utilities through avoided grid buildout costs."225 Yet another analysis found that BEVs can "contribute significantly to grid stability" and provide value to the grid through "deferred or avoided capital expenditure on additional stationary storage, power electronic infrastructure, transmission build-out, and more."226 Additionally, utilities can deploy proven and emerging rate designs that ensure utilities recover costs, reliably serve BEV charging load, improve BEV owner experience, and take advantage of grid strengthening services from these vehicles.227 [EPA-HQ-OAR-2022-0985-1640-A1, p. 54]

In addition, the historic investments of the BIL and IRA are helping utilities build a stronger, cleaner grid and prepare for advanced electrification while minimizing customer costs. Duke Energy, for example, has stated that "[the BIL] provides an important down payment on the infrastructure and incentives that are needed to electrify transportation and secure the grid," and "[the IRA] can create significant cost savings for our customers."228 New York utilities have indicated that they will be applying for $900 million in grants from the BIL and IRA to advance grid resilience.229 National Grid in particular notes that "EV charging make-ready infrastructure is identical to electric infrastructure that serves other purposes, this is the kind of work electric utilities do every day,"230 and that "areas of the [BIL] funding are enabling increased investment."231 [EPA-HQ-OAR-2022-0985-1640-A1, pp. 54 - 55]

Organization: Clean Fuels Development Coalition et al.

H. The proposed rule neglects the impact of EPA's many other proposed rules on these rules.

Finally, the proposed rule is made even more infeasible when EPA's other proposed rules are considered. On the same day EPA announced this proposed rule it also announced the corresponding rule for light-and medium-duty vehicles. That proposed rule, "Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles," 88 Fed. Reg. 29,184 (May 5, 2023), would require nearly 70 percent of light-duty vehicles to be electrified by 2032. These light-duty vehicles will compete with heavy-duty vehicles for minerals, batteries, charging infrastructure, and more. But there is little mention of this competition. [EPA-HQ-OAR-2022-0985-1585-A1, p. 30]

EPA has also proposed new carbon pollution standards for coal and natural gas-fired power plants. See "New Source Performance Standards for Greenhouse Gas Emissions From New, Modified, and Reconstructed Fossil Fuel-Fired Electric Generating Units; Emission Guidelines for Greenhouse Gas Emissions From Existing Fossil Fuel-Fired Electric Generating Units; and Repeal of the Affordable Clean Energy Rule," 88 Fed. Reg. 33,240 (May 23, 2023). Among other things, this proposal assumes it would lead all coal facilities to close by 2040 or implement—largely unproven—carbon capture and storage technology with at least a 90 percent capture rate. The proposal would also require the use of hydrogen blending or carbon capture in all natural gas plants. These new rules will drive up electricity costs—by adding large new expenses to the coal and gas the currently provides a majority of our nation's electricity—and reduce grid reliability by driving offline the large thermal generation sources that provide most of our electric grid's reliable power. [EPA-HQ-OAR-2022-0985-1585-A1, p. 30]

This grid reliability is a serious concern. A decline in steady thermal sources like coal makes our grid susceptible to the "fatal trifecta": "overreliance on weather-dependent solar and wind, just-in-time natural-gas backstops, and imports of electricity from neighboring states." Michael Buschbacher & Taylor Myers, FERC Gaslights America, American Conservative (Sep. 6, 2022), https://www.theamericanconservative.com/ferc-gaslights-america/. The effects of decreasing baseload power are already being felt. The North American Electric Reliability Corporation's ("NERC") most recent Long-Term Risk Assessment found that found that most of the country is already at elevated risk of blackouts, with some regions being at high-risk during even normal peak conditions. 2022 Long-Term Reliability Assessment, North American Electric Reliability Corporation (Dec. 2022), https://www.nerc.com/pa/RAPA/ra/Reliability%20Assessments%20DL/NERC_LTRA_2022.pdf . These problems are exacerbated by rules like EPA's new power plant rules because those rules drive the adoption of less reliable intermittent resources like solar and wind. NERC explained that "[a]s solar decreases as sunset approaches, the total of all available resources can fall short of the demand, especially [during] higher demand levels." Id. [EPA-HQ-OAR-2022-0985-1585-A1, pp. 30 - 31]

These reliability concerns are exacerbated by the deployment of electric vehicles. A recent NERC report explained that when up-ticks in electrical vehicle charging coincide with increasingly frequent grid disturbances in the bulk power system. Electric Vehicle Dynamic Charging Performance, North American Electric Reliability Corporation (Apr. 10, 2023), https://www.nerc.com/comm/RSTC/Documents/Grid_Friendly_EV_Charging_Recommendations.pdf. When these events coincide they could "have catastrophic consequences for grid reliability if left unchecked (i.e., cascading blackouts and widespread power interruptions)." Id. [EPA-HQ-OAR-2022-0985-1585-A1, p. 31]

But the proposal waves away concerns about grid reliability by explaining that "U.S. electric power utilities routinely upgrade the nation's electric power system to improve grid reliability and to meet new electric power demand." 88 Fed. Reg. 25,983. This is inadequate. If the Biden Administration is going to adopt a "whole of government" approach to rulemaking, it must consider the interaction of all these rules. [EPA-HQ-OAR-2022-0985-1585-A1, p. 31]

Organization: Daimler Truck North America LLC (DTNA)

Electrical infrastructure buildout pace is a barrier to significant ZEV adoption that should be factored in to Phase 3 CO2 standard levels.

The pace of electrical infrastructure buildout remains the biggest barrier for customer adoption of HD BEVs and poses the greatest threat to successful implementation of the Proposed Rule. As EPA observes, BEV infrastructure is critically important for the success of increasing development and adoption of BEV technologies.108 DTNA thus appreciates the opportunity to respond to EPA's request for comment on the concerns that have already been expressed to EPA regarding the slow growth of ZEV charging and refueling infrastructure. This Proposed Rule is unique in that compliance will rely heavily on the development of infrastructure that manufacturers have no control over, and providers are not obligated to expand infrastructure to support the scope and timing of the Proposed Rule. [EPA-HQ-OAR-2022-0985-1555-A1, p. 45]

108 See Proposed Rule, 88 Fed. Reg. at 26,000.

DTNA—in partnership with Portland General Electric—is proud to have built the first-of-its-kind public charging island for commercial ZEVs in Portland, Oregon. In addition, DTNA's expert eConsulting team is dedicated to supporting fleets on all aspects of the ZEV transition, including site design and interfacing with utilities. Therefore, DTNA is uniquely positioned to offer insight into the challenges associated with commercial ZEV infrastructure development. [EPA-HQ-OAR-2022-0985-1555-A1, p. 45]

DTNA has concerns about EPA's treatment of electric infrastructure in the Proposed Rule, and the Agency's assumptions that all suitable vehicle applications and willing customer adopters will have charging infrastructure available, or that such infrastructure can be made available within the timeframes that EPA assumes and at the costs projected in HD TRUCS. In this section, DTNA highlights the unique challenges with HD charging infrastructure (especially with respect to electricity transmission and distribution); explains why EPA significantly underestimates infrastructure costs; discusses specific timing challenges; and highlights case studies from its customer fleets. Finally, DTNA concludes by recommending that EPA use an electric infrastructure scalar to ensure that infrastructure development pace is adequately factored in to EPA's adoption rate projections, as discussed in more detail on Section II.C of these comments. [EPA-HQ-OAR-2022-0985-1555-A1, p. 45]

EPA projects that modest increases in electric power generation will be required to support the Proposed Rule. Specifically, the Agency estimates that Proposed Rule requirements would increase HD BEV electric power end use by 0.1% over 2021 levels in 2027, increasing to 2.8% over 2021 levels in 2055.109 EPA notes, however, that these figures do not include the electricity increase required to produce hydrogen.110 [EPA-HQ-OAR-2022-0985-1555-A1, pp. 45-46]

109 Id. at 25,983; DRIA at 430, Table 6-1.

110 See DRIA at 431 (noting that EPA's projected electricity consumption increases attributable to the Proposed Rule do 'not include changes in electricity generation to produce hydrogen').

EPA's figures appear to underestimate the increase in electric power generation that will be required to support implementation of the Proposed Rule. As discussed below, according to the Company's calculations, 45 gigawatts of installed charging capacity will be required to support the vehicle volumes in the Proposed Rule from 2027 - 2032. Based on EIA's estimate that there was 1,143,757 megawatts (MW) of total utility-scale electricity generating capacity in the United States at the end of 2021,111 Proposed Rule implementation will require a 3.9% increase in domestic generation capacity (over the 2021 level) by 2032, conflicting with EPA's projection that only a 2.8% increase will be required by 2055. [EPA-HQ-OAR-2022-0985-1555-A1, p. 46]

111 See U.S. Energy Information Administration, 'Electricity explained: Electricity generation, capacity, and sales in the United States,' https://www.eia.gov/energyexplained/electricity/electricity-in-the-us-generation-capacityand-sales.php.

Further, DTNA is concerned that EIA's commercial vehicle forecast does not align with EPA's ZEV market projections in the Proposed Rule. EIA's AEO 2022 commercial vehicle projections are summarized in Table 15 below EIA projects zero commercial vehicle BEV sales through 2050, and minimal FCEV penetration up to 1,600 vehicles per year per category. It is critical that federal agencies are aligned on these commercial vehicle projections and communicate them clearly to the electric utility industry. Given the misalignment with EIA on ZEV uptake rates, it is likely that EPA underestimates the electricity generation increase needed to support HD BEVs.[EPA-HQ-OAR-2022-0985-1555-A1, p. 46] [Refer to Table 15 on p. 46 of docket number EPA-HQ-OAR-2022-0985-1555-A1].

EPA points to the adoption of residential air conditioners and growth of power-intensive data centers as historical evidence of the electric utility industry's ability to deliver additional power to customers.113 Residential air conditioners provide a reasonable comparison for light-duty vehicle electricity demand levels, as they represent a relatively low load that is evenly distributed across utility service territories. The electricity demands associated with medium- and heavy-duty electrification will, however, be fundamentally different and must be treated as such. [EPA-HQ-OAR-2022-0985-1555-A1, p. 46]

113 See Proposed Rule, 88 Fed. Reg. at 25,983.

Unlike light-duty vehicles, most HD ZEVs cannot charge using existing 120-volt and 240-volt AC electrical infrastructure, and they require dedicated DC infrastructure. HD ZEVs are also disproportionally located in concentrated urban areas, creating highly localized grid capacity addition needs in constrained spaces (see Figure 3 below, showing heat maps of potential future loads). [EPA-HQ-OAR-2022-0985-1555-A1, p. 47] [Refer to Figure 3 on p. 47 of docket number EPA-HQ-OAR-2022-0985-1555-A1]

Power-intensive data centers and server farms were rapidly constructed across the United States in the last 20 years and were largely greenfield projects that had the flexibility to be sited where grid capacity was available or could be made available relatively easily. By contrast, the commercial transportation industry is already entrenched and invested in existing logistics facilities. Most of these are located in or around high density urban population centers, often clustered tightly together, where grid capacity is not available, and the process of acquiring land and rights-of-way for upgrades is complex. The use of data centers and server farms as anecdotal examples of electric utility adaptability suggests that EPA is significantly underestimating the demand presented by commercial transportation charging infrastructure. [EPA-HQ-OAR-2022-0985-1555-A1, p. 47]

DTNA generally agrees with EPA's assertion that scale-up of electric power generation is not likely to significantly limit the development of BEV electric vehicle charging infrastructure. Rather, the challenge for medium- and heavy-duty charging lies in distribution of that power. As ICCT observed in a recent white paper on near-term medium- and heavy-duty ZEV infrastructure development, 'Most uncertainties regarding infrastructure buildout concern the capacity of distribution systems to bring that energy to the right place in a timely manner and accommodate the highly localized power requirements of [medium- and heavy-duty vehicle] charging.'114 Accordingly, DTNA recommends that EPA engage with electric utilities and their trade associations to further understand the unique challenges that HD ZEVs charging will pose for distribution systems, and how those factors should be accounted for in this rulemaking. [EPA-HQ-OAR-2022-0985-1555-A1, p. 47]

114 See ICCT, 'Near-Term Infrastructure Deployment to Support Zero-Emission Medium- and Heavy-Duty Vehicles in the United States (May 2023) at 1, https://theicct.org/wp-content/uploads/2023/05/infrastructure-deployment-mhdv-may23.pdf (ICCT ZEV Infrastructure White Paper).

Infrastructure Costs

EPA asserts 'there is considerable uncertainty associated with future distribution upgrade needs, and in many cases, some costs may be borne by utilities rather than directly incurred by BEV or fleet owners. Therefore, we do not model them directly as part of our infrastructure analysis.'115 DTNA appreciates that there is significant complexity and uncertainty in modeling these costs, but believes that omitting front-of-meter costs is a significant error in the TCO calculation that has major implications for EPA's proposed CO2 standard stringency levels. [EPA-HQ-OAR-2022-0985-1555-A1, p. 48]

115 Proposed Rule, 88 Fed. Reg. at 25,983.

How fleet owners pay for infrastructure will depend on a variety of factors, including utility structure (investor-owned, municipal, cooperative), existing available grid capacity, project scale, real estate needs, etc. For fleets in cooperative and municipality service territories, including many in critical urban freight hubs, upgrade costs are likely borne directly by the fleet. For fleets working with investor-owned utilities, the cost mechanism will vary. If infrastructure is needed by more than one utility customer, the utility will typically ask the fleet for a pro-rata share of those costs, or in some cases, increase electricity rates to cover those costs. Where fleets do not meet the minimum utilization rates for the contracted time period (5 to 10 years), fleets may be required to reimburse the utility for infrastructure upgrades, or costs are distributed among all ratepayers. One DTNA customer fleet has cancelled an order for 25 Class 8 tractors because of what they viewed as risky contract terms, including requirements for load management and a 10-year commitment to construct capacity for a 3 MW site. Regardless of the pathway, fleets will bear the cost of infrastructure upgrades to support charging needs, and those costs should be included in the proposed rule. [EPA-HQ-OAR-2022-0985-1555-A1, p. 48]

DTNA relied on a cost study by the Boston Consulting Group (BCG) to estimate an optimized and non-optimized dollar-per-kilowatt cost figure for grid updates.116 To estimate per-vehicle grid update costs for Class 3 - 8 BEVs, we applied the BCG dollar-per-kilowatt cost estimates to an assumed average daily power need for each vehicle class that would be subject to the Phase 3 CO2 standards, shown in Table 11 ('DTNA Proposed Grid Update Cost Inputs for HD TRUCS') presented in Section II.B.3.b. As reflected in Table 11, these costs are non-negligible, significantly impact the TCO proposition, and must be considered in EPA's HD TRUCS analysis. [EPA-HQ-OAR-2022-0985-1555-A1, p. 48]

116 See Boston Consulting Group, 'The Costs of Revving Up the Grid for Electric Vehicles' (Dec. 20, 2019), https://www.bcg.com/publications/2019/costs-revving-up-the-grid-for-electric-vehicles.

Using the same average daily power assumptions, DTNA estimated the additional installed capacity that will be needed to support HD BEVs at the adoption rates projected in the Proposed Rule. The Company calculated a 5-year average of commercial vehicle sales in all 50 states from the Polk Automotive database from 2017-2021, applied EPA's projected ZEV volumes for 2027-2032, and calculated the total installed charging capacity that will be required by these vehicles in 2027 - 2032 to be approximately 45 gigawatts. In Appendix C to these comments, DTNA estimates the investments in charging infrastructure and grid upgrades, as well as total installed charging capacity, that will be required in each of the 50 states to support implementation of the Proposed Rule.117 DTNA considers installed capacity in this context to mean the total power available as EVSE to charge commercial vehicle batteries. Using installed capacity is a more appropriate metric for evaluating available charging capacity than the number of chargers alone, as installed capacity better reflects the variability in charging speeds needed to support different vehicle dwell times and truck-to-charger ratios. [EPA-HQ-OAR-2022-0985-1555-A1, pp. 48-49]

This installed capacity must be available at a combination of public and private purpose-built HD-accessible charging stations. To be HD-accessible, public charging stations must include pull-through charging lanes and accommodate wide ingress and egress to support all vehicle types. Commercial vehicles are often unable to utilize existing passenger car charging infrastructure, due to space constraints that are not compatible with HDVs. [EPA-HQ-OAR-2022-0985-1555-A1, p. 49] [Refer to graphics on p. 49 of docket number EPA-HQ-OAR-2022-0985-1555-A1]

Based on the projected vehicle mix in the Proposed Rule and installed capacity needed to support these vehicles, DTNA estimated the total costs of EVSE charging equipment and necessary supporting grid updates to support Class 3-8 BEVs that would be required under the Proposed Rule. These figures, summarized in Table 16 below, do not include the additional capacities and investments needed to support passenger car electrification. [EPA-HQ-OAR-2022-0985-1555-A1, p. 49] [Refer to Table 16 on p. 49 of docket number EPA-HQ-OAR-2022-0985-1555-A1]

Even with incentive funding available, many fleets are unable to make the capital investments required to add BEVs to their fleets. DTNA is currently working with one school bus fleet that has secured Clean School Bus funds from EPA for 23 buses, as well as a payment plan through their utility's Make Ready program, and is still facing a $500,000 funding gap for site construction that threatens to jeopardize the project. Private fleet deployments are likely to face similar gaps, even where some combination of incentive program funding is available. [EPA-HQ-OAR-2022-0985-1555-A1, p. 50]

Timing for Infrastructure Development

EPA implies that in the next five years, electric infrastructure will be sufficiently built out to support the BEVs required by the Proposed Rule, and that buildout will continue to support substantially higher fleet adoption rates by 2032. Without major regulatory and/or legislative action, DTNA does not believe the infrastructure needed will materialize on the timeline required to enable compliance with the Phase 3 CO2 standards as proposed. New interconnection requests are processed on a first-come-first-serve basis, and transportation electrification competes with all other utility priorities, including decarbonization mandates, resiliency, and other residential and commercial interconnection requests. [EPA-HQ-OAR-2022-0985-1555-A1, p. 50]

Utilities are noting extended timelines for installing critical hardware, both in front of and behind the meter, due to supply chain and other constraints. During the ACF rulemaking process, for example, one electric utility commented to CARB that the lead time for transformers was 40 weeks, and that the lead time customer side meter panels/switchgears was 70 weeks.118 In the Company's experience, utilities will wait for this hardware to be received to perform other upgrades, and these types of sequential gating events can add significant time to transportation electrification projects. [EPA-HQ-OAR-2022-0985-1555-A1, p. 50]

118 See Comments of Pacific Gas and Electric Company, Proposed Advanced Clean Fleets Regulation (Oct. 17, 2022), https://www.arb.ca.gov/lists/com-attach/370-acf2022-AXEFZFUxUFxRY1Bl.pdf.

In a recent joint presentation by Southern California Edison (SCE), Pacific Gas & Electric (PG&E), and San Diego Gas & Electric (SDG&E) at a California Energy Commission (CEC) workshop, the following table was presented reflecting the utilities' estimations of typical timelines for distribution capacity improvements: [EPA-HQ-OAR-2022-0985-1555-A1, p. 50] [Refer to Table 17 on p. 50 of docket number EPA-HQ-OAR-2022-0985-1555-A1]

As the scope of the necessary distribution capacity improvements is often unknown until detailed site planning is underway, predicting how long fleets will wait for interconnection requests is challenging. DTNA believes many depot electrification projects may require increases in substation capacity, sub-transmission improvements, or new substations to serve the concentrated power demands. One of DTNA's customers cancelled a BEV deployment because their utility returned a 5-8 year lead time for a new substation. Another fleet's initial ZEV deployment at scale required construction of a 6 MW facility, able to charge 32 Class 8 drayage tractors simultaneously.120 Providing these capacities to many sites clustered together, as will be required to support concentrated freight hubs and logistics centers, is likely to require substantial grid upgrades. [EPA-HQ-OAR-2022-0985-1555-A1, pp. 50-51]

120 See 'Schneider's Electric Heavy-Duty Trucks Start Off on Regional Routes' (June 8, 2023) https://www.truckinginfo.com/10200304/new-electric-heavy-duty-trucks-start-off-on-regional-routes.

Because of California's climate policies, including Executive Order N-79-20 requiring all new passenger car and truck sales to be zero emission by 2035, and CARB's ACT and ACF regulations, a number of transportation electrification planning procedures and make-ready programs have already been implemented or have begun to develop in California. Thus, it is important to keep in mind that electric utilities in other states may generally be less prepared to respond to transportation electrification requests. [EPA-HQ-OAR-2022-0985-1555-A1, p. 51]

In the Company's experience, fleets typically purchase their vehicles 6 - 12 months ahead of need, and often utilities require proof of purchase to show the fleet is committed to move forward with infrastructure development. DTNA has experienced fleet customers cancelling BEV orders when utilities respond to interconnection requests with multi-year lead times. Many of these cancellations include the return of incentive program funds, such as HVIP or Clean School Bus Program vouchers. Purchasers who apply for and are granted HVIP funds for example, must redeem the voucher within 90 days, or apply for three-month extensions up to 540 total days.121 It is not uncommon for infrastructure projects to exceed the 540 day timeline, which would require the fleet to take delivery of BEVs with no charging infrastructure, resulting in a stranded capital investment and no air quality improvements. One of DTNA's customers cancelled an order and returned HVIP funding for 20 Class 8 tractors when their utility estimated their site would take 3 years (1,095 days) to energize. [EPA-HQ-OAR-2022-0985-1555-A1, p. 51]

121 See Implementation Manual for the Hybrid and Zero-Emission Truck and Bus Voucher Incentive Project (HVIP) (March 15, 2022) at 20, https://californiahvip.org/wp-content/uploads/2022/03/HVIP-FY21-22-Implementation-Manual-03.15.22.pdf.

Furthermore, it is unlikely that fleets will make major investments in long-term infrastructure that require commitments longer than the vehicle trade cycle. For example, if a fleet plans for a 4-year vehicle product cycle, but the infrastructure lead time is 4 years for an increase in substation capacity, by the time the infrastructure is available, the fleet will be working with the next generation of vehicles, which may or may not have the same power needs. Similarly, where utilities have made capital investments in infrastructure, fleets may be required to commit to a certain utilization rates for 5 to 10 years. Fleets working with shorter trade cycles, contracted routes, or leased properties are likely to see operational changes well before they are released from their utilization obligations. Committing to minimum utilization rates may be a major financial risk for fleets, which is unaccounted for in the cost estimates in the Proposed Rule. [EPA-HQ-OAR-2022-0985-1555-A1, p. 51]

Fleets have also cited the lack of firm interconnection dates as a major deterrent to committing to long-term infrastructure projects. DTNA appreciates that infrastructure buildout projects are difficult to project, and may encounter unanticipated delays, but fleets are unable to make fleet transition plans, place orders for electric vehicles, or apply for funding without firm interconnection timelines. Some of DTNA's fleet customers committed to ZEV deployment have sought temporary power solutions to address these timeline issues. However, temporary power solutions incur additional costs and generally must be paid up front by the fleet. For instance, SDG&E Rule 13 ('Temporary Service') provides that an applicant for temporary service 'shall pay, in advance or otherwise as required by the utility, the estimated cost installed plus the estimated cost of removal, less the estimated salvage of the facilities necessary for furnishing service.'122 [EPA-HQ-OAR-2022-0985-1555-A1, pp. 51-52]

122 See SDG&E Rule 13, https://www.sdge.com/sites/default/files/elec_elec-rules_erule13.pdf.

In addition to electrical interconnection complexities, fleets must navigate their local building codes and permitting processes. As noted by the Northeast States for Coordinated Air Use Management (NESCAUM) in a 2019 paper on DCFC deployment, 'the permitting process for DCFC stations is sometimes lengthy and fraught with delays due to unfamiliarity with the technology, protracted zoning reviews, and undefined requirements for permitting DCFC. As a result, the DCFC permitting process can be resource-intensive for both applicants and [authorities having jurisdiction (AHJs)].'123 Since the NESCAUM paper was published, DTNA's eConsulting team has encountered many AHJs that lack defined processes for DCFC installation projects and the expertise needed to move projects along quickly. [EPA-HQ-OAR-2022-0985-1555-A1, p. 52]

123 NESCAUM, 'Preparing Our Communities for Electric Vehicles: Facilitating Deployment of DC Fast Chargers' (May 2019), https://www.nescaum.org/documents/dcfc-permit-streamlining-whitepaper-final-5-14-19.pdf.

Fleets may encounter additional complications related to EVSE installation that impact BEV technology adoption rates. For example, when converting vehicles to BEVs, the infrastructure needed for charging equipment takes up physical space that could otherwise be occupied by additional trucks. Figure 4 below illustrates the components needed for combined charging systems (CCS). Megawatt Charging Systems (MCS) require additional space for installation as well. [EPA-HQ-OAR-2022-0985-1555-A1, p. 52] [Refer to Figure 4 on p. 53 of docket number EPA-HQ-OAR-2022-0985-1555-A1]

Figure 5 below shows an overhead view of one such fleet operation in Southern California where physical space will limit the number of BEVs that can be deployed. This site will require additional power poles, new transformers, and new switchgears to support only a fraction of the fleet. To convert additional tractors to BEVs, fleets working with constrained spaces like the site shown below will likely be required to purchase additional real estate. Recently, Denver's Regional Transportation District (RTD) announced the cancellation of an $18 million deal for new electric buses, citing space constraints for charging and EVSE equipment.124 RTD officials estimated they would need an additional $85 million to construct a new building to support this deployment. Space constraint issues of this type—and the associated costs—are not accounted for in EPA's cost estimates for the Proposed Rule. [EPA-HQ-OAR-2022-0985-1555-A1, p. 53] [Refer to Figure 5 on p. 53 of docket number EPA-HQ-OAR-2022-0985-1555-A1]

124 See Denver Post, 'RTD cancels purchase of 17 electric buses it doesn't have space to maintain—and orders fleet transition strategy' (April 26, 2023), https://www.denverpost.com/2023/04/26/regional-transportation-district-battery-electric-buses-contract/.

DTNA's fleet customers have faced a number of similar challenges, which have resulted in order cancellations or reductions, revealing the following issues :

- Fleet customers have been quoted 1.5 - 8 years for depot site electrification for deployments that are modest compared to the scale of those discussed in the Proposed Rule.
- Depot installation projects are complex and resource intensive for fleets, utilities, and AHJs. DTNA often observes differing views of roles and responsibilities in transportation electrification projects and a lack of expertise in this developing space.
- Infrastructure lead time is not synchronized with funding program lead time, leading fleets to return vouchers they spent resources securing, highlighting that available funding and the calculated TCO is only part of the adoption equation.
- Utilities and fleets sometimes cannot come to agreement on contractual terms, including load restrictions, managed charging, and guaranteed utilization time periods. It is unlikely these issues will be resolved without significant regulatory or legislative changes.

- State and municipal building codes and processes lack transparency and add significant time to depot electrification projects. [EPA-HQ-OAR-2022-0985-1555-A1, p. 54]

Utility Long Range Planning vs. Fleet Planning

Utilities today rely on long-range forecasts in the 5 - 10 year timeframe to plan investment and system upgrades. During CARB's ACF rulemaking process, a number of electric utilities submitted comments recommending that CARB facilitate the ongoing sharing of data with utilities about fleet customers' detailed near-term and long-term charging infrastructure needs, including fleet transition plans by year, whether the fleet would need to charge full-time or on peak, what percentage of time fleets would charge on peak and at what level, and if fleets anticipated seasonal peaks. [EPA-HQ-OAR-2022-0985-1555-A1, p. 55]

As discussed above, fleets typically order their vehicles 6 - 12 months in advance, and it is unlikely fleets are able to make accurate predictions of what the future fleets' energy needs might be, as fleet operations are subject to change with changes in contracted routes, technology maturity, etc. Some fleets rent their depot facilities, and short term leases will prevent the tenant fleet from making long range plans. Where long term leases are in place, the fleet tenant often cannot make substantial changes to the property without the landlord's permission. Even with the landlord's permission, fleets are unlikely to make a long-term investment in sites that they do not own. Landlords could choose to install EVSE if they anticipated a positive business case, but are similarly unable to provide detailed long range forecasts. [EPA-HQ-OAR-2022-0985-1555-A1, p. 55]

DTNA has made vehicle telematics data available for interested utilities to predict where future loads may occur, but this dataset only represents a subset of the Company's products, and not the market as a whole. Without substantive regulatory and/or legislative intervention to prompt utilities to plan for and buildout for transportation electrification, DTNA does not believe significant buildout of electrical infrastructure will occur on the timeline required to support EPA's proposed CO2 stringency levels. [EPA-HQ-OAR-2022-0985-1555-A1, p. 55]

Recommendations to Facilitate ZEV Infrastructure Buildout and CO2 Standard Feasibility

While EPA does not have regulatory authority over many of the factors that currently pose challenges to ZEV infrastructure development, the Agency could help to mitigate these challenges by supporting the policies, legislation, and regulatory initiatives that are detailed in Section I.B.4 of these comments, including:

- Align with EIA vehicle uptake estimates, to ensure accurate estimates of real power demand by MHD and HHD ZEVs and net CO2 emissions.
- Work with FERC to direct utilities to incorporate demand projects into both a system-wide transportation electrification electricity forecast and a utility distribution grid capacity requirement forecast, to serve these medium- and heavy-duty transportation electrification loads on a geographic basis.
- Assume financial liability as a demand guarantor for infrastructure buildout that is undertaken based upon EPA's ZEV penetration forecasts.
- Work with FERC to identify high traffic freight hubs that are likely to see rapid increase in BEVs, and direct utilities to proactively upgrade this infrastructure.

- Encourage state utility regulatory commissions to adopt PBRs to incentivize faster interconnection timelines for charging infrastructure projects. [EPA-HQ-OAR-2022-0985-1555-A1, p. 57]
- Work with stakeholders to develop model building codes that can be adopted by state and local governments to streamline authorizations for EVSE installation projects and encourage state and local adoption of these model codes.
- Require reporting of medium- and heavy-duty ZEV infrastructure and make this information available to fleets.
- Work with FHWA to revise the NEVI formula program to more actively encourage states to provide HD-accessible public charging infrastructure. [EPA-HQ-OAR-2022-0985-1555-A1, p. 58]

Finally, as described in more detail in Sections I.B.3 and II.C. of these comments, EPA should incorporate a scalar to be used in its calculations of appropriate CO2 standard stringency levels, designed (and regularly updated) to reflect actual installed capacity of HD-accessible charging equipment. [EPA-HQ-OAR-2022-0985-1555-A1, p. 58]

Organization: Edison Electric Institute (EEI)

EPA notes that several stakeholders have raised concerns that ‘slow growth in ZEV charging and refueling infrastructure can slow the growth of heavy-duty ZEV adoption, and that this may present challenges for vehicle manufacturers ability to comply with future EPA GHG standards.’ 88 Fed. Reg. 25,934. EEI member companies have addressed similar infrastructure build out issues in the past. Like those issues, these concerns can be addressed through deliberate effort and collaboration among electric companies, fleet operators, and stakeholders, including planning for increased demand, customer engagement, and fleet electrification. [EPA-HQ-OAR-2022-0985-1509-A2, p. 7]

Electric companies can accommodate increased energy demand.

As EPA notes, the electric power sector has a long history of accommodating growth in electricity demand from the adoption of new technologies, including electric home appliances, residential and commercial air conditioning, and data centers. See id. At 25,983. Electricity use from EVs today is modest. Argonne National Lab estimates the approximately 2.3 million EVs on the road as of the end of 2021 consumed 6.1 terawatt-hours of electricity in that year, or about 0.16 percent of the total electric sales to U.S. customers in that year.18 As EPA also notes, the increase in electricity use resulting from the Proposed Rule also will be modest, increasing electricity end-use by less than 3 percent in 2055. See id. On a macro-level, meeting the increased energy usage from electric truck adoption as contemplated in the Proposed Rule will not be a significant challenge for the electric power sector. Meeting the location-specific power needs of large electric vehicle (EV) charging facilities can be a more pressing challenge. However, this is a challenge that can be addressed with deliberate effort and collaboration among electric companies, fleet operators, and stakeholders. [EPA-HQ-OAR-2022-0985-1509-A2, pp. 7-8]

18 See Gohlke, et al., Assessment of Light-Duty Plug-in Electric Vehicles in the United States, 2010 – 2021, https://publications.anl.gov/anlpubs/2022/11/178584.pdf and U.S. Energy Information Administration, Electric Power Monthly

Electric companies can accommodate localized power needs at the pace of customer demand, provided appropriate customer engagement and enabling policies are in place. The power required by a customer is essential when considering the infrastructure needed at the facility level, because the capacity of the local distribution circuit is sized to meet the peak power requirements of customers on that circuit. Some large EV charging facilities have power requirements in the tens of megawatts (MW). Electric companies are well accustomed to serving facilities with those types of power needs, but large fleet customers differ from traditional electric customers (e.g., commercial or industrial buildings) in several important aspects. These aspects include, but are not limited to:

- Construction timelines: A new, large commercial building with a multi-MW power demand, for example, will typically have a multi-year construction timeline, giving the local electric company time to plan and make appropriate upgrades to the electric distribution system serving that customer. A fleet operator, in contrast, may be able to procure vehicles and complete construction on a multi-MW charging facility in a matter of months. This creates a potential misalignment between the fleet operators' timeline to procure vehicles and charging equipment and the electric company's timeline for making the necessary system upgrades to provide power to that facility. [EPA-HQ-OAR-2022-0985-1509-A2, p. 8]
- Customer familiarity with procuring electric power: Commercial and industrial electric customers are used to working with electric companies for the operation of their facilities as part of their normal course of business, including working with electric companies as part of the construction process for launching new facilities. In particular, national corporate customers often have long-standing relationships with the electric companies that serve them. Electric companies typically assign these customers an account manager, given their scale and complexity. A fleet operator, in contrast, is used to procuring diesel to operate its vehicles, and may consider procuring electricity in the same paradigm. Fleet operators may be small electricity users today and thus that division may not yet be considered a managed account for the electric company. However, EEI members have identified this issue and are expanding their working relationship with these customers. [EPA-HQ-OAR-2022-0985-1509-A2, pp. 8-9]
- Uncertain and dynamic load profiles: The power usage throughout the day, known as the 'load profile,' of typical commercial and industrial buildings is well understood (e.g., large retail store, data center, or manufacturing facility). Typical load profiles for electric fleet customers are not yet well understood and often hypothetical given the early stage of electric truck commercialization. A fleet charging load profile is the product of many factors, including the routes of the vehicles, the state of charge of the EV when returning to the facility, the number of operating shifts, etc. Unlike a typical commercial building, the load profile of a fleet facility could also drastically change with a change in vehicle operations (e.g., changing from a one-shift to two-shift operation). This uncertainty adds complexity for electric companies when determining how best to serve the power requirements of a fleet customer. [EPA-HQ-OAR-2022-0985-1509-A2, p. 9]

These factors could result in misalignment between expectations and reality regarding the timing, cost, and complexity of procuring electric power for fleet charging. Electric companies are taking a multi-pronged approach to remedy this potential misalignment, as discussed in the following sections. [EPA-HQ-OAR-2022-0985-1509-A2, p. 9]

Earlier customer engagement through education and coordination will alleviate infrastructure delays.

Early engagement between the relevant fleet customer and electric company is important as it allows planning for the infrastructure to support EV charging to occur much earlier and accommodate longer lead-times. In 2020, EEI began a collaboration with a large, national corporate customer that was planning to electrify a significant portion of its fleet operation. EEI facilitated meetings for this customer to share its conceptual plans with EEI's members and establish points of contact at the customer and each electric company. Over the course of more than a year, the customer identified the locations within each member's territory where it planned to deploy EVs and developed a five-year forecast to inform the electric company how the power demand would increase at each location over time. This unprecedented level of collaboration has resulted in this customer deploying thousands of electric vehicles to date. This includes alternative locations that were identified by the electric company after consulting with the customer. [EPA-HQ-OAR-2022-0985-1509-A2, pp. 9-10]

The extent of collaboration described in this example may not be feasible, or necessary, for every fleet customer. But it does provide a helpful template for how early engagement and planning can streamline fleet electrification. The Electric Power Research Institute (EPRI) is developing a data-sharing platform as part of its EVs2Scale2030 initiative that will formalize and expand this model by allowing fleet customers to upload their forward-looking fleet electrification plans to a common database.19 Electric companies will then be able to access this data to visualize where on its system upgrades will be needed to accommodate growing power needs from fleet customers. [EPA-HQ-OAR-2022-0985-1509-A2, p. 10]

19 See Electric Power Research Institute, EVs2Scale2030, https://www.epri.com/research/products/000000003002025622.

Many electric companies are developing tools and resources to assist fleet customers. These include, but are not limited to:

- Grid capacity evaluation tools: Several electric companies have launched capacity hosting maps that are available on public websites that illustrate local grid capacity in their service territory.20 These maps can be helpful early indicators for fleet customers when considering the level of upgrades that may be required at a particular facility. These maps have limitations, as they are a snapshot in time and do not substitute for a formal engineering study. Even if they have not published such a capacity map, many electric companies have the ability to assist fleet customers by providing an early screen for local grid capacity by location directly. In either case, the outcome is the same: for customers that have the ability to consider multiple locations for their EV deployment plans, pre-screening the local distribution system capacity at these locations allows the fleet to factor grid upgrade timelines into their deployment plans. [EPA-HQ-OAR-2022-0985-1509-A2, pp. 10-11]

  20 Examples include: AVANGRID (United Illuminating, NYSEG, Rochester Gas & Electric), Ameren Illinois, Con Edison, Dominion Energy, Eversource, Exelon (Atlantic City Electric, Delmarva Power, Pepco, Comed, PECO), Jersey Central Power & Light, National Grid, Orange & Rockland, Public Service Electric & Gas, San Diego Gas & Electric, and Southern California Edison.

- Fleet assessments and advisory services: Many electric companies have launched programs to provide in-depth consulting services to fleets that are considering electrification, including elements like feasibility studies based on total cost of ownership.21 These programs also may include dedicated staff resources to guide customers through the fleet electrification journey, including choosing the appropriate charging strategy and charging infrastructure to meet their operational needs. These programs help to educate fleet customers about the nuances of procuring power for their fleet operations and allow electric companies to learn more about the expected operations of electric fleets. [EPA-HQ-OAR-2022-0985-1509-A2, p. 11]

  21 See Alliance for Transportation Electrification, Fleet Advisory Services (FAS) for Fleet Electrification: Meet Customer Needs and Provide Grid Benefits, https://evtransportationalliance.org/wp-content/uploads/2023/02/PRESS-ATE-EC-White-Paper.pdf, which includes case studies from DTE Energy, Exelon, Portland General Electric, Southern California Edison, and Xcel Energy.

These and other resources being developed and deployed today by electric companies are essential to ensuring that infrastructure plans and efforts are matched to forthcoming electrification efforts from fleets and other operators. [EPA-HQ-OAR-2022-0985-1509-A2, p. 11]

Electric companies are planning for fleet electrification.

Investor-owned electric companies are regulated by state commissions, which approve electric company capital plans to maintain and upgrade the electric grid. While policies vary by state commission, two generally applicable principles have important implications for fleet electrification. First, the 'used and useful' standard means that regulators will only approve the electric company to build infrastructure that will be utilized and provide value. The onus is on electric companies to provide evidence that their capital plans will meet this standard. Second is the principle that the customer that incurs the cost must pay for the cost. Typically, a customer seeking new or upgraded electric service must submit a formal service request to the electric company, which prompts the electric company to perform an engineering study to determine the cost of the upgrades needed to provide that service. [EPA-HQ-OAR-2022-0985-1509-A2, pp. 11-12]

The implication for fleet electrification, a potentially fast-growing source of significant new demand on the electric system, is that electric companies are not authorized to upgrade the electric system in anticipation of new demand without robust evidence that those upgrades will be 'used and useful.' Only when a fleet customer submits a service request is the electric company permitted to make the upgrades necessary to serve that customer. Electric company forecasts for load growth, including that due to electrification, are typically at a system level, not the local distribution system level for individual fleet facilities. Given the nascent commercialization of fleet electrification, there is a lack of visibility into how, where, and when fleet electrification will appear on the system sufficient evidence to give electric companies (and their regulators) confidence to build for it. [EPA-HQ-OAR-2022-0985-1509-A2, p. 12]

Importantly, electric companies are recognizing the risks of this approach and are getting ahead of the need. Given the long lead times to make distribution upgrades, particularly if the upgrades are significant to extend further upstream to the substation and transmission level, it will increasingly be unacceptable to customers to wait for the customer service request-driven process. There is a risk that fleet customers, facing increased regulatory pressure to electrify their fleets, will be unable to plan their businesses around these infrastructure lead times and fail to meet their electrification goals. Electric companies must find mechanisms to plan and build for these increased loads now, so that the power is available when the customer needs them. [EPA-HQ-OAR-2022-0985-1509-A2, pp. 12-13]

In California, the investor-owned electric companies use the California Energy Commission's Integrated Energy Policy Report (IEPR) as their base forecast. Southern California Edison (SCE) in its recent General Rate Case found a significant gap between the electric transportation load growth in the IEPR forecast and that expected due to the state's policies, specifically the California Air Resources Board's Advanced Clean Cars II, Advanced Clean Trucks, and Advanced Clean Fleets rules.22 SCE developed a Transportation Electrification Grid Readiness (TEGR) analysis to account for this gap in its General Rate Case that will set the electric company's grid investments for the next several years. SCE used a top-down methodology to apply this higher forecast to the circuit level for electric transportation loads, as well as a bottom-up methodology for certain high growth areas. [EPA-HQ-OAR-2022-0985-1509-A2, p. 13]

22 See Southern California Edison, 2025 General Rate Case, WP SCE-02, Vol. 07 Bk. A, TEGR Forecast Development Workpaper.

SCE has deployed a variety of new methods to account for HDV development and deployment, including the Power Service Availability (PSA) initiative to support transportation electrification. The PSA initiative, working in concert with the TEGR analysis, focuses on improving SCE's internal processes to streamline interconnection, engaging fleet operators to better understand their plans for electrification, improving their ability to forecast and assess the impacts of load growth from electrification, and leveraging new technologies as grid infrastructure solutions. Because some projects will require more time than others to build, SCE actively encourages fleet owners to engage with them early in the process so that SCE can better understand and plan for their needs. For grid upgrades that require a longer construction schedule, SCE is developing temporary solutions that can deploy quickly while those upgrades are being built. These solutions may include mobile battery storage or a mobile substation brought in on a semi tractor-trailer. [EPA-HQ-OAR-2022-0985-1509-A2, pp. 13-14]

In New York, the Public Service Commission opened a proceeding in April to address barriers to medium-and heavy-duty electric vehicle infrastructure. In particular, the order recognizes that 'proactive planning for the grid infrastructure needed to serve future electrification load must anticipate the location and magnitude of future demand' and notes an analogy to previous policies in which the commission directed the electric companies in New York to 'develop proactive planning processes to anticipate the need for local transmission and distribution system upgrades to enable the renewable interconnections required to achieve the State's renewable energy goals.' 23 [EPA-HQ-OAR-2022-0985-1509-A2, p. 14]

23 State of New York Public Service Commission, Case 23-E-0070, Proceeding on Motion of the Commission to Address Barriers to Medium- and Heavy-Duty Electric Vehicle Charging Infrastructure.

EPA's assessment that 'there is sufficient time for the infrastructure, especially for depot charging, to gradually increase over the remainder of this decade to levels that support the stringency of the proposed standards for the timeframe they would apply' is accurate. 88 Fed. Reg. 25,999. As seen above, EEI members actively are planning for and deploying infrastructure today. However, the increased deployment of this infrastructure over the next decade and beyond will not happen on its own. Proactive planning processes, whether initiated by the relevant electric company or state regulatory commission, will be critical to accommodate fleet electrification to meet customer expectations and planning requirements, while also providing affordable and reliable service. [EPA-HQ-OAR-2022-0985-1509-A2, pp. 14-15]

EPA specifically requests comment on ‘whether there are additional stakeholders EPA should work with during implementation of the Phase 3 standards.’ 88 Fed. Reg. 26,000. EPA, states, engine and truck manufacturers, and fleet operators should work with electric companies on a regional or state level to glean additional insight into their planning processes and help bolster proactive planning and infrastructure investments. As discussed above, electric companies and their regulators benefit from the confidence that fleet electrification load will materialize through additional forward planning and outreach, which also provides visibility into where and when that load will materialize on the system. Final adoption of the Proposed Rule will help provide confidence that fleet electrification will occur through the period of the rule, but at a national level. [EPA-HQ-OAR-2022-0985-1509-A2, p. 15]

Additionally, the States, Congress, EPA, and other federal partners should work with the electric power industry to ensure policies are aligned across the federal government to reduce the cost and timelines associated with building infrastructure to support increased electrification. This includes but is not limited to:

- Investing in domestic manufacturing of critical electrical infrastructure, including efforts to alleviate the labor pool shortage limiting domestic manufacturing of critical electrical infrastructure and provide loan or purchase guarantees to manufacturers. [EPA-HQ-OAR-2022-0985-1509-A2, p. 15]
- Not exacerbating the supply shortage of distribution transformers with unsupported efficiency rules. The U.S. Department of Energy should choose an efficiency standard for transformers that does not require switching to a new type of steel or make a determination that no new standard is needed.24 [EPA-HQ-OAR-2022-0985-1509-A2, pp. 15-16]

  24 EEI’s comments are attached as Appendix A.

- Reforming permitting, both at the bulk power level with respect to building electricity generation and transmission, and at the state and local levels with respect to building distribution infrastructure. [EPA-HQ-OAR-2022-0985-1509-A2, p. 16]

EEI and its members stand ready to work with our regulatory and legislative partners to ensure these challenges are appropriately addressed. [EPA-HQ-OAR-2022-0985-1509-A2, p. 16]

Organization: Energy Innovation

V. THE MODERN ELECTRIC GRID CAN SUPPORT WIDESPREAD TRANSPORTATION ELECTRIFICATION OF HDVS OVER TIME.

As part of its analysis, the EPA modeled changes to power generation due to the increased electricity demand from more EVs and projects that the “additional generation needed to meet the demand of the heavy-duty BEVs in the proposal [will be] relatively modest (as shown in DRIA Chapter 6.5). As the proposal is estimated to increase electric power end use by heavy-duty electric vehicles by 0.1 percent in 2027 and increasing to 2.8 percent in 2055. The U.S. electricity end use between the years 1992 and 2021, a similar number of years included in our proposal analysis, increased by around 25 percent, without any adverse effects on electric grid reliability or electricity generation capacity shortages. Grid reliability is not expected to be adversely affected by the modest increase in electricity demand associated with HD BEV charging."55 We concur with this finding. [EPA-HQ-OAR-2022-0985-1604-A1, p. 23]

55 U.S. EPA, "Proposed Rules," 25983

A similar analysis in the 2035 2.0 study found that the DRIVE Clean Scenario resulted in demand growth from increased electrification averages about 2 percent per year, a growth rate slower than that achieved between 1975 and 2005. See Figure 15. To meet this demand with a 90 percent clean grid (analyzed as part of the DRIVE Clean Scenario), the U.S. would need to install on average 105 GW of new wind and solar and 30 GW of new battery storage each year—nearly four times the current deployment rate.56 Even with additional electric loads in the DRIVE Clean Scenario, grid modeling found a 90 percent clean grid would be dependable without coal plants or new natural gas plants by 2035. The grid model also found that during normal periods of generation and demand, wind, solar, and batteries provide 72 percent of total annual generation, while hydropower and nuclear provide 16 percent. During periods of high demand and/or low renewable generation, existing natural gas plants (primarily combined-cycle plants) cost-effectively compensate for remaining mismatches between demand and renewables-plus-battery generation—accounting for about 10 percent of total annual electricity generation. The increased electrification and pervasive renewable energy and battery storage deployments require investments mainly in new transmission spurs connecting renewable generation to existing high-capacity transmission, rather than new investments in bulk transmission.57 Of note, the rates of HDV EV adoption envisioned in the DRIVE Clean Scenario are considerably higher than the adoption rates in the proposed rules, even if a more stringent alternative is finalized. [EPA-HQ-OAR-2022-0985-1604-A1, p. 23.] [See Figure 16, electricity Demand Growth, on page 23 of docket number EPA-HQ-OAR-2022-0985-1604-A1.]

56 Phadke et al., "2035 2.0: Plummeting Costs and Dramatic Improvements in Batteries Can Accelerate Our Clean Transportation Future" vi.

57 "Transitioning to All-Electric Cars and Trucks Won't Crash the Power Grid," 2035 2.0, n.d., https://www.2035report.com/transportation/evs-the-power-grid/.

The examples the EPA provides in its proposed rule offer useful reminders that increased electric demand from new technologies has, throughout recent history, been met with commensurate increases in investments, grid upgrades, and reinforcements to comply with grid reliability standards. Examples include the rapid adoption of air conditioners in the 1960s and 1970s and the rapid growth of power-intensive data centers and server farms over the past two decades.58 As noted in the proposed rule, the U.S. electric power utilities have already successfully designed and built the distribution system infrastructure required for 1.4 million BEVs and have successfully integrated 46.1 GW of new utility-scale electric generating capacity into the grid between 2020 and 2021.59 The challenges posed by the prospect of gradual growth in ZEVs in the HDV sector over the next decade can be addressed with the continued adoption of policies, regulations, planning, and prudent investments. Numerous reports articulate what's needed to support a highly electrified transportation future, including Accelerating Clean, Electrified Transportation by 2035: Policy Priorities: A 2035 2.0 Companion Report and the ACEEE State Transportation Electrification Scorecard.60 [EPA-HQ-OAR-2022-0985-1604-A1, p. 24]

60 Bryan Howard and Shruti Vaidyanathan, “State Transportation Electrification Scorecard” (American Council for an Energy-Efficient Economy, 2021), https://www.aceee.org/electric-vehicle-scorecard.

Finally, more nascent vehicle-to-grid (V2G) technologies, vehicle grid integration (VGI), and managed charging programs have the potential to be game changers for HDV electrification and the electric grid. Certain HDVs are especially well suited to deliver on the promise of V2G, given how they are used and where they are located. V2G can help HDV fleet owners recoup energy costs while also meeting power needs during grid constraints. For example, a fleet of electric-powered school buses in El Cajon can send electricity back to California’s grid, thanks to V2G technology developed by a San Diego company and a partnership with San Diego Gas & Electric.61 More utilities are working with original equipment manufacturers, fleets, and government officials to adopt V2G technologies and develop V2G programs, and the IRA and BIL both contain funding to support pilots and nex-tgeneration R&D.62 The EPA points to several other entities engaged in VGI research.63 [EPA-HQ-OAR-2022-0985-1604-A1, p. 24]

63 U.S. EPA, “Proposed Rules,” 25983.

Based on other analyses and continued advancements in technologies, we agree strongly with the EPA’s finding that the increase in electric power demand attributable to vehicle electrification is not expected to adversely affect grid reliability due to the modest increase in electricity demand associated with EV charging.64 [EPA-HQ-OAR-2022-0985-1604-A1, p. 24]

64 U.S. EPA, 25983.

Organization: Energy Strategy Coalition

Members of this coalition are already engaging in long-term planning to meet the increased demand for electricity attributable to vehicle electrification, and the HDV Proposal will provide a regulatory backstop supporting further investments in electrification and grid reliability. Demand for electricity will increase under both the HDV Proposal and recently-proposed multi-pollutant standards for light-duty and medium-duty vehicles (“LMDV Proposed Rule”),5 but the electricity grid is capable of planning for and accommodating such demand growth and has previously experienced periods of significant and sustained growth. Moreover, historic growth in demand and generation resources does not reflect the investments that will be made under the Infrastructure Investment and Jobs Act (“IIJA”) and the Inflation Reduction Act (“IRA”) to support the deployment of new renewable and zero-carbon generation resources, energy storage and charging infrastructure. Coalition members are already making investments in the resources and infrastructure needed to support transportation electrification and realize the benefits that integration of electric vehicles ("EVs")—including HDVs—can provide to the electricity grid. The Coalition encourages EPA to work closely with state and local partners and other federal agencies to ensure that deployment of this infrastructure occurs on the pace and scale needed to achieve the EV penetration-rates contemplated by these proposals, while ensuring grid reliability. [EPA-HQ-OAR-2022-0985-1626-A1, pp. 1 - 2]

5 Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles, 88 Fed. Reg. 29,184 (published May 5, 2023).

II. The proposed rule supports long-term planning and investment

Long-term planning and investment for vehicle electrification is a business imperative for the Coalition's members and a necessary element of their efforts to provide affordable, clean, and reliable power to their customers. By setting a clear trajectory for vehicle electrification that complements existing regulatory and market forces, EPA's HDV and LMDV proposals facilitate further investment in the generation and charging infrastructure needed to meet increased demand associated with electrification of the vehicle fleet. [EPA-HQ-OAR-2022-0985-1626-A1, p. 2]

In 2021, sales of electric buses increased 40% over the previous year (even as the global bus market remained consistent) and global sales of electric medium- and heavy-duty trucks more than doubled over 2020 volumes.6 In its 2023 Global EV Outlook, the International Energy Agency found that the number of models of zero-emission trucks continued to expand with nearly 840 current and announced medium- and heavy-duty vehicle models.7 And, as EPA notes, manufacturers are increasingly announcing targets to expand production and sales of zero-emission trucks.8 [EPA-HQ-OAR-2022-0985-1626-A1, p. 2]

6 INT'L ENERGY AGENCY, GLOBAL EV OUTLOOK 2022: SECURING SUPPLIES FOR AN ELECTRIC FUTURE 35, https://iea.blob.core.windows.net/assets/ad8fb04c-4f75-42fc-973a-6e54c8a4449a/GlobalElectricVehicleOutlook2022.pdf.

7 INT'L ENERGY AGENCY, GLOBAL EV OUTLOOK 2023: CATCHING UP WITH CLIMATE AMBITIONS 40, https://iea.blob.core.windows.net/assets/dacf14d2-eabc-498a-8263-9f97fd5dc327/GEVO2023.pdf.

8 88 Fed. Reg. at 25,941. For example, Volvo Trucks and Scania announced a global target of 50% of trucks sold being electric by 2030, and Navistar has a goal of having 50% of its sales volume be ZEVs by 2030. Id.

These market trends complement government commitments and incentives to expand the heavy-duty vehicle fleet. Due to IRA incentives, between 39–48% of all truck sales are projected to be electric by 2030 and between 44–52% of sales will be electric by 2032.9 The IIJA similarly provides substantial incentives for the deployment of zero-emission heavy-duty vehicles: two IIJA programs alone provide over $10 billion in incentives to support zero-emission bus deployment.10 States like California, New York, and New Jersey also offer their own recurring rebates for electric buses and trucks.11 In addition to these generous subsidies, 17 states, the District of Columbia, and Québec, have formulated a road map to achieve 30% zero-emission truck sales by 2030.12 And under California's Advanced Clean Trucks regulation, zero-emission vehicle sales will need to comprise 75% of Class 4–8 straight truck sales and 40%

of tractor truck sales by 2035.13 Other states that have adopted California's truck regulation include Colorado, Massachusetts, Maryland, New Jersey, New York, Oregon, Vermont, and Washington.14 As an example of utility planning to achieve such high penetration-rates, National Grid co-authored a November 2022 study to "support utility long-term capital planning,"15 which assumed that the two states in its service territory (New York and Massachusetts) reached 100% sales of zero-emission passenger vehicles by 2035 and complied with California's Advanced Clean Trucks regulation.16 Although EPA's HDV Proposal is not projected to result in zero-emission vehicle penetration-rates as high as projected under California's Advanced Clean Trucks regulation, EPA's HDV rule will provide regulatory certainty for planning and investment decisions in all states, beyond California and the states that adopt its regulation. [EPA-HQ-OAR-2022-0985-1626-A1, pp. 2 - 3]

9 See INT'L COUNCIL ON CLEAN TRANSP. AND ENERGY INNOVATION POL'Y & TECH., ANALYZING THE IMPACT OF THE INFLATION REDUCTION ACT ON ELECTRIC VEHICLE UPTAKE IN THE UNITED STATES (Jan. 2023), https://theicct.org/wp-content/uploads/2023/01/ira-impact-evs-us-jan23-2.pdf; see also 88 Fed. Reg. at 25,941 (citing the same study).

10 88 Fed. Reg. at 25,943 (noting EPA's Clean School Bus Program and the Federal Transit Administration's Low or No-Emission Grant Program). The IIJA contains other incentives to support vehicle electrification as well, such as a $7.5 billion program to build out electric charging and hydrogen fueling infrastructure through the Federal Highway Administration. Id. at 25,943-25,944.

11 Some of these programs include the California Hybrid and Zero-Emission Truck and Bus Voucher Incentive Project, the New York Truck Voucher Incentive Program, and the New Jersey Zero Emission Incentive Program. 16 Id. at 5.

Electric utilities, regional transmission organizations ("RTOs") and independent system operators ("ISOs") engage in long-term planning to ensure adequate generation resources will be available to meet anticipated demand for electricity. Expectations for electrification of the vehicle fleet and other end uses of energy are already being incorporated into long-term planning decisions, even the absence of the HDV and LMDV rules. The incremental demand attributable to these rules would increase electricity demand on a nationwide basis, while areas with higher concentrations of major transit corridors carrying a higher volume of medium and heavy-duty vehicles may experience even greater demand growth. But the electricity grid can, with adequate planning and investment, accommodate this growth and has previously experienced periods of significant and sustained growth,17 including relatively recently.18 Moreover, these historical periods do not reflect the pace and scale of generation growth anticipated as a result of implementation of the IRA and IIJA. By providing regulatory certainty needed for long-term resource planning and investment decisions, the HDV and LDMV rules will help ensure that the necessary resources are deployed to accommodate anticipated growth in demand due to electrification of the vehicle fleet. [EPA-HQ-OAR-2022-0985-1626-A1, pp. 3 - 4]

17 From 1960 to 1980, net generation in the electric power sector increased a remarkable 5.7% per year, with net generation more than tripling from just 756 GWh to 2,286 GWh. See ENERGY INFO. ADMIN., MONTHLY ENERGY REVIEW 134 tbl. 7.2b (May 2023), https://www.eia.gov/totalenergy/data/monthly/pdf/mer.pdf.

18 Between 1995 and 2007, average nationwide generation demand grew approximately 1.9% per year. See id. (noting an increase from 3,194 GWh to 4,005 GWh over this 13-year period).

III. Coalition members are investing in EV charging infrastructure

Members of this Coalition have begun making significant investments in the charging infrastructure needed to support a growing number of electric heavy-duty trucks, vans, and passenger cars. For example, NextEra Energy is pursuing a $650 million joint venture called Greenlane with BlackRock Alternatives and Daimler Truck North America to design, develop, install, and operate a nationwide charging and hydrogen fueling network for medium- and heavy-duty vehicles.19 Coalition members are also making significant investments in the charging infrastructure for electric passenger cars and trucks:

- National Grid recently received approval for a $206 million initiative to enable up to 32,000 additional charging ports in Massachusetts.20
- The New York Power Authority will have up to 400 fast chargers installed or in construction through its EVolve NY program by the end of 2025.21
- The Pacific Gas and Electric Company ("PG&E") has successfully installed through March 2023 over 5,700 charging ports through its EV Charge Network, EV Fleet, EV Fast Charge and EV Schools programs.22
- Austin Energy provides rebates of up to $1,200 and $4,000 for customers installing Level 2 charging stations at their homes and workplaces respectively.23
- The Sacramento Municipal Utility District ("SMUD") offers up to $1,000 toward residential charging equipment and installation costs through its Charge@Home program.24
- Constellation Energy Corporation's venture arm (Constellation Technology Ventures, or "CTV") has invested in portfolio companies focused on EV and charging infrastructure.25 [EPA-HQ-OAR-2022-0985-1626-A1, pp. 4 - 5]

25 For instance, CTV invested in Qnovo, which offers a solution suite that uses advanced computation to optimize the chemical reactions within lithium-ion batteries, resulting in faster charging, increased daily run times, and longer battery lifetimes. See Constellation Technology Ventures, https://www.constellationenergy.com/our-work/innovation-and-advancement/technology-ventures.html.

Coalition members are making these investments in part because of the benefits that EVs can provide to grid reliability. EVs' primary near-term grid benefits stem from their enablement of load shifting—whether from periods of higher load demand to periods of lower load demand, or from periods of more carbon-intensive power generation to periods where more renewable energy is available.26 Load shifting can involve both deferral (to avoid charging during periods of peak load) and more targeted scheduling (to take advantage of periods of excess energy supply).27 In addition to enhancing grid reliability, load shifting can also reduce customer electricity rates, increase the value of renewable energy investments (by maximizing usage of excess solar energy produced during the day), and mitigate the need for equipment upgrades (e.g., increased storage capacity to accommodate excess solar energy).28 [EPA-HQ-OAR-2022-0985-1626-A1, pp. 5 - 6]

For example, PG&E has partnered with the BMW Group to explore ways to incentivize EV drivers to shift their charging times to support grid reliability.29 This program—called ChargeForward—first kicked off in 2015 and moved into its third phase in 2021.30 Building on the success of the first two phases, phase three expanded the program's scope to 3,000 EV drivers (from prior pilots of 100 and 400 drivers in phases one and two).31 Phase two of ChargeForward demonstrated the ability to shift nearly 20% of charging from a particular hour to another time and to shift up to 30% of charging to a particular hour.32 SMUD is also engaged in a managed charging pilot program with BMW, Ford, and GM, and is planning to add Tesla vehicles to the pilot as well, targeting participation of around 2,000 vehicles through 2024.33 [EPA-HQ-OAR-2022-0985-1626-A1, p. 6]

Coalition members are also exploring Vehicle-to-Grid ("V2G") technology, through which EVs can send power back to load sources (e.g., homes) and the grid from their batteries. While still in the early stages of development, V2G technology can offer reliability benefits by serving as a grid resource during periods of peak demand.34 PG&E and BMW recently extended their ChargeForward partnership until March 2026 and, as part of that program, will conduct a field trial of V2G-enabled vehicles in order to explore their potential to increase grid reliability.35 In addition, PG&E has announced vehicle-grid integration ("VGI") pilot programs with Ford36 and General Motors to test the ability of EVs to provide backup power to homes.37 SMUD is also in the process of conducting an electric school bus V2G demonstration project with the Twin Rivers Unified School District.38 SMUD is planning to expand the program to additional school districts and is also pursuing other projects to explore V2G capabilities for light-duty EVs.39 [EPA-HQ-OAR-2022-0985-1626-A1, pp. 6 - 7]

IV. EPA should work closely with state and local partners to ensure deployment of the resources and infrastructure needed to accelerate transportation electrification while maintaining grid reliability

EPA's HDV Proposal will help support deployment of the charging and generation resources needed to meet anticipated demand from vehicle electrification. Yet effective and efficient deployment of these resources will require coordination among electric utilities, state public utility commissions, and local governments to ensure loads from EVs are factored into long-range resource planning and to permit distribution and transmission system upgrades and siting of new generation and storage resources. To ensure these resources are deployed on the pace and scale needed to support vehicle electrification and grid reliability, EPA should play a leadership role in ensuring coordination occurs among relevant federal, state and local agenices to remove barriers, emphasizing the benefits to the electricity grid, public health, and climate that will be achieved as a result. [EPA-HQ-OAR-2022-0985-1626-A1, p. 7]

Organization: Environmental Defense Fund (EDF)

4. The benefits of bi-directional charging from buses should also be considered

EPA's rulemaking should consider the potential benefits of using school buses for bi-directional charging. Electric school buses can function as large batteries to support the power grid, providing energy to municipalities through the use of vehicle-to-grid (V2G) technologies. According to WRI, at least 15 utilities across 14 states have committed to pilot electric school bus V2G programs, which allow electricity to be stored in the bus batteries and later discharged onto the grid.128 The bus batteries' stored power "can help stabilize fluctuating energy conditions, alleviate the need to start up additional power generation sources by shaving peak energy needs and provide mobile emergency power to shelters and other essential facilities. Because school buses operate on set daily schedules and often sit idle in the summer and during portions of the school day when electricity demand is high, they are ideal for this purpose. The power they can provide to the grid or buildings could offer revenue to help pay for the buses, a win-win for schools and the utility or other entity using the electricity."129 [EPA-HQ-OAR-2022-0985-1644-A1, p. 52]

128 Norma Hutchinson and Greggory Kresge, "3 Design Considerations for Electric School Bus Vehicle-to-Grid Programs," World Resources Institute (February 14, 2022). https://www.wri.org/insights/electric-school-bus-vehicle-grid-programs

129 Id.

b) The electric grid can support widespread HD ZEV adoption

The U.S. electric grid has provided reliable, cheap, instantaneous power to millions of homes and businesses every second of every day for well over a century. For so many end uses, electrification represents the cheapest and most attainable decarbonization pathway. [EPA-HQ-OAR-2022-0985-1644-A1, p. 65]

Growing the electric grid to meet increased demand is nothing new. Since 1960, about a third of the year over year increases in state electricity sales have been higher than 5% with 7% of those years having increases higher than 10% annual growth.166 The compound annual growth rate for the entire grid since 1960 is 2.8%. The total increase in electricity consumption as a result of the proposed rule is expected to be 1.3%, less than half of the average annual increase that has occurred since 1960. Research shows that, with planning, utilities will meet the demand for additional electricity needed to charge our nation's fleet of heavy-duty vehicles, and those vehicles may improve the reliability of the grid. [EPA-HQ-OAR-2022-0985-1644-A1, p. 65] [See Figure 11 on p. 66 of Docket Number EPA-HQ-OAR-2022-0985-1644-A1]

166 U.S. Energy Information Administration, EIA-861: Annual Electric Power Industry Report, 1960-2021, https://www.eia.gov/electricity/data/state/

EDF commissioned a report by Analysis Group to understand how the expected growth in HDV charging will impact the grid and what processes are in place or need to be added to enable the grid to meet the increased demand.167 Their main findings include:

5. The overall magnitude of growth in demand that would result from EPA's proposed rule is very small relative to historic periods of growth in the electric industry, and will not pose a challenge from the perspectives of power system generation or transmission infrastructure needs.
6. Charging station needs that may result from EPA's proposed rule range greatly in size and location; most counties and utilities in the U.S. analyzed in ICCT's report will likely not face new distribution system infrastructure needs due to charging load different from past experience.
7. Some utilities will need to plan for the development of new distribution system infrastructure to accommodate fairly large point sources of new charging station demand.
8. Adding significant new distribution system infrastructure is not a new experience for states, public utility commissions, or electric companies, and there are long-standing policies and practices in place to process development of infrastructure needed to ensure system reliability.
9. The need for a high level of certainty around the timely integration of charging stations and associated distribution system infrastructure at the scale and speed needed for HDV electrification warrants – and has already prompted – proactive action on behalf of some states and utilities to engage and expand planning and regulatory practices at the scale necessary to ensure timely readiness of the power system.
10. There are many emerging technologies, ratemaking practices, and distributed resource solutions that have the potential to significantly and efficiently reduce the expected impacts on distribution systems associated with vehicle electrification. [EPA-HQ-OAR-2022-0985-1644-A1, p. 66-67]

167 Paul Hibbard et al. Heavy Duty Vehicle Electrification: Planning for and Development of Needed Power System Infrastructure. 2023. Analysis Group, https://blogs.edf.org/climate411/wp-content/blogs.dir/7/files//Analysis-Group-HDV-Charging-Impacts-Report.pdf. Analysis Group, https://blogs.edf.org/climate411/wp-content/blogs.dir/7/files//Analysis-Group-HDV-Charging-Impacts-Report.pdf. (Attachment W).

Evolution of distribution systems to meet the potential increase in charging station demand associated with EPA's proposed Phase 3 rule for HDVs is eminently achievable. [EPA-HQ-OAR-2022-0985-1644-A1, p. 67]

Additionally, they found that 83% of utility service territories would not see more than 5 MW of increased load from HDV charging based on a study done by ICCT. The localized nature of the expected growth of HDV charging demand presents unique challenges but also allows for focused action. [EPA-HQ-OAR-2022-0985-1644-A1, p. 67]

ii. Robust solutions exist and are being implemented to ensure rapid interconnection and widespread vehicle electrification

The main concern that has been raised by OEMs and other parties related to the grid is the ability to build out infrastructure quickly enough to meet demand.177 In addition to the existing policies and practices around upgrading distribution systems that have served to build things like data centers which have high load requirements, additional practices have been developed and are being implemented in some areas to address specific challenges around HD ZEV charging. [EPA-HQ-OAR-2022-0985-1644-A1, p. 68]

177 https://documents.dps.ny.gov/public/Common/ViewDoc.aspx?DocRefId={D05A8E88-0000-CE16-8EA2-97D9432AAEE9}

These include practices and policies that maximize the existing grid capacity, proactively building the grid, and updating planning procedures. [EPA-HQ-OAR-2022-0985-1644-A1, p. 69]

By maximizing the existing grid capacity, fleet owners can transition to ZEVs without requiring immediate grid upgrades allowing more time for utilities to build out infrastructures. Techniques such as leveraging non-wires alternatives (managed charging, onsite storage and generation, and energy efficiency programs) have had great success in minimizing the upgrades required, and allowing for continued load growth while waiting for a necessary upstream grid upgrade. One clear example of this is Con Edison' BQDM program which resulted in a 7-year grid upgrade deferral.178 A report by the Smart Electric Power Alliance (SEPA) found a wide range of non-wires alternatives succeeded at enabling rapid interconnection and HDV electrification.179 [EPA-HQ-OAR-2022-0985-1644-A1, p. 69]

178 Coley Girouard. BQDM program demonstrates benefits of non-traditional utility investments. 2019. Utility Dive, https://www.utilitydive.com/news/bqdm-program-demonstrates-benefits-of-non-traditional-utility-investments/550110/

179 Brenda Chew et al. Non-Wires Alternatives: Case studies from leading U.S. projects. 2018, Smart Electric Power Alliance, https://sepapower.org/resource/non-wires-alternatives-case-studies-from-leading-u-s-projects/

Where fleets install managed charging software and/or onsite storage and solar generation to minimize charging costs including demand charges, their net load can be significantly lower than the utility-assigned capacity requirements for the site. To connect to the grid, they may be required to undergo site and utility upgrades to provide significantly higher capacity than what is actually needed and in some cases these solutions result in some sites never exceeding the existing capacity on their site making the upgrades unnecessary. Flexible interconnection, where customers agree to limit their peak load to a specified level below that of the cumulative nameplate capacity of their equipment, is one solution to energize chargers while those grid upgrades are ongoing. This mitigates any site and upstream grid upgrades in the short term in exchange for early energization of their charging equipment, and can even lower long-term upgrade needs. EPRI has shown the benefits of flexible interconnections for broader grid decarbonization.180 [EPA-HQ-OAR-2022-0985-1644-A1, p. 69]

180 Chris Warren. Can allowing curtailment speedup DER growth? EPRI Journal, https://eprijournal.com/getting-flexible-about-interconnection/

States are working towards allowing utilities, with guardrails in place to protect ratepayers, to proactively build the grid to need ahead of interconnection requests for new load, such as EV charging. [EPA-HQ-OAR-2022-0985-1644-A1, p. 70]

There are legislative efforts that are paving the way for this solution. California's AB 2700, which in addition calls for the collection of fleet electric vehicle deployment plans, also allows for utilities to submit pro-active grid expansion proposals to the utility commission in areas with identified future congestion using fleet deployment data.181 SB 410 in California would take this a step further, setting requirements for utilities to have their grid ready for interconnection requests and calls for utilities to plan and evaluate potential grid impact of Advanced Clean Fleets (ACF) and Advanced Clean Trucks (ACT) rules as well as submit plans to address potential areas of congestion to meet energization timelines. This bill also requires utilities to report interconnection requests and delays to better track progress and hold utilities accountable.182 [EPA-HQ-OAR-2022-0985-1644-A1, p. 70]

181 Transportation electrification: electricial distribution grid upgrades. AB2700. 2021-2022 Regular Session, (California 2022) https://legiscan.com/CA/bill/AB2700/2021

182 Powering Up Californians Act, SB410, 2023-2024 Regular Session, (California, 2023) https://legiscan.com/CA/text/SB410/id/2813946

Other states have also taken steps to ensure utilities are able to proactively build infrastructure. New York senate bill S4830, which recently passed both houses of the New York legislature, directs the New York State Energy Research and Development Authority (NYSERDA) to identify the number and location of fleet charging zones and highway charging hubs where significant demand from EV charging, including electric HDVs, is expected in line with meeting state and federal transportation sector emissions regulations, and the associated grid impact of that charging.183 [EPA-HQ-OAR-2022-0985-1644-A1, p. 70]

183 Establishing a highway and depot charging action plan, Senate Bill S4830A, 2023-2024 Legislative Session. (New York, 2023) https://www.nysenate.gov/legislation/bills/2023/S4830

Efforts to update planning processes have also improved the ability for the grid to meet demand from HDV charging. If utilities have accurate forecasts well in advance of when grid needs arise, they can complete needed upgrades without as great of a need for mitigating solutions like grid deferment and flexible interconnection. In a recent article, Southern California Edison (SCE) emphasized the importance of planning for utilities: "On the forecasting and planning side, utilities and energy system planners must adapt planning efforts to reflect expected EV growth, including impacts from proposed and adopted policies and incentives. For example, to account for the new developing needs of the Advanced Clean Cars II and Advanced Clean Fleets policies in California, SCE and the other California investor-owned utilities were recently approved to use higher forecasts for transportation electrification than previously used."184 [EPA-HQ-OAR-2022-0985-1644-A1, p. 70-71]

184 Pamela MacDougall and Katie Sloan, As the electric truck transition shifts into high gear, utilities must lead the charge. 2022. Utility Dive, https://www.utilitydive.com/news/electric-truck-bus-ev-utilities-sce-edison-edf/634214/

The New York Joint Utilities' Coordinated Grid Planning Process and California PUC's Freight Infrastructure Planning Framework, both currently under development, also represent examples of improved planning processes to enable accelerated HDV electrification and grid interconnection.185 186 [EPA-HQ-OAR-2022-0985-1644-A1, p. 71]

185 https://documents.dps.ny.gov/public/MatterManagement/CaseMaster.aspx?MatterCaseNo=20-e-0197&CaseSearch=Search

186 Zero-Emissions Freight Infrastrucutre Planning. California Public Utilities Commission, https://www.cpuc.ca.gov/industries-and-topics/electrical-energy/infrastructure/transportation-electrification/freight-infrastructure-planning

iii. Upgrade costs for charging HD ZEVs can help more efficiently use the grid and drive down costs

Large-scale electrification of medium- and heavy-duty vehicles will require grid upgrades, largely at the distribution grid level, to support the added load from charging. But, research shows that EVs can help strengthen the grid, and the costs of the needed upgrades can be covered by the additional revenue from fleets charging without raising consumers' electricity rates.187 [EPA-HQ-OAR-2022-0985-1644-A1, p. 71]

187 Lucy Metz, Melissa Whited, Paul Rhodes and Ellen Carlson. Distribution System Investments to Enable Medium- and Heavy-Duty Vehicle Electrification: A Case Study of New York, Synapse Energy Economics, Inc., prepared for EDF. (April 2023). (Attachment X) https://acrobat.adobe.com/link/track?uri=urn%3Aaaid%3Ascds%3AUS%3Ab0fd0780-9882-3a25-9ef2-f8c73bd80c92&viewer%21megaVerb=group-discover

According to electricity company executives, EVs can boost grid reliability.188 EVs are schedulable loads that typically charge off peak (at night). Utilities can encourage EV owners to charge when and where they want, leading to more efficient use of existing grid infrastructure.189 [EPA-HQ-OAR-2022-0985-1644-A1, p. 72]

188 Tomlinson, Chris. "Will electric vehicles crash the Texas grid? It's not complicated." Houston Chronicle (April 10, 2023). https://www.houstonchronicle.com/business/columnists/tomlinson/article/electric-vehicles-ercot-grid-reliabilty-17880578.php

189 Jennifer Chen. 2023. Leveraging Locational and Temporal Flexibility in Transportation Electrification to Benefit Power Systems. Energy Systems Integration Group. https://www.esig.energy/leveraging-locational-and-temporal-flexibility-in-transportation-electrification-to-benefit-power-systems/

EV charging can also finance and justify needed grid updates. Recent analysis conducted by Synapse Energy Economics for EDF finds that if U.S. utilities rate-base the cost of infrastructure upgrades needed for fleet charging, the utilities will see increased revenue without the need to raise consumers' electricity rates.190 The analysis used two New York State utilities as case studies and found that if utilities cover the "make-ready" cost for both private and municipal medium- and heavy-duty fleets at the pace necessary for 100 percent electrification by 2045, the investment will pay off for utilities and have a positive to neutral impact on ratepayers in both utility service areas. The analysis' findings are applicable beyond New York to states across the country due to the varying grid costs, geography and electricity demand profiles of the utilities studied. Con Edison primarily serves New York City, while National Grid provides electricity to portions of upstate New York. [EPA-HQ-OAR-2022-0985-1644-A1, p. 72]

190 Metz et al Distribution System Investments to Enable Medium- and Heavy-Duty Vehicle Electrification: (April 2023).

The study finds that if fleets are assumed to engage in modest managed charging (shifting charging times by only two hours at night), Con Edison's make-ready program could generate $690 million in net revenue between 2023-2045, while National Grid's program could generate $89 million in the same time period. Even without managed charging, investing in make-ready programs was shown to have a positive to neutral impact on ratepayers in both utility service areas. As more fleets are incentivized to plug in - and therefore spend more of their operating budget on electricity and less on diesel - utilities can invest a portion of that revenue on grid upgrades elsewhere that would have otherwise been paid for by all ratepayers. [EPA-HQ-OAR-2022-0985-1644-A1, p. 72-73]

iv. Managed charging represents an opportunity for fleet owners to reduce their costs and to increase grid benefits from HDV electrification

Medium- and heavy-duty fleets can experience short but high energy demand events that can significantly increase their grid impact and energy bills. When these fleets go beyond merely managing charging to leveraging onsite distributed energy resources (DERs) such as solar and battery storage, they can benefit from an even more powerful lever for reducing charging costs. A GNA study examined two types of clean DERs: on-site solar panels and batteries. When combined with managed charging, DERs produced additional annual electric savings of $625,000 (Schneider) and $835,000 (NFI) for fleets of 40-50 electric HDVs. Moreover, managed charging and DERs together reduced annual on-peak load by 611 kW for the Schneider fleet and 4 MW for the NFI fleet.191 Thus, such techniques would not only reduce costs for the truck companies, but the utility and ratepayers as a whole as well owing to the reduced need for grid buildout. If scaled to all trucks in a utility's territory, these load reductions could drastically decrease the amount of grid upgrades needed to accommodate electric fleets. [EPA-HQ-OAR-2022-0985-1644-A1, p. 73]

191 Gladstein, Neandross & Associates, California Heavy-Duty Fleet Electrification Summary Report, March 2021, http://blogs.edf.org/energyexchange/files/2021/03/EDF-GNA-Final-March-2021.pdf Gladstein, Neandross & Associates, California Heavy-Duty Fleet Electrification Summary Report, March 2021, http://blogs.edf.org/energyexchange/files/2021/03/EDF-GNA-Final-March-2021.pdf. (Attachment Y)

A recent New Jersey study evaluated the statewide grid impact of meeting ACT, as well as the grid savings when implementing managed charging and utilizing on-site solar and storage for all Class 3-7 vehicles in the state. Avoided peak load ranges from ~8,400 MW for managed charging, to ~10,000 MW for managed charging with solar + battery. Total avoided infrastructure costs are between $320 million and $1.80 billion for managed charging, and between $382 million and $2.15 billion for managed charging with solar + battery.192 [EPA-HQ-OAR-2022-0985-1644-A1, p. 73-74]

192 Jeffery Greenblatt. New Jersey Medium Duty Fleet Electrification Infrastructure Summary Report. 2022. Emerging Futures, https://blogs.edf.org/energyexchange/files/2022/05/New_Jersey_Medium_Duty_Fleet_Elecrtification_Infrastructure_Summary_Report.pdf Emerging Futures, https://blogs.edf.org/energyexchange/files/2022/05/New_Jersey_Medium_Duty_Fleet_Elecrtification_Infrastructure_Summary_Report.pdf (Attachment Z)

Furthermore, these largely avoided infrastructure costs are sure to be an underestimate for HDV electrification as a whole for the state since they do not account for the benefits of electrifying Class 8 vehicles with managed charging or managed charging with solar + battery. [EPA-HQ-OAR-2022-0985-1644-A1, p. 74]

The flexibility associated with vehicle charging is also extremely valuable to the grid operator. A study by the Midwest ISO shows the untapped potential of EV load flexibility as a DER resource in the wholesale markets. This study evaluated the impact of expected electrification of both MHDVs as well as LDVs in the MISO footprint. A key factor in this study was determining the potential flexibility of these vehicles when applying managed and bidirectional charging tactics to mitigate ramp and peak load. It showed that at any given hour this additional load can provide a minimum of 10 GW of combined ramp up capacity and just under 10 GW of ramp down or generation capacity using the flexibility of EV charging alone. To reiterate, this ramp capacity was based on vehicle charging alone and would be even greater if combined with other on-site DERs.193 [EPA-HQ-OAR-2022-0985-1644-A1, p. 74]

193 Greenblatt, Jeff and Margaret McCall, Exploring enhanced load flexibility from grid-connected electric vehicles on the Midcontinent Independent System Operator grid (Feb. 2021), available at https://cdn.misoenergy.org/Exploring%20enhanced%20load%20flexibility%20from%20grid%20connected%20EVs%20on%20MISO%20grid543291

Of critical importance, this load flexibility also comes at a fraction of the cost of traditional fixed battery storage. A study by Lawrence Berkeley National Lab shows that managed charging of EVs—modulating when and at what rate the EVs are charged— can provide reliable storage at approximately a tenth of the cost of equivalent storage provided by single-purpose, stationary batteries. When scaled to California’s projected 1.5 million light-duty EVs by 2025, the storage potential of managed charging alone is 1 GW, resulting in savings of approximately $1 billion compared to investments needed for equivalent stationary storage. This number also does not include the thousands of MHDVs such as buses and trucks expected to be electrified in the near future.194 By leveraging the flexibility of newly electrified resources, stakeholders can significantly reduce grid management costs ultimately, resulting in savings for end-customers and mitigating grid upgrade needs, further supporting accelerated HDV electrification. [EPA-HQ-OAR-2022-0985-1644-A1, p. 74-75]

Organization: National Rural Electric Cooperative Association (NRECA)

EPA Should Account for Grid-side Investments in Proposed Rule’s Analysis

Bearing these realities in mind, we write to express our significant concern that EPA has failed to adequately account for the costs associated with serving the new load that will be created via heavy-duty highway vehicle (HDV) electrification as outlined in this proposed rule. While EPA accounts for the cost to purchasers for the hardware and installation of charging equipment, EPA fails to include the electric grid-side upgrades that will likely be needed, if not now, certainly in the future as electrification spreads and this could have serious negative consequences to American consumers. Specifically, within the proposed rule section on Charging Infrastructure Costs, EPA states:1 “there may be additional infrastructure needs and costs beyond those associated with charging equipment itself. While planning for additional electricity demand is a standard practice for utilities and not specific to BEV charging, the buildout of public and private charging stations (particularly those with multiple high-powered DC fast charging units) could in some cases require upgrades to local distribution systems." [EPA-HQ-OAR-2022-0985-1515-A1, p. 2]

1 Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles – Phase 3, 88 Fed. Reg. 25,982 (April 27, 2023)

It is important for EPA to correct this failure in the proposed rule stage by updating its analysis with inclusion of a range of expected costs associated with serving the new load from the HDV fleet created by EPA's proposal. Failure to do so will likely result in unrealistic expectations on the part of fleet operators and possibly delay plans for electrification as they learn of the full costs that will be required to serve this new load from their electric cooperatives or other electric utilities. Neither these HDV fleet operators, nor the EPA, should expect that electric cooperatives can bear the burden of these new costs alone, particularly when these costs will ultimately need to be passed on to the end of the line consumer-members of the cooperative.[EPA-HQ-OAR-2022-0985-1515-A1, p. 2]

Overall, it is important for EPA to recognize that electrification of the transportation sector, and the increased flexibility of this newly electrified demand, will require substantial distribution infrastructure investment over time to meet increased average local electric demand and to meet increased demand in new locations (e.g., EV charging stations). Significant transmission infrastructure investment may also be required to meet increased average electric demand and changes in the spatial distribution of electric demand among load centers. According to the National Academy of Sciences, to transition the transportation sector through increased electrification, electric utilities will need to increase generation by up to 170% and see a three-fold expansion of the transmission grid by 2050. Over time, electrification of the transportation sector will require additional generation investment to ensure resource and energy adequacy to meet increased average electric demand and changing consumption profiles. Unfortunately, this investment challenge is becoming more complex due to several recent EPA actions that are jeopardizing flexible, dispatchable always available generation resources.2 These actions would require increased reliance on intermittent energy sources. Particular attention will be needed to ensure that generation investment is adequate in amount and in operational characteristics to meet the demands of electrification while ensuring grid stability, security, and reliability. [EPA-HQ-OAR-2022-0985-1515-A1, pp. 2-3]

2 These actions include: Supplemental Effluent Limitations Guidelines and Standards for the Steam Electric Power Generating Point Source Category, 88 FR 18824 (March 29, 2023); National Emission Standards for Hazardous Air Pollutants: Coal- and Oil-Fired Electric Utility Steam Generating Units Review of the Residual Risk and Technology Review, 88 FR 24854 (April 24, 2023); Hazardous and Solid Waste Management System: Disposal of Coal Combustion Residuals From Electric Utilities; Legacy CCR Surface Impoundments, 88 FR 31982 (May 18, 2023; New Source Performance Standards for Greenhouse Gas Emissions From New, Modified, and Reconstructed Fossil Fuel-Fired Electric Generating Units; Emission Guidelines for Greenhouse Gas Emissions From Existing Fossil Fuel-Fired Electric Generating Units; and Repeal of the Affordable Clean Energy Rule, 88 FR 33240 (May 23, 2023); and Federal Good Neighbor Plan for the 2015 Ozone National Ambient Air Quality Standards, 88 FR 36654 (June 5, 2023).

Specific Costs for EPA to Consider Incorporating in the Proposed Rule's Analysis

Again, we urge EPA to update its analysis to account for the costs needed to make updates to the grid to support HDV electrification. Grid upgrade costs for EV charging will vary by region, neighborhood, cooperative, circuit, and feeder. However, to illustrate the types and ranges of costs that EPA should account for, we provide the following costs sourced from four different cooperative regions, broken down by charge level:

- Residential (Level 1 and Level 2): One out of three households will need an expanded electric panel to accommodate 240 V Breakers. If a household purchases two electric vehicles, then four slots on a breaker will be needed to accommodate this load. The average cost will be approximately $4,000 for a Level 2 residential charger with a panel upgrade.
    - Upgrading panel (20% of panels must be upgraded) ¡V can start around $600
    - Transformer upgrades - $2,600 and climbing
    - Service wire gauge upgrades to accommodate higher amperage - $3,000
- Public (Level 2 and DC Fast Charging (DCFC)): For commercial sites, transformer upgrade needs will vary. Most sites will already have three-phase power available; however, in very rural locations single-phase power will need to be upgraded to three-phase. If transformers do need to be upgraded on a three-phase line, then three transformers will need to be upgraded.
    - Level 2 charger including panel - approx. $4,000 on average
    - National EV Infrastructure Program (NEVI)-Compliant DCFC - approx. $25,000-$150,000
        - Transformer - $25,000 - $40,000 (reflects current prices for three transformers)
        - Service entrance - $3,000-$4,000
        - Metering package (including instrumentation, voltage transformers (PT) and current transformers (CT) - $2,000
        - Line extension, if required (site dependent) - $50,000 - $75,000 [EPA-HQ-OAR-2022-0985-1515-A1, pp. 3-4]

Circumstances vary across cooperatives, but some of these costs will be borne directly by the consumer-members and others will be paid for by the cooperative. Regardless, these costs help to illustrate more accurately the investment it will take to implement on EPA's proposed rule. [EPA-HQ-OAR-2022-0985-1515-A1, p. 4]
