use a supplemental source only for part of the year, if multiple samples are required to be collected every year, it would be reasonable for a state to require one or more sample be collected when the supplemental source used seasonally is in operation and others when the supplemental source is not in operation. For the small minority of systems that have entry points that only operate when a supplemental source of water is in operation, seasonally, the state would also work with the system to establish a monitoring schedule that meets the requirements in the regulations as closely as possible. If this source is on quarterly monitoring, compliance would be based on the quarters in which this seasonal entry point is in operation. For example, if the source operates only from March to August, the system would collect three quarterly samples (in Q1, Q2, and Q3), and the RAA calculation will be based on these results; as the source is not in operation from September to February, no samples would be collected in Q4. For additional discussion of initial monitoring requirements, please see section 8.1.1 of the EPA response in this *Response to Comments* document; for additional discussion of compliance monitoring requirements, please see section 8.1.2 of the EPA response in this *Response to Comments* document.

Robert Hollander (Doc. #1516, SBC-042715)

8. 88 FR 18730, Section IX – Monitoring and Compliance Requirements, 3rd bullet

PWSs should be allowed to have each EPTDS on a compliance scheduled based on entry point sampling results, similar to what exists for current contaminant monitoring. This would provide the greatest level of public health protection for customers served by the EPTDS in question.

9. 88 FR 18730, Section IX – Monitoring and Compliance Requirements, 4th bullet

A two pronged approach would be appropriate here, where water systems can apply for monitoring waivers where both sampling results are consistently below trigger levels and vulnerability assessments indicate low risk to future contamination. This should be accompanied by updated vulnerability analyses, where feasible. If there is a potential change in vulnerability in the future (e.g., due to the addition of an industrial activity in the area), the vulnerability analysis should be revisited.

10. 88 FR 18730, Section IX – Monitoring and Compliance Requirements, 6th bullet

Yes, why not? See comment for 88 FR 18682, 2nd column, 1st paragraph, above regarding using previous monitoring results (e.g. UCMR 5 data).

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document for compliance monitoring schedule requirements. For discussion of monitoring waivers, please see section 8.5 of the EPA response in this *Response to Comments* document. For the EPA's response related to using previously-collected monitoring data to satisfy initial monitoring requirements, please see section 8.3 of the EPA response in this *Response to Comments* document.

Robert Hollander (Doc. #1516, SBC-042712)

5. 88 FR 18682, 2nd column, 1st paragraph

Regarding the EPA request for comment on EPTDSs having different compliance schedules based on previous monitoring data, this is already being done for SOCs. It is reasonable and understandable by systems already monitoring for SOCs. The proposed rule articulates individual EPTDSs will have different risks based on location with the system.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document.

Missouri Department of Natural Resources (Doc. #1563, SBC-042528)

Section IX—Monitoring and Compliance Requirements

EPA requests comment on the proposed monitoring flexibility for groundwater systems serving 10,000 or fewer to only collect two samples at each EPTDS to satisfy initial monitoring requirements.

The Department believes that there is no need to modify monitoring from the synthetic organic contaminant (SOC) standard monitoring framework. The fact that PFAS are defined as being a class of man-made chemicals consisting of carbon and fluoride chemical bonds makes them synthetic and organic. There is also no reason to deviate from allowing the flexibility of reliable and consistent (R&C) determinations of results below the MCL for a minimum of two-four quarters for a groundwater system. There is an issue, however, with the language requiring "no less than 90 days" between quarterly samples. The intent for that requirement is to prevent a public water system from collecting a sample during the 1st quarter on March 31 and a second sample in the second quarter on April 1st, and consider those to be 2 "quarterly samples" when they are only separated by 1 day. The second intent is to allow for possible seasonal concentration changes. However, logistically it is nearly impossible for systems, and for states like Missouri that coordinate sampling for systems, to align quarterly monitoring to that level of precision. Having more than 90 days between quarterly sampling is not necessary to provide for seasonal variation. The Department recommends EPA revise this part of the rule to provide greater flexibility for collecting quarterly samples to a more acceptable range, such as no less than 30 days between samples.

EPA requests comment on the proposed allowance of a water system to potentially have each EPTDS on a different compliance monitoring schedule based on specific entry point sampling results (i.e., some EPTDS being sampled quarterly and other EPTDS sampled only once or twice during each three-year compliance period), or if compliance monitoring frequency should be consistent across all of the system's sampling points.

The Department recommends not changing source water sampling requirements, and continuing the practice of allowing groundwater sources within a PWS that also has surface water sources to

treat sampling the sources based on the source water risk. Groundwater sources continue to have less risk than surface water contamination.

EPA Response: Please see section 8.1.1 of the EPA response in this *Response to Comments* document for a discussion of initial monitoring requirements (including the required intervals between samples) and section 8.1.2 of the EPA response in this *Response to Comments* document regarding compliance monitoring requirements, including determinations that a sampling point is "reliably and consistently" below the MCL and differences between monitoring requirements for PFAS versus those for other SOCs. Additionally, in the final regulation, the EPA has specified that the requirements for a surface water system or groundwater system are dependent on the type of source water that is provided at an EPTDS.

Missouri Department of Natural Resources (Doc. #1563, SBC-042530)

EPA requests comment on if all water systems, regardless of system size, be allowed to collect and analyze one sample per three-year compliance period if the system does not detect regulated PFAS in their system at or above the rule trigger level.

The Department supports community and nontransient noncommunity water systems utilizing groundwater, regardless of size, to be allowed to collect a SOC/PFAS sample once every 6 years if results can be shown to be reliably and consistently (R&C) below the MCL, assuming the MCL is set above the PQL with a sufficient spread of limits. Due to the vulnerability of surface water systems to SOC/PFAS, the Department supports annual monitoring of systems with R&C results below the MCL.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document. Please see section 5.1.2 of the EPA response in this *Response to Comments* document summary for a discussion of the relationship between MCLs and PQLs.

Oregon Health Authority (OHA) (Doc. #1582, SBC-042763)

• EPA requests comment on the proposed allowance of a water system to potentially have each EPTDS on a different compliance monitoring schedule based on specific entry point sampling results (i.e., some EPTDS being sampled quarterly and other EPTDS sampled only once or twice during each three-year compliance period), or if compliance monitoring frequency should be consistent across all of the system's sampling points.

OHA supports the proposed allowance of a water system to potentially have each EPTDS on a different compliance monitoring schedule based on specific entry point sampling results. This is consistent with current requirements for other regulated contaminants that are monitored at the EPTDS and reflects the fact that EPTDS may be served by sources that reflect different water quality characteristics, for example, groundwater wells in different aquifers or geographically distant from each other.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document.

Michigan Department of Environment, Great Lakes, and Energy (EGLE) Drinking Water and Environmental Health Division (DWEHD) (Doc. #1597, SBC-042985)

However, for reduced compliance monitoring purposes, EGLE DWEHD proposes an approach based on source vulnerability rather than PWS size.

a) EPA proposes flexibility for groundwater supplies not detecting PFAS above the "Trigger Level," with those serving 3,300 or fewer permitted to sample once per three-year period AND those serving more-than 3,300 required to sample twice per three-year period. EGLE DWEHD proposes instead that EPA maintain a consistent requirement for sampling frequency across size categories in groundwater PWS.

b) Similarly, EGLE DWEHD proposes that surface water supplies and those groundwater supplies under direct influence (GUDI) not detecting PFAS above the trigger level also maintain a consistent sampling frequency requirement, although higher than that of groundwater supplies. EGLE DWEHD recommends EPA consider a reduced frequency of no less than annual sampling for these supplies.

By focusing on vulnerability as the determining factor, EGLE DWEHD posits that the proposed rule would be more protective of human health. In the case of surface water and GUDI supplies, unexpected changes in PFAS contamination may result from release events, changes in currents/weather patterns, or other environmental factors.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document.

Lehigh County Authority (LCA) (Doc. #1600, SBC-042818)

Reduced Monitoring

The proposed rule uses trigger levels, set at one-third of the PQL, to determine if a system is eligible for reduced monitoring. EPA has requested comment on whether individual entry points should be allowed to achieve reduced monitoring status. LCA strongly encourages EPA to allow individual entry points to be placed on reduced monitoring. EPA as followed this protocol with other contaminants, and the same should be considered for PFAS.

A key benefit of allowing reduced monitoring by individual entry points is overall cost control. LCA's water systems consist of dozens of entry points. Laboratories in Pennsylvania are charging $800 or more per sample to test for PFAS, which will equate to nearly $100,000 in compliance sampling costs per year for our systems. Allowing for reduced monitoring on an individual entry point basis will ensure LCA's resources and compliance efforts are focused on the water sources that require more careful monitoring.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document.

American Water Works Company Inc. (Doc. #1608, SBC-044011)

American Water also supports the proposed regulatory approach that monitoring requirements will be determined independently for each entry point in a given water system, including reduced monitoring. This is consistent with implementation of other rules and recognizes the differences between water quality at different treatment plants.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document.

Colorado Water Utility Council (CWUC) (Doc. #1622, SBC-044036)

18. EPA requests comment on the proposed allowance of a water system to potentially have each EPTDS on a different compliance monitoring schedule based on specific entry point sampling results (i.e., some EPTDS being sampled quarterly and other EPTDS sampled only once or twice during each three-year compliance period), or if compliance monitoring frequency should be consistent across all of the system's sampling points.

A. There is no problem with different sampling frequencies at different EPTDS, this already happens frequently. Keep it consistent with the other SDWA requirements.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document.

Colorado Water Utility Council (CWUC) (Doc. #1622, SBC-044039)

20. EPA requests comment on if all water systems, regardless of system size, be allowed to collect and analyze one sample per three-year compliance period if the system does not detect regulated PFAS in their system at or above the rule trigger level.

a. One sample per 3 years with non-detects seems acceptable. However this could make an RAA approach problematic with only one or fewer sampling events in a year. CWUC disagrees with EPA's suggestion of determining compliance with the RAA using the trigger level. That is too complicated and does not afford the utility the opportunity to address and correct the issue, which we interpret to be the purpose of the trigger level. The RAA value should be the MCL (which we propose should be set at 8.0 ppt).

b. Please clarify in the rule, for establishing monitoring period frequencies, if the individual MCLs/His will be treated with individual compliance periods, or will they be lumped together? For instance, if the system meets the trigger level for HI and PFOA, but exceeds it for PFOS, will the system be on reduced monitoring for the prior two and standard monitoring for only PFOS? Or do they move to the same monitoring frequency for all elements as a group?

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document. The RAA calculation only applies to systems conducting quarterly monitoring, as is the case with other SOCs, and is only used to evaluate compliance with the MCL (i.e., to judge whether the RAA is at or below the MCL). In light of the public comments about the proposed threshold for a "reliably and consistently" below the MCL determination (to determine compliance-monitoring frequency), the EPA deleted the proposed requirement to compare the RAA to the trigger levels. Instead, the state is to consider whether results from four consecutive quarters are below the MCL to justify a shift from quarterly to annual monitoring. Similarly, the state is to consider whether the results from three consecutive years of annual monitoring are below trigger levels to justify a shift from annual to triennial monitoring. Thus, the RAA is not compared to trigger levels in the final rule. Regarding establishing compliance monitoring schedules, samples will be analyzed for all PFAS on the same schedule, as noted in the final rule. Please see section 8.2 of the EPA response in this *Response to Comments* document for further discussion of determining compliance with the MCLs. This includes a description of how the MCL is the basis for compliance determinations. Values below the PQLs are not utilized in the calculation of RAAs (results below the PQL are treated as zero in that calculation). Please see section 5 of the EPA response in this *Response to Comments* document for further discussion of the final MCLs.

Aqua America, an Essential Utilities Company (Doc. #1623, SBC-043062)

6. The use of the Standard Monitoring Framework (SMF) for PFAS is appropriate with the use of a trigger level that is one-half of the MCL to determine when PFAS levels are reliably below the MCL.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document. For discussion of the trigger levels, please see section 8.8 of the EPA response in this *Response to Comments* document.

Aqua America, an Essential Utilities Company (Doc. #1623, SBC-043100)

Finally, the EPA's proposed approach to require monitoring under the Standard Monitoring Framework and the use of the one-half of the MCL as a trigger level is appropriate.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document. For discussion of the trigger levels, please see section 8.8 of the EPA response in this *Response to Comments* document.

Pennsylvania Department of Environmental Protection (Doc. #1626, SBC-044886)

According to [sec] 109.XX(b)(2)(i) Table 2, reduced triennial monitoring for systems serving more than 3,300 persons consists of two samples per EP in a consecutive 12-month period during each three-year compliance period, at least ninety days apart; for systems serving 3,300 or fewer

persons, reduced monitoring consists of just one sample per EP per three-year compliance period. DEP does not agree with this distinction in monitoring frequency based on system population. While this appears to follow the reduced monitoring requirements for SOCs, there does not appear to be sufficient justification for requiring two samples at larger water systems. The differentiation of population is arbitrary.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document.

Pennsylvania Department of Environmental Protection (Doc. #1626, SBC-044877)

DEP supports compliance determinations that may allow different entry points (EP) at the same water system to be on different monitoring frequencies, based on monitoring results. Additional comments regarding determination of monitoring frequencies are provided later in this letter.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document.

Association of State Drinking Water Administrators (ASDWA) (Doc. #1628, SBC-044096)

ASDWA recommends that EPA allows water systems to have different monitoring schedules for different entry points.

ASDWA recommends that EPA not require that all entry points be monitored on the same monitoring frequency. This flexibility in the final rule would allow systems to reduce analytical costs and would align with the current approach for chemical monitoring, especially for systems that have several sources.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document.

Association of State Drinking Water Administrators (ASDWA) (Doc. #1628, SBC-044093)

Monitoring Requirements

ASDWA recommends using the standard monitoring framework (SMF) for Synthetic Organic Chemicals (SOCs) to provide consistency and clarification for PFAS monitoring requirements.

Using the SMF for quarterly monitoring and allowing water systems to stagger monitoring would provide clarification and consistency for PFAS monitoring requirements. The specification of the 90-day monitoring requirements, rather than requiring typical quarterly sampling per the SMF, is confusing. This confusion is exacerbated when, for example, the water system is seasonally operated and must retake a sample due to the sample being invalidated (but that was taken in the correct timeframe). This component of the rule needs more details and clarification. This every 90-day requirement was included in the Stage 2 Disinfectants and

Disinfection Byproducts Rule (DBPR), and some primacy agencies noted that their water systems were unable to meet the specific timing requirements. Based on EPA guidance, many primacy agencies allowed the samples to be taken within three calendar months. Some existing state PFAS drinking water regulations specify that the timeframe for compliance monitoring is restarted in the event that a sample is invalidated. In addition, the language in the proposed rule regarding staggered monitoring is vague and, as currently written, may not be evenly staggered. The language, as written, appears to allow water systems to test anytime within the three-year window, and all water systems could wait until the end of the monitoring period to conduct sampling. This timing could further stress laboratory capacity.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document for compliance monitoring requirements and timing. Regarding initial monitoring requirements and the proposed requirement that quarterly samples be collected during initial monitoring at least 90 days apart, please see section 8.1.1 of the EPA response in this *Response to Comments* document. As discussed in section 8.1.2 of the EPA response in this *Response to Comments* document, in the final rule, the EPA followed the model of the SMF for SOCs, but adjusted some aspects of the required compliance monitoring framework specific for PFAS. Pursuant to §141.902(b)(2)(vii) of the regulations, "Each public water system must monitor at the time designated by the State within each monitoring period." States are to make their expectations known to systems with respect to how to address special situations, such as those cited in this comment. For a discussion of laboratory capacity, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

North Carolina Division of Water Resources (NCDEQ) (Doc. #1652, SBC-044180)

G. Monitoring Requirements

1. NCDEQ recommends using the standard monitoring framework (SMF) for Synthetic Organic Chemicals (SOCs) to provide consistency and clarification for PFAS monitoring requirements.

Using the SMF for quarterly monitoring and allowing water systems to stagger monitoring would provide clarification and consistency for PFAS monitoring requirements. The specification of the 90-day monitoring requirements, rather than requiring typical quarterly sampling per the SMF, is confusing. This confusion is exacerbated when, for example, the water system is seasonally operated and must retake a sample due to the sample being invalidated (but that was taken in the correct timeframe). This component of the rule needs more details and clarification. In addition, the language in the proposed rule regarding staggered monitoring is vague and, as currently written, may not be evenly staggered. The language, as written, appears to allow water systems to test anytime within the three-year window, and all water systems could wait until the end of the monitoring period to conduct sampling. This timing could further stress laboratory capacity, in addition to the other capacity factors previously mentioned.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document for compliance monitoring requirements and timing. Regarding initial

monitoring requirements and the proposed requirement that quarterly samples be collected during initial monitoring at least 90 days apart, please see section 8.1.1 of the EPA response in this *Response to Comments* document. As discussed in section 8.1.2 of the EPA response in this *Response to Comments* document, in the final rule, the EPA followed the model of the SMF for SOCs, but adjusted some aspects of the required compliance monitoring framework specific for PFAS. Pursuant to §141.902(b)(2)(vii) of the regulations, "Each public water system must monitor at the time designated by the State within each monitoring period." For a discussion of laboratory capacity, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

Texas Commission on Environmental Quality (TCEQ) (Doc. #1632, SBC-044135)

[To alleviate the initial laboratory capacity issues and reduce public water system sampling costs, TCEQ supports:]

• Allowing each EPTDS's compliance monitoring schedule to be based on specific entry point sampling results as each EPTDS is supplied by a unique source and/or treatment and can have different levels of PFAS.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document.

Citizens Against Ruining the Environment (CARE) (Doc. #1638, SBC-043446)

CARE Comment 2 – U.S. EPA Should Establish Clear and Protective Guidelines for State Implementation of the New MCLs.

Since regulations promulgated under SDWA will be implemented and enforced by State Primary Agencies, careful guidance and narrow guide rails from the EPA should be in place to ensure the proposed PFAS MCLs are enforced as intended. In particular, U.S. EPA should establish strict limits on Primary Agencies' authority to (1) reduce the frequency of PFAS monitoring and (2) grant exemptions for PFAS exceedances should be carefully drafted to minimize the variability in Primary Agency enforcement that might reduce the public health benefits of the proposed MCLs.

Monitoring and Compliance Requirements Must Be Strengthened

MCL values are protective only to the extent that they are supported by robust monitoring and enforcement. To ensure that the proposed MCLs have the intended effect of protecting human health, the proposed monitoring and compliance requirements must be strengthened.

Monitoring and compliance requirements should be designed in consideration of the physical properties of PFAS, including the limitations of current PFAS understanding. The mobility of PFAS chemicals in air, water, and soil is well established. [FN28: Addressing Challenges of PFAS: Protecting Groundwater and Treating Contaminated Sources, EPA (Sept. 20, 2021),

.epa.gov/sciencematters/addressing-challenges-pfas-protecting-groundwater-and-treating-contaminated-sources.] Its transport rate is dependent on numerous variables. [FN29: Goode, D.J., and Senior, L.A., 2020, Groundwater withdrawals and regional flow paths at and near Willow Grove and Warminster, Pennsylvania—Data compilation and preliminary simulations for conditions in 1999, 2010, 2013, 2016, and 2017: U.S. Geological Survey Open-File Report 2019–1137, p. 4.] PFAS have been found in groundwater plumes 24 kilometers from known point sources. [FN30: Drinking Water Health Advisory: Hexafluoropropylene Oxide (HFPO) Dimer Acid (CASRN 13252-13-6) and HFPO Ammonium Salt, Also Known as "GenX Chemicals", U.S. EPA, p. 8 (June 2022).] PFAS can travel long distances through the air before being deposited onto soil and surface waters, then finally migrating into subsurface soil and groundwater. [FN31: Drinking Water Health Advisory: Perfluorooctane Sulfanate (PFOS), U.S. EPA, p. 16 (May 2016).] Taking these factors into account, low quantities of PFAS in a given sample are not predictive of low quantities of PFAS in future samples because new or distant sources of PFAS that do not degrade continue to pose a threat as they migrate through the environment.

Monitoring Frequency Must Be Increased

CARE strongly disagrees with the provision in Proposed Rule Section IX that would allow all systems to analyze only one sample per three year reporting period if the system does not detect any regulated PFAS in their system at or above the trigger level. [FN32: PFAS National Primary Drinking Water Regulation Rulemaking, 88 Fed. Reg. at 18730.] Given the known ability of PFAS to transport throughout environmental media and the variability in transport rates, sampling once every three years is inadequate. PFAS is known to persist for decades after initial release into the environment and to travel at different rates depending on the substrate and other conditions. It migrates from air to soil to water and will contaminate water both near and far from its initial source. These physical properties require ongoing vigilance by PWS to ensure that drinking water is free from PFAS and remains so.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document. This NPDWR establishes the minimum requirements for sampling of regulated PFAS by a CWS or NTNCWS. Under SDWA, states cannot implement less stringent requirements and may institute requirements that are more stringent, so the EPA agrees that they would not be able to reduce the frequency of PFAS monitoring below what is required in this regulation. The requirements for a system to receive an exemption for this NPDWR as allowable under SDWA are consistent with requirements to be granted an exemption under other NPDWRs (see Subpart F of 40 CFR Part 141). For a discussion of comments related to exemptions and extensions, please see section 12.1 of the EPA response in this *Response to Comments* document.

Aidan Cecchetti (Doc. #1640, SBC-044369)

• EPA requests comment on the proposed allowance of a water system to potentially have each EPTDS on a different compliance monitoring schedule based on specific entry point sampling

results (i.e., some EPTDS being sampled quarterly and other EPTDS sampled only once or twice during each three-year compliance period), or if compliance monitoring frequency should be consistent across all of the system's sampling points (pg. 18682 Federal Register Volume 88, Number 60).

O The commenters agree with EPA's proposed reduced monitoring approach to allow lower-risk water systems to conduct compliance monitoring on different schedules at each EPTDS. This would be consistent with the implementation of monitoring schedules for other NPDWRs.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document.

Aidan Cecchetti (Doc. #1640, SBC-044371)

• EPA requests comment on if all water systems, regardless of system size, be allowed to collect and analyze one sample per three-year compliance period if the system does not detect regulated PFAS in their system at or above the rule trigger level (pg. 18682 Federal Register Volume 88, Number 60).

O It is the opinion of the commenters that the proposed approach of allowing all water systems to collect one sample per three-year compliance period if the system does not detect regulated PFAS would be appropriate. This would be consistent with the manner in which the primary drinking water standards for other synthetic organic contaminants are applied and provides sufficient health protection for systems at low risk of detecting PFAS.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document.

National Rural Water Association (NRWA) (Doc. #1641, SBC-043275)

• EPA requests comment on the proposed allowance of a water system to potentially have each EPTDS on a different compliance monitoring schedule based on specific entry point sampling results (i.e., some EPTDS being sampled quarterly and other EPTDS sampled only once or twice during each three-year compliance period), or if compliance monitoring frequency should be consistent across all of the system's sampling points.

Response: If sample results are low – there is no reason to sample frequently and create a greater financial burden on the water systems.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document.

Savannah River Nuclear Solutions LLC (Doc. #1647, SBC-043329)

SRNS SPECIFIC COMMENTS:

Comment 1

Section IX.A. Monitoring and Compliance Requirements (pg. 18682)

EPA is requesting comment on the allowance of a water system to potentially have each entry points to the distribution system (EPTDS) on a different compliance monitoring schedule based on specific entry point sampling results (i.e., some EPTDS being sampled quarterly and other EPTDS sampled only once or twice during each three-year compliance period). SRNS supports the flexibility that such an approach would provide water systems, however, there is a concern that having differing compliance monitoring schedules for different EPTDS might be complicated to implement and potentially lead to missing sampling periods, especially for those EPTDS that are only sampled once or twice during the three-year compliance period. SRNS recommends that compliance monitoring frequency should be consistent across all of the systems sampling points.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document.

North Carolina Division of Water Resources (NCDEQ) (Doc. #1652, SBC-044182)

3. NCDEQ recommends that EPA allow water systems to have different monitoring schedules for different entry points.

NCDEQ recommends that EPA does not require that all entry points be monitored on the same monitoring frequency. This allows systems to reduce analytical costs and would align with the current approach for chemical monitoring, especially at systems that have several sources.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document.

Nebraska Department of Environment and Energy (NDEE) (Doc. #1653, SBC-043201)

EPTDS should be on its own monitoring schedule based on prior monitoring results.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document.

Washington State Department of Health (DOH) (Doc. #1665, SBC-044398)

DOH supports the ability of public water systems with sources reliably and consistently (R&C) below PFOA and PFOS trigger levels to qualify for reduced monitoring.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document.

Washington State Department of Health (DOH) (Doc. #1665, SBC-044419)

EPA requests comment on monitoring-related flexibilities that should be considered to further reduce burden while also maintaining public health protection including a rule trigger level at different values than the currently proposed values of 1.3 ppt for PFOA and PFOS and 0.33 for the HI PFAS (PFHxS, HFPO–DA, PFNA, and PFBS), specifically alternative values of 2.0 ppt for PFOA and PFOS and 0.50 for the HI PFAS. EPA also requests comments on other monitoring flexibilities identified by commenters.

• A trigger for PFOA and PFOS of 2 ppt would place less burden on labs and PWSs while still allowing for public health protection. Since all results below the PQL for the HI PFAS are calculated as zero, it might make sense to use 0.5 as the trigger. Increasing these triggers would allow for some reduction in monitoring for sources that don't exceed the slightly higher trigger but are below the MCL. To ensure public health protection, EPA could also assign two years of annual monitoring or an R&C annual for sources with detections consistently below the MCL instead of having them remain on quarterly.

EPA requests comment on the proposed allowance of a water system to potentially have each EPTDS on a different compliance monitoring schedule based on specific entry point sampling results (i.e., some EPTDS being sampled quarterly and other EPTDS sampled only once or twice during each three-year compliance period), or if compliance monitoring frequency should be consistent across all the system's sampling points.

• While PFAS contaminant plumes can be extensive, they likely follow groundwater flow directions in such a way that timing monitoring in sources in distinctly different areas would be more burdensome than helpful. This is especially true for water systems where sources are spread across a wide area. For those systems which have been collecting quarterly samples there have not been significant differences in the concentrations temporally. Impacts were identified to surrounding/downgradient source concentrations when a large producing source was taken offline due to high PFAS detections while the PWS installed treatment. Systems assigned quarterly monitoring will likely collect samples at sources in a similar area at the same time to save on labor and shipping costs. DOH have also had multiple issues with lab analysis, which has required repeat samples be taken from sources; this could negate any timing attempts. This level of timing would only serve to make the rule more complex. Please ensure states continue to have the authority to increase monitoring as needed.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document. The EPA agrees that a "reliably and consistently below the MCL" determination would appropriately allow a system to qualify for annual monitoring and has made that change in the final rule, along with stating that this determination would be based on a direct comparison to the MCL. Additionally, the rule provides that states may impose more stringent requirements. Regarding rule trigger levels, please see section 8.8 of the EPA response in this *Response to Comments* document.

City of Allentown and Lehigh County Authority (LCA), Pennsylvania (Doc. #1667, SBC-043679)

Reduced Monitoring: The proposed rule uses trigger levels, set at one-third of the PQL, to determine if a system is eligible for reduced monitoring. EPA has requested comment on whether individual entry points should be allowed to achieve reduced monitoring status. The City strongly encourages EPA to allow individual entry points to be placed on reduced monitoring. EPA has followed this protocol with other contaminants, and the same should be considered for PFAS.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document.

Aurora Water, City of Aurora, Colorado (Doc. #1669, SBC-043713)

Additionally, Aurora Water agrees with the allowance for separate monitoring schedules based on sampling results at separate entry point locations. Aurora has several entry points into its distribution system that have varying sources of water. As a result, there are varying PFAS results at each entry point. Aurora has separate monitoring schedules for other contaminants based on entry point such as VOC, SOC, and nitrates. It is best if EPA stays consistent with other rules that are in effect by allowing different entry points to be on separate monitoring schedules and it will reduce costs while allowing the system to focus on the sample sites that are most concerning.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document.

Cleveland Water, City of Cleveland, Ohio (Doc. #1672, SBC-044913)

Section 5: Monitoring and Compliance Requirements

Section 5.1: Monitoring

EPA has requested comment on several pieces related to monitoring requirements. The agency has proposed a monitoring regime based on the Standard Monitoring Framework (SMF) for Synthetic Organic Contaminants (SOC). Cleveland Water is supportive of using this framework to ensure uniformity among rules covering similar compounds. We also strongly support maximum flexibilities in monitoring that will reduce burdens on PWSs and still be protective of public health, as EPA has done with other chemicals with chronic health risks.

Cleveland Water is pleased EPA has considered situations in which reduced monitoring is appropriate. However, the agency is proposing a trigger level well below the Practical Quantification Level (PQL) for PFOA and PFOS. Under this proposal, a PWS qualifies for reduce monitoring if its RAA is below the trigger level of 1.3 ppt for PFOA and PFOS and a 0.33 HI for the additional PFAS. This allows water systems to sample once or twice in a three-

year period, depending on system size. Because the health effects of PFAS are chronic, we recommend EPA make this reduced monitoring uniform and require all systems, regardless of size, to sample once in the three-year period under this reduced monitoring framework. This would allow for further reduction in burdens on utilities while also not compromising public health.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document. Regarding rule trigger levels, please see section 8.8 of the EPA response in this *Response to Comments* document.

New York State Department of Health (NYS DOH) (Doc. #1677, SBC-044946)

8. Although the Department recognizes the reasoning behind Entry Point to Distribution System (EPDS) monitoring for organic chemicals, the fate and transport of PFAS compounds, occurrence, and the low MCL makes this approach less conservative, and therefore less protective of public health.

Concentrations of PFAS compounds can vary significantly within a single well field within the same aquifer, and traditional methods of EPDS monitoring may not be appropriate. With a proposed MCL at 4 ppt, there are many instances where a single well that can be operated independently may exceed the MCL, while other wells within the aquifer remain below the standard. Although regulations specify typical operation, a public water system that has source water data can collect samples at EPDS during times when the lower concentration wells are in service to remain in compliance with the proposed standard. The complexity of many water systems makes it challenging for primacy agencies to be able to fully capture what happens during typical operation.

The Department currently requires monitoring at each source, however, we recognize that there may be opportunities to lower costs, particularly at small water systems, while concurrently obtaining a more robust dataset than we believe can be accomplished by entry point monitoring alone. The Department suggests EPA require 4 consecutive quarters of monitoring at each source if a public water system has an EPDS result greater than the trigger level for any PFAS compound during initial monitoring. Using an EPDS to determine compliance should be at the discretion of the primacy agency based on operational conditions of the water system that include but are not limited to number of sources, the presence of treatment to remove PFAS, number of EPDS, and the presence of source water monitoring data.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document. The EPA agrees that there would be a considerably higher cost to systems if they were to sample at each drinking water source. Samples at those locations would not necessarily be representative of concentrations to which consumers are exposed. The NPDWRs focus on finished drinking water, and, for many NPDWRs on sampling at each EPTDSs, because it is the water that consumers drink and use for other domestic purposes.

New York City Department of Environmental Protection (NYCDEP) (Doc. #1679, SBC-044214)

In section IX. A., p. 18682, EPA requests comment on having different monitoring schedules for entry point based on trigger level status. PWSs already adapt to complicated monitoring schedules. Having different monitoring schedules is an added burden for sample scheduling that should be able to be adapted to. However, each testing event results in obtaining data for all PFAS in the method, regardless of schedule. P. 18682 states that the system must average all samples taken in the quarter. These samples will be taken on schedule, the analysis will be conducted by approved method, and results will be available for all PFAS included in the method. There is likely to be PFAS data collected outside of the intended monitoring schedule. How are the extra data to be handled? Is the supplier expected to request that the laboratory not report some PFAS data because they are not yet scheduled for monitoring? Will labs be in the position of knowing of an MCL issue and not reporting the level to the water supplier? Monitoring reductions do not actually save effort or reduce complications unless all PFAS chemicals follow the same schedule.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document. The EPA has updated the language regarding the requirement to average multiple samples collected during a quarter (or other monitoring period) to indicate that the only samples to be included in the quarterly averages are compliance samples a system is directed to take by a state. See, for example, § 141.902(b)(2)(v), § 141.903(e), §§ 141.903(f)(1) and 141.903(f)(2), and Table 2 in § 141.904(b). Typically, these compliance samples would be limited to the sample for the monitoring period and any confirmation samples required by the state. Apart from these compliance samples, any other samples collected during a single monitoring period are not to be included in a quarterly, annual, or triennial average. Any extra samples collected voluntarily by a system are not required to be reported to the EPA or the state (unless the state provides otherwise). If the state requires reporting of results from voluntary sampling, those results should be managed separately such that only the results from compliance monitoring are included in RAA calculations.

City of Vancouver Water Utility, Vancouver, WA (Doc. #1684, SBC-044313)

Compliance Monitoring Frequency:

Vancouver agrees that each source should be allowed to have an independent compliance monitoring schedule and that it is not necessary to have compliance monitoring consistent across all system's sampling points.

Although Vancouver agrees that a PFAS MCL exceedance should be a Tier 2 violation given past practice for other bioaccumilating contaminants, the proposed limits will cause laboratories to become overburdened with sampling, which will lead to further delays and costs increases in what are already very expensive samples. Quarterly sampling is excessive given that the majority of utilities with PFAS issues do not see significant changes in levels within a 3-month period. This is especially true for water systems where sources are spread across a wide area. For those

systems which have been collecting quarterly samples there have not been significant differences in the concentrations temporally. Sampling twice a year is adequate.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document. Please see section 9.2 of the EPA response in this *Response to Comments* document for a discussion of public notice requirements. Please see section 5.1.2 of the EPA response in this *Response to Comments* document for a discussion of laboratory availability.

New Hampshire Department of Environmental Services (NHDES) (Doc. #1690, SBC-044350)

d. Page 18730, Column 3, Bullet 2 - EPA requests comment on if all water systems, regardless of system size, be allowed to collect and analyze one sample per three-year compliance period if the system does not detect regulated PFAS in their system at or above the rule trigger level.

NHDES Comment - NH agrees that all water systems, regardless of system size, should be allowed to collect one sample per three-year compliance period if the system does not detect regulated PFAS in their system at or above the rule trigger level. Tracking and implementing a "2 samples in three years" schedule would be cumbersome with our current non-SDWIS database and would cause confusion for our water systems that are accustomed to monitoring frequencies of either triennial, annual, or quarterly. Frequencies based on sample results alone still maintains protection of public health for all consumers of public drinking water. [Rule Reference: 141.902 (b)(2)(i) – Page 18751, Column 3]

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document.

New Jersey Department of Environmental Protection (NJDEP) (Doc. #1699, SBC-045032)

NJDEP agrees with EPA's proposal to determine compliance at each EPTDS. NJDEP utilized this approach successfully in the implementation of New Jersey's MCLs for PFOA, PFOS and PFNA. Furthermore, NJDEP does not foresee issues implementing different compliance monitoring schedules at different EPTDS within the same system, as this is currently allowed under other existing rules.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document.

New Jersey Department of Environmental Protection (NJDEP) (Doc. #1699, SBC-045028)

Implementation

Monitoring and Compliance Requirements

EPA has proposed using the Standard Monitoring Framework (SMF) for Synthetic Organic Contaminants (SOCs) for PFAS. NJDEP recommends EPA develop a new monitoring

framework specifically for PFAS that utilizes a modified VOC framework that does not allow for reduction to triennial or use of monitoring waivers. The SOC framework as proposed allows for systems to be reduced to triennial monitoring after completion of their initial round of quarterly monitoring, includes a modification of the SOC SMF groundwater systems, and includes the option of monitoring waivers. Based on NJDEP's experience this framework may not be appropriate for PFAS.

For its MCLs, NJDEP had opted to utilize the VOC framework, which does not allow for immediate reduction to triennial but requires systems to collect three years of annual "non-detect" results to then be reduced to triennial. Based on NJDEP's experience, PWSs can detect PFAS, and in some cases exceed the New Jersey PFAS MCLs, following quarters of receiving non-detect or very low results. In New Jersey, 42 water systems have received MCL violations during the second or third year of data collection. Allowing a reduction first to annual monitoring as utilized in the VOC framework will provide a reduction for the systems but also give an added layer of protection to avert unintended PFAS exposure to impacted residents. While the reduction to triennial may be more economical to some systems, for most it will result in only one less sample event (two in one year every three years vs. one annually for three years).

Furthermore, NJDEP recommends that EPA consider removing the option to reduce systems to triennial monitoring. Based on NJDEP's experience, some water systems have detected PFAS, and in some cases have exceeded the New Jersey PFAS MCLs, following quarters of receiving non-detect results. Requiring water systems to continuously collect annual samples will provide assurance that public health protection is being met, particularly with the evolving nature of the science and analytical capabilities surrounding these contaminants. At the proposed levels, small variations in the dataset may result in an exceedance of the MCL and therefore, it is important to continue monitoring.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document. The EPA notes that the allowance of monitoring waivers were not included in the proposed rule nor are they allowable under the final rule. Please see also section 8.5 of the EPA response in this *Response to Comments* document.

State of Vermont Agency of Natural Resources and Department of Health (Doc. #1708, SBC-047696)

5) 3-year sampling if initial monitoring was non-detect?

Vermont has at least two rounds of PFAS sampling at all PCWS and NTNC water systems, meaning systems have established a PFAS sampling history. Vermont is supportive of a system being placed into 3-year monitoring if the initial or state accepted existing sampling results are non-detect as discussed below. Given the importance of PFAS regulation, EPA should establish a health protective and unique monitoring framework for PFAS.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document.

State of Vermont Agency of Natural Resources and Department of Health (Doc. #1708, SBC-045104)

2) Monitoring-related flexibilities to reduce burden while protecting public health.

As discussed previously in these comments, there needs to be another sampling frequency in between quarterly or every 3-years and therefore graduated "tiers" of attention. It will place a considerable burden on the system and state staff to adhere to the draft provisions. There has been no discussion of the added workload, in fact the preamble incorrectly assumes that the states can accommodate this workload without an increase in hours or staffing. Our experience implementing our regulation in 2019 required 3 staff full-time for a year to train, set up SDWIS, work with labs, review data and get the program implemented. In a small state with a limited staff, this meant the majority of the compliance-related staff otherwise tasked with other responsibilities.

As it is written in the draft regulation, the sampling framework is too specific. The sampling frequency states "at least 90 days apart" when samples are to be collected under initial monitoring. Systems will not understand this very specific requirement, as they are only accustomed to sampling on a quarterly frequency, meaning anytime in a 3-month window. This same "flexibility" must be applied, otherwise systems and states would need to manage down to the specific DAY that the samples are required for subsequent samples. It is not likely that this was EPA's intent, so that must be remedied. Perhaps state that the samples must be collected in each respective calendar quarter, no less than 30 days between samples, that allows freedom to sample within the calendar quarter and will prevent someone sampling on the last day of quarter 1 and the first day of quarter 2, if that sampling behavior was sought to be eliminated by the "at least 90 days apart". Alternatively, perhaps the information should instead state "at most 90 days apart" which would then fall into more conventional quarterly monitoring.

3) EPTDS on its own schedule

Each respective entry point to the distribution should have its own schedule, it should not be regulated system wide. In Vermont we have small systems and there still may be multiple entry points many miles apart from one another. It does not make sense from a source contamination or source protection approach to "lump" all of the entry points in with one another. In Vermont our data indicate that PFAS exposure is quite localized, so systems with multiple wells in the same basic vicinity of one another may have one well with PFAS and one without. To say that 8 miles away a different entry point needs to sample more frequently does not make sense and will place a considerable undue burden on the water system.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document. Please see section 8.1.1 of the EPA response in this *Response to*

Comments document for a discussion of initial monitoring requirements, including the revised requirements for the intervals between samples. Please see section 13.3 of the EPA response in this *Response to Comments* document related to estimating costs, including primacy agency costs, which are discussed in the section 13.3.1 summary.

State of Vermont Agency of Natural Resources and Department of Health (Doc. #1708, SBC-045093)

The proposed sampling framework as established is confusing and burdensome on both water system and state resources. The routine sampling framework needs a step between quarterly and 3-year sampling, Vermont would support an annual sampling requirement for those systems with triggers/detections but below 4 ppt. In a situation where a system under 3,300 in population has consistent results of around 3.0 ppt for PFOA (a level to down to which Vermont receives data and have received data for nearly 4 years), the system would exceed the trigger of 1.3 ppt and be placed on quarterly monitoring. Then, after 4 quarters, the RAA would be 0 based on the calculation of (0 + 0 + 0 + 0)/4 = 0 since the results are below the PQL. So, the system could then transition to 3-year monitoring. There is no guidance or statement about how soon after the last quarterly sample was taken the next 3-year sample must be collected (for example, the Lead and Copper Rule sets the timeline by which the next sample must be collected when the sampling frequency changes). So, because of this, the logical thing to do would be to put the system on 3-year monitoring either immediately or sampling the next calendar year from the last quarterly sample. Alternatively, it could be a year from the last sample, but change would be made knowing what would happen next: the system will then have a result around 3.0 ppt and would be bumped back to quarterly monitoring for at least 4 quarters at which point this cycle would continue. We have approximately 30 systems that would be "stuck" in the unending loop, creating frustration, irregular sampling frequencies, and considerable manual oversight by the state. It would lead to non-compliance and missed samples. For watching results under 4, we would suggest doing so via annual monitoring to avoid confusion of the quarterly-to-3-year monitoring and/or longer timelines between samples when on 3-year monitoring.

b. Separation of Monitoring Schedules:

The water quality data in Vermont does not support the breaking out of separate monitoring schedules between surface water and groundwater or system size. There is no justification provided in the preamble as to why systems over 3,300 and surface water systems are treated the way they are with respect to PFAS vulnerability. The desire to slot PFAS into an existing framework makes sense on its face, but not in reality/practice. It would be perfectly understandable to create a PFAS-specific sampling framework outside of that of SOCs. PFAS are regulated to lower standards and have different responses than traditional SOCs, why would they be sampled under the same framework? Additionally, SOCs are easier to identify the source and have a solid regulatory framework and history under TSCA. This difference has not been taken into account and the clear differences between SOCs and PFAS are not considered. Under EPA method 537.1 - in Vermont, out of the approximately 615 systems having collected

samples, we have had detections of any of the 18 compounds reported at 107 systems. Six of those systems are surface water sources, the rest are groundwater. And of those six surface water systems, we have a total of 8 detections, with only one for PFOA and two for PFBS (the rest are for non-regulated compounds).

c. Water System Size and PFAS detections:

There also does not appear to be correlation between water system size and PFAS prevalence, in fact quite the opposite, where small schools and locations may have impacts from on-site septic or land use outside of the area of control, where many larger systems have better land use and source protection area regulations surrounding their sources.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document. The EPA agrees that PFAS should not only follow the SMF for SOCs as this provides a consistent sampling approach, but also incorporate some PFAS-specific modifications as discussed in sections 8.1.1 and 8.1.2 of the EPA response in this *Response to Comments* document. With respect to the start date for the next sampling period when a system reduces its monitoring frequency, the EPA agrees this merits clarification and has specified in § 141.902(b)(2)(viii) that the next compliance sample must be collected in the monitoring period that begins the calendar year following state approval of a reduction in monitoring frequency. Regarding initial monitoring requirements and the differences in systems served by different source water types, please see section 8.1.1 of the EPA response in this *Response to Comments* document. For the determination of reduced monitoring and rule trigger levels, please see section 8.8 of the EPA response in this *Response to Comments* document. The EPA clarifies that monitoring frequency determinations are not based on an RAA and sample results below the PQLs are considered. Hence, water systems should not be "stuck in an unending loop" as suggested by the commenter.

Massachusetts Department of Environmental Protection (MassDEP) (Doc. #1726, SBC-045156)

The requirement in § 141.902(b)(1)(iv) to collect quarterly samples "at least ninety days apart" introduces an unnecessary complexity. If the intent is to space consecutive samples apart this can be done in several ways such as reducing this period to at least 30 or 60 days or by requiring all samples be collected in the middle month of the quarter. These options allow for flexibility within the quarter without potentially causing a monitoring violation if, for example, samples were collected a reasonable 80 days apart in separate quarters.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document. Regarding initial monitoring requirements, including the revised requirements related to the intervals between samples, please see section 8.1.1 of the EPA response in this *Response to Comments* document.

Massachusetts Department of Environmental Protection (MassDEP) (Doc. #1726, SBC-045167)

MassDEP recommends that EPA allows water systems to have different monitoring schedules for different entry points.

MassDEP recommends that EPA does not require that all entry points be monitored on the same monitoring frequency. This allows systems to reduce analytical costs. This would align with the current approach for chemical monitoring, especially at systems that have several sources.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-045964)

Section 5: Monitoring and Compliance Requirements

Section 5.1: Monitoring

EPA has requested comments on several pieces related to monitoring requirements. The agency has proposed a monitoring regime based on the Standard Monitoring Framework (SMF) for Synthetic Organic Contaminants (SOC). AMWA has been and still is supportive of using this framework to ensure uniformity among rules covering similar compounds (Attachment 5). AMWA also strongly supports maximum flexibilities in monitoring that will reduce burdens on PWSs and still be protective of public health, as EPA has done with other chemicals with chronic health risks.

AMWA is pleased EPA has considered situations in which reduced monitoring is appropriate. However, the agency is proposing a trigger level well below the Practical Quantification Level (PQL) for PFOA and PFOS. Under this proposal, a PWS qualifies for reduce monitoring if its RAA is below the trigger level of 1.3 ppt for PFOA and PFOS and a 0.33 HI for the additional PFAS. This allows water systems to sample once or twice in a three-year period, depending on system size. Because the health effects of PFAS are chronic, AMWA recommends EPA make this reduced monitoring uniform and require all systems, regardless of size, to sample once in the three-year period under this reduced monitoring framework. This would allow for further reduction in burdens on utilities while also not compromising public health.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document. Please see section 8.8 of the EPA response in this *Response to Comments* document regarding rule trigger levels.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-045967)

Section 5.2: Individual entry point compliance monitoring

EPA seeks comment on allowing water systems to potentially have entry points to the distribution system (EPTDS) on different monitoring schedules. This would allow a system with

multiple entry points to potentially be required to monitor quarterly at one entry point and qualify for reduced monitoring at another. AMWA agrees with this decision and believes that this reduction in sampling will save valuable resources for PWSs with more than one entry point that may have different RAAs for the proposed PFAS. It is important to note that it is also not mandatory that a water system participates in reduced monitoring if it qualifies, so a system does have the option to keep all its EPTDS on the same sampling schedule.

If EPA were to mandate a uniform monitoring schedule for all EPTDS, it would result in significantly more samples that utilities must collect, analyze, and report. However, this uniformity would not enhance public health protection if a particular entry point qualifies for reduced monitoring. The potential consequences of such a requirement, including increased costs and strain on laboratory capacity, lend substantial support to EPA's proposition of allowing different monitoring schedules based on individual EPTDS circumstances.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document.

Washington County Department of Public Health and Environment (Doc. #1739, SBC-043572)

Frequency of Reduced Monitoring

Per Part XIV, Section IX of the rule proposal: "EPA requests comment on if all water systems, regardless of system size, be allowed to collect and analyze one sample per three-year compliance period if the system does not detect regulated PFAS in their system at or above the rule trigger level."

Comments:

The county, in line with MDH, supports allowing one sample per 3-year compliance period for all systems on reduced monitoring rather than requiring 2 samples per 3-year period for systems with >3,300 population. - Transient detections and significant seasonal variability are not typically observed with PFAS contamination based on our state's experience with past monitoring since PFAS is stable in the environment. Therefore, one sample is sufficient to determine if contamination is present.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document.

LSP Association (LSPA) (Doc. #1742, SBC-043601)

There is a significant difference between sampling every quarter and sampling once or twice every three years. The LSPA recommends that USEPA consider a more tiered approach to monitoring.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document.

Connecticut Department of Public Health (CT DPH) (Doc. #1745, SBC-045224)

3. EPA is requesting comment on the allowance of a water system to potentially have each Entry Point to the Distribution System (EPTDS) on a different compliance monitoring schedule based on specific entry point sampling results.

CT DPH agrees with attempting to lower the sampling burden for low-risk PWS, and having EPTDS on different monitoring schedule is one possible way to do so. If a system cannot handle the administrative task of tracking compliance, the PWS could choose to increase sampling of all points to be on the same schedule.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document.

West Virginia Rivers Coalition et al. (Doc. #1746, SBC-045251)

Strengthen the reduced monitoring requirements to enhance public health protections.

We recommend EPA strengthen the compliance monitoring requirements in the proposed rule by limiting the reduced monitoring frequency to once every year for all PWSs. As proposed, PWSs eligible for reduced monitoring would conduct compliance monitoring only 1-2 times per three-year compliance period. Systems that serve 3,300 or fewer customers would only be required to analyze one sample for all regulated PFAS every three years. Due to the ubiquity, environmental persistence, and transport abilities of PFAS, infrequent monitoring may mask dangerous PFAS concentrations in drinking water and potential violations of MCLs. For example, in West Virginia, there are 325 small community water systems. Under the proposed rule, the 361,883 customers served by these water systems could potentially consume drinking water that may exceed of one of more PFAS MCLs for years before detected and treatment required. We urge EPA to modify its proposal such that all PWSs eligible for reduced monitoring be required to monitor annually. This would help ensure compliance with the proposed MCLs and maximize the potential health benefits of the rule.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document.

Las Cruces Utilities (LCU) (Doc. #1753, SBC-043908)

In response to Section IX-Monitoring and Compliance Requirements, EPA requests comment on the proposed allowance of a water system to potentially have each [entry point to the distribution system] EPTDS on a different compliance monitoring schedule based on specific entry point sampling results (i.e., some EPTDS being sampled quarterly and other EPTDS sampled only once or twice during each three- year compliance period), or if compliance monitoring frequency should be consistent across all of the system's sampling points.

• Different compliance schedules would be preferred over defaulting to the stricter frequency across the entire PWS.

Consider if all 36 LCU wells are categorized as individual EPTDSs. PFAS samples at Hall can cost up to $500 each depending on the list of analytes requested. If LCU needs to sample all the wells quarterly due to one well exceeding the rule trigger level, the additional PFAS sample costs to LCU could be up to $72,000 each year. Other labor costs are incurred for collecting the samples, for review of results, and reporting. Allowing for different compliance schedules will allow for necessary sampling at areas that have exceedance without inducing excessive costs.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document.

Las Cruces Utilities (LCU) (Doc. #1753, SBC-043910)

In response to Section IX-Monitoring and Compliance Requirements, EPA requests comment on if all water systems, regardless of system size, be allowed to collect and analyze one sample per three-year compliance period if the system does not detect regulated PFAS in their system at or above the rule trigger level.

• One sample per EPTDS per three-year compliance period is preferred, regardless of system size.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-045565)

5. The use of the Standard Monitoring Framework (SMF) for PFAS is appropriate where a running annual average (RAA) below one-half of the MCL is considered to be reliably below the MCL. However, the agency's proposed approach to require reporting results below the practical quantification level (PQL) to calculate the RAA for reduced monitoring is inappropriate and will cause equity issues with respect to access to high quality laboratories. This will lead systems with less financial capacity to have more stringent monitoring requirements. EPA should move forward with the SMF, where all results below the PQL are considered 0 ppt.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document. Additionally, regarding rule trigger levels for reduced triennial monitoring, please see section 8.8 of the EPA response in this *Response to Comments* document. Please see section 5.1.2 of the EPA response in this *Response to Comments* document for a discussion of laboratory capability and capacity.

California State Water Resources Control Board (Doc. #1760, SBC-044224)

[The State Water Board offers the following specific comments and recommendations for consideration regarding implementation of the rule:]

Recommend using the standard monitoring framework of quarterly monitoring utilized for synthetic organic chemicals rather than a specific 90-days between monitoring. Allowing public water systems flexibility to monitor within a quarter rather than a very specific schedule will ease implementation costs for water systems and yield data that is just as accurate. This will also allow for water systems to schedule with labs and help address lab capacity issues.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document. Regarding initial monitoring requirements, including the revised requirements for the intervals required between samples, please see section 8.1.1 of the EPA response in this *Response to Comments* document. For laboratory availability, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

Western Urban Water Coalition (WUWC) (Doc. #1768, SBC-043954)

D. Monitoring Schedule Flexibility is Appropriate

WUWC also supports allowing water systems the flexibility to place entry points to the distribution system on divergent compliance monitoring schedules based on specific entry point sampling results rather than mandating that compliance monitoring frequency proceed on the same schedule for all sampling points. [FN44: Id.] In WUWC members' experience, individual monitoring schedules are preferable to large urban water utilities from a cost and administrability perspective. Large water utilities are likely to have to monitor compliance at several points of compliance at once. Forcing uniform monitoring schedules would deprive WUWC members of the ability to adjust to site-specific considerations and result in redundant labor expense compared to a more adjustable schedule. WUWC reiterates its general comment that partially mitigating administrative burdens resulting from the Proposed Rule is insufficient to demonstrate economic feasibility.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document.

Environmental Protection Network (EPN) (Doc. #1773, SBC-043868)

Monitoring Requirements

EPN agrees that the PFAS monitoring scheme should be based on the existing standard monitoring framework established for Synthetic Organic Compounds and other chemical regulations, which tailors the monitoring frequency to previous monitoring results. This reduces monitoring cost if the likely result is already known. The danger is that PWS may not monitor because they believe incorrectly that their monitoring has been waived. It is critical that the

primacy state communicates the required monitoring frequency to each PWS large and small and reports a monitoring/reporting violation to EPA and the public. If states fail to do this, there is a high likelihood of severe underreporting of monitoring violations.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document. The EPA agrees that compliance monitoring frequency should be based on prior sampling results. Additionally, the EPA agrees that primacy agency and PWS communication on required monitoring frequency is critical to ensuring effective implementation and defers to the primacy agency to address this communication. The EPA clarifies for the commenter that the final rule includes monitoring and reporting violations per 141.905(c).

San Diego County Water Authority, CA (Doc. #1779, SBC-045291)

Entry Point to the Distribution System

The Water Authority supports EPA's allowance for water system to have different compliance monitoring schedules for entry points to the distribution system based on entry point sampling results. This approach is reasonable and would potentially provide resource savings for water systems without impacting public health.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document.

San Diego County Water Authority, CA (Doc. #1779, SBC-045289)

We request EPA also allow for reduced monitoring based on four quarters of sampling when results are lower than the detection limits.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document. The EPA has adopted the use of trigger levels in this NPDWR. These are analogous to the "detection limits" that determine a system's monitoring frequency for some other regulated SOCs.

City of Tulsa Water and Sewer Department (CoT WSD) (Doc. #1785, SBC-043782)

4. 88 FR 18682 (also 88 FR 18730). EPA requests comment on water systems potentially having each EPTDS on different monitoring schedules based on specific entry point sampling results, or if compliance monitoring should be consistent across all the system's sampling points.

CoT WSD responds that it is our opinion that compliance monitoring should be consistent across all the system's sampling points. This will avoid the possibility that the system could actually have all sampling points on quarterly monitoring (past the initial monitoring timeframe) at different times within the year. This would cause confusion and continual sampling, pulling system field resources away from other required duties and monitoring for other NPDWR. In addition, proposed rule language at §141.903(a) (88 FR 18752) states, "If one sampling point is

in violation of an MCL, the system is in violation of the MCL (emphasis added)." All EPTDS sampling points represent the system, and one sampling point in violation of MCL causes the system to be in violation; therefore, monitoring frequency should apply to the system as a whole, which would include all sampling points on one monitoring schedule.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document.

Earthjustice et al. (Doc. #1808, SBC-046119)

The SDWA requires NPDWRs to include monitoring requirements that will "[e]nsure compliance" with the relevant MCLs. [FN201: 42 U.S.C. § 300f(1)(D).] EPA's proposal does not satisfy this requirement insofar as it gives primacy agencies discretion to reduce required compliance monitoring to just 1–2 monitoring events per three-year compliance period if a system's initial year of monitoring documents PFAS concentrations below the proposed trigger level. [FN202: See Proposed Rule, 88 Fed. Reg. at 18,681; Economic Analysis at 5-32.] Indeed, EPA's proposal does not attempt to demonstrate that this reduced monitoring scheme would be adequate to "insure" compliance with the MCLs, [FN203: 42 U.S.C. § 300f(1)(D).] claiming instead that its proposal would "save resources" for purportedly "lower-risk water systems." [FN204: Proposed Rule, 88 Fed. Reg. at 18,682.] As explained below, existing PFAS monitoring data, as well as literature on PFAS toxicity and fluctuations in drinking water sources, indicate that EPA's proposal must be strengthened to ensure compliance with the MCLs.

Available data from PWSs that have tested for PFAS on a quarterly or more frequent basis demonstrate significant variation in PFAS detections and measured concentrations, which indicates that consistent monitoring is needed to ensure that PFAS levels remain below the MCLs. [FN205: See, e.g., Merrimack Vill. Dist. Water Works, Historical Charts for PFAS Water Sampling Test Resultwww.mvdwater.org/historical-water-sampling-charts/, and PFAS Results, Distribution Syswww.mvdwater.org/wp-content/uploads/2023/03/PFAS-Distribution- System-02-15-2023.pdf (distribution system notes); City of Ann Arbor, Mich., Drinking Water Sampling Datwww.a2gov.org/departments/water-treatment/Documents/PFAS-forweb- RESERVIOR-031523.pdf (updated Mar. 15, 2023); Orange Water and Sewer Auth., Trends in PFAS Detections in Finished Drinking Water (Quarterly Sample Results), Detections in Drinking Watewww.owasa.org/pfas-monitoring-program/ (scroll down to the "Complete Set of Historical PFAS Monitoring Data" and select "Raw Data." Review table on upper left corner titled "Finished Drinking Water").] For example, the Merrimack Village Water District reported non-detect results for PFOS at the Turkey Hill Road location within its drinking water distribution system during four sampling events between December 2, 2021, and July 27, 2022, then detected 15.20 ppt of PFOS during a subsequent sampling event on October 19, 2022, followed by another non-detect result on January 25, 2023. [FN206: Merrimack Vill. Water Dist. Water Works, PFAS Results, Distribution Sys., at 8.] Monitoring data from industrial PFAS dischargers likewise demonstrates the potential for significant intra-annual variation in PFAS discharges to drinking water sources, which will in turn impact the levels of PFAS in finished drinking water

from systems that have not installed PFAS treatment technology. [FN207: See, e.g., Colo. Dep't of Public Health & Env't, Suncor Water Quality Permits, Surface Water Suncor PFAS Data (Outfall 20phe.colorado.gov/suncor-water-quality-permits (updated Apr. 2023) (scroll down to the section titled "Resources and Pollution Data" and select "Toxic firefighting foam chemicals (PFAS)" from the drop drown menu. Select and view "Surface water Suncor PFAS data (Outfall 20)").] Peer-reviewed literature also documents significant intra-annual variation in PFAS concentrations in both source water and finished drinking water due to factors including variable flow rates, variation in industrial processes/production cycles, variable stormwater runoff from contaminated sites, mobilization of legacy PFAS contamination in sediment or groundwater, and the potential introduction of new sources of PFAS contamination. [FN208: See Minh A. Nguyen et al. Seasonal Trends of Per- and Polyfluouroalkyl Substances in River Water Affected by Fire Training Sites and Wastewater Treatment Plants, 308 Chemosphere Art. No. 136467 (2022doi.org/10.1016/j.chemosphere.2022.136467; M.-A. Pétré et al., Per- and Polyfluoroalkyl Substances (PFAS) in River Discharge: Modeling Loads Upstream and Downstream of a PFAS Manufacturing Plant in the Cape Fear Watershed, North Carolina, 831 Sci. of the Total Env't Art. No. 154763 (2022doi.org/10.1016/j.scitotenv.2022.154763.] Taken together, this evidence indicates that allowing compliance monitoring as infrequently as 1–2 times per three-year compliance period may mask dangerous PFAS concentrations in monitored drinking water and potential violations of the MCLs.

Further, as EPA acknowledges, PFAS subject to the proposed NPDWRs can pose health risks at concentrations substantially lower than the proposed trigger values. Indeed, in the Proposed Rule EPA acknowledges that PFOA and PFOS can cause adverse health effects at "near zero" levels. [FN209: Proposed Rule, 88 Fed. Reg. at 18,715.] While EPA has previously justified significant monitoring reductions on the grounds that "analytical results . . . below the MCL" for the contaminants at issue "do not pose a health threat," [FN210: 56 Fed. Reg. at 3,526, 3,562.] that logic is demonstrably inapposite for PFAS. Under EPA's proposal, exceedances of one or more PFAS MCL(s) could persist for years before they are detected and treatment is required, posing significant health risks for people served by the affected water system. And in situations where a water system has detectable PFAS concentrations below the proposed trigger values, EPA's proposal would deprive the public of information relevant to assessing health risks from consuming that PFAS-contaminated drinking water. [FN211: See 42 U.S.C. 300j-4(g)(6) (providing for inclusion in public database of "information on the detection of [regulated] contaminant[s] at a quantifiable level in public water systems (including detection of the contaminant at levels not constituting a violation of the maximum contaminant level for the contaminant).").]

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document. Based on the totality of available occurrence data (see sections III.C and VI of the final rule preamble) and additional related public comments, the EPA determined the compliance frequencies are appropriate to enable sufficiently accurate detection of and response to regulated PFAS contamination in drinking water sources. Moreover, these frequencies are adequate as the regulated PFAS are associated with chronic human health effects. Regarding the

comment that "exceedances of one or more PFAS MCLs could persist for years before they are detected and treatment is required," the agency disagrees. Under the final rule water systems demonstrate their initial PFAS baseline levels over a consistent number of samples and then will be required to monitor at a frequency corresponding to those levels. Therefore, using these analytical results as the basis for potential PFAS contamination risk is a highly informative measure of how frequently a water system should be required to sample in order to demonstrate compliance with the MCLs, and if there are future changes in measured concentrations the water system will be required to change their sampling frequency as applicable. In water systems where there may be suspected new sources of PFAS contamination, the final rule also allows for primacy agencies to require more frequent monitoring. Additionally, please see sections 9.1 and 9.2 of the EPA response in this *Response to Comments* document, which discuss notification requirements to consumers under the CCR Rule and the Public Notification (PN) Rule. A CWS is required to include information on detected contaminants in its CCR, and a PWS must provide public notice when there is a violation or situation that has the potential to have adverse health effects. For further discussion of the MCLs, please see section V of the preamble to the final rule and section 5 of the *Response to Comments* document.

Earthjustice et al. (Doc. #1808, SBC-046117)

C. EPA Should Strengthen the Proposed Monitoring Requirements to Comply with the SDWA and Enhance Public Health Protections

We urge EPA to strengthen the compliance monitoring requirements in the proposed rule by (1) relying on the MDL as the "trigger level" that can qualify a PWS for reduced monitoring where that value is lower than one-third of the PQL, and (2) requiring PWSs with consistent detections below the MDL to monitor annually for the regulated PFAS instead of triennially.

EPA's proposed monitoring requirements are insufficient to ensure compliance with the proposed MCLs, would undermine the potential health benefits of the rule, and would deprive the public of vital information regarding exposures to PFAS in drinking water at levels that threaten human health.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document. Regarding rule trigger levels for reduced triennial monitoring, please see section 8.8 of the EPA response in this *Response to Comments* document. For discussions of CCR requirements and PN requirements, please see sections 9.1 and 9.2 of the EPA response in this *Response to Comments* document, respectively. The EPA-approved methods do not include Method Detection Limits (MDLs), but rather define and require the confirmation of Minimum Reporting Levels (MRLs) which are distinctly different from MDLs. For the PFAS NPDWR, the EPA did not define MRLs for PFAS contaminants, but established PQLs, as discussed in sections V and VII of the final rule preamble, to evaluate analytical feasibility for the determination of MCLs.

Corix Infrastructure Inc. (Doc. #1834, SBC-045370)

[With regards to the specific items EPA has requested comment on, Corix provides below:]

• We support EPA's approach to allowing the collection of one sample per three-year compliance period if the system does not detect regulated PFAS in their system at or above the rule trigger level.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document.

Little Hocking Water Association (Doc. #1835, SBC-045516)

Quarterly testing frequency is not enough for all systems and decisions on less frequent monitoring needs to be made with knowledge of PFAS levels in pretreated water.

The proposed rule does not require any testing of pretreated water. LHWA understands that EPA is only concerned with finished water that goes to customers. LHWA strongly disagrees that this should be the only concern. It defies common sense that a regulator and the regulated water systems would respond to the PFAS crisis with only the knowledge of levels of contamination in finished water. If a water system does not know what levels of contamination are in its source water, then it cannot possibly react and solve the problem. Likewise, EPA cannot possibly develop and implement regulations protective of public health without knowing to what extent source waters need to be cleaned up.

The proposed rule requires monitoring frequencies and provides for relaxed monitoring frequencies that are not protective of health because the level of contamination in the pretreated water is not taken into account. For water supplies that are known to be highly contaminated with PFAS or are at a high risk of contamination, quarterly sampling is not enough. LHWA recommends initial sampling every 60 days.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document. Regarding initial monitoring requirements, please see section 8.1.1 of the EPA response in this *Response to Comments* document. The NPDWR regulates PFAS levels in finished drinking water only as that is what is served to users of PWSs; this rule does not establish requirements applicable to drinking water sources. Treatment technologies installed between the source water and the finished water can reduce levels of PFAS and other contaminants to below levels of health concern in finished water. The EPA notes that the IIJA, also known as the BIL, has provided significant funding ($10 billion in total) available to PWSs through the State Revolving Fund (SRF) and grant programs to reduce people's exposure to PFAS and other emerging contaminants through their drinking water, to help address discharges through wastewater, and to support source water protection efforts.

Citizens Energy Group (Doc. #1838, SBC-044862)

EPA requests comment on the proposed allowance of a water system to potentially have each EPTDS on a different compliance monitoring schedule based on specific entry point sampling results (i.e., some EPTDS being sampled quarterly and other EPTDS sampled only once or twice during each three-year compliance period), or if compliance monitoring frequency should be consistent across all of the system's sampling points.

Citizens believes that it is appropriate for a water system to have each EPTDS on a different compliance monitoring schedule based on the sampling results. Citizens, for example, has multiple sources of supply to its system, including three reservoirs and multiple wellfields around the community. Each of these sources of supply has a unique 'fingerprint' when it comes to the raw water. Morse Reservoir, for example, is located in a primarily rural area, influenced by agriculture. Geist Reservoir is located in a highly urbanized area of the community, with active recreational uses in addition to agriculture in the headwaters of Fall Creek. Citizens' groundwater source of supply includes wellfields located in historically agricultural areas.

This difference in source of supply for each of the treatment plants should be recognized in sampling obligations imposed at the EPTDS. Water systems are responsible for implementing the standard monitoring framework for the suite of constituents regulated under the Safe Drinking Water Act, with monitoring obligations ranging from monthly to once every 10 years. Incorporating different schedules for PFAS-related monitoring obligations at the EPTDS can be managed by water systems.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document.

Citizens Energy Group (Doc. #1838, SBC-044867)

Additionally, given the very low concentrations of PFAS that many water systems see in their analytical results, water systems should have the opportunity for confirmatory sampling if water samples at the EPTDS have detections for PFAS compounds that have not been previously detected in samples or if there are significant (unexpected based on historical data) changes in concentrations of PFAS before taking action that may alarm the general public.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document. States may require systems to take confirmation compliance samples, but other samples collected voluntarily by a system (e.g., after an unusual detection) are not factored into calculations of the average for a quarter, year, or three-year period. With respect to the concern that a single high result might not be representative, the use of an RAA to determine MCL compliance (and PN related to MCL compliance), as discussed in section 8.2 of the EPA response in this *Response to Comments* document, does allow water systems to average samples collected over the course of four quarters accounting for potential fluctuations. Water systems must report detections from the previous year in their CCRs. Please see section 9 of the EPA

response in this *Response to Comments* document for a discussion of PN requirements; CCR requirements are addressed in section 9.1 and public notice requirements are discussed in section 9.2 of the EPA response in this *Response to Comments* document.

City of Fort Collins (Doc. #2320, SBC-046521)

I have a couple of questions about the relationship between the trigger level and reduced monitoring frequency in the proposed PFAS regulation, published on March 29, 2023.

The Hazard Index is only applicable to four (PFNA, PFHxS, PFBS, and HFPO-DA) of the six PFAS in this regulation, yes?

We have only one Entry Point to the Distribution System (EPTDS). If our initial quarterly EPTDS monitoring results exceed the trigger level for one PFAS but not for the other 5, is the system still eligible for reduced monitoring for the 5 parameters and then required to perform quarterly monitoring for the one PFAS? For example, if our initial running annual average for PFOS monitoring is 1.4 and the other 5 PFAS are less than the trigger level, can we analyze for the 5 PFAS twice every three years, but analyze for PFOS quarterly?

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document. As it notes, the required monitoring frequency applies to all regulated PFAS. Regarding rule trigger levels, please see section 8.8 of the EPA response in this *Response to Comments* document. The commenter is correct that the Hazard Index only applies to four of the regulated PFAS (PFNA, PFHxS, PFBS, and HFPO-DA).

Richard Gelderman (Doc. #2820, SBC-047470)

4) The EPA should require quarterly monitoring of PFAS for all water systems. After a year of undetectable levels for the six PFAS, systems should reduce to annual monitoring, as opposed to monitoring just once or twice every three years.

I strongly support the EPA's proposed PFAS national primary drinking water regulations. I urge the EPA to finalize the standards as quickly as possible while simultaneously working to reduce PFAS pollution at the source.

Respectfully,

Richard Gelderman

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document. Regarding initial monitoring requirements, please see section 8.1.1 of the EPA response in this *Response to Comments* document.

Nancy Bouldin (Doc. #2822, SBC-047333)

3. The EPA should require quarterly monitoring of PFAS for all water systems. After a year of undetectable levels for the six PFAS, systems should reduce to annual monitoring, as opposed to monitoring just once or twice every three years.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document. Regarding initial monitoring requirements, please see section 8.1.1 of the EPA response in this *Response to Comments* document.

Melda Clark (Doc. #2823, SBC-047335)

3. The EPA should require quarterly monitoring of PFAS for all water systems. After a year of undetectable levels for the six PFAS, systems should reduce to annual monitoring, as opposed to monitoring just once or twice every three years.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document. Regarding initial monitoring requirements, please see section 8.1.1 of the EPA response in this *Response to Comments* document.

Karen Valentine (Doc. #2834, SBC-047337)

3. The EPA should require quarterly monitoring of PFAS for all water systems. After a year of undetectable levels for the six PFAS, systems should reduce to annual monitoring, as opposed to monitoring just once or twice every three years.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document. Regarding initial monitoring requirements, please see section 8.1.1 of the EPA response in this *Response to Comments* document.

Monty Fowler (Doc. #2836, SBC-047339)

3. The EPA should require quarterly monitoring of PFAS for all water systems. After a year of undetectable levels for the six PFAS, systems should reduce to annual monitoring, as opposed to monitoring just once or twice every three years.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document. Regarding initial monitoring requirements, please see section 8.1.1 of the EPA response in this *Response to Comments* document.

Steven Cole (Doc. #2837, SBC-047340)

2. The EPA should require quarterly monitoring of PFAS for all water systems. After a year of undetectable levels for the six PFAS, systems should reduce to annual monitoring, as opposed to monitoring just once or twice every three years.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document. Regarding initial monitoring requirements, please see section 8.1.1 of the EPA response in this *Response to Comments* document.

John Doyle (Doc. #2840, SBC-047342)

3. The EPA should require quarterly monitoring of PFAS for all water systems. After a year of undetectable levels for the six PFAS, systems should reduce to annual monitoring, as opposed to monitoring just once or twice every three years.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document. Regarding initial monitoring requirements, please see section 8.1.1 of the EPA response in this *Response to Comments* document.

Laurine Yates (Doc. #2900, SBC-047344)

3. The EPA should require quarterly monitoring of PFAS for all water systems. After a year of undetectable levels for the six PFAS, systems should reduce to annual monitoring, as opposed to monitoring just once or twice every three years.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document. Regarding initial monitoring requirements, please see section 8.1.1 of the EPA response in this *Response to Comments* document.

Mass comment campaign submitted by Jill Fischer (Doc. #3070, SBC-047346)

3. The EPA should require quarterly monitoring of PFAS for all water systems. After a year of undetectable levels for the six PFAS, systems should reduce to annual monitoring, as opposed to monitoring just once or twice every three years.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document. Regarding initial monitoring requirements, please see section 8.1.1 of the EPA response in this *Response to Comments* document.

Student, Vanderbilt University (Doc. #3072-72, SBC-047398)

Good afternoon. My name is Siyuan. Thank you so much for this opportunity, and I'm a PhD student in environmental engineering at Vanderbilt University right now. Five years ago, when I was in North Carolina where the GenX issue happened, PFAS caught my attention, and right now it turns to be my research topic and I'm trying my best to contribute to this field. Even though studies showing the hazardous and the ubiquity of PFAS, it makes no sense to turn a blind eye on this issue. That's why this proposal from EPA is super essential. Well, based on my own research experience, I understand the technical difficulties of PFAS detection and separation, but this should not block the pace to protect public health from PFAS pollution.

Therefore, I will suggest a step-by-step action. The first is monitoring, a monthly or quarterly monitoring report should be conducted since people feel uneasy and anxious about the unknown PFAS pollution levels.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document. Regarding initial monitoring requirements, please see section 8.1.1 of the EPA response in this *Response to Comments* document. Water systems must report detections from the previous year in their CCRs. Please see section 9 of the EPA response in this *Response to Comments* document for a discussion of PN requirements; CCR requirements are addressed in section 9.1 of the EPA response in this *Response to Comments* document and public notice requirements are discussed in section 9.2 of the EPA response in this *Response to Comments* document.

Anonymous (Doc. #1506, SBC-042576)

We also recommend that more strict testing and regulation measures are adopted in order to prevent high concentrations of PFAS from affecting residents. This means testing drinking water every 6 months to ensure acceptable levels of PFAS.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document.

Minnesota Department of Health (MDH) (Doc. #1610, SBC-042857)

Frequency of Reduced Monitoring

Per Part XIV, Section IX of the rule proposal:

"EPA requests comment on if all water systems, regardless of system size, be allowed to collect and analyze one sample per three-year compliance period if the system does not detect regulated PFAS in their system at or above the rule trigger level."

MDH Comments:

· MDH supports allowing one sample per 3-year compliance period for all systems on reduced monitoring rather than requiring 2 samples per 3-year period for systems with >3,300 population.

· Transient detections and significant seasonal variability are not typically observed with PFAS contamination based on our state's experience with past monitoring since PFAS is stable in the environment. Therefore, one sample is sufficient to determine if contamination is present.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document.

Aqua America, an Essential Utilities Company (Doc. #1623, SBC-043086)

Use of Standard Monitoring Framework

The proposed approach to use the Standard Monitoring Framework (SMF) is appropriate.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document.

Village of Woodbury (Doc. #1629, SBC-042953)

7. The EPA requested comments on allowing systems to monitor Entry-Point to Distribution Systems (EPTDS) at different schedules based on results received. This flexibility saves in costs for unnecessary sampling, which in our view is agreeable. Nonetheless, for systems to maintain compliance the required schedules should be clearly communicated with operators annually.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document. The EPA agrees that primacy agency and PWS communication on required monitoring frequency is critical to ensuring effective implementation. The EPA defers to the primacy agency to address this communication.

New York State Department of Health (NYS DOH) (Doc. #1677, SBC-044960)

23. The Department supports allowing systems with multiple entry points to the distribution system (EPDS) to have different monitoring schedules for each EPDS.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document.

Citizens Energy Group (Doc. #1838, SBC-044863)

EPA requests comment on if all water systems, regardless of system size, be allowed to collect and analyze one sample per three-year compliance period if the system does not detect regulated PFAS in their system at or above the rule trigger level.

Citizens encourages EPA to incorporate monitoring flexibilities that can reduce the administrative burden into the final rule, including flexibilities that allow systems that do not detect regulated PFAS in their system to reduce their monitoring. Communities will face differing challenges with PFAS in the source of supply to their water systems, depending on the types of historical manufacturing and defense-related activities that occurred in the community's watershed. Those communities where PFAS is present at low levels (below the proposed trigger levels) given the ubiquitous nature of PFAS compounds in the environment should be given the flexibility to monitor less frequently. Allowing this flexibility reduces the overall burdens associated with implementation of the proposed rule without compromising public health.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document.

Great Lakes Water Authority (GLWA) (Doc. #1558, SBC-042552)

Proposed allowance of a water system to potentially have each EPTDS on a different compliance monitoring schedule based on specific entry point sampling results (i.e., some EPTDS being sampled quarterly and other EPTDS sampled only once or twice during each three-year compliance period), or if compliance monitoring frequency should be consistent across all of the system's sampling points.

Different compliance monitoring schedules based on EPTDS locations makes sense for systems like GLWA that consist of more than one treatment facility and/or source water. Different compliance monitoring frequencies should be allowed.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document.

Michigan Department of Environment, Great Lakes, and Energy (EGLE) Drinking Water and Environmental Health Division (DWEHD) (Doc. #1597, SBC-042986)

9. The proposed rule includes a required 90-day minimum interval for consecutive compliance samples. It is the opinion of EGLE DWEHD that this requirement presents a serious implementation issue. With quarters having between 90 and 92 days, a maximum of 2 days would be available for flexibility in quarterly sampling. Taking weekends and holidays into account, this represents a significant lack of flexibility and a likely source of schedule violations. Also note that, should a supply sample later in a quarter, they would be unable to mitigate this in the future as they would be forever required to sample at the end of each quarter to meet the 90-day requirement. EGLE DWEHD asks that EPA consider a timeframe that allows flexibility, while not permitting back-to-back sampling, such as a minimum of 30 days between sampling events.

EPA Response: In the proposed rule, there were two instances when samples were specified as needing to be collected "at least 90 days" apart. The proposed requirement, as it applied to compliance monitoring, was that any system serving at least 10,000 people that was following a triennial monitoring schedule would collect two samples every three years, at least 90 days apart. The requirements for triennial monitoring were changed in the final rule to require all systems to collect one sample every three years. Please see also section 8.1.2 of the EPA response in this *Response to Comments* document related to the compliance monitoring requirements. With respect to the proposed requirement to collect initial monitoring samples at least 90 days apart (for systems collecting quarterly initial monitoring samples), the final rule now specifies that such samples be collected within each quarter and two to four months apart. Please see also section 8.1.1 of the EPA response in this *Response to Comments* document.

New York State Department of Health (NYS DOH) (Doc. #1677, SBC-044941)

3. EPA solicited comment on establishing the proposed rule trigger level values of 1.3 ppt for PFOA and PFOS and 0.33 for the PFAS regulated by the Hazard Index (HI). Although the Department currently considers any detection above the method detection limit a "detect" and requires quarterly monitoring as a result, there is a mechanism for the water system to reduce monitoring to annually if they are reliably and consistently below the MCL of 10 ppt, The Department recommends that EPA consider allowing water systems with levels between the trigger level and MCL to be permitted to monitor annually if, after 4 quarters of monitoring, levels are consistently between the trigger level and the MCL.

EPA Response: Please see section 8.1.2 of the EPA response in this *Response to Comments* document.

Robert Hollander (Doc. #1516, SBC-042711)

3. 88 FR 18677, paragraph after Table 14, end of 1st sentence

Correct Table 15 to read Table 14.

4. 88 FR 18682, 1st column, paragraph after 2nd bulleted paragraph

This is confusing. If a system shows results that are below the trigger levels, would that not be reliably and consistently below the MCL? Perhaps this should read "...the primacy agency may allow a system to move to a reduced monitoring frequency when the primacy agency determines that the system is below the rule trigger level and/or reliably and consistently below the MCL".

EPA Response: Regarding the comment about the paragraph after Table 14 in the preamble, the EPA corrected the sentence in the preamble that previously compared Table 15 to itself. The comparison at the end of the sentence has been changed to refer to the preceding table. In the final rule, those tables are Tables 13 and 12. Regarding the commenter's #4 comment, the EPA agrees that trigger levels are inherently below the MCLs. Please see section 8.1.2 of the EPA response in this *Response to Comments* document for a discussion of compliance monitoring requirements. In the final rule, "the system is below the rule trigger level" is no longer a criterion that must be met for a determination of reliably and consistently below the MCL and was removed from part IX of the preamble, as well as the regulatory text.

8.2 PWS Compliance and Violations

Summary of Major Public Comments and EPA Responses

Consistent with existing rules for determining compliance with NPDWRs, the EPA proposed that compliance would be determined based on the analytical results obtained at each sampling point (i.e., each EPTDS). For systems monitoring quarterly, compliance with the proposed MCLs would be determined by calculating RAAs for each sampling point. The agency received multiple comments on how the compliance determination and violations were proposed to be

assessed. Many commenters supported the EPA's approach to assess violations, including that violations are only assessed through an RAA for systems conducting quarterly monitoring. Some commenters suggested that in a scenario where a particular high quarterly sample (e.g., result greater than four times the MCL) would cause the RAA to exceed an MCL, the system should not be deemed out of compliance until the end of the quarter (to allow utilities to conduct additional monitoring during that quarter and average the results from the multiple samples). The EPA agrees that the results from confirmatory compliance monitoring specified by the primacy agency should be accounted for (in calculating an average for that quarter) but notes that additional voluntary sampling by the PWS may not be used in calculating the quarterly average. The final rule requires that a compliance sample be taken during each quarter for those systems conducting quarterly monitoring. Further, as prescribed under 141.902(b)(2)(v), the state may require a confirmation sample for any sampling results and, if this sample is required, the result must be averaged with the initial sampling results and used for the compliance determination.

A few commenters suggested changing the time periods for determining compliance (for both systems conducting quarterly monitoring and those conducting triennial monitoring). These recommendations included assessing compliance based on the results from eight consecutive quarterly samples (rather than four). For those systems conducting triennial monitoring, some commenters proposed that the compliance determination be based on one triennial sample result. For systems determining compliance through an RAA calculation, the EPA believes four consecutive quarterly samples is an adequate representation of the regulated PFAS levels while also assessing compliance in a timely manner. For systems conducting triennial monitoring, if a water system has a sample result at or above the EPA's trigger levels, the system will immediately be required to begin quarterly monitoring. This is consistent with monitoring requirements for other SOCs and, given the change in measured concentration, will provide additional information over a consistent and longer period of time to better assess the average level of regulated PFAS within the water supply and ensure the water system is reliably and consistently below the MCL.

In the proposal, when calculating the RAAs to determine compliance, if a sample result is less than the PQL for the monitored PFAS, the EPA proposed to use zero for that result. The EPA requested comment on whether the agency should consider an alternative to the approach of using zero when calculating the RAAs. Specifically, in the case where a regulated PFAS is detected but the result is below its proposed PQL, the proposed rule invited comment on whether the trigger level (proposed as one third of the PQL) should be used as the value in calculating the RAA for compliance purposes.

The EPA received numerous comments related to the proposed approach for calculating the RAA for compliance with the NPDWRs, particularly on the incorporation of sample results below the PQLs for the regulated PFAS (see sections V and VII of the preamble to the final rule for more information on PQLs.) Many commenters, including some states, supported the EPA's proposed approach to utilize zero for results below PQL to calculate the RAA and determine compliance. These commenters cited the definition of the PQL as "the lowest concentration of an

analyte that can be reliably measured within specified limits of precision and accuracy during routine laboratory conditions" and noted that this is a level that all laboratories should be able to achieve. Consequently, they suggested that values below these PQLs should not be used for the RAA compliance calculation. Several of these commenters expressed concern that using estimated or other values with less precision in the compliance calculation could result in utilities needing to take actions to address levels of regulated PFAS that are not well-quantified and may not be representative of regulated PFAS levels. Many commenters suggested that since some laboratories cannot achieve values less than the PQLs, this would result in equity issues with respect to disparate laboratories capabilities. Some also suggested that the approach could exacerbate any potential laboratory capacity issues.

The EPA agrees with these commenters that values below the PQLs for the regulated PFAS should not be used in the RAA compliance calculation. As cited previously by commenters and the EPA, in sections V and VII of the preamble, PQLs are the lowest concentration that can be reliably measured within specified limits of precision and accuracy during routine laboratory operations. As noted in the rule proposal, "the agency must have a high degree of confidence in the quantified result as it may compel utilities to make potentially costly compliance decisions in order to comply with the MCL." Moreover, because compliance with the MCL is determined by analysis with approved analytical techniques, the ability to analyze consistently and accurately for a contaminant is important to enforce a regulatory standard. The EPA recognizes the potential for minor analytical variabilities within sampling procedures and laboratory analyses below the PQL and this approach offers more operational certainty to utilities, provides better assurances of precision and accuracy in the concentrations at or above the PQL that are achievable for all laboratories, ensures more equitable access to all laboratories with comparable analytical capabilities for the purposes of compliance sample results, and reduces the potential for laboratory capacity issues.

Many other commenters did not support the EPA's proposed approach and offered that all sample results between MDLs and PQLs, even if estimated, should be included in the RAA and used to determine compliance. Alternatively, some suggested that any results that laboratories are able to quantify should be used in calculating the RAA for compliance. A subset of these commenters suggested that using zero (instead of an estimated or semi-quantitative value) biases the RAA compliance calculation, is even less precise and accurate than using the values below the PQLs, is contrary to the RAA compliance calculation for other SOC NPDWRs and demonstrates a reduction in public health protection. Some commenters also suggested that this could result in public communication challenges if laboratories are able to estimate or quantify values below the PQLs and zero is instead used in the calculation. Further, several commenters submitted that, in their experiences, some laboratories are capable of reliably and accurately reporting below the PQLs.

While the EPA recognizes that using zero for values below the PQL will result in a differing RAA compliance calculation result than if the values below the PQL were instead used, on a national scale, these values below the PQL do not consistently represent values with the

precision, accuracy, and reliability the EPA believes are necessary for compliance determination purposes. Therefore, the EPA's national approach to achieve consistency (recognizing that laboratories have varying analytical capabilities) is to judge compliance based on results at or above the PQL. Using values below the PQL may result in MCL compliance determination inequities across systems. The EPA notes that lower-level values (i.e., below the PQL) will be used for the determination of monitoring frequency. That determination is also based on individual sample results and not averages; therefore, systems with any PFAS results at or above the rule trigger levels will be required to monitor more frequently to ensure compliance with the MCLs (see sections 8.1.2 and 8.8 of the EPA response in this *Response to Comments* document related to compliance monitoring requirements and rule trigger levels, respectively).

The EPA agrees that some laboratories are capable of reliably measuring the regulated PFAS below the EPA's PQLs. This is supported by a subset of state PFAS monitoring data that represents some sampling with quantified values below the EPA's PQLs. Further, in the March 2023 proposal, the EPA recognized that "quantitation of the contaminants can be achieved between the method detection limit and the PQL" though the EPA also noted in the proposal that this is "not necessarily with the same precision and accuracy that is possible at and above the PQL." The EPA must set consistent requirements based on the circumstances of all PWSs and laboratory capabilities throughout the country. The agency notes that states must establish requirements at least as stringent as the EPA to maintain primacy; however, under SDWA, states with primacy may establish more stringent requirements. In instances where a laboratory can demonstrate it is capable of precisely and accurately quantifying values below the PQLs, some states may choose to establish their own requirements that are more stringent and use results below the agency's PQL for the compliance calculation.

The agency also received a few comments on the possible alternative approach of using the proposed trigger level as the value in calculating the RAA for compliance purposes when an estimated value is reported as between the trigger level and PQL. Most commenters did not agree with that approach and noted that using these values could result in inequitable implementation of the rule based on laboratory analytical capabilities.

After consideration of all these comments and for the reasons described previously, the EPA does not believe it is appropriate for the agency to require the use of trigger level values (or any other values below the PQL), as part of the RAA compliance calculation based on the information available to the agency as part of this final rulemaking. As described in section 8.8 of the EPA response in this *Response to Comments* document, the agency has concluded that results below the EPA's PQL (i.e., between the trigger level and PQL) are appropriate to determine if the contaminant is present (i.e., detected) and for the determination of reduced monitoring frequency, however the EPA concludes that values below the PQL would not consistently and reliably demonstrate the accuracy necessary for compliance determination purposes that can result in potentially costly expenditures, such as the installation of drinking water treatment, for PWSs.

A few commenters asked about how to account for regulated PFAS that are included in the Hazard Index when their concentrations are reported as "non-detect" and requested the EPA clarify what value to use in the Hazard Index calculation to evaluate compliance. The EPA confirms that when a laboratory reports that a result is below a PQL, the system is to use a zero in its calculation of the RAA Hazard Index MCL, similar to treating values below PQLs as zero in RAA compliance calculations for the PFAS with their own MCLs.

Individual Public Comments

Missouri Department of Natural Resources (Doc. #1563, SBC-052824)

Additionally, the Department does not agree with using the proposed hazard index approach as a trigger level indicator or for MCL compliance determinations. The HI does not follow the synthetic organic contaminant (SOC) standard monitoring framework (SMF) of basing decisions on reliable and consistent (R&C) analytical data as the HI levels are below the practical quantification limit (PQL). In order to make a R&C determination, decisions must be made on reportable results above the PQL.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document. The EPA disagrees that the Hazard Index MCL does not follow the SOC standard monitoring framework; the approach is the same as for PFOA and PFOS, with the same modification made for other regulated PFAS contaminants. Regarding trigger levels, please see section 8.8 of the EPA response in this *Response to Comments* document. The EPA also disagrees that the trigger levels for the Hazard Index PFAS are below their respective PQLs. The trigger level for the Hazard Index is 0.5 and all of the Health Based Water Concentration (HBWCs) for the four Hazard Index PFAS (2000 ppt for PFBS or 10 ppt for the other Hazard Index PFAS) are at least twice their respective PQLs (3.0 ppt for PFHxS and PFBS, 4.0 ppt for PFNA, 5.0 ppt for HFPO-DA). Therefore, there are no pertinent analytical limitations for these four PFAS. Further, any measurements below the PQLs will not be utilized when determining Hazard Index MCL compliance. Additionally, please see section 8.1.2 of the EPA response in this *Response to Comments* document for a discussion of eligibility for different monitoring frequencies, including changes made to the criteria for determinations that a system is reliably and consistently (R&C) below the MCL. Under the final rule, the EPA has made changes to allow for measurable results below the MCL, but above the trigger level, to be sufficient for an R&C determination, which would allow a system to shift to annual monitoring.

Great Lakes Water Authority (GLWA) (Doc. #1558, SBC-042555)

Whether EPA should consider an alternative approach to what is currently proposed when calculating compliance with proposed MCLs. Specifically, in the case where a regulated PFAS is detected but below its proposed PQL, rather than using zero for the measurement value of the specific PFAS in the running annual average compliance calculation, that the proposed mile trigger levels (1.3 ppt for PFOA and PFOS and 0.33 of each of the HI PFAS PQLs (i.e.,

PFHxS=1.0, HFPO— DA=1. 7, PFNA=1.3, and PFBS=1.0)) be used as the values in calculating the running annual average for compliance purposes.

As previously stated, each of the trigger levels are below the PQL. We agree that detections below the PQL should be entered as a zero into the LRAA calculation due to the lack of certainty and precision.

Further, we suggest consideration that the trigger level requiring more frequent sampling be defined as a single exceedance using the LRAA calculation or health index value rather than an arbitrary concentration of a single sample. This would be more similar to the requirements of other drinking water regulations including the D/DBP Rule.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document. For a discussion of the EPA's rationale for the trigger levels, please see section 8.8 of the EPA response in this *Response to Comments* document. In the final rule, as in the proposed rule, the trigger level is used to evaluate individual sample results to determine monitoring frequency. MCL compliance, on the other hand, is based on an RAA for systems that conduct quarterly monitoring. Please see section 8.1.2 of the EPA response in this *Response to Comments* document regarding compliance monitoring requirements. The EPA also clarifies for the commenter that while the PFOA and PFOS trigger levels are below their respective PQLs, the commenter incorrectly states that the trigger levels for the four Hazard Index PFAS (PFHxS, PFNA, HFPO-DA, and PFBS) are below their respective PQLs; the final rule trigger level for the Hazard Index is 0.5 and all of the HBWCs for the four Hazard Index PFAS (2000 ppt for PFBS or 10 ppt for the other Hazard Index PFAS) are at least twice their respective PQLs (3.0 ppt for PFHxS and PFBS, 4.0 ppt for PFNA, 5.0 ppt for HFPO-DA). Therefore, there are no pertinent analytical limitations for these four PFAS.

Missouri Department of Natural Resources (Doc. #1563, SBC-042532)

EPA requests comment on whether EPA should consider an alternative approach to what is currently proposed when calculating compliance with proposed MCLs. Specifically, in the case where a regulated PFAS is detected but below its proposed PQL, rather than using zero for the measurement value of the specific PFAS in the running annual average compliance calculation, that the proposed rule trigger levels (1.3 ppt for PFOA and PFOS and 0.33 of each of the HI PFAS PQLs (i.e., PFHxS=1.0, HFPO– DA=1.7, PFNA=1.3, and PFBS=1.0)) be used as the values in calculating the running annual average for compliance purposes.

The Department does not agree with using levels below the PQL for compliance purposes. The approach should be to raise the MCL to be sufficiently above the need of a ±50% Method QA/QC acceptance level so that reliable and consistent (R&C) reportable results above the PQL can be used for compliance determinations.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document. The EPA clarifies for the commenter that levels below the PQLs will not

be used for compliance determination purposes. Regarding PQLs, please see section 7.2 of the EPA response in this *Response to Comments* document. For discussion of feasibility of PFOA and PFOS MCLs, please see section 5.1.1 of the EPA response in this *Response to Comments* document.

Minnesota Pollution Control Agency (MPCA) (Doc. #1569, SBC-042500)

In addition, and importantly, MPCA is concerned that EPA's proposal for evaluating compliance with the MCLs, which does not account for any analytical results below 4 ng/L for PFOS and PFOA, is not health protective and does not reflect the reality that most laboratories are providing results well below the 4 ng/L PQL, as is documented in the RFC. We urge EPA to revise this approach and allow the use of actual laboratory analytical results in evaluating compliance and the need for treatment of drinking water.

Thank you for this opportunity to comment.

Sincerely,

Katrina Kessler

Minnesota Pollution Control Agency (MPCA) (Doc. #1569, SBC-042493)

Section VI - Maximum Contaminant Level (MCL)

1) EPA requests comment on its proposed approach for an alternative to using zero in the formula to determine compliance with the proposed MCLs. EPA's primary proposal for when a PFAS is detected at less than the laboratory PQL (practical quantitation limit), which also happens to be the MCL for PFOS and PFOA, is to use zero. EPA proposes an alternative that

utilizes the proposed rule trigger levels, set at one-third of the proposed MCL, in place of zero in situations where PFAS are detected but below their proposed PQLs.

MPCA response:

• The proposed use of zero when PFOS and PFOA are not reported above 4 ng/L is not health protective, especially when many labs will be reporting at PQLs well below 4 ng/L. EPA's proposed alternative of using the proposed trigger values in place of zero is a slight improvement.

• A much better approach, which MPCA urges EPA to adopt, is to allow the use of a laboratory's best available reporting limit and any detections of PFAS that are reported, even when below 4 ng/L. While laboratory reporting limits will vary from state to state and from lab to lab, this enables regulatory actions to reflect the actual analytical results and the best available technology, not an artificially set PQL/reporting limit that is judged to be universally achievable.

• Along with MPCA's preferred approach (described above), MPCA strongly encourages EPA to propose an MCL for the combined analytical result for PFOS and PFOA in drinking water (i.e. an additive MCL for PFOS and PFOA), to be set at 4 ng/L. This is needed when reporting limits of less than 4 ng/L are used, as MPCA urges, to address the situation where PFOS plus PFOA exceed the proposed MCL of 4 ng/L, but neither PFOS or PFOA exceed individually. For example, if a sample was reported to contain PFOS at 3 ng/L and PFOA at 3 ng/L - with the proposed individual MCLs, no treatment of the drinking water would be required. With a combined PFOS plus PFOA MCL, it would – resulting in a more health protective result that better reflects knowledge of the risks posed by these forever chemicals. For reference, PFOS and PFOA are included in Minnesota's existing process for evaluating cumulative risk from PFAS. The specific chemicals used in Minnesota's existing process include: PFOS, PFOA, PFBA, PFHxA, PFHxS, and PFBS.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document. Please also see section 5.1.2 of the EPA response in this *Response to Comments* document regarding the relationship between PQLs and MCLs for PFOA and PFOS which have been determined by the agency as 4.0 ppt each for PFOA and PFOS. As discussed in section 8.2 of the EPA response in this *Response to Comments* document, for the determination of the RAA for MCL compliance purposes only, all results below these PQLs will use zero in the calculation. Therefore, a combined MCL for PFOA and PFOS of 4.0 ppt would not be feasible as a result of the analytical limitations described in section 5.1.2 of the EPA response in this *Response to Comments* document and the values below the PQLs (such as 3 ppt for PFOA provided in the commenter's example) will not be used in the determination of MCL compliance discussed in section 8.2 of the EPA response in this *Response to Comments* document. Additionally, please see section 5.1.3 of the EPA response in this *Response to Comments* document pertaining to PFOA and PFOS regulatory alternatives where the EPA discusses comments related to MCLs for PFOA and PFOS lower than 4.0 ppt.

San Antonio Water System (SAWS) (Doc. #1570, SBC-042480)

o To calculate the running annual average, EPA is allowing the use of a "0" for values below the PQL; however, the frequency of sampling events is predicated on quantifying those values. EPA should not use quantifiable values < PQL sometimes and not others. This inconsistency has the potential to increase PWS compliance sampling.

o There should be a consistent approach between running annual average and reduced monitoring. If the value is less than the PQL it should be a non-detect throughout the rule both for running annual average and monitoring requirements.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document. Please see sections 8.8 and 8.2.1 of the EPA response in this *Response to Comments* document regarding rule trigger levels for reduced triennial monitoring.

Oregon Health Authority (OHA) (Doc. #1582, SBC-042765)

• EPA requests comment on whether EPA should consider an alternative approach to what is currently proposed when calculating compliance with proposed MCLs. Specifically, in the case where a regulated PFAS is detected but below its proposed PQL, rather than using zero for the measurement value of the specific PFAS in the running annual average compliance calculation, that the proposed rule trigger levels (1.3 ppt for PFOA and PFOS and 0.33 of each of the HI PFAS PQLs (i.e., PFHxS=1.0, HFPO-DA=1.7, PFNA=1.3, and PFBS=1.0)) be used as the values in calculating the running annual average for compliance purposes.

OHA supports using zero in calculating the running annual average for compliance purposes for results below the minimum reporting level (MRL) regardless of the MRL the lab can achieve (some labs may be able to achieve lower MRLs than the PQLs in the proposed rule), as long as the PQLs in the proposed rule are met. OHA believes that only quantified results (values at or above the MRL) should be used for compliance calculations. In cases where a regulated PFAS is detected but below its proposed PQL and below the lab's MRL, the proposed trigger levels should not be used since the trigger levels are not actual measured/quantified results. If a PFAS is detected above the lab's MRL but below the PQL, that actual value detected should be used, rather than zero.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document.

Washington Suburban Sanitary Commission (WSSC Water) (Doc. #1585, SBC-042773)

EPA is proposing that systems with existing monitoring data from UCMR5 will not be required to conduct separate initial monitoring for regulated PFAS. WSSC Water supports this approach. However, although some labs are capable of performing at a PQL of 2 ppt, the UCMR5 framework involves different QA/QC requirements than non-UCMR methods 537.1 and 533,

making it impossible for labs to report any quantifiable results below the required PQL of 4 ppt. This makes it impossible to evaluate UCMR5 results against trigger levels below the PQL. Considering these limitations, WSSC Water supports EPA's approach for any results below the PQL to be reported as zero in determining running annual average, consistent with the method used in Standard Monitoring Framework.

Running annual average approach:

EPA is proposing that compliance with the proposed MCLs for regulated PFAS will be determined by calculating running annual averages at the sampling point. PFAS is ubiquitous in the environment, and analysis of PFAS is subject to greater variability compared to other contaminants regulated as a running annual average under the Standard Monitoring Framework. A single monitoring result exceeding four times the MCL in a quarter will result in non-compliance, even if it is a false positive. WSSC Water recommends that EPA consider extending the period for calculating the running average from four quarters to eight consecutive quarters to ensure that compliance is based on a representative amount of data. In addition, EPA may consider allowing primacy agencies to invalidate false positive data meeting specific criteria. For instance, State of California has implemented repeat sampling protocols following a detection above the Notification Level. These protocols allow invalidation of original sample results if subsequent repeat samples indicate non-detect. Similarly, EPA has successfully implemented comparable procedures, as outlined in 40 CFR 141.21(c)(1)(ii), to grant states the authority to invalidate false positive bacteriological results based on the repeat sampling results. Incorporating a statistical measure in the compliance calculation method, such as procedures to remove outliers outside of the standard deviation, could also eliminate the impacts of false positive sampling results. Compliance calculation over a two-year period or removing false positive results would not adversely affect public health protection as the human health impacts of PFAS are based on lifetime exposure.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document. Please see section 8.1.1 of the EPA response in this *Response to Comments* document for discussion of initial monitoring and section 8.3 of the EPA response in this *Response to Comments* document for a discussion of using existing data to meet the initial monitoring requirements. Related to the use of UCMR 5 data to satisfy the rule's initial monitoring requirements, the EPA clarifies that, while use of these data are allowable to satisfy the rule's initial monitoring requirements, water systems are required to collect the specified number of initial monitoring samples; therefore, large groundwater systems participating in UCMR 5 would have to collect two additional samples beyond those collected pursuant to UCMR 5 requirements. Additionally, while this previously-collected data can be used to satisfy some or all of the initial monitoring requirements, it is the results of the data that determine reduced monitoring eligibility. Along these lines, the EPA disagrees with the commenter's claim that a water system would not be able to use UCMR 5 data to demonstrate they may be eligible for reduced monitoring. Please see section 13.3.4 of the EPA response in this *Response to Comments* document for the discussion of how water systems can request UCMR 5 data below

MRLs from laboratories for use in satisfying some or all of the NPDWR's initial monitoring requirements and determination of compliance monitoring frequency.

The agency also refers the commenter to sections 8.8 and 8.2.1 in this *Response to Comments* document regarding rule trigger levels for reduced triennial monitoring and compliance monitoring requirements, respectively. Under the final rule, the EPA allows states to establish requirements for confirmation samples. In the event a system collects a confirmation sample required by the state, the system may average the two results (original and confirmation) and use the average in the compliance calculation. This approach (see § 141.902(b)(2)(v)) follows the precedent set for compliance samples and state-required confirmation samples collected to analyze most other chemical contaminants with chronic effects. Lastly, please see section 8.7 of the EPA response in this *Response to Comments* document for a discussion of background contamination concerns and potential "false positives."

Michigan Department of Environment, Great Lakes, and Energy (EGLE) Drinking Water and Environmental Health Division (DWEHD) (Doc. #1597, SBC-042981)

4. Michigan's SDWA requires a reporting limit of 2 ng/l for all seven PFAS compounds with MCLs. For running annual average calculations, would it be more appropriate to include numerical values for any detections below the PQL but above this RL in Michigan?

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document.

Lehigh County Authority (LCA) (Doc. #1600, SBC-042817)

A final point about the proposed MCLs for PFOA and PFOS is that compliance is proposed to be based on an annual running average. The proposed rule allows the use of a "0" (Zero) in the calculation when results are shown are below the PQL and MDL. The EPA is requesting comment on whether the proposed trigger level of 1.3 ppt should be used in lieu of "0." This approach would not be appropriate nor reliable. The EPA should not require arbitrary numbers to be used in a compliance calculation. Should a laboratory result be reported at a value less than the PQL and MDL, it is reasonable and appropriate to report that result as "0" (Zero).

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document.

American Water Works Company Inc. (Doc. #1608, SBC-044012)

Use of the Practical Quantitation Limits (PQLs)

American Water supports the proposed approach of using the PQLs as the limit for quantifying values when making compliance determinations. We agree that water systems will receive valuable information when results are provided to them below the PQLs, but strongly believe

that data should be used to assist in making treatment determinations. Concerns about accuracy and lab capacity support the PQLs as listed in the proposed rule.

American Water further supports using a value of zero (0) in compliance calculations for results below the PQLs. Choosing an arbitrary number such as one-half or one-third of the PQLs may lead to water systems being required to install costly treatment when actual levels do not support such actions.

American Water also cautions the U.S. EPA about the implications of making changes to the PQLs for PFAS analytes might have on this regulation. Any changes that would impact compliance determinations or monitoring requirements under this rule would need to be carefully considered and vetted through a new rulemaking process that clearly conveys the health risks that are being addressed and the associated costs and implementation challenges.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document. Additionally, the EPA evaluates NPDWRs as part of the Six Year Review process. Any changes made to the regulations, including new PQLs, would follow this process outlined under SDWA.

Minnesota Department of Health (MDH) (Doc. #1610, SBC-042852)

· To address the issues described here, EPA should make one of the following changes to the proposed NPDWR for PFAS:

o Allow any results above laboratory RLs to be used for determining a QRAA for compliance and set a required RL for laboratories that is below the MCL and achievable, such as 2 ppt for PFOS and PFOA.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document.

Minnesota Department of Health (MDH) (Doc. #1610, SBC-042849)

RE: PFAS National Primary Drinking Water Regulation Rulemaking (Docket EPA-HQ-OW-2022-0114)

Dear Assistant Administrator Fox:

The Minnesota Department of Health (MDH) appreciates the opportunity to provide comment on the PFAS National Primary Drinking Water Regulation Rulemaking proposal. We further recognize the effort that U.S. EPA has made to reach this important milestone in addressing PFAS. As the primacy agency responsible Safe Drinking Water Act (SDWA) implementation in Minnesota, MDH offers its comments from the perspective of decades leading SDWA implementation, as well as years of experience in addressing PFAS. Our agency's comments integrate perspectives from our MDH Public Health Laboratory and well as our MDH Environmental Health Division, both of which have, and will continue to, play key roles in assessing and addressing the presence of PFAS in drinking water. MDH also is a member of the Association of State Drinking Water Administrators (ASDWA), and MDH staff participate in several ASDWA work groups focused on PFAS. As such, our comments herein are provided in addition to perspectives voiced in comments submitted by ASDWA. As described in ASDWA's comments, we would further emphasize that significant resources will be needed to implement this proposed rule in order to reduce PFAS exposure nationwide and here in Minnesota.

Please contact Sandeep Burman, MDH Drinking Water Protection Section Manager, at 651-201-4647 or sandeep.burman@state.mn.us should you wish to discuss our comments in greater detail.

Sincerely,

Tom Hogan, Director

Environmental Health Division

Minnesota Department of Health (MDH) Comment

PFAS NATIONAL PRIMARY DRINKING WATER REGULATION

RULEMAKING PROPOSAL (DOCKET ID EPA -HQ-OW-2022-0114)

The Minnesota Department of Health (MDH) is providing the following comments to the United States Environmental Protection Agency (EPA) regarding the proposed National Primary Drinking Water Regulation (NPDWR) for PFAS as published in the Federal Register on March 29, 2023.

Proposal to Treat Results Below the PQL as Zero for Compliance Purposes

In part IX, subpart B of the rule preamble, the following is stated:

"When calculating the running annual averages, if a sample result is less than the PQL for the monitored PFAS, EPA is proposing to use zero to calculate the average for compliance purposes. For example, if a system has sample results for PFOA that are 2.0, 1.5, 5.0, and 1.5 ppt for their last four quarters at a sample location, the values used to calculate the running annual average would be 0.0, 0.0, 5.0, and 0.0 with a resulting PFOA running annual average of 1.3 ppt. As described in sections VI and VIII of this preamble, EPA is proposing that values below the PQL will not be used to determine compliance with the proposed MCLs as these PQLs are the lowest concentration of analyte that can be reliably measured within specified limits of precision and accuracy during routine laboratory conditions. As such, quantifying concentrations below the PQL for compliance purposes may decrease the precision and accuracy of the measured value and may not be achievable for some individual laboratories."

MDH Comments:

• MDH asserts that any PFAS results from a certified laboratory that are above the laboratory RLs should be included when determining compliance with the MCLs.

o Due to the MCLs for PFOS and PFOA being set at the PQLs, and EPA's proposal to treat any result below the PQL as zero for compliance purposes, systems with valid data from laboratories showing they are out of compliance based on a traditionally-calculated Quarterly Running Annual Average (QRAA) will be treated as in compliance. This is problematic in regard to public perception, as it conflicts with how the QRAA for MCL compliance is typically determined for other contaminants (where results below the MCL are included in QRAA calculations), and moreover reduces the public health protection that could be provided under this proposed rule.

o The example used in the rule preamble is not informative for this issue. Instead, the following example should be considered: if a system has sample results for PFOA that are 3.9, 4.9, 5.0, and 5.1, which results in a QRAA of 4.7 ppt (above the MCL) when all results are included, the proposed rule would consider this for compliance as 0, 4.9, 5.0, 5.1, which results in a QRAA of 3.8 ppt (below the MCL). This difference is created by having just one single result below the PQL that is treated as zero. While this system is obviously not reliably and consistently below the MCL, the proposed rule would treat it as in compliance. MDH is not comfortable treating such a case as in compliance.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document. The EPA notes it has included additional illustrative examples of compliance calculations in the final rule preamble section VIII.B.3.

Oklahoma Department of Environmental Quality (DEQ) (Doc. #1616, SBC-043045)

Compliance Calculations

If a sample result is less than the practical quantitation limit (PQL) for a regulated PFAS, zero is to be used for that analyte in calculations, and 141.903(f)(l)(i)(C) provides the PQL for the six regulated PFAS. Clarification is needed of what values would be used if the PQL's for these contaminants change.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document. Additionally, the EPA evaluates NPDWRs as part of the Six Year Review process. Any changes made to the regulations, including new PQLs, would follow this process outlined under SDWA.

Colorado Water Utility Council (CWUC) (Doc. #1622, SBC-044041)

22. EPA requests comment on whether EPA should consider an alternative approach to what is currently proposed when calculating compliance with proposed MCLs. Specifically, in the case where a regulated PFAS is detected but below its proposed PQL, rather than using zero for the measurement value of the specific PFAS in the running annual average compliance calculation, that the proposed rule trigger levels be used as the values in calculating the running annual average for compliance purposes.

a. CWUC strongly disagrees with the use of any value other than zero for measurements below the PQL when determining compliance, because the reliability and accuracy of data below the PQL is not certain enough to use in a running annual average. This methodology is also inconsistent with all other chemical contaminant rules. Align this rule with SOC, VOC, DBPs. Include cumulative/additive MCLs over the HI, below detection are counted as zero, and less than half the MCL (ie the TL) qualifies the system for reduced monitoring.

b. This is yet another example of why raising the Trigger Level to 4.0 ppt and the MCL to 8.0 ppt is advisable. That data would be readily available and is confirmed to be accurate and reliable, and would negate the necessity to use j-flag data for compliance calculations.

c. CWUC also does not support using trigger levels to determine Running Annual Averages. That is not in alignment with any other rule. RAA should only be determined based on the MCL.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document. Please see sections 8.8 and 8.1.2 of the EPA response in this *Response to Comments* document for discussion of rule trigger levels for reduced triennial monitoring and compliance monitoring requirements, respectively. The EPA clarifies for the commenter that in

the final rule, the RAA is not compared to the trigger levels or used to determine monitoring frequency, but is only compared to the MCLs for compliance determination purposes. Additionally, please see section 5.1.2 of the EPA response in this *Response to Comments* document for a discussion of the relationship between the PFOA and PFOS MCLs and PQLs.

Aqua America, an Essential Utilities Company (Doc. #1623, SBC-043082)

Monitoring Requirements

The Agency is providing a 3-year timeline for water systems subject to the rule to perform initial monitoring requirements for PFAS at each entry point to the distribution system. The initial monitoring requirements may be waived for some systems that are either participating in UCMR 5 or have participated in eligible state monitoring programs since January 2019. Initial monitoring will determine if systems are eligible for a reduced monitoring frequency under the proposed framework and if the system will need to install treatment (or take non-treatment action) to reduce PFAS to levels below the MCL. According to the Proposal, compliance with the rule be determined using the running annual average (RAA) at each entry point to the distribution system. As part of the calculation of the RAA, EPA is also proposing that systems use zero ppt for results that are below the practical quantification limit (PQL) of 4.0 ppt. At the same time, EPA is proposing that to calculate the RAA for determining a system's eligibility for reduced monitoring, that only values below the detection limit be considered as zero ppt and all reported results above the detection limit be used. The following sections provide a detailed review of these requirements and their proposed alternatives.

In addition, the language in 141.903(f)(2)(i) is worded in a confusing way. It could be interpreted to mean that having an average Hazard index for a quarter over the MCL means that you are out of compliance with the MCL. This is not aligned with the 141.903(f)(1) that clearly states that compliance is determined via a running annual average of four quarters.

EPA Response: The commenter's characterizations of the requirements of the proposed rule are generally accurate, with one exception. The EPA clarifies that it is not the case that initial monitoring requirements are being "waived" for systems with existing data meeting the requirements specified under the NPDWR. Instead, a water system may submit previously-collected data consistent with the rule requirements and then the state can use these as initial monitoring data to determine the monitoring schedule required at the start of the compliance monitoring period. The EPA also clarifies that the RAA is used to judge compliance with the MCLs and is not relevant to determining monitoring frequency. Instead, eligibility for reduced monitoring is determined based on individual sampling results from prior rounds of monitoring, and a single sample result can prompt more frequent monitoring. This topic is discussed in more detail under section 8.1.2 of the EPA response in this *Response to Comments* document.

With respect to the comment about §141.903(f)(2)(i), the EPA has updated the language in the final rule to reflect that the RAA must exceed the MCL for there to be a MCL violation. Results equal to the MCL do not constitute a violation.

Pennsylvania Department of Environmental Protection (Doc. #1626, SBC-044876)

DEP supports using zero in the running annual average (RAA) compliance calculation for PFAS levels detected below either a practical quantitation level (PQL) or minimum reporting level (MRL). By definition, the PQL is the lowest level that can be consistently measured with precision and accuracy; therefore, any detections below that level are not accurate or precise and should not be used for compliance determination or any other regulatory decision making. Additional comments relative to the proposed PQLs and detection and reporting limits are provided later in this letter.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document. Please see sections 8.8 and 8.1.2 of the EPA response in this *Response to Comments* document for discussion of rule trigger levels for reduced triennial monitoring and compliance monitoring requirements, respectively.

Association of State Drinking Water Administrators (ASDWA) (Doc. #1628, SBC-044099)

ASDWA recommends that EPA clarify and revise conflicting language about the capability and expectation of laboratories to report PFAS detections at the lowest levels for reduced monitoring and compliance.

ASDWA's members could not reach a consensus on supporting the methods EPA has used to calculate the running annual average for determining both compliance and reduced monitoring. The PQL is defined as the "lowest concentration of an analyte that can be reliably measured within specified limits of precision and accuracy during routine laboratory operating conditions." Clarification is needed to explain how sample results with detections below the PQLs can or cannot be used for both reduced monitoring and compliance.

Some primacy agencies have highlighted that allowing the use of samples with PFAS detection levels lower than the PQL "for purposes of screening and to determine compliance monitoring frequency" conflicts with the definition and use of the PQL. The use of this language creates an expectation that laboratories can accurately report detection levels of 1.3 ppt. Primacy agencies have reported that some laboratories can reliably detect PFOA and PFOS as low as 1.8 ppt, but they cannot accurately detect them at 1.3 ppt. This information further supports setting the trigger levels for reduced monitoring at one-half (instead of one-third) of the MCLs.

Based on the rule proposal, it appears that the 1.3 ppt for PFOA and PFOS is meant to be used only for determining reduced monitoring, and that EPA is not expecting laboratories to be able to test to these low levels. If this is true, the rule should be clearer. Additionally, the current understanding is that any data below the PQL of 4.0 ppt will be used solely for calculating the running annual average for reduced monitoring and that anything deemed "non-detect" will count as "zero" for this calculation. Again, the proposed rule as written is unclear on this important issue, and it is unclear whether EPA is expecting a laboratory to be able to detect PFOA and PFOS at 1.3 ppt for that data to be eligible for reduced monitoring. ASDWA

recommends that EPA include an example of this calculation within the rule and supporting materials to reduce confusion.

Example of a running annual average calculation for initial monitoring to determine whether a system will qualify for reduced monitoring:

Quarter 1 Sampling – Non-Detect (0)

Quarter 2 Sampling - (2.2 ppt)

Quarter 3 Sampling – Non-Detect (0)

Quarter 4 Sampling – Non-Detect (0)

Running Annual Average: 0.55 ppt

Even when laboratories can test below the PQL, some primacy agencies have experienced significant issues with laboratory quality assurance and control for these results and question the legality of changing the monitoring frequency on levels below what laboratories can reliably and consistently report. In addition, some states with existing PFAS drinking water regulations only allow reduced monitoring for water systems that have samples with non-detects.

ASDWA's members could not reach a consensus on using either j-flag qualified or non-qualified data below the PQL of 4.0 ppt for compliance, noting some primacy agencies could not use jflag data, some want to use j-flag results below the 4.0 ppt PQL, and other primacy agencies reported some labs have the ability to report results around a 2.0 ppt MRL without the use of a j-flag. Some primacy agencies have highlighted that having the PQL set at 4.0 ppt for PFOA and PFOS in the proposed rule creates a protocol for laboratories to report any sample results with lower-level detections and non-detects as zeros. ASDWA recommends that EPA provide additional clarification regarding the Agency's expectations as to how laboratories will report levels below the PQL. Some of ASDWA's members have noted that primacy agencies may want the numerical results of these sampling events regardless of being below 4.0 ppt. Additionally, if EPA has lifetime health advisories for levels less than the PQL, the public will demand to see any data a system has below the PQL. Finally, primacy agencies have highlighted variations and inconsistencies in how laboratories report and primacy agencies accept (or do not accept) j-flag qualified data.

Some primacy agencies have asserted that using zeros for samples below 4.0 ppt does not calculate the RAA appropriately if the quarterly samples below 4.0 ppt have non-qualified detections just under 4.0 ppt (e.g., 3.9 ppt). These primacy agencies have noted that if a system's quarterly samples include non-qualified data below 4.0 ppt, that would result in a system being over the 4.0 MCL if included in the running annual average (rather than included as a "zero"), the system is not "reliably and consistently below the MCL" and should not be considered in compliance determinations based on the data reported to the primary agency.

Additionally, these primacy agencies noted that public communication surrounding the use of zeros for compliance calculations when there is a validated number from the laboratories will be

challenging for primacy agencies and water systems. These primacy agencies are particularly concerned with public communication when levels below 4.0 ppt may equate to a violation of the RAA when using zeros would not, as noted above.

Other primacy agencies have asserted that the rule should not allow either j-flag qualified data or non-qualified data below 4.0 ppt to be used in making compliance determinations, and these sample results should remain as "zero" within the calculations. These primacy agencies argued that if EPA can verify that most laboratories can reliably detect lower than 4.0 ppt, then EPA should lower the PQL within the regulation rather than using data below the PQL for compliance calculations. In this case, anything below 2.0 ppt would count as "zero" in a compliance determination. Some ASDWA members have highlighted that they have laboratories capable of reliably and accurately reporting down to 1.8 ppt.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document. Please see sections 8.8 and 8.1.2 of the EPA response in this *Response to Comments* document for discussion of rule trigger levels for reduced triennial monitoring and compliance monitoring requirements including use of values below PQLs. In the final rule, the EPA has provided clarification on use of these values for their intended purpose, including several illustrative examples of compliance calculations and monitoring frequency calculations (see sections VIII.B.3 and VIII.A.2). The commenter is correct in their understanding that any data below the PQLs will be used solely to determine monitoring frequency; for the calculation of the RAAs that support compliance determination, results below the PQL are treated as zero. Additionally, monitoring frequency is not based on averages, but rather individual sample results. Regarding laboratory capacity and capability, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

For a response to the commenter's statements about "j-flag data" and "non-qualified data below the PQL," please see sections 8.2 and 8.8 of the EPA response in this *Response to Comments* document. With respect to the potential for the public to request "any data a system has below the PQL," every CWS is required to include information on detected contaminants in its CCR. Under this rule, 141.151(d) defines "detected" for the regulated PFAS. Moreover, the EPA considers results at or above the trigger levels as "detections." With respect to the concern that "having the PQL set at 4.0 ppt for PFOA and PFOS in the proposed rule creates a protocol for laboratories to report any sample results with lower-level detections and non-detects as zeros," the EPA has addressed this by specifying in § 141.901(b)(2)(iii) that laboratories must report data for concentrations as low as the trigger levels, if available. As the EPA develops implementation materials following final rule promulgation, the agency will consider additional resources to support states and water systems for notifying their customers.

Village of Woodbury (Doc. #1629, SBC-042954)

8. If the EPA opts to utilize a running annual average to calculate compliance, we believe it is appropriate for the calculation to include zero for concentrations that are below the detectable

limit. It would be inappropriate for the EPA to require suppliers to utilize the trigger level in these calculations knowing the trigger level is not based on actual detectable levels of contaminants within the water supply, but rather just the notable presence at any concentration.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document.

Aidan Cecchetti (Doc. #1640, SBC-044379)

The commenters have also prepared the following comments on topics related to the proposed PFAS NPDWR that were not specifically requested by EPA:

• The proposed requirements detailed in §141.903(f) of the new regulations appear to require all samples collected at a compliance location within a monitoring period to be included in compliance calculations (e.g., "If more than one compliance sample for the analyte is available in the quarter, systems must average all the results in a quarter…") The commenters request clarification from EPA on the meaning for "compliance sample" in this context. Does "compliance samples" refer to all samples collected from a compliance location? Might this encourage water systems to take multiple samples during a monitoring period to try to dilute the impact of a sample with a concerning result? The commenters suggest that EPA should consider requiring PFAS monitoring plans to be reviewed and approved by state primacy agencies that would indicate the number of samples to be collected during each monitoring period. The commenters contend that this type of approach may help avoid purposeful under- or over-sampling by water systems to obtain more advantageous average results. Other approaches may help achieve the intended result.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document. The EPA does not define a compliance sample as a sample collected at a compliance location. Rather, the EPA defines a compliance sample as sample a system is directed to collect by a state or primacy agency. States identify the required monitoring schedule for a system and in what circumstances, if any, a system must collect and analyze a confirmation sample. Aside from a state-directed confirmation sample, additional samples collected by the system would be considered voluntary samples, not compliance samples, and the results of voluntary samples are not to be included in quarterly averages. In most circumstances, the EPA anticipates that a system would have no more than two compliance samples (the routine sample and a confirmation sample, if required) per quarter, and in both cases the sampling would occur at the direction of the primacy agency. This approach avoids the potential for problems associated with any "under- or over-sampling by water systems to obtain more advantageous average results," as the commenter states. The regulatory text has been revised as needed to specifically refer to the use of compliance-monitoring samples to demonstrate that MCLs are being met. With respect to the requirement for primacy packages to include a monitoring plan that addresses when systems will be scheduled to conduct initial monitoring, in light of public

comments, the EPA removed this requirement from the final rule. Please see section 11.1 of the EPA response in this *Response to Comments* document for more information.

Aidan Cecchetti (Doc. #1640, SBC-044373)

EPA requests comment on whether EPA should consider an alternative approach to what is currently proposed when calculating compliance with proposed MCLs. Specifically, in the case where a regulated PFAS is detected but below its proposed PQL, rather than using zero for the measurement value of the specific PFAS in the running annual average compliance calculation, that the proposed rule trigger levels (1.3 ppt for PFOA and PFOS and 0.33 of each of the HI PFAS PQLs (i.e., PFHxS=1.0, HFPO-DA=1.7, PFNA=1.3, and PFBS=1.0)) be used as the values in calculating the running annual average for compliance purposes (pg. 18682 Federal Register Volume 88, Number 60).

• The commenters agree with EPA's proposal to use zero to calculate RAAs for compliance purposes when a sample result is less than the PQL. It is the commenters' opinion that EPA should not at this time consider the alternative approach of using a trigger level that is set below the PQL in calculating RAAs when contaminants are detected below the PQL. This alternative approach would be inappropriate because it could lead to inequitable implementation of the rule based on laboratory analytical capabilities. EPA has determined that detections of PFAS below the PQL are not reliably quantifiable, but method detection limits for laboratories may be substantially lower than the proposed trigger levels. Therefore, it cannot be assumed that a PFAS detection below the PQL is necessarily greater than the trigger level or that quantified levels below the trigger level are of adequate precision to determine that the trigger level has not been exceeded. Unless EPA can demonstrate that laboratory analytical capabilities are already broadly precise enough that the trigger level of 1.3 ppt for PFOA and/or PFOS can be adequately detected and reliably distinguished from a detection of a lower concentration, it is inappropriate to use this value for compliance calculations. If EPA can demonstrate the above, EPA should consider lowering the PQL for PFOA and PFOS. In summary, it is the commenters' opinion that it would be inappropriate to require water systems to use any non-zero value in calculations of RAAs when compounds are detected below the PQL, even in the name of potentially increased public health protection.

• Alternatively, it may be appropriate to use a trigger level below the PQL in compliance determination calculations if there should be a requirement for regulatory agencies to include a minimum method detection limit for accreditation for laboratories to perform quantification of PFAS.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document. Additionally, the EPA did not propose to establish a detection limit for PFAS in the proposed rule and has not done so in the final rule. For discussion of PQLs, please see section 7.2 of the EPA response in this *Response to Comments* document and section VII of the final rule preamble. Regarding rule trigger levels, please see section 8.8 of the EPA response

in this *Response to Comments* document. As discussed in the proposed and final rule preambles, results below the PQLs do not have the same precision and accuracy as those at or above the PQLs, and thus are not being utilized in the compliance calculation. The EPA has not stated that results below PQLs "are not reliably quantified." Moreover, the EPA notes that though the definition of the PQL is "the lowest level at which contaminant can be reliably quantified within specific limits of precision and accuracy during routine laboratory operating conditions using the approved methods", that does not suggest that measurements below the PQL should not be used to support monitoring frequency decisions, even if those results are associated with a lower level of precision and accuracy than higher-level results.

Aidan Cecchetti (Doc. #1640, SBC-044380)

• There do not appear to be separate compliance calculation requirements for systems that utilize treatment to remove PFAS. The commenters are concerned that requiring water systems that employ treatment to include all samples collected from a compliance location in the compliance calculations could discourage those water systems from taking investigatory samples out of fear of exceeding the new standards. The commenters encourage EPA to consider this and revise the proposed rule with additional provisions to help avoid discouraging systems from taking investigatory samples. As with the previous comment, requiring water systems to submit monitoring plans to primacy agencies for review and approval would help water systems and primacy agencies to clarify what samples must be included in compliance calculations to avoid these types of issues.

We thank EPA for their continued efforts toward implementing the federal SDWA and protecting public health. We hope that our input will help EPA to develop practicable and enforceable regulations that will be effective in limiting nationwide exposure to PFAS in drinking water. We encourage you to reach out to us at the contact information provided with this contact letter should EPA have any questions or require clarification on any of our comments.

Warm regards,

Aidan Cecchetti, PhD, PE

Scott E. Miller, PhD, PE

EPA Response: The EPA agrees that there are no separate requirements for systems that are treating their water for PFAS; please see section 8.2 of the EPA response in this *Response to Comments* document. However, the EPA disagrees that its regulatory framework discourages the collection of voluntary, investigatory samples because voluntary samples that go beyond the state-established requirements for compliance samples are not considered in the RAA or as part of establishing monitoring frequency. The EPA also disagrees that monitoring plans are needed specifically to clarify which samples will be included in compliance calculations; the agency has made it clear that only samples collected based on a primacy-agency requirement are to be used

to support compliance determinations. For samples collected during the initial monitoring period, the most recent data are to be used (see § 141.902(b)(1)). For further discussion of the proposed requirement for primacy packages to include a monitoring plan, which was removed from the final rule, please see section 11.1 of the EPA response in this *Response to Comments* document.

Massachusetts Water Resources Authority (Doc. #1645, SBC-043286)

d. Rule Requirements Must Employ High Quality Data

EPA's proposed approach to consider monitoring results below the practical quantification limits (PQLs) as zero is appropriate for the MCL. This approach should also be applied to criteria for reduced monitoring. PQLs represent nationally achievable and accurate reportable limits. Results below the PQL should not be reported for regulatory purposes, as not all laboratories and analytical equipment can reliably perform below the PQL. Analytical resources for implementing this proposed regulation will be in high demand. That demand may limit the availability of laboratory capacity to analyze samples; crafting a regulation that bases sampling requirements on levels below the PQL is impractical and unfair. Limited, highly sensitive analytical laboratory capacity may result in additional PWSs having to collect quarterly samplings, further increasing the overall cost for implementation of this regulation. MWRA recommends that EPA assume all monitoring results below the PQL are zero for the purposes of reduced monitoring.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document. Regarding rule trigger levels and compliance monitoring requirements including use of results below PQLs for monitoring frequency determination purposes, please see sections 8.8 and 8.2.1 of the EPA response in this *Response to Comments* document.

Savannah River Nuclear Solutions LLC (Doc. #1647, SBC-043330)

Comment 2

Section IX.B. Monitoring and Compliance Requirements (pg. 18682)

SRNS supports EPA's proposal to utilize a running average annual approach to calculate compliance with the proposed rule. As proposed, a single occurrence of perfluorooctanoic acid (PFOA) or perfluorooctanoic sulfonate (PFOS) that is slightly above the proposed maximum contaminant levels (MCLs) would not result in an MCL violation, assuming other quarterly samples remain below the MCLs. SRNS also supports EPA's proposal to use zero (0) to calculate the average for compliance purpose when calculating the running annual averages if a sample result is less than the PQL for the monitored PFAS and allowing water systems to collect and analyze one sample per three-year compliance period if the systems does not detect regulated PFAS in their system at or above the trigger level.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document. Requirements for systems to be determined eligible for triennial monitoring during the compliance monitoring period are discussed in section 8.1.2 of the EPA

response in this *Response to Comments* document, and requirements to be determined eligible for triennial monitoring after the initial monitoring period are discussed in section 8.1.1 of the EPA response in this *Response to Comments* document.

North Carolina Division of Water Resources (NCDEQ) (Doc. #1652, SBC-044185)

7. NCDEQ recommends that EPA clarify and fix conflicting language about the capability and expectation of laboratories to report PFAS detections at the lowest levels for reduced monitoring and compliance.

NCDEQ requests additional clarification on the methods EPA has used to calculate the running annual average for determining both compliance and reduced monitoring. The PQL is defined as the "lowest concentration of an analyte that can be reliably measured within specified limits of precision and accuracy during routine laboratory operating conditions." Clarification is needed to explain how sample results with detections below the PQLs can or cannot be used for both reduced monitoring and compliance.

Allowing the use of samples with PFAS detection levels lower than the PQL "for purposes of screening and to determine compliance monitoring frequency" conflicts with the definition and use of the PQL. The use of this language creates an expectation that laboratories can accurately report detection levels of 1.3 ppt. Some states have reported that many laboratories can reliably detect PFOA and PFOS at 2.0 ppt, but they cannot accurately detect them at 1.3 ppt.

Based on the rule proposal, it appears that the 1.3 ppt for PFOA and PFOS is meant to be used only for determining reduced monitoring, and EPA is not expecting laboratories to be able to test to these low levels, but the rule should be clearer. Additionally, the current understanding is that any data below the PQL of 4.0 ppt will be used solely for calculating the running annual average for reduced monitoring and that anything deemed "non-detect" will count as "zero" for this calculation. Again, the proposed rule as written is unclear on this important issue, and it is unclear whether EPA is expecting a laboratory to be able to detect PFOA and PFOS at 1.3 ppt for that data to be eligible for reduced monitoring. NCDEQ recommends that EPA include an example of this calculation within the rule and supporting materials to reduce confusion.

Example of a running annual average calculation for initial monitoring to determine whether a system will qualify for reduced monitoring:

Quarter 1 Sampling – Non-Detect (0)

Quarter 2 Sampling - (2.2 ppt)

Quarter 3 Sampling – Non-Detect (0)

Quarter 4 Sampling – Non-Detect (0)

Running Annual Average: 0.55 ppt

Even when laboratories are able to test below the PQL, there may be issues with laboratory quality assurance and control for these results and question the legality of changing monitoring frequency on levels below what laboratories can reliably and consistently report.

Having the PQL set at 4.0 ppt for PFOA and PFOS in the proposed rule creates a protocol for laboratories to report any sample results with lower-level detections and non-detects as zeros. NCDEQ recommends that EPA provide additional clarification regarding the Agency's expectations as to how laboratories will be reporting levels below the PQL. NCDEQ wants the numerical results of these sampling events regardless of being below 4.0 ppt. Additionally, if EPA has lifetime health advisories for levels less than the PQL, the public will demand to see any data a system has below the PQL.

Using zeros for any samples below 4.0 ppt does not calculate the RAA appropriately if the quarterly samples below 4.0 ppt have non-qualified detections that are just under 4.0 ppt (e.g., of 3.9 ppt). If a system's quarterly samples include non-qualified data below 4.0 ppt, that would result in a system being over the 4.0 MCL if included in the running annual average (rather than included as a "zero"), the system is not "reliably and consistently below the MCL" and should not be considered in compliance determinations based on the data reported to the primary agency.

Public communication surrounding the use of zeros for compliance calculations when there is a validated number from the laboratories will be challenging for state agencies and water systems. We are particularly concerned with public communication when levels below 4.0 ppt may equate to a violation of the RAA when using zeros would not, as noted above.

The rule should not allow either j-flag qualified data or non-qualified data below 4.0 ppt to be used in making compliance determinations, and these sample results should remain as "zero" within the calculations. If EPA can verify that most laboratories can reliably detect lower than 4.0 ppt, then EPA should lower the PQL within the regulation rather than using data below the PQL for compliance calculations. In this case, anything below 2.0 ppt would count as "zero" in a compliance determination.

In addition, the reporting and recordkeeping requirements for compliance within the rule should provide an option for not requiring the RAA to be reported by the laboratories if the state agency performs the RAA calculations for the water system.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document. Please see sections 8.8 and 8.1.2 of the EPA response in this *Response to Comments* document for discussion of rule trigger levels for reduced triennial monitoring and compliance monitoring requirements including use of values below PQLs. In the final rule, the EPA has provided clarification on use of these values for their intended purpose, including several illustrative examples of compliance calculations and monitoring frequency calculations (see sections VIII.B.3 and VIII.A.2). The commenter is correct in their understanding that any data below the PQLs will be used solely to determine monitoring frequency; for the calculation of RAAs that support compliance determinations results below the PQL are treated as zero.

Additionally, monitoring frequency is not based on averages, but rather individual sample results. Regarding laboratory capacity and capability, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

For a response to the commenter's statements about "j-flag data" and "non-qualified data below the PQL," please see sections 8.2 and 8.8 of the EPA response in this *Response to Comments* document. With respect to the potential for the public to request "any data a system has below the PQL," every CWS is required to include information on detected contaminants in its CCR. Under this rule, 141.151(d) defines "detected" for the regulated PFAS. Moreover, the EPA considers results at or above the trigger levels as "detections." With respect to the concern that "having the PQL set at 4.0 ppt for PFOA and PFOS in the proposed rule creates a protocol for laboratories to report any sample results with lower-level detections and non-detects as zeros," the EPA has addressed this by specifying in § 141.901(b)(2)(iii) that laboratories must report data for concentrations as low as the trigger levels, if available. Regarding primacy agency reporting requirements and reporting of the RAA, please see section 11.3 of the EPA response in this *Response to Comments* document. As the EPA develops implementation materials following final rule promulgation, the agency will consider additional resources to support states and water systems for notifying their customers.

Nebraska Department of Environment and Energy (NDEE) (Doc. #1653, SBC-043208)

• EPA requested comment on an alternative approach to the proposed compliance calculation for MCLs where detects below the PQL use a zero value for the running annual average.

o The Department supports this idea and suggest the trigger level be set at one-half of the PQL which is consistent with standard assessment methods used in determining compliance with surface water quality standards under the Clean Water Act.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document. Regarding rule trigger levels, please see section 8.8 of the EPA response in this *Response to Comments* document.

Nebraska Department of Environment and Energy (NDEE) (Doc. #1653, SBC-043203)

o A running annual average of quarterly monitoring results that may be less than the PQL and have a 50% error rate is expected to be cut in thirds and used to make compliance determinations. These factors significantly decrease the confidence in the monitoring to hold public water systems liable for the monetary ramification of compliance.

• The Department suggests removing the proposed triggers levels and using the PQL as the trigger. However, there are benefits of a trigger level that is less than the PQL as it allows the PWS to observe increasing levels of PFAS and more fully prepare to address PFAS contamination through increased monitoring.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document. Regarding rule trigger levels, please see section 8.8 of the EPA response in this *Response to Comments* document. The EPA disagrees with the commenter's claim that the monitoring results "have a 50% error rate" and refers to sections 5.1.2 and 7 of the EPA response in this *Response to Comments* document regarding laboratory considerations and analytical methods.

Washington State Department of Health (DOH) (Doc. #1665, SBC-044422)

EPA requests comment on whether EPA should consider an alternative approach to what is currently proposed when calculating compliance with proposed MCLs. Specifically, in the case where a regulated PFAS is detected but below its proposed PQL, rather than using zero for the measurement value of the specific PFAS in the running annual average compliance calculation, that the proposed rule trigger levels (1.3 ppt for PFOA and PFOS and 0.33 of each of the HI PFAS PQLs (i.e., PFHxS=1.0, HFPO– DA=1.7, PFNA=1.3, and PFBS=1.0)) be used as the values in calculating the running annual average for compliance purposes.

• DOH is concerned with the concept of using estimated data to impact so significantly a utilities action and a laboratories ability to analyze at the proposed triggers. If a PFAS is detected above the MDL but below the PQL, then it would bias the running annual average downwards to tally as a zero. It appears that anything below the PQL is considered as an estimate, but that depends on where the laboratory MDL and LOQ are in relation the PQL. It is unclear whether laboratories can analyze with accuracy or precision at the triggers set in the proposed rule, especially for PFHxS and PFBS.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document. Regarding rule trigger levels, please see section 8.8 of the EPA response in this *Response to Comments* document. The EPA also clarifies for the commenter that while the PFOA and PFOS trigger levels are below their respective PQLs, the trigger levels for PFHxS and PFBS (or any of the Hazard Index PFAS) are below their respective PQLs; the final rule trigger level for the Hazard Index is 0.5 and all of the HBWCs for the four Hazard Index PFAS (2000 ppt for PFBS or 10 ppt for the other Hazard Index PFAS) are at least twice their respective PQLs (3.0 ppt for PFHxS and PFBS, 4.0 ppt for PFNA, 5.0 ppt for HFPO-DA). Therefore, there are no pertinent analytical limitations for these four PFAS.

City of Allentown and Lehigh County Authority (LCA), Pennsylvania (Doc. #1667, SBC-043678)

A final point about the proposed MCLs for PFOA and PFOS is that compliance is proposed to be based on an annual running average. The proposed rule allows the use of a "0" (Zero) in the calculation when results are shown are below the PQL and MDL. The EPA is requesting comment on whether the proposed trigger level of 1.3 ppt should be used in lieu of "0." This approach would not be appropriate nor reliable. The EPA should not require arbitrary numbers to

be used in a compliance calculation. Should a laboratory result be reported at a value less than the PQL and MDL, it is reasonable and appropriate to report that result as "0" (Zero).

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document.

City of Hillsboro, Oregon (Doc. #1668, SBC-043119)

Furthermore, Hillsboro Water requests that EPA clarify the exact reporting needs for both the utility reporting to primacy agencies as well as how to address reporting in the CCR. For example, given that the Minimum Detection Level (MDL) for the approved methods is 4 ppt for PFOS and PFOA and the Maximum Contaminant Level (MCL) for the mentioned PFAS is also 4 ppt, but the trigger level for reduced monitoring is 1.3 ppt. Some laboratories may be able to detect PFAS at lower levels than the method MDL (often referred to as J-flagged data). This data means a substance was detected, but the value may not be accurate or precise because it is below the method MDL. Additionally, the proposed NPDWR specifies that the MCL is determined by a running annual average (RAA) calculation, but that detections must also be reported. For both RAA calculation and reporting in the CCR, will utilities report the official lab result (4ppt or greater), or will utilities be required to report detections (including J-flagged data), though they may be below the MDL? EPA specifically used the word "detected" in the proposed NPDWR; however, clarification is needed to differentiate a detection and a detection above the MDL.

Hillsboro Water request that EPA clarify these reporting requirements and provide utilities and primacy agencies with guidance on how to communicate to the public on these technical details.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document. The EPA clarifies for the commenter that the EPA-approved methods do not include MDLs, as the commenter stated, but rather define and require the confirmation of MRLs which are distinctly different from MDLs. For the PFAS NPDWR, the EPA did not define MRLs for PFAS contaminants, but established PQLs, as discussed in sections V and VII of the final rule preamble, to evaluate analytical feasibility for the determination of MCLs. Data below these PQLs are not used for compliance determinations, which is calculated using a RAA, but these data are used for determining if a system is eligible for reduced monitoring (please see section 8.2.1 of the EPA response in this *Response to Comments* document for discussion of compliance monitoring requirements and section 8.8 of the EPA response in this *Response to Comments* document for rule trigger levels). The CCR Rule requires CWSs to provide consumers with information about detected levels of PFAS in their reports. CCR reporting is based on detected contaminants; for the purpose of CCR reporting, "detected" is defined as reported at a concentration equal to or exceeding a trigger level (please see section IX of the preamble to the rule and section 9.1 of the EPA response in this *Response to Comments* document for more information on CCR requirements). The concentrations reported to a system by a laboratory (for valid compliance samples) would be reported to the primacy agency, consistent with any primacy agency-specific requirements.

Cleveland Water, City of Cleveland, Ohio (Doc. #1672, SBC-044917)

Section 5.3: Compliance calculation

EPA is proposing a RAA approach to compliance calculation. PWSs must take quarterly samples, a minimum of 4 per year per EPTDS, and use the average the four. This is consistent with other regulation and would provide stability and familiarity with sampling calculations.

Cleveland Water also strongly supports EPA's proposal to report values below the PQL as 0 for the purpose of calculating the RAA. An alternate approach EPA considered in the proposal is using the trigger level (1/3 of the PQL), as the value when concentrations are below the PQL. If EPA were to adopt this version, no water system would be able to qualify for reduced monitoring. If a utility has all quarterly samples below 4.0 ppt, the proposed method will give them a RAA of 0, and they would be below the trigger level and qualify for reduced monitoring. That same utility under EPA's alternative approach would have a RAA of 1.3 ppt. The preamble states that water systems qualify for reduced monitoring if it "do[es] not detect regulated PFAS in their system at or above the rule trigger level." So being at the trigger level does not qualify a system for reduced monitoring.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document. The final rule reflects that the RAA is only used to determine compliance with the MCLs, not to determine monitoring frequency (which, instead, is based on individual sample results). For the purposes of determining monitoring frequency only, all data (including laboratory results below the PQLs) from individual samples will be used. Please see section 8.1.2 of the EPA response in this *Response to Comments* document regarding eligibility for different sampling frequencies and section 8.8 of the EPA response in this *Response to Comments* document on rule trigger levels for reduced triennial monitoring.

Association of California Water Agencies (ACWA) (Doc. #1675, SBC-044934)

COMMENT 4 – TRIGGER LEVEL – The trigger levels should not be used for compliance purposes.

EPA is proposing the use of a trigger level for less frequent compliance monitoring under certain circumstances [FN25: 88 Fed. Reg. at 18, 681.]. EPA plans for the trigger level to be used both for calculating the running annual average (RAA) for compliance determination and for determining the frequency of compliance monitoring. ACWA supports the flexibility that EPA has introduced related to the trigger level, but ACWA has concerns about using any numeric value below the practical quantitation limits (PQL) [FN26: PQL is the lowest concentration that PFOA and PFOS can be reliably quantified within specific limits of precision and accuracy during routine laboratory operating conditions. (88 Fed. Reg. at 18,666).] for compliance purposes. Additionally, ACWA has concerns about laboratory capacity issues for values associated with requiring numeric values below the PQL.

EPA concluded "that 4.0 ppt is the lowest concentration that PFOA and PFOS can be reliably quantified within specific limits of precision and accuracy during routine laboratory operating conditions." [FN27: 88 Fed. Reg. at 18,666.]. ACWA agrees with the EPA that values below the PQL are less precise and accurate. As such, ACWA believes that values below the PQL should not be used for compliance purposes, including calculating the RAA. ACWA supports the current proposal to use zero for calculating RAA whenever a sample result is below its PQL. ACWA does not support using the trigger level for calculating RAA when PFAS are detected below their PQL.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document. The final rule reflects that the RAA is only used to determine compliance with the MCLs, not to determine monitoring frequency (which, instead, is based on individual sample results). For the purposes of determining monitoring frequency only, all data (including laboratory results below the PQLs) from individual samples will be used. Please see section 8.1.2 of the EPA response in this *Response to Comments* document regarding eligibility for different sampling frequencies and section 8.8 of the EPA response in this *Response to Comments* document on rule trigger levels for reduced triennial monitoring.

New York State Department of Health (NYS DOH) (Doc. #1677, SBC-044959)

21. Please see 88 FR 18697, Section XIII.C(1)(f) which indicates that systems that have an MCL exceedance will collect one additional sample from the relevant entry point to confirm the results. This appears to be inconsistent with compliance monitoring prescribed for the running annual average calculation.

22. In accordance with Section 141.XX.c(b)(2)(iv) states may delete results of obvious sampling errors from the compliance calculations. It is not clear what constitutes an obvious sampling error, or if this latitude extends beyond sampling and also affords states the freedom to delete results due to obvious analytical errors or other circumstances. While we appreciate the discretion afforded to states, we believe that this provision is too broad, and provides an opportunity for inconsistent application. Analysis of the field reagent blank (FRB) should identify any sample contamination that occurred during sample collection. States should be given the ability to invalidate results with detections in the FRB as well as the ability to invalidate results with detections in the laboratory blanks.

EPA Response: The portion of the Federal Register Notice (FRN) cited in this comment (section XIII.C(1)(f)) is a summary of the method for estimating the costs associated with rule implementation. The commenter is correct that requirement for confirmation samples to be collected after an MCL exceedance is not found in the proposed Code of Federal Regulations (CFR) amendments and is therefore not binding on systems. Rather, the final rule does allow for confirmation samples. Whether and under what circumstances a confirmation sample might be required is a decision made by each primacy agency. However, in the location the commenter cited, for the purposes of analyzing potential costs, the EPA made one uniform assumption about

whether confirmation samples would be needed and described the assumption it used in its approach to modeling. Thus, as this is not a rule requirement, accounting for all systems taking an additional confirmation sample in the EPA's monitoring cost estimates would likely reflect an overestimate of real monitoring costs borne by water systems.

Regarding the comment on the proposed rule CFR section 141.XX.c(b)(2)(iv), the final-rule language about states having the discretion to invalidate results associated with obvious sampling errors is consistent with precedent, as there is parallel language in the portions of the regulations addressing most other chemical contaminants (see §141.23(f)(3), § 141.24(f)(13), and § 141.24(h)(9)). "Sampling" errors may include those that occur during sample collection and/or preparation. State regulations or guidance may provide additional clarity about the types of results that may be invalidated in that state. The EPA disagrees that it is necessary to provide additional clarity in the PFAS regulations, as the rules provide specific direction on invalidation options. The EPA requires that all samples pass method quality control (QC), including laboratory reagent blank (LRB) and field reagent blank (FRB) samples that would indicate contamination, and any results that do not pass acceptance criteria are considered invalid. The EPA agrees that samples identified as invalid by the laboratory should not be included in compliance calculations. Please see section 8.7 of the EPA response in this *Response to Comments* document regarding background contamination concerns.

New York State Department of Health (NYS DOH) (Doc. #1677, SBC-044942)

4. EPA requested comment on whether an alternative approach to calculating the running annual averages should be considered. The Department does not object to the compliance calculation as initially proposed, with results below the Practical Quantitation Limit (PQL) considered to be 0.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document.

New York City Department of Environmental Protection (NYCDEP) (Doc. #1679, SBC-044215)

In section IX. A., p. 18682, EPA requests comment on the proposal to use either zero or the trigger level for the purpose of calculating the running annual average. The usage of any value other than the laboratory reported value for performing calculations imparts a bias on the overall results. Replacing raw values with zero underestimates occurrence. Replacing values with the trigger level overestimates the occurrence. Additionally, replacement values add to the overall complexity of compliance reporting procedures.

Sincerely,

Paul V. Rush, Deputy Commissioner Bureau of Water Supply

cc: Lori Emery, Director, Water Quality & Innovation, BWS Charlene Graff, Director, Environmental Health and Safety, BWS Casey McCormack, BLA

Melinda Sherer, BLA

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document.

City of Vancouver Water Utility, Vancouver, WA (Doc. #1684, SBC-044310)

RAA Calculation:

Vancouver does not support the alternative method for calculating the running annual average where a regulated PFAS is detected but below its proposed PQL, rather than using zero for the measurement value of the specific PFAS in the running annual average compliance calculation, that the proposed rule trigger levels (1.3 ppt for PFOA and PFOS and 0.33 of each of the HI PFAS PQLs (i.e., PFHxS=1.0, HFPO– DA=1.7, PFNA=1.3, and PFBS=1.0)) be used as the values in calculating the running annual average for compliance purposes. 0 ppt should be used in the calculation in these cases.

This same comment applies when the levels are below the MRL and not detectable. 0 ppt should be used in this case as well.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document.

New Hampshire Department of Environmental Services (NHDES) (Doc. #1690, SBC-044352)

f. Page 18730, Column 3, Bullet 4 – EPA requests comment on whether EPA should consider an alternative approach to what is currently proposed when calculating compliance with proposed MCLs. Specifically, in the case where a regulated PFAS is detected but below its proposed PQL, rather than using zero for the measurement value of the specific PFAS in the running annual average compliance calculation, that the proposed rule trigger levels (1.3 ppt for PFOA and PFOS and 0.33 of each of the HI PFAS PQLs (i.e., PFHxS=1.0, HFPO–DA=1.7, PFNA=1.3, and PFBS=1.0)) be used as the values in calculating the running annual average for compliance purposes.

NHDES Comment – NH suggests using the actual value of any sample result above the recommended reporting limit of 2 ppt when calculating a running annual average (RAA). This will reduce the burden of implementing this rule for non-SDWIS States, as well as the confusion caused by replacing values with zeros for these calculations. In practice, using the actual value (if above the reporting limit of 2 ppt) may be more protective of public health because RAAs would be more conservative and representative of the actual amount of PFAS detected in drinking water, causing more water systems to be out of compliance with the MCL or HI and therefore performing public notification. [Rule Reference: 141.903(f)(1)(iii) – Page 18752, Column 3, 141.903 (f)(2)(iii) – Page 18753, Column 3 and 141.905(b)(2)(iii) – Page 18753, Column 2]

g. Rule Reference: 141.903 (d). Page 18752, Column 2 – (d) Systems monitoring triennially whose sample result equals or exceeds the trigger level of 1.3 ppt for either PFOS or PFOA, or a Hazard Index of 0.33 for PFNA, PFHxS, HFPO–DA, and PFBS must begin quarterly sampling. If the sample result exceeds an MCL, the system will not be considered in violation of the MCL until it has completed one year of quarterly sampling with the triggering sample used as the first quarter of monitoring for the running annual average calculation.

Rule Reference: 141.905(b)(2). Page 18753, Column 1 – (2) Systems monitoring triennially whose sample result is at or exceeds the trigger level as defined by § 141.902(a)(7) of this section must begin quarterly sampling. The system will not be considered in violation of the MCL until it has completed one year of quarterly sampling.

NHDES Comment – NH is against issuing an MCL violation only after a system has completed 1 year of quarterly monitoring following a triennial sample above the MCL. What we often see in NH is operators waiting to address treatment issues until they are notified that the system is in violation of an MCL, mostly due to the cost of replacing filters and resin. Therefore, in NH if a system is sampling annually or triennially and one sample is above the MCL, they are placed on quarterly monitoring and are also issued a notice of violation requiring public notification. We recommend compliance with an MCL be determined as soon as a triennial sample is above the MCL so that 1) operators take action to address treatment and 2) consumers are notified in a timely manner.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document.

Clean Water Action/Clean Water Fund (Doc. #1697, SBC-045003)

EPA has requested comment on alternative approaches to calculating running annual averages for compliance.

As noted in the comments we joined with NRDC, Earthjustice et al, using monitoring results above the Minimum Detection Level (MDL) to determine MCL compliance would be more consistent with existing NPDWRs and more protective of public health. The proposed procedure for calculating the running annual average in the proposal would use zero for any sample above the MDL but below the Practical Quantitation (PQL). EPA should revisit whether this aspect of the proposal since it discounts sample results that indicate the presence of regulated PFAS at levels that present public health risk.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document.

New Jersey Department of Environmental Protection (NJDEP) (Doc. #1699, SBC-045033)

EPA has proposed compliance with the MCLs to be determined based on running annual averages (RAAs) at each EPTDS. EPA states (88 Fed. Reg. 18682) that "if a system does not

collect required samples for a quarter, the running annual average will be based on the total number of samples collected for the quarters in which sampling was conducted." NJDEP strongly suggests EPA clarify and explain how this requirement should be implemented in scenarios where this may occur. Particularly, this could impact seasonal systems, missed samples, or a facility being placed offline. NJDEP advises EPA to develop guidance for states to ensure that compliance is determined consistently.

Regarding calculating the RAA to determine compliance with the proposed MCLs, NJDEP recommends that EPA be consistent in implementation of data assessment methodologies for monitoring reduction determinations and RAA calculations for compliance purposes. NJDEP recommends that EPA evaluates requiring laboratories to report data above trigger values but below the PQL. Analytical results at the proposed trigger value are considered reliable enough to determine whether a system can be placed on reduced monitoring; therefore, if a system's sample results are at or above the proposed trigger value, these results should be used in calculating compliance with the MCL.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document. Regarding rule trigger levels for reduced triennial compliance monitoring, please see section 8.8 of the EPA response in this *Response to Comments* document. The portion of the comment, "if a system does not collect required samples for a quarter, the RAA will be based on the total number of samples collected for the quarters in which sampling was conducted," is consistent with similar language that applies to most other chemical contaminants with chronic effects. In the final rule, in response to public comments, the EPA updated the quoted language to read, "If a system fails to collect the required number of samples specified in § 141.902 (Monitoring requirements), this is a monitoring violation as described in § 141.905©, and compliance calculations must be based on the total number of samples collected." This revised language underscores the fact that only required compliance samples are considered in the compliance calculations. It is reasonable to assert that reasons for not collecting required samples during a quarter could include all three scenarios the commenter identifies; however, compliance for an active system will be based on those quarters in which samples are collected. If an entry point is not in operation during a specific quarter then no representative sample can be collected. As it develops implementation materials for the PFAS rule, the EPA will consider the suggestion that guidance cover this topic.

<u>State of Vermont Agency of Natural Resources and Department of Health (Doc. #1708, SBC-045106)</u>

7) Way to calculate compliance, <PQL = 0

States should not use qualified/"j" flagged data to calculate compliance with the MCL because these results are estimates. Use of the Running Annual Average when results are quantified above the PQL to calculate compliance with the MCL makes sense if the health effects of PFAS are consistent with other primary drinking water contaminants with chronic health effects. However, using the trigger level of an estimated value to assess compliance does not make sense.

It is more likely that labs can achieve actual, verified concentrations down to 2 ppt, which would be half of the respective MCL for PFOA or PFOS, not 1.3 ppt which may be "j" flagged or qualified data as the result of an estimated concentration. Use of estimates in a regulatory framework is not an established practice under the Safe Drinking Water Act. These estimates would then be reported in CCRs and available to system users upon request, which would then require explanation of why 2.3 ppt is not "really" a number despite very much appearing to be a valid number. In our experience with our regulation since 2019, water system professionals have a difficult time understanding the difference between detection levels and reporting levels and now adding the practical quantification level into the mix, it will be increasingly difficult to convey information to users about water quality results, validity of samples, and comparison with the health advisories/MCLGs.

SDWIS is currently not set up to accommodate and accept both a method reporting level and estimated/qualified values pertaining to data to be used in screening. It is unrealistic for EPA to expect implementation of the MCLs without adequate tools to do so, because no other contaminant is managed the way EPA is proposing states manage PFAS yet it is expected to fit into an existing framework which is not a good fit.

Additionally, reporting of results below the respective reporting limits or PQLs sets a challenging precedent moving forward. Will this be expected of all compounds/chemicals reported? If so, has there been consideration as to how that is reported to the general public and/or included in CCRs? Opening the door to estimated values for compliance monitoring data reporting risks degrading the viability and the states' regulatory authority of every other established MCL. There are significant data management concerns and the inability to manage these consistently across the program and across states. If the number reported is below the reporting limit, then it should not be quantified, therefore whatever estimated result is reported should not be reflected as a number. While qualified data provides useful information including for the presence or absence of PFAS, there are challenges to using it in the regulatory compliance context as discussed here. Would SDWIS be built out to flag samples with qualifiers, or are states expected to manage the estimated results themselves without this capability being in SDWIS? This is a particularly urgent need for states that are already receiving compliance monitoring data for PFAS with the intent of using it to satisfy initial monitoring requirements. We cannot wait a year or more following the final PFAS regulation to receive the data management instructions. This needs to be sorted out before the final regulation is promulgated. If UCMR5 data can be used to count toward initial sampling, will the results be reported to the detection limit or reporting limit, and will they be "J" flagged?

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document, which discusses the use of concentrations below PQLs, which are not used in calculating RAAs. In addition, please see sections 8.1.2 and 8.8 of the EPA response in this *Response to Comments* document, which discuss rule trigger levels and compliance monitoring frequencies. The CCR Rule requires CWS to provide consumers with information about "detected" levels of PFAS in their reports, and, for this purpose, "detected" is defined as reported

at a concentration equal to or exceeding a trigger level (please see section IX of the preamble to the rule and section 9.1 of the EPA response in this *Response to Comments* document for more information on CCR requirements). As the EPA develops implementation materials following final rule promulgation, the agency will consider additional resources to support states and water systems for notifying their customers.

Concerning data management capabilities required to implement this rule, including potential changes to existing data management systems such as the Safe Drinking Water Information System (SDWIS), please see section 11.2 of the EPA response in this *Response to Comments* document. While beyond the scope of this rulemaking itself, the EPA is actively working on PFAS data management solutions, such as updating the SDWIS suite of applications to manage data reported from this rule. The EPA does not believe these data management systems must be available at the time of rule promulgation. Please see section 11.3 of the EPA response in this *Response to Comments* document for discussion of development of Data Entry Instructions. With respect to implications of this NPDWR on the NPDWRs that apply to other chemical contaminants, this rulemaking only applies to the specific chemicals identified in the rule.

Philadelphia Water Department (PWD) (Doc. #1709, SBC-045752)

16. EPA's requirement that any single point that would cause the LRAA to exceed the MCL would immediately trigger a violation

In Section 141.903(e) of the proposed rulemaking, EPA states "If any sample result will cause the running annual average to exceed the MCL at any sample point, the system is out of compliance with the MCL immediately." PWD believes that this is intended to capture any single results that are so high (i.e., greater than 4x the MCL) that would trigger an exceedance even if the remaining quarters are non-detect. While PWD does not oppose this stipulation, it believes that this stipulation as written will disincentivize systems from establishing routine monitoring at the entry point to distribution on a more frequent schedule than the regulatory requirement. An example: If PWS A is already over a year into compliance monitoring then a new LRAA will be generated every quarter. PWS A has established a monthly compliance monitoring program to provide more granular insight into PFAS levels in their system. Over the last three quarters, PWS A has had quarterly averages of 0 ppt, 0 ppt, and 4 ppt and their LRAA at the end of last quarter was calculated as 2 ppt (i.e., 0 ppt). This first monthly result of the next quarter was 12.5 ppt and would result in the subsequent LRAA being above the MCL if the LRAA was calculated after just this first quarterly sample. Based on the rule's current language, PWS A would be out of compliance before the remaining two monthly samples could be collected for the quarter, which could have resulted in the quarterly average being well below 12.5 ppt (as low as 4.2 ppt if the second and third month were below the PQL). This clause in the rulemaking may disincentivize systems from voluntarily implementing more than the minimum monitoring schedules to avoid situations like the example above.

EPA Response: In the final rule, the EPA has clarified the language to indicate that only compliance samples collected at the direction of a state (and any required confirmation samples) will be included in the RAAs used to determine MCL compliance. This removes any potential disincentive to systems to collect additional voluntary samples, in alignment with the commenter's request. Please see section 8.2 of the EPA response in this *Response to Comments* document for further discussion of compliance calculations.

Philadelphia Water Department (PWD) (Doc. #1709, SBC-045750)

14. Using the trigger level to calculate Locational Running Annual Averages (LRAA)

Under the current proposed rule, any results for PFOA and PFOS that are less than the respective PQLs would be included in the LRAA as zero. In section VI.A of the preamble, the EPA requested comment on using proposed trigger level for any results below the PQL in the calculation of the locational running annual averages. PWD recommends that EPA retain their current proposal to use zero in the calculation of the LRAA for results that are below the PQL. This would remain consistent with other regulations, such as the Stage 2 Disinfectant and Disinfection By-Products Rule, that utilize LRAA calculations for determining compliance which use zero in place of results less than the PQL/MRL.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document.

Citizens Campaign for the Environment (CCE) (Doc. #1710, SBC-045136)

Additional recommendation to strengthen EPA proposed regulations:

• EPA should determine MCL and Hazard Index violations quarterly, not annually as proposed. New York State currently determines violations quarterly. Doing this annually could result in the public being put at risk to drinking contaminated water for an unnecessarily long period of time. Increased frequency of determining violations, at least quarterly, will help protect public health from dangerous exposures.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document. The EPA has determined that, consistent with precedent for most other chemical contaminants with chronic effects, violations will be determined on the basis of an RAA. This monitoring and compliance framework allows for temporal fluctuations in concentrations that may occur because of unexpected events such as premature regulated PFAS breakthrough or temporary elevated source water concentrations. Thus, periodic occurrences of regulated PFAS that are slightly above the PQLs do not necessarily result in a violation of the MCL if other quarterly samples are below the PQL. The EPA's use of a RAA to determine compliance is consistent with currently available information, that suggests that the developmental and chronic effects associated with exposure to the regulated PFAS are not

known to represent immediately life-threatening health impacts. Thus, the EPA has determined that its monitoring and compliance framework will be sufficiently protective of public health.

HRSD (Doc. #1719, SBC-043548)

Other policy decisions warrant careful consideration as they have direct implications for operational costs and burden on communities. One such decision revolves around the calculation of the Running Annual Average (RAA) for PFAS. EPA does appropriately propose that all analytical results less than the Practical Quantitation Limit (PQL) be treated as "0" for the purposes of calculating the RAA. This recognizes the high degree of uncertainty in analytical results below the PQL and yet still provides assurance of compliance with an MCL for which the risk calculation is predicated upon chronic exposures. This practice is consistent with the approach used for calculating RAAs for the other MCLs for which RAA is the means of evaluating compliance. Utilizing trigger values of 1/3 the PQL to substitute for values below the PQL in compliance calculations can result in greater operational costs with, as expressed by EPA, only a "slight increase" in public health protection. The potential increase in operational costs for uncertain values with only the potential for a "slight increase" in public health protection is not warranted and represents a potential misuse of public funds.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document.

Louisville Water Company (Doc. #1720, SBC-043553)

[In that regard, we are providing the following comments on key issues that we think require consideration.]

3. Louisville Water supports EPA's proposal of using a running annual average (RAA) to calculate compliance. We have noted some seasonality to the variation in our source water monitoring. Using the RAA is consistent with other regulations and provides a more earnest assessment of the chronic risks posed by PFAS.

[In that regard, we are providing the following comments on key issues that we think require consideration.]

4. Louisville Water supports EPA's proposal to report values below the PQL as zero for the purpose of calculating the RAA. However, we understand that the agency is struggling with this issue. For most labs, the method reporting limit (MRL) for PFOA and PFOS is 2.0 ng/L. We believe it would be appropriate to require that data values below the PQL but above the MRL be used for calculating the RAA, but not appropriate to use J-flagged data (<MRL).

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document.

Massachusetts Department of Environmental Protection (MassDEP) (Doc. #1726, SBC-045164)

In § 141.903(f)(2)(ii)(B), the process to deal with multiple results for one or more of the HI PFAS during a quarter is not clear and doesn't appear to address the situation where multiple results exist for some but not all of the HI PFAS. MassDEP recommends that the set of results for each of the HI PFAS be averaged for the quarter and one set of Hazard Quotients (HQ) be derived to generate one HI (e.g., average all the PFBS results for the quarter, divide that average by the PFBS HBWC to get one PFBS HQ for the quarter add this to the other three HQs to obtain the HI for the quarter).

EPA Response: The paragraph referenced was removed from the final regulations because, as explained in section 8.1.2 of the EPA response in this *Response to Comments* document, the final rule does not provide for a situation when a system might collect two samples during a three-year compliance period. With respect to the possibility that there might be multiple samples to average in a quarter, the EPA has clarified that the only samples that are to be included in compliance calculations are compliance samples collected at the direction of the state. Further, each sample is to be analyzed for all regulated PFAS. Thus, the EPA would not anticipate a likely situation where multiple quarterly results would exist for some but not all of the regulated PFAS. Nonetheless, the final regulations would cover this situation, were it to occur, in a fashion consistent with the commenter's recommendation in § 141.903(b)(2)(i), which reads: "If the State requires one or more confirmation samples for an analyte in the quarter, systems must average these results for each analyte in that quarter and then determine the Hazard Quotient(s) from those average values, then sum the Hazard Quotients [to determine the Hazard Index for the quarter]."

Massachusetts Department of Environmental Protection (MassDEP) (Doc. #1726, SBC-045171)

• Systems monitoring quarterly should not have a requirement to report whether the trigger level was met or exceeded. If a system is already subject to quarterly monitoring the relationship of its PFAS concentrations to the trigger would be meaningless because the only consequence of exceeding the trigger would be to be put on quarterly monitoring.

• Systems monitoring less frequently than quarterly should not have a requirement to report a Running Annual Average (RAA). According to § 141.903(d), a RAA isn't calculated unless a system is triggered into quarterly monitoring and then completes one year of quarterly monitoring.

EPA Response: The EPA retained the requirement for systems conducting quarterly monitoring to report whether the trigger level was met or exceeded because this information will provide states with a snapshot of systems that have experienced or are at risk of experiencing MCL exceedances. The EPA agrees that systems monitoring less frequently than quarterly should not be required to report an RAA. The agency clarified this in the final rule.

Massachusetts Department of Environmental Protection (MassDEP) (Doc. #1726, SBC-045162)

MassDEP supports EPA's proposal to substitute zero for sample results less than the PQL in both § 141.903(f)(1)(iii) and § 141.903(f)(2)(iii). MassDEP may consider establishing lower PQLs than are in the proposed rule, if appropriate.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document.

Massachusetts Department of Environmental Protection (MassDEP) (Doc. #1726, SBC-045169)

The final rule should explicitly state that water systems that conduct UCMR5 monitoring do not need to conduct initial monitoring. While the UCMR5 only requires large groundwater systems to sample twice, this should be sufficient, even though the proposed rule requires quarterly sampling. Is EPA requiring UCMR5 laboratories to report qualified results, or nonqualified results where the lab used an MRL lower than that required by UCMR5, or are all results below EPA's MRLs reported as "<MRL?" This could affect whether MassDEP would allow the use of UCMR5 results to satisfy the initial monitoring requirements as we require lower MRLs than are being used in UCMR5.

Using zeros for any results below 4.0 ppt miscalculates the Running Annual Average (RAA) if these results are non-qualified detections. Such a system's RAA could exceed the MCL when these results are included. For example, the set of quarterly results: 4.2, 4.2, 4.1 and 3.8 exceeds the MCL when all four results are used (4.1) but does not (3.1) when zero replaces the lowest result. Public communication surrounding the use of zeros for compliance calculations when there is a quantified detection will be challenging especially where including such detections is the difference between a violation or not.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document for discussion of the compliance calculation. Please see sections 8.1.1 and 8.3 of the EPA response in this *Response to Comments* document for discussions of using existing data to meet initial monitoring requirements and for a description of the rationale for requiring large groundwater samples to collect four samples to satisfy initial monitoring requirements. The EPA notes it is not requiring UCMR 5 laboratories to report sample results below the UCMR 5 MRLs, but water systems can request UCMR 5 data below MRLs from their laboratories for use in satisfying some or all of this NPDWR's initial monitoring requirements and determination of compliance monitoring frequency. Please see section 13.3.4 of the EPA response in this *Response to Comments* document.

Massachusetts Department of Environmental Protection (MassDEP) (Doc. #1726, SBC-045173)

§ 141.905(2) states that "[s]ystems monitoring triennially whose sample result is at or [emphasis added] exceeds the trigger level as defined by § 141.902(a)(7) of this section must begin quarterly sampling." According to § 141.902(b)(2)(ii) the trigger level must be exceeded before

quarterly monitoring is required. Since there is inconsistent language throughout the proposal, it is unclear what EPA's intent is and therefore which sections need correction.

EPA Response: The EPA agrees that the language in the proposed rule was inconsistent and has remedied this in the final rule. The EPA's intent (as described in the final rule) is for a system to initiate quarterly monitoring if a sample result is equal to or exceeds the trigger level. This is consistent with the requirements in § 141.24(h)(7) for other SOCs. Please see section 8.1.2 of the EPA response in this *Response to Comments* document regarding compliance monitoring requirements.

Massachusetts Department of Environmental Protection (MassDEP) (Doc. #1726, SBC-045178)

Running Annual Average Approach

EPA's proposal in the NPDWR to utilize a RAA approach to calculate compliance with the proposed MCLs is not adequately protective of development effects. An alternative approach should be considered, such as the use of a shorter duration averaging period.

Setting the PFOA and PFOS MCL at a Practical Quantitation Limit

Setting the PFOA and PFOS MCL at a PQL, established at a level of 4.0 ppt, raises a number of issues. Extensive experience among states that are already regulating PFOA and PFOS support a current PQL of 2.0 ppt. That said, setting an MCL at a PQL raises a risk of compliance "yo-yoing", where systems with concentrations hovering near the PQL will bounce into and out of compliance simply based on analytical variability within the range that is acceptable for the method. To avoid that problem, we recommend setting the MCL at a level above the PQL that reasonably exceeds (say by a factor of 2-3) the acceptable method variability, based on a lower PQL.

Conclusion

MassDEP is committed to the protection of public health and the environment against the impacts of PFAS contamination and strongly supports EPA's efforts to establish drinking water standards for PFAS. We urge EPA to carefully consider our comments, which are based on three years of experience implementing one of the most stringent PFAS limits for drinking water in the nation, urge EPA to take swift action in implementing its own standards, and applaud EPA for its ongoing efforts to develop this NPDWR.

Sincerely,

Bonnie Heiple

Commissioner, MassDEP

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document regarding the compliance calculation determination and use of RAA. The use of the RAA will likely decrease the odds of systems "yo-yoing" as the commenter states,

since it allows some minor fluctuations in measured concentrations and likely accounts for a single outlier sample result. Please see section V of the preamble to the rule and section 5.1.2 of the EPA response in this *Response to Comments* document for discussion of MCLs for PFOA and PFOS. Further discussion of the PQLs can be found in section 7.2 of the EPA response in this *Response to Comments* document.

Massachusetts Department of Environmental Protection (MassDEP) (Doc. #1726, SBC-045158)

There is an inconsistency between § 141.902(b)(2)(ii) and (iii). The former states that quarterly monitoring is required when the trigger level is exceeded whereas the later states that systems that are at or exceed the trigger levels must conduct quarterly monitoring. MassDEP recommends that the trigger level must be exceeded to require increased monitoring. MassDEP also recommends that the same criteria apply to making the "reliably and consistently below the MCL" determinations in § 141.902(b)(2)(iii) – anything at or below the trigger level should be acceptable.

EPA Response: The EPA agrees that the language in the proposed rule was inconsistent about when quarterly monitoring is triggered. The EPA's intent (as described in the final rule) is for a system to initiate quarterly monitoring if a sample result is equal to or exceeds the trigger level. This is consistent with the requirements in § 141.24(h)(7) for other SOCs. Please see section 8.2 of the EPA response in this *Response to Comments* document. With respect to the state's ability to make a determination of R&C below the MCL, the EPA has removed the requirement for the RAA of at least four consecutive quarters to be less than the trigger level. The state must consider at least four consecutive quarters of data, and, at a minimum, the R&C determination must be supported by analytical results below the MCLs. If applicable, a state may apply its own additional criteria for R&C determinations.

Florida Section American Water Works Association - Water Utility Council (FSAWWA WUC) (Doc. #1737, SBC-044484)

With that overarching request, we now turn to the individual components of EPA's rule proposal:

IX. Monitoring and Compliance Requirements, A. What are the monitoring requirements?

• The Florida Water Sector supports EPA's proposed approach to monitoring results below the practical quantification limits as zero for the MCL. This approach should also be used in the reduced monitoring framework.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document. For a discussion of rule trigger levels for reduced triennial monitoring, please see section 8.8 of the EPA response in this *Response to Comments* document.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-045969)

Section 5.4: Compliance calculation

EPA is proposing a RAA approach to compliance calculation. PWSs must take quarterly samples, a minimum of 4 per year per EPTDS, and use the average of the four. This is consistent with other regulation and would provide stability and familiarity with sampling calculations.

AMWA also strongly supports EPA's proposal to report values below the PQL as 0 to calculate the RAA. An alternate approach EPA considered in the proposal is using the trigger level (1/3 of the PQL), as the value when concentrations are below the PQL. If EPA were to adopt this version, no water system would be able to qualify for reduced monitoring. If a utility has all quarterly samples below 4.0 ppt, the proposed method will give them a RAA of 0, and they would be below the trigger level and qualify for reduced monitoring. That same utility under EPA's alternative approach would have a RAA of 1.3 ppt. The preamble states that water systems qualify for reduced monitoring if they "do not detect regulated PFAS in their system at or above the rule trigger level," so being at the trigger level does not qualify a system for reduced monitoring.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document.

Del-Co Water Company, Inc. (Doc. #1744, SBC-043617)

II. Del-Co internal testing of PFOA would result in oscillating compliance around the 4.0 ppt MCL

Del-Co Water has been monitoring for PFAS chemicals since 2020. Over that time, background concentrations of PFOA have ranged between non-detectable to 5.8 ppt. During this time, and under certain circumstances, we would have exceeded the proposed MCL for PFOA. Under the proposed sampling scheme and running annual average calculation, this exceedance would only last for one quarter (or 3 months), after which our RAA would fall below the proposed PFOA MCL of 4.0 ppt. The manner in which we will oscillate below, then above the proposed MCL will lead to difficulties in compliance and in customer messaging and communication. It will lead to the unnecessary erosion of public confidence in our water quality.

This circumstance will likely occur at all surface water PWSs, as the national background PFOA concentration is approximately 4 – 5 ppt. This will place other drinking water utilities in the same situation as Del-Co, in that for the overwhelming majority of the time the PWS will be lower than the proposed 4.0 ppt for PFOA, but one high measurement could result in exceeding the proposed MCL, thus leading to millions in upgrades and difficult messaging to the customers.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document. Since MCL compliance will be determined based on an RAA, the EPA

disagrees that the scenario described with one or two samples containing regulated PFAS at concentrations between non-detect and 5.8 ppt would result in an MCL violation assuming concentrations of regulated PFAS are below the PQLs in at least two quarters out of every four. As described in section 8.2 of the EPA response in this *Response to Comments* document, the use of the RAA allows for these type of temporary minor fluctuations and could, instead, reduce the number of times a system oscillates in and out of compliance. If the fluctuations were greater, to provide adequate public health protection and ensure compliance with the MCLs, it would be necessary to assess a violation, the water system to take necessary action to reduce the concentrations, and to notify the public. As the EPA develops implementation materials following final rule promulgation, the agency will consider additional resources to support states and water systems for notifying their customers.

Regarding the commenter's statement that "the national background PFOA concentration is approximately 4 – 5 ppt", the commenter does not provide any supporting information for this claim nor does the EPA agree based on available occurrence information presented in section III.C and VI of the final rule which is not demonstrative of this level.

Connecticut Department of Public Health (CT DPH) (Doc. #1745, SBC-045226)

CT DPH suggests that EPA utilize "J" flagged data consistently. For compliance, "J" flagged data is not accurate enough and a non-detect value of zero is used. However, this same data can be used as a present/absence indicator of a contaminant in the sample to trigger reduced monitoring and the actual numerical value matters and is used. "J" flagged data is an estimate. This can potentially create challenges to the rule if an estimate is used for regulatory compliance determinations. This inconsistent use of "J" flagged data makes messaging difficult for PWSs to communicate the results to customers, and the PWS must explain why the concentration is zero in some circumstances but the numerical value in others.

5. EPA is requesting comment on whether an alternative approach should be considered when calculating the running annual averages for compliance.

CT DPH agrees that the running annual average is an appropriate approach to monitor compliance as it has proven appropriate for other SOC contaminants. Using a similar approach will assist with Rule compliance for PWSs.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document. Regarding compliance monitoring requirements, rule trigger levels, and associated data use and reporting, please see sections 8.1.2 and 8.8 of the EPA response in this *Response to Comments* document. As the EPA develops implementation materials following final rule promulgation, the agency will consider additional resources to support states and water systems for notifying their customers.

Connecticut Department of Public Health (CT DPH) (Doc. #1745, SBC-045217)

CT DPH requests EPA provide clarification on how to handle data below the PQL. There are three types of data that can occur below the PQL set by the EPA: qualified result, "J" flagged result, and non-detect result. The EPA makes no mention of qualified results below the PQL. Will states be required to use this qualified numerical data in the compliance running average, or will the data be treated as zero as "J" flagged data. Many states have reported that laboratories can reach below the PQL, and the fact EPA wants to use data below the PQL for trigger levels may indicate that the PQL is not set appropriately.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document. Regarding rule trigger levels, please see section 8.8 of the EPA response in this *Response to Comments* document.

Connecticut Department of Public Health (CT DPH) (Doc. #1745, SBC-045223)

2. EPA requests comment on the use of data below PQLs for reduced monitoring regarding feasibility of the proposed MCLs and more generally on laboratory capacity.

The EPA should utilize "J" flagged data consistently, and consistently apply either a non-detect (0) value for this data or utilize the numerical result. By definition, "J" flagged data is an estimate. Basing compliance decisions on estimated data could result in challenges that would further add to the impact on state primacy programs to implement the rule. Laboratory capacity cannot be fully evaluated because of the change in monitoring requirements stemming from the trigger level.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document. Regarding rule trigger levels, please see section 8.8 of the EPA response in this *Response to Comments* document. Please see section 5.1.2 of the EPA response in this *Response to Comments* document for discussion of laboratory capacity.

West Virginia Rivers Coalition et al. (Doc. #1746, SBC-045250)

EPA must account for all PFAS detections when determining MCL compliance.

To ensure compliance with the MCL and to protect communities from dangerous PFAS exposures, EPA must consider all PFAS detections when calculating MCL compliance. EPA has proposed to utilize a running annual average over four consecutive quarters to calculate compliance with the proposed rule. When calculating the running annual average, if a sample result is less than the PQL - 4 ppt for PFOA, PFOS, and PFNA; 5 ppt for HFPO-DA; and 3 ppt for PFHxS and PFBS - EPA is proposing to use zero. In doing so, EPA is treating PFAS detections below the PQL but above the method detection limit (MDL) as if they were non-detects. This approach ignores measurable PFAS exposures and understates PFAS risks.

Instead, EPA should consider all PFAS detections above the MDL to calculate MCL compliance. Similarly, when calculating the annual running average of the HI PFAS to calculate the hazard index, EPA must consider all detectable levels of HFPO-DA, PFBS, PFNA and PFHxS. This is the approach used for regulations governing monitoring and analytical requirements for organic chemicals, as well as inorganic chemicals such as arsenic and mercury. EPA should apply the same, health-protective approach to the calculation of average PFAS concentrations. This will increase public health protection and provide PWSs greater forewarning that their results may exceed the MCLs.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document.

City of Thornton, Colorado (Doc. #1748, SBC-044794)

In determining compliance with the MCL, Thornton suggests that EPA revise its proposed approach for values below the PQL. First, EPA should reevaluate the PQL based on demonstrated lab feasibility; the contract laboratory that Thornton uses for PFAS analysis has a PQL of 1.9 ppt and MDLs around 0.5 ppt for most compounds. Data between the MDL and PQL, commonly referred to as J-flag data, is estimated at these levels from the calibration curve, peak integration, and analyst's technical expertise. In EPA's proposed compliance approach, zero is used for compliance calculations for samples below the 4 ppt PQL, this gives the public a false sense of security of how well protected they are from PFAS. In a hypothetical example where a utility regularly has samples of 3.8 ppt, their RAA will be zero. The public will believe that their water is free of PFAS, while their utility is actually very close to violating the MCL. EPA's alternative approach of using 1.3 ppt for compliance calculations for samples below the PQL is also flawed for the opposite reason. In a hypothetical example of a utility with GAC treatment targeting the MCLG with samples regularly below the MDL (0.5 ppt), the RAA will be 1.3 ppt. Customers will falsely believe their water has PFAS, when it might actually be PFAS free. Thornton suggests that the EPA allow utilities to use J-flag data for determining compliance with the proposed rule; data below the MDL should be considered zero for compliance calculations. This approach also allows utilities to show their progress towards treating down to the MCLG.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document. The EPA notes that concentrations of regulated PFAS equal to or exceeding the trigger levels are required to be reported in the CCRs; please see section 9.1 of the EPA response in this *Response to Comments* document for a discussion of those requirements.

American Water Works Association (AWWA) (Doc. #1759, SBC-045622)

According to the proposal, compliance with the proposed rule will be determined using the RAA at each entry point to the distribution system. As part of the calculation of the RAA, EPA is also proposing that systems use 0 ppt for results that are below the practical quantification limit

(PQL) of 4.0 ppt. At the same time, EPA is proposing that to calculate the RAA for determining a system's eligibility for reduced monitoring, that only values below the detection limit be considered as 0 ppt and all reported results above the detection limit be used. The following sections provide a detailed review of these requirements and their proposed alternatives.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document. The EPA has modified the requirements for a system to be eligible for reduced monitoring in the final rule, such that the RAA is no longer pertinent, instead requiring that individual sampling results be compared to the trigger levels. Please see section 8.1.2 of the EPA response in this *Response to Comments* document for further discussion of compliance monitoring requirements.

Bowling Green Municipal Utilities (Doc. #1767, SBC-043931)

Rule Requirements Must Employ High Quality Data: EPA's proposed approach to consider monitoring results below the practical quantification limits (PQLs) as 0 (zero) is appropriate for the MCL. This approach should also be applied to criteria for reduced monitoring. Results below the PQL should not be reported for regulatory purposes as not all laboratories and systems can reliably perform to or below the PQL.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document. Regarding compliance monitoring requirements and rule trigger levels for reduced triennial monitoring, please see sections 8.1.2 and 8.8 of the EPA response in this *Response to Comments* document.

Western Urban Water Coalition (WUWC) (Doc. #1768, SBC-043950)

IV. Other Implementation, Monitoring, and Compliance Aspects of the Proposed Rule Warrant Additional Consideration

A. Below-PQL Samples Should be Counted as Zero

Under the Proposed Rule's monitoring requirements, when a public water system detects a regulated PFAS at a concentration below the practical quantitation limit (PQL), the rule stipulates that the value is counted as zero when calculating the running annual average for compliance monitoring. This methodology is entirely appropriate and consistent with existing law governing compliance determinations with drinking water standards. [FN37: Examples of rules adopted under SDWA that use zero when calculating locational running annual averages or running annual averages for results are less than the PQL include the Disinfectants and Disinfection Byproducts Rule, Synthetic Organic Compounds Rule, Volatile Organic Compounds Rule, and Radiological Rule.]

WUWC sees no reason to deviate from this standard practice. EPA requests comment on whether it should consider an alternative approach under which below-PQL detections would be counted at the proposed rule trigger levels (1.3 ppt for PFOA and PFOS and 0.33 of each of the

HI PFAS PQLs (i.e., PFHxS=1.0, HFPO– DA=1.7, PFNA=1.3, and PFBS=1.0)). [FN38: 88 Fed. Reg. at 18682] The Proposed Rule itself is premised upon EPA's finding that the PQL is the lowest feasible quantitation level. [FN39: Id. at 18639] By contrast, the proposed trigger levels are based upon EPA's view of laboratories' calibration limits. [FN40: Id. at 18667] These trigger levels are in the J value range and should not be considered reliable for the purpose of calculating a running annual average for compliance, especially since the Proposed Rule already proposes to set MCLs at the lowest quantitation level.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document. Regarding compliance monitoring requirements and rule trigger levels, please see sections 8.1.2 and 8.8 of the EPA response in this *Response to Comments* document.

Environmental Protection Network (EPN) (Doc. #1773, SBC-043870)

The rule proposes running average concentrations to calculate compliance and proposes using zero if the sample result is less than the quantitation level even though labs can reliably measure lower than that level. EPN strongly recommends that EPA use a level that is 1/3 of the MCL (1.3 ppt for PFOA/PFOS, 1.0 ppt PFHxS, 1.7 ppt HFPO-DA, 1.3 ppt PFNA, 1.0 ppt PFBS) instead of zero for samples less than the quantitation level. The use of zero for these samples is not health-protective, as we show in our comments below on section 141.903.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document.

California-Nevada Section American Water Works Association (CA-NV AWWA) (Doc. #1775, SBC-045272)

3. EPA should be consistent and follow established and standardized procedures for compliance determination.

EPA's proposed approach to consider monitoring results below the practical quantitation limits (PQLs) as "not detected" and use of "0" (zero) for the calculation of annual average is an appropriate statistical approach for the regulation. This approach should also be applied to criteria for reduced monitoring and compliance reporting requirements. However, to be consistent with requirements stipulated in EPA's PFAS analytical methods, EPA should consider developing and using a Minimum Reporting Level (MRL) instead of the PQL. The MRL is the lowest concentration of an analyte that demonstrates both precision and accuracy. Results below the MRL are considered calculated estimates and they do not satisfy quality control requirements. EPA updated guidance for public water systems required to monitor under UCMRs in 1999, and in 2004 developed recommendations to assign a MRL for each contaminant and directed laboratories to report all occurrences of the contaminants at concentrations that are equal to or greater than the established MRL [FN2: US EPA. 2004. Statistical Protocol for the Determination of the Single-Laboratory Lowest Concentration Minimum Reporting Level (LCMRL) and Validation of Laboratory Performance at or Below the

Minimum Reporting Level (MRL); EPA 815-R-05-006; Office of Water: Cincinnati, OH, November 2004]. Based on EPA Method 533 [FN3: US EPA. 2019. Method 533: Determination of per- and polyfluoroalkyl substances in drinking water by isotope dilution anion exchange solid phase extraction and liquid chromatography/tandem mass spectrometry; Office of Ground Water and Drinking Water: Cincinnati, OH, November 2019.] for the analysis of 25 PFAS for UMCR 5, the procedure to determine the lowest concentration minimum reporting level (LCMRL) and validation of laboratory performance at or below the minimum reporting level (MRL), all results below the MRL should be considered "not detected" (ND) and reported as ND or less than the MRL (e.g., <2.0).

PQLs are based on data from a Performance Evaluation Study or by applying a multiplication factor to the analytical Method Detection Limit (MDL). EPA should use UCMR 5 data to develop MRLs for each PFAS they intend to regulate and compliance with MCLs should be determined based on the annual average at each sampling point for results that are at or above EPA's established MRLs for each PFAS. If EPA intends to use trigger levels, the use of a trigger level below the MRL, which is below the established analytical method's ability to reliably measure the target chemical, is inappropriate.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document. Regarding the use of results below PQLs for determining monitoring frequency and rule trigger levels, please see sections 8.2.1 and 8.8 of the EPA response in this *Response to Comments* document, respectively. For a discussion of laboratory capability and the PQLs, please see section 5.1.2 of the EPA response in this *Response to Comments* document. As is often used for other NPDWRs, the EPA has adopted PQLs for PFAS instead of MRLs. These PQLs are based on the UCMR 5 MRLs. For a discussion of the PQLs, please see section VII of the final rule preamble and section 7.2 of the EPA response in this *Response to Comments* document.

Metropolitan Water District of Southern California (Doc. #1777, SBC-045433)

A related issue is EPA's following proposal: "[W]hen calculating the running annual averages, rather than using zero for sample results less than the PQL, EPA seeks comment on instead using the proposed rule trigger levels (i.e., 1.3 ppt for PFOA and PFOS) in the case where PFAS are detected but below their proposed PQLs. This would have the potential to be more protective in the long run than counting sampling results below the PQL as zero and provide PWSs greater forewarning that their results may exceed the MCLs."[FN15: 88 Fed. Reg. at 18667; see also 88 Fed. Reg. at 18682.] According to the SDWA, EPA typically assigns zero to samples below the method detection limit (MDL), not to samples below the associated PQL. [FN16: 66 Fed. Reg. 6990 (Jan. 22, 2001).] Metropolitan recommends that EPA consider EPA Region 3's Regional Guidance on Handling Chemical Concentration Data Near the Detection Limit in Risk Assessments for possible approaches to reporting non-detects, such as using half the detection limit. [FN17: https://www.epa.gov/risk/regional-guidance-handling-chemical-concentration-data-near-detection-limit-risk- assessments.]

EPA Response: The EPA agrees that under NPDWRs for some other chemical contaminants, values below a specified threshold (such as the "detection limit") are replaced with zeroes in compliance calculations. The EPA-approved methods do not include MDLs, but rather define and require the confirmation of MRLs which are distinctly different from MDLs. For the PFAS NPDWR, the EPA did not define MRLs for PFAS contaminants, but established PQLs, as discussed in sections V and VII of the final rule preamble, to evaluate analytical feasibility for the determination of MCLs. The EPA considered this feedback and the regional guidance document referenced before developing the final rule; the referenced guidance was prepared for the Hazardous Waste Management Division, not for the purposes of evaluating drinking water data. Please see section 8.2 of the EPA response in this *Response to Comments* document for more information about the EPA's decision that levels below the PQLs will be replaced with zeroes in compliance calculations. Additionally, the EPA notes that results below the PQLs will only be utilized for the determination of monitoring frequency (please see sections 8.1.2 and 8.8 of the EPA response in this *Response to Comments* document).

San Diego County Water Authority, CA (Doc. #1779, SBC-045290)

Running Annual Average

The Water Authority supports EPA's proposed approach of using a running annual average to calculate compliance. We also support using zero to calculate the average for compliance purposes if a sample result is less than the PQL. We believe this approach makes sense considering the reduced accuracy of testing at the very low concentrations in the proposed rule.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document.

Palm Beach County Water Utilities Department (Doc. #1802, SBC-045336)

Page 18682, IX.B. Third column last paragraph, "When calculating the running annual averages, if a sample result is less than the PQL for the monitored PFAS, EPA is proposing to use zero to calculate the average for compliance purposes. For example, if a system has sample results for PFOA that are 2.0, 1.5, 5.0, and 1.5 ppt for their last four quarters at a sample location, the values used to calculate the running annual average would be 0.0, 0.0, 5.0, and 0.0 with a resulting PFOA running annual average of 1.3 ppt.":

PBCWUD Comment: If calculating compliance based on the anything below the PQL of zero is used in the calculation, PBCWUD recommends using the MCLs levels to determine when to go on reduced monitoring, like as performed by inorganic standards. Once 4 quarters are below MCL, reduced monitoring can be approved.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document. For a discussion of criteria to qualify for different monitoring frequencies

and rule trigger levels for reduced triennial monitoring, please see sections 8.1.2 and 8.8 of the EPA response in this *Response to Comments* document, respectively.

National Ground Water Association (NGWA) (Doc. #1804, SBC-045458)

EPA should create a management path of review for samples that fail the MCL but have previously met the standard. Follow up sampling should be considered before designating a water system as out of compliance.

NGWA has prepared "The Practical Guide for PFAS Sampling" to guide field sampling. This guide is published on the NGWA website at: https://my.ngwa.org/NC__Product?id=a18Ht00000ExtFaIAJ.

Compliance - The proposed rule is dynamic and potentially difficult to comply with, as different constituents may drive the risk from sampling event to sampling event. Furthermore, conditions may exist in which a water system is within standards for one sampling event only to be found above standards on the next, the difference being a small change in concentration. Process requirements of the regulation should provide for follow up sampling in such cases before finding a water system out of compliance, particularly for small systems which may have to invest substantially in treatment technology.

EPA Response: The EPA acknowledges the resource provided on PFAS sampling. Basing MCL compliance, which will likely drive treatment decisions, on an RAA appropriately accounts for variability in concentrations present in the same location on different dates and will likely alleviate the commenter's concern that "a small change in concentration" would result in noncompliance. Regarding follow-up sampling, states may require confirmation samples in situations they specify. Please see the section 8.2 of the EPA response in this *Response to Comments* document for a discussion of calculating the RAA and the samples that are considered when performing the calculation.

Earthjustice et al. (Doc. #1808, SBC-046116)

B. EPA Should Account for PFAS Detections Below the PQL When Determining MCL Compliance

To ensure compliance with the MCL and to protect communities from dangerous PFAS exposures, EPA must consider all PFAS detections when calculating MCL compliance. EPA has proposed determining initial MCL compliance based on a "running annual average," which considers a water provider's average PFOA concentration, PFOS concentration, or hazard index over four consecutive quarters to determine whether the provider has exceeded the MCL. [FN185: Id. at 18,667.] But when calculating the running annual average, EPA has proposed treating all PFAS detections below a chemical's PQL—4 ppt for PFOA, PFOS, and PFNA; 5 ppt for GenX; and 3 ppt for PFHxS and PFBS—as if they were non-detects. [FN186: Id. at 18,667; see id. at 18,680 (listing PQLs for different PFAS chemicals).] This approach ignores measurable

PFAS exposures and understates PFAS risks. For instance, if a water provider detected quarterly PFOA concentrations of 3.8 ppt, 3.8 ppt, 3.8 ppt, and 15 ppt, the mathematical average would be 6.6 ppt—more than 50 percent higher than the 4 ppt MCL. However, the average for the purpose of determining MCL compliance would be 3.75 ppt, since all of the 3.8 ppt detections would be replaced with zeros, meaning the provider would be considered in compliance with the MCL and no additional treatment would be required. EPA's discounting of sub-PQL detections is scientifically unsupported, contrary to longstanding SDWA regulations, and inconsistent with other parts of EPA's proposed rule.

As EPA acknowledges, "almost all laboratories" can detect the PFAS at issue at levels below the chemicals' respective PQLs. [FN187: Id. at 18,667.] The PQL reflects the capacities of some of the least sophisticated laboratories; it is, according to EPA, the "minimum quantitation level that . . . can be achieved by capable analysts at 75 percent or more of the laboratories using a specified analytical method." [FN188: Id. at 18,666.] In a prior rulemaking, EPA found that "49 of the 54 laboratories seeking EPA approval" to test PFAS in drinking water "included a lowest PFAS calibration standard level at 1 ppt or lower, with the median lowest calibration level among all laboratories at 0.5 ppt." [FN189: Id. at 18,667; see also id. (finding that "the overwhelming majority of laboratories with the necessary instrumentation to support PFAS monitoring have the capability to provide screening measurement results above … 1⁄3 of the MCL (i.e., 1.3 ppt for PFOS or PFOS)."] Given that "the overwhelming majority of laboratories" can detect PFOA, PFOS, and other PFAS below their PQLs, there is no reason for EPA to disregard those detections and treat PFAS-contaminated water as if it were PFAS-free when determining MCL compliance.

EPA's proposed approach is contrary to longstanding EPA regulations, which consider all detections above the method detection limit ("MDL"), a level that is distinct from—and lower than—the PQL. The MDL reflects the "minimum measured concentration of a substance that can be reported with 99% confidence that the measured concentration is distinguishable from method blank results." [FN190: 40 C.F.R. Part 136 App'x B; 40 C.F.R. § 141.2.] As a "general rule," EPA sets the PQL at a level that is 5–10 times greater than the MDL. [FN191: Id. at 18,666; National Primary Drinking Water Regulations; Volatile Synthetic Organic Chemicals, 50 Fed. Reg. 46, 902, 46,906 (Nov. 13, 1985) ("EPA believes that setting the PQLs in a range between 5 and 10 times the MDL achieved by the best laboratories is a fair expectation for most State and commercial laboratories.").] EPA's SDWA regulations governing monitoring and analytical requirements for organic chemicals, such as PFAS, state that "[i]f a sample result is less than the detection limit, zero will be used to calculate the annual average." [FN192: 40 C.F.R. § 141.24(f)(15)(v) (emphasis added).] Similarly, EPA's SDWA regulations governing inorganic chemicals, such as arsenic and mercury, provide that "any sample below the method detection limit shall be calculated at zero for the purpose of determining the annual average." [FN193: 40 C.F.R. § 141.23(i)(1) (emphasis added).] EPA acknowledges that the consideration of sub-PQL detections is "consistent with EPA's [National Primary Drinking Water Regulations] related to other [synthetic organic chemicals] and has the potential to . . . increase the public health

protection provided by this proposed regulation." [FN194: Proposed Rule, 88 Fed. Reg. at 18,682–83.] EPA should apply that same health-protective approach in its PFAS NPDWR.

EPA's justification for disregarding sub-PQL PFAS detections is unsupported and internally inconsistent. EPA claims that, even though most laboratories are able to detect PFAS below the PQL, "quantifying concentrations below the PQL for compliance purposes may decrease the precision and accuracy of the measured value." [FN195: Id. at 18,682.] But EPA's proposed approach is even less precise and accurate, since it would treat detectable PFAS levels as if they did not exist. Even if EPA has more confidence in PFAS detections above the PQL than below it, the relevant question is whether a detection above the MDL but below the PQL is more likely to reflect actual contamination or a false positive. EPA itself has acknowledged that "[f]or results between the detection limit and the PQL, EPA has determined that utilities would be able to reliably conclude analyte presence," meaning EPA's proposed approach of treating of all sub-PQL detections as zero understates real-world exposures and risks. [FN196: Id. at 18,670.] Moreover, elsewhere in its proposed rule, EPA considers detections at or below one-third of the PQL sufficiently reliable to "trigger . . . less frequent compliance monitoring." [FN197: Id. at 18,681.] In particular, EPA allows water systems to reduce their monitoring frequency from quarterly to once-every-three-years if their average PFAS concentrations are less than one-third of the MCL (i.e., 1.3 ppt for PFOA and PFOS and a hazard index of 0.33 for the HI PFAS). [FN198: Id.] In calculating that average, EPA considers PFAS detections that are well below the PQL. But there is no basis for considering sub-PQL detections to reduce water systems' monitoring obligations while ignoring those same detections when determining water systems' treatment obligations. For PFOA, PFOS, and the HI PFAS, EPA should instead consider all detections above the MDL to calculate a water system's annual running average and determine MCL compliance, including in hazard index calculations for HI PFAS.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document for a discussion of the use of results below the PQLs in calculating the RAA for compliance and sections 8.1.2 and 8.8 of the EPA response in this *Response to Comments* document for a discussion of the use of results below the PQLs for determining monitoring frequency and rule trigger levels. For further discussion of the PQLs, please see also section 7.2 of the EPA response in this *Response to Comments* document. The EPA-approved methods do not include MDLs, but rather define and require laboratory confirmation of MRLs which are quantifiable values and distinctly different from MDLs. For the PFAS NPDWR, the EPA did not define MRLs for PFAS contaminants, but established PQLs (based on the UCMR 5 MRLs), as discussed in sections V and VII of the final rule preamble, to evaluate analytical feasibility for the determination of MCLs. The agency maintains that using results below the PQLs for monitoring frequency determination purposes only will provide sufficient public health protection as it will require water systems to monitor more frequently if levels of regulated PFAS are detected at or above the rule trigger levels to ensure that water systems are not exceeding the MCLs (acknowledging that results below PQLs do not have the same level of precision and accuracy as the higher concentrations used to evaluate MCL compliance). Based on this, the EPA disagrees with the commenter that it is treating "detectable concentrations as if they did not

exist" because, the agency is, in fact, utilizing these values for their most appropriate purpose (i.e., to inform monitoring frequency).

Groundwater Resources Association of California (Doc. #1831, SBC-045356)

[Based on our review of this document, GRA offers the following general comments and recommendations for consideration by the EPA as they finalize these regulations:]

4. Clarity and Flexibility for PFAS Sampling and Monitoring Requirements: EPA is proposing PFOA/PFOS MCLs at their practical quantitation level (PQL) of 4 ppt with MCL goals (MCLGs) at zero. The Hazard Index based MCL for mixtures of PFHxS, HFPO-DA, PFNA, and PFBS is proposed at 1. The Hazard Index (HI) value is based on the additive ratio of the PFAS concentrations to each constituent's Health Based Water Concentration (HBWC), specified at 9 ppt, 10 ppt, 10 ppt, and 2000 ppt for PFHxS, HFPO-DA, PFNA, and PFBS, respectively. The PQL for PFHxS, HFPO-DA, PFNA, and PFBS are 3 ppt, 5 ppt, 4 ppt, and 3 ppt, respectively. Hence, the MCLs for PFHxS, HFPO-DA, PFNA, and PFBS are at 3x, 2x, 2.5x, and 667x the PQL for these constituents. The EPA's proposed regulations also define "trigger levels" at 1/3 of the MCLs based on the running annual averages from quarterly samples [FN6: Sampling frequencies may be reduced for small water systems or based on prior PFAS concentrations in relation to the trigger level and MCLs.]. Minimum Detection Levels (MDLs) for these PFAS range from 0.5 ppt to 1 ppt for PFOA/PFOS based on existing sampling and analysis standards. Section VI.A states that samples with concentrations less than the PQL would use a value of zero for their running annual average. We understand that the proposed approach allows for operational flexibility and reduces the impact from outliers or sampling/analysis errors. However, this approach makes it more difficult for PWS to track, report, and manage low levels of PFOA/PFOS at concentrations between the MDL and PQL. Ubiquitous low levels of PFAS [FN7: Recent studies indicate that certain PFAS can be present in rainwater at the proposed MCL concentrations, even in remote areas (https://pubs.acs.org/doi/10.1021/acs.est.2c02765)] complicate the sampling, monitoring, and management of PFAS. We recommend that EPA account for the MDL and PQL (same as the MCL for PFOA/PFOS) in the trigger levels established to make the distinction between PFOA/PFOS detections (above MDL but below PQLs) and non-detects (indicating the likely absence of PFOA/PFOS). One possibility would be to treat non-detects as zero and concentrations between MDL and MCL at half the MCL (MCL/2) or lower. Setting the MCLs higher than the PQL would also allow for operational flexibilities at low concentrations (at or below PQL). Setting the trigger levels for these constituents below the PQL will make it challenging for PWS to track, report, and manage low level PFOA/PFOS occurrences. In this regard, treating PFOA/PFOS concentrations below the PQL as zero would allow the PWS more operational flexibility and avoid undue sampling and monitoring costs due to erratic or erroneous PFAS data. Note that setting the concentrations at 0 for concentrations below PQL seems reasonable for PFHxS, HFPO-DA, PFNA, and PFBS as the HBWC (used for the HI calculation) for these contaminants is higher than the corresponding PQLs. As such, we recommend that EPA give due consideration to the balance between the

health protective, practical, and financial implications of setting the PFOA/pFOS MCLs and trigger levels at or below the PQLs for these contaminants.

EPA Response: Please see section V of the preamble and section 5.1.2 of the EPA response in this *Response to Comments* document regarding the PFOA and PFOS MCLs and their relationship to the PQLs. Please see sections 8.1.2 and 8.2 of the EPA response in this *Response to Comments* document for a discussion of the use of results below the PQLs and section 8.8 of the EPA response in this *Response to Comments* document for a discussion of rule trigger levels. The EPA notes that in the final rule, it made changes to the available monitoring frequencies and eligibility criteria for each. The final rule specifies that monitoring frequency is not determined based on an RAA concentration, rather they are based on individual sample results. The agency notes that sampling frequencies may be reduced for all sized water systems, not just small water systems (as incorrectly stated in the comment), based on sampling results being compared to the trigger levels and MCLs. The EPA disagrees with the commenter's concern that setting trigger levels below the PQLs would make it challenging for a PWS to track, report, and manage low level PFOA and PFOS occurrences. Laboratory results clearly indicate which PFAS were detected and which were not detected in a sample. The existence of trigger levels below the MCLs will increase a system's knowledge related to lower level PFOA/PFOS presence, even if the lower-level concentrations present are not known with as much precision and accuracy as higher values. For further information about data management infrastructure, please see also section 11.2 of the EPA response in this *Response to Comments* document. The agency notes that results for regulated PFAS equal to or exceeding the trigger levels are required to be reported by PWSs in their CCRs; please see section 9.1 of the EPA response in this *Response to Comments* document for a discussion of those requirements.

Pennsylvania Municipal Authorities Association (Doc. #1832, SBC-045792)

[PMAA's specific comments on the Proposal are as follows:]

16. EPA requested input on various issues in the Proposal, including whether it should consider an alternative approach to what is currently proposed for calculating compliance with MCLs. Specifically, EPA is requesting comment on situations where a PFAS chemical is detected, but the detection is below its proposed PQL. One option proposed by EPA is that, rather than using zero as the value of the specific PFAS chemical in the running annual average compliance calculation, the proposed trigger levels for the respective PFAS chemicals should be used in lieu of zero (1.3 ppt for PFOA and PFOS and 0.33 for each of the other four PFAS chemicals used in the Hazard Index approach – PFNA, PFHxS, PFBS and HFPO-DA, the latter of which are commonly referred to as GenX Chemicals). PMAA's position on this specific issue is that any detection of a PFAS chemical below its PQL should be entered as a zero in the running annual average calculation.

[PMAA's specific comments on the Proposal are as follows:]

17. The Proposal's requirements for monitoring and compliance indicates that most systems will not be in violation of an MCL until they have completed one year of quarterly sampling. However, in a situation where a quarterly sampling result will cause the running annual average to exceed an MCL, a system will be considered out of compliance with respect to that MCL immediately. This strict application ignores the practical impact of an anomalous sample during a particular quarter. PMAA believes that a better approach to addressing compliance would be to remove the "automatic" noncompliance determination from the Proposal. Rather, such determination should not be made until the end of a sampling quarter to allow municipal entities to take additional samples if, indeed, one sample provided an anomalous value. Such an approach would provide a more accurate picture of MCL compliance through a weighted approach, rather than sole reliance on a suspected anomalous sampling result.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document. The final rule establishes that results below the PQLs will be treated as zeroes in calculating the RAA and this provides an additional analytic buffer for utilities in their compliance calculations. Additionally, the RAA calculation is intended to account for fluctuations (e.g., where a quarterly sample may be slightly above the MCLs, but other quarterly samples are below the MCLs). Per the final rule, a primacy agency may require a confirmation sample in certain situations it specifies (e.g., following an unusually high result), and, in those instances, compliance determinations are made based on the average of all results immediately following all compliance samples being reported for the quarter. However, the EPA notes that, aside from any primacy agency-directed confirmation sample, additional samples collected by the system are considered voluntary samples, not compliance samples. The results of voluntary samples are not to be included in quarterly averages. In most circumstances, the EPA anticipates that a system would have no more than two compliance samples (the original, routine sample and a confirmation sample, if required) per quarter, and in both cases the sampling would occur at the direction of the primacy agency. For a discussion of potential "false positives," please see section 8.7 of the EPA response in this *Response to Comments* document.

Little Hocking Water Association (Doc. #1835, SBC-045512)

Objection to the use of a zero for the measurement value for values below the proposed PQL in the running average compliance calculation.

"EPA requests comment on whether EPA should consider an alternative approach to what is currently proposed when calculating compliance with proposed MCLs. Specifically, in the case where a regulated PFAS is detected but below its proposed PQL, rather than using zero for the measurement value of the specific PFAS in the running annual average compliance calculation, that the proposed rule trigger levels (1.3 ppt for PFOA and PFOS and 0.33 of each of the HI PFAS PQLs (ie., PFHxS=1.0, HFPO-DA = 1.7, PFNA = 1.3, and PFBS = 1.0)) be used as the values in calculating the running annual average for compliance purposes." LHWA provides the following comments in objection to using a zero for the measurement value of a specific PFAS

in the running annual average compliance calculation wherein the specific PFAS is detected below its proposed PQL:

1. EPA has specifically stated that many laboratories can reliably analyze PFAS to levels much less than the established PQL. Indeed, reporting limits for 18 PFAS under Method 537.1 are typically less than 2.0 ppt in datasets reported to LHWA.

2. The EPA has established an interim health advisory for PFOA and PFOS at 0.004 ppt and 0.020 ppt, respectively as well as proposed a MCLG of 0 for PFOA and PFOS.

3. For compliance purposes, the proposed methodology already allows for water to be delivered to a customer with concentrations that exceed the proposed MCL of 4.0 ppt for PFOS and PFOA to allow for variable concentrations, according to EPA.

4. Therefore, it follows that in order to be protective of the health of persons that are being exposed to concentrations that can exceed not only the proposed MCLG of zero, but also exceed, at times, the MCL, a value other than zero should be used.

5. One example dataset would be quarterly concentrations of either PFOS or PFOA at 3.9 ppt, 4.6 ppt, 4.8 ppt and 5.7 ppt. The running average of this dataset using zero for the one value of 3.9 ppt would be 3.775 ppt. Therefore, this system would be in regulatory compliance, but deliver water over the MCL 75% of the time and 100% of the time over the MCLG. This would not achieve the goal of protecting human health.

6. If the proposed rule trigger level of 1.3 ppt for PFOA and PFOS is substituted for the example dataset in #5 above, the result is 4.1 ppt and the system would be determined to be out of compliance and above the MCL. This type of analysis is particularly important where there is an exposed population and the reduction of exposure to additional PFAS is critical.

7. LHWA objects to the use of zero in the calculation of annual running averages for compliance purposes where reported concentrations are below the proposed PQL of 4.0 ppt for PFOA and PFOS.

8. Similarly, LHWA objects to the use of zero in the calculation of annual running averages for compliance purposes where reported concentrations are below the proposed PQLs for HFPO-DA, PFHxS, PFNA and PFBS for the same reasons stated above.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document. The EPA's use of an RAA to determine compliance is consistent with the currently available information that suggests that the developmental and chronic effects associated with exposure to the regulated PFAS are not known to represent immediate life-threatening health impacts. Additionally, the EPA clarifies that MCLs, not MCLGs, are the legally enforceable levels. MCLGs do not consider feasibility of treatment or analytical capabilities. Health advisories are also not legally enforceable levels, are distinctly different from an NPDWR, and do not account for feasibility of treatment or analytical measurement

capabilities. Please see section 5 of the EPA response in this *Response to Comments* document regarding MCLs and the determination of feasibility.

Citizens Energy Group (Doc. #1838, SBC-044856)

Citizens does not support using estimated results for compliance determination.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document.

Anonymous (Doc. #2311, SBC-047300)

Please provide guidance on how non-detect (ND) PFAS results will be handled when calculating the hazard index. EPA has failed to provide guidance on the handling of ND results for other contaminants regulated as total concentrations such as PCBs and dioxins leading to great conflict between regulatory agencies and responsible parties determining an approach. Some State regulatory agencies require the use of the limit of quantitation (LOQ) or 1/2 the detection limit (DL) be substituted for NDs for summations whereas most responsible parties prefer treating NDs as zeros, and most states do not have specific guidance on the matter making this a continuous source of contention. With commercial analytical laboratories barely meeting the proposed regulatory limits let alone the 1/3 trigger levels, this is going to be a big issue in determining compliance.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document for a discussion of determining compliance calculations. The final rule does not provide for replacing results below PQLs with a "limit of quantitation" or "half the detection limit" when calculating the Hazard Index for compliance determination purposes. For calculating compliance, such results would be treated as zero. Please see also section 8.1.2 of the EPA response in this *Response to Comments* document for a discussion of compliance monitoring frequencies and section 8.8 of the EPA response in this *Response to Comments* document for rule trigger levels to determine reduced triennial monitoring. Additionally, the EPA disagrees that commercial laboratories cannot consistently meet the proposed MCLs or trigger levels as the commenter claims. Please see section 5.1.2 of the EPA response in this *Response to Comments* document for a discussion of laboratory capability. Finally, the requirements for PCBs and dioxins are outside the scope of the final rule.

Richard Gelderman (Doc. #2820, SBC-047469)

Dear Assistant Administrator Fox,

I am writing to comment on the EPA's proposed National Primary Drinking Water Regulation for six per- and polyfluoroalkyl substances (PFAS).

I support the EPA's proposal to set strong, science-based drinking water standards and commend the EPA's recognition that both individual PFAS and chemical mixtures of PFAS threaten human health. PFAS-contaminated water has harmed the health of West Virginians for decades; this is a critical and long overdue step to protect our public health.

I urge the EPA to consider the following comments to strengthen the proposed rule to further protect and prioritize public health:

1) Compliance with the new drinking water standards should involve consideration of all detectable levels of PFAS, as opposed to treating all samples below the practical quantitation level as zero.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document.

Nancy Bouldin (Doc. #2822, SBC-047332)

2. When determining compliance with the new drinking water standards, the EPA should consider all detectable levels of PFAS, as opposed to treating all samples below the practical quantitation level as zero.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document.

Melda Clark (Doc. #2823, SBC-047334)

2. When determining compliance with the new drinking water standards, the EPA should consider all detectable levels of PFAS, as opposed to treating all samples below the practical quantitation level as zero.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document.

Karen Valentine (Doc. #2834, SBC-047336)

2. When determining compliance with the new drinking water standards, the EPA should consider all detectable levels of PFAS, as opposed to treating all samples below the practical quantitation level as zero.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document.

Monty Fowler (Doc. #2836, SBC-047338)

2. When determining compliance with the new drinking water standards, the EPA should consider all detectable levels of PFAS, as opposed to treating all samples below the practical quantitation level as zero.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document.

John Doyle (Doc. #2840, SBC-047341)

2. When determining compliance with the new drinking water standards, the EPA should consider all detectable levels of PFAS, as opposed to treating all samples below the practical quantitation level as zero.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document.

Laurine Yates (Doc. #2900, SBC-047343)

2. When determining compliance with the new drinking water standards, the EPA should consider all detectable levels of PFAS, as opposed to treating all samples below the practical quantitation level as zero.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document.

Mass comment campaign submitted by Jill Fischer (Doc. #3070, SBC-047345)

2. When determining compliance with the new drinking water standards, the EPA should consider all detectable levels of PFAS, as opposed to treating all samples below the practical quantitation level as zero.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document.

Citizens Campaign for the Environment (Doc. #3072-64, SBC-047393)

We also recommend EPA determine MCL and Hazard Index violations quarterly, not annually as proposed. Here in New York State, we look at these currently determined MCL violations quarterly. Doing this annually could result in the public being put at risk with contaminated drinking water for an unnecessarily long period of time.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document. The EPA has determined that, consistent with precedent for most other

chemical contaminants with chronic effects, compliance will be determined on the basis of an RAA. This monitoring and compliance framework accounts for temporal fluctuations in concentrations that may occur (e.g., because of unexpected events such as premature regulated PFAS breakthrough or temporary elevated source water concentrations). Thus, periodic occurrences of regulated PFAS that are slightly above the PQLs do not necessarily result in a violation of the MCL if other quarterly samples are below the PQL and the resulting RAA value is at or below the MCL. The EPA's use of a RAA to determine compliance is consistent with currently available information that suggests that the developmental and chronic effects associated with exposure to the regulated PFAS are not known to represent immediate life-threatening health impacts. Thus, the EPA has determined that its monitoring and compliance framework will be sufficiently protective of public health.

Greater Cincinnati Water Works (GCWW) (Doc. #1550, SBC-042697)

Section IX (Monitoring and Compliance Requirements) states that a system will not be considered in violation of an MCL until it has completed one year of quarterly sampling except for when a quarterly sampling result will cause the running annual average to exceed an MCL. In this case the system will be considered out of compliance immediately. We propose this be changed such that the system would not be out of compliance with the MCL until the end of the quarter to allow utilities to average out an anomalous value with additional samples. Including additional samples in the quarterly averaging is already required if additional compliance samples are collected, so this approach is consistent with existing requirements. For example, if a sample is collected at the beginning of the quarter for PFOA or PFOS with a concentration of 17 ppt (more than 4 times the MCL) the utility would be in immediate non-compliance. However, if they believe this is an anomalous value, additional samples could be collected throughout the quarter. Expanding on the example, if they began conducting monthly sampling, and had levels of 5 the other two months, the quarterly average would drop to 8.3. If other quarterly samples are even lower, the system could stay in compliance. This approach safeguards against giving undue weight to a single anomalous value and still ensures long term exposure is not excessive.

Thank you for the opportunity to comment on this proposed regulation. If I can answer any questions, please feel free to contact me at Bruce.Whitteberry@qcww.cincinnati-oh.qov.

Sincerely,

Bruce Whitteberry

Assistant Superintendent

Water Quality & Treatment Division

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document. The RAA calculation is intended to allow for fluctuations (e.g., where a quarterly sample may be slightly above the MCLs, but other quarterly samples are below the MCLs). Per the final rule, a primacy agency may require a confirmation sample in certain

situations it specifies (e.g., following an unusually high result), and, in those instances, compliance determinations are made based on the average of all results immediately following all compliance samples being reported for the quarter. However, the EPA would note that, aside from any primacy agency-directed confirmation sample, additional samples collected by the system are considered voluntary samples, not compliance samples. The results of voluntary samples are not to be included in quarterly averages. In most circumstances, the EPA anticipates that a system would have no more than two compliance samples (the routine sample and a confirmation sample, if required) per quarter, and in both cases the sampling would occur at the direction of the primacy agency. For a discussion of sampling contamination issues, please see section 8.7 of the EPA response in this *Response to Comments* document.

American Water Works Company Inc. (Doc. #1608, SBC-044010)

Determining Compliance

American Water supports the proposed regulatory approach of using a running annual average for determining compliance. This approach is consistent with the approach used for other contaminants that are sampled at the point of entry to the distribution system.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document.

Wyoming Department of Environmental Quality (WDEQ) (Doc. #1716, SBC-044750)

4. EPA Should Not Require Regulated PFAS Concentration Reporting Below the Practical Quantitation Limit (PQL) To Determine Monitoring Frequency

EPA has requested comment on the statement that EPA has "sufficient confidence that while measurements below the PQL may be slightly less precise and accurate, they are achievable by individual laboratories and appropriate for this intended purpose." However, EPA later states that "values below the PQL will not be used to determine compliance with the proposed MCLs as these PQLs are the lowest concentration of analyte that can be reliably measured within specified limits of precision and accuracy during routine laboratory conditions...and may not be achievable for some laboratories." EPA suggests that when calculating running annual averages for compliance assessment, any sample result less than the PQL of 4.0 parts per trillion (ppt) would be replaced by a zero concentration value. EPA also states that laboratory capacity issues would be anticipated if MCLs were proposed below 4.0 ppt. Consequently, EPA is requesting recommendations on alternative approaches for determining monitoring frequency and assessing PWS compliance. One approach EPA has suggested is using a Rule Trigger Level of one-third the MCL for PFOA and PFOS and one-third the HI for PFHxS, PFBS, PFNA, and HPFO-DA to determine monitoring frequency.

WDEQ is concerned that if the Rule Trigger Level approach is implemented as proposed, PWSs that report concentrations at or below the Rule Trigger Level may never be approved for reduced

compliance monitoring, due to the reduced precision and accuracy inherent in reporting analyte concentrations below their PQLs. Potentially, this could lead to rejected data, redundant sampling, and increased costs, even for systems below the PFAS MCLs. This in tum could lead to laboratory capacity issues while PWSs continue to submit samples that may not be quantifiable. Lab capacity issues would be further exacerbated by PWSs that hope to qualify for reduced monitoring submitting a high volume of samples to the few labs that can generate accurate, precise, quantifiable results at lower concentrations. This could potentially put at a disadvantage those PWSs that cannot realistically use those labs for their analysis, either because of increased cost or geography. Without access to qualified labs that can provide accurate data, small PWSs may ultimately implement more technical and expensive treatment technologies than are necessary to meet MCLs. Such technologies may not be feasible for small communities to install, much less operate and maintain over time. Additionally, WDEQ has concerns about setting a precedent for using analytical concentrations below PQLs for purposes of regulatory compliance, as the data is by definition lacking appropriate measurement precision and accuracy.

WDEQ recommends maintaining consistency with the proposed MCL concentrations for PFOA and PFOS and proposed HI calculation for assessing PWS compliance. WDEQ also recommends that monitoring frequency be based on MCL concentration values rather than setting a Rule Trigger Level of one-third the MCLs for determining compliance monitoring frequencies, due to the current inconsistency in PFAS analytical method precision and accuracy when measuring PFAS concentrations below 4.0 ppt. Doing so will meet the objective of protecting public health while ensuring that communities, particularly small communities, are not burdened with the implications and costs of obtaining data that lack precision and accuracy for purposes of regulatory compliance.

5. WDEQ Recommends Revising the Running Annual Average Calculation for Determining PWS Compliance with the Proposed PFAS NPDW Rule

EPA states, "a system will not be considered in violation of an MCL until it has completed one year of quarterly sampling, except in the case where, if a quarterly sampling result will cause the running annual averages to exceed an MCL at any sampling point (i.e. the analytical result is greater than four times the MCL). In that case, the system is out of compliance with the MCL immediately." If each entry point to the distribution system (EPDTS) is required to be a sampling point, the above statement assumes that each EPTDS provides an equal proportion of water to the total PWS distribution volume, which may not be realistic.

WDEQ recommends the running annual average calculations be revised to reflect the concentration of regulated PFAS from an EPTDS in context with the volume that that EPTDS provides to the PWS. This will prevent instances where an EPTDS with a PFAS MCL exceedance is of significantly lower volume that does not actually reflect a PFAS MCL exceedance in the PWS distribution as a whole, ensuring that a PFAS MCL violation and associated increased monitoring are not unnecessarily assigned to the PWS. Similarly, operator training will be critical to avoid quality assurance/quality control issues during sampling to ensure samples used in calculating annual averages are representative.

WDEQ also recommends that EPA clarify whether it will require periodic monitoring of the final distribution point of each PWS in addition to the EPTDS sampling points.

EPA Response: Regarding the use of values below the PQLs for the determination of monitoring frequency only and rule trigger levels, please see sections 8.8 and 8.2.1 of the EPA response in this *Response to Comments* document. For laboratory considerations, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

The EPA clarifies for the commenter that the RAA calculation will not utilize results below the PQLs as discussed in section 8.2 of the EPA response in this *Response to Comments* document, therefore no actions to address MCL exceedances will result from results below the PQLs. In the final rule, all results below the PQLs will be treated as zeroes in the compliance calculations, consistent with the commenter's recommendation.

The EPA disagrees with changing compliance calculations to account for the percentage of water a EPTDS provides to a PWS as a whole. As one EPTDS has the potential to provide water to a group of customers, the EPA has determined that compliance should be based on comparison of sampling results for each EPTDS to the MCL. As specified under § 141.905(b), if one sampling point is in violation of the MCL, the system is in violation of the MCL. This same approach is used in the regulations for other SOCs and VOCs. The EPA notes that there is no requirement to sample at the "final distribution point" of each PWS for regulated PFAS. Related to sampling issues, including background contamination concerns, please see section 8.7 of the EPA response in this *Response to Comments* document. As it develops implementation materials for the PFAS rule, the EPA will consider the suggestion that guidance cover operator training to reduce the potential for quality assurance (QA)/QC or sampling issues.

Wyoming Department of Environmental Quality (WDEQ) (Doc. #1716, SBC-044765)

14. Unclear Procedure Following a PFAS MCL Exceedance in a Regulated PWS

WDEQ recommends EPA provide clarification on the procedures that follow a PWS exceeding a proposed MCL. As written, the proposed PFAS NPDW rule is not clear on whether a PWS will be given a period of time to collect and provide confirmation samples or to adjust any PFAS treatment methods in place before the PWS is considered non-compliant. The WDEQ emphasizes the importance of quality assurance/quality control (QAQC) measures to ensure accurate and consistent data are obtained, and WDEQ encourages giving PWSs an opportunity to obtain confirmation samples to rule out QAQC issues if an exceedance is detected. The WDEQ recommends that EPA provide, for each PFAS with MCL values and PFAS with HI values, clarification on what PWSs can expect if a PFAS MCL exceedance occurs, what process will be followed to assess the exceedance and any potential QAQC issues, and how compliance will be measured, reported, and achieved.

EPA Response: Primacy agencies identify the required monitoring schedule for a system (consistent with the NPDWR) and in what circumstances, if any, a system must collect and

analyze a confirmation sample. Aside from a confirmation sample collected at the direction of a primacy agency, such as for a suspected QC issue, additional samples collected by the system would be considered voluntary samples, not compliance samples, and the results of voluntary samples are not to be included in quarterly compliance averages. In most circumstances, the EPA anticipates that a system would have no more than two compliance samples (the routine sample and a confirmation sample, if required) per quarter, and in both cases the sampling would occur at the direction of the primacy agency. With respect to an individual PFAS exceedance, at the national level, the EPA is not specifying the specific action that a water system must take, only that the water system is required to provide PN of the exceedance and take some action to reduce regulated PFAS concentrations to at or below the MCLs. MCL compliance is based on an RAA, as discussed in section 8.2 of the EPA response in this *Response to Comments* document, which is reassessed after every quarter. The exact timeframe for assessing MCL violations is determined by the primacy agency and will depend on whether a confirmation sample is requested. For a discussion of laboratory QA/QC concerns, please see section 8.7 of the EPA response in this *Response to Comments* document. A system achieves MCL compliance by providing drinking water at an EPTDS with RAA concentrations of regulated PFAS that are consistently no higher than the MCLs. MCL violations are assessed by the primacy agency, and the primacy agency reports the violations to the EPA. MCL violations also require public notice and must be summarized in CCRs. Please see sections 9.1 and 9.2 of the EPA response in this *Response to Comments* document for discussions of comments on CCR and public notice requirements, respectively. These requirements are discussed in section IX of the preamble to the final rule and are codified in Subparts O and Q of Part 141 in the CFR.

Wisconsin Department of Natural Resources (Doc. #1828, SBC-044807)

Laboratory Reporting Levels and Calculating the Running Annual Average

WDNR believes laboratories can reliably detect and report PFOA and PFOS at 2.0 ppt. Therefore, it is not appropriate to use zeros in the running annual average (RAA) for any samples below 4.0 ppt (e.g. 3.9 ppt would equal 0 ppt for purposes of RAA calculation in the proposed rule). Averaging zeros for quarters where the system was just below 4.0 ppt along with any quarterly results above 4.0 ppt would result in a system being under the 4.0 MCL for the RAA. However, if results between 2.0 ppt and 4.0 ppt are included in the running annual average (rather than included as a "zero") along with results that are above 4.0 ppt, the system would be determined to be above the MCL and would be out of compliance based on reported data.

WDNR looks forward to further engagement with EPA as we work together to implement this PFAS drinking water regulation.

Please contact me (steve.elmore@wisconsin.gov, 608-259-6100) if you have questions or would like to discuss these comments.

Sincerely,

Steven Elmore, Director

Drinking Water and Groundwater Program

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document.

Washington County Department of Public Health and Environment (Doc. #1739, SBC-043567)

Proposal to treat results below the PQL as zero for compliance purposes

Part IX, subpart B of the rule preamble discusses how to handle sample results that are less than the PQL for monitored PFAS.

Comments:

The county, in agreement with the Minnesota Department of Health (MDH), asserts that any PFAS results from a certified laboratory that are above the laboratory RLs should be included when determining compliance with the MCLs. Due to the MCLs for PFOS and PFOA being set at the PQLs, and EPA's proposal to treat any result below the PQL as zero for compliance purposes, systems with valid data from laboratories showing they are out of compliance based on a traditionally-calculated Quarterly Running Annual Average (QRAA) will be treated as in compliance. This is problematic in regard to public perception, as it conflicts with how the QRAA for MCL compliance is typically determined for other contaminants (where results below the MCL are included in QRAA calculations), and moreover reduces the public health protection that could be provided under this proposed rule.

It is our understanding that at least in Minnesota, laboratories already confidently achieving RLs below 4 ppt and information from our Public Health Laboratory (PHL) and the Environmental Monitoring Coalition (EMC), it appears that 4 ppt is currently not "the lowest concentration of analyte that can be reliably measured within specified limits of precision and accuracy during routine laboratory conditions."

To address the issues described here, EPA should make one of the following changes to the proposed NPDWR for PFAS:

• Allow any results above laboratory RLs to be used for determining a QRAA for compliance and set a required RL for laboratories that is below the MCL and achievable, such as 2 ppt for PFOS and PFOA.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document. For discussions of the PQL and laboratory capabilities, please see sections 5.1.2 and 7.2 of the EPA response in this *Response to Comments* document, as well as sections V and VII of the preamble to the final rule. The agency clarifies for the commenter that the EPA has established PQLs for regulated PFAS, but no MRLs. Under both EPA-approved PFAS

drinking water analytical methods, a laboratory verifies its own MRL and the MRL can vary (see section 7 of the EPA response in this *Response to Comments* document).

City of Tulsa Water and Sewer Department (CoT WSD) (Doc. #1785, SBC-043780)

2. 88 FR 18667 (also 88 FR 18682, 18730). EPA requests comment on using zero for sample results less than PQL, or using alternative of one-third PQL for each PFAS.

CoT WSD responds that using zero for sample results less than PQL is consistent with current compliance calculations for other Synthetic Organic Compounds (SOC) NPDWRs at 40 CFR 141.24(h)(11)(v). The proposed PFAS compounds will be added to the table of SOC MCLs at §141.61(c) (see 88 FR 18748), therefore, the current SOC compliance calculation method should apply. EPA erroneously states at 88 FR 18682 that using one-third of the PQL is "largely consistent with EPA's NPDWRs related to other SOCs," but that is not what is in the regulation at this time.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document. In the final rule, the PFAS MCLs are not added to the table of SOC MCLs in §141.61(c), but are presented in their own table Additionally, while the monitoring requirements are similar to the SMF for other SOCs, the regulated PFAS monitoring requirements are separate and included in their own Subpart Z.

Regarding the commenter's claim of an erroneous EPA statement in the proposed rule preamble (that using one-third the PQL is "largely consistent with EPA's NPDWR's related to other SOCs"), the agency notes the following as a more complete excerpted text, "While this approach may be more complicated to implement than using zero when below the PQL, it is largely consistent with EPA's NPDWRs related to other SOCs and has the potential to slightly increase the public health protection provided by this proposed regulation." The EPA notes this language was in the context of the agency requesting public comment on use of alternative values to zero in compliance calculations. For the PFAS NPDWR, the EPA has adopted the use of trigger levels, rather than "detection limits" as it done for some other regulated SOCs.

Jeniece Neville (Doc. #1924, SBC-046544)

Many communities in our local area of Northeastern Illinois have non-detectable levels of the newly proposed regulated PFAS constituents in drinking water, but some communities have a history of certain of the PFAS compound(s) hovering around the detection limit.

Since most lab methods (LC/MS/MS) per Methods 533 and 537.1 cannot detect PFAS constituents below approximately 2 ppt, my colleagues and I are wondering if, when calculating the H.I. ratios that pertain to each of the 4 H.I. PFAS chemicals, for N.D. levels of these chemicals, should we input a value of 2 ppt to account for the possibility of the constituents existing up to that amount without being detected in a sample? Or, should we simply assume a value of 0 ppt for the non-detected PFAS constituent?

We are specifically wondering about the cases where there have been detectable levels of the compound(s) in question in other tests that happen to hover around the detect limit. Otherwise, we would assume that a N.D. lab result would equate to a ppt of 0 to be factored into the reported H.I.

Thank you!

Jeniece Neville

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document. Compliance determinations rely exclusively on results at or above PQLs. If a laboratory result for a regulated PFAS is below the PQL, a value of zero would be substituted, whether calculating an RAA to compare to a single-PFAS MCL or to a Hazard Index MCL.

Jonathan O'Donnell (Doc. #2338, SBC-046260)

Treating concentrations of PFOA and PFOS that are less than 4 ppt as 0 ppt for compliance annual averages will allow many sites that are consistently above the trigger level but just below 4 ppt to avoid quarterly testing. I recommend treating concentrations that are less than 4 ppt as 2 ppt for compliance annual averages.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document regarding the determination of compliance and use of values below the PQLs. The use of results below the PQLs for establishing monitoring frequencies and trigger levels are discussed in sections 8.1.2 and 8.8 of the EPA response in this *Response to Comments* document. As results below the PQLs will be used in the determination of monitoring frequency, the EPA disagrees with the commenter that water systems with results between the rule trigger levels and MCLs will not be required to monitor more frequently because they will be required to conduct either quarterly or annual monitoring depending on the specific results.

Greater Cincinnati Water Works (GCWW) (Doc. #1550, SBC-042696)

EPA has requested comment on whether the proposed trigger levels (i.e. 1.3 ppt for PFOA and PFOS) should be used instead of zero when calculating the running annual averages for compliance when PFAS are detected but below their proposed PQLs. GCWW supports the currently proposed approach of using zero for compliance. Using the proposed trigger level is arbitrary and is essentially requiring compliance based on numbers which, by definition, cannot be reliably quantified by all laboratories. In section IX of the preamble (Monitoring and Compliance Requirements), the EPA states "...at the proposed trigger level, the measurement is primarily useful in determining whether the contaminant is present in a sample and for evaluating monitoring flexibilities, rather than to determine its specific concentrations." It is inappropriate to base compliance on measurements which are not useful in determining specific concentrations. This is overly conservative and will not result in significant health benefit.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document.

Massachusetts Water Works Association (MWWA) (Doc. #1601, SBC-042889)

In some instances, Massachusetts PWSs have been advised to take sources out of service so that finished water PFAS concentrations are below the MMCL. This option will not be possible for most water systems. Some water systems have limited sources and those sources may be constrained by other regulatory programs that govern water withdrawal quantities (in Massachusetts, this is the Water Management Act). Flexibility for limited use of impacted sources during peak demand periods may be necessary for public safety (adequate pressure and fire protection) or to maintain reasonable operating costs while permanent solutions are implemented. For this reason, we support determining compliance on a running annual average.

EPA Response: Please see section 8.2 of the EPA response in this *Response to Comments* document.

8.3 Previously-Acquired Data

Summary of Major Public Comments and EPA Responses

The EPA received many comments on the provision described in the proposed rule that allows PWSs to use previously-collected data to satisfy some or all of the initial monitoring requirements. This provision, under 141.902(b)(1)(vi), allows systems with appropriate historical monitoring data for each EPTDS, collected using EPA Methods 533 or 537.1 as part of UCMR 5 or a state-level or other appropriate monitoring campaign, to use that monitoring data to satisfy some or all of the initial monitoring requirements. The EPA proposed that data collected after January 1, 2023, be accepted for EPTDS samples, and data collected between January 1, 2019, and December 31, 2022, also be accepted if below the proposed rule trigger level. Additionally, the EPA proposed that if a system had conducted prior monitoring involving fewer than the number of samples required for initial monitoring under this PFAS NPDWR, then all surface water systems, GWUDI systems, and groundwater systems serving greater than 10,000 would be required to collect at least one sample in each quarter of a calendar year that was not acquired and groundwater systems serving 10,000 or fewer would be required to collect one sample in a different quarter of the calendar year than the one in which the previous sample was acquired.

Of commenters that provided input on this proposed allowance, nearly all supported the use of previously-collected data to support the initial monitoring requirements. The EPA agrees with these commenters that appropriate, previously-collected data should be allowed and notes that there will be significant data available from UCMR 5 monitoring and from the many states that have been proactively conducting PFAS drinking water monitoring. This will allow for a significant opportunity to reduce burden for numerous water systems, as well as decrease the potential for laboratory capacity issues. One commenter suggested that the use of this data may not be sufficiently representative of current PFAS concentrations in drinking water systems as

the laboratory analyses previously used may not have been sufficiently sensitive to detect the analytes, relative to the proposed PFAS regulatory standards. The EPA disagrees with this commenter as the analytical methods proposed for PFAS analysis were available for the majority of the time period (i.e., 2019 and after) in which data are allowed to be used to satisfy the initial monitoring requirements. Furthermore, the rule provides that a primacy agency may choose to not allow these data to satisfy initial monitoring requirements and may require more frequent monitoring on a system-specific basis. Additionally, the EPA clarifies that previous monitoring does not automatically qualify water systems for reduced compliance monitoring; rather it is the results from that monitoring that determine the eligibility for a reduced compliance monitoring schedule.

Many commenters suggested that the use of these data should be at the state's discretion and requested that the EPA provide additional flexibility to the primacy agencies in the determination of which data are allowed, including the number of samples and the QA requirements. Moreover, several commenters asked that the EPA clarify how much additional data would be needed to satisfy the initial monitoring requirements if a previous monitoring campaign included less sampling than required under the rule initial monitoring requirements. Specifically, a few commenters noted that, under the requirements of UCMR 5 monitoring, groundwater systems serving greater than 10,000 would have results from two sampling events, not the four needed to satisfy the initial monitoring requirements of this rule. Commenters requested that the EPA explain if these UCMR 5 systems would need to collect additional (supplemental) samples. A few commenters suggested UCMR 5 monitoring should sufficiently meet the requirements for all systems, even though the proposed rule requires quarterly sampling for all groundwater systems serving greater than 10,000. In the final rule under 141.902(b)(1)(viii), the EPA is maintaining that if a system has some previously collected results, but fewer than the number required to satisfy the initial monitoring requirements, they must conduct additional monitoring such that it, coupled with the previous monitoring, meets the requirements of this rule under 141.902(b)(1)(v). All surface water and GWUDI systems, and groundwater systems serving greater than 10,000, must collect the required additional samples 2-4 months apart from the months with available data, without regard to year, such that all quarters are represented. This would apply to all types of previously collected data, including from UCMR 5 systems. Please see section 8.1.2 for the EPA's responses regarding the initial monitoring requirements, specifically for groundwater systems serving greater than 10,000 that would need to supplement UCMR 5 data to satisfy the initial monitoring requirement.

Several commenters requested that the EPA clarify whether only samples collected under UCMR 5 would be allowed to fulfill initial monitoring requirements, or if data under other monitoring efforts, such as state monitoring, would also be acceptable. As provided in the final rule, a state may accept results from all appropriate monitoring efforts, as determined by the state, including, but not limited to, UCMR 5 and other state-led efforts.

Several commenters provided various comments related to QA requirements for previously collected data, including data analysis methods, MRLs, and data collection timeframe. A few

commenters expressed that the EPA should allow the use of results from modified EPA methods and/or other state-developed analytical methods. The EPA disagrees with these commenters. While there are other methods that have been used for data collection and analysis, the EPA is requiring that any data used for this rule be collected and analyzed using Methods 533 and 537.1 to ensure consistency across analytical results, as well as to align with the final rule analytical method requirements described in 141.901. A few commenters requested that the EPA provide additional information on reporting level requirements of the data, with one commenter suggesting that the EPA should not allow this data to be used for initial monitoring purposes if the reporting limits of the laboratory are higher than the EPA's proposed PQLs. The rule provides that the available data can be used regardless of reporting or detection limits to satisfy the initial monitoring requirements; however, given these factors, the results may not support determinations for reduced compliance monitoring. Regarding data collection timeframes, a few commenters questioned why data collected prior to 2023 would not be accepted where the laboratory was not able to produce results below the proposed rule trigger levels. In response, the EPA has modified the rule to allow data from January 1, 2019, and later to satisfy initial monitoring requirements, even if the laboratory is not able to produce results below the final rule trigger levels if it meets all other requirements (including being analyzed using Methods 533 and 537.1). Data collected prior to 2019 may not be representative of water quality conditions and likely would not have been analyzed using these methods (given when they were published). The EPA notes if the results exceed the final rule trigger levels the system will not be eligible for a reduced monitoring schedule at that EPTDS.

Individual Public Comments

Great Lakes Water Authority (GLWA) (Doc. #1558, SBC-042554)

Allow the use of previously acquired monitoring data to satisfy initial monitoring requirements including the data collection timeframe requirements and if other QA requirements should be considered.

Proactive utilities that have already been monitoring their systems should not be required to go backwards because USEPA is catching up with states that have regulated. Additionally, most QA/QC issues involved with sample collection and analysis are more likely to yield a false positive or higher concentration reported than the opposite. Therefore, previously acquired monitoring data should be able to satisfy initial monitoring requirements.

EPA Response: Please see section 8.3 of the EPA response in this *Response to Comments* document.

Missouri Department of Natural Resources (Doc. #1563, SBC-042531)

EPA requests comment on its proposal to allow the use of previously acquired monitoring data to satisfy initial monitoring requirements including the data collection timeframe requirements and if other QA requirements should be considered.

The Department supports the use of previously acquired monitoring data at the state's discretion. This includes QA requirements. For instance, the Department used a modified 537 method (no field blanks) to decrease the cost of sampling during our occurrence screening. For systems with no detections, this would have no impact on the validity of the data and this data should be acceptable for initial monitoring. For systems with detections, the Department collected and analyzed confirmation samples using both approved methods without modification. The Department believes that all of this data should be valid for purposes of initial monitoring and the rule should provide flexibility to allow this.

EPA Response: Please see section 8.3 of the EPA response in this *Response to Comments* document.

American Water Works Company Inc. (Doc. #1608, SBC-044014)

Using Previously Collected Data

American Water agrees with the U.S. EPA's intention to reduce the burden on groundwater systems serving 10,000 or fewer people by only requiring two samples within a ninety-day period for initial monitoring. We also appreciate the proposed use of previously collected data to fulfill initial monitoring requirements, but urge the U.S. EPA to:

• Review the regulatory language to ensure that it accurately reflects the intent of the preamble language that any samples collected after January 1, 2023, that were collected consistent with the methods described under UCMR 5 would be acceptable to be used as previously collected data. As currently written, the regulatory language could be misinterpreted to only allow data specifically required and collected under UCMR 5 to qualify, which does not appear to be the intent based on the preamble.

o Regulatory language: "Such data may only be used if it was collected in accordance with § 141.40 and that such samples were collected starting on or after January 1, 2023." (Page 18751)

o Preamble language: As proposed, systems would be allowed to use previously collected monitoring data to satisfy the initial monitoring requirements. In general, a system with appropriate historical monitoring data for each distribution system entry point, collected using EPA Methods 533 or 537.1 as part of UCMR 5 or a state-level or other appropriate monitoring campaign, could use that monitoring data to satisfy initial monitoring requirements. EPA is proposing that systems with previously acquired monitoring data from UCMR 5 will not be required to conduct separate initial monitoring for regulated PFAS. To satisfy the initial monitoring requirements for these systems using UCMR 5 data, data collected after January 1st, 2023, can be used for entry point samples. While EPA expects most systems serving 3,300 or greater will have UCMR 5 data, EPA is also proposing that systems with previously acquired monitoring data from outside UCMR 5, including State-led or other appropriate occurrence monitoring using EPA methods 533 or 537.1 will also not be required to conduct separate initial monitoring for regulated PFAS. This addition may allow systems serving fewer than 3,300 to

satisfy the initial monitoring requirements. Data collected after January 1st, 2023, can be used for entry point samples. Data collected between January 1st, 2019, and December 31, 2022, may also be used if it is below the proposed rule trigger level of 1.3 ppt for PFOA and PFOS and an HI of 0.33 for PFHxS, HFPO–DA, PFNA, and PFBS. The additional analytical requirement for older data is to ensure the use of these data is adequately representative of current water quality conditions. If systems have multiple years of data, the most recent data must be used." (Page 18683)

• Acknowledges that UCMR 5 sampling for groundwater systems serving over 10,000 people will not be adequate to qualify for reduced monitoring. The U.S. EPA should review cost estimates to confirm that the inability of these systems to qualify for reduced monitoring is accurately captured.

Further, using previously collected data is appropriate for reduced monitoring but not for determining compliance, as water systems may have made treatment changes or other changes to impact the quality of the water reaching their customers.

EPA Response: Please see section 8.3 of the EPA response in this *Response to Comments* document. For the EPA response related to the EPA's sampling cost estimates, please see section 13.3.4 of the EPA response in this *Response to Comments* document.

Minnesota Department of Health (MDH) (Doc. #1610, SBC-042856)

Use of Previously Acquired Data to Meet Initial Monitoring Requirements

Per Part XIV, Section IX of the rule proposal:

"EPA requests comment on its proposal to allow the use of previously acquired monitoring data to satisfy initial monitoring requirements including the data collection timeframe requirements and if other QA requirements should be considered."

MDH Comments:

· Minnesota, and many other states, have proactively completed PFAS monitoring at public water systems in order to better identify systems with elevated PFAS levels and allow for communication and action in advance of rule finalization. The ability to use this previously collected data, as well as UCMR 5 data, provides an opportunity for the efficient use of public resources where the state already possesses appropriate information on PFAS presence. As such, we support the use of previously collected to satisfy initial monitoring requirements. Our further comments seek both clarification and some flexibility in how this data is used.

· The rule proposal does not clearly define how much previous data needs to be collected to satisfy initial monitoring. In part IX, subpart C of the rule preamble, the following is stated: "EPA is proposing that systems with previously acquired monitoring data from UCMR 5 will not be required to conduct separate initial monitoring for regulated PFAS." However, previously in part IX, subpart A, it is stated that "EPA is proposing that, consistent with the SMF for SOCs,

groundwater systems serving greater than 10,000 and all surface water systems are initially required to monitor quarterly within a 12-month period." Since groundwater systems are only sampled twice under UCMR5, it is unclear if UCMR5 sampling is sufficient to meet initial monitoring requirements for large groundwater systems or if additional data would be needed in between UCMR5 sampling events.

· For small groundwater systems not sampled under UCMR5, it is unclear how much previously acquired state monitoring data is needed to satisfy initial monitoring. Minnesota conducted statewide PFAS testing between 2020 and 2023, but most systems were only tested once.

· MDH requests that EPA allow states flexibility to determine if previously acquired monitoring data satisfies initial monitoring for these small systems. For example, if a system was tested only once under our statewide PFAS sampling effort, but there were no detections for any PFAS – and detection limits were below the trigger level – MDH would like the opportunity to consider those results for use in satisfying initial monitoring and starting the system on reduced monitoring.

EPA Response: Please see section 8.3 of the EPA response in this *Response to Comments* document.

Colorado Water Utility Council (CWUC) (Doc. #1622, SBC-044040)

21. EPA requests comment on its proposal to allow the use of previously acquired monitoring data to satisfy initial monitoring requirements including the data collection timeframe requirements and if other QA requirements should be considered.

a. See 19.b and 32. Consider allowing up to 5 years of previous data as long as the PQL of 4.0 ppt has been met. However...EPA has to allow labs to provide UCMR5 results down to the MDL (ie "j-flag" data) which currently isn't allowed. Contract laboratories performing UCMR5 analysis have been directed by EPA to not report any data below the established PQL of 4.0 ppt. This would be an incredible burden on labs to re-send every single report to every single system and this time include the MDL data.

b. This is another example of why raising the Trigger Level to 4.0 ppt and the MCL to

8.0 ppt is advisable. That data would be readily available and is confirmed to be accurate and reliable.

c. Another QA requirement to consider is that with updated EPA regulation on MDL calculations, MDLs are likely to be higher and to fluctuate year to year and with new and expanding equipment/facilities. Therefore, the EPA should only utilize data to determine compliance using established reliable and accurate PQL data, and do not utilize any data below 4.0 ppt for compliance determinations.

EPA Response: Please see section 8.3 of the EPA response in this *Response to Comments* document. For the EPA's response related to trigger levels please see section 8.8 of

the EPA response in this *Response to Comments* document. For the EPA's response related to compliance determinations, please see section 8.2 of the EPA response in this *Response to Comments* document.

Colorado Water Utility Council (CWUC) (Doc. #1622, SBC-044038)

b. Up to 5 years of previously acquired data should be allowed to be used for initial compliance, as long as the current established PQL of 4.0 ppt has been met. For this reason, EPA must immediately allow contract laboratories to report UCMR5 PFAS results to the MDL.

EPA Response: Please see section 8.3 of the EPA response in this *Response to Comments* document. For the EPA's assumptions that water systems can request UCMR 5 data below MRLs from laboratories for use in satisfying some or all of the NPDWR's initial monitoring requirements and determination of compliance monitoring frequency, please see section 13.3.4 of the EPA response in this *Response to Comments* document.

Aqua America, an Essential Utilities Company (Doc. #1623, SBC-043083)

Initial Monitoring: Use of Existing Data and Timeline

Aqua appreciates the Agency's interest in reducing public water system monitoring burdens, especially where existing monitoring data exists. The Agency's proposed approach to accept data collected since January 1, 2019, is appropriate. While it is uncertain what magnitude of impact this will have on water systems, this will be a welcome relief for water systems already working to understand PFAS levels in their water. This is especially true, given that the use of this data will be subject to state primacy agency approval and the overall quality and scope of the previous data collection. For example, many states may have data for PFOA, PFOS, PFHxS, and PFNA but not PFBS and HFPO-DA. In other cases, water systems may not have received results for PFAS below the proposed PQL.

EPA Response: Please see section 8.3 of the EPA response in this *Response to Comments* document.

Pennsylvania Department of Environmental Protection (Doc. #1626, SBC-044874)

DEP supports allowing water systems to use previously collected data for initial compliance as one potential way to minimize costs. Additional questions and comments relative to the use of previously collected data are provided later in this letter.

EPA Response: Please see section 8.3 of the EPA response in this *Response to Comments* document.

Pennsylvania Department of Environmental Protection (Doc. #1626, SBC-044884)

Compliance Monitoring Considerations

• DEP supports allowing water systems to use data collected for compliance with state PFAS MCL rules, including the Commonwealth's PFAS MCL rule, to meet the initial compliance monitoring requirements of EPA's proposed rule. Allowing systems to use this data would provide significant cost savings and reduce burden while maintaining health protection.

• DEP requests clarification on specifically what "previously collected" data will be acceptable to count for initial monitoring.

o Currently, it appears that state data in general was excluded as a grandfathering option for previously-collected data. DEP believes that more data that falls outside the scope of the state grandfathering allowance in the proposed rule needs to be included.

o DEP also believes that the rules for previously-collected data need to be consistent. If data for the Fifth Unregulated Contaminant Monitoring Rule (UCMR 5) does not need to meet the proposed trigger level, other data should similarly not be required to meet that low level.

o The trigger level of 1.3 ppt for PFOA and PFOS is too low for the allowance of previously-collected data. As noted previously, laboratories are generally not capable of accurately detecting PFAS to that level.

EPA Response: Please see section 8.3 of the EPA response in this *Response to Comments* document.

Association of State Drinking Water Administrators (ASDWA) (Doc. #1628, SBC-044065)

5. ASDWA recommends that EPA clarify and allow maximum flexibility to use previously acquired state sampling data for determining initial monitoring and waivers. States support the maximum flexibility for using existing state data to determine initial monitoring that was not included under the Fifth Unregulated Contaminant Monitoring Rule (UCMR 5) and for allowing waivers utilizing both state and UCMR 5 data. Clarification in the final rule is necessary to provide the details of the requirements for using previous state sampling and the number of samples necessary to meet the initial monitoring requirements.

EPA Response: Please see section 8.3 of the EPA response in this *Response to Comments* document.

Association of State Drinking Water Administrators (ASDWA) (Doc. #1628, SBC-044097)

ASDWA recommends that EPA clarify and allow maximum flexibility to use previously acquired state sampling data for determining initial monitoring and allowing waivers.

ASDWA recommends that maximum flexibility be allowed for using existing state data that was not included to meet the initial monitoring requirements and for allowing waivers using both state and UCMR 5 data. This flexibility should include providing primacy agencies with the ability to refrain from allowing water systems to use UCMR 5 data in lieu of initial monitoring. Clarification is needed in the final rule on the requirements for using previous state sampling and

the number of samples needed to meet the requirements for initial monitoring with the necessary stipulations for PFAS detections. Additionally, the final rule should explicitly state that water systems that conduct UCMR 5 monitoring do not need to conduct initial monitoring. While the UCMR 5 only requires large ground water systems to sample twice, this should be sufficient, even though the proposed rule requires quarterly sampling.

The final rule should answer the following questions in a way that allows the maximum flexibility for primacy agencies to make determinations about using existing data, to know what additional data the state may want to acquire before the rule goes into effect, and preemptively fill the gaps by taking additional samples to meet rule requirements for existing data, and for data reporting.

• Would one sampling event with no detections (done for statewide sampling using EPA Method 533) be allowed for initial monitoring? Or does the state data for water system samples have to be from four consecutive quarters?

• Will state data count if the primacy agency used a modified method when the only part that was modified was not running a field reagent blank, and instead, the laboratory did confirmation samples?

• How do varying reporting limits among the different primacy agencies affect this decision?

• Will it be up to the primacy agency to decide whether existing water system sampling data can be used for waiver requirements and reduced monitoring?

• How will primacy agencies verify and share the sampling data when it has not been entered into SDWIS?

• Will the CCR create SDWIS reporting for PFAS?

EPA Response: Please see section 8.3 of the EPA response in this *Response to Comments* document. For SDWIS reporting and recordkeeping, please see sections 11.2 and 11.3 of the EPA response in this *Response to Comments* document. The EPA will develop tools to assist PFAS reporting in the CCR. For responses related to CCR requirements, please see section 9.1 of the EPA response in this *Response to Comments* document. Revisions to the CCR rule and responses to public comments received on that proposed rule will be addressed as part of a separate action, see www.regulations.gov, Docket ID: EPA-HQ-OW-2022-0260, and are outside the scope of this action.

Texas Commission on Environmental Quality (TCEQ) (Doc. #1632, SBC-044134)

[To alleviate the initial laboratory capacity issues and reduce public water system sampling costs, TCEQ supports:]

• Allowing previously collected monitoring data to satisfy initial monitoring and allowing reduced monitoring requirements if the system has historical monitoring data for each entry point

to the distribution system (EPTDS), analyzed using EPA Methods 533 or 537.1 if collected after January 1, 2023, for UCMR5 or state-led monitoring program.

EPA Response: Please see section 8.3 of the EPA response in this *Response to Comments* document.

Aidan Cecchetti (Doc. #1640, SBC-044372)

• EPA requests comment on its proposal to allow the use of previously acquired monitoring data to satisfy initial monitoring requirements including the data collection timeframe requirements and if other QA requirements should be considered (pg. 18683 Federal Register Volume 88, Number 60).

o It is the opinion of the commenters that EPA should allow the use of previously collected data to satisfy initial monitoring requirements if those data meet specific QA requirements. For example, data in which the method detection limit reported by the laboratory exceeds EPA's PQL should not be accepted for the initial monitoring requirements.

EPA Response: Please see section 8.3 of the EPA response in this *Response to Comments* document.

National Rural Water Association (NRWA) (Doc. #1641, SBC-043276)

• EPA requests comments on its proposal to allow the use of previously acquired monitoring data to satisfy initial monitoring requirements including the data collection timeframe requirements and if other QA requirements should be considered.

Response: Previously acquired monitoring data should absolutely be allowed to satisfy initial monitoring requirements.

EPA Response: Please see section 8.3 of the EPA response in this *Response to Comments* document.

Savannah River Nuclear Solutions LLC (Doc. #1647, SBC-043332)

Comment 3

Section IX.C. Can Systems Use Previously Collected Data To Satisfy The Initial Monitoring Requirement? (pg. 18683)

SRNS supports EPA's proposal to allow systems with previously acquired monitoring data from Fifth Unregulated Contaminant Monitoring Rule (UCMR 5) collected after January 1st, 2023 to not be required to conduct separate initial monitoring for regulated PFAS for entry point samples. This will allow systems to avoid duplicative and costly sampling and analysis and will further reduce burden on analytical laboratories.

SRNS seeks further clarification on whether monitoring data collected pursuant to the proposed rule (if promulgated) can be used to satisfy the monitoring requirements for UCMR 5.

EPA Response: Please see section 8.3 of the EPA response in this *Response to Comments* document. The EPA clarifies that it is allowing the use of UCMR 5 results, or other appropriate monitoring data, to satisfy some or all the PFAS NPDWR initial monitoring requirements. While required under separate actions, data collected to satisfy the initial monitoring requirements of this NPDWR may or may not meet the requirements for UCMR 5 monitoring. Should a PWS wish to conduct "dual purpose" monitoring (to comply with both UCMR 5 and the PFAS NPDWR), the PWS should carefully consider the requirements of each rule and discuss questions with the EPA or the primacy agency as needed.

North Carolina Division of Water Resources (NCDEQ) (Doc. #1652, SBC-044183)

4. NCDEQ recommends that EPA clarify and allow maximum flexibility to use previously acquired state sampling data to satisfy initial monitoring requirements and qualify for waivers.

NCDEQ recommends that maximum flexibility be allowed for using existing state data that was not included in UCMR 5 to meet the initial monitoring requirements. Clarification is needed in the rule to explain the requirements for using previous state sampling and the number of samples needed to meet the requirements for initial monitoring with the necessary stipulations for PFAS detections. The final rule should explicitly state that water systems that conduct UCMR 5 monitoring do not need to conduct initial monitoring. While the UCMR 5 only requires large ground water systems to sample twice, this should be sufficient, even though the proposed rule requires quarterly sampling. The final rule should answer the following questions in a way that allows the maximum flexibility for state agencies to make determinations about using existing data, to know what additional data the state may want to acquire before the rule goes into effect, and preemptively fill the gaps by taking additional samples to meet rule requirements for existing data, and for data reporting.

• Would one sampling event with no detections be allowed for initial monitoring? Does state data for water system samples have to be from four consecutive quarters?

• Will state data count if the state agency used a modified method?

• Will it be up to the state agency to decide whether existing water system sampling data can be used for waiver requirements and reduced monitoring?

• How will state agencies verify and share the sampling data when it has not been entered into SDWIS?

EPA Response: Please see section 8.3 of the EPA response in this *Response to Comments* document. For SDWIS reporting and recordkeeping, please see sections 11.2 and 11.3 of the EPA response in this *Response to Comments* document.

Santa Clara Valley Water District (Valley Water) (Doc. #1664, SBC-043127)

Comment 3 – Prior Voluntary Sampling Should be Allowed to Support Compliance with the NPDWR Provided it is Consistent with Certain Criteria

Valley Water as a wholesaler is exempt from participating in the Fifth Unregulated Monitoring Contaminant Rule (UCMR 5), which requires monitoring for 29 PFAS. In addition, state-sponsored monitoring campaigns focused primarily on groundwater. Valley Water believes in being proactive in the protection of public health and conducted PFAS monitoring on a voluntary basis at its surface water drinking water treatment plants influent and treated water, which is the entry point to the wholesale transmission system. Valley Water used approved EPA methods when conducting voluntary monitoring. Though Valley Water's data was provided to the state, the monitoring we conducted was not required by the state. We request that EPA expand the criteria listed in Part C of Section IX. Monitoring and Compliance Requirements, to include historical data that was acquired through voluntary monitoring to satisfy the initial monitoring requirements, provided that appropriate analytical methods were used.

EPA Response: Please see section 8.3 of the EPA response in this *Response to Comments* document.

Washington State Department of Health (DOH) (Doc. #1665, SBC-044421)

EPA requests comment on its proposal to allow the use of previously acquired monitoring data to satisfy initial monitoring requirements including the data collection timeframe requirements and if other QA requirements should be considered.

• DOH supports the use of previously acquired monitoring data to satisfy initial monitoring requirements. In Washington State, approximately 698 public water systems participated in a PFAS sampling pilot project in 2022 and approximately 1,136 sources were sampled for PFAS. Under Washington's current regulation all community and non-transient non-communities must complete initial PFAS monitoring by December 31, 2025.

EPA Response: Please see section 8.3 of the EPA response in this *Response to Comments* document.

Aurora Water, City of Aurora, Colorado (Doc. #1669, SBC-043715)

The proposed rule allows for the use of previously acquired monitoring data collected during the UCMR 5 rule monitoring. This monitoring rule uses EPA analytical method 533, which has a minimum reporting level of 4 ppt. If a system decides to use data collected during this time for the initial monitoring requirements in the new proposed rule, that water system would automatically not be eligible for reduced monitoring. This is another example as to why the proposed trigger level and MCLs need to be adjusted. Any system that applies for reduced monitoring would be unable to use past measurements if the trigger level is set to 4 ppt.

Therefore, Aurora Water supports using previously acquired data but believes it is irrelevant unless the trigger levels and MCLs are adjusted.

EPA Response: Please see section 8.3 of the EPA response in this *Response to Comments* document. For the EPA's response related to trigger levels, please see section 8.8 of the EPA response in this *Response to Comments* document.

Cleveland Water, City of Cleveland, Ohio (Doc. #1672, SBC-044916)

Section 5.2: Initial compliance monitoring

EPA is proposing to allow PWSs to use previously acquired monitoring data from UCMR 5, state-led, or other applicable monitoring programs using EPA Methods 533 or 537.1 as the initially monitoring data for determining compliance. We strongly agree with this decision and recognize the initial monitoring burdens this will erase for systems that would have been required to conduct a separate sampling campaign. We support the utilization of UCMR and other monitoring data whenever possible, as this will help with lab capacity and sample analysis costs.

EPA Response: Please see section 8.3 of the EPA response in this *Response to Comments* document.

New York State Department of Health (NYS DOH) (Doc. #1677, SBC-044958)

20. In accordance with Section 141.CC.c(b)(1)(v), data collected between January 1, 2019, and December 31, 2022, may also be used if it is below the rule trigger level of 1.3 ppt for PFOA and PFOS and below an HI of 0.33. It is not clear why results above the trigger level couldn't also be used to satisfy the initial compliance period.

EPA Response: Please see section 8.3 of the EPA response in this *Response to Comments* document.

New Hampshire Department of Environmental Services (NHDES) (Doc. #1690, SBC-044351)

e. Page 18730, Column 3, Bullet 3 - EPA requests comment on its proposal to allow the use of previously acquired monitoring data to satisfy initial monitoring requirements including the data collection timeframe requirements and if other QA requirements should be considered.

NHDES Comment - NH requests that all State-led PFAS monitoring data from 2019-2022 be used for the initial monitoring period, regardless of sample results. When NH first implemented the State PFAS MCLs (2019), we set the laboratory reporting limit at 2 ppt. That reporting limit was consistent with what laboratories were accurately able to report at the time. Any value lower than 2 ppt was reported to the State as a "non-detect" (or zero). We have systems that haven't sampled since 2020 or 2021 because PFAS was not detected (below 2 ppt) in their initial monitoring results, so they were set to a triennial monitoring frequency. It would be an undue

burden for those systems to have to repeat initial monitoring when their initial State-led monitoring showed such low levels of PFAS detected, if at all. [Rule Reference: 141.XX (b)(1)(v) – Page 18751, Column 1]

In addition, NH requests that EPA consider allowing the use of sample results that were analyzed using State-accredited proprietary methods such as Isotope Dilution. NH pushed the accredited laboratories to develop these methods when we first began regulating PFAS, which was prior to EPA methods being available. Many of our early results were analyzed with these methods.

EPA Response: Please see section 8.3 of the EPA response in this *Response to Comments* document.

New Jersey Department of Environmental Protection (NJDEP) (Doc. #1699, SBC-045031)

EPA requested comment on its proposal to allow the use of previously acquired monitoring data to satisfy initial monitoring requirements. NJDEP recognizes that, nationwide, water systems may have collected PFAS monitoring data and recommends EPA provide maximum flexibility to primacy agencies to determine use of previously collected data. However, NJDEP is concerned that this historical data may not be useful to assist in evaluating compliance in all cases, as the laboratory analyses used previously may not have been sufficiently sensitive to detect the analytes to the regulatory standards in this proposal. While data from New Jersey may be sufficient, additional monitoring may be necessary in many cases.

EPA Response: Please see section 8.3 of the EPA response in this *Response to Comments* document.

State of Vermont Agency of Natural Resources and Department of Health (Doc. #1708, SBC-045105)

6) Use of previously acquired data to satisfy initial monitoring requirements including timeframe and other QA considerations:

Existing pre-2023 data should be accepted if the data was through a certified laboratory, using approved EPA methods 537.1 or 533, and the data were accepted by the State. Drawing the arbitrary line of "pre-2023" does not make sense when in fact all of our data in Vermont since 2019 has met the same "current" standard. Either reliance on certification of the EPA Method or data collected under a state framework that is at least as stringent as the existing requirements. The need to have a PQL of 1.3 for data prior to 2023 is arbitrary and not based in science or supported by the data present. Existing data, regardless of when it was collected and how close the samples were collected, such as 2 calendar quarters from the same calendar year, must be allowed. Requiring 2 samples in a 12-month period is arbitrary and may not capture potential seasonal variability in the sample results the way annual sampling would. State data received according to an EPA method should be allowed to "count" for the initial monitoring requirements. Many systems in Vermont have extensive data that would not qualify for

consideration as initial sampling because they were not taken within one calendar year. To reduce the burdens on states and water systems, existing data following EPA methods documenting low/reduced risk should count toward the initial sampling requirements of the proposed regulation. Drawing the line at January 1, 2023 is arbitrary and our data is the same quality from 2019 – 2023 as it will be beyond 2023.

EPA Response: Please see section 8.3 of the EPA response in this *Response to Comments* document.

State of Vermont Agency of Natural Resources and Department of Health (Doc. #1708, SBC-045103)

The proposed regulation of accepting UCMR 5 data is inequitable for those systems required to sample and pay for the sampling out of their own budgets. EPA should accept valid data from certified laboratories on-file with states to meet the demands of the initial sampling requirements with pre-2023 data or otherwise provide an equitable path forward where some systems' samples are not subsidized.

EPA Response: Please see section 8.3 of the EPA response in this *Response to Comments* document.

Massachusetts Department of Environmental Protection (MassDEP) (Doc. #1726, SBC-045168)

MassDEP recommends that EPA clarify and allow maximum flexibility to use previously acquired state sampling data to satisfy initial monitoring.

MassDEP recommends that maximum flexibility be allowed for using existing state data to meet the initial monitoring requirements and for allowing the use of both state and UCMR5 data.

EPA Response: Please see section 8.3 of the EPA response in this *Response to Comments* document.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-045968)

Section 5.3: Initial compliance monitoring

EPA is proposing to allow PWSs to use previously acquired monitoring data from UCMR 5, state-led, or other applicable monitoring programs using EPA Methods 533 or 537.1 as the initial monitoring data for determining compliance. AMWA strongly agrees with this decision and recognizes the initial monitoring burdens this approach will erase for systems that would have been required to conduct a separate sampling campaign. AMWA supports the utilization of UCMR and other monitoring data whenever possible, as this will help with lab capacity and sample analysis costs.

EPA Response: Please see section 8.3 of the EPA response in this *Response to Comments* document.

Washington County Department of Public Health and Environment (Doc. #1739, SBC-043571)

Use of Previously Acquired Data to Meet Initial Monitoring Requirements

Per Part XIV, Section IX of the rule proposal: "EPA requests comment on its proposal to allow the use of previously acquired monitoring data to satisfy initial monitoring requirements including the data collection timeframe requirements and if other QA requirements should be considered."

Comments:

Minnesota, and many other states, have proactively completed PFAS monitoring at public water systems in order to better identify systems with elevated PFAS levels and allow for communication and action in advance of rule finalization. Our state department of health, MDH, works closely with the many affected communities to regularly monitor wells for PFAS, in addition to sampling of private wells. The ability to use this previously collected data, as well as UCMR 5 data, provides an opportunity for the efficient use of public resources where the state already possesses appropriate information on PFAS presence. As such, we support the use of previously collected to satisfy initial monitoring requirements. Our further comments seek both clarification and some flexibility in how this data is used.

EPA Response: Please see section 8.3 of the EPA response in this *Response to Comments* document.

Connecticut Department of Public Health (CT DPH) (Doc. #1745, SBC-045228)

7. Additionally, EPA is requesting comment on allowing similar monitoring waivers to be granted based on previously acquired monitoring data.

CT DPH agrees with attempting to lower the sampling burden on systems and supports the use of previously collected data for compliance. EPA should provide clarification on allowable data.

• For trigger levels, does the laboratory minimum reporting limit need to be below the trigger level, or just any numerical values, such as "J" flagged results?

• Data collected under UCMR 5 has a minimum reporting limit of 4 for PFOA and PFOS, but the proposed MCL is 4.0. What is an acceptable minimum reporting level for results outside of the UCMR 5 data?

• Do any specific quality assurance or quality control tests need to be included? For example, does a field blank need to be analyzed for every sample?

It is important to have consistent accurate data for initial monitoring, but flexibility is important. The greater number of previously analyzed samples allowed will reduce the pressure on the laboratories and limit the financial burden to PWSs.

EPA Response: Please see section 8.3 of the EPA response in this *Response to Comments* document. The approved analytical methods list the quality control samples and acceptance criteria required for sample analysis. Please see section 8.7 of the EPA response in this *Response to Comments* document regarding the frequency of FRB analysis. For monitoring frequency determinations, please see section 8.1.2 of the EPA response in this *Response to Comments* document. For rule trigger levels, please see section 8.8 of the EPA response in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-045623)

Initial Monitoring: Use of Existing Data and Timeline

AWWA appreciates the agency's interest in reducing public water system monitoring burdens, especially where existing monitoring data exists. The agency's proposed approach to accept data collected since January 1, 2019 is appropriate. Reduced regulatory monitoring demands will be a welcome relief for water systems already working to understand PFAS levels in their water, but it is uncertain what magnitude of impact this will have on water systems.

It is difficult to estimate the magnitude of the reduced monitoring impact because data will be (i) dependent on fully fulfilling the initial monitoring requirements and the quality control that they require and (ii) subject to state primacy agency approval. For example, many states may have data for PFOA, PFOS, PFHxS, and PFNA but not PFBS and HFPO-DA. In other cases, water systems may not have received results for PFAS below the proposed PQL. Another challenge for systems to use previously collected data, such as data from UCMR 5, is that the results may not have been reported at the necessary level to be used for EPA's monitoring and will likely not be feasible for all water systems to acquire data below the PQL.

EPA Response: Please see section 8.3 of the EPA response in this *Response to Comments* document. For the EPA's assumptions that water systems can request UCMR 5 data below MRLs from laboratories for use in satisfying some or all of the NPDWR's initial monitoring requirements and determination of compliance monitoring frequency, please see section 13.3.4 of the EPA response in this *Response to Comments* document.

California State Water Resources Control Board (Doc. #1760, SBC-044222)

The State Water Board offers the following specific comments and recommendations for consideration regarding implementation of the rule:

Recommend that EPA clarify and allow maximum flexibility to use previously acquired sampling data for determining initial monitoring and waivers. California public water systems have already performed extensive monitoring, and more will precede the establishment of this

rule. EPA should allow for the maximum flexibility for using existing data to determine initial monitoring that was not included under the Fifth Unregulated Contaminant Monitoring Rule (UCMR 5) and for allowing waivers utilizing both state and UCMR 5 data. Clarification is needed within the rule to explain the requirements for using previous sampling data and the number of samples necessary to meet the requirements for initial monitoring. The State Water Board recommends the broadest allowance possible for usage of existing data as this will save on implementation costs by not requiring repeat samples that will provide essentially no additional information and help alleviate expected lab capacity issues when nationwide testing begins.

EPA Response: Please see section 8.3 of the EPA response in this *Response to Comments* document.

Western Urban Water Coalition (WUWC) (Doc. #1768, SBC-043951)

B. The Option to Leverage Existing Monitoring Data Will Not Necessarily Accelerate Compliance or Increase Feasibility

WUWC supports EPA's proposal to allow the use of previously acquired monitoring data obtained during UCMR5 or similar state-led monitoring to satisfy initial monitoring requirements. [FN41:Id. at 18683.] WUWC partly agrees with EPA's assertion that allowing water utilities to utilize existing sampling results will result in a "significant burden reduction" and "sufficient timing to take necessary actions and ensure rule compliance." [FN42:Id.]

However, EPA should not assume for the purpose of its economic feasibility evaluation that water utilities will choose to utilize existing data and forego additional sampling. Many public water systems should be expected to elect to perform additional sampling where UCMR5 or state data could result in a finding of noncompliance. As noted above, EPA's assumption that the existing data provision will result in reduced burdens for laboratories is not a foregone conclusion.

EPA Response: Please see section 8.3 of the EPA response in this *Response to Comments* document. The agency is confident that allowing use of this data will result in burden reduction and alleviate laboratory demand. Under the final rule, primacy agencies may require or water systems may choose to collect additional data even if they have available previously collected data. However, with this provision, the EPA is seeking to reduce burden and reduce potential laboratory capacity issues by allowing this flexibility. The agency makes some reasonable assumptions, consistent with the overwhelming support from commenters, that the allowance of this data will reduce burden for thousands of water systems and that water systems will choose to use this data if available. Furthermore, if the available data (supporting initial monitoring requirements) were to demonstrate that a water system has results above the MCLs, it would be both required under the final rule (per initial monitoring requirements under 141.902(b)(1)(vi)) and in the interest of the water system to conduct additional monitoring. This would allow the system to identify necessary actions to ensure they are providing drinking water to their customers that meets all NPDWRs in advance of the MCL compliance date.

Pennsylvania Municipal Authorities Association (Doc. #1832, SBC-045791)

[PMAA's specific comments on the Proposal are as follows:]

15. EPA should permit the use of monitoring data generated prior to any final PFAS regulation to satisfy the initial monitoring requirements set forth in the Proposal. Municipal entities that proactively monitored their systems or did so pursuant to a state regulation or mandate should not be required by EPA to undertake additional sampling simply because EPA issued the Proposal after states developed their respective PFAS- related initiatives.

EPA Response: Please see section 8.3 of the EPA response in this *Response to Comments* document.

Corix Infrastructure Inc. (Doc. #1834, SBC-045371)

[With regards to the specific items EPA has requested comment on, Corix provides below:]

• We strongly support the use of previously acquired monitoring data as long as the MDLs are low enough and appropriate EPA methods are used.

EPA Response: Please see section 8.3 of the EPA response in this *Response to Comments* document.

Citizens Energy Group (Doc. #1838, SBC-044864)

EPA requests comment on its proposal to allow the use of previously acquired monitoring data to satisfy initial monitoring requirements including the data collection timeframe requirements and if other QA requirements should be considered.

The timing of UCMR 5 activities for water systems in the U.S., as well as state- or local-lead PFAS monitoring activities that exist, provide data that can be used to satisfy initial monitoring requirements. These data inform water systems of whether they will achieve compliance with the proposed MCLs at the effective date of the rule (3 years following publication of the final rule in the Federal Register). Those water systems that detect PFAS compounds at their EPTDS during this initial monitoring period may choose to conduct additional sampling to better inform their engineering and design of treatment plant modifications.

Those systems that, based on the suite of data available to them, do not have PFAS compounds at their EPTDS that indicate potential compliance challenges, should not be obligated to monitor just for the sake of monitoring during the initial 3-year period ahead of the compliance date. Doing so risks adding to the overall burden facing water systems without any benefit to the customers.

EPA Response: Please see section 8.3 of the EPA response in this *Response to Comments* document. Additionally, the EPA clarifies that as provided in the final rule, water

systems are only required to either provide previously collected data or conduct initial monitoring in one 12-month period during the three years following rule promulgation. Following that initial monitoring, compliance monitoring is required beginning three years following rule promulgation.

Alicia Jacobs (Doc. #2396, SBC-046279)

Question on behalf of Kentucky EEC and Kentucky Rural Water Association: How will UCMR5 sampling results be used as preliminary monitoring to determine sample schedule (i.e., proving that results do not exceed 1/3 of MCL or HI) when labs are simply using non-detect if result is below 4.0 ppt? Some UCMR5 laboratories will show actual value while others indicate a ND. How can we show we are below 1/3 of the MCL if laboratories can only measure to 4.0 ppt?

EPA Response: Please see section 8.3 of the EPA response in this *Response to Comments* document. If initial monitoring data do not show that a laboratory confirmed that results are below trigger levels (see section 8.8 of the EPA response in this *Response to Comments* document on rule trigger levels), then a state would assign a system to conduct quarterly sampling at the start of the compliance monitoring period. Regarding availability of UCMR 5 results below the trigger level, as well as the EPA's assumptions that water systems can request UCMR 5 data below MRLs from laboratories for use in satisfying some or all of the NPDWR's initial monitoring requirements and determination of compliance monitoring frequency, please see section 13.3.4 of the EPA response in this *Response to Comments* document.

8.4 Composite Sampling

Summary of Major Public Comments and EPA Responses

The EPA proposed that compositing of samples would not be allowed as part of the rule's monitoring framework. The EPA received a few comments related to composite sampling. The majority of these commenters agreed with the EPA's proposal to not allow samples to be composited due to analytical limitations and the increased potential for background contamination, along with the physical and chemical characteristics of PFAS. One commenter noted grab samples as more appropriate and suggested that individual systems be permitted to request alternative sampling methodologies if needed. One other commenter suggested that compositing samples from varying EPTDS should not be allowed. Conversely, a few commenters suggested that composite sampling could be implemented and would reduce the cost of analyses. Further, it was suggested that with proper guidelines and procedures for analyzing samples, possible contamination issues could be mitigated and asserted that issues with false negative and positive samples also impact discrete samples (i.e., that they are not unique to composite sampling).

For commenters who offered that composite sampling could be implemented, the EPA agrees it would potentially decrease sampling analysis costs and that sampling errors can occur when

handling and analyzing discrete samples. However, the compositing of samples necessarily involves additional handling, opening, and transfer steps than are required for the collection and analysis of individual samples. Therefore, the combining of samples that must be done for composite sample analysis represents an increased risk of sampling error, which could result in decreased public health protection and additional sampling costs. The agency also does not agree that alternative sampling methodologies should be permitted and requires the use of EPA Methods 533 and 537.1 for monitoring per the requirements of the rule. Please see section VII of the final rule preamble for more information on methods.

The agency received input from consulting with state regulators and small business entities (operators of small PWSs) noting that PFAS are ubiquitous in the environment at low concentrations, which necessitates robust laboratory analytical precision at these low concentrations. The EPA agrees with these concerns, and based on this input, as well as in considerations of the public comments, the EPA maintains in the final PFAS NDPWR that composite sampling is not sufficiently public health protective. The agency, therefore, is not allowing the use of composite samples to satisfy the final rule monitoring requirements.

Individual Public Comments

Colorado Water Utility Council (CWUC) (Doc. #1622, SBC-044059)

37. CWUC agrees with EPA that composited sampling for PFAS should not be allowed, as this increases the risk of contamination. Grab samples are more appropriate for sampling. Individual systems can request alternative sampling methodologies if needed.

CWUC also wishes to acknowledge and support comments submitted by AWWA and NACWA. Thank you again for the opportunity to engage with this important rulemaking.

Sherry Scaggiari, Chair Colorado Water Utility Council sscaggia@auroragov.org

303-739-7390

EPA Response: Please see section 8.4 of the EPA response in this *Response to Comments* document.

Association of State Drinking Water Administrators (ASDWA) (Doc. #1628, SBC-044095)

In addition, ASDWA agrees with EPA's proposed deviation from the SMF for SOCs to not allow samples to be composited based on the low concentrations of PFAS that must be analyzed from different entry points.

EPA Response: Please see section 8.4 of the EPA response in this *Response to Comments* document.

Wyoming Department of Environmental Quality (WDEQ) (Doc. #1716, SBC-044752)

6. Justification for Disallowing Composite Sampling of all EPTDS for a PWS under the proposed PFAS NPDW Regulation Is Not Clear

EPA states that "incidental contamination from or adherence to surface laboratory equipment may artificially lower contaminant concentrations or result in false negatives." These risks apply to any sample collected-composited across multiple PWS EPTDS or individually sampled from each EPTDS-and is insufficient justification for not allowing composite samples to be submitted for compliance monitoring. Similarly, EPA's statement that "PFAS are demonstrated to be ubiquitous in the environment such that the risk for false positives may increase when combining samples for composite analysis" also does not provide sufficient justification. The ubiquitous nature of PFAS in the environment, risks of sampler-introduced contamination, and risk of ambient environment introduction of PFAS to a sample exists in either sampling method. These risks are controlled for by proper training prior to sampling for PFAS, the use of proper Personal Protective Equipment (PPE), proper sampling materials and sampling protocols (including the use of laboratory provided PFAS-free field blanks that should be collected at every location sampled for PFAS), and proper sample shipping protocols, regardless of whether composite or individual samples are collected. Justification for the apparent claim that compositing samples increases the risk of false positive results for PFAS has not been provided, and further discussion of this proposed departure from the previously implemented Standardized Monitoring Framework for Synthetic Organic Compounds should occur prior to finalizing the PFAS NPDW regulation.

WDEQ is not advocating for or against composite sampling. As stated in comment #5 above, if EPTDSs are sampled, a flow-weighted approach is important to ensure one higher-concentration, low-flow sample doesn't skew results for the distribution system as a whole. However, if EPA disallows composite sampling in the final rule, we encourage EPA to provide a stronger justification. WDEQ notes that standardized PFAS sampling training and guidance from EPA will be critical for both types of sampling, composite or individual, to ensure high-quality data is obtained. Guidance materials along these lines will need to be provided to all PWSs affected by the proposed PFAS NPDW rule for consistency of implementation.

EPA Response: Please see section 8.4 of the EPA response in this *Response to Comments* document.

Massachusetts Department of Environmental Protection (MassDEP) (Doc. #1726, SBC-045160)

MassDEP supports EPA’s proposal to not allow samples to be composited.

EPA Response: Please see section 8.4 of the EPA response in this *Response to Comments* document.

Groundwater Resources Association of California (Doc. #1831, SBC-045357)

Section IX. D states that the proposed regulations do not allow for composite sampling of PFAS to avoid risk of false positives when combining samples for composites analysis from the contributing entry points. Composite sampling can potentially reduce analytical costs because the number of required analyses is reduced by combining multiple samples into one and analyzing the composited sample. Not allowing composites reduces the operational flexibility and increases the costs for PFAS sampling. Moreover, this may be unduly restrictive if the different samples all feed into the same delivery system (hence, the water at the receptor points would be mixed anyway). Proper guidelines and care in collection and compositing procedures can allow the composite sampling approach to be implemented to reduce the cost of analyses. Issues with false positives due to the ubiquitous low level PFAS concentrations impact discrete samples as well. With proper guidelines and care in collecting and compositing procedures, a composite sampling approach can be implemented to reduce the cost of analyses. As such, we recommend that EPA allow for composite samples under proper guidance and revised standards. With these guidance and standards, EPA may allow PWS to composite samples if they demonstrate proper sample collection and compositing procedures and if the samples collected feed into a common water delivery system.

EPA Response: Please see section 8.4 of the EPA response in this *Response to Comments* document.

8.5 Monitoring Waivers

Summary of Major Public Comments and EPA Responses

The EPA did not include a provision to allow primacy agencies to grant monitoring waivers as a regulatory flexibility in the proposed rule. Several commenters agreed that monitoring waivers should not be allowed for this rule. Several additional commenters cited the persistence and mobility of PFAS in the environment and advised that reduced monitoring frequencies should be no less than every three years on the basis that drinking water consumers in unmonitored areas may unknowingly be exposed to these PFAS. Furthermore, many other commenters suggested that PFAS contamination can migrate significantly over a three-year period.

Many other commenters were supportive of monitoring waivers for this rule under certain circumstances similar to those applicable to other SOCs. Several commenters indicated that waivers would be appropriate if they were based on monitoring results. A few commenters recommended that if monitoring waivers were to be allowed, they should not be based solely on a traditional vulnerability assessment. A couple of commenters stated that waivers based on vulnerability alone should not be allowed during the initial monitoring period. One commenter recommended waiting until UCMR 5 monitoring is complete before allowing monitoring waivers to be granted through vulnerability assessments. A few commenters suggested that waivers be considered if they are based on a combination of vulnerability and monitoring results, while one other commenter suggested that assessing watershed characteristics to demonstrate

eligibility for monitoring waivers would be protective of chronic health risks. One commenter noted that merely allowing waivers to be granted would not necessarily reduce public health protection under the rule, as primacy agencies will retain the ability to deny waiver applications.

After consideration of these comments which raised significant concerns about the use of waivers for PFAS, and due to the specific mobility and persistence characteristics of the regulated PFAS as compared with other NPDWRs, the final rule does not allow monitoring waivers and establishes triennial monitoring as the least frequent monitoring timeframe. These specific properties of the regulated PFAS and their observed ubiquity in both drinking water and many other sources make waivers impractical and complicate the ability to maintain public health protection. Moreover, the EPA is not confident that allowing monitoring any less frequently than every three years or conducting vulnerability assessments will accurately capture potential concentration variations over the long term or protect against risks from new contamination sources.

Individual Public Comments

Great Lakes Water Authority (GLWA) (Doc. #1558, SBC-042553)

Allowance of monitoring waivers of up to nine years if after at least one year of sampling results are below the proposed rule trigger.

If the proposed language is not modified to distinguish between water producers and receivers in consecutive systems, then it is even more critical that the monitoring waivers of up to nine years be permitted to decrease the burden on both secondary systems which do not provide treatment.

EPA Response: Please see section 8.5 of the EPA response in this *Response to Comments* document. For consecutive-system requirements under the final rule, please see section 1.4 of the EPA response in this *Response to Comments* document.

Great Lakes Water Authority (GLWA) (Doc. #1558, SBC-042556)

Whether there are specific conditions that should be mandated for systems to be eligible for exemptions under 1416 to ensure that they are only used in rare circumstances where there are no other viable alternatives and what those conditions would be.

If the proposed language is not modified to distinguish between water producers and receivers in consecutive systems, then it is critical that the monitoring waivers be allowed to decrease the burden on both secondary systems which do not provide treatment.

Further, the model used by EPA to simulate EPTDS assumed within-system concentrations are … distributed and variability in concentrations is entirely across entry points (p. 44 of rule). This assumption infers that unlike DBP, LCR or TCR there is no change in PFAS concentration associated with time of travel in the distribution system and most notably between the water supplier and any secondary utilities.

Thank you again for the opportunity to provide comments on this critically important matter.

Sincerely,

Suzanne Coffey

Chief Executive Officer

Cc: William Wolfson

Cheryl Porter

Randal Brown

EPA Response: Please see section 8.5 of the EPA response in this *Response to Comments* document. For consecutive system requirements under the final rule, please see section 1.4 of the EPA response in this *Response to Comments* document. Regarding exemptions under SDWA 1416, please see section XII of the final rule preamble and section 12.1 of the EPA response in this *Response to Comments* document.

Missouri Department of Natural Resources (Doc. #1563, SBC-042529)

EPA requests comments on whether water systems should be permitted to apply to the primacy agency for monitoring waivers. Specifically, EPA is requesting comment on the allowance of monitoring waivers of up to nine years if after at least one year of sampling results are below the proposed rule trigger level. Similarly, EPA also requests comment on whether allowance of monitoring waivers of up to nine years should be permitted based on previously acquired monitoring data results that are below the proposed rule trigger level. Additionally, EPA is also requesting comment on the identification of possible alternatives to traditional vulnerability assessments that should be considered to identify systems as low risk and potentially eligible for monitoring waivers.

The Department does not recommend monitoring waivers based solely on traditional vulnerability assessments. Experience has shown PFAS contamination occurs mainly through improper disposal or concentration of PFAS through traditional landfill leachate, air deposition miles from the source, wastewater effluent discharge, or biosolids land application. Often these contamination occurrences can only be detected through sampling. However, a system in a rural community surrounded by farmland, forests, mountains, or deserts have minimal risk that would affect groundwater wells. For this reason, the Department supports PFAS waivers with sampling at least once in a 9-year compliance cycle.

EPA Response: Please see section 8.5 of the EPA response in this *Response to Comments* document.

Oregon Health Authority (OHA) (Doc. #1582, SBC-042764)

• EPA requests comments on whether water systems should be permitted to apply to the primacy agency for monitoring waivers. Specifically, EPA is requesting comment on the allowance of monitoring waivers of up to nine years if after at least one year of sampling results are below the proposed rule trigger level. Similarly, EPA also requests comment on whether allowance of monitoring waivers of up to nine years should be permitted based on previously acquired monitoring data results that are below the proposed rule trigger level. Additionally, EPA is also requesting comment on the identification of possible alternatives to traditional vulnerability assessments that should be considered to identify systems as low risk and potentially eligible for monitoring waivers.

OHA supports the allowance of 9-year monitoring waivers where both monitoring data and susceptibility assessment indicates PFAS exposure to customers is low, and requests that EPA consider incorporating this flexibility into the monitoring requirements in the final rule. Oregon, like many other states, developed criteria for identifying public water systems that may be vulnerable to exposure to PFAS contamination as part of a targeted PFAS sampling project in 2021/2022. As part of this project, Oregon developed a geographic information system (GIS) database and screening tool that identified known and potential sources of PFAS contamination within a water system's drinking water source areas that could be used to assess eligibility for 9-year waivers under this rule. OHA believes that in Oregon PFAS contamination is localized and associated w/ certain known activities, for example, airports, defense/military sites, fuel storage/transport and regulated terminals, rail facilities, fire stations with potential aqueous film-forming foam (AFFF) training, landfills, environmental cleanup sites that may involve PFAS sources, and wastewater facilities with potential PFAS sources within the service area based on industry type indicating potential PFAS use (NAICS business codes). Oregon's PFAS screening and assessment criteria, along with evaluation of aquifer susceptibility and well construction for groundwater, consideration of time-of-travel from upstream potential PFAS discharges to downstream surface water intakes, and PFAS monitoring results (at least one round of initial PFAS monitoring under the rule or previously acquired such as voluntary, state sampling, or UCMR5 data that meets the rule requirements) could be used to evaluate water system eligibility for 9-year waivers. OHA believes that under these circumstances, waivers could be granted with a reasonable degree of confidence that the risk of PFAS exposure to customers is low.

EPA Response: Please see section 8.5 of the EPA response in this *Response to Comments* document.

National Tribal Water Council-Tribal PFAS Working Group (NTWCTPWG) (Doc. #1598, SBC-042338)

On page 18370 of the FRN, it is stated that:

EPA requests comments on whether water systems should be permitted to apply to the primacy agency for monitoring waivers. Specifically, EPA is requesting comment on the allowance of

monitoring waivers of up to nine years if after at least one year of sampling results are below the proposed rule trigger level. Similarly, EPA also requests comment on whether allowance of monitoring waivers of up to nine years should be permitted based on previously acquired monitoring data results that are below the proposed rule trigger level. Additionally, EPA is also requesting comment on the identification of possible alternatives to traditional vulnerability assessments that should be considered to identify systems as low risk and potentially eligible for monitoring waivers.

Tribes remain concerned that existing monitoring data are insufficient for understanding the risks of PFAS to tribal resources from upstream water and wastewater systems. The proposed regulation indicates that EPA continues to consider monitoring waivers for systems that can claim that PFAS has not been used in the area or that the area or its water sources are not susceptible to PFAS contamination. It should be acknowledged by EPA in the regulation that there are data in the literature (Butt et. al. 2014) that suggest long-chain PFAS such as PFNA can be generated by degradation of fluorotelomer alchohols (FTOH), thus complicating claims about the source of potential contaminants. If waivers from monitoring are granted to water systems, downstream populations should be notified and granted an opportunity to challenge the waiver. Vulnerability assessments used to request waivers should consider all exposure pathways that the release of persistent bioaccumulative toxic contaminants have on downstream tribes that practice subsistence lifeways.

EPA Response: Please see section 8.5 of the EPA response in this *Response to Comments* document.

Colorado Water Utility Council (CWUC) (Doc. #1622, SBC-044037)

19. EPA requests comments on whether water systems should be permitted to apply to the primacy agency for monitoring waivers. Specifically, EPA is requesting comment on the allowance of monitoring waivers of up to nine years if after at least one year of sampling results are below the proposed rule trigger level. Similarly, EPA also requests comment on whether allowance of monitoring waivers of up to nine years should be permitted based on previously acquired monitoring data results that are below the proposed rule trigger level. Additionally, EPA is also requesting comment on the identification of possible alternatives to traditional vulnerability assessments that should be considered to identify systems as low risk and potentially eligible for monitoring waivers.

a. CWUC believes that discussing a 9-year reduced monitoring schedule is a premature request as the nation has just begun sampling these parameters for UCMR5. Once the magnitude of the occurrence of PFOA and PFOS are truly established, then this determination can be better made. There is just not enough information to make this decision right now. Since PFAS originate from human factors, and not environmental factors, the fluctuation in presence and levels can vary drastically from one sample to the next. With any typical system being at equal risk of having a detection for the compounds at any given time, CWUC believes that reduced monitoring should

be at the most 3 years. Monitoring should be allowed no less than annually for facilities with specific PFAS treatment in place.

EPA Response: Please see section 8.5 of the EPA response in this *Response to Comments* document. Related to monitoring requirements for systems that install treatment to address PFAS drinking water contamination, please see section 8.1.2 of the EPA response in this *Response to Comments* document.

Pennsylvania Department of Environmental Protection (Doc. #1626, SBC-044888)

• DEP recommends not allowing nine-year monitoring waivers for any regulated PFAS compounds, regardless of the basis for the waiver determination. Allowing nine-year monitoring waivers assumes that changes in contaminant levels are not expected over a long period of time. However, PFAS are still considered emerging contaminants because researchers are still learning more about their fate and transport in the environment. As such, DEP believes it is inappropriate to make that assumption with these contaminants.

• DEP also recommends not allowing any type of vulnerability waiver for PFAS. Since PFAS do not readily break down in the environment, they are considered forever chemicals, and the vulnerability of a water source cannot be assessed. If any waivers are to be allowed, DEP support is only allowing use waivers, where the public water system must document that PFAS have not been used, stored, or transported in their source water protection area. Refer to DEP's waiver criteria in 25 Pa. Code Chapter 109 for more information.

EPA Response: Please see section 8.5 of the EPA response in this *Response to Comments* document.

Association of State Drinking Water Administrators (ASDWA) (Doc. #1628, SBC-044094)

ASDWA does not recommend allowing solely vulnerability assessments for monitoring waivers during the initial monitoring period and does not recommend using composite samples.

The final rule should not allow monitoring waivers solely based on vulnerability assessments during the rule's initial monitoring period. States that have conducted monitoring have found PFAS in drinking water sources that were not expected due to the location and proximity to potential sources of PFAS. Knowledge is lacking on PFAS occurrence and transport, and insufficient data is available to make these determinations. New sources of PFAS contamination are being found on a consistent basis across the country. Vulnerability assessments may be appropriate in the future as water systems obtain more data.

EPA Response: Please see section 8.5 of the EPA response in this *Response to Comments* document. Regarding composite sampling, please see section 8.4 of the EPA response in this *Response to Comments* document.

Citizens Against Ruining the Environment (CARE) (Doc. #1638, SBC-043457)

Primary Agency Authority to Grant Monitoring Waivers Must Be Strictly Limited

CARE opposes allowing Primary Agencies to grant monitoring waivers to PWS for up to nine years after one year of data showing that the PWS is below the trigger level. The NPDWR regulations after which that proposed rule appears to be modeled were written for the inorganic contaminants antimony, arsenic, barium, beryllium, cadmium, chromium, cyanide, fluoride, mercury, nickel, selenium and thallium. [FN33: 40 C.F.R. 141.23(c).] Those contaminants, their sources, fate, and environmental transport are well understood and generally predictable based on the large body of accumulated research and experience related to them. Reliable risk models are available to assess a system's vulnerability to contamination from those contaminants, including the age and composition of the system and the types of industry and waste in the area. [FN34: National Primary Drinking Water Regulations, EPA,https://www.epa.gov/ground-water-and-drinking-water/national-primary-drinking-water-regulations#Inorganic (Jan 6, 2023).]

PFAS monitoring should not mirror that for the above-named inorganic contaminants because PFAS do not have the same physical properties, are not as predictable, and have much broader source categories than the other inorganic contaminants. As an example, if a system is not contaminated by selenium from petroleum refinery activity, one can infer that it will not later be contaminated by selenium unless petroleum refinement has begun in that watershed. With that in mind, the potential to waive monitoring for selenium for up to nine years is appropriate. Conversely, PFAS contamination comes from all manner of sources, is ubiquitous in household products, consumer goods, commercial applications, and can migrate into water systems along numerous pathways. Absent a more sophisticated and sensitive risk assessment model to predict a system's vulnerability to PFAS contamination, Primary Agencies cannot predict whether a waiver from monitoring would be appropriate.

It would be reckless to permit a State Primary Agency to approve waivers from PFAS monitoring for up to nine years. This is an excessive duration of time and unsupported by the research and documentation provided by the EPA to support its proposed rule.

EPA Response: Please see section 8.5 of the EPA response in this *Response to Comments* document.

Aidan Cecchetti (Doc. #1640, SBC-044370)

• EPA requests comments on whether water systems should be permitted to apply to the primacy agency for monitoring waivers. Specifically, EPA is requesting comment on the allowance of monitoring waivers of up to nine years if after at least one year of sampling results are below the proposed rule trigger level. Similarly, EPA also requests comment on whether allowance of monitoring waivers of up to nine years should be permitted based on previously acquired monitoring data results that are below the proposed rule trigger level. Additionally, EPA is also requesting comment on the identification of possible alternatives to traditional vulnerability

assessments that should be considered to identify systems as low risk and potentially eligible for monitoring waivers (pg. 18683 Federal Register Volume 88, Number 60).

o It is the opinion of the commenters that it would be appropriate for EPA to allow primacy agencies to grant monitoring waivers up to once per 9-years. This is consistent with the regulatory framework for other synthetic organic contaminants and provides adequate public health protection for systems at low risk of exceeding the trigger levels, the MCLs, or the HI.

EPA Response: Please see section 8.5 of the EPA response in this *Response to Comments* document.

North Carolina Division of Water Resources (NCDEQ) (Doc. #1652, SBC-044181)

2. NCDEQ does not recommend solely allowing vulnerability assessments for monitoring waivers during the initial monitoring period and does not recommend the use of composite samples.

The rule should not allow monitoring waivers solely based on vulnerability assessments during the rule's initial monitoring period. There is currently not enough known about PFAS occurrence and transport, and not enough data are available to make these determinations. Vulnerability assessments may be appropriate in the future as water systems obtain more data. In addition, NCDEQ agrees with EPA's proposed deviation from the SMF for SOCs to not allow samples to be composited based on the low concentrations of PFAS that must be analyzed from different entry points.

EPA Response: Please see section 8.5 of the EPA response in this *Response to Comments* document. Regarding composite sampling, please see section 8.4 of the EPA response in this *Response to Comments* document.

Nebraska Department of Environment and Energy (NDEE) (Doc. #1653, SBC-043199)

May 30, 2023

Submitted via www.regulations.gov

U.S. Environmental Protection Agency Office of Ground Water and Drinking Water 1200 Pennsylvania Avenue NW Washington, D.C. 20460

Attention: Jennifer McLain, Director

EPA Office of Ground Water and Drinking Water

RE: Nebraska Department of Environment and Energy Comments Docket No. EPA-HQ-OW-2022-0114

Dear Director McLain:

Thank you for the opportunity to submit comments on the proposed National Primary Drinking Water Rule to regulate per- and polyfluoroalkyl substances (PFAS). The Nebraska Department of Environment and Energy (Department) offers the following comments to enhance the clarity and effectiveness of the proposed rule.

• EPA requested comment on allowing all public water systems (PWS), regardless of size be allowed to collect one sample per three-year compliance period if PFAS is not detected at or above the trigger level. The current monitoring framework allows nine-year waivers.

• The Department would support the flexibility for all PWS to utilize a three-year compliance period and when appropriate, a nine-year waiver.

EPA Response: Please see section 8.5 of the EPA response in this *Response to Comments* document.

Washington State Department of Health (DOH) (Doc. #1665, SBC-044401)

Page 18683. IX. Monitoring and Compliance Requirements. E. Can primacy agencies grant monitoring waivers?

• DOH supports allowing for provisions for systems to apply for monitoring waivers based on source vulnerability combined with sampling results that show PFAS below trigger levels or non-detects. One sample per source is appropriate for source(s) in low-risk areas with a documented history of no PFAS detections.

EPA Response: Please see section 8.5 of the EPA response in this *Response to Comments* document.

Washington State Department of Health (DOH) (Doc. #1665, SBC-044396)

While DOH agrees with EPA that source vulnerability should not allow a waiver for initial monitoring of PFAS, DOH supports the use of monitoring waivers if appropriate safeguards are in place for public water system sources. If both sampling history, source vulnerability, and geographic location indicate no historical PFAS detections, and there are no potential PFAS sources that could impact public water system sources. Allowing public water systems to apply for monitoring waivers is consistent with EPA's approach previously implemented for other drinking water contaminants.

EPA Response: Please see section 8.5 of the EPA response in this *Response to Comments* document.

Washington State Department of Health (DOH) (Doc. #1665, SBC-044420)

EPA requests comments on whether water systems should be permitted to apply to the primacy agency for monitoring waivers. Specifically, EPA is requesting comment on the allowance of

monitoring waivers of up to nine years if after at least one year of sampling results are below the proposed rule trigger level. Similarly, EPA also requests comment on whether allowance of monitoring waivers of up to nine years should be permitted based on previously acquired monitoring data results that are below the proposed rule trigger level. Additionally, EPA is also requesting comment on the identification of possible alternatives to traditional vulnerability assessments that should be considered to identify systems as low risk and potentially eligible for monitoring waivers.

• EPA and states have provided waiver opportunities for other contaminants as well and still provide public health protection. States can develop a waiver model that allows sources that are less vulnerable and susceptible, and have non-detect PFAS, can reduce monitoring to a 6 or 9 year schedule while still providing public health protection. Our current waiver model allows us to rescind waivers if conditions change. Please allow states the flexibility to develop and provide waivers.

EPA Response: Please see section 8.5 of the EPA response in this *Response to Comments* document.

Cleveland Water, City of Cleveland, Ohio (Doc. #1672, SBC-044915)

Cleveland Water urges EPA to reconsider its decision decline monitoring waivers or reduced monitoring based on reduced risks and watershed characteristics, such as proximity to contaminant sources or previous uses within the watershed. Omitting this is not consistent with other contaminants with chronic health impacts. While we understand the nature of PFAS chemicals are persistent and transportable, for a system that cannot prove it is below the trigger level due to lab reporting constraints, it will never be able to stay in the reduced monitoring schedule. This is because once a system qualifies for reduced monitoring based on their RAA, if it cannot prove it maintains concentrations below the trigger level, the system is automatically thrown back into quarterly monitoring. This can result in systems repeatedly going back and forth between monitoring schedules with no option for providing stability in monitoring timelines unless the system chooses to stick to quarterly monitoring, increasing total costs and resources.

EPA Response: Please see section 8.5 of the EPA response in this *Response to Comments* document. Regarding the rule trigger levels and eligibility for reduced triennial monitoring, please see section 8.8 of the EPA response in this *Response to Comments* document.

New York State Department of Health (NYS DOH) (Doc. #1677, SBC-044943)

5. While we support regulatory flexibility for those public water systems that have demonstrated an absence of these compounds, their ubiquitous nature makes developing and implementing science-based criteria to assess a source's vulnerability to contamination impractical. If waivers are considered, we recommend that eligibility is based on at least 4 consecutive quarters of monitoring data at each source rather than an assessment of vulnerability.

EPA Response: Please see section 8.5 of the EPA response in this *Response to Comments* document.

City of Vancouver Water Utility, Vancouver, WA (Doc. #1684, SBC-044314)

EPAs proposal to allow water systems to apply to primacy agencies for monitoring waivers of up to nine years seems too long. Reducing this waiver allowance time period will ensure protection of public health.

EPA Response: Please see section 8.5 of the EPA response in this *Response to Comments* document.

New Hampshire Department of Environmental Services (NHDES) (Doc. #1690, SBC-044349)

c. Page 18730, Column 3, Bullet 1 - EPA requests comments on whether water systems should be permitted to apply to the primacy agency for monitoring waivers. Specifically, EPA is requesting comment on the allowance of monitoring waivers of up to nine years if after at least one year of sampling results are below the proposed rule trigger level. Similarly, EPA also requests comment on whether allowance of monitoring waivers of up to nine years should be permitted based on previously acquired monitoring data results that are below the proposed rule trigger level. Additionally, EPA is also requesting comment on the identification of possible alternatives to traditional vulnerability assessments that should be considered to identify systems as low risk and potentially eligible for monitoring waivers.

NHDES Comment - Due to the widespread use of PFAS in commercial, industrial, institutional, and domestic settings and the possibility of still unknown occurrences in the environment, NH does not believe there is any basis to allow monitoring waivers based on sampling results.

EPA Response: Please see section 8.5 of the EPA response in this *Response to Comments* document.

New Jersey Department of Environmental Protection (NJDEP) (Doc. #1699, SBC-045030)

NJDEP disagrees with the use of monitoring waivers for PFAS contaminants. Based on its experience in implementing the New Jersey-specific MCLs, NJDEP notes that some New Jersey water systems have incurred MCL violations after multiple years of quarterly monitoring which may have included observed values that were at/or below the proposed trigger level. Water systems may have multiple sources that contribute to one EPTDS and the impact of these different sources varies operationally and seasonally, which can be seen in the analytical results.

If EPA were to consider a monitoring waiver for nine years, NJDEP recommends EPA consider utilizing data collected at both the EPTDS as well as source water data. Furthermore, NJDEP does not support the use of vulnerability assessments for use in determining eligibility for monitoring waivers. In addition to water system compliance monitoring, NJDEP has added

PFAS monitoring to NJDEP's ambient surface water monitoring and groundwater monitoring networks, and New Jersey's Private Well Testing Act. Based on these data the presence of PFAS is widespread throughout the state and often is not able to be attributed to any known source or potential source in the environment. Therefore, vulnerability assessments may not result in accurate assessment of potential impact of PFAS on drinking water systems. NJDEP recommends decisions for consideration of reduced monitoring be based on monitoring data.

EPA Response: Please see section 8.5 of the EPA response in this *Response to Comments* document.

State of Vermont Agency of Natural Resources and Department of Health (Doc. #1708, SBC-047695)

4) Monitoring waivers – up to 9 years if initial monitoring is below the trigger level.

The standard SOC monitoring framework proposed by EPA does not seem to be a good fit for PFAS as discussed above. A protective framework should be part of the final regulation.

EPA Response: Please see section 8.5 of the EPA response in this *Response to Comments* document.

Thurston Public Utility District (PUD), WA (Doc. #1729, SBC-043587)

6. The EPA should allow the Washington State Department of Health Office of Drinking Water the authority to grant waivers of monitoring if both sampling history, source vulnerability, and geographic location indicate a wavier is warranted.

EPA Response: Please see section 8.5 of the EPA response in this *Response to Comments* document.

Thurston Public Utility District (PUD), WA (Doc. #1729, SBC-043591)

9. On Page 18,683, relating to Monitoring and Compliance Requirements, the EPA should authorize and provide the Washington State Department of Health the flexibility of allowing systems to apply for monitoring waivers based on source vulnerability combined with sampling results that show PFAS below trigger levels or non-detects. One sample per source is appropriate for source(s) in low-risk areas with a documented history of no PFAS detections.

EPA Response: Please see section 8.5 of the EPA response in this *Response to Comments* document.

Arizona Corporation Commission (ACC) (Doc. #1735, SBC-045189)

Allowance of monitoring waivers of up to nine years if after at least one year of sampling results are below the proposed rule trigger.

The ACC strongly supports waivers of up to nine years if after sampling results are below the proposed rule trigger.

EPA Response: Please see section 8.5 of the EPA response in this *Response to Comments* document.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-045966)

AMWA urges EPA to reconsider its decision to not grant monitoring waivers or reduced monitoring based on reduced risks and watershed characteristics, such as proximity to contaminant sources or previous uses within the watershed. Omitting this is inconsistent with other contaminants with chronic health impacts and introduces unnecessary costs. Furthermore, a PWS that cannot prove it is below the trigger level due to lab reporting constraints would never be able to stay in the reduced monitoring schedule. This is because once a system qualifies for reduced monitoring based on its RAA, if it cannot prove it maintains concentrations below the trigger level, the system is automatically thrown back into quarterly monitoring. This can result in systems repeatedly going back and forth between monitoring schedules with no option for providing stability in monitoring timelines unless the system chooses to stick to quarterly monitoring, increasing total costs and resources.

Allowing systems to use watershed characteristics and demonstrations of reduced risk to qualify for reduced monitoring or monitoring waivers would still be protective of the chronic health risks of PFAS. Utilities could demonstrate their reduced risk through a growing abundance of resources and tools. For example, EPA released its PFAS Analytic Tools to bring together multiple sources of information on PFAS sources in one spot with mapping, charting, and filtering functions [FN15: EPA. (2023, May 22). PFAS Analytic Tools. https://echo.epa.gov/trends/pfas-tools.]. Another tool by Azimuth provides information on PFAS-contaminated sites throughout the country that could be used to show a system is not located in these risk areas [FN16: Azimuth. (2021, April 07). How data science provides a new view into PFAS contaminated sites. https://www.azimuth1.com/blog/pfas].

Additionally, more data continues to be available on PFAS occurrence as EPA takes actions to identify and report PFAS industrial discharges and sources. A PWS would still be sampling at a reduced rate to check for detections of PFAS but will lessen the burdens and confusion of qualifying for reduced monitoring based on RAA and then being disqualified for an individual sample they cannot accurately demonstrate is below the trigger level.

AMWA appreciates EPA's consideration of reducing burdens on PWSs in the proposed rule and believes the above recommendations will achieve that goal without compromising any health benefits. Allowing PWSs with lower concentrations and risks to have a reduced monitoring schedule will ease burdens of costs and labor on the utility while still requiring the system to show continued low concentrations and risks.

EPA Response: Please see section 8.5 of the EPA response in this *Response to Comments* document. Regarding the rule trigger levels and eligibility for reduced triennial monitoring, please see section 8.8 of the EPA response in this *Response to Comments* document.

Connecticut Department of Public Health (CT DPH) (Doc. #1745, SBC-045229)

8. EPA is seeking comment on the identification of possible alternatives to traditional vulnerability assessments that should be considered to identify systems as low risk and potential eligibility for monitoring waivers.

CT DPH does not support the use of vulnerability assessments as a possible alternative to identify low risk PWSs. In 2018 and 2019, CT DPH required all community public water systems that serve more than 1,000 individuals (84 PWSs) to assess potential PFAS generators within their public drinking water source water areas. While useful in helping PWSs prioritize sources for PFAS testing, there have been several instances where a PWS detected PFAS through voluntary sampling at sources where no apparent generator was identified.

EPA Response: Please see section 8.5 of the EPA response in this *Response to Comments* document.

Connecticut Department of Public Health (CT DPH) (Doc. #1745, SBC-045227)

6. EPA is considering and taking comment concerning waivers based on sampling results. Specifically, EPA is requesting comment on whether water systems should be permitted to apply to the primacy agency for a monitoring waiver of up to nine years (one full compliance cycle) for these proposed PFAS if after at least one year of quarterly sampling the results are below the rule trigger level, or for systems that may be monitoring less frequently than quarterly if at least two consecutive three-year compliance period sample results are below the rule trigger level.

Due to PFAS persistence and mobility in the environment, CT DPH suggests limiting the reduced monitoring frequency to no more than every three years. CT DPH agrees with EPA's desire to reduce sampling on PWSs that have consistently demonstrated non-detect PFAS concentrations or concentrations below the trigger level; however, PFAS contamination can significantly migrate over a three-year period. Due to the wide range of potential pathways into the environment, measurement for PFAS once every nine years may not be protective of human health as conditions can significantly change during that period.

EPA Response: Please see section 8.5 of the EPA response in this *Response to Comments* document.

Connecticut Department of Public Health (CT DPH) (Doc. #1745, SBC-045202)

3. CT DPH recommends vulnerability assessments not be used as the sole determinant to identify low risk public water systems that might be granted a waiver. In 2018 and 2019 CT DPH

required all community public water systems that serve more than 1,000 individuals (n=84) to assess potential PFAS generators within their public drinking water source water areas. While useful for prioritizing areas for PFAS testing, there were several instances where a public water system detected PFAS through voluntary sampling at sources where no apparent generator could be identified. This suggests that in Connecticut PFAS contamination may not correlate to assessed vulnerability.

EPA Response: Please see section 8.5 of the EPA response in this *Response to Comments* document.

City of Thornton, Colorado (Doc. #1748, SBC-044796)

Thornton recommends that EPA does not grant monitoring waivers of 9 years to systems below the trigger level. Without appropriate occurrence data, it is inappropriate to grant this long of an extension. Likewise, because PFAS source contamination is not well understood and typically originates from discharges or seepages, the fluctuations in PFAS compounds and concentrations could drastically change within the proposed monitoring waiver framework. A system that believes they are free of PFAS and on reduced monitoring could suddenly have a new upstream contamination that they are unaware of and unprepared to treat, leading to up to 9 years of unprotected public health. Likewise, utilities that implement a PFAS treatment technique must monitor for breakthrough of PFAS; an extended monitoring waiver could result in utility complacency and lack of replacement of treatment media thus endangering public health. Thornton urges EPA to adopt monitoring waivers with a sampling frequency of no less than annually. If EPA does allow for reduced monitoring extending past annually, they must also clarify how the RAA will be calculated.

EPA Response: Please see section 8.5 of the EPA response in this *Response to Comments* document. Regarding the rule compliance monitoring requirements and the compliance calculation, please see sections 8.1.2 and 8.2 of the EPA response in this *Response to Comments* document, respectively.

Las Cruces Utilities (LCU) (Doc. #1753, SBC-043909)

In response to Section IX-Monitoring and Compliance Requirements, EPA requests comments on whether water systems should be permitted to apply to the primacy agency for monitoring waivers. Specifically, EPA is requesting comment on the allowance of monitoring waivers of up to nine years if after at least one year of sampling results are below the proposed rule trigger level. Similarly, EPA also requests comment on whether allowance of monitoring waivers of up to nine years should be permitted based on previously acquired monitoring data results that are below the proposed rule trigger level.

Additionally, EPA is also requesting comment on the identification of possible alternatives to traditional vulnerability assessments that should be considered to identify systems as low risk and potentially eligible for monitoring waivers.

• Waivers should be granted. With respect to alternatives to traditional vulnerability assessments, EPA could consider proximity to other PWSs that do not have PFAS detections.

EPA Response: Please see section 8.5 of the EPA response in this *Response to Comments* document.

Western Urban Water Coalition (WUWC) (Doc. #1768, SBC-043955)

E. State Primacy Agencies Should Have the Authority to Grant Monitoring Waivers in Appropriate Circumstances

Last, WUWC supports an adjustment to the Proposed Rule to allow state primacy agencies to issue monitoring waivers under circumstances where a public water system observes covered

PFAS for at least one year below the corresponding rule trigger level. [FN45: Id. at 18683.] Traditional vulnerability assessments in line with existing SDWA regulations that evaluate the potential for a water system to be susceptible to PFAS contamination should be utilized to support such waivers. [FN46: Cf. 40 C.F.R. § 141.24]

The Proposed Rule does not currently contemplate state primacy agency waiver authority based on EPA's belief that "due to the ubiquity, environmental persistence, and transport abilities of PFAS, granting waivers based on these conditions would be challenging." [FN47: Id.] WUWC disagrees because the Proposed Rule would set MCLs for PFOA and PFOS at 4 ppt, the lowest feasible quantitation level according to EPA's own findings. Under the Proposed Rule, assuming it is even feasible to implement, there would be very low potential for monitoring to result in false negatives.

Moreover, while the covered PFAS are indeed ubiquitous and persistent in the environment, the mere existence of a state primacy agency waiver authority would not result in under-monitoring. State primacy agencies would share EPA's interest in protecting public health and would simply deny monitoring waiver requests under circumstances where public water systems have not demonstrated appropriate circumstances. In the unlikely event that a state primacy agency was found to consistently grant monitoring waivers in inappropriate circumstances, EPA would also have authority to revoke its grant of state primacy. [FN48: See generally 40 C.F.R. § 142, Subpart B] Therefore, WUWC does not agree with EPA that the ubiquity or pervasiveness of these PFAS substances presents a sound justification for depriving states of monitoring waiver authority that is common under the SDWA.

* * *

Our members are experienced, on-the-ground partners with EPA and the states in the implementation of the SDWA and other related authorities. WUWC recognizes the importance of regulating PFAS in line with WUWC's mission to ensure that western water agencies and their customers are assured a public water supply that is reliable, affordable, and safe for consumption. Based on this experience, WUWC wants to work with EPA, other federal and state

regulatory agencies, and members of Congress to address this important issue. We look forward to continued dialogue and collaboration on legislative and regulatory initiatives affecting PFAS and water quality.

Thank you for the opportunity to provide these comments. For more information, please contact me at (303) 739-7378 or mbrown@auroragov.org, or WUWC's national counsel, Ted Boling, at (202) 661-5872 or TedBoling@perkinscoie.com.

Very truly yours,

Marshall P. Brown Chairman

EPA Response: Please see section 8.5 of the EPA response in this *Response to Comments* document.

Uttara Jhaveri (Doc. #1778, SBC-045451)

Granting Waivers under 40 CFR 141.24 Subpart C

The grant of waivers under 40 CFR 141.24 Subpart C based on the proximity of the system to contaminant sources (i.e., susceptibility to contamination) and previous uses of the contaminant within the watershed (including transport, storage, or disposal) would not be a fair decision. [FN32: Environmental Protection Agency, supra note 4.] PFAS are "forever chemicals" and can be transported to substantial distances in the atmosphere, groundwater, surface water, and soil. [FN33: Earthjustice, supra note 1.] Therefore, granting waivers based on certain exceptional conditions may lead to transportation and contamination of a nearby source and defeat the purpose of the proposed regulation. Instead, an effort to bring down the levels of certain contaminant sources over a period of time would be more aligned with the purpose of the proposed regulations.

EPA Response: Please see section 8.5 of the EPA response in this *Response to Comments* document.

Earthjustice et al. (Doc. #1808, SBC-046118)

At the outset, we support EPA's proposal to disallow monitoring waivers as part of the PFAS NPDWR in light of the "ubiquity, environmental persistence and transport abilities of PFAS." [FN199: Id. at 18,683.] But as explained below, these same factors—as well as the toxic effects of PFAS at very low concentrations—undermine EPA's proposal for reduced monitoring requirements for systems with initial PFAS detections below EPA's proposed trigger level of one-third the relevant MCL. [FN200: Id. at 18,681.]

EPA Response: Please see section 8.5 of the EPA response in this *Response to Comments* document. Regarding the EPA's compliance monitoring requirements, please see section 8.1.2 of the EPA response in this *Response to Comments* document.

Sharon Levy (Doc. #1824, SBC-044278)

One aspect of the proposed rule is granting monitoring wavers to certain areas.

All communities must be monitored and protected. People should know what they are being exposed to, and the potential acute or chronic effects that can come from these chemicals.

Reduced monitoring will only lead to the potential risk of health effects associated with PFAS. Even small exposures can lead to health effects that can be harmful to people who are ingesting PFAS, especially if their community isn't being monitored.

In summary, The EPA must act urgently to protect vulnerable communities by shifting costs to polluters and monitor all communities for PFAS.

Sincerely,

Sharon Levy

EPA Response: Please see section 8.5 of the EPA response in this *Response to Comments* document.

Wisconsin Department of Natural Resources (Doc. #1828, SBC-044806)

The ASDWA comment raises important issues regarding monitoring requirements.

The WDNR does support the application of vulnerability assessment processes for monitoring waivers. States have varying vulnerability assessment processes which may warrant the application of waivers. Public water supply systems operate in numerous geological and hydrogeological environments where, along with well construction criteria, evaluation of potential contaminant sources and analytical history, provide justification for the implementation of a vulnerability assessment process.

EPA Response: Please see section 8.5 of the EPA response in this *Response to Comments* document.

Little Hocking Water Association (Doc. #1835, SBC-045517)

Further, water supplies that are known to be highly contaminated with PFAS or are at a high risk of contamination should not be eligible for monitoring waivers, especially a waiver allowing monitoring only once every nine years. At the very least, eligibility for waivers for less frequent monitoring needs to be made with knowledge of the levels of contamination in pretreated waters, which is likely to show that less frequent monitoring would not be protective of public health.

EPA Response: Please see section 8.5 of the EPA response in this *Response to Comments* document.

Anonymous (Doc. #2312, SBC-047428)

3/29/2023

RE: Docket ID No. EPA-HQ-OW-2022-0114, Environmental Justice Considerations for the Development of the Proposed Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation

I am currently a student at Loyola University Chicago who is researching contaminants in drinking water and their regulations. One aspect of the proposed rule that I have seen other people comment on is the idea of granting monitoring waivers to certain areas. I believe that reduced monitoring will only lead to more exposure to PFAS and is unfair to those living in the unmonitored areas. I fear that through the use of waivers, low income areas will be disproportionately affected by the lack of monitoring.

EPA Response: Please see section 8.5 of the EPA response in this *Response to Comments* document.

Susan Suggs (Doc. #3038, SBC-047463)

One aspect of the proposed rule is granting monitoring wavers to certain areas.

All communities must be monitored and protected. People should know what they are being exposed to, and the potential acute or chronic effects that can come from these chemicals.

Reduced monitoring will only lead to the potential risk of health effects associated with PFAS. Even small exposures can lead to health effects that can be harmful to people who are ingesting PFAS, especially if their community isn't being monitored.

In summary, The EPA must act urgently to protect vulnerable communities by shifting costs to polluters and monitor all communities for PFAS.

Copy and paste this statement to your EPA comment

To Whom It May Concern,

I am writing in regards to the proposed rule for Per- and Polyfluoroalkyl Substances (PFAS) to be included into the National Primary Drinking Water Regulations.

On March 14, 2023, the EPA proposed the first ever national drinking standards with regards to PFAS in public drinking water. EPA is issuing a preliminary regulatory determination to regulate PFHxS, HFPO-DA (also known as GENX), PFNA, PFBS, PFOA, PFOS and a mixtures of these PFAS as contaminants under SDWA.

PFHxS, HFPO-DA (also known as GENX), PFNA, PFBS, PFOA and PFOS have all been found in large concentrations across North Carolina.

The Chemours plant in Bladen County produces GenX, and discharges upwards of 250 different PFAS chemicals into our drinking water.

The PFAS production at the site is responsible for groundwater and surface water contamination in the surrounding area, according to water samples from Chemours and the N.C. Department of Environmental Quality.

Since learning about our PFAS water contamination in 2017, we have learned how harmful PFAS are to populations that are exposed to "forever chemicals".

Pregnant women, young children, low income communities and people of color are extremely vulnerable.

PFAS are dangerous chemicals that bioaccumulate in the body's organs. Continuous small exposures can lead to larger health effects that can be harmful to people who are ingesting PFAS.

One aspect of the proposed rule is granting monitoring wavers to certain areas.

All communities must be monitored and protected. People should know what they are being exposed to, and the potential acute or chronic effects that can come from these chemicals.

Reduced monitoring will only lead to the potential risk of health effects associated with PFAS. Even small exposures can lead to health effects that can be harmful to people who are ingesting PFAS, especially if their community isn't being monitored.

In summary, The EPA must act urgently to protect vulnerable communities by shifting costs to polluters and monitor all communities for PFAS.

Sincerely,

Susan Suggs

1101 Herford Ct

Wilmington, NC 28411

EPA Response: Please see section 8.5 of the EPA response in this *Response to Comments* document.

Deena Craig (Doc. #3045, SBC-047466)

One aspect of the proposed rule is granting monitoring wavers to certain areas.

All communities must be monitored and protected. People should know what they are being exposed to, and the potential acute or chronic effects that can come from these chemicals.

Reduced monitoring will only lead to the potential risk of health effects associated with PFAS. Even small exposures can lead to health effects that can be harmful to people who are ingesting PFAS, especially if their community isn't being monitored.

In summary, The EPA must act urgently to protect vulnerable communities by shifting costs to polluters and monitor all communities for PFAS.

I have metastatic breast cancer. At the time of my diagnosis I had very high estrogen levels despite being age 64, post menopausal and being born with just one ovary. I drank water contaminated with GenX/PFAS for many years. I asked my oncologist if PFAS could cause high estrogen levels and he immediately said yes. He was from Parkersburg, WV where DuPont dumped carcinogens in their water. GenX is essentially what was dumped in the water in Parkersburg but designed to clear the bloodstream (not be detectable) in a short period of time. Yet PFAS is a forever chemical, its effects remaining in the body for many years.

DuPont Chemours has a history of placing profits over people.

Please protect us and monitor the levels of GenX, PFAS and other forever chemicals.

Sincerely,

Deena Craig

EPA Response: Please see section 8.5 of the EPA response in this *Response to Comments* document.

Mass comment campaign submitted by Arthur Bell (Doc. #3071, SBC-047468)

One aspect of the proposed rule is granting monitoring wavers to certain areas.

All communities must be monitored and protected. People should know what they are being exposed to, and the potential acute or chronic effects that can come from these chemicals.

Reduced monitoring will only lead to the potential risk of health effects associated with PFAS. Even small exposures can lead to health effects that can be harmful to people who are ingesting PFAS, especially if their community isn't being monitored.

In summary, The EPA must act urgently to protect vulnerable communities by shifting costs to polluters and monitor all communities for PFAS.

Sincerely, Art Bell

EPA Response: Please see section 8.5 of the EPA response in this *Response to Comments* document.

Groundwater Resources Association of California (Doc. #1831, SBC-045358)

Finally, EPA is considering not granting any waivers for monitoring requirements. We suggest that if a water system conduct a study to evaluate all the points of entry to the system for potential PFAS sources, and the consecutive monitoring results for one year have shown no MCL exceedances, then the primacy agency shall have the authority to waive the monitoring requirements. If the study finds no potential for PFAS sources to enter to the system and the monitoring results confirm that for a set period of time, then the waiver could be granted.

EPA Response: Please see section 8.5 of the EPA response in this *Response to Comments* document.

8.6 Laboratory Certification Requirements

Summary of Major Public Comments and EPA Responses

A few commenters requested that the EPA develop guidance and training for drinking water laboratory certification programs to evaluate laboratories seeking certification. The EPA agrees that training for laboratory certification officers is appropriate. The EPA will develop training materials and guidance for drinking water certification programs to evaluate laboratories to ensure adherence to the requirements of EPA Methods 533 and 537.1.

One commenter requested that the EPA establish reciprocity between laboratory certification programs to utilize all potential laboratory capacity available. As described in the EPA's Manual for the Certification of Laboratories Analyzing Drinking Water, laboratory certification programs may recognize drinking water laboratory certifications (or comparable "accreditation") from other laboratory certification programs, by reciprocity (USEPA, 2005). Most laboratory certification programs do utilize the practice of reciprocal certification. For purposes of supporting this NPDWR, reciprocal certification can only be granted to laboratories utilizing EPA Methods 533 and 537.1.

Individual Public Comments

Association of Public Health Laboratories (APHL) (Doc. #1646, SBC-043298)

Detailed recommendations are appended to this letter, but a few are emphasized below:

• The Laboratory Drinking Water Certification Manual must be updated to provide clear guidance to certification bodies and laboratories if these 6 PFAS are regulated.

EPA Response: Please see section 8.6 of the EPA response in this *Response to Comments* document. The EPA is currently working on a revision to the Laboratory Certification Manual.

National Ground Water Association (NGWA) (Doc. #1804, SBC-045467)

[Actions that EPA should consider to enable more laboratory capacity are:]

3. Provide training for needed additional laboratory staff certification

[Actions that EPA should consider to enable more laboratory capacity are:]

4. Establish reciprocity of certification across states to utilize all potential capacity available

EPA Response: Please see section 8.6 of the EPA response in this *Response to Comments* document.

Oklahoma Department of Environmental Quality (DEQ) (Doc. #1616, SBC-043053)

• EPA needs to expand their drinking water laboratory certification program to include PFOS/PFAS testing via LCMSMS technology (EPA methods 533, 537.1, and 1633). Currently, TNI is the only option to ensure laboratory competency and compliance for this type of analytical testing.

• PFOS/PFAS testing requires a unique and uncommon knowledge and skill set that requires extensive training and experience. Funding and training options to advance expertise on such applications for both laboratory scientists and lab assessors is very limited.

EPA Response: Please see section 8.6 of the EPA response in this *Response to Comments* document.

Rockbridge Area Conservation Council (RACC) (Doc. #1678, SBC-044298)

[With that said, we would respectfully request that:] (4) establish a timeline for lowering the limit of quantification for EPA lab certification with a parallel automatic reduction in the MCL.

EPA Response: Please see section 8.6 of the EPA response in this *Response to Comments* document. Additionally, the EPA evaluates NPDWRs as part of the Six Year Review process. Any changes made to the regulations, including changes to PQLs and/or MCLs, would follow this process outlined under SDWA.

Missouri Department of Natural Resources (Doc. #1563, SBC-042509)

In addition, the Department is concerned that the proficiency testing (PT) used to approve laboratories for Unregulated Contaminant Monitoring Rule (UCMR 5) sampling was not sufficient to confirm a viable minimum reporting level (MRL), also referred to in the rule as a practical quantification limit (PQL). It is not clear from information that EPA has made publically available to date whether any of the 8 PT studies conducted included true values "at or near" the proposed MCL. In coordination with laboratories that EPA has approved for UCMR 5 analysis, we are aware that at least six of the eight PT studies had an average concentration of 55

ppt true value. Since EPA approves laboratories based on two PT tests, it is not clear how many approved laboratories have demonstrated proficiency "at or near" the proposed MRL and MCL of 4.0 ppt. Without the opportunity to review all of the proficiency testing data, it is difficult for interested parties to adequately comment on whether or not the MRL established was based on sufficient supporting evidence that laboratories could meet low-level, true values around the proposed MCL.

EPA Response: Please see section 8.6 of the EPA response in this *Response to Comments* document. Laboratories that wish to be certified under this rule will need to participate in new proficiency testing (PT) studies to apply for certification from the state certification programs. This rule requires laboratories to pass at least one performance evaluation (PE) study (or PT study) per method and analyte on an annual basis. In addition, as part of state certification for methods EPA 533 and EPA 537.1, Version 2.0, laboratories must demonstrate proficiency at the laboratory reporting limit, per method reporting limit confirmation requirements. Laboratories will be required to submit initial demonstration of capability data to the state certification programs prior to the state program conducting an assessment of the laboratory. These data include a passing PE/PT result.

<u>The NELAC Institute (Doc. #1575, SBC-042458)</u>

Comments on PFAS National Primary Drinking Water Rulemaking (03/29/2023)

Docket ID. No: EPA–HQ– OW–2022–0114

May 22, 2023

Prepared by: The NELAC Institute

PO Box 2439

Weatherford, TX 76086 817-598-1624

https://nelac-institute.org

The NELAC Institute (TNI) is a 501(c)(3) non-profit organization whose mission is to foster the generation of environmental data of known and documented quality through an open, inclusive, and transparent process that is responsive to the needs of the community. Among other matters, TNI manages a national proficiency testing (PT) program for environmental laboratories that covers drinking water, non-potable water, and hazardous wastes.

TNI appreciates the opportunity to comment on the proposed PFAS National Primary Drinking Water Rulemaking (03/29/2023). This comment requests changing the proposed Performance Evaluation sample acceptance limits outlined in Table 2 Paragraph (b)(2)(iii)(B).

141.901 Sub part Z. Section B states, "… the laboratory must achieve quantitative results on the PE sample analyses that are within the following acceptance limits:"

Table 2 to Paragraph (b)(2)(iii)(B) shows these acceptance limits as 70-130 percent recovery of true values. TNI requests these acceptance limits be adjusted to 60-140 percent recovery of true values to be consistent with UCMR 5 Performance Evaluation Sample acceptance criteria. Making this change would ensure data quality objectives for analysis completed in support of this rule would be consistent with UCMR 5 regarding Performance Evaluation data evaluation. Performance Evaluation sample data has not been gathered outside of UCMR and can thus not be evaluated to determine if limits of 70-130% would be supported. Furthermore, performance evaluation samples are not at a set true value. The true value of the compounds of interest can vary within the range specified in PT Provider instructions or Fields of Proficiency Testing (FoPT) Tables. These concentrations are randomly assigned according to the TNI PT standards. In reviewing Laboratory Fortified Blank (LFB) criteria in PFAS analytical methods, there is a percent recovery range specified at the Method Reporting Limit (MRL) level as well as the mid/high level. As PE (PT) samples could potentially incorporate multiple compounds spiked into one sample, recovery acceptance limits of 60-140% would be more inclusive to account for this range.

As specified in EPA Method 533 regarding LFB criteria:

9.2.3.2 Results for analytes fortified at concentrations near or at the MRL (within a factor of two times the MRL concentration) must be within 50–150% of the true value. Results for analytes fortified at all other concentrations must be within 70–130% of the true value. If the LFB results do not meet these criteria, then all data for the problem analytes must be considered invalid for all samples in the Extraction Batch.

As specified in EPA Method 537.1 regarding Laboratory Fortified Blank criteria:

9.3.3. Results of the low-level LFB analyses must be 50-150% of the true value. Results of the medium and high-level LFB analyses must be 70-130% of the true value. If the LFB results do not meet these criteria for method analytes, then all data for the problem analyte(s) must be considered invalid for all samples in the extraction batch.

Thank you for your consideration,

The TNI Proficiency Testing Program Executive Committee

Stacie Crandall, Chair

SCrandall@hrsd.com

EPA Response: Please see section 8.6 of the EPA response in this *Response to Comments* document. The PT portion of the UCMR 5 laboratory approval program differed from previous UCMR laboratory approval programs. When the EPA implemented the UCMR 3 laboratory approval program, PT acceptance criteria were indeed 60-140 percent for the perfluorinated compounds included in UCMR 3 monitoring program. The criteria were set wider than the laboratory fortified blank (LFB) acceptance criteria in UCMR 3, primarily because the analytical techniques used in the methods approved under UCMR 3 were new to the certified

laboratory community. Under UCMR 5, the EPA used PT acceptance criteria of 70-130 percent in the UCMR 5 laboratory approval program. Additionally, laboratories participating in the UCMR 5 laboratory approval program were required to pass two PT studies prior to becoming approved to analyze samples for UCMR 5. The EPA conducted eight PT studied prior to sample collection for UCMR 5, using the 70-130 percent acceptance criteria. Even while utilizing this tighter criterion for PTs, there was an overall passing rate for individual analytes of 97.8 percent. The UCMR 5 PT data and the UCMR 5 laboratories' Initial Demonstrations of Capability support the criteria proposed in this rule.

8.7 Other Laboratory Considerations

Summary of Major Public Comments and EPA Responses

Many commenters suggested the potential for false positives to misrepresent actual levels of the regulated PFAS within the drinking water sample due to the ubiquity of PFAS and the possible background interference. The EPA is aware of the potential for background contamination. The EPA agrees that PFAS sampling at very low levels is highly sensitive and there is potential for sample contamination. However, with proper training tools and communications, that potential can be mitigated, though not sufficiently enough to allow for composite sampling as discussed in section 8.4 of the EPA response in this *Response to Comments* document. For example, the UCMR program has released several sampling guidance documents and a small-systems sampling video to assist small and medium utilities with the PFAS sampling. These products have also been distributed to the UCMR laboratory community, which has been encouraged to share them with their PWS clients.

Also, Method 533 and Method 537.1 require the analysis of a Laboratory Reagent Blank (LRB) with each extraction batch. If method analytes are detected in the LRB at or above 1/3 the MRL, suggestive of background contamination, all positive field sample results associated with that extraction batch are invalid for the impacted analytes. Both methods also require the analysis of a FRB (a blank that is prepared at the sampling location) when any PFAS are detected above the MRL in field samples. The use of laboratory and field blanks were incorporated into the methods as QC to reduce the potential for false positives due to background contamination. Additionally, in the instance where there is evidence that the PFAS may be a result of background contamination and not representative of the drinking water, the final rule, at 141.902(b)(2)(v), allows a primacy agency to invalidate results associated with obvious sampling errors and/or require an additional confirmation sample to be taken if necessary.

Individual Public Comments

Mike Pettit (Doc. #1542, SBC-043348)

Sample Collection

PFAS (per- and polyfluoroalkyl substances) are synthetic chemicals that have been used in a wide range of industrial and consumer products for decades, including non-stick cookware, waterproof clothing, stain-resistant carpets, and firefighting foam. Due to their widespread use and persistence in the environment, PFAS are now found in soil, water, air, and biomes across the globe. The ubiquitous nature of PFAS molecules can create challenges for sample collection and analysis. One major challenge is the potential for contamination of samples during collection, handling, and analysis. PFAS are known to adhere strongly to laboratory equipment, such as tubing and containers, which can lead to false positives or elevated concentrations. As such special precautions need to be taken during sample collection, including the use of PFAS-free equipment and taking care to avoid cross-contamination. Another challenge is that PFAS can be present in a wide range of sample matrices, including water, soil, sediment, and biomass, and can exist in various forms, such as dissolved, particulate-bound, or adsorbed onto organic matter. This variability in PFAS form and distribution in samples can lead to differences in detection limits and biases in sampling results. Therefore, it is important to carefully select sampling and extraction methods that are appropriate for the specific sample matrix and analyte. To address these challenges, some potential solutions include using pre-cleaned or disposable sampling equipment, optimizing sampling and extraction methods, and using quality control measures, such as field and laboratory blanks, and reference materials. Additionally, it is important to carefully document sampling and analysis procedures to ensure data quality and reproducibility. Overall, careful consideration and attention to sampling and analysis procedures are critical for obtaining accurate and representative data on PFAS contamination in the environment

EPA Response: Please see section 8.7 of the EPA response in this *Response to Comments* document.

Maine Water Utilities Association (MWUA) (Doc. #1567, SBC-042730)

Sampling Protocols & Training:

PFAS sampling requires unique protocols that are extremely sensitive to prevent cross-contamination. Our PWS have been instructed to take precautions such as avoiding use of sharpie markers, sticky notes, and plastic clipboards; not to wear waterproof or stain-repellant clothing; not to use fabric softener on clothing to be worn in field, do not use cosmetics, moisturizers, hand cream, sunscreen, or other personal care products the morning of sampling, do not use plastic clipboards, etc. All these precautions cause us to believe that samples may easily be contaminated. When considering enforceable regulatory limits in the low parts per trillion, barely above a laboratory's capability to reliably detect and quantify these compounds, cross contamination must be considered. EPA must have protocols in place to invalidate samples with PFAS detections that may be a result of human error through sample collection, improper shipping practices, or other avenues. EPA and primacy states must ensure that PWS have training on proper sampling protocols and provide the appropriate technical assistance and outreach to PWS once the rule is implemented.

EPA Response: Please see section 8.7 of the EPA response in this *Response to Comments* document.

Lehigh County Authority (LCA) (Doc. #1600, SBC-042814)

PFOA and PFOS

The proposed regulation sets a Maximum Contaminant Level (MCL) of 4.0 parts per trillion (ppt) for PFOA and PFOS. The laboratory methods approved for analysis are methods EPA 533 and 537.1, which have a Practical Quantification Limit (PQL) and Method Detection Limit (MDL) of 4.0 ppt. PQLs are defined as "the lowest achievable level of analytical quantitation during routine laboratory operating conditions within specified limits of precision and accuracy" (50 Federal Register 46902, November 13, 1985). Thus, the PQL reflects both the physical limitation of approved analytical methods and the practical limitations of variability in laboratory performance.

While other analytes' MCLs have been set at the PQL (such as heptachlor, chlordane, or thallium), the likelihood of cross-contamination or interference was not as likely to occur in those cases. Conversely, PFAS compounds are known to be present in many everyday products such as cosmetics, food packaging, fabrics, etc. Every day, it seems, a story is published in the news media about PFAS being found in more products and in our natural environment in seemingly unlikely places.

To address the issue of potential cross-contamination of water samples from external sources, some states have established PFAS regulatory protocols that allow for samples to be invalidated based on obvious sampling errors. EPA should consider taking this approach in the final rulemaking, so utilities (and the communities they serve) are not unnecessarily penalized for a cross-contaminated sample. The very low limit, set at the PQL, and the ubiquitous nature of PFAS compounds make cross-contamination of water samples as very real concern for all utilities.

EPA Response: Please see section 8.7 of the EPA response in this *Response to Comments* document. Although the commenter correctly states that the PQLs for PFOA and PFOS are 4.0 ppt, the EPA-approved methods do not include MDLs as the commenter provided. Rather, the methods require the confirmation of MRLs which are distinctly different from MDLs. For the PFAS NPDWR, the EPA did not define MRLs for PFAS contaminants, but established PQLs, as discussed in sections V and VII of the final rule preamble, to evaluate analytical feasibility for the determination of MCLs.

Massachusetts Water Works Association (MWWA) (Doc. #1601, SBC-042880)

Sampling Protocols & Training:

PFAS sampling requires unique protocols that are extremely sensitive to prevent cross-contamination. Our PWS have been instructed to take precautions such as avoiding use of

sharpie markers, sticky notes, and plastic clipboards; not to wear waterproof or stain-repellant clothing; not to use fabric softener on clothing to be worn in field, not to use cosmetics, moisturizers, hand cream, sunscreen, or other personal care products the morning of sampling, etc. All these precautions cause us to be concerned that samples may easily be contaminated. When considering enforceable regulatory limits in the low parts per trillion, barely above a laboratory's capability to reliably detect and quantify these compounds, cross contamination must be considered a significant problem. EPA must have protocols in place to invalidate samples with PFAS detections that may be a result of human error through sample collection, improper shipping practices, or other avenues. EPA and primacy states must ensure that PWS have training on proper sampling protocols and provide the appropriate technical assistance and outreach to PWS once the rule is implemented.

EPA Response: Please see section 8.7 of the EPA response in this *Response to Comments* document.

Environmental Monitoring Coalition (EMC) (Doc. #1625, SBC-043113)

4. Background Contamination

Regarding the background contamination level, there appears to always be an impurity in the isotope dilution standard. The compounds in the isotope dilution standard are labeled versions of the analytes, usually 13C, and there is always a small impurity of unlabeled analyte present. Since the isotope dilution standard is added to every sample, and always in the same amount, there will be the potential to have this contamination in every sample. When the reporting limit is driven to ever lower levels, this small impurity becomes a larger factor. For UCMR 5, the concentration of the isotope dilution standard is equivalent to 40 ppt in sample. So even a 1% impurity represents 0.4 ppt in the sample. Generally, laboratories see less than 1%, but it could be an issue.

There is also always systematic background in the laboratory reagent or extraction blanks. This background contamination can vary by laboratory, by compound, and between lots of reagents and other consumables used in each test. Even with tight control, by the laboratory, to minimize contamination the prevalent use of PFAS in manufacturing processes and consumer products means that this source of laboratory contamination will always be present. When using a MRL of 2 ng/L as most labs currently do, the 1/3 of the MRL blank requirement is possible (~0.66 ng/L), however, if laboratories attempt to lower the MRL to the trigger level of 1.3 ng/L the blank requirement will not be met resulting in a QC failure.

EPA Response: Please see section 8.7 of the EPA response in this *Response to Comments* document. Unlabeled analyte interferences from isotopic standards are not expected to be significant and would be accounted for by method quality control samples.

Association of Public Health Laboratories (APHL) (Doc. #1646, SBC-043321)

Washington State Department of Health (DOH) (Doc. #1665, SBC-044423)

Page 18730. Section IX-Monitoring and Compliance Requirements Continued.

EPA requests comment on other monitoring related considerations including laboratory capacity and QA/ QC of drinking water sampling.

• Increased emphasis on meeting all method required QC would help ensure consistent data quality and aid state Primacy agencies.

EPA Response: Please see section 8.7 of the EPA response in this *Response to Comments* document.

A. O. Smith Corporation (Doc. #1674, SBC-043696)

However, in the Company's view this challenge is addressed and documented in the methods themselves, including the quality assurance and quality control measures (i.e., QA/QC) that must be followed to ensure the sensitivity of the measurement instruments and laboratory settings. The

key, however, will be ensuring that the drinking water samples sent to the certified laboratories are free of any PFAS cross-contamination.

EPA Response: Please see section 8.7 of the EPA response in this *Response to Comments* document.

New York City Department of Environmental Protection (NYCDEP) (Doc. #1679, SBC-044211)

Laboratory Capability

In section VIII., p. 18681, the discussion of analytical methods excludes any mention of or assessment of contamination and positive bias. As PFAS are ubiquitous contaminants, it seems likely that the existing historic data will include positive bias resulting from contamination. Was this evaluated for the UCMR3 occurrence data? Notably, on p. 18697, EPA notes that blanks will be considered going forward. It is unclear if positive bias exists in the occurrence or toxicity data used as a basis for the levels stated in the rule.

EPA Response: Please see section 8.7 of the EPA response in this *Response to Comments* document.

U.S. Poultry & Egg Association et al. (Doc. #1765, SBC-044545)

There is a long list of potential interferences that can cause inaccurate reporting and interpretation of Method 537.1 results (falsely biasing results either high or low). Currently, the best standards of practice for collecting water samples and then interpreting results received from the lab are not well known by most water providers, especially non-transient, non-community water providers that typically do not have this level of experience and expertise on staff. Importantly, PFAS contamination may occur during sample collection, and robust procedures are necessary to elimination cross-contamination (e.g., nitrile gloves, use of the correct sample bottles and caps, appropriately flushing the system, adding the buffering agent correctly, use of sample blanks, appropriate shipping temperature and holding times). Specially trained personnel are needed to appropriately collect samples and interpret results obtained from the laboratories. Due to the low detection limit and the fact that decision thresholds are at the detection limit, the collection and analysis of samples will be extremely costly, time intensive and laborious, and mistakes will be extremely costly. EPA has not adequately considered the lack of properly trained personnel, especially for non-transient and non-community water providers that will be subject to this regulation.

The need to hire and/or train personnel to learn the best practices for selecting a lab certified in running Method 537.1, sample collection, and laboratory data interpretation has not been appropriately factored into the EPA costs and economic impact analysis.

EPA Response: Please see section 8.7 of the EPA response in this *Response to Comments* document. Regarding laboratory certification, please see section 8.6 of the EPA response in this *Response to Comments* document. The EPA disagrees that it has not

appropriately considered all costs associated with monitoring required by the final rule (please see section 13.3.4 of the EPA response in this *Response to Comments* document).

National Ground Water Association (NGWA) (Doc. #1804, SBC-045456)

Sample Bias – NGWA is concerned that the potential for sample bias and cross contamination is amplified based on the very low (stringent) criteria for sample test results as well as the sensitivity at ng/L levels.

EPA Response: Please see section 8.7 of the EPA response in this *Response to Comments* document.

New England Water Works Association (Doc. #1836, SBC-045382)

Sampling Protocols & Training:

PFAS sampling requires unique protocols that are extremely sensitive to prevent cross-contamination. Our PWS have been instructed to take precautions such as avoiding use of sharpie markers, sticky notes, and plastic clipboards; not to wear waterproof or stain-repellant clothing; not to use fabric softener on clothing to be worn in field; not use cosmetics, moisturizers, hand cream, sunscreen, or other personal care products the morning of sampling; to not use plastic clipboards, etc. All these precautions highlight the need for broader regulation but also cause concern that samples may easily be contaminated. When considering enforceable regulatory limits in the low parts per trillion—barely above a laboratory's capability to reliably detect and quantify these compounds—cross contamination must be considered. EPA must have protocols in place to invalidate samples with PFAS detections that may be a result of human error through sample collection, improper shipping practices, or other avenues. EPA and primacy states must ensure that PWS have training on proper sampling protocols and provide the appropriate technical assistance and outreach to PWS once the rule is implemented.

EPA Response: Please see section 8.7 of the EPA response in this *Response to Comments* document.

Citizens Energy Group (Doc. #1838, SBC-044866)

Further, the ubiquitous nature of PFAS compounds in the environment and the risk of low- level contamination of samples given the presence of these PFAS compounds in clothing, personal care products, etc., consideration should be given for "outliers", or analytical results that are inconsistent with prior sampling events.

EPA Response: Please see section 8.7 of the EPA response in this *Response to Comments* document.

New Hampshire Water Works Association, Inc. (NHWWA) (Doc. #1576, SBC-042452)

In addition, EPA's proposed MCLs are vulnerable to excess false positive analytical results from factors such as Teflon-based materials commonly used in drinking water treatment systems.

EPA Response: Please see section 8.7 of the EPA response in this *Response to Comments* document.

City of Allentown and Lehigh County Authority (LCA), Pennsylvania (Doc. #1667, SBC-043675)

PFOA and PFOS: The proposed regulation sets a Maximum Contaminant Level (MCL) of 4.0 parts per trillion (ppt) for PFOA and PFOS. The laboratory methods approved for analysis are methods EPA 533 and 537.1, which have a Practical Quantification Limit (PQL) and Method Detection Limit (MDL) of 4.0 ppt. PQLs are defined as "the lowest achievable level of analytical quantitation during routine laboratory operating conditions within specified limits of precision and accuracy" (50 Federal Register 46902, November 13, 1985). Thus, the PQL reflects both the physical limitation of approved analytical methods and the practical limitations of variability in laboratory performance. While other analytes' MCLs have been set at the PQL (such as heptachlor, chlordane, or thallium), the likelihood of cross-contamination or interference was not as likely to occur in those cases. Conversely, due to proposed limits, cross contamination during PFAS sampling is highly likely as PFAS compounds are known to be present in many everyday products.

To address the issue of potential cross-contamination of water samples from external sources, some states have established PFAS regulatory protocols that allow for samples to be invalidated based on obvious sampling errors. We request that EPA consider adopting this approach in the final rulemaking, so utilities (and the communities they serve) are not unnecessarily penalized for a cross-contaminated sample. The exceptionally low limit, set at the PQL, and the ubiquitous nature of PFAS compounds make cross-contamination of water samples a very real concern for all utilities.

EPA Response: Please see section 8.7 of the EPA response in this *Response to Comments* document.

California Farm Bureau Federation (Doc. #1704, SBC-045077)

Accuracy also remains a concern given the proposed MCLs for PFOA and PFOS are incredibly low. There is a high risk of contamination during the testing process and inaccurate results has the potential to result in costly compliance measures.

EPA Response: Please see section 8.7 of the EPA response in this *Response to Comments* document.

Massachusetts Department of Environmental Protection (MassDEP) (Doc. #1726, SBC-045159)

Criteria for sample invalidation needs to be added to accommodate issues such as Quality Control failures including but not limited to detections of target analytes in the FRB, as well as whether replacement samples must be collected along with a timeline for doing so.

EPA Response: Please see section 8.7 of the EPA response in this *Response to Comments* document.

Pennsylvania Chamber of Business and Industry (Doc. #1592, SBC-042795)

At the extremely low levels being proposed, it will be extremely difficult for commercial and public laboratory testing facilities to keep the testing areas, as well throughout the chain of custody, pure of any residual PFAS contamination that will result in inaccurate testing.

EPA Response: Please see section 8.7 of the EPA response in this *Response to Comments* document.

Environmental Monitoring Coalition (EMC) (Doc. #1625, SBC-043115)

While EMC acknowledges that current screening technology sensitivity levels are not adequate to help for these proposed PFAS MCL levels, it would be useful for EPA to investigate potential screening technologies versus analyzing all samples through LC/MS/MS or HRMS. This would help address laboratory capacity issues.

To also help address laboratory capacity issues, EMC believes it would be useful to decrease the field blank testing requirement by changing the current requirement of one field blank per site to one of the following, in priority order of preferred change:

1. Collect a field blank only when resampling to confirm detect/violation.

2. Collect a field blank, but only analyze it if the analyte is detected above the MCL. Since PFAS do not break down for long periods of time, is it necessary to have holding times for field blanks?

3. Collect a field blank once per collection event, versus every site. Then the laboratory could test the field blank (within the hold time requirement) if the result warrants examining whether the collection process was the contamination source. This would be similar to how it is approached with VOCs.

EPA Response: Please see section 8.7 of the EPA response in this *Response to Comments* document. Consistent with the commenter's point, the EPA is not aware of screening technology with the sensitivity that would be needed to support this NPDWR. Lastly, the EPA notes that the methods specify when laboratories are to analyze FRBs; the method approach was designed to limit the number of FRBs that are ultimately analyzed.

Association of Public Health Laboratories (APHL) (Doc. #1646, SBC-043323)

While EMC acknowledges that current screening technology sensitivity levels are not adequate to help for these proposed PFAS MCL levels, it would be useful for EPA to investigate potential screening technologies versus analyzing all samples through LC/MS/MS or HRMS. This would help address laboratory capacity issues.

To also help address laboratory capacity issues, EMC believes it would be useful to decrease the field blank testing requirement by changing the current requirement of one field blank per site to one of the following, in priority order of preferred change:

1. Collect a field blank only when resampling to confirm detect/violation.

2. Collect a field blank, but only analyze it if the analyte is detected above the MCL. Since PFAS do not break down for long periods of time, is it necessary to have holding times for field blanks?

3. Collect a field blank once per collection event, versus every site. Then the laboratory could test the field blank (within the hold time requirement) if the result warrants examining whether the collection process was the contamination source. This would be similar to how it is approached with VOCs.

EPA Response: Please see section 8.7 of the EPA response in this *Response to Comments* document. Consistent with the commenter's point, the EPA is not aware of screening technology with the sensitivity that would be needed to support this NPDWR. Lastly, the EPA notes that the methods specify when laboratories are to analyze FRBs; the method approach was designed to limit the number of FRBs that are ultimately analyzed.

Water Quality Association (WQA) (Doc. #1694, SBC-044983)

EPA should consider the risks of inaccurate water sample results when measuring at 4 ppt or below, considering the extensive use of PFAS in everyday products and those used under regular laboratory testing. EPA should refer to knowledgeable, experienced stakeholders on the best methods for water testing in the field and laboratory before and after treatment to help ensure results are accurate and are not compromised by cross-contamination.

EPA Response: Please see section 8.7 of the EPA response in this *Response to Comments* document.

8.8 Trigger Level Values

Summary of Major Public Comments and EPA Responses

To determine compliance monitoring frequency only, the EPA proposed a rule trigger level of one-third the MCLs (1.3 ng/L for PFOA and PFOS and 0.33 for Hazard Index PFAS (PFHxS, PFNA, HFPO-DA, and PFBS)). If results for an EPTDS are below the trigger level, systems

would be eligible for reduced monitoring. The EPA requested comment on monitoring-related flexibilities that should be considered to further reduce burden while also maintaining public health protection, including setting a rule trigger level at different values than the proposed values of 1.3 ng/L for PFOA and PFOS and 0.33 for the Hazard Index PFAS (PFHxS, PFNA, HFPO-DA, and PFBS). Alternative values of 2.0 ng/L for PFOA and PFOS and 0.50 for the Hazard Index PFAS were identified as possibilities. The EPA received numerous comments on the proposed rule trigger levels. Comments addressed the proposed values, specifically for PFOA and PFOS, and their intended purpose for determination of compliance monitoring frequency. Several commenters suggested that the proposed values (i.e., 1.3 ng/L for PFOA and PFOS and 0.33 for the Hazard Index) are too high and the EPA should instead set lower trigger level to ensure greater public health protection. Many other commenters suggested the opposite, stating that the proposed levels are too low, that laboratories will not be able to achieve these levels, and that it may exacerbate any laboratory capacity issues. Consequently, some of these commenters were concerned that water systems would be ineligible for reduced monitoring based on their laboratory's analytical limitations. Several commenters suggested that the proposed values are inconsistent with the SMF for SOCs.

Many who commented on the subject were fully supportive of the EPA's proposed alternative trigger level values of 2.0 ng/L for PFOA and PFOS and 0.50 for the Hazard Index, while others expressed support for the inclusion of trigger levels only if these higher levels were incorporated. Some noted that these higher trigger levels (i.e., one-half the MCL) would better align with current laboratory capabilities and allow greater use of previously collected drinking water data (to demonstrate systems are eligible for reduced triennial monitoring under the rule's initial monitoring requirements). A few commenters recommended alternative values of 70-80 percent of the MCLs be used as the trigger levels.

The EPA agrees with commenters that the trigger levels should be finalized as one-half of the MCLs (i.e., PFOA and PFOS at 2.0 ng/L each, PFHxS, PFNA, and HFPO-DA at 5 ng/L each, and Hazard Index at 0.5). Using data submitted as part of the UCMR 5 Laboratory Approval Program as a reference point, the EPA notes that 47 of 53 laboratories (89 percent) that applied for UCMR 5 approval generated an MRL confirmation at 2 ng/L (one-half the proposed MCL) or less for Method 533. This suggests that most laboratories with the necessary instrumentation to support PFAS monitoring have the capability to provide screening measurement results at the revised trigger level of one-half of the MCL. This corresponds with other comments described in section VIII.C of the final rule preamble that provided their experience that laboratories are capable of reliably quantifying values below the PQLs, particularly to 2.0 ng/L for PFOA and PFOS.

Additionally, based on the EPA's evaluation of state drinking water data, updating the final rule trigger levels (to one-half of the MCL) will result in a considerable number of additional water systems significantly reducing their ongoing monitoring frequency from quarterly or annual monitoring to triennial monitoring. Although this modification from one-third of the MCLs to one-half of the MCLs may provide slightly less information on a water system's measured PFAS

levels as a result of their less frequent monitoring, the trigger levels for the final rule (i.e., one-half of the MCLs) are sufficiently low that they will ensure that the monitoring frequency will provide primacy agencies, water systems, and the public with information well below the MCLs and inform any decisions regarding actions to address elevated levels of regulated PFAS when appropriate, while also reducing monitoring burden for water systems.

Many other commenters stated that either trigger levels should be removed from the rule entirely or that trigger levels should not be set to any levels below PQLs since these represent the level that can be reliably measured with a high degree of precision and accuracy across all laboratories. Several of these commenters suggested that data below the PQL are unreliable, would result in higher costs, and should not be used as the basis for any regulatory decisions. Thus, they suggested that if trigger levels are incorporated, they should be the same as the PQLs. These commenters also cited laboratory challenges in achieving measurement below the PQLs and suggested that water systems would not be eligible for reduced triennial monitoring as a result of these limitations. Additionally, some of these commenters suggested that decision making based on any values below the PQLs may exacerbate laboratory capacity issues, claiming that such trigger levels would result in errors, such as false positives, which would lead to increased monitoring where samples need to be re-tested.

The EPA emphasizes that the use of trigger levels set at values below the MCLs is consistent with other SOCs under the SMF and not novel for drinking water regulations (as described in the subsequent paragraph). Their use allows water systems the opportunity to reduce their monitoring schedule and burden where it can be demonstrated through sampling results that they are at low risk of PFAS contamination. In the absence of trigger levels, or some other below-MCL threshold, all water systems would be deprived of the opportunity for reduced monitoring even where there is little or no risk of PFAS contamination. At a national level, were the EPA to eliminate reduced monitoring options, this would result in a significant increase in costs to utilities without any corresponding increase in health benefits because there is little or no risk to public health associated with PFAS in the water from these water systems. Consequently, the EPA is choosing to incorporate these levels to allow flexibility and reduce burden for water systems while maintaining health protection.

For commenters that suggest the trigger levels should be identical to the PQLs, particularly for PFOA and PFOS, the EPA disagrees as the agency must have greater assurance that the levels are below the regulatory standard, the systems are actually lower risk, and a reduced monitoring schedule is appropriate. Specifically, in the case of PFOA and PFOS, the EPA believes it would represent an unacceptable public health risk to set trigger levels at the PQLs because the EPA is setting the MCL at the PQL which means that it represents the "maximum permissible level." Moreover, the approach of considering measured levels lower than PQLs for determining monitoring frequency is not novel but has been part of the drinking water standards for many years. Many of the EPA's other drinking water standards use an MDL, which, by definition, is lower than the PQL. Under the SMF for SOCs, for example, results both at or below detection limits and between detection limits and the MCL are utilized for monitoring frequency

determination. Additionally, 40 CFR § 141.24(h)(7) prescribes the monitoring frequency for organic contaminants based on sample results relative to detection limits (as defined in in paragraph (h)(18) of the same section). In each of these cases, detection limits are below their PQLs (often by a factor of 10). The approach in this rule – using levels lower than the PQL to determine monitoring frequency – is consistent with the EPA's approach for other NPDWRs.

As described earlier, some commenters raised concerns about potential laboratory analytical and capacity issues. For more on laboratory capability and capacity, please see section 5.1.2 of the EPA response in this *Response to Comments* document. Some suggested that laboratories cannot achieve levels below the PQLs, which would result in water systems not being eligible for reduced monitoring based on not demonstrating results below trigger levels. The EPA recognizes that some laboratories may not be able to produce results at these lower levels with the same degree of accuracy and precision as results at or above the PQLs, and notes that there is not a requirement that they do so for these purposes. The EPA uses the PQL to inform the MCL feasibility determination and the same level of precision and accuracy is not required to determine monitoring frequency.

Along these lines, several commenters questioned if the sample results must be quantified to be used for the determination of monitoring frequency, given the proposed trigger level values were set below the PQLs, requesting further clarity from the EPA on how to interpret and utilize quantified and non-quantified data. Furthermore, some commenters suggested that if values below the PQLs are used, only quantified results should be used for determining monitoring frequency. Other commenters stated there should not be a numerical value associated with results below the PQL (e.g., results between the trigger levels and the PQLs) and instead such results should only be reported on an absence/presence basis.

The EPA agrees that results below the PQL may not have the same precision and accuracy as higher-level measurements; however, results below the PQL can be sufficiently determined for particular purposes. Data below the PQL will be critical to ensuring that systems are monitoring at the correct frequency and whether a contaminant is present within a certain range. Moreover, while results near the trigger level may be less definitive than results at or above the PQL, such results nonetheless provide sufficient information with adequate reliability that they are appropriate for establishing monitoring frequency, as well as for reporting as part of the annual CCR. CCR reporting is based on detected contaminants and for the purposes of the PFAS NPDWR, 141.151(d) defines "detections" as results at or above the rule trigger levels (see section IX of this preamble for more information on CCR requirements).

Under this final rule, for monitoring frequency determination purposes, systems are required to use all compliance sample results, including those below the PQLs and not quantified with the same precision and accuracy as is associated with the MCL compliance determination. Additionally, the determination of monitoring frequency is not based on a running annual average result, but each individual sampling result. As an illustration of the approach, if a water system has quarterly sampling results at an EPTDS from initial monitoring for PFOA that are 2.0, 1.5, 5.0, and 1.5 ng/L, there are two results (i.e., 2.0 and 5.0 ng/L) at or above the EPA's

final trigger level for PFOA (i.e., 2.0 ng/L). Thus, the water system would not be eligible for triennial monitoring at this EPTDS for all regulated PFAS when compliance monitoring begins. Providing a different example, if a water system that is currently required to conduct quarterly compliance monitoring has quarterly sampling results at an EPTDS for PFOA that are 2.0, 3.5, 2.5, and 1.5 ng/L, all results are below the MCL for PFOA (i.e., 4.0 ng/L), however three results are above the PFOA trigger level. In this case, because four quarters of data have been collected and assuming all other regulated PFAS sampling results are below their MCLs as well, the water system could be deemed reliability and consistently below the MCL by the primacy agency and be eligible to monitor annually at this EPTDS. For all frequencies of ongoing compliance monitoring, including quarterly, annual and triennial, this determination will be done the same (i.e., all sample results are used, even those below the PQLs).

Many commenters requested that the EPA provide clarification on how laboratories and PWSs should report levels below the PQLs for monitoring frequency purposes. All results at or above the trigger level are to be reported as numeric values and used for determining monitoring frequency. Under the EPA approved analytical methods discussed in section XII of the final rule preamble, numeric values as low as the rule trigger levels will be available because of the need to meet ongoing QC requirements of the method for blanks, demonstrating no background contamination. Within each analytical batch of samples, the laboratory must document passing blank QC criteria by attaining qualitative measurements of the regulated PFAS that are no higher than one-third of the laboratory's reporting limit, which must be at or below the PQL. The EPA intends to provide guidance materials with details and examples on this to support successful implementation of the final rule.

Some commenters suggested the potential for confusion related to the differences in how results less than PQLs are used in monitoring frequency determination and the MCL compliance determination. Several commenters suggested that there should be a consistent approach. Most commenters suggested that the approach should follow that of the MCL compliance determination, where zero is used in the calculation of annual averages when measured values are below PQLs. To alleviate possible confusion, the EPA intends to provide communication materials to support successful implementation of the final rule. Nevertheless, the difference in approach (between data used for compliance monitoring determinations and data used to determine monitoring frequency) reflects the most appropriate application of the data for each of the intended purposes. As a result, water systems will monitor with a frequency based on the system's sampling results which are most demonstrative of their risks, ensuring that any regulated PFAS contamination is detected promptly, and enabling the water system to provide any needed reduction in PFAS levels as required by this rule. The EPA's rationale is described in detail in subsection VIII.B of the final rule preamble.

Individual Public Comments

Town of Lincoln Water Department (Doc. #1613, SBC-043028)

EPA should abandon its plans to have any trigger below the MCL and revert to the Standard Monitoring Framework which considers all results below the Practical Quantification Limit to be considered 0 ppt.

EPA Response: The EPA disagrees with the commenter's claim that under the SMF all results below the PQL are considered zero as this is incorrect and described in section 8.8 of the EPA response in this *Response to Comments* document. Please see section 8.2 summary of the EPA response in this *Response to Comments* document for a discussion of using values below PQLs in compliance calculations.

Town of Tewksbury, Massachusetts (Doc. #1637, SBC-043246)

EPA should abandon its plans to have any trigger below the MCL and revert to the Standard Monitoring Framework which considers all results below the Practical Quantification Limit to be considered 0 ppt.

EPA Response: The EPA disagrees with the commenter's claim that under the SMF all results below the PQL are considered zero as this is incorrect and described in section 8.8 of the EPA response in this *Response to Comments* document. Please see section 8.2 summary of the EPA response in this *Response to Comments* document for a discussion of using values below PQLs in compliance calculations.

COMM Water Department (Doc. #1577, SBC-042440)

EPA should abandon its plans to have any trigger below the MCL and revert to the Standard Monitoring Framework which considers all results below the Practical Quantification Limit to be considered 0 ppt.

EPA Response: The EPA disagrees with the commenter's claim that under the SMF all results below the PQL are considered zero as this is incorrect and described in section 8.8 of the EPA response in this *Response to Comments* document. Please see section 8.2 summary of the EPA response in this *Response to Comments* document for a discussion of using values below PQLs in compliance calculations.

Water Supply District of Acton (Doc. #1662, SBC-043663)

EPA should abandon its plans to have any trigger level below the MCL and revert to the Standard Monitoring Framework which considers all results below the Practical Quantification Limit to be considered 0 ppt.

EPA Response: The EPA disagrees with the commenter's claim that under the SMF all results below the PQL are considered zero as this is incorrect and described in section 8.8 of the EPA response in this *Response to Comments* document. Please see section 8.2 summary of the EPA response in this *Response to Comments* document for a discussion of using values below PQLs in compliance calculations.

Marlene Ladderbush (Doc. #1612, SBC-042916)

EPA should abandon its plans to have any trigger below the MCL and revert to the Standard Monitoring Framework which considers all results below the Practical Quantification Limit to be considered 0 ppt.

EPA Response: The EPA disagrees with the commenter's claim that under the SMF all results below the PQL are considered zero as this is incorrect and described in section 8.8 of the EPA response in this *Response to Comments* document. Please see section 8.2 summary of the EPA response in this *Response to Comments* document for a discussion of using values below PQLs in compliance calculations.

Great Lakes Water Authority (GLWA) (Doc. #1558, SBC-042551)

Monitoring related flexibilities that should be considered to further reduce burden while also maintaining public health protection including a rule trigger level at different values than the currently proposed values of 1.3 ppt for PFOA and PFOS and 0.33 for the Hazard Index (HI) PFAS.

Trigger levels for PFOA and PFOS as defined by the proposed language are well below the PQL. GLWA strongly believes that if a trigger level is used to require more frequent sampling, it should be used as an absence/presence test for PFAS rather than a numerical value.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document.

Missouri Department of Natural Resources (Doc. #1563, SBC-042538)

EPA requests comment generally on its estimation of sampling costs. The Agency is also specifically requesting comment on the ability of systems to demonstrate they are reliably and consistently below 1.3 ppt for PFOA and PFOS and 0.33 ppt for PFAS regulated by the HI in order to qualify for reduced monitoring.

As discussed in detail previously, demonstration of reliable and consistent (R&C) results can only be achieved with detectible results that are quantifiable (i.e., not estimated). As 1.3 ppt and 0.33 ppt are below available analytical technologies these values cannot be used as detections that are considered R&C below a PQL. As such, the HI is not implementable. Additionally, PFHxS has a HBWC of 2000 ppt. Regardless of a 0.33 ppt or 0.5 ppt HI level to trigger

increased quarterly monitoring, a reportable detected concentration of 667-1000 ppt would keep systems monitoring unnecessarily without being close to the HBWC level.

EPA Response: The EPA disagrees with this commenter that reliably and consistently below the MCL results must be quantifiable for the purposes of determining a system may be eligible for monitoring at an annual frequency. Please see section 8.1.2 of the EPA response in this *Response to Comments* document for additional information regarding compliance monitoring requirements. Pertaining to the EPA's trigger levels for reduced triennial monitoring, please see section 8.8 of the EPA response in this *Response to Comments* document. The EPA further disagrees with the commenter because all of the PFAS within the Hazard Index (PFHxS, PFNA, HFPO-DA, and PFBS) all have HBWCs that are equal to or greater than one half of their HBWC, therefore there are no analytical limitations and those values, while not required for monitoring frequency determination purposes, can be quantified as needed. The commenter also incorrectly cites that the HBWC for PFHxS is 2000 ppt, as it was proposed as 9.0 ppt and is being finalized at 10 ppt, and the PQL for PFHxS is 3.0 ppt. Thus, the PQL is clearly less than one-half of the HBWC.

San Antonio Water System (SAWS) (Doc. #1570, SBC-042476)

• The Practical Quantitation Limit (PQL) represents what can reasonably and accurately be measured between different labs across the nation. The proposed trigger level is substantially lower than the PQL and relies on a lowest calibration standard. This is a departure from standard practice. PWSs will be regulated based on a value that most labs will not be able to reach. EPA recognizes this and states that the values lower than the PQL will not have the required precision but will serve as a "warning" that the PWS may have a PFAS issue, as described in the following:

o It is not reasonable to require a PWS to increase their sampling 6-fold based on a trigger level lower than the PQL.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document.

Lakewood Water District (LWD) (Doc. #1574, SBC-042753)

Trigger Level Inappropriate

The proposed regulation clearly documents that the minimum Practical Quantitative Limit (PQL) for PFOA and PFOS is 4 ppt. Contrary to this fact, EPA proposes using a value of one-third of the PQL to trigger monitoring requirements for water systems. It is inappropriate and unreasonable to base regulatory decisions on data that, by definition, is unreliable.

Further, using two different regulatory levels will create massive risk communication challenges for water purveyors like LWD. No values below PQL should be used for regulatory purposes.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document.

Oregon Health Authority (OHA) (Doc. #1582, SBC-042762)

• EPA requests comment on monitoring-related flexibilities that should be considered to further reduce burden while also maintaining public health protection including a rule trigger level at different values than the currently proposed values of 1.3 ppt for PFOA and PFOS and 0.33 for the HI PFAS (PFHxS, HFPO-DA, PFNA, and PFBS), specifically alternative values of 2.0 ppt for PFOA and PFOS and 0.50 for the HI PFAS. EPA also requests comment other monitoring flexibilities identified by commenters.

OHA believes it may be confusing for primacy agencies and public water systems to consider values above detection but below quantitation for the purposes of monitoring frequency. It is OHA's opinion that only quantified results (values at or above the minimum reporting level or MRL) should be used for determining monitoring schedule frequency. Setting the trigger at 1.3 ppt would be below the MRLs that most labs can achieve at this time. Using unquantified data for decision-making is a risky precedent and states would need more clarity on how the data should reported, interpreted, and entered (OHA has a policy of not accepting J-flagged drinking water data for compliance).

If EPA keeps the trigger levels below the practical quantitation limit (PQL), OHA recommends that EPA change the trigger levels to one-half the MCLs (2.0 ppt for PFOA and PFOS and to 0.50 of the MCL for the Hazard Index) for determining monitoring frequency. Many labs can achieve MRLs of 2.0 ppt at this time and making the trigger a demonstrated quantifiable number (mostly in regard to PFOA and PFOS) may provide an incentive for other labs to work toward lower MRLs, and it is likely that more labs will be able to achieve lower MRLs over time anyway.

If EPA decides to set the trigger level below the PQL and below the MRLs some labs can achieve, states may be receiving both quantified and unquantified results. If this is to be the case, OHA requests that EPA provide guidance for how lab results should be reported for purposes of uniformity and clarity.

Lastly, OHA also believes that water systems that can reliably and consistently show PFAS results below the MCL should be eligible for annual monitoring just as for other organic chemicals. A small groundwater system serving 25 people with PFOS in their drinking water below the MCL but above the trigger (for example 2.4 ppt) would be on quarterly monitoring in perpetuity under the currently proposed rule and subject to the monitoring costs associated with analyzing a sample plus a blank for PFAS each quarter which seems overly burdensome.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document. Regarding compliance monitoring requirements, including annual

monitoring, please see section 8.1.2 of the EPA response in this *Response to Comments* document.

Washington Suburban Sanitary Commission (WSSC Water) (Doc. #1585, SBC-042772)

Trigger Levels:

EPA set trigger levels at one third of the proposed MCLs: 1.3 ppt for PFOA and PFOS, and 0.33 for PFAS regulated by the HI (PFHxS, HFPO-DA, PENA, and PFBS). Trigger levels are used to determine monitoring requirements: after one-year initial monitoring, systems with PFAS less than the trigger levels are eligible for reduced monitoring. Systems already under reduced monitoring must revert to standard monitoring after one incidence of PFAS exceeding the trigger level.

Proposed trigger levels for PFOA and PFOS are not supported by the PQL of 4 ppt established by EPA for this rule and UCMR5, making it difficult for water systems to obtain quantifiable data at these levels. WSSC Water recommends that EPA establish the trigger level for PFOS and PFOA at 4 ppt or another reliable quantifiable level supported by current analytical technologies. This aligns with WSSC Water's earlier proposal to set the MCL initially at 10 ppt, providing sufficient margin of confidence. As analytical technology advances in the future, EPA can reconsider the feasibility of lowering MCLs and trigger levels.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document.

Alameda County Water District (ACWD) (Doc. #1595, SBC-042350)

2. Establishment of a Trigger Level Criteria that is below the PQL to qualify for reduced monitoring

EPA is proposing a "trigger level" that will be set at levels below the Practical Quantitation

Level (PQL), for less frequent compliance monitoring in systems which can demonstrate PFAS concentrations in drinking water are below 1.3 ppt for PFOA and PFOS and 0.33 for the Hazard Index PFAS. EPA states that these lower monitoring levels are achievable by individual laboratories, and therefore, these low levels can be used for screening purposes and to determine compliance frequency.

The PQL is defined as the lowest concentration of an analyte that can be reliably measured within specified limits of precision and accuracy during routine laboratory operating conditions. EPA has determined that establishing a PQL at 4.0 ppt for PFOA & PFOS, which were derived from laboratory participation in establishing UCMR-5 MRLs, to be appropriate in this proposed rulemaking.

Until more laboratories upgrade their instrumentation, achieving lower values than the PQL may be a challenge. Additionally, the data that would be collected would need to be qualified as not

meeting the method requirements and there may not be any means to attach a qualifier to such (compliance) data. To avoid potential issues with producing qualified data at levels below the PQL, commercial laboratories may need to change their lowest calibration levels to the trigger levels. It is unlikely that such a change could be implemented in the middle of the current UCMR-5 monitoring program, where these have already been set at the PQLs.

ACWD appreciates EPA's inclusion of a criteria to qualify for a reduction in required monitoring. Given the challenges with reliably achieving precise and accurate monitoring results at levels below the PQL, establishing the levels to qualify for reduced monitoring far below the PQL, and below the MRLs will make it challenging for systems to qualify for the reduction in monitoring frequency and potential relief from the associated costs. EPA should consider establishing trigger levels for reduced monitoring at the PQL.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document.

Michigan Department of Environment, Great Lakes, and Energy (EGLE) Drinking Water and Environmental Health Division (DWEHD) (Doc. #1597, SBC-042980)

D. Monitoring and Compliance Requirements

Having reviewed Section IX of the proposed NPDWR, EGLE DWEHD presents the following comments for consideration:

1. EGLE DWEHD requests clarification regarding how the proposed "Trigger Level" will be used, both during initial monitoring and ongoing compliance monitoring. The language in Section IX appears to present this threshold as a single point in time, for which a detection above would lead to a monitoring decision. Is this the case, or would the "Trigger Level" instead be calculated using a running annual average?

2. "Trigger Level" is a new definition within the SDWA. EGLE DWEHD proposes using "detection above X% of the MCL" to identify the threshold, rather than establishing an additional definition.

3. EPA proposes a "Trigger Level" at 1/3 of each MCL. This is presented as appropriate based on the ability of individual laboratories to detect at levels well below the practical quantitation limit (PQL). However, it is unlikely all laboratories are capable of this level of reliable detection, given their requirement to meet the 4.0 ng/l PQL threshold. Regulations should be based on values all laboratories can and are expected to meet. Otherwise, it may present an inequity for supplies, and their ability to potentially reduce monitoring. EGLE DWEHD proposes a "Trigger Level" of 1/2 each MCL, to alleviate this and to maintain consistency with other portions of the SDWA.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document. Regarding initial monitoring and compliance monitoring requirements,

please see sections 8.1.1. and 8.1.2 of the EPA response in this *Response to Comments* document, respectively, as well as section VIII.A. of the final rule preamble. For monitoring frequency determination purposes, the frequency is based on single sample results, not averages. The EPA acknowledges the suggestion provided by the commenter on the definition of the trigger level. The agency believes it has clearly defined what the trigger levels are and has updated them to be one-half of the MCLs for final rule, as recommended by the commenter.

Water Works Board of the City of Birmingham (BWWB) (Doc. #1602, SBC-043655)

9. The EPA is requesting comment on establishing the proposed rule trigger at 1/3 versus 1/2 of the proposed MCL for all PFAS species. There are cost implications associated with a lower trigger level (i.e., possible additional sampling) that need to be considered in trigger level determination.

It is recommended that EPA use 1/2 of the MCL as the trigger, as this level better aligns with most laboratory reporting limits (which are typically around 1.9-2.0 ng/L for PFAS species currently).

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document.

American Water Works Company Inc. (Doc. #1608, SBC-044013)

Reduced Monitoring

American Water supports including provisions that allow water systems to reduce their monitoring requirements. A trigger level of one-half the associated MCLs, not one-third as proposed, using results below the PQL as zero (0), would be an appropriate approach. It is

critical that the final approach be achievable and reliable, so water systems are able to attain reduced monitoring, where appropriate, and retain that status.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document. Values below the PQLs are treated as zero only for compliance determination purposes, and not for monitoring frequency purposes . Please see section 8.2 of the EPA response in this *Response to Comments* document regarding the determination of compliance and violations.

Minnesota Department of Health (MDH) (Doc. #1610, SBC-042850)

Since the rule proposal's trigger levels are set to 1/3 the MCLs, laboratories must report data below the PQLs for PFOS and PFOA. States and PWSs will receive this data in laboratory reports as public record, demonstrating a clear disconnect in how data is considered for compliance versus monitoring schedule purposes.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document.

Oklahoma Department of Environmental Quality (DEQ) (Doc. #1616, SBC-043044)

Reduced Compliance Monitoring

DEQ recommends that EPA clarify and fix conflicting language related to the capability and expectation of laboratories to report PFOA and PFOS detections at low levels for reduced monitoring.

DEQ supports reduced monitoring when the compliance monitoring running annual averages for PFOA and PFOS are each less than the respective practical quantitation limit of 4.0 ppt, and when the Hazard Index is one-half (instead of one-third) of the MCL, i.e., 0.5. Setting the Hazard Index trigger level at one-half of the MCL would fit the Synthetic Organic Contaminant (SOC) standard monitoring framework.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document.

Pennsylvania Department of Environmental Protection (Doc. #1626, SBC-044882)

• DEP does not support using the proposed trigger level of 1.3 ppt in the RAA calculation for compliance determinations instead of zero when PFOA and/or PFOS are detected at a level below the PQL. As already noted, detections below the PQL would be reported as qualified data and would not be legally defensible. Using the proposed trigger level of 1.3 ppt in the RAA calculation instead of zero is arbitrary and assigns a value that is not based on actual defensible analytical results for a compliance determination.

• Trigger levels should not be set at levels lower than the PQL. Trigger levels for PFOA and PFOS are specified in [sec] 141.XX(b)(2)(iii) as one-third the MCL, which is also equal to one-third the PQL, or 1.3 ppt. As already noted, by definition, the PQL is the lowest level that can be accurately and precisely measured. Therefore, at a level below the PQL, the measured concentration may not be accurately quantified. It is not feasible to implement drinking water standards based on data that is not accurate or precise and, therefore, not legally defensible. EPA acknowledges in its FAQs for Drinking Water Primacy Agencies that "measurements below the PQLs may be less definitive," but then goes on to argue that those low levels are "appropriate for determining if PFAS are present and establishing monitoring frequency." However, it is not appropriate to use data that is not legally defensible in any way in a regulation. DEP does not agree with regulating PFAS monitoring frequencies based on levels detected lower than the PQL as a presence/absence detection.

• The use of 1.3 ppt as a trigger level for monitoring frequency for PFOA and PFOS is inconsistent within the proposed rulemaking. [sec] 141.XX(a)(7) defines the trigger levels as ppt for PFOA and PFOS and 0.33 for the HI but does not clarify whether these are based on discrete sample results or an RAA. In [sec] 14 I.XX(a)(8), the trigger level appears intended to be used as a calculated value to determine reduced monitoring frequency based on a RAA calculation for systems on a quarterly initial monitoring frequency. However, the trigger level also appears to be used as a discrete value (i.e., "reliably and consistently below the MCL") to trigger increased monitoring frequency back to quarterly([sec] 141.903(d)). DEP disagrees with using 1.3 ppt as a trigger level for monitoring frequency determination for PFOA and PFOS for several reasons:

o Based on information gathered by DEP during a survey of laboratories accredited in Pennsylvania to inform our state rulemaking process, and confirmed by the DEP Bureau of Laboratories, very few (if any) laboratories are capable of detecting PFAS at a level of 1.3 ppt. It is therefore not feasible to use the trigger level of 1.3 ppt in a single sample to require an increase to quarterly monitoring.

o In addition to the lack of laboratory capabilities to detect PFAS at such a low level, detections due to cross contamination should be considered. Because PFAS are generally considered to be ubiquitous, such low-level detections may not be indicative of actual water quality.

o Data reported below the PQL would be reported as qualified data, notated with the "J" qualifier. J-qualified data are considered to be a detection that is an estimated value. Qualified data is not acceptable for compliance determinations. Therefore, it is not appropriate to make regulatory decisions based on J-qualified data, even for monitoring frequency determinations.

• Instead of using the proposed trigger levels of one-third the MCLs for determining monitoring frequencies, DEP recommends using levels that are "reliably and consistently below the MCL" (R&C), to be consistent with existing regulations for chronic contaminants. As per 40 CFR, Part 141, the federal R&C criteria for nitrate (an acute contaminant) is set at 50% of the MCL. EPA defers to the states to set R&C criteria for chronic contaminants. For example, for chronic contaminants, DEP uses a R&C level of 80% of the MCL. Since DEP agrees that PFAS are

chronic contaminants, the R&C level for PFAS should be set at a level more appropriate for chronic contaminants. DEP suggests that it would be inconsistent for EPA to set the R&C criteria for a chronic contaminant such as PFAS lower than the R&C criteria for an acute contaminant. However, it is important to note that, if the MCLs for PFOA and PFOS are set at 4.0 ppt, which is the same as the PQL, then even 80% of the MCL, or 3.2 ppt, is still at a level that is below the PQL, which is not feasible. This further supports DEP's earlier comment that the MCLs should be set at a level that is a minimum of 30% above the PQL.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document. Regarding initial monitoring and compliance monitoring requirements (including the determination of reliably and consistently below the MCL), please see sections 8.1.1. and 8.1.2 of the EPA response in this *Response to Comments* document, respectively, as well as section VIII.A. of the final rule preamble. For monitoring frequency determination purposes, the frequency is based on single discrete sample results, not averages (e.g., for an EPTDS to be eligible for annual compliance monitoring, all quarterly samples results must be below the MCLs). Additionally, values below the PQLs are treated as zero only for compliance determination purposes. Please see section 8.2 of the EPA response in this *Response to Comments* document regarding the determination of compliance and violations. Pertaining to the commenter's concerns on cross contamination, please see section 8.7 of the EPA response in this *Response to Comments* document.

Association of State Drinking Water Administrators (ASDWA) (Doc. #1628, SBC-044102)

ASDWA recommends that EPA change the trigger levels to one-half the MCLs for determining compliance monitoring frequency.

The proposed rule is not clear regarding whether EPA expects that some laboratories will be able to reliably test as low as 1.3 ppt. Setting the trigger levels at one-half (instead of one-third) of the MCLs will help alleviate this misconception. Additionally, increasing the trigger level will allow more states to use previously collected data for determining systems that qualify for reduced monitoring and help with laboratory capacity, as well as the previously stated challenges with laboratory QA/QC for sample results at 1.3 ppt for PFOA and PFOS and 0.33 for HI PFAS - perfluorohexane sulfonic acid (PFHxS), hexafluoropropylene oxide dimer acid (HFPODA) and its ammonium salt, perfluorononanoic acid (PFNA), and perfluorobutane sulfonic acid (PFBS). For the proposed MCL of 4.0 ppt, this would change the trigger level to 2.0 ppt for PFOA and PFOS and 0.5 of the MCL for the Hazard Index (HI).

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document.

Association of State Drinking Water Administrators (ASDWA) (Doc. #1628, SBC-044066)

6. ASDWA recommends that EPA change the trigger levels to one-half the MCLs for determining compliance monitoring frequency. Setting the trigger levels at one-half (instead of

one-third) of the MCLs would alleviate confusion regarding using the 1.3 parts per trillion for PFOA and PFOS, which some may incorrectly assume means laboratories can accurately test to that level. Setting the trigger levels for reduced monitoring at one-half (instead of one-third) of the MCLs would improve laboratory capacity and allow more states to use previously collected data for determining reduced monitoring.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document.

Village of Woodbury (Doc. #1629, SBC-042948)

2. Following the initial monitoring period, if samples reach a "trigger level", which is currently proposed as 1/3 of the proposed MCL, then public water suppliers will be required to monitor for contaminants quarterly. The EPA utilized Practical Quantitation Limits (PQLs) to determine the MCL. The PQL is the concentration of a contaminant that can be reliably detected during normal laboratory testing. For some laboratories, the "trigger level" as one-third of the MCL is only useful for detecting whether a contaminant is present in a sample. The EPA requested comments on this or suggested alternate trigger level. In our view, anything less than the MCL based on the PQL is useful for only establishing the presence of the compound. Accordingly, one-third or one-half which is not reliably quantified has no bearing.

EPA acknowledges that measuring PFOA and PFOS results below the PQLs may not be achievable from all laboratories and may not have the same precision as higher-level measurements, nor does EPA believe it is appropriate to make potentially costly compliance decisions based on such lower-level measurements. Yet, trigger levels are proposed at 1/3 the PQL, which will be suggestive of required action (cost) and suggest that the level of reduction from the established NYS MCL of 10 ppt, is impractical and provides no significantly greater degree of public health protection.

We recommend the trigger rule be set to the proposed MCL's established based on reliable detection and the MCL's be raised. Alternatively, the current NYS MCL should be adopted as the Federal MCL.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document. Regarding the EPA's determination of MCLs for PFOA and PFOS, please see sections 5.1 and 5.1.5 of the EPA response in this *Response to Comments* document.

Citizens Against Ruining the Environment (CARE) (Doc. #1638, SBC-043456)

Trigger Values for Reduced Monitoring Frequency Must Be Lowered

CARE strongly opposes setting the trigger values for reduced monitoring at 1.3 ppt for PFOA and PFOS and 0.5 HI for PFNA, GenX, PFHxS, and PFBS. Monitoring frequency should not be reduced when the values are so high above the MCLG of 0.0 ppt and 1.0 HI and when that trigger value is disconnected from a risk analysis. Monitoring should continue without exception

because there is no risk or vulnerability analysis available to predict which systems are likely to exceed the PFAS MCLs in the future.

A reduced monitoring frequency triggered by 1.3 ppt PFOA and PFOS or 0.5 HI for PFNA, GenX, PFHxS, and PFBS would allow too much time to pass without water quality data when there is known and detectable PFAS contamination in the system. Rather than triggering reduced monitoring frequency, system values of 1.3 ppt and .5 HI should be a trigger for ongoing monitoring to ensure the system values do not increase further towards the 4.0 ppt and 1.0 HI MCLs.

Monitoring frequency should not be reduced at any trigger level until more information is available about where and how quickly PFAS may enter each system. That information would allow a more sophisticated risk analysis to be completed for each PWS before determining eligibility for reduced monitoring frequency.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document. Regarding the commenter's concerns about reduced monitoring frequency, please see section 8.1.2 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1808, SBC-046119 in section 8.1.2 in this *Response to Comments* document.

Aidan Cecchetti (Doc. #1640, SBC-044368)

• EPA requests comment on monitoring-related flexibilities that should be considered to further reduce burden while also maintaining public health protection including a rule trigger level at different values than the currently proposed values of 1.3 ppt for PFOA and PFOS and 0.33 for the HI PFAS (PFHxS, HFPO-DA, PFNA, and PFBS), specifically alternative values of 2.0 ppt for PFOA and PFOS and 0.50 for the HI PFAS. EPA also requests comment other monitoring flexibilities identified by commenters (pg. 18682 Federal Register Volume 88, Number 60).

o It is the commenters' opinion that setting trigger levels below the current PQL is inappropriate. Although EPA asserts there is broad laboratory capability to detect the regulated PFAS at least down to those trigger levels, EPA has not chosen to reevaluate the PQL to a lower value. This suggests to the commenters that there is not sufficient evidence to demonstrate broad laboratory capability to reliably quantify at those values. If laboratories cannot reliably quantify below the PQL, they would not have the capability to distinguish between a trigger level of 1.3 ppt and a level of 2.0 ppt for PFOA or PFOS, meaning there would be no meaningful difference or added monitoring flexibility in setting the trigger level at either value. If laboratories already have the capacity to quantify down to levels of 1.3 ppt, EPA should consider revising the PQL for those contaminants. Alternatively, it may be appropriate to set a trigger level below the PQL if there should be a requirement for regulatory agencies to include a minimum method detection limit for accreditation for laboratories to perform quantification of PFAS.

o However, the commenters agree that a trigger level of 0.5 for the HI PFAS would be appropriate to allow a larger number of water systems to reduce their monitoring frequency. This would be analogous to the way nitrate is regulated in California in groundwater sources (e.g., a 5.0 mg/L as nitrate-N trigger level requires greater monitoring, which is half the level of the 10 mg/L MCL), which has been demonstrated to provide sufficient flexibility for water systems to reduce monitoring frequency without resulting in insufficient assurance of the regulated levels or decreased public health protection. Additionally, a level of 0.5 for the HI PFAS would not have the same issues described above for PFOA and PFOS because the HBWCs for all the HI PFAS compounds are a minimum of twice the PQLs for those contaminants.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document.

National Rural Water Association (NRWA) (Doc. #1641, SBC-043274)

• EPA requests comment on monitoring-related flexibilities that should be considered to further reduce burden while also maintaining public health protection including a rule trigger level at different values than the currently proposed values of 1.3 ppt for PFOA and PFOS and 0.33 for the HI PFAS (PFHxS, HFPO–DA, PFNA, and PFBS), specifically alternative values of 2.0 ppt for PFOA and PFOS and 0.50 for the HI PFAS. EPA also requests comments on other monitoring flexibilities identified by commenters.

Response: One-half of the MCL is the EPA precedent for a trigger level. We don't believe trigger levels are necessary nor advisable for this rule, but if EPA includes them in a final rule then one-half the MCL makes sense.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document.

North Carolina Division of Water Resources (NCDEQ) (Doc. #1652, SBC-044187)

8. NCDEQ recommends that EPA change the trigger levels to one-half the MCLs for determining compliance monitoring frequency.

Seng the trigger levels at one-half (instead of one-third) of the MCLs would alleviate confusion about the use of the 1.3 ppt and one-third levels in general, as well as the previously stated challenges with laboratory QA/QC for sample results at 1.3 ppt for PFOA and PFOS and 0.33 for HI PFAS - perfluorohexane sulfonic acid (PFHxS), hexafluoropropylene oxide dimer acid (HFPODA) and its ammonium salt, perfluorononanoic acid (PFNA), and perfluorobutane sulfonic acid (PFBS) . For the proposed MCL of 4.0 ppt, this would change the trigger level to 2.0 ppt for PFOA and PFOS and to 0.5 of the MCL for the Hazard Index (HI).

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document.

Nebraska Department of Environment and Energy (NDEE) (Doc. #1653, SBC-043202)

• The proposed Hazard Index (HI) levels were set below the practical quantitation limit (PQL) with an allowable error rate of 50% using two significant figures.

o The proposed trigger levels are set at one-third of the maximum contaminate level (MCL) and HI, however, EPA suggested changing this to one-half in order to reduce burden while also maintaining public health. If trigger levels are required, the Department supports setting these levels at one-half or 2 ppt for the MCLs and .5 for the HI and allowing States to build escalation triggers into their enforcement policies.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document. Regarding the Hazard Index, the EPA clarifies that the commenter incorrectly stated that the HBWCs for the four PFAS included with the Hazard Index (PFHxS, PFNA, HFPO-DA, and PFBS) are below their PQLs. All PQLs for these four PFAS are less than one-half of their respective HBWCs.

Washington State Department of Health (DOH) (Doc. #1665, SBC-044400)

Page 18667. Paragraph 2. Measuring PFOA and PFOS results below the PQLs may not be achievable from all laboratories and may not have the same precision as higher-level measurements, nor does EPA believe it is appropriate to make potentially costly compliance decisions based on such lower-level measurements". Nonetheless, the ability to know that PFOA and PFOS may be present within a certain range at these low concentrations (i.e., below the PQLs) can be used to inform decisions for already installed treatment (e.g., a utility can evaluate when break though is most likely to occur or is imminent) and to judge appropriate monitoring frequency".

• Not every laboratory applied to participate in UCMR5. Assuming 1.3 ppt is an achievable target nationwide may not be appropriate. Using an analytical result below the PQL only indicates that PFAS is present. Very little, if anything, is known about the actual concentration of PFAS in this instance. Relying upon low concentrations below the PQL for ongoing monitoring, reduced monitoring or compliance monitoring is not appropriate. Using a trigger level greater than or equal to 2.0 ppt for PFOS and PFOA would be preferred, as well as using 0.5 for the hazard index. This will allow laboratories flexibility, balance variability in the measurement, and allow for reduced monitoring for systems with sample results at or below 50% of the MCL.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document.

Washington State Department of Health (DOH) (Doc. #1665, SBC-044397)

DOH supports using the EPA suggested alternative values of 2.0 ppt for PFOA and PFOS and 0.5 for the HI PFAS as the trigger level. This alternative trigger level is more consistent with trigger levels previously used in EPA's Standardized Monitoring Framework.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document.

Aurora Water, City of Aurora, Colorado (Doc. #1669, SBC-043712)

Monitoring Requirements

Trigger Level Sections VIII and IX

As proposed, the trigger level for monitoring is one-third of the proposed MCLs (1.33 ppt for PFOA and PFOS). The proposal states that labs cannot report values below 4 ppt. This means a value of 1.33 ppt is not reportable and not reliable. It follows that any system below 4 ppt is automatically ineligible for reduced monitoring. If a lab reports numbers below the PQL of 4 ppt, this could present issues with consistent and reliable data reporting. This unfairly disqualifies some water systems from obtaining reduced monitoring if they cannot analyze their samples to the proposed trigger levels. On page 30 of the proposed regulation, when justifying the MCL of 4 ppt for PFOA and PFOS the EPA states that the rigorous laboratory certification procedures "limit the number of laboratories that can achieve lower quantitation levels and many water systems would not be able to secure the services of laboratories that are capable of consistently providing precise and accurate quantitation of concentrations of PFOA and PFOS at levels lower than 4.0 ppt." This EPA statement confirms any measurements below 4.0 ppt are unreliable. Therefore, using a trigger level for monitoring below 4 ppt is unfair for any water systems who are trying to achieve a reduced monitoring schedule.

In summary of statements above, with an MCL of 10 ppt as suggested by Aurora Water, setting a trigger level of 4 ppt would be much more reliable than what is currently proposed and within the PQL level. This would create more reliable data and a reduced monitoring schedule could be reliably determined.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document. The EPA disagrees with the commenter that the rule proposal stated that "labs cannot report values below 4 ppt." The EPA proposal did not state this and instead discussed that the PQLs represent the lowest levels at which contaminants can be reliably quantified within specific limits of precision and accuracy during routine laboratory operating conditions using the approved methods; accordingly, the EPA utilized these values in its MCL feasibility determination. However, values below the PQLs may be reported by a laboratory (albeit with lesser precision and accuracy than that for results at higher levels) and used for certain purposes (such as the determination of monitoring frequency and reporting in CCRs).

Cleveland Water, City of Cleveland, Ohio (Doc. #1672, SBC-044914)

Cleveland Water has strong concerns with EPA proposing a trigger level below the PQL. As defined in the preamble, the PQL is "the lowest concentration of an analyte that can be reliably measured within specified limits of precision and accuracy during routine laboratory operating conditions." For EPA to consider using values below this would mean using unreliable and potentially inaccurate data to make monitoring decisions. This could lead to costly monitoring requirements at a system that in reality meets safe water standards, but laboratory results do not reflect that due to inaccuracy.

Because of the difficulties mentioned above with a proposed 1/3 MCL trigger level, if EPA moves forward with a 4.0 ppt MCL, Cleveland Water recommends EPA go with the alternate route discussed in the preamble where the trigger level is 50% of the MCL, or 2.0 ppt individually for PFOA and PFOS, and 0.5 for the HI PFAS. Water systems who qualify for reduced monitoring based on RAA's from UCMR 5 will still need to show they are below 2.0 ppt to continue the reduced monitoring schedule. While this would alleviate some of the burdens for PWSs that do receive sample information below 1.3 ppt, the proposed trigger level, Cleveland Water stresses that this level is not readily available to all PWSs, particularly those with less resources and limited budgets.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document.

Association of California Water Agencies (ACWA) (Doc. #1675, SBC-044935)

COMMENT 5 – ALTERNATIVE TRIGGER LEVEL – ACWA supports the alternative trigger levels values but is concerned trigger levels may exacerbate laboratory capacity issues.

EPA is proposing the use of a trigger level for less frequent compliance monitoring under certain circumstances in which systems can demonstrate PFAS concentrations in drinking water are below 1.3 parts per trillion (ppt) for PFOA and PFOS and 0.33 for the Hazard Index PFAS [FN28: 88 Fed. Reg. at 18, 681.]. ACWA supports the flexibility offered by trigger level values including reduced monitoring and allowance of different compliance monitoring schedules at each entry point to the distribution system. These provisions save resources for many water systems. However, we have concerns with the accuracy of testing at levels below the PQL as well as the added burden on laboratory capacity nationwide.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document.

Association of California Water Agencies (ACWA) (Doc. #1675, SBC-044937)

Many laboratories have only shown reliable detection of PFAS compounds down to 2.0 ppt.

Setting any trigger levels below 2.0 ppt would introduce a greater potential for unreliable results and variability which would not be preferred when water systems must make decisions in order to meet new MCL monitoring requirements.

EPA recognizes this issue and poses the alternative trigger levels of 2.0 ppt for PFOA and PFOS and 0.50 for the Hazard Index PFAS [FN31: 88 Fed. Reg. at 18,682]. ACWA supports the alternative trigger level values of 2.0 ppt for PFOA and PFOS and 0.50 for the Hazard Index PFAS, however, we maintain our concerns about the trigger levels impact on laboratory capacities.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document.

New York City Department of Environmental Protection (NYCDEP) (Doc. #1679, SBC-044213)

Monitoring

In section VIII.A., p. 18681, and section IX. A., p. 18682, EPA proposes to set a monitoring trigger level at 1.3ppt for PFOA and PFOS and 0.33 for HI. This level is about one third of the MRLs stated in the required analytical methods EPA 537.1 and 533 (which range from 3.5-4 ppt depending on chemical). EPA has underestimated the level of noise in the analytical methods at the trigger level. The data quality objective for a trigger level should not be established where the variability of the data is extreme, as it is below the MRL. The definition of the MRL in EPA method 537.1 is stated as having recovery of 50-150%. At 1/3 the MRL, the recovery will be more variable than 50-150% and will include a higher likelihood of both false negatives and false positives. Essentially, EPA is setting a trigger level that is based on random noise, perhaps inclusive of contamination and bias. Increased false negatives contribute to concerns for the primary objectives of the rule. Increased false positives are associated the unnecessary public concern, increased monitoring, and unwarranted treatment changes.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document. The EPA disagrees with the commenter that it is "setting a trigger level that is based on random noise." While the agency fully agrees that there is less precision and accuracy in results below the PQL, the EPA maintains that it is appropriate to use these values for the determination of whether water systems should be allowed to monitor less frequently where there is a demonstrated lower risk of PFAS contamination. Such results do not require the same level of precision that should accompany a determination that treatment or other action is needed to reduce PFAS exposure; the latter determination triggers potentially much more costly action and should be based on more precise and reliable analytical measurements as the EPA is implementing in the final rule. Regarding the commenter's concerns on sampling contamination, please see section 8.7 of the EPA response in this *Response to Comments* document.

City of Vancouver Water Utility, Vancouver, WA (Doc. #1684, SBC-044311)

Trigger Level:

Relying upon low concentrations below the PQL for ongoing monitoring, reduced monitoring or compliance monitoring is not appropriate. The proposed regulation will set a trigger level at one-third of the MCL for PFOS and PFOA (1.3 ppt). With a MRL of 2 ppt, how will any utility meet the requirement for reduced sampling? The trigger level should be set at ½ of the MCL and hazard index to allow utilities that are non-detect to reduce sampling frequency and therefore decreasing the burden on water systems and labs.

EPAs use of trigger levels set at 1/3 the PQL increases the estimated cost of sampling while increasing variability in sampling data. Setting the trigger at ½ the PQL would increase the number of laboratories that can meet QA/QC levels bringing down the cost of sampling and provide better data for decision making. Washington supports using the EPA's suggested alternative trigger level of ½ the PQL. Currently laboratories are charging for both the PWS sample, and if there are detections, for testing the field reagent blank, effectively doubling the cost for PWSs with detections. It is unclear if EPA considered this in their cost estimates.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document.

New Hampshire Department of Environmental Services (NHDES) (Doc. #1690, SBC-044348)

b. Page 18730, Column 2, Bullet 8 - EPA requests comment on monitoring-related flexibilities that should be considered to further reduce burden while also maintaining public health protection including a rule trigger level at different values than the currently proposed values of 1.3 ppt for PFOA and PFOS and 0.33 for the HI PFAS (PFHxS, HFPO–DA, PFNA, and PFBS), specifically alternative values of 2.0 ppt for PFOA and PFOS and 0.50 for the HI PFAS. EPA also requests comment other monitoring flexibilities identified by commenters.

NHDES Comment - NH supports a rule trigger level of ½ the compliance levels (2 ppt for PFOA and PFOS and 0.5 for the HI PFAS). After reaching out to NH accredited laboratories and reviewing their reporting limits, we don't believe these laboratories can confidently report values as low as 1.3 ppt. Setting a reporting limit of 2 ppt will be more feasible for the laboratories and reduce the monitoring burden for more systems, while maintaining public health protection. [Rule Reference: 141.902 (a)(7) – Page 18751, Column 2]

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document.

Philadelphia Water Department (PWD) (Doc. #1709, SBC-045749)

EPA should provide additional clarification and support around compliance and implementation:

13. PWD recommends reducing rule complexity by removing the proposed trigger level

The proposed MCLs for PFOA and PFOS are at, or very close to, laboratories' measurement capability. The application of a trigger level less than the proposed PQLs for PFOA and PFOS creates confusion since measured concentrations greater than the method detection limit but lower than the reporting (or quantitation) limit are only considered estimates by the labs making those measurements. EPA states in this proposed rulemaking that "EPA has sufficient confidence that while measurements below the PQL may be slightly less precise and accurate, they are achievable by individual laboratories…". It is stretching the limits of the analytical technology to base actionable triggers on concentrations that are so low that they are only considered to be estimated concentrations. Additionally, EPA states in section VI.A that it "anticipates there would not be sufficient laboratory capacity if the quantitation level were set at a level below 4.0 ppt". If EPA does not expect there to be sufficient lab capacity for analyzing PFOA and PFOS below the PQL, then it should not be considering setting trigger levels or screening thresholds below these levels as this will have disproportionate negative impacts on underfunded systems and all PWSs.

Establishing the trigger level below the determined PQL will also result in confusion regarding the enforcement of the trigger level between PWSs and primacy agencies. Some primacy agencies, such as PADEP, will not allow PWSs or laboratories to report qualified results that are reported below the MRL. It is unclear in this rulemaking how PWSs should report and qualify these results to primacy agencies in order to assess whether a system is able to move to reduced monitoring. This may result in some states enforcing their current reporting requirements and no system in that state are able to move to reduced monitoring not because they are above the trigger level, but because the primacy agency will not allow them to report results below the MRL. For some primacy agencies, results below the MRL are instructed to be reported as zero. PWD recommends that results below the MRL should be reported as zero.

EPA has previously established a "trigger level" in the LCRR. The proposed trigger level in the LCRR has created a large amount of confusion both for water utilities and the public in how to interpret sample results. As a part of the on-going review of the LCRR and the solicitation for comments related to the development of the LCRI, the EPA is already considering removing the trigger level to "reduce rule complexity" before the compliance date for the LCRR has even passed. PWD recommends that EPA avoid causing similar confusion in this PFAS MCL rulemaking and remove the proposed trigger level altogether. Reduced monitoring should be implemented if a system can reliably demonstrate that results are below the PQL.

In Section IX.A, EPA requests comment on whether alternate values should be used for the trigger level, specifically 2.0 ppt for PFOA and PFOS and 0.50 for the HI PFAS. PWD, as stated above, believes that EPA should remove the trigger level altogether and not rely on results below the PQL.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document.

U.S. Chamber of Commerce et al. (Doc. #1713, SBC-045900)

3. The trigger levels EPA proposes for the six PFAS cannot be reliably measured

In setting MCL levels EPA must also ensure that the Proposed Rule's trigger levels are also feasible. EPA proposes trigger levels that are one-third of the MCL for PFOA and PFOS (1.3 ppt), while also acknowledging that this is below the practical quantitation limit (PQL). Similarly, EPA proposes a trigger level that is 0.33 for the hazard index for PFHxS, HFPO-DA, PFNA, and PFBS. It is not realistic or feasible to set a national standard where measurement at the required trigger level is not reliably obtainable [FN78: See comments submitted by the PFAS Regulatory Coalition, submitted to the Proposed Rule docket number EPA- HQ-OW-2022-0114, May 31, 2023 which provide the report entitled "Survey Summary of Commercial Drinking Water Analytical Laboratories to Support the Proposed National Primary Drinking Water Maximum Contamination Levels (MCLs) for Perfluorooctanoic Acid (PFOA) and Perfluorooctane Sulfonoic Acid (PFOS) and Proposed Hazard Index For Perfluorohexane Sulfonic Acid (PFHxS), Hexafluoropropylene Oxide Dimer Acid (HFPO-DA), Perfluorononanoic Acid (PFNA), and Perfluorobutane Sulfonic Acid (PFBS)."].

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document. Specifically, regarding the Hazard Index, because the PQLs for the four PFAS included with the Hazard Index (PFHxS, PFNA, HFPO-DA, and PFBS) are all less than one-half of their respective HBWCs, there are no analytical limitations.

Protecting Our Water, Environment, and Ratepayers (POWER) (Doc. #1714, SBC-045944)

Because the proposed trigger levels are lower than many of the method LCMRLs or UCMR 5 MRLs, the samples that would induce action under the trigger levels are insufficiently accurate.

Besides the issue with the PQLs, the trigger levels of 1.3ppt for PFOA and PFOS and 0.33 for the HI are unreasonable considering the both the LCMRLs described in Method 533 and 537.1 and the MRLs described in UCMR5. Typically the EPA has set the trigger level at the MRL with the exception of lead. [FN28: HDR, One Water: Exploring Interconnectivity – Safe Drinking Water Act Wall Chart (17th Edition 2022) (https://www.hdrinc.com/sites/default/files/2022-05/hdr-sdwa-wall-chart-2022.pdf)] Even for lead, the trigger level is above the MRL or LCMRL to ensure that the data points are accurate. [FN29: See e.g. trigger level for nitrate is 5mg/L (https://www.epa.gov/sites/default/files/2021-01/documents/wsg_213_nitrate_wsg_11-30-2020_signed_508-compliantfinal.pdf) which is higher than the LCMRL which were between 25 -39 ug/L. (https://pubs.acs.org/doi/pdf/10.1021/es072456n); Method 200.5 Determination of trace Elements in Drinking Water by Axially Viewed Inductively Coupled Plasma – Atomic Emission Spectrometry, Revision 4.2, EPA-600-R-06-115; EPA National Exposure Research Laboratory Office and Research and Development, Cincinnati OH, 45268; https://nepis.epa.gov/Exe/ZyPDF.cgi/P10096US.PDF?Dockey=P10096US.PDF]

Here, both Method 533 and 537.1 have LCMRLs that are above the trigger level, which indicates that samples that could require action are not accurate. Method 533 establishes a LCMRL of 3.4ppt for PFOA and 4.4ppt for PFOS, both of which are above the proposed trigger level. Additionally, the Method 533 LCMRL of just PFHxS, PFNA, or HFPO-DA individually would exceed the trigger level of the Hazard Index independently. Method 537.1 presents similar issues since the LCMRL for PFOS is 2.7 ppt and the LCMRL of just HFPO-DA would exceed the trigger level of the Hazard Index. Therefore, the samples that could trigger action include a high degree of inaccuracy.

Furthermore, the UCMR 5 MRLs for these compounds are higher than the proposed trigger levels. UCMR 5 establishes that the MRLs for PFOA and PFOs are 4.0 ppt. Additionally, the UCMR5 MRL of just PFHxS, PFNA, or HFPO-DA individually would exceed the trigger level of the Hazard Index independently.

Samples that are below the LCMRL and MRL have a known high degree of inaccuracy. Setting the trigger level far below this standard is arbitrary and capricious and will lead to inaccurate results and regulatory requirements unsupported by reliable evidence or sound science.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document. As discussed in this response, the EPA both disagrees that these levels have a "known high degree of inaccuracy" and that setting these trigger levels below the PQLs is "arbitrary and capricious" as the commenter claims. The agency fully agrees that the measurements do have less precision and accuracy than those at or above the PQLs; however, they are sufficiently reliable to indicate the presence of PFAS and thus to support less frequent monitoring where sampling results demonstrate a lower risk of PFAS contamination, which is their intended purpose as previously described in the preamble and this document. Furthermore, the approach of considering measured levels lower than PQLs for determining monitoring frequency is not novel but has been part of the drinking water standards for many years.

Louisville Water Company (Doc. #1720, SBC-043554)

In this same vein, Louisville Water believes that establishing the trigger level below the MRL is problematic because it would rely on J-flagged data. In a sense, the trigger level is a compliance threshold as it affects monitoring frequency and may inform treatment decisions. We believe it is inappropriate to use J-flagged monitoring data for compliance-related requirements and recommend that trigger level be established at the MRL (2 ng/L) or 50% of the PQL.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document.

Thurston Public Utility District (PUD), WA (Doc. #1729, SBC-043590)

Assuming that 1.3 ppt is an achievable target nationwide may not be appropriate or reasonable. Using an analytical result below the PQL only indicates that PFAS is present. Very little, if

anything, is known about the actual concentration of PFAS in this instance. Relying upon low concentrations below the PQL or ongoing monitoring, reduced monitoring or compliance monitoring is not appropriate. Using a trigger level greater than or equal to 2.0 ppt for PFOS and PFOA would be preferred, as well as using 0.5 for the hazard index. This will allow laboratories flexibility, balance variability in the measurement, and allow for reduced monitoring for systems with sample results at or below 50 percent of the MCL.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document.

Clean Air Council, et al. (Doc. #1731, SBC-043883)

EPA also proposes trigger values as a practical uniform stand-in for the 'zero' or 'not detected' designations currently used (which may vary depending on the laboratory conducting the tests) [FN58: For example, in Table 1 of the Pennsylvania PFAS rule, values of zero are followed by the designation "ND," meaning "not detected." 53 Pa.B. 335, Table 1.] The trigger values would be used to identify the presence of a compound in the water tested since detection down to zero is not feasible. As discussed in the proposed regulation, trigger levels will not be used in a quantitative sense or to determine compliance. Rather, their role is to identify systems that can be exempted from the standard monitoring frequency, which would be any system with levels below the trigger value [FN59: 88 Fed. Reg. 18681–82.]. Therefore, although the trigger values are for some compounds below the MDLs, they are reasonable and appropriate.

[Table: see docket ID EPA-HQ-OW-2022-0114-1731]

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document.

Arizona Corporation Commission (ACC) (Doc. #1735, SBC-045188)

RESPONSES TO SPECIFIC EPA QUESTIONS

Monitoring related flexibilities that should be considered to further reduce burden while also maintaining public health protection including a rule trigger level at different values than the currently proposed values of 1.3 ppt for PFOA and PFOS and 0.33 for the Hazard Index (HI) PFAS.

The proposed trigger levels for PFOA and PFOS (1.3 PPT) are set well below the PQL [FN4: Practical Quantitation Limit ("PQL") means the value established as a target value by the EPA that is the lowest concentration of a substance that can be consistently determined within +/- 20 percent of the true concentration by 75 percent of the laboratories tested in a performance evaluation.] (4.0 PPT) threshold. As the trigger level is lower than the PQL, the ACC questions how to reliably determine concentrations below the PQL. The ACC highlights an example where a Class A utility, despite testing for PFAS, could only detect concentrations as low as 1.7 PPT, which is above the trigger level. Therefore, the alert level should be a concentration that can be

consistently detected using currently available detection technology. Alternatively, the EPA could consider an absent/present approach. Under this approach, if a utility's PFAS or PFOA concentration is below the PQL of 4.0 PPT, that system would be considered to have a concentration of 0 and would only need to undergo PFAS testing once or twice at EPTDS [FN5: Entry point to distribution system.] every three years.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-045965)

AMWA has strong concerns with EPA proposing a trigger level below the PQL. As defined in the preamble, the PQL is "the lowest concentration of an analyte that can be reliably measured within specified limits of precision and accuracy during routine laboratory operating conditions." For EPA to consider using values below this would mean using unreliable and potentially inaccurate data to make monitoring decisions. This could lead to costly monitoring requirements at a system that in reality meets these conditions, but laboratory results do not reflect that due to inaccuracy.

PWSs may encounter many difficulties acquiring sampling results required by this proposed rule. Several AMWA members currently have contracts with commercial labs that provide information down to 4.0 ppt, or in some instances 2.0 ppt, depending on the contract details and lab. For those labs to provide any more information, many PWSs would have to amend or renegotiate their established contracts, likely adding costs. Labs are also not always willing to provide information they deem unreliable or inaccurate, meaning values below the lab's own PQL may not be available to many water systems. A prominent commercial lab used by many PWSs has told AMWA members that if they are on UCMR 5 contract and want to see results below 4.0 ppt, they would need an entirely separate sampling event due to quality assurance and quality control (QAQC) differences between UCMR 5 methods and regular EPA methods 537.1 and 533. This would require water systems to sample twice and pay twice to still only be able to see results between 2.0 and 4.0 ppt.

Because of the difficulties associated with a proposed 1.3 ppt trigger level, if EPA moves forward with a 4.0 ppt MCL, then AMWA recommends EPA set the trigger level at 50% of the MCL, or 2.0 ppt individually for PFOA and PFOS, and 0.5 for the HI PFAS. Water systems that qualify for reduced monitoring based on RAAs from UCMR 5 will still need to show they are below 2.0 ppt to continue the reduced monitoring schedule. While this would alleviate some of the burdens for PWSs that do receive sample information below 1.3 ppt, the proposed trigger level, the association stresses that this level is not readily available to all PWSs, particularly those with fewer resources and limited budgets.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document. For an explanation and support for the EPA's assumptions that water systems can request additional UCMR 5 data below MRLs from laboratories for use in satisfying

some or all of the NPDWR's initial monitoring requirements and determination of compliance monitoring frequency, please see section 13.3.4 of the EPA response in this *Response to Comments* document.

Washington County Department of Public Health and Environment (Doc. #1739, SBC-043570)

Proposed Trigger Level for Determining Monitoring Schedules

Per Part XIV, Section IX of the rule proposal, in line with MDH, the county supports the alternative trigger values of 2.0 ppt for PFOA and PFOS and 0.50 for the HI PFAS.

• Based on the state's experience with laboratory RLs for EPA Method 533, most laboratories have RLs for PFOA and PFOS above 1.3 ppt. Therefore, setting the trigger level at 1/3 of the MCL will require laboratories to report results below their RLs as qualified "J-flagged" data. This may be an additional burden on laboratories and is not typically done for compliance monitoring.

• If any results below the PQLs will be treated as zero for compliance as proposed in the rule, it is not necessary to increase to quarterly monitoring based on a trigger level that is significantly below the PQL. As an example, if a system has a PFOA detection at 1.4 ppt, then collects quarterly samples with PFOA results of 1.5, 2.0, and 2.5, all of these results would be treated as zero. Increased sampling at this level is not needed for determining compliance unless results below 4 ppt are allowed to be used in the QRAA calculations. As proposed, the rule's trigger level will cause undue burden with regards to sampling, which also increases the laboratory capacity necessary to handle these samples.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document.

LSP Association (LSPA) (Doc. #1742, SBC-043600)

Slide 21: EPA is requesting comment on establishing the proposed rule trigger levels at 1/3 of the proposed MCLs and on alternative trigger levels such as 1/2 of the proposed MCLs.

• The trigger level of 1.3 ppt for PFOS/PFOA is below typical Reporting Levels for laboratories (which are generally 2 ppt). USEPA indicates that this trigger level is intended to determine presence/absence rather than a specific concentration; however, the trigger is established as a discrete value. It is not scientifically defensible to establish a threshold value well below the practical quantitation limit (PQL) where precision and accuracy cannot be reliably achieved. Typical Acceptance Criteria for PFAS surrogates are 70 to 130%. The LSPA requests that USEPA consider establishing a trigger value that is 70% of the MCL (2.8 ppt for PFOS/PFOA if the MCL is set at 4 ppt), which would provide reasonable certainty that the compound is not present at a concentration exceeding the MCL and is above typical analytical reporting limits.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document.

Connecticut Department of Public Health (CT DPH) (Doc. #1745, SBC-045225)

4. EPA is also requesting comment on establishing the proposed rule trigger level values of 1.3 ppt for PFOA and PFOS and 0.33 for the PFAS regulated by the HI (PFHxS, HFPO–DA, PFNA, and PFBS). EPA is seeking comment on establishing the trigger level at other levels, specifically alternative values of 2.0 ppt for PFOA and PFOS and 0.50 for the HI PFAS.

CT DPH is seeking clarification on what data can be used to trigger reduced monitoring. Can PWS only use laboratory data where the method reporting limit (MRL) is below the trigger level? If this is the case, very few water systems will be able to qualify for reduced monitoring. As the EPA argues in setting the PQL, the majority of labs cannot reach MRLs below 4 ppt in normal laboratory operation. If any non-detect value from a lab meeting the PQL can be used to trigger the reduced monitoring, this will encourage PWS to seek out laboratories that only report to the PQL or do not report "J" flagged detections. This could lead to backlogs at certain laboratories and PWSs not getting the most complete data.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document.

West Virginia Rivers Coalition et al. (Doc. #1746, SBC-045258)

[In particular, we strongly support their calls for EPA to:]

• Set the trigger value at the MDL where that value is lower than one-third the MCL

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document.

Las Cruces Utilities (LCU) (Doc. #1753, SBC-043907)

In response to Section IX-Monitoring and Compliance Requirements, EPA requests comment on monitoring-related flexibilities that should be considered to further reduce burden while also maintaining public health protection including a rule trigger level at different values than the currently proposed values of 1.3 ppt for PFOA and PFOS and 0.33 for the HI PFAS (PFHxS, HFPO–DA, PFNA, and PFBS), specifically alternative values of 2.0 ppt for PFOA and PFOS and 0.50 for the HI PFAS. EPA also requests comment other monitoring flexibilities identified by commenters.

• LCU recommends a rule trigger level of 2.0 ppt. Hall Environmental Analysis Laboratory (the State approved laboratory, located in Albuquerque, NM) standard limits for method 537.1 are 2.0 ppt. Until laboratories have developed the methodology to detect PFAS to less 1.3 ppt, then this rule trigger level is impossible to implement.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document.

El Paso Water (Doc. #1757, SBC-044521)

Heightened testing and treatment could increase costs with questionable benefits for ratepayers

The requirement for a PWS to conduct testing beyond the current trigger levels raises concerns for the utility as it will mandate testing at a level the does not produce reliable or at times even readable results. The reduction in the trigger for testing from 4 ppt to 2 ppt could force utilities to double their testing costs while receiving test results that are not reliable due to the small amount of testable material.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document.

El Paso Water (Doc. #1757, SBC-044524)

The EPA should revise the testing requirement trigger to remain at the current level unless PFAS has already been detected at current levels, in which case, certain PWSs should be required to do further investigation to understand the extent or scale of the problem. For utilities that have had no or negligible detection, the cost is an undue burden on the PWS and ratepayers.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document. Please see section 8.1.2 of the EPA response in this *Response to Comments* document regarding compliance monitoring requirements.

California State Water Resources Control Board (Doc. #1760, SBC-044223)

[The State Water Board offers the following specific comments and recommendations for consideration regarding implementation of the rule:]

Recommend that EPA change the trigger levels to one-half the MCLs for determining compliance monitoring frequency. Setting the trigger levels at one-half (instead of one-third) of the MCLs would alleviate confusion regarding using the 1.3 parts per trillion for PFOA and PFOS, which some may incorrectly assume means laboratories can accurately test to that level. This change would also improve laboratory capacity by allowing more states to use previously collected data for determining reduced monitoring. Also, we believe that a one-half trigger level is appropriate for MCLs that are being set at the parts per trillion level.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document.

PFAS Regulatory Coalition (Doc. #1761, SBC-046076)

2. It is not appropriate to set trigger levels below the PQL.

The Proposal suggests trigger levels at 1/3 the MCLs, which equates to 1.3 ppt for PFOA/PFOS and a 0.3 HI. EPA should not set trigger levels below what can be accurately measured.

In the Proposal, EPA itself recognizes the challenges of finding laboratories that can provide accurate quantitation below 4 ppt: "EPA anticipates there would not be sufficient laboratory capacity if the quantitation level were set at a level below 4.0 ppt. The rigorous laboratory certification and quality assurance/quality control (QA/QC) procedures could limit the number of laboratories that can achieve lower quantitation levels and many water systems would not be able to secure the services of laboratories that are capable of consistently providing precise and accurate quantitation of concentrations of PFOA and PFOS at levels lower than 4.0 ppt." 88 Fed. Reg. 18667.

In our members' experiences, laboratories do not routinely report data below the PQL. If a laboratory does report this date in response to a client's request, the data is typically qualified as "estimated." Estimated values should not be used for regulatory reporting due to the high levels of uncertainty when reporting below the PQL. In addition, when calibrating analytical instrumentation, most laboratories use their PQL as the lowest calibration standard. Therefore, any reported values below the PQL are outside the laboratory's calibration range. Again, this introduces significant uncertainty into the reliability of these results. In fact, Coalition members have received false positive results from laboratories.

There is no logical reason that EPA should allow a lesser level of confidence for trigger levels than it does for MCLs. Incorporating data with inherently lower levels of accuracy also further complicates risk communication. Given the additional regulatory obligations for monitoring and compliance that would apply if sampling results are above the trigger level, values below the PQL should not be used.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document.

Western Urban Water Coalition (WUWC) (Doc. #1768, SBC-043953)

C. Less Restrictive Trigger Values are Warranted

WUWC supports setting rule triggers at more lenient values of 2.0 ppt for PFOA and PFOS and 0.50 for the HI PFAS, consistent with EPA's request for comments on alternative values. [FN43: d. at 18730.] In WUWC members' experience, trigger values of 2.0 ppt and 0.50 ppt would fall in line with laboratories' current calibration limits for measuring PFAS constituents. WUWC agrees that adopting these more lenient trigger values would potentially result in reduced burdens to water utilities in the form of less frequent reporting. Similar to other comments above,

WUWC reiterates its view that partially mitigating the administrative burdens resulting from the Proposed Rule is insufficient to demonstrate that the Proposed Rule is economically feasible.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document. Regarding the EPA's economic analysis and cost-benefit determination of the final rule, please see section 13.8 of the EPA response in this *Response to Comments* document.

California-Nevada Section American Water Works Association (CA-NV AWWA) (Doc. #1775, SBC-045274)

5. EPA's proposed trigger level criteria below the PQL to calculate compliance or qualify for reduced monitoring is incoherent and impracticable. The trigger level for reduced monitoring should not be set below the PQL.

EPA defines the PQL (a more appropriate term should be the "Minimum Reporting Level" or MRL – see comment #3 above, with footnote) as the lowest concentration of PFOA and PFOS that can be reliably quantified in drinking water within specified limits of precision and accuracy during routine laboratory operating conditions. EPA has also determined a PQL at 4.0 ppt, each, for PFOA and PFOS, to be appropriate in this proposed rulemaking. These levels were derived from laboratory participation in establishing UCMR 5 minimum reporting levels (MRLs) for EPA methods 531.7 and 533. EPA then proposes using values based on 1/3 of the PQLs as "trigger levels" for determination of either more or less frequent compliance monitoring, depending on routine monitoring results. EPA also proposes to use trigger levels of 1.3 ppt, each, for PFOA and PFOS or a HI of 0.33 for PFNA, PFHxS, PFPO-DA, and PFBS, instead of zero, for calculating annual averages and compliance determination. However, EPA explains that the MCL for PFOA and PFOS should be 4.0 ppt because "this is the lowest concentration that PFOA and PFOS can be reliably quantified within specific limits of precision and accuracy during routine laboratory operating conditions." Therefore, if current analytical methods cannot reliably quantify at the proposed trigger levels, such as 1.3 ppt for PFOA and PFOS, as supported by EPA's reasoning for setting the MCL at 4.0 ppt, it does not make sense to require trigger levels below the levels that can be reliably quantified. Setting the trigger levels below the PQLs may lead to false positives and excessive, unnecessary monitoring and reporting, which will create confusion and diminish public confidence.

EPA also proposes trigger levels for less frequent compliance monitoring under certain circumstances in which systems can demonstrate PFAS concentrations in drinking water are below 1.3 ppt for PFOA and PFOS and 0.33 for the Hazard Index PFAS. EPA states that lower monitoring levels "are achievable by individual laboratories, and therefore lower levels can be used for purposes of screening and to determine compliance monitoring frequency." As explained above, use of the proposed trigger levels is arbitrary, and it is inappropriate to base compliance on theoretical measurements. Moreover, this approach is overly conservative and not likely to provide significantly better health protection benefits over the proposed conservative trace level MCLs.

Achieving reliable values lower than the PQL may require laboratories to upgrade their equipment and technology at significant cost and cause additional strain on already limited laboratory capacity to handle all the testing demand. Given the challenges with reliably achieving precise and accurate monitoring results at levels below the PQL, establishing the levels to qualify for reduced monitoring far below the PQL, and below the MRLs will make it challenging for systems to qualify for the reduction in monitoring frequency and potential relief from the associated costs. CA-NV AWWA requests EPA consider establishing trigger levels for reduced monitoring no lower than the PQL.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document.

Metropolitan Water District of Southern California (Doc. #1777, SBC-045431)

3. Current analytical methods cannot reliably quantify PFOA and PFOS at the proposed trigger level of 1.3 parts per trillion (ppt)

EPA proposes using practical quantitation limits for the six PFAS of between 3.0 to 5.0 ppt, and to use values based on 1/3 of the MCL for trigger levels. The trigger levels would be 1.3 ppt, each, for PFOA and PFOS, or a Hazard Index of 0.33 for PFNA, PFHxS, PFPO-DA, and PFBS, and could be used by primacy agencies to reduce the monitoring frequency if monitoring results are below the trigger level. However, EPA explains that the MCL for PFOA and PFOS should be 4.0 ppt because "this is the lowest concentration that PFOA and PFOS can be reliably quantified within specific limits of precision and accuracy during routine laboratory operating conditions."[FN11: 88 Fed. Reg. at 18666.] Current analytical methods cannot reliably quantify at the proposed trigger level of 1.3 ppt for PFOA and PFOS, as supported by EPA's reasoning for setting the MCL at 4.0 ppt, because PFOA and PFOS cannot be "reliably quantified" at 1.3 ppt. In the absence of a reliable analytical method, setting the trigger level at 1.3 ppt may lead to false positives.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document.

Uttara Jhaveri (Doc. #1778, SBC-045441)

The EPA also recommends a proposed "trigger level" for PFOA or PFOS. [FN9: Environmental Protection Agency, supra note 4.] Water utilities may use the proposed trigger level as a "warning that they may be nearing the PFOA and PFOS MCLs of 4.0 ppt prior to exceeding them" and can make informed treatment decisions about managing their systems. [FN10: Id.] The trigger levels are an interesting addition to the regulations and may be beneficial to guide the utilities to adjust their technology and filtration systems when they hit the trigger level. The warning would help utilities adapt their systems and reduce the risk of exceeding the proposed limit of PFAS in drinking water.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document.

San Diego County Water Authority, CA (Doc. #1779, SBC-045288)

Trigger Values

EPA has proposed trigger levels as a basis to reduce monitoring frequency for large public water systems. EPA is requesting comment on setting trigger levels at 1/3 of the proposed maximum contaminant level s(MCLs) and on alternatives such as 1/2 of the proposed MCLs. Of the two proposed alternatives, we request EPA set trigger levels no lower than 1/2 Proposed MCLs. However, we are concerned that setting trigger levels below minimum reporting levels would introduce additional inaccuracy in measurements and provide inconsistency between laboratories. EPA set the proposed MCLs for the six PFAS using Practical Quantitation Levels (PQLs), which are already the lowest concentrations that can be reliably achieved within specified limits of precision and accuracy during the routine laboratory operating conditions.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document.

City of Tulsa Water and Sewer Department (CoT WSD) (Doc. #1785, SBC-043783)

5. 88 FR 18681-18682 (also 88 FR 18731). EPA requests comment on proposed trigger level values of 1.3 ppt for PFOA and PFOS and 0.33 for the PFAS regulated by the HI (PFHxS, HFPO–DA, PFNA, and PFBS), and if systems will be able to demonstrate they are reliably and consistently below 1.3 ppt for PFOA and PFOS and 0.33 ppt for PFAS regulated by the HI in order to qualify for reduced monitoring.

CoT WSD responds that there should be more reservation by EPA in utilizing analytical measurements below PQLs, which are the lowest level of reliable, quantifiable measurement of an analytical method. EPA admits multiple times within the preamble that these measurements are less precise and less accurate, even stating that it doesn't believe "it is appropriate to make potentially costly compliance decisions" based on these measurements; however, those are exactly the decisions that will be made using these measurements as trigger levels. Media replacement and other operational decisions, as well as monitoring frequency are set to be determined by these non-quantifiable measurements. EPA should look at setting MCLs at one of the alternative higher levels to allow trigger levels to be within the quantifiable limits of the analytical method.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document. Regarding the EPA's MCL determinations, please see sections 5.1 and 5.2 of the EPA response in this *Response to Comments* document.

Safe Drinking Water Branch, Hawaii Department of Hawaii (Doc. #1801, SBC-043755)

The Trigger Level of the Quarterly Monitoring

As PQL of PFSA compounds is 3.0 to 5.0 ppt, the 1.3 ppt ppt (for PFOS and PFOA) of trigger-level is lower than PQL which indicates it cannot be reliably achieved during the routine laboratory operating conditions. It is a potential loophole and an invitation of lawsuits. EPA should consider increasing the trigger-level to 2 ppt which major labs can achieve as the minimum report level.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document.

Palm Beach County Water Utilities Department (Doc. #1802, SBC-045334)

May 29, 2023

RE: Palm Beach County Water Utilities Department On-Line Submission of Comments Proposed Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation

Docket: EPA-HQ-OW-2022-0114-0027

Federal Register, March 29, 2023 (88 FR 18638) (FRL-8543-01-OW) Start End Page: 18638-18754 https://www.regulations.gov/document/EPA-HQ-OW-2022-0114-0027

Dear EPA

Palm Beach County Water Utilities Department (PBCWUD) appreciates this opportunity to submit comments pertaining to the proposed EPA Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation. This rule is important for the protection of our water supply. There are several components of the proposed rule for which we respectively submit the following comments:

Page 18667, VI.A. First column first full paragraph," .... Method 537.1 ":

PBCWUD Comment: Laboratory results reported by the approved methods like EPA 537.1, are considered estimated between the MDL and PQL and are qualified appropriately; some labs will not be able to achieve reliable data less than the PQL. This would pose a problem with the criteria to achieve reduced monitoring where the results have to be <1.3 ppt or 1/3 MCL.

Page 18667, VI.A. Second column first full paragraph," in the case where PFAS are detected but below their proposed PQLs…":

PBCWUD Comment: Method 537.1 laboratory results are estimated between the MDL and PQL; so many labs will not be able to achieve reliable data. This would interfere with reduced monitoring where the results have to be <1.3 ppt or 1/3 MCL.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document.

Earthjustice et al. (Doc. #1808, SBC-046120)

Finally, as discussed above, EPA's proposal to allow reduced monitoring based on PFAS detections below the trigger values, which in some cases are substantially below the relevant PQL, is inconsistent with EPA's proposal to zero-out all detections below the PQL for purposes of demonstrating MCL compliance. This approach is also inconsistent with EPA's assertion that detections "at the proposed rule trigger level" are "primarily useful in determining whether the contaminant is present in a sample . . . rather than to determine its specific concentration." [FN212: Proposed Rule, 88 Fed. Reg. at 18,681–82.]

To address these issues, EPA should modify its proposal to (1) set the trigger value at the MDL where that value is lower than one-third of the MCL, and (2) provide that systems with four consecutive quarters of non-detects for the 6 PFAS may reduce to annual monitoring. Lowering the trigger value would better align the proposal with EPA's Standardized Monitoring Framework for Synthetic Organic Compounds [FN213: See 40 C.F.R. § 141.24(f)(11)(i) (requiring quarterly monitoring for organic contaminants detected above 0.0005 mg/L).] as well as monitoring requirements in state- level PFAS MCLs. [FN214: See N.J. Admin. Code § 7:10-5.2(a)(5)(i)(2), (ii)(2) (requiring quarterly monitoring for PFOA, PFOS, and PFNS when detected above 0.002 ppt); N.Y. Comp. Codes R. & Regs. tit. 10 § 5-1.52 (establishing MDL as trigger value for reduced PFAS monitoring).] Allowing annual, instead of triennial, monitoring for PWSs with consistent detections below the trigger value also would align the federal requirements with existing requirements in multiple states. [FN215: See N.J. Admin. Code § 7:10-5.2(a)(5)(ii)(3), (iii)(3); N.Y. Comp. Codes R. & Regs. tit. 10 § 5-1.52; Mich. Admin. Code R 325.10717d(9), (11).]

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document. Regarding compliance monitoring requirements, please see section 8.1.2 of the EPA response in this *Response to Comments* document. The EPA has added a tier of annual monitoring in the final rule in response to public comments.

Citizens Energy Group (Doc. #1838, SBC-044861)

EPA requests comment on monitoring-related flexibilities that should be considered to further reduce burden while also maintaining public health protection including a rule trigger level at different values than the currently proposed values of 1.3 ppt for PFOA and PFOS and 0.33 for the HI PFAS (PFHxS, HFPO-DA, PFNA, and PFBS), specifically alternative values of 2.0 ppt for PFOA and PFOS and 0.50 for the HI PFAS. EPA also requests comment other monitoring flexibilities identified by commenters.

Citizens appreciates EPA's consideration of monitoring-related flexibilities, including those that can reduce the regulatory burden for communities where PFAS contamination does not originate

as a result of historical manufacturing, but rather in low levels (at or near detection limits, for example) as a result of the ubiquitous nature of PFAS in the environment.

Given the detection limits of the analytical methods, Citizens also encourages EPA to adopt the proposed alternative values in the rule trigger level to reduce the monitoring obligations. These alternative values do not compromise public safety, but rather give water systems the flexibility to leverage analytical results that fall in the range between the method detection limit (MDL) and the practical quantitation limit (PQL) – "J-flagged" data – to reduce the burdens associated with this rule, while at the same time ensuring that public health is safe- guarded.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document.

Arcadis (Doc. #3072-17, SBC-047368)

And the second one is, I'm a little confused with the proposed trigger level. If the laboratories are able to measure precisely and accurately at 4 parts per trillion or more, how come the same laboratory can measure concentrations less than 4 parts per trillion with the same confidence level? I heard one of the speakers earlier explain but the language in the current docket is confusing, but what the speaker mentioned earlier was quite clear. So, I would request EPA clarify that better in the revised edition. That's all I have. Thank you very much.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document.

Suffolk County Water Authority (SCWA) (Doc. #1589, SBC-043369)

4. Use of Trigger Levels Below Practical Quantitation Levels Will Add Unreliabilty to Implementation of Regulation

The SCWA's drinking water laboratory has been analyzing PFAS for several years, and it has established a New York minimum reporting level of 2 ppt for each of the PFAS proposed for EPA regulation. SCWA's minimum reporting level is likely what EPA would consider its practical quantitation level (PQL). With proposed MCLs for PFOA and PFOS of 4.0 ppt, the SCWA would be supportive of trigger levels of 1/2 of these proposed MCLs because they are within the PQL of the SCWA's laboratory. SCWA would have concerns about a trigger level set at 1/3 of the proposed MCLs for PFOA and PFOS because it would be below SCWA PQLs and therefore unreliable.

Since the SCWA's 2 ppt PQL for the other four PFAS are less than 1/3 of the HBWCs that would make up the proposed health index based MCL, SCWA would be supportive of either a 1/3 or 1/2 of the proposed MCL for these PFAS. However, as set forth above, SCWA would prefer contaminant specific MCLs and MCLGs for these four PFAS over a health index.

Notwithstanding the foregoing, it may be imprudent to set trigger levels below PQLs. A PQL is defined as the "lowest concentration of an analyte that can be reliably measured within specified limits of precision and accuracy during routine laboratory operating conditions." The basis for setting PQLs includes quantitation, precision and accuracy. Because the proposed PQLs for PFOA and PFOS are the same as the proposed MCLs, the proposed trigger levels will necessarily be unreliable. The same could be true if trigger levels are set at 1/3 of the MCL for PFNA and GenX Chemicals under the proposed PQLs for those chemicals depending upon the levels of other PFAS proposed for the health index.

This issue can be resolved by utilizing a 1/2 MCL trigger level and either raising proposed MCLs for PFOA and PFOS or by lowering their respective PQLs. Since EPA is required to set the MCL as close as feasible to the MCLG, perhaps the best course of action would be to lower the proposed PQLs for PFOA and PFOS accordingly.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document. Regarding the MCL determination for PFOA and PFOS, please see section 5.1 of the EPA response in this *Response to Comments* document. For discussion of the Hazard Index MCL and contaminant specific MCLs and MCLGs for the four Hazard Index PFAS, please see sections 5.2 and 5.3 of the EPA response in this *Response to Comments* document.

Minnesota Department of Health (MDH) (Doc. #1610, SBC-042855)

Proposed Trigger Level for Determining Monitoring Schedules

Per Part XIV, Section IX of the rule proposal:

"EPA requests comment on monitoring-related flexibilities that should be considered to further reduce burden while also maintaining public health protection including a rule trigger level at different values than the currently proposed values of 1.3 ppt for PFOA and PFOS and 0.33 for the HI PFAS (PFHxS, HFPO-DA, PFNA, and PFBS), specifically alternative values of 2.0 ppt for PFOA and PFOS and 0.50 for the HI PFAS."

MDH Comments

· MDH supports the alternative trigger values of 2.0 ppt for PFOA and PFOS and 0.50 for the HI PFAS.

o Based on our experience with laboratory RLs for EPA Method 533, most laboratories have RLs for PFOA and PFOS above 1.3 ppt. Therefore, setting the trigger level at 1/3 of the MCL will require laboratories to report results below their RLs as qualified "J-flagged" data. This may be an additional burden on laboratories and is not typically done for compliance monitoring.

o If any results below the PQLs will be treated as zero for compliance as proposed in the rule, it is not necessary to increase to quarterly monitoring based on a trigger level that is significantly below the PQL. As an example, if a system has a PFOA detection at 1.4 ppt, then collects quarterly samples with PFOA results of 1.5, 2.0, and 2.5, all of these results would be treated as

zero. Increased sampling at this level is not needed for determining compliance unless results below 4 ppt are allowed to be used in the QRAA calculations. As proposed, the rule's trigger level will cause undue burden with regards to sampling, which also increases the laboratory capacity necessary to handle these samples.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document.

American Council of Independent Laboratories (ACIL) (Doc. #1692, SBC-044740)

The trigger level is set at 1/3 the minimum reporting level, and exceedance above this trigger levels results in increased monitoring requirements for drinking water utilities, which has significant financial implications for the utilities. The EPA discusses this issue at length in section VI and states on page 18667:

"Therefore, for almost all laboratories, the proposed PQLs for PFOA and PFOS of 4.0 ppt are at least 4 times greater than the lowest calibration standard. This suggests the overwhelming majority of laboratories with the necessary instrumentation to support PFAS monitoring have the capability to provide screening measurement results above the proposed trigger level of 1⁄3 of the MCL (i.e., 1.3 ppt for PFOS or PFOS). Hence, a utility may use the lower-level measurements as a warning that they may be nearing the PFOA and PFOS MCLs of 4.0 ppt prior to exceeding them and can make informed treatment decisions about managing their systems (e.g., replacing GAC)"

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document. The final rule approach to monitoring frequency provides prudent information that the water systems can and should use to inform optimal drinking water treatment operations.

Wisconsin Department of Natural Resources (Doc. #1828, SBC-044804)

Trigger Level

WDNR recommends that EPA change the compliance monitoring frequency trigger level for PFOA and PFOS to be half the proposed Maximum Contaminant Level (MCL) (2.0 ppt). The one third trigger level (1.3 ppt) is not readily achievable by laboratory analysis and does not match the standard monitoring framework for synthetic organic compounds.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document.

Travis Voorhees (Doc. #2928, SBC-046531)

Good morning. I would like to submit a couple comments regarding the trigger levels (IX. Monitoring and Compliance Requirements):

I believe that increasing the number of trigger level exceedances before being required to return to regular monitoring frequency from one (1) to three (3), would be more indicative of a PFAS presence/trend. There are many variables that could cause a single detection/trigger level exceedance, including contamination by the samplers. Multiple exceedances would significantly increase confidence that there was a presence and something to be further investigated.

Additionally, I believe increasing the trigger level to at least one half the PQL would be logical, especially given that the EPA has acknowledged on multiple occasions that detections under the PQL may not be reliable/accurate.

Thank you for the opportunity to comment, really appreciate it.

Respectfully,

Travis Voorhees

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document. Regarding compliance monitoring requirements, please see section 8.1.2 of the EPA response in this *Response to Comments* document.

Environmental Monitoring Coalition (EMC) (Doc. #1625, SBC-043110)

Based on customer specifications, laboratories typically have two different ways of reporting results. The first option is to report any result below the MRL not detected as Not Detected. The other option is to report any result between the MDL and MRL as an estimated value. (Note: Method 533 does not have published MDLs.) This issue is further complicated by a requirement in the methods that blanks do not contain concentrations of any PFAS compounds above 1/3 the MRL. The proposed trigger levels create a third option, and as summarized in the table below, EMC seeks clarity on how laboratories should report data.

Table 2. Reporting Options for Laboratories

[Table 2: See Docket ID EPA-HQ-OW-2022-0114-1625]

As discussed above, the language is confusing. Option 1 is typically how drinking water results are reported but does not meet the Agency's goal of screening for concentrations below the MCL. Option 2 is how laboratories typically report results for other EPA programs. Option 3 would significantly change how laboratories report data and may represent a challenge for some laboratories' Laboratory Information Management Systems (LIMS). Option 4 would be an acceptable alternative to Option 2 as EPA indicated 48 of 53 laboratories can quantitate to this level. Option 5 may present similar problems to Option 3. Option 6 is also possible. There is a possible Option 7 relative to blanks being < 1/3 the MRL which would also create LIMS issues, but the EMC believes blank contamination is a Quality Control (QC) issue and not a reporting issue.

All of these options are possible, and EPA should provide clear, consistent requirements and guidelines to achieve those requirements.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document.

Association of Public Health Laboratories (APHL) (Doc. #1646, SBC-043314)

Based on customer specifications, laboratories typically have two different ways of reporting results. The first option is to report any result below the MRL not detected as Not Detected. The other option is to report any result between the MDL and MRL as an estimated value. (Note: Method 533 does not have published MDLs.) This issue is further complicated by a requirement in the methods that blanks do not contain concentrations of any PFAS compounds above 1/3 the MRL. The proposed trigger levels create a third option, and as summarized in the table below, EMC seeks clarity on how laboratories should report data.

Table 2. Reporting Options for Laboratories

[Table 2: See Docket ID: EPA-HQ-OW-2022-0114-1646]

As discussed above, the language is confusing. Option 1 is typically how drinking water results are reported but does not meet the Agency's goal of screening for concentrations below the MCL. Option 2 is how laboratories typically report results for other EPA programs. Option 3 would significantly change how laboratories report data and may represent a challenge for some laboratories' Laboratory Information Management Systems (LIMS). Option 4 would be an acceptable alternative to Option 2 as EPA indicated 48 of 53 laboratories can quantitate to this level. Option 5 may present similar problems to Option 3. Option 6 is also possible. There is a possible Option 7 relative to blanks being < 1/3 the MRL which would also create LIMS issues, but the EMC believes blank contamination is a Quality Control (QC) issue and not a reporting issue.

All of these options are possible, and EPA should provide clear, consistent requirements and guidelines to achieve those requirements.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document.

Massachusetts Department of Environmental Protection (MassDEP) (Doc. #1726, SBC-045154)

§ 141.902(a)(9) requires reporting of detections at or above 1/3 the PQL, which by definition is below the concentration that can be confidently quantified. Estimated concentrations should not be used to establish the compliance monitoring frequency or to trigger quarterly monitoring under § 141.902(b)(2)(ii) and § 141.903(d).

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document. The referenced requirement has been updated in the final rule. This item,

now listed as § 141.902(a)(7) instead of § 141.902(a)(9), requires that, "For purposes of this section, each water system must ensure that all results provided by a laboratory are reported to the State and used for determining the required sampling frequencies. This includes values below the practical quantitation levels defined in § 141.903(f)(1)(iv); zero must not be used in place of reported values." See also section 8.1.2 for a discussion of the use of data below PQLs for establishing monitoring frequencies. Please see section 8.2 of the EPA response in this *Response to Comments* document regarding the use of values below PQLs in compliance calculations.

San Antonio Water System (SAWS) (Doc. #1570, SBC-042477)

The cost and effort that will be required for data that is below nationally established precision is substantial. EPA should not consider any limits below a PQL.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document. Regarding the use of levels below the PQLs in the compliance calculation determination, please see section 8.2 of the EPA response in this *Response to Comments* document.

Aqua America, an Essential Utilities Company (Doc. #1623, SBC-043090)

It is recommended that EPA eliminate the use of analytical results below the PQL and instead use zero ppt for all analytical results below the PQL. Additionally, Aqua recommends that one-half the MCL be used to determine if PFAS levels at an entry point are reliably below the MCL.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document. For compliance monitoring requirements, including the determination of reliably and consistently below the MCL under this rule, please see section 8.1.2 of the EPA response in this *Response to Comments* document. For discussion of using values below the PQLs in RAA compliance calculations, please see section 8.2 of the EPA response in this *Response to Comments* document.

Aqua America, an Essential Utilities Company (Doc. #1623, SBC-043117)

However, the proposed approach to use reporting results below the PQL is inappropriate and will cause equity issues with respect to access to high quality laboratories. This will lead systems with less financial capacity to have more stringent monitoring requirements. EPA should move forward with the SMF, where all results below the PQL are considered 0 ppt.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document. Additionally, regarding compliance monitoring requirements, please see section 8.1.2 of the EPA response in this *Response to Comments* document. For discussion of using values below the PQLs in RAA compliance calculations, please see section 8.2 of the EPA response in this *Response to Comments* document. Please see also section 5.1.2 of the EPA

response in this *Response to Comments* document for a discussion of laboratory capability and capacity.

Aqua America, an Essential Utilities Company (Doc. #1623, SBC-043101)

However, the use of reporting results below the PQL is inappropriate as it requires water systems to rely on unreliable data to determine monitoring requirements as part of the regulatory requirements. As a result of this requirement, to minimize the risk of inaccurate results triggering quarterly monitoring, water systems will be driven to pay higher monitoring costs to have access to laboratories with the ability to reliably achieve reporting results below the PQL.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document. Additionally, regarding compliance monitoring requirements, please see section 8.1.2 of the EPA response in this *Response to Comments* document. For discussion of using values below the PQLs in running annual average compliance calculations, please see section 8.2 of the EPA response in this *Response to Comments* document. Please see section 5.1.2 of the EPA response in this *Response to Comments* document for a discussion of laboratory capability and capacity.

Colorado Water Utility Council (CWUC) (Doc. #1622, SBC-044035)

17. EPA requests comment on monitoring-related flexibilities that should be considered to further reduce burden while also maintaining public health protection including a rule trigger level at different values than the currently proposed values of 1.3 ppt for PFOA and PFOS and 0.33 for the HI PFAS (PFHxS, HFPO- DA, PFNA, and PFBS), specifically alternative values of 2.0 ppt for PFOA and PFOS and 0.50 for the HI PFAS. EPA also requests comment on other monitoring flexibilities identified by commenters.

a. The trigger values should be set to 4.0 ppt, 1/2 the MCL of 8.0 ppt. Values below 4.0 ppt could present issues with consistent and reliable data reporting, and may not be precise or accurate. The HI trigger level should be raised to 0.5. Data review of concentrations below the MRL begin to shift towards qualitative and results below these levels can be suspect and unreliable. Values below the reportable limit should not be used for compliance.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document. For a discussion regarding treating values below the PQL as zero in RAA compliance calculations, please see section 8.2 of the EPA response in this *Response to Comments* document. For discussions of the MCLs, see section 5 of this document, including section 5.1.2 where the MCLs and PQLs for PFOA and PFOS are discussed.

Aqua America, an Essential Utilities Company (Doc. #1623, SBC-043087)

In review of the Proposal, however, there are significant concerns surrounding the proposed approach requiring water systems to consider low quality, unreliable analytical results below the

PQL. Specifically, the EPA is proposing that 1.3 ppt PFOA and PFOS and one-third of the hazard index be used as a trigger level for reporting for the purposes of determining reduced monitoring eligibility under the SMF. The EPA also requested input on the use of 2.0 and one-half the hazard index.

Aqua believes the use of any data below the PQL to drive regulatory requirements, is unacceptable and scientifically inappropriate. The PQLs for PFOA and PFOS are set at 4.0 ppt each in the Proposal, which is consistent with the currently active UCMR 5 monitoring program's minimum reporting limits. In finalizing the UCMR 5 monitoring program in 2021, the EPA recognized that while EPA Methods 533 and 537.1 can both be used by laboratories to achieve lower reporting limits but concluded that the available lab capacity could not support establishing lower reporting limits to collect national occurrence data. Data below this level is less accurate and is not achievable by all water systems.

As a matter of policy, it is not recommended for EPA to set a precedent to use results that are not nationally achievable for all water systems as this would create an equity issue.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document. For discussion of compliance monitoring requirements, please see section 8.1.2 of the EPA response in this *Response to Comments* document. Regarding laboratory capability and capacity, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

Texas Commission on Environmental Quality (TCEQ) (Doc. #1632, SBC-044126)

Practical Quantitation Limits (PQL)

Data below the PQL is only an estimation and this data should not be used to determine reduced monitoring frequency. EPA has defined the PQL as the "lowest concentration of an analyte that can be reliably measured within specified limits of precision and accuracy during routine laboratory operating conditions."

Due to the uncertainty and estimated values below the PQL, use of this data to determine monitoring frequencies will create doubt in the reliability of data used to make compliance decisions. As required by accreditation quality standards, results on laboratory analytical reports will specify the result is an estimate. For all chemical analytes, TCEQ requires reporting the PQL and the determined result, as well as reporting that the reported result is below the laboratory's PQL. TCEQ views all results below the PQL as a non-detection when determining compliance. When calculating a public water system's running annual average, if non-qualified data below 4.0 parts per trillion is included in the calculation—rather than included as a "zero"—it could result in the system not meeting the "reliably and consistently below the MCL" requirement to be considered in compliance. To be consistent with other NPDWR standards, TCEQ recommends that PFAS data below the PQL be reported as a non-quantifiable detection and have a compliance value of "zero."

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document. Regarding compliance monitoring requirements and frequencies, please see section 8.1.2 of the EPA response in this *Response to Comments* document. For a discussion regarding treating values below the PQL as zero in RAA compliance calculations, please see section 8.2 of the EPA response in this *Response to Comments* document. For further discussion of PQLs, please see section 7.2 of the EPA response in this *Response to Comments* document.

Santa Clara Valley Water District (Valley Water) (Doc. #1664, SBC-043128)

Comment 4 – The Proposed Trigger Level Criteria to Qualify for Reduced Monitoring Will be Challenging for Laboratories to Achieve

EPA is proposing a "trigger level" for less frequent compliance monitoring under certain circumstances in which systems can demonstrate PFAS concentrations in drinking water are below 1.3 parts per trillion (ppt) for PFOA and PFOS and 0.33 for the Hazard Index PFAS. EPA states that lower monitoring levels "are achievable by individual laboratories, and therefore lower levels can be used for purposes of screening and to determine compliance monitoring frequency."

The Practical Quantitation Level (PQL) is defined as the lowest concentration of an analyte that can be reliably measured within specified limits of precision and accuracy during routine laboratory operating conditions. EPA has determined that establishing a PQL at 4.0 ppt for PFOA & PFOS is appropriate in this proposed rulemaking. This PQL was derived from laboratory participation in establishing UCMR 5 method reporting limits (MRLs) using EPA Methods 537.1 and 533. Achieving lower values than the PQL is a technological challenge and requires laboratories to make significant financial and other resource investments to upgrade their analytical equipment.

Given the challenges with reliably achieving precise and accurate results at levels below the PQL, establishing the levels to qualify for reduced monitoring far below the PQL, and below the MRLs will make it challenging for systems to qualify for the reduction in monitoring frequency and potential relief from the associated costs. Valley Water requests EPA consider establishing trigger levels for reduced monitoring at the PQL.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document. Regarding compliance monitoring requirements and frequency, please see section 8.2.1 of the EPA response in this *Response to Comments* document.

Clean Air Council, et al. (Doc. #1731, SBC-043860)

c. Laboratory detection methods can accurately measure the regulated PFAS species at the proposed PQL, MCLs, and HBWCs, and the proposed trigger levels are appropriate.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-045625)

Use of Standard Monitoring Framework

The proposed approach to use the SMF as a basis for triggering reduced monitoring is appropriate. In review of the proposal, however, AWWA has significant concerns surrounding the proposed approach to require water systems to consider low quality, unreliable analytical results below the PQL. Specifically, the EPA is proposing that 1.3 ppt PFOA and PFOS and one-third of the hazard index be used as a trigger level for reporting for the purposes of determining reduced monitoring eligibility under the SMF. The EPA also requested input on the use of 2.0 and one-half the hazard index.

AWWA recommends against the use of any data below the PQL to drive regulatory requirements. Data should likewise not be used to determine nor treatment, or more frequent monitoring. For the reasons detailed below, use of this below-PWL data would be arbitrary and capricious.

The PQLs for PFOA and PFOS are set at 4.0 ppt each in the proposal, which is consistent with the currently active UCMR 5 monitoring program's minimum reporting limits. In finalizing the UCMR 5 monitoring program in 2021, EPA recognized that while EPA Methods 533 and 537.1 can both be used by laboratories to achieve lower reporting limits but concluded that the available lab capacity could not support establishing lower reporting limits to collect national occurrence data. Data below this level is less accurate and is not achievable by all water systems.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document. As discussed in this response, the EPA disagrees that data below PQLs should not be used for the determination of monitoring frequency or that use of this data is "arbitrary and capricious" as the commenter claims. The agency fully agrees that the measurements do have less precision and accuracy than those at or above the PQLs, however they are appropriate for their intended purpose of determining whether water systems should be allowed to monitor less frequently where sampling results have demonstrated lower risk of PFAS contamination as previously described in the preamble and this document. Furthermore, the approach of considering measured levels lower than PQLs for determining monitoring frequency is not novel but has been part of the drinking water standards for many years. Regarding the determination of how MCL compliance is to be determined, please see section 8.2 of the EPA response in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-045642)

EPA's proposed approach to require monitoring under the Standard Monitoring Framework and the use of the one-half of the MCL as a trigger level is appropriate. However, the use of reporting results below the PQL is inappropriate as it requires water systems to rely on unreliable data to determine monitoring requirements as part of the regulatory requirements.

EPA Response: Please see section 8.8 of the EPA response in this *Response to Comments* document. Regarding compliance monitoring requirements and frequency, please see section 8.1.2 of the EPA response in this *Response to Comments* document.

8.9 Other Monitoring Flexibilities

Individual Public Comments

California Municipal Utilities Association (CMUA) (Doc. #1639, SBC-043256)

III. The Regulation Needs to Take Unintended Consequences into Consideration

There are certain unintended consequences of the Regulation that need to be taken into consideration before the EPA adopts the Regulation.

General practice for many public water agencies is to take a water supply offline if that supply gets to 50% of an enforceable drinking water standard. That water supply is then treated and brought back online once it no longer tests at 50% of the enforceable drinking water standard. When supplies are offline, the water agency is forced to rely more heavily on other water supplies to meet customer needs. For agencies with multiple water sources, this practice may mean they must import more water, divert more water, or use stored water. Smaller agencies, on the other hand, are less likely to have more than a few water sources. Suppose a smaller agency has to take a groundwater well offline because the testing shows 50% or more of the PFAS MCLs. In that case, the agency has fewer other sources to rely on and will be disproportionally impacted. Accommodations should be made for agencies that follow that practice and work to remain compliant but are nonetheless struggling to meet customer needs.

EPA Response: The EPA notes that NPDWRs require systems to meet the MCLs and do not require a system to take a water source offline if it contains concentrations exceeding half of any MCL. Water systems seeking assistance with achieving compliance with regulatory requirements are encouraged to coordinate with the applicable primacy agency. The commenter does not specify examples of accommodations it is seeking or a clear rationale for these accommodations that cites precedents under other NPDWRs. The SDWA permits the EPA or primacy agencies to grant extensions, exemptions, or variances under certain circumstances. Regarding exemptions and extensions, please see section 12.1 of the EPA response in this *Response to Comments* document and section XII of the final rule preamble. Additionally, as noted in section II.E of the preamble to the final rule, funding under the IIJA, often referred to as the BIL, will assist many disadvantaged communities, small systems, and others with the costs of addressing emerging contaminants, like PFAS, when it might otherwise be cost-challenging. Finally, to support BIL implementation, the EPA is offering WaterTA to help communities identify water challenges and solutions, build capacity, and develop application materials to access water infrastructure funding (USEPA, 2023).

National Center for Health Research (NCHR) (Doc. #1749, SBC-044497)

2. This is an important first step in PFAS regulation, but it needs to be strengthened in several ways to protect human health.

• We understand the agency's desire to be flexible, but flexibility in monitoring requirements will likely generate a huge loophole. EPA needs more explicit limits to prevent a weakening of these regulations.

EPA Response: The commenter requested "more explicit limits," but did not make a specific recommendation. Most elements of this rule related to compliance monitoring and determining MCL compliance are similar to the NPDWR requirements for other chemical contaminants. For any monitoring flexibilities offered, the EPA has utilized a data-driven rationale. Initial monitoring requirements, compliance monitoring requirements, and compliance determinations are discussed in sections 8.1.1, 8.1.2, and 8.2 of the EPA response in this *Response to Comments* document, respectively. The EPA disagrees that more explicit limitations are needed. The requirements are explicit, and the agency is promulgating this rule based on the extensive record discussed in this document and the final rule preamble that support the EPA's findings that the final MCLs and monitoring schedules will be protective of public health but will at the same time not impose unnecessary burdens on systems where the risk of PFAS contamination is minimal.

9 SDWA Right-to-Know Requirements

9.1 Consumer Confidence Report Requirements

Summary of Major Public Comments and EPA Responses

A few commenters requested clarification of the health effects language included in the Consumer Confidence Report (CCR). Specifically, a couple of commenters said the proposed standard health effects language included in the CCR for a Hazard Index Maximum Contaminant Level (MCL) exceedance was not clear. One commenter suggested that the EPA utilize "plain language' explanations about the Hazard Index and the way that the EPA has framed the calculations based on risk" (Doc. #1838, SBC-044870). Another commenter asserted that "the required language does not sufficiently explain the HI" (Doc. #1626, SBC-052953). The EPA has considered this input and revised the health effects language associated with PFAS exposure, including the Hazard Index. The change is responsive to the commenters' concern regarding clarity because the EPA has provided additional text in the health effects language which describes how PFAS included in the Hazard Index can result in adverse health effects when combined in a mixture in drinking water. In response to these comments, the agency has also added a definition of the Hazard Index in 40 CFR 141.153(c)(3)(v) to provide further clarity.

A few commentors raised concerns about requiring reporting of results below the practical quantitation level (PQL) in the CCR as these data may not be quantified with what they deem is appropriate precision. One commentor requested that any detected PFAS, not just the six regulated contaminants, be reported in the CCR. The EPA disagrees with commenters who voice concern over reporting measurements below the PQLs for PFOA and PFOS as "detected" contaminants in the CCR because reporting these measurements in the CCR will allow customers to understand that the contaminant was detected in the water supply. While measurements below the PQL will not be used to calculate compliance with MCLs for the final rule, measurements lower than the PQL are achievable by individual laboratories, and therefore these measurements can be used for screening, to determine compliance monitoring frequency, and to educate consumers about the existence of PFAS (for further discussion of PQLs for regulated PFAS, please see section VII of the preamble for this action). As such, the EPA believes that measurements below the PQL can reasonably be reported as "detected" for purposes of the CCR. This requirement is consistent with the CCR Rule in 40 CFR 141.153(d) which requires community water systems (CWSs) to report information on detected contaminants for which monitoring was required by the EPA or the state. The CCR reporting requirement includes unregulated contaminants for which monitoring is required pursuant to the Unregulated Contaminant Monitoring Rule (UCMR) as well as regulated contaminants in accordance with Safe Drinking Water Act (SDWA) 1414(c)(4). If the system has performed additional monitoring, the EPA strongly encourages them to include the results in the CCR, consistent with 40 CFR 141.153(e)(3). For purposes of reporting contaminant information in the CCRs, "detected" is defined in § 141.151(d).

As part of this regulatory action, the EPA has modified the trigger level value for quarterly monitoring from one-third of the MCL to one-half of the MCL in response to concerns that laboratories would not have the capacity to consistently measure as low as the threshold of one-third of the MCL (see section VIII.A.2 of the preamble for this action for further discussion about changes to the trigger level from the proposed to final regulation). To reflect this change in the trigger level, the EPA has modified 40 CFR 141.151(d), which identifies what is considered detected for purposes of reporting in CCRs consistent with SDWA 1414(c)(4). The EPA had also proposed adding a provision to require CWSs that detect any PFAS above the MCL to include health effects language for PFAS and stated in the preamble for the rule proposal that CWSs would be required to report detected PFAS as part of their CCRs. Because SDWA 1414(c)(4)(B) specifies that the Administrator may only require health effects language be reported in the CCR for situations other than an MCL violation for not more than three regulated contaminants, the EPA has removed the amendment to section (g) of 40 CFR 141.154 included in the proposed rule from the final rule and has instead updated Appendix O of Part 141 for the final rule to only require CWSs that have violations of the PFAS MCLs to include health effects language for PFAS. Since systems must complete initial monitoring within three years of rule promulgation, systems will be required to report results and other required information in CCRs beginning with 2027 reports. As the MCL compliance date is set at five years following rule promulgation, systems will be required to report MCL violations in the CCR, accompanied by the required health effects language and information about violations, starting in 2029.

For the final rule, in response to commenter requests for plain language explanations of the Hazard Index, the EPA is adding a definition of the Hazard Index in 40 CFR 141.153(c)(3)(v) of the CCR Rule to improve clarity and understandability for customers. Additionally, after considering public comments, the final rule includes revised mandatory health effects language required as part of CCRs, to address commenters' concerns, in cases where MCL violations have occurred. The updated health effects language can be found in Appendix A to Subpart O and is summarized in section IX.A.3 of the preamble for this action.

Individual Public Comments

National Tribal Water Council-Tribal PFAS Working Group (NTWCTPWG) (Doc. #1598, SBC-042340)

Public Notification

The FRN on page 18684 states that:

Under this proposal CWSs would be required to report detected PFAS in their CCR; specifically, PFOA, PFOS, PFHxS, HFPO–DA, PFNA, and PFBS, and the HI for the mixtures of PFHxS, HFPO–DA, PFNA, and PFBS. [CWSs refers to Community Water Systems, CCR refers to Consumer Confidence Report and HI is Hazard Index]

The NTWC-TFWG thanks EPA for inclusion of this requirement, which is a priority for us. This requirement should be clarified to indicate "report detected PFAS and amounts."

EPA Response: The EPA acknowledges the commenter's support of this requirement. With respect to the commenter's suggestion that CCRs should "report detected PFAS and amounts," the EPA agrees and has finalized the requirement that community water systems must report information on detected PFAS contaminants regulated under this final rule in CCRs in § 141.151(d). The EPA notes that the existing CCR requirements in 40 CFR Subpart O further require reporting this information in the contaminant data tables, to include PFAS, in § 141.153(d)(4). When MCL compliance is determined using a running annual average (RAA) of all samples taken at a monitoring location, as is the case for the PFAS National Primary Drinking Water Regulation (NPDWR), the highest average of any of the monitoring locations and the range of all monitoring locations must be reported, see § 141.153(d)(4)(iv)(B) for additional information.

WaterPIO (Doc. #1624, SBC-047683)

[A strong case can even be made that the EPA wants the end of the public's confident use of its tap water, based on the clear, cumulative effect of:]

• the "Don't Say Safe" provision in the proposed changes to the Consumer Confidence Report Rule;

EPA Response: Revisions to the CCR Rule and responses to public comments received on that proposed rule will be addressed as part of a separate action, see www.regulations.gov, Docket ID: EPA-HQ-OW-2022-0260, and are outside the scope of this action. As part of this regulatory action, the EPA is finalizing requirements for information to be included in CCRs for the six PFAS that are regulated under this final rule.

Cleveland Water, City of Cleveland, Ohio (Doc. #1672, SBC-047692)

An important message that has been made difficult to communicate to the public is letting customers know that their water is safe to drink, even when PFAS concentrations are below detection limits. EPA's announcements of health advisories that are in the parts per quadrillion realm made it difficult to say that the water was safe to drink, because water systems cannot detect the presence of contaminants at those levels – and therefore cannot tell customers whether their water meets EPA's health advisory. Additionally, EPA had proposed using drinking water health advisory levels for HBWC's in this NPDWR rulemaking. Questions will arise on why the health advisories are used for some PFAS but not others, and the public will lose trust in drinking water if it is not effectively communicated. EPA made these decisions based on its own analysis, and therefore should be the leader in these communication efforts. This communication would be helpful for utilities to use in their CCRs.

EPA Response: Please see section 9.1 of the EPA response in this *Response to Comments* document for discussion of reporting results below PQL values in the CCR and section 9.2 of the EPA response in this *Response to Comments* document for discussion of the EPA's health advisories for PFAS. The EPA notes that the agency intends to produce risk communication materials that can be used by utilities and others as they deem appropriate to communicate about PFAS in drinking water. As the EPA develops implementation materials following final rule promulgation, the agency will consider additional resources to support states and water systems in communicating with and notifying their customers. For discussion of risk communication materials that the agency intends to develop related to this action, please see section 1.2 of the EPA response in this *Response to Comments* document .

State of Vermont Agency of Natural Resources and Department of Health (Doc. #1708, SBC-045124)

Comment: The Department of Health suggests that EPA provide clear and health-protective advice on PFOA and PFOS in drinking water above the reporting level and below 4 ppt that align with the severity of noncancer health effects described in the document. Please explain how discounting any detections of PFOA or PFOS below 4 ppt aligns with the severity of noncancer health effects. Please explain how states should message reliable detections of PFOA and PFOS less than 4 ppt.

Explanation: In Vermont, the reporting level for PFAS in drinking water is almost always lower than 4 ppt. The reporting level is typically 2 ppt for public drinking water sampled between 2019 and 2023. While additional monitoring is required in the draft framework above the trigger level, the messaging to the public is unclear. It appears that valid detections of either PFOA or PFOS below 4 ppt would be messaged to the public as "not detected." Detections below 4 ppt would be entered into the running annual average calculation as "0". The public, including sensitive populations, would continue to drink the water containing PFAS between 2 ppt and 4 ppt, and these reliable detections would not contribute to the running annual average. This seems at odds with the severity of the noncancer health effects described in the draft document.

EPA Response: The EPA disagrees with the commenter's suggestion that the agency is "discounting any detections of PFOA or PFOS below 4 ppt;" please see section 9.1 of the EPA response in this *Response to Comments* document for discussion of reporting "detected" results in CCRs, which includes values below the PQLs. Concentrations of PFAS at levels equal to or exceeding trigger levels, but below MCLs, are used to determine the required monitoring frequency. For a discussion of replacing values below PQLs with zero for the purpose of calculating compliance with MCLs, see section 8.2 of the EPA response in this *Response to Comments* document.

Massachusetts Department of Environmental Protection (MassDEP) (Doc. #1726, SBC-045151)

Consumer Confidence Reports (CCR)

Edits to 40 CFR § 141.151(d) reference "levels prescribed § 141.902(a)(9)" which appears to be missing the word "by" prior to the citation. Note also that § 141.902 appears as "§ 141.XX" on page 18751 of the Federal Register notice. § 141.902(a)(9) defines a "reportable detection" as those "at or above one-third of the levels described in the table outlined in § 141.903(f)(1)(i)(3)."

This table contains the PQLs, which, by definition in § 141.2, are "the minimum concentration of an analyte (substance) that can be measured with a high degree of confidence that the analyte is present at or above that concentration." This requirement would mean reporting PFAS detections in the CCR below the PQL which would be estimated concentrations (qualified results). As the proposal does not use these estimated concentrations when calculating compliance with the MCLs, reporting these in the CCR would generate public confusion and suggest these are the true levels. Rather than citing § 141.902(a)(9), the CCR revision should cite § 141.903(f)(1)(i)(3) directly and only require CCR reporting of detections at or above the PQL.

The revision to Appendix A to Subpart O of Part 141 – Regulated Contaminants should include an edit to the "Traditional MCL in mg/L" header to add "(unless otherwise noted)" as was proposed to the table in §141.61(c). The purpose of footnote 2 on the HI MCLG value is also not clear (on page 18749 of the Federal Register notice). If the intent is to refer to the HI definition, then move the footnote to the Contaminant entry.

EPA Response: The EPA disagrees with the commenter's assertion that reporting values below the PQL will "generate public confusion and suggest these are the true levels" because, as stated in section 9.1 of the EPA response in this *Response to Comments* document, "measurements lower than the PQL are achievable by individual laboratories, and therefore these measurements can be used for screening, to determine compliance monitoring frequency, and to educate consumers about the existence of PFAS". These are accurate values that just measure with less precision than values above the PQL and "can reasonably be reported as "detected" for purposes of the CCR". For further discussion of reporting values below the PQL in CCRs, please see section 9.1 of the EPA response in this *Response to Comments* document.

Additionally, in response to the commenter's suggested grammatical corrections, the EPA added a preposition where the commenter noted "by" was missing in § 141.151(d). In the section following § 141.901, originally on page 18751, § 141.XX was changed to § 141.902. In Appendix A to Subpart O, the EPA has deleted footnote 2 and added the definition of *Hazard Index* to § 141.153(c)(3)(v). In the same appendix, while a parenthetical saying "unless otherwise noted" was not added to the column header as per the commenter's suggestion, this parenthetical note is provided in §141.50 and Table 4 to paragraph (c) of §141.61, which provide information on the Maximum Contaminant Level Goal (MCLG) and MCL values and units for the final rule, respectively.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-045971)

One additional unintended consequence of this delay in results is the current proposed revisions to the Consumer Confidence Report (CCR) Rule. The proposed revisions would require a PWS

to update its CCR later in the year after delivery of the first if new UCMR data is received after delivery of the first report. With continued and worsened delays in receiving PFAS results, utilities who typically finalize reports in February or March before a quarterly billing cycle will have to update their CCR later in the year, delaying the delivery of results to customers by up to 12 months. The alternative would be to spend additional resources sending out the CCR separately from quarterly billing, which is neither efficient nor cost-effective.

EPA Response: Revisions to the CCR Rule and responses to public comments received on that proposed rule will be addressed as part of a separate action, see www.regulations.gov, Docket ID: EPA-HQ-OW-2022-0260, and are outside the scope of this action. As part of this regulatory action, the EPA is finalizing requirements for information to be included in CCRs for the six PFAS that are regulated under this final rule.

City of Thornton, Colorado (Doc. #1748, SBC-044795)

In addition, EPA should provide language for use in CCRs that explains that those values are estimated but are protective of public health because they are below the MCL.

EPA Response: For a discussion of reporting values below the PQL in CCRs, please see section 9.1 of the EPA response in this *Response to Comments* document. The EPA notes that the agency intends to produce risk communication materials that can be used by utilities and others as they deem appropriate to communicate about PFAS in drinking water. As the EPA develops implementation materials following final rule promulgation, the agency will consider additional resources to support states and water systems in communicating with and notifying their customers. For discussion of risk communication materials that the agency intends to develop related to this action, please see section 1.2 of the EPA response in this *Response to Comments* document. For discussion of the final trigger levels for this rule, please see section 8.8 of the EPA response in this *Response to Comments* document.

Council of State and Territorial Epidemiologists (CSTE) (Doc. #1770, SBC-044260)

Please see below for a summary of our comments and recommendations:

1. Data Collection and Statistical Methods: CSTE supports the recommendation that a CWS must prepare and deliver to its customers an annual Consumer Confidence Report (CCR) in accordance with requirements in 40 CFR 141 Subpart O. A CCR provides customers with information about their local drinking water quality as well as information regarding the water system compliance with drinking water regulations. Under this proposal CWSs would be required to report detected PFAS in their CCR; specifically, PFOA, PFOS, PFHxS, HFPO-DA, PFNA, and PFBS, and the HI for the mixtures of PFHxS, HFPO-DA, PFNA, and PFBS. However, adoption of the proposed MCLs will result in challenges with data collection, processing, analysis, and reporting. In addition to preparing customers with CCRs, testing results from the public drinking water system should be made easily available and accessible to the public. While these data are usually available through the Environmental Quality Department,

the information that the Environmental Quality Department may be limited and can be challenging to access. Additional guidance is necessary specifying how the data should be reported as well as guidance on interpretation of results. Further, data interpretation and processing can be difficult if Public Health Agencies don't have access to the data collected by partner agencies. Currently, due to limited sample analysis capacity, more laboratories will be needed to conduct analyses. Additional standardized guidance and coordination to support Public Health Agencies to access, process, analyze, report, and disseminate the information is required to improve consistency, transparency, and accuracy.

EPA Response: Please see section 9.1 of the EPA response in this *Response to Comments* document for discussion of CCR requirements for the final rule, including reporting of detected PFAS and MCL violations. The CCR Rule requires all community water systems to prepare and distribute a brief annual water quality report summarizing information regarding source water, detected contaminants, compliance, and educational information. The EPA notes that CCRs provide information about local drinking water quality to customers of CWSs. With respect to the commenter's concerns regarding data collection and processing, instructions are available from the EPA, including as part of the description of the approved PFAS analytical methods. Also, the EPA intends to provide materials to aid in implementation of the rule, including information related to public notification and calculation of the Hazard Index. For more information on primacy agency reporting requirements for the final rule, please see section XI.C of the preamble for this action. With respect to any data analysis concerns related to laboratory capacity, please see section V.A.2 of the preamble for this action and section 5.1.2 of the EPA response in this *Response to Comments* document for discussion of laboratory considerations, including capability and capacity.

Uttara Jhaveri (Doc. #1778, SBC-045449)

The monitoring system also requires a Community Water System to prepare and deliver an annual "Consumer Confidence Report (CCR)" to its consumers in accordance with requirements in 40 CFR 141 Subpart O. [FN28: Environmental Protection Agency, supra note 4.] The intention of the EPA is to keep consumers well-informed about their local drinking water quality and the water system compliance with drinking water regulations. The proposed regulation also mentions a "Public Notification (PN)" rule, which ensures that consumers are informed of any risk to public health because of a problem with the drinking water. [FN29: Id.]

The CCR and PN are important informational tools to involve the public and inform them of their drinking water. [FN30: Id.] However, the CCR may be a costly system to inform consumers nationwide, and a simple system through public informational tools such as the news channels and social media should be roped to disseminate such information easily. The Public Notification, on the other hand, should be more private and only affected areas and individuals should be informed of any public health risk. However, considering the transportability of PFAS, the neighboring areas of such sites should also be informed to ensure public safety.

EPA Response: Please see sections 9.1 and 9.2 of the EPA response in this *Response to Comments* document. The EPA agrees that CCRs and Public Notification (PN) are important for informing customers of drinking water issues. The EPA notes that no fundamental changes to the CCR or PN Rules were made as part of this action. All community water systems are required under 40 CFR 141 Subpart O to provide annual CCRs to their customers and to make a good faith effort to reach consumers who do not receive a water bill using a combination of methods appropriate to the particular water system, which may include news media and other means recommended by the primacy agency. This action adds PFAS reporting requirements to the CCR, by requiring an additional data element on PFAS be included in the list of required contaminant sampling data already provided in the CCR. With respect to the commenter's assertion that "the CCR may be a costly system to inform consumers nationwide", by requiring that PFAS information be provided through the CCR, this new health risk information will be provided in a least cost manner (when compared to alternative PFAS-specific communication strategies that might be employed apart from the CCR) which still reaches the at-risk community in a format which has been in place since 1998 and is therefore likely known as a source of water quality information to most system customers. The EPA has evaluated the costs to comply with the CCR Rule under a separate rulemaking action and evaluating those costs again under this regulatory action would result in a double counting of burden to systems and consumers.

The EPA has previously submitted the extension of the Information Collection Request (ICR) for the Public Water System Supervision Program (EPA ICR Number 0270.48, OMB Control Number 2040-0090) to the Office of Management and Budget (OMB) in March 2023. The ICR includes the estimated annual burden and costs associated with CCRs as approximately $37 million for public water systems (PWSs) and $2 million for states. For the proposed revisions to the CCR, published on April 5, 2023, the agency found that the action was considered not significant under Section 3(f)(1) of Executive Order 12866. The EPA estimated the total average annual cost of the revised CCR rule would be $22.2 million. For more information on the estimated costs of the revised CCR rule, including the Economic Impact Analysis, visit regulations.gov, docket ID EPA-HQ-OW-2022-0260.

Additionally, with respect to the commenter's assertion that public notification "should be more private and only affected areas and individuals should be informed of any public health risk", under 40 CFR 141 Subpart Q, water systems are required to provide public notice in a form and manner reasonably calculated to reach all persons served, using methods described in 40 CFR 141 subpart Q, depending on the applicable tier and potential adverse health effects for the violation or situation. This action does not change the PN implementation requirements previously codified that would be applicable to the MCL violations that would require public notice. The form, manner, and timing of the notices was addressed in the 2000 revisions to the PN Rule and the costs of public notification are described in the analysis of the rule; for additional information, see: https://www.epa.gov/dwreginfo/public-notification-rule.

Citizens Energy Group (Doc. #1838, SBC-044870)

Examples of such messages and tools could include 'plain language' explanations about the Hazard Index and the way that EPA has framed the calculations based on risk; additional clarification for water systems on reporting obligations in the Consumer Confidence Report, and tips on what homeowners can do if they are concerned with PFAS in the environment.

EPA Response: With respect to the commenter's request to include "'plain language' explanations about the Hazard Index," please see section 9.1 of the EPA response in this *Response to Comments* document. CWSs may include additional information as they deem necessary for public education consistent with, and not detracting from, the purpose of the CCRs, as indicated in § 141.153(h)(5). CCRs must also include information on the availability of a source water assessment, as described in § 141.153(b)(2). The EPA notes that while the CCR Rule does not require that CCRs include guidance for homeowners, PN issued in the case of an MCL violation does include information on actions consumers can take, including possibly using a filter or switching to an alternate source of water, as appropriate.

Midwest Environmental Advocates +more (Doc. #1846, SBC-045839)

The examples above emphasize the need for EPA to issue a guidance document for water systems to use when issuing right-to-know reports. To ensure consumers receive adequate information about PFAS in their drinking water, the guidance must provide necessary context to understand PFAS detections. In the guidance, EPA should indicate the content required to be in the notification, including, but not limited to:

• A plain language statement about what PFAS compounds are and what they have been used for;

• A description of sources of PFAS in the drinking water, including specific sources for that particular water system, if known;

• A description of the various health impacts of PFAS;

• A guide on how to reduce exposure to PFAS, including from other media;

• A clear statement of what levels of PFAS were detected for purposes of MCL compliance, with all monitoring results available in a transparent manner on the water system's website;

• To the extent the water system is undertaking efforts to reduce PFAS in its water, i.e., installation of new treatment technologies, a description of the status of those efforts.

Additionally, the guidance should urge water systems to issue notifications in a manner that should reasonably reach all people served by the water utility, including consumers who do not deal directly with water bills like renters who tend to be lower income. EPA should ensure that all receive the right-to-know benefits of the SDWA.

EPA Response: Please see section 9.1 of the EPA response in this *Response to Comments* document for responses related to CCR requirements and section 9.2 of the EPA response in this *Response to Comments* document for responses related to PN requirements. With respect to the commenter's request for the EPA to issue a guidance document for water systems to use when issuing right-to-know reports, the EPA acknowledges the suggestions provided by this and other commenters regarding communication needs targeted towards the public, water utilities, primacy agencies, and the EPA itself. The agency intends to consider producing implementation materials, including some recommended materials provided by commenters, during the implementation stage of this final PFAS NPDWR. For additional discussion regarding guidance and communications materials for this action, please see section 1.2 of the EPA response in this *Response to Comments* document.

Additionally, the EPA notes that some of the information that the commenter suggests including in a guidance document is already included in right-to-know reports. For instance, consistent with existing rule requirements, public notices must include: 1) a description of the violation or situation, including (as applicable) the contaminant level(s); 2) when the violation or situation occurred; 3) any potential adverse health effects; 4) the population at risk; 5) whether alternative water supplies should be used; 6) actions consumers should take, including when they should seek medical help; 7) what the system is doing to correct the violation or situation; 8) when the water system expects to return to compliance or resolve the situation; 9) the contact information for the water system; and 10) a statement to encourage the notice recipient to distribute the public notice to other persons served. Systems must provide the notices in a form and manner reasonably calculated to reach all persons served, as described in the PN Rule. Additionally, the agency notes that CWSs have the discretion to include additional information in CCRs as they deem necessary for public education, as long as it is consistent with, and not detracting from, the purpose of the report, consistent with existing CCR Rule provisions 40 CFR 141.153(h)(5).

The EPA agrees that it is important for all consumers to "receive the right-to-know benefits of the SDWA" as asserted by the commenter. However, with respect to the commenter's suggestion that the agency "should urge water systems to issue notifications in a manner that should reasonably reach all people served by the water utility, including consumers who do not deal directly with water bills like renters who tend to be lower income," the EPA notes that this comment is outside the scope of this rulemaking effort.

Midwest Environmental Advocates +more (Doc. #1846, SBC-045837)

Effective communication about PFAS detections is critical as PFAS pollution is novel to many Americans. And as outlined in a comment letter related to EPA's revisions to the Consumer Confidence Report Rule, [FN38: National Primary Drinking Water Regulations: Consumer Confidence Report Rule Revisions, 88 Fed. Reg. 20092 (proposed April 5, 2023).] right-to-know reports have historically failed to serve their intended purpose because "far too many water systems converted these reports into public relations documents with confusing, unintelligible, and sometimes false and misleading information often designed to placate consumers into

believing their water was fine regardless of the results of contaminant monitoring." [FN39: Comments on EPA' Proposed "National Primary Drinking Water Regulations: Consumer Confidence Report Rule Revisions" [EPA-HQ-OW-2022-0260] submitted by Natural Resources Defense Council et al. 3, https://www.regulations.gov/comment/EPA-HQ-OW-2022-0260-0113 (the comment letter supports this claim through examples on how right-to-know reports have been used to obfuscate water quality problems rather than convey accurate information about pollution and its associated risks).]

EPA Response: See section 9.1 of the EPA response in this *Response to Comments* document for discussion about CCR reporting requirements specific to this rule. The EPA agrees with the commenters' assertion that "effective communication about PFAS detections is critical". CCRs and PN are important for informing customers of drinking water issues and the CCR and PN requirements set forth as part of this final rule will work toward ensuring effective communication about PFAS detections to water system consumers. To this end, the EPA also notes that the agency intends to produce risk communication materials that can be used by utilities and others as they deem appropriate to communicate about PFAS in drinking water. As the EPA develops implementation materials following final rule promulgation, the agency will consider additional resources to support states and water systems in communicating with and notifying their customers.

The EPA disagrees with the commenters' assertion that right-to-know reports "have historically failed to serve their intended purpose". For this regulation, the EPA believes that the agency has developed appropriate rule-specific CCR reporting requirements that meet all statutory obligations and provide necessary information for consumers.

The EPA notes that revisions to the CCR Rule and responses to public comments received on that proposed rule will be addressed as part of a separate action, see www.regulations.gov, Docket ID: EPA-HQ-OW-2022-0260, and are outside the scope of this action.

City of Tulsa Water and Sewer Department (CoT WSD) (Doc. #1785, SBC-043784)

6. 88 FR 18684. Reporting detected PFAS in Consumer Confidence Report.

CoT WSD has concerns about what is defined as a "reportable detection."

• Proposed language at §141.151(d), at end of the paragraph, defines "detected" (for purposes of CCR reporting) as at or above the levels prescribed in §141.902(a)(9).

• Proposed language at §141.902(a)(9) defines reportable detection as "at or above 1/3 of levels in proposed section §141.903(f)(i)(iii)." Note: Actual proposed language contains a typographical error, which refers to a non-existent section. It is assumed that §141.903(f)(i)(iii) is the correct citation.

• Proposed language at §141.903(f)(i)(iii), Table 1, lists PQLs of all 6 individual PFAS

Using all the citations and references above, it is determined that CCR reportable detections are analytical measurements below PQLs, specifically 1/3 of each PFAS's PQL. PQLs are the lowest level of reliable, quantifiable measurement of an analytical method. EPA admits multiple times within the preamble that these measurements are less precise and less accurate. It goes against good laboratory practice to report such measurement as "detectable." EPA should propose another definition for "reportable detection."

EPA Response: Please see section 9.1 of the EPA response in this *Response to Comments* document for discussion of reporting results below PQL values in the CCR. As described in section 9.1 of the EPA response in this *Response to Comments* document, the EPA notes that as part of this regulatory action, the EPA has modified the trigger level value for quarterly monitoring from one-third of the MCL to one-half of the MCL in response to concerns that laboratories would not have the capacity to consistently measure as low as the threshold of one-third of the MCL (see section VIII.A.2 of the preamble for this action for further discussion about changes to the trigger level from the proposed to final regulation).

Additionally, the EPA notes that the citation listed in § 141.902(a)(9) of the rule proposal was incorrect and was intended to reference § 141.903(f)(1)(iii); please see the EPA response to Doc. #1785, SBC-043790 in section 16.5 in this *Response to Comments* document.

9.2 Public Notification Requirements and Tiering

Summary of Major Public Comments and EPA Responses

Many commenters support the Tier 2 PN requirement for MCL violations, which requires public notice as soon as practical but no later than 30 days after the system learns of the violation. Commenters assert that Tier 2 notification is appropriate and consistent with other MCLs for chemicals with chronic effects. Conversely, many commenters suggest that the PN tiering be raised from Tier 2 to Tier 1 or that the EPA consider other PN approaches given concerns about health impacts resulting from exposure on timescales shorter than chronic exposure. Commenters assert that raising PN for MCL violations from Tier 2 to Tier 1 would ensure that consumers are informed of potential harm associated with elevated PFAS levels in a timelier manner so they can make informed risk management decisions. Additionally, a few commenters request that the EPA re-categorize repeat MCL violations to Tier 3 due to the expected length of time needed for a PWS to design and construct treatment. Commenters argue that quarterly PN would not offer added value and could possibly result in confusion for consumers.

The EPA agrees with commenters that Tier 2 PN is appropriate for MCL violations based on analysis of a wide range of scientific studies that shows that long-term exposure may have adverse health effects. The EPA disagrees with commenters who recommend issuing Tier 1 notification for MCL violations. Tier 1 notices must "be distributed as soon as practicable, but no later than 24 hours, after the public water system learns of the violation" pursuant to section 1414(c)(2)(C)(i) of SDWA. The PN Rule preamble characterizes contaminants with violations routinely requiring a Tier 1 notice as those with "a significant potential for serious adverse health

effects from short-term exposure", stating that other violations do not require Tier 1 notice because elevated levels of these contaminants are not "strongly or consistently linked to the occurrence of the possible acute health effects" (USEPA, 2000). The EPA has not characterized health risks resulting from acute exposure (i.e., < or = 24 hours) to PFAS and the EPA believes that issuing Tier 2 PN for MCL violations constitutes a health protective approach given that the MCLG values are based on health effects that occur after chronic exposure to PFAS (i.e., cancer). Based on the available health effects information, the EPA has characterized developmental effects, including immune impacts, associated with developmental PFAS exposure (i.e., during pregnancy and/or childhood) in addition to health effects that occur after chronic exposure (i.e., exposure over many years). The agency considers it reasonable to notify consumers within 30 days of a PWS learning of an MCL violation because it generally provides protection of the adverse health effects that may occur from exposure to PFAS during sensitive lifestages such as gestation. The EPA typically reserves Tier 1 notifications for acutely toxic contaminants. For example, nitrate, nitrite, or total nitrate and nitrite require Tier 1 notice because exceedances can result in immediate life-threatening health impacts for infants (i.e., methemoglobinemia). Based on the currently available information, the developmental and chronic effects associated with exposure to these PFAS are not known to represent immediate acute health effects. For more information on the EPA's characterization of health effects resulting from PFAS exposure, please see (USEPA, 2024a; USEPA, 2024b). This approach is also consistent with the PN requirements for other synthetic organic contaminants regulated under SDWA. The EPA acknowledges that there may be instances in which it is appropriate to elevate the tiering of PN on a case-by-case basis. Under the existing PN Rule in 40 CFR 141.202(a), a violation that routinely requires a Tier 2 notice but poses elevated risk from short-term exposure may be elevated to Tier 1 at the discretion of the primacy agency. Additionally, the EPA will develop appropriate implementation guidance to assist in the understanding of PN requirements among other final rule requirements.

The EPA disagrees with commenters that recommended reclassifying ongoing MCL violations to Tier 3 for repeat notices. The EPA believes there is sufficient flexibility in the existing PN Rule 40 CFR 141.203(b)(2) that allows primacy agencies to allow a less frequent repeat notice on a case-by-case basis for unresolved violations, but no less than once per year, and the determination must be in writing. The EPA believes repeat notices are valuable to consumers that may not receive the initial notice and allow water systems to provide any updates to consumers, such as actions being taken to resolve the situation and estimated timelines. Additionally, the EPA notes that the agency has not modified the PN requirement for repeat notice and this requirement for PFAS MCL violations is no different than the requirement for any other contaminant regulated under SDWA and deemed to require Tier 2 notification; repeat notice is required until the violation or situation is resolved. Repeat notices are required every 3 months, unless the primacy agency determines that appropriate circumstances warrant a different repeat notice frequency. In no circumstance may the repeat notice be given less frequently than once per year [40 CFR 141.203(b)(2)]. Likewise, the EPA has not modified the form and manner of Tier 2 PN which includes "any other method reasonably calculated to reach persons regularly

served by the system" [40 CFR 141.203(c)(ii)]. The intent of SDWA's right-to-know rules, including the PN Rule, is to provide consumers with information on their drinking water, including information about violations, to allow them to make informed decisions to protect their health. Providing repeat notices ensures that customers stay informed about the quality of their drinking water in the event that they do not receive the initial notice. The EPA has also found public notice to be a motivational factor for water systems to address the issue.

A few commenters recommended that the EPA update the proposed PN health effects language. Commenters stated that the proposed health effects language was confusing and needed to be clarified to better communicate to the public about the safety of their water. Specifically, commenters cited concerns that the language "loses the focus on sensitive subpopulations" and suggested that the agency's inclusion of both "acute and chronic, or at least, subchronic, effects in the PN language" may be confusing. Additionally, a few commenters noted what they believe to be inconsistencies in how health effects language is presented in the CCR and in the EPA's previously issued PFAS health advisories. These commenters point out that the language found in the right-to-know notices discusses the health effects of PFAS levels above the MCL while the health advisories language addresses the effects of lower PFAS levels. As such, commenters believe the different focus may cause confusion for the public.

The EPA agrees with commenters that additional clarification of the health effects associated with PFAS exposure will more effectively communicate risk to consumers when they receive PN from their water system. The EPA has considered this input and has revised health effects language for the final rule to further clarify the health effects associated with PFAS exposure. These changes are responsive to the commenters' concerns regarding clarity because the EPA has modified the health effects language to more explicitly differentiate between health effects anticipated to occur due to exposure over many years and those anticipated to occur due to developmental exposures, which will allow consumers to make more informed decisions to protect their health. These edits also address commenters' concerns about losing focus on sensitive subpopulations, as the health effects language is now more explicit about risks associated with PFAS exposure during pregnancy and/or childhood. The updated health effects language for the rule is summarized in section IX.A.3 of the preamble for this action.

The EPA's previous issuance of the PFAS health advisories (HAs) is outside the scope of this action. Drinking water health advisories are distinct from MCLs and MCLGs as each serves a different purpose. HAs provide technical information on chemical and microbial contaminants that can cause human health effects and are known or anticipated to occur in drinking water. HAs primarily serve to provide information to drinking water systems and officials responsible for protecting public health when emergency spills or other contamination events occur. The HAs help Tribes, states, and local governments inform the public and determine whether local actions are needed to address public health impacts in affected communities. The EPA's HA documents describe information about health effects, analytical methodologies, and treatment technologies. HAs are not legally enforceable federal standards and are subject to change as new information becomes available.

The final rule's regulatory language sets forth the required health effects language that must be included as part of PN or within the CCR when there is an MCL violation under this regulatory action and as such characterizes health effects anticipated when levels of PFAS are in excess of the MCL values. Because the PN and CCR requirements for this rule are intended to specify to customers concisely and in non-technical terms what adverse health effects may occur as a result of an MCL violation, PN and CCR health effects language is often more succinct than language associated with the EPA's health advisories, which includes more technical detail intended for officials responsible for protecting public health and utilities. In this action, the EPA is limiting reporting of health effects language as part of PN or in the CCR to when there is an MCL violation. While SDWA authorizes the EPA to require a health effects statement in the CCR for three contaminants in the absence of a violation or an exceedance of the lead action level, the EPA has already used this authority for lead, arsenic, and nitrates. See SDWA 1414(c)(4)(B) and 40 CFR 141.154(b), (c), and (d).

The final rule requires the PN of violations of all MCLs promulgated under this final rule to be designated as Tier 2 and as such, PWSs would be required to comply with 40 CFR 141.203. The final rule also designates monitoring and testing procedure violations as Tier 3, requiring systems to provide notice no later than one year after the system learns of the violation. Systems are also required to repeat the notice annually for as long as the violation persists. As systems must comply with initial monitoring requirements within three years of rule promulgation, systems will be required to provide Tier 3 notification for monitoring and testing procedure violations starting in 2027. As the MCL compliance date is set at five years following rule promulgation, systems will be required to provide Tier 2 notification for MCL violations starting in 2029. However, the EPA notes that primacy agencies have the authority in the existing PN Rule (Table 1 to § 141.201) to require systems to provide notices for "situations determined by the primacy agency to require public notice" which would allow them to require public notice to customers prior to the MCL compliance date. As discussed above, the EPA has also made edits to clarify the mandatory health effects language required in the PN of an MCL violation; the updated health effects language can be found in Appendix B to Subpart Q and is summarized in section IX.A.3 of the preamble for this action.

Individual Public Comments

Missouri Department of Natural Resources (Doc. #1563, SBC-042536)

Section X—Safe Drinking Water Right to Know

EPA requests comment on its proposal to designate violations of the proposed MCLs as Tier 2.

The Department agrees with EPA's approach to treat MCLs as Tier 2 and as lifetime health advisory contaminants. If an analyte is shown to have life threatening, acutely toxic health effects like methemoglobinemia with nitrate, the Department would support a Tier 1 designation. At this time, however, PFAS research has not conclusively shown a life threatening acute toxicity with the proposed analytes for regulation.

EPA Response: Please see section 9.2 of the EPA response in this *Response to Comments* document.

Maine Water Utilities Association (MWUA) (Doc. #1567, SBC-042740)

Communication:

EPA proposes that a PWS must repeat public outreach to its consumers every 3 months if a violation or situation persists unless the primacy agency determines otherwise, but that at a minimum, systems must give repeat notice at least once per year. Because it will take time for a PWS to design and construct treatment, we do not find quarterly Public Notice to have added value (in fact, it would most likely cause confusion for consumers) and suggest instead that a Tier III notice is the more appropriate level if a violation persists.

EPA Response: Please see section 9.2 of the EPA response in this *Response to Comments* document. The EPA notes that the purpose of having repeat PN notices is no less relevant during the time a PWS designs and constructs treatment.

Blue Ridge Environmental Defense League (BREDL) (Doc. #1568, SBC-042996)

Docket ID No. EPA-HQ-OW-2022-0114

U.S. Environmental Protection Agency

EPA Docket Center

Office of Ground Water and Drinking Water Docket

Mail Code 2822IT

1200 Pennsylvania Avenue, NW

Washington, DC 20460

Comments on EPA Docket ID No. EPA-HQ-OW-2022-0114 PFAS National Primary Drinking Water Regulation Rulemaking

To Whom It May Concern:

On behalf of Blue Ridge Environmental Defense League, I am submitting comments on the PFAS National Primary Drinking Water Regulation Rulemaking.

Public Notification

As stated in the proposed rule posting in the Federal Register, "as part of SDWA [Safe Drinking Water Act], the Public Notification (PN) rule ensures that consumers will know if there is a problem with their drinking water. Notices alert consumers if there is risk to public health. They also notify customers: If the water does not meet drinking water standards; if the water system fails to test its water; if the system has been granted a variance (use of less costly technology); or if the system has been granted an exemption (more time to comply with a new regulation)" [FN1: Federal Register/Vol. 88, No. 60/ Wednesday, March 29, 2023/Proposed Rules, p. 18684].

Under the draft proposal, EPA is proposing that violations of the three Maximum Contaminant Levels in the proposal would be designated as Tier 2 and as such, Public Water Systems would be required to comply with 40 CFR 141.203. Per 40 CFR 141.203(b)(1), notification of an MCL violation should be provided as soon as practicable but no later than 30 days after the system learns of the violation [FN2: Ibid.].

BREDL submitted comments on June 10, 2019 on Docket ID No. EPA-HQ-OLEM-2019-0229 regarding Interim Recommendations for Addressing Groundwater Contaminated with PFOA and PFOS. In our comments, we concurred with scientists and experts who recommend using a "class" approach for all PFAS. According to her testimony before a congressional subcommittee, East Carolina University Associate Professor Jamie DeWitt, PhD, DABT said, "It is not feasible from a time or resource perspective to 'TEST' our way out of this crisis. Employing a 'CLASS' approach for ALL PFAS will be protective for vulnerable populations and the general public." [FN3: Jamie DeWitt, PhD, DABT, Associate Professor, Department of Pharmacology & Toxicology, Brody School of Medicine at East Carolina University; Testimony; May 1-exposure]

BREDL concurs that public notification, in addition to the Consumer Confidence Report requirement, is a necessary requirement as part of this rulemaking. However, we strongly recommend that the Tier 2 public notification be expanded to include more than just the six listed PFAS in this draft rulemaking. Public notification should include the discovery of any PFAS contaminant in drinking water. Public notification should consider the entire class of PFAS.

EPA Response: Please see section 9.2 of the EPA response in this *Response to Comments* document for discussion of the tiering of public notification for the final rule. The EPA notes that the PN and CCR requirements established in this rulemaking are only for the six PFAS contaminants regulated under the final rule. However, PN for certain additional PFAS contaminants will be required under the existing PN Rule. This is because the fifth UCMR (UCMR 5) currently requires monitoring for 29 PFAS, and under existing PN Rule requirements, systems must notify consumers on the availability of UCMR results. Similarly, CWSs are also

required to report results in their CCR for regulated contaminants that are detected and the reported levels of unregulated contaminants for which monitoring is required by the EPA (i.e., through the UCMR) or the state. If a system performs additional (voluntary) monitoring, the EPA encourages it to include the information in their reports [§ 141.153(e)(3)]. For violations or situations not specifically identified in the PN Rule as requiring PN, primacy agencies may use their existing authority to require a system to provide public notice for other violations or situations with significant potential to have adverse effects on human health, as determined by the primacy agency either in its regulations or on a case-by-case basis [Appendix A to 40 CFR subpart Q].

Blue Ridge Environmental Defense League (BREDL) (Doc. #1568, SBC-042998)

In summary

Dumbfounded by the lack of public notification related to the Spring Hollow Reservoir contamination, BREDL worked with local legislators in an attempt to get some basic public notification passed by the Virginia General Assembly. While the bill passed unanimously on the Senate side, it was tabled in a House of Delegate's subcommittee.

It's clear that local water systems and politicians cannot be relied upon to notify the public about contaminants in the public drinking water. EPA must include public notification as part of this rulemaking. This public notification has to include letters sent directly to consumers. Posting notices only on websites is not sufficient.

Thank You for this opportunity to comment.

Respectfully submitted,

Mark E. Barker

Executive Assistant

Blue Ridge Environmental Defense League

Fair Use Notice: This appendix contains copyrighted material the use of which has not been specifically authorized by the copyright owner. We are making such material available in our efforts to advance understanding of environmental issues, etc. We believe this constitutes a 'fair use' of any such copyrighted material as provided for in section 107 of the US Copyright Law. In accordance with Title 17 U.S.C. Section 107, the material in this appendix is distributed without profit to those who have expressed a prior interest in receiving the included information for research and educational purposes.

Appendix 2

[Figure 2: See docket ID: EPA-HQ-OW-2022-0114-1568]

Appendix 3

BREDL email correspondence with EPA requesting a list of waterworks testing for UCMR #5.

[Figure 3: See docket ID: EPA-HQ-OW-2022-0114-1568]

EPA Response: Please see section 9.2 of the EPA response in this *Response to Comments* document and section IX.B of the preamble for this action for information on the PN requirements for the final PFAS NPDWR. The form and manner of public notice for required public notices under the PN Rule (40 CFR Part 141, Subpart Q) was established in the PN rulemaking and is beyond the scope of this rulemaking for PFAS. For more information on requirements under the PN Rule, including delivery requirements, please see Subpart Q of CFR 141.

New Hampshire Water Works Association, Inc. (NHWWA) (Doc. #1576, SBC-042456)

Hundreds of systems are likely to be in a continuous public notification cycle for years. This will initially cause public alarm, followed by desensitization and resistance to increasing water rates for necessary funding, overall eroding public trust in public water supplies.

EPA Response: Please see section 9.2 of the EPA response in this *Response to Comments* document for discussion of PN requirements for repeat notice. Additionally, the EPA notes that the PN Rule requirements related to the frequency of the notice, which may result in repeat notices for PFAS or any other contaminant covered by the PN Rule requirements, are beyond the scope of this rulemaking for PFAS.

COMM Water Department (Doc. #1577, SBC-042443)

Communicating to our customers about PFAS has been challenging. A Tier II notice might be appropriate for the initial violation of the MCL, but if the violation persists, a Tier III notice is the appropriate follow up communication until treatment is installed.

EPA Response: Please see section 9.2 of the EPA response in this *Response to Comments* document.

Michigan Department of Environment, Great Lakes, and Energy (EGLE) Drinking Water and Environmental Health Division (DWEHD) (Doc. #1597, SBC-042987)

E. Safe Drinking Water Right to Know

Having reviewed Section X of the proposed NPDWR, EGLE DWEHD agrees with EPA's proposed public notification requirements, as these are largely consistent with those established for other NPDWR and for PFAS MCLs in Michigan.

EPA Response: The EPA acknowledges the commenter's support of the rule's PN requirements. Please see section 9.2 of the EPA response in this *Response to Comments* document for further discussion.

Massachusetts Water Works Association (MWWA) (Doc. #1601, SBC-042891)

Communication:

In Massachusetts, MassDEP has required consumer notification in communities where the PFAS6 levels are above 20 ppt. The first verified result over 20 ppt requires a Public Education notice and exceedance of the MMCL requires a Tier II Public Notice. We believe the Tier II notification is the appropriate initial notice level. The added layer of Public Education in Massachusetts is problematic because a customer can receive a notice one month and then two months later, they receive a very similar notice in the formal Tier II Public Notice. EPA proposes that the system must repeat notice every three months if the violation or situation persists unless the primacy agency determines otherwise, but that at a minimum, systems must give repeat notice at least once per year. Because it will take time for a PWS to design and construct treatment, we do not find quarterly Public Notice to have added value and suggest instead that a Tier III notice is the more appropriate level if the violation persists.

EPA Response: Please see section 9.2 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1567, SBC-042740 and Doc. #1576, SBC-042456 in section 9.2 in this *Response to Comments* document.

American Water Works Company Inc. (Doc. #1608, SBC-044015)

Right-to-Know Provisions

American Water supports the proposal to designate violations of the proposed PFAS MCLs as a Tier 2 violation. We also support the proposed Consumer Confidence Report requirements.

[Figure 1: See Docket ID EPA-HQ-OW-2022-0114-1608]

[Figure 2: See Docket ID EPA-HQ-OW-2022-0114-1608]

EPA Response: Please see sections 9.1 and 9.2 of the EPA response in this *Response to Comments* document. The EPA acknowledges the commenter's support of the PN and CCR requirements for this action.

Marlene Ladderbush (Doc. #1612, SBC-042919)

Communicating to our customers about PFAS has been challenging. The public is not versed in the scientific levels of quantification of these chemicals. A Tier II notice might be appropriate for the initial violation of the MCL, but if the violation persists, a Tier III notice is the appropriate follow up communication until treatment is installed. EPA needs to ensure that any required educational statements have clear and appropriate messaging. EPA needs to revisit its proposed required Standard Health Language for Public Notice as it is not well written, nor easily understood by the lay person.

EPA Response: Please see section 9.2 of the EPA response in this *Response to Comments* document.

Town of Lincoln Water Department (Doc. #1613, SBC-043031)

Communicating to our customers about PFAS is a challenge. A Tier Il notice might be appropriate for the initial violation of the MCL, but if the violation persists, a Tier Ill notice is the appropriate follow up communication until treatment is installed. EPA needs to ensure that any required educational statements have clear and appropriate messaging. EPA needs to revisit its proposed required Standard Health Language for Public Notice as it is not well written, nor easily understood by the lay person. EPA also needs to inform consumers about the other routes of exposure; it does a disservice to the public if the EPA and the states focus on drinking water to the exclusion of other, perhaps more significant PFAS contributions to one's body burden (e.g., consumer products, food). EPA must consult with risk communication professionals to develop the messaging, as the materials EPA has made available thus far are not particularly helpful.

EPA Response: Please see section 9.2 of the EPA response in this *Response to Comments* document. The EPA notes that the agency intends to produce risk communication materials that can be used by utilities and others as they deem appropriate to communicate about PFAS in drinking water. As the EPA develops implementation materials following final rule promulgation, the agency will consider additional resources to support states and water systems in communicating with and notifying their customers. For discussion of risk communication materials that the agency intends to develop related to this action, please see section 1.2 of the EPA response in this *Response to Comments* document. In this action, the EPA is addressing

PFAS exposure via drinking water, however through other efforts, the EPA is addressing other PFAS exposure pathways (see https://www.epa.gov/pfas/pfas-strategic-roadmap-epas-commitments-action-2021-2024). Including information on additional routes of exposure aside from drinking water is outside the scope of the information traditionally included in CCRs and PN as these topics do not specifically relate to drinking water.

Oklahoma Department of Environmental Quality (DEQ) (Doc. #1616, SBC-043040)

Public Notice

DEQ recommends EPA clarify the health effects language proposed to be included in the public notification requirements.

The proposed EPA health effects language for public notification is not consistent with the language EPA used for the previous health advisories. In addition, the proposed public notice language discusses PFAS levels in excess of the MCL as being of concern, while the health advisory language discusses health impacts at much lower levels. This will create additional confusion with the public regarding the safety of their water.

EPA Response: Please see section 9.2 of the EPA response in this *Response to Comments* document.

Colorado Water Utility Council (CWUC) (Doc. #1622, SBC-044043)

24. EPA requests comment on its proposal to designate violations of the proposed MCLs as Tier 2.

a. CWUC agrees that Tier 2 is the appropriate and preferred PN level. This should be based on the RAA exceedance, and not an individual result exceedance.

EPA Response: Please see section 9.2 of the EPA response in this *Response to Comments* document. In the final rule, compliance with the MCLs, and thus the issuance of PN under the rule, will be determined based on a running annual average (RAA) of PFAS monitoring results. For more information on monitoring and compliance requirements for the final rule, see sections 8.1 and 8.2 of the EPA response in this *Response to Comments* document.

Aqua America, an Essential Utilities Company (Doc. #1623, SBC-043091)

Public Notifications

Public notifications serve a key role in protecting public trust in drinking water. Aqua supports the Proposal requiring that water systems with PFAS levels exceeding the MCLs provide a Tier 2 notification to the public. This would require that a water system provide a notification as soon as practicable but no later than 30 days after the system learns of the violation. The Proposal would also require that water systems provide a Tier 3 notice when a monitoring and testing

procedure violation has occurred. Finally, as part of the Consumer Confidence Report, water systems will be required to provide information regarding the detection of any regulated PFAS compounds.

EPA Response: Please see sections 9.1 and 9.2 of the EPA response in this *Response to Comments* document. The EPA acknowledges the commenter's support of the PN requirements for this action.

Pennsylvania Department of Environmental Protection (Doc. #1626, SBC-044873)

May 30, 2023

U.S. Environmental Protection Agency EPA Docket Center

Office of Ground Water and Drinking Water Docket Mail Code: 2822IT

1200 Pennsylvania Avenue NW Washington, DC 20460

Attention: Docket ID EPA-HQ-OW-2022-0114

Dear Administrator Regan:

Thank you for the opportunity to comment on the U.S. Environmental Protection Agency's (EPA) proposed PFAS National Primary Drinking Water Regulation Rulemaking, published on Wednesday, March 29, 2023 at 88 FR 18638. The Pennsylvania Department of Environmental Protection (DEP) fully supports EPA' s efforts to protect public health by setting national drinking water standards for per- and polyfluoroalkyl substances (PFAS). Pennsylvania is one of a handful of states that moved quickly to address PFAS in drinking water and welcomes federal action to improve public health protection and ensure more consistent regulation of PFAS across the country.

DEP supports and agrees with the intent of EPA's proposed rulemaking in the following key areas:

• DEP agrees with EPA's decision to consider PFAS chronic contaminants and to require Tier 2 public notification (PN) for MCL exceedances.

EPA Response: The EPA acknowledges the commenter's support of the EPA' s efforts to protect public health by setting national drinking water standards for PFAS. The EPA also acknowledges the commenter's support for considering PFAS chronic contaminants and to require Tier 2 public notification for MCL violations. Please see section 9.2 of the EPA response in this *Response to Comments* document for further discussion related to PN requirements.

Association of State Drinking Water Administrators (ASDWA) (Doc. #1628, SBC-044083)

Public Notice

ASDWA recommends EPA clarify the health effects language proposed to be included in the public notification requirements.

ASDWA's members support EPA's decision to utilize Tier 2 public notification (PN) for the PFAS NPDWR, as this approach is consistent with other chemical MCLs with chronic effects. However, the proposed health effects language to be included is confusing and needs additional clarification. As is currently written, EPA seems to have included both acute and chronic, or at least sub-chronic, effects in the PN language. Additionally, this PN language is inconsistent with the language the Agency used for the previous health advisories. The PN language discusses PFAS levels above the MCL being of concern, while the health advisory language discusses health impacts at much lower levels. This will create additional confusion with the public regarding the safety of their water. Finally, the language within the rule also loses the focus on sensitive sub-populations and only refers to "children." ASDWA recommends that the Agency change this to include "pregnant individuals and infants."

EPA Response: Please see section 9.2 of the EPA response in this *Response to Comments* document for discussion of public notification tiering and updates to the mandatory health effects language for the final rule. The EPA acknowledges the commenter's support for Tier 2 public notification. The updated health effects language, which can be found in Appendix A to Subpart O and Appendix B to Subpart Q and is summarized in section IX.A.3 of the preamble for this action, includes language that focuses on potential developmental impacts during pregnancy and/or childhood.

Village of Woodbury (Doc. #1629, SBC-042949)

3. The proposed NPDWR public would be Tier 2 violations, requiring public water suppliers notify public within 30-days of an MCL exceedance. Additionally, this information would be reported in the Annual Consumer Confidence Reports. We take no exception to this and believe transparency to the public is best policy.

EPA Response: Please see sections 9.1 and 9.2 of the EPA response in this *Response to Comments* document.

Town of Tewksbury, Massachusetts (Doc. #1637, SBC-043249)

Communicating to our customers about PFAS has been challenging. The standard language that has been proposed and used by EPA and State regulators is very alarming to consumers. A Tier II notice might be appropriate for the initial violation of the MCL, but if the violation persists, a Tier III notice is the appropriate follow up communication until treatment is installed. EPA needs to ensure that any required educational statements have clear and appropriate messaging. EPA needs to revisit its proposed required Standard Health Language for Public Notice as it is not well written, nor easily understood by the lay person. EPA also needs to inform consumers about the other routes of exposure; it does a disservice to the public if the EPA and the states focus on drinking water to the exclusion of other, perhaps more significant PFAS contributions to one's

body burden (e.g., consumer products, food). EPA must consult with risk communication professionals to develop the messaging, as the materials EPA has made available thus far are not particularly helpful.

EPA Response: Please see section 9.2 of the EPA response in this *Response to Comments* document. The EPA notes that the agency intends to produce risk communication materials that can be used by utilities and others as they deem appropriate to communicate about PFAS in drinking water. As the EPA develops implementation materials following final rule promulgation, the agency will consider additional resources to support states and water systems in communicating with and notifying their customers. For discussion of risk communication materials that the agency intends to develop related to this action, please see section 1.2 of the EPA response in this *Response to Comments* document. In this action, the EPA is only addressing PFAS contamination via drinking water, however through other efforts, the EPA is addressing other PFAS exposure pathways (see https://www.epa.gov/pfas/pfas-strategic-roadmap-epas-commitments-action-2021-2024). Including information additional routes of exposure aside from drinking water is outside the scope of the information traditionally included in CCRs and PN as these topics do not specifically relate to drinking water.

Aidan Cecchetti (Doc. #1640, SBC-044375)

• EPA requests comment on its proposal to designate violations of the proposed MCLs as Tier 2 (pg. 18684 Federal Register Volume 88, Number 60).

o The commenters agree with EPA's proposal to designate violations of the proposed MCLs as Tier 2. The commenters are not aware of any acute health impacts that are of great enough concern to elevate violations of the proposed MCLs to Tier 1. However, the health impacts and public concern associated with potential violations of the proposed PFAS NPDWR are too significant for violations to be designated as Tier 3.

EPA Response: Please see section 9.2 of the EPA response in this *Response to Comments* document.

National Rural Water Association (NRWA) (Doc. #1641, SBC-043277)

• EPA requests comment on its proposal to designate violations of the proposed MCLs as Tier 2.

Response: Tier 2 Public Notice is appropriate per the Public Notification Rule. An MCL Exceedance for these constituents should not require a Tier 1 Public Notice.

EPA Response: Please see section 9.2 of the EPA response in this *Response to Comments* document.

North Carolina Division of Water Resources (NCDEQ) (Doc. #1652, SBC-044177)

3. NCDEQ recommends EPA clarify the health effects language proposed to be included in the public notification requirements.

NCDEQ supports EPA's decision to utilize Tier 2 public notification (PN) for the PFAS NPDWR, as this approach is consistent with other chemical MCLs with chronic effects. However, the proposed health effects language to be included is confusing and needs additional clarification. As it is currently written, EPA seems to have included both acute and chronic, or at least subchronic, effects in the PN language. Additionally, this PN language is inconsistent with the language the Agency used for the previous health advisories. The PN language discusses PFAS levels above the MCL being of concern, while the health advisory language discusses health impacts at much lower levels. This will create additional confusion with the public regarding the safety of their water. Finally, the language within the rule also loses the focus on sensitive subpopulations and only refers to "children." NCDEQ recommends that the Agency change this to include "pregnant individuals and infants."

EPA Response: Please see section 9.2 of the EPA response in this *Response to Comments* document for discussion of public notification tiering and updates to the mandatory health effects language for the final rule. The EPA acknowledges the commenter's support of Tier 2 public notification. The updated health effects language, which can be found in Appendix A to Subpart O and Appendix B to Subpart Q and is summarized in section IX.A.3 of the preamble for this action, includes language that focuses on potential developmental impacts during pregnancy and/or childhood.

Blue Ridge Environmental Defense League (BREDL) (Doc. #1663, SBC-044382)

We have the following additional recommendations:

• The public should be notified in the same way described in the proposed regulations when any PFAS are found in drinking water. EPA must get tough on state agencies that are dithering about providing the public with information that could impact their health.

EPA Response: Please see section 9.2 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1568, SBC-042996. The EPA notes that the PN and CCR requirements established in this rulemaking are only for the six PFAS contaminants regulated under the final rule.

Blue Ridge Environmental Defense League (BREDL) (Doc. #1663, SBC-044385)

• EPA should review federally funded agency responses on public notification of PFAS detected in drinking water.

Notification—General

While BREDL supports the notification requirements for the six, we urge the Environmental Protection Agency (EPA) to include all PFAS detected in drinking water in the requirements. State and local agencies are doing an abysmal job of notifying the public when PFAS are found. So that the public can make informed decisions about possible mitigation measures, this needs to change. BREDL has found that in North Carolina, state agencies and local government responses range from inadequate to non-existent.

EPA Response: Please see section 9.2 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1568, SBC-042996. The EPA notes that the PN and CCR requirements established in this rulemaking are only for the six PFAS contaminants regulated under the final rule.

The commenter's recommendation that the EPA "should review federally funded agency responses on public notification of PFAS detected in drinking water" is unclear; the EPA notes that as part of regulatory action, the agency has reviewed and considered all public comments on the proposed rule, including comments about public notification requirements.

Washington State Department of Health (DOH) (Doc. #1665, SBC-047715)

• Environmental Justice should be considered and addressed using language translation and accessibility tools in all PN resources.

EPA Response: Consideration of language translation and accessibility tools in all PN resources is outside the scope of this rulemaking effort. Consistent with the existing PN Rule, systems that serve a large proportion of consumers with limited English proficiency (as determined by the state) must include a notice in the appropriate language(s) regarding the importance of the notice or contact information to receive assistance or a translated copy of the report (40 CFR 141.205(c)(2)).

Advancing environmental justice (including language access) is an important priority for the agency and, as resources allow, the EPA will consider the commenter's recommendation when developing implementation materials for the final rule. For information on the EPA's environmental justice (EJ) analysis for this regulatory action, please see Chapter 8 of the Economic Analysis (EA) (USEPA, 2024c); for a summary of the EPA's response to comments related to the EPA's EJ analysis, please see section 14.10 of the EPA response in this *Response to Comments* document.

Washington State Department of Health (DOH) (Doc. #1665, SBC-044392)

DOH agrees that tier 2 public notification is appropriate as it is consistent with the current framework for minimum contaminant levels (MCLs) for contaminants with chronic effects. DOH asks that EPA clarifies language for health effects above the MCL and differentiates between health advisory language addressing potential health effects and lower PFAS levels.

EPA Response: Please see section 9.2 of the EPA response in this *Response to Comments* document.

Washington State Department of Health (DOH) (Doc. #1665, SBC-044426)

Page 18731. Section X – Safe Drinking Water Right to Know

EPA requests comment on its proposal to designate violations of the proposed MCLs as Tier 2.

• This is consistent with how EPA addresses 2,3,7,8-TCDD (dioxin), which is also a bioaccumulating contaminant that that poses immune, developmental and cancer risks.

EPA Response: Please see section 9.2 of the EPA response in this *Response to Comments* document.

Cleveland Water, City of Cleveland, Ohio (Doc. #1672, SBC-044921)

Section 6: Safe Drinking Water Right to Know

EPA is proposing a Tier 2 public notification for a violation of one or more of these three proposed MCLs. Cleveland Water believes this is consistent with existing regulation and general practice and therefore supports EPA's decision.

EPA Response: Please see section 9.2 of the EPA response in this *Response to Comments* document. The EPA acknowledges the commenter's support for the PN requirements for this action.

City of Vancouver Water Utility, Vancouver, WA (Doc. #1684, SBC-044316)

Public Notification Requirements:

Although Vancouver agrees that a PFAS MCL exceedance should be a Tier 2 violation given past practice for other bioaccumilating contaminants, we do not believe that quarterly notification is necessary, unless alternative methods of delivery are allowed.

The City of Vancouver recently completed a public notification to 122,876 customers in the form of a mailed hard copy letter. This was at an expense of $48,000 for printing and mailing. If this is required each quarter, our rate payers will be paying $192,000 a year just for the public notifications. It would be beneficial if EPA published some options for electronic delivery methods for Tier 2 public notification. Consider that different types of communication methods may reach different audiences. Public notification options should include a balance of methods to both save on costs for repeat public notification while attempting to ensure more customers maintain awareness. Electronic delivery is allowed for CCRs, for which EPA has provided guidelines, but not for tier 2 public notification.

EPA Response: Please see section 9.2 of the EPA response in this *Response to Comments* document for discussion of PN tiering. The requirements governing the form and manner of Tier 2 public notifications are set forth in the EPA's PN Rule at 40 CFR Part 141, Subpart Q and are beyond the scope of this rulemaking. Consistent with the existing PN Rule, PWSs must provide the notice in a form and manner reasonably calculated to reach all persons served. Primacy agencies have the authority to approve alternative delivery methods in writing [§141.202(c)(4), § 141.203(c) and § 141.204(c)].

The EPA acknowledges the commenter's submission of cost information associated with issuing PNs. With respect to the commenter's assertion about PN-related costs, the EPA assumes 100 percent compliance for its national level analysis in the EA for the final PFAS NPDWR because the EPA has determined that the final rule is feasible given known occurrence concentrations and efficacy of the technologies available. For the EPA's response to comments on public notification burden, please see section 13.3.5 of the EPA response in this *Response to Comments* document.

Additionally, with respect to PN-related costs more generally, the EPA has evaluated the costs to comply with the PN Rule under a separate rulemaking action.

New Jersey Department of Environmental Protection (NJDEP) (Doc. #1699, SBC-045034)

Safe Drinking Water Right To Know

EPA has proposed to designate violations of the proposed MCLs as Tier 2 and, pursuant to 40 CFR 141.203(b)(1), notification would be provided as soon as practicable but no later than 30 days after the system learns of the violation. NJDEP recommends that EPA evaluate the frequency and method of delivery for public notification, as well as providing additional tools for states and water systems to address questions and concerns from consumers. It has been New Jersey's experience that the unique nature of PFAS and their health impacts are difficult to communicate effectively within the structure of a public notice document. Water systems in New Jersey have faced enhanced interest from customers after issuing their public notices. Water systems, state agencies, and EPA must work together to provide consistent messaging to the public regarding these proposed drinking water standards. NJDEP has found it crucial to proactively engage water systems and the public by conducting media outreach, hosting stakeholder events, and building easily accessible resources.

Clarification is needed from EPA regarding Tier 2 public notice requirements for all triggering violations, not just PFAS, specifically for ongoing and subsequent MCL violations as 40 CFR 141.203 requires public notice to be issued every three months as long as the violation or situation continues. Requiring a 30- day public notice for each quarterly violation in addition to a 3-month public notice is redundant, an additional cost burden, and may diminish the intent behind public notice.

Once a water system triggers the public notice requirements under Public Notification Rule at 40 CFR 141 Subpart Q because of an initial MCL violation, NJDEP recommends that, for any subsequent violation occurring at the same location for the same parameter, a water system should issue public notice on the established three-month schedule based on the initial violation. Under this framework, a water system would only issue four public notifications a year instead of eight public notifications, including an ongoing public notice and an additional quarterly public notification where compliance sampling does not fall within the ongoing timeframe. The subsequent public notice will meet the goals of a 30-day notice by capturing the most recent violation, running annual average, and providing an update on the water system's actions to return to compliance. NJDEP's recommendation is informed by its experience implementing its own PFAS standards; many New Jersey water systems have been unable to remediate and comply with the MCL by the next quarter. A significant number of New Jersey water systems are currently conducting ongoing public notice.

In addition to the frequency of public notice, NJDEP recommends that EPA evaluate the method of delivery for ongoing public notice. Commonly in New Jersey, corrective actions for PFAS can take many years to complete, which the proposed rule allows. Since the required language is lengthy and repetitive, continuous public notice can become redundant and have the effect of desensitizing customers to important information. Continuous public notice also becomes very costly for a water system and potentially diverts funding that could be used towards corrective actions. Therefore, NJDEP recommends EPA evaluate allowing additional delivery methods for Tier 2 notices. EPA should consider, after the initial public notice, allowing for water systems to issue public notice electronically (e.g., via email) or through other methods as appropriate to any customer that has previously received a notice as a hard copy, with an option for customers to request to receive the public notice hard copy continuously.

EPA requested comments on what may be needed for water systems to effectively communicate information to the public. EPA currently does not have a public notice template for the proposed MCLs. The requirements of the Public Notification Rule at 40 CFR 141 Subpart Q are broad, ambiguous in application, and often challenged by water systems. NJDEP is requesting that, during implementation, EPA provide more guidance and clarity on the required contents and configuration of the public notice and provide public notification templates for all regulated PFAS contaminants including approved health language. Additionally, as previously stated, it has been New Jersey's experience that the unique nature of PFAS and its health impacts are difficult to communicate effectively within the structure of a public notice document. NJDEP recommends EPA consider evaluating public notice templates and developing additional tools for risk communication to consumers. These include materials that can be utilized by states and water systems to better communicate the differences between the Health Advisories and the proposed MCLs and HI.

EPA Response: Please see section 9.2 of the EPA response in this *Response to Comments* document for discussion of the tiering of public notification, PN requirements for repeat notice, and updates made to the mandatory health effects language for the final rule. In

response to the commenter's concerns about messaging to the public about the PFAS NPDWR and the commenter's recommendations regarding public outreach and communication, the EPA intends to develop public notification templates as part of the guidance that will be developed following rule promulgation and will consider the commenter's recommendations during the implementation of the final rule as resources allow. For further discussion of risk communication materials that the agency intends to develop related to this action, please see section 1.2 of the EPA response in this *Response to Comments* document.

In response to the commenter's recommendation that the agency "evaluate the method of delivery for ongoing public notice", the EPA notes that the requirements governing the form and manner of public notifications are set forth in the EPA's PN Rule at 40 CFR Part 141, Subpart Q and are beyond the scope of this rulemaking. Consistent with the existing PN Rule, PWSs must provide the notice in a form and manner reasonably calculated to reach all persons served. Primacy agencies have the authority to approve alternative delivery methods in writing [§141.202(c)(4), § 141.203(c) and § 141.204(c)].

In response to the commenter's assertion that "continuous public notice also becomes very costly for a water system," please see the EPA response to comment Doc. #1684, SBC-044316 in section 9.2 in this *Response to Comments* document.

State of Vermont Agency of Natural Resources and Department of Health (Doc. #1708, SBC-045108)

Section X – Safe Drinking Water Right to Know

1) EPA Requests comment on its proposal to designate violations of the proposed MCLs as Tier 2.

Vermont would support EPA's decision to utilize Tier 2 public notification (PN) for the PFAS NPDWR, if the health effects of PFAS are consistent with other chemical MCLs with chronic health effects. However, the proposed health effects language is confusing and would benefit from further clarification. EPA has included both acute and chronic, or at least sub-chronic, effects in the Public Notice (PN) language. Additionally, this PN language is inconsistent with the language the Agency used for the previous health advisories. The PN language discusses PFAS levels in excess of the MCL being of concern, while the health advisory language discusses health impacts at much lower levels. This will create additional confusion with the public regarding the safety of their water. The language within the rule also loses the focus on sensitive sub-populations and only refers to "children." This should be clarified by the EPA to include "pregnant individuals and infants."

EPA Response: Please see section 9.2 of the EPA response in this *Response to Comments* document for discussion of public notification tiering and updates to the mandatory health effects language for the final rule. The updated health effects language, which can be found in Appendix A to Subpart O and Appendix B to Subpart Q and is summarized in section

IX.A.3 of the preamble for this action, includes language that focuses on potential developmental impacts during pregnancy and/or childhood.

Massachusetts Department of Environmental Protection (MassDEP) (Doc. #1726, SBC-045148)

Public notice

MassDEP supports EPA's decision to utilize Tier 2 public notification (PN) for the PFAS NPDWR. Note that, as the proposed rule is presented in the Federal Register, the proposed updates to Appendices A and B of Subpart Q of 40 CFR Part 141 appear incomplete. The new PFAS entries under the Synthetic Organic Chemicals (SOC) heading, rows 31-33 in Appendix A, lack Contaminant names and the citations for "Monitoring & testing procedure violations" are incomplete ("141.XX") (88 Fed. Reg. 18638, 18749). The new PFAS rows in Appendix B to Subpart Q of Part 141 lack the row numbers 90-92 (88 Fed. Reg. at 18750). Additionally, based on the existing SOC entries, when the MCLG is zero the word is spelled out rather than listing the number "0." The "MCLG mg/L" and "MCL mg/L" headers need to be modified to add "(unless otherwise noted)" to accommodate the HI. If the intent of footnote 24 is to refer to the HI definition, then move the footnote to the Contaminant entry.

EPA Response: The EPA acknowledges the commenter's support of the agency's decision to utilize Tier 2 public notification for this action. Please see section 9.2 of the EPA response in this *Response to Comments* document for a discussion of PN tiering. As the commenter recommended, for the final rule the EPA has added the chemical names to Appendix A to Subpart Q and inserted valid CFR citations in the "Monitoring & testing procedure violations" column. In Appendix B to Subpart Q, the EPA also agrees with the commenter and added numbers preceding the chemical names, changed instances of 0 to "zero," and deleted footnote 24, choosing instead to add the definition of *Hazard Index* to § 141.153(c). In both appendices cited in this comment, while a parenthetical saying "unless otherwise noted" was not added to the column headers for the MCLG and MCL columns, the EPA notes that this parenthetical note ("unless otherwise noted") is provided in §141.50 and Table 4 to paragraph (c) of §141.61, which provide information on MCLG and MCL values and units for the final rule, respectively.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-045974)

Section 6: Safe Drinking Water Right to Know

Section 6.1: Public notification

EPA is proposing a tier 2 public notification for a violation of one or more of these three proposed MCLs. AMWA believes this is consistent with existing regulation and general practice and, therefore, supports EPA's decision.

EPA Response: The EPA acknowledges the commenter's support for requiring Tier 2 public notification for violations of this rule's MCLs. Please see section 9.2 of the EPA response in this *Response to Comments* document for further discussion of PN requirements.

Connecticut Department of Public Health (CT DPH) (Doc. #1745, SBC-045237)

Public Communications

1. EPA requests comment on its proposal to designate violations of the proposed MCLs as Tier 2.

Designating the PFAS NPDWR public notification (PN) as Tier 2 is appropriate and consistent with other MCLs. The Tier 2 PN requires an MCL violation notification as soon as practicable, but no later than 30 days, and to repeat every 3 months if the violation persists (unless the primacy agency deems unnecessary). In keeping with the PN rule of the Safe Drinking Water Act, Tier 2 PN will help ensure that customers know if there is a problem with their drinking water. A more relaxed notification schedule, such as Tier 3, could potentially result in Connecticut residents being exposed to PFAS for as long as a year before they were made aware of the problem.

EPA Response: The EPA acknowledges the commenter's statement that requiring Tier 2 public notification for violations of this rule's MCLs is appropriate and consistent with other MCLs. Please see section 9.2 of the EPA response in this *Response to Comments* document for further discussion of PN requirements.

West Virginia Rivers Coalition et al. (Doc. #1746, SBC-045259)

[In particular, we strongly support their calls for EPA to:]

• Adjust the public notice designation for violations of the PFAS MCLs from Tier 2 to Tier 1

EPA Response: Please see section 9.2 of the EPA response in this *Response to Comments* document.

City of Thornton, Colorado (Doc. #1748, SBC-044797)

Although Thornton supports the implementation of the PFAS MCL, we urge the EPA to consider using Tier 3 Public Notice guidance for systems that exceed the MCL. Since the health risks associated with the PFAS contaminants are more chronic in nature rather than acute, annual notice should acceptably protect public health. While complicating the rule, Thornton could support a multi-tiered approach where systems that exceed twice the MCL (>8ppt/HI > 2) issue a Tier 2 Public Notice, while systems between 1-2 times the MCL issue a Tier 3 Public Notice. Thornton supports the use of a RAA for compliance and public notice requirements; a one-time sampling exceedance of the MCL should not cause a violation or require public notice. EPA should also consider revisions to public notice required for monitoring failures. In 2023,

Thornton has already had trouble with UCMR5 PFAS testing wherein a PFAS sample was taken early in the quarter, but the contract lab did not notify the city of a QC failure until almost ten weeks later. With contract lab turnaround times frequently exceeding two months, this would leave insufficient time to sample and report results within the proposed quarterly monitoring framework. With expected increases in PFAS monitoring needs as the proposed rule is implemented, Thornton anticipates lab turnaround times will get even worse. Lab capacity already cannot meet demand and adding additional capacity will be slower than the rate of increased demand due to shortages of staff capable of performing such a technically challenging analysis and the difficulty labs face in meeting certification requirements for the analysis. Thornton suggests that the EPA exempt systems that have made best faith efforts to monitor PFAS from Tier 3 Public Notice. Alternatively, Thornton suggests that the EPA consider extending reporting time requirements to reflect the known issues with lab capacity, so that samples taken late in the quarter can still be counted towards a system's monitoring requirement. Thornton also requests that the EPA develop the communication and health-based language required for the CCR and Public Notice for the health effects of PFAS. However, it is imperative that EPA also communicates, or allows utilities to communicate to the public, that consumer risk from PFAS is not solely from drinking water due to the ubiquity of PFAS in other consumer products. Thornton does not want customers to think they are completely safe from the risks of PFAS just because their drinking water provider has met the MCL. Also, in the Tier 2 Public Notice language, EPA also needs to clearly communicate that bottled water may not be a safe alternative since it is regulated differently and may contain higher concentrations of PFAS than the drinking water from the utility required to issue the notice.

EPA Response: The EPA acknowledges the commenter's support of the implementation of the PFAS MCLs that will be promulgated as part of this action. The EPA disagrees with the commenter's suggestion that the agency use "Tier 3 Public Notice guidance for systems that exceed the MCL" and the commenter's suggestion to use a "multi-tiered approach" for public notification tiering; please see section 9.1 of the EPA response in this *Response to Comments* document for discussion related to CCR requirements and section 9.2 of the EPA response in this *Response to Comments* document for discussion related to PN requirements, including discussion of PN tiering and updates to the mandatory health effects language for the final rule. The EPA agrees that PFAS is a chronic contaminant and has required Tier 2 PN notification for an MCL violation consistent with public notification for other chronic contaminants.

The EPA acknowledges the commenter's support of the use of a RAA for MCL compliance. The EPA notes that the RAA, not a single sample result, determines whether there is a violation (and thus the issuance of PN). For further discussion of use of RAAs, please see section 8.2 of the EPA response in this *Response to Comments* document and section VIII.B of the Federal Register Notice for this action.

The EPA disagrees with the commenter's suggestion that the final rule should exempt systems from Tier 3 PN if they fail to monitor or extend the timeframe for reporting on PFAS contaminants due to laboratory capacity issues cited by the commenter. This requirement for

water systems to report monitoring results is the same for all other NPDWRs and the EPA's evaluation of feasibility reflects that there will be sufficient laboratory capacity to support implementation of the PFAS NPDWR. Please see section 5.1.2 of the EPA response in this *Response to Comments* document for discussion of laboratory considerations, including capability and capacity. Additionally, the EPA notes that it is the water system's responsibility to ensure that required testing is completed, and if it is not completed the system has a responsibility to notify the public. Public notices are required to address whether alternative water supplies should be used and what actions consumers should take [§ 141.205(a)], for example, using a filter.

In response to the commenter's suggestion that the EPA should "clearly communicate that bottled water may not be a safe alternative", the EPA notes that CCRs are required to include a brief explanation of contaminants which may reasonably be expected to be found in drinking water, including bottled water [§ 141.153(h)(1)]. The Food and Drug Administration (FDA) regulations establish limits for contaminants in bottled water which must provide the same protection for public health. As the EPA develops implementation materials following final rule promulgation, the agency will consider additional resources to support states and water systems for notifying their customers. In developing the PN templates, the EPA will consider adding directions and recommendations for consumers with respect to suggested actions they can take or for seeking alternative sources of water, such as bottled water. The EPA will evaluate and consider if adding a reminder for consumers to verify the water quality of bottled water is appropriate in developing the PN templates.

Harris County Attorney's Office (HCA) (Doc. #1751, SBC-045264)

EPA should ensure communities are given sufficient notice regarding PFAS contamination and potential health consequences.

Under current rules, all PWS must give public notice for all violations of NPDWRs and for other situations. EPA proposes that violations of the three PFAS MCLs would be designated as Tier 2. As such, PWS would be required to issue a notification of an MCL violation as soon as practicable but no later than 30 days after the system learns of the violation. Additionally, CWS would be required to provide Tier 2 public notices by mail or other direct delivery to each customer receiving a bill and to other service connections to which water is delivered by the public water system and by any other method reasonably calculated to reach other persons regularly served by the system, if they would not normally be reached by the former method (e.g. apartment and house renters, university students, and prison inmates etc.). Other methods may include: publication in a local newspaper, delivery of multiple copies for distribution by customers that provide their drinking water to others (e.g., apartment building owners or large private employers), posting in public places served by the system or on the Internet, or delivery to community organizations. [FN9: 40 CFR 141.203(c) (emphasis added).]

HCA asks EPA to encourage water systems to utilize a higher level of notice than what is required for Tier 2, especially given the urgent health effects and limited public knowledge and name recognition of PFAS. These encouraged methods could include the optional Tier 2

methods or required Tier 1[FN10:40 CFR 141.202(c).] methods – newspaper and broadcast publication, posting in public places, delivery to community organizations, etc. HCA also asks community outreach and alerts, specifically related to the health effects of PFAS exposure, be provided in plain, accessible language and that notification templates be provided by the EPA in multiple spoken languages.

EPA Response: Please see section 9.2 of the EPA response in this *Response to Comments* document for discussion of the EPA's decision regarding PN tiering for the final rule. With respect to the comments suggesting that the EPA encourage use of a higher level of notice and certain methods for PN, the EPA will consider these comments in developing implementation guidance. With respect to the commenter's request that "notification templates be provided by the EPA in multiple spoken languages," please see the EPA response to comment Doc. #1665, SBC-047715 in section 9.2 in this *Response to Comments* document. As the EPA develops implementation materials following final rule promulgation, the agency will consider additional resources to support states and water systems for notifying their customers, as resources allow.

American Water Works Association (AWWA) (Doc. #1759, SBC-045629)

10. Public Notifications

Public notifications serve an important role in protecting public trust in drinking water and their usefulness for communities relies on a solid foundation for risk communication. The proposal requires that water systems with PFAS levels exceeding the MCLs must provide a Tier 2 notification to the public and Tier 3 notifications when a monitoring and/or testing procedure violation has occurred. Water systems will also be required to include information about detections of regulated PFAS in the CCR.

AWWA supports the proposed approach for public notifications for PFOA and PFOS. While AWWA is recommending in this letter that the proposed regulation for PFHxS, PFNA, HFPO-DA, and PFBS be revised based on the discussed technical and legal issues, the agency is reminded that the risk communication for PFAS must be carefully and thoughtfully structured. The role of public communications is to provide useful information to the public about their drinking water. As EPA considers any rule for PFAS through a hazard index, it is important that regulations be structured in a manner that facilitates useful risk communication.

EPA Response: Please see section 9.1 of the EPA response in this *Response to Comments* document regarding CCR requirements and section 9.2 of the EPA response in this *Response to Comments* document regarding PN requirements. The EPA acknowledges the commenter's support for the PN requirements for PFOA and PFOS in this action.

With respect to communication of the Hazard Index standard, the EPA is including a definition of the *Hazard Index* in 40 CFR 141.153(c)(3)(v) of the CCR Rule to improve clarity and understandability for consumers. As the EPA develops implementation materials following final

rule promulgation, the agency will consider additional resources to support states and water systems for notifying their customers.

Bowling Green Municipal Utilities (Doc. #1767, SBC-043933)

Public Notifications: Public notice of a violation as a Tier 2 notification is unnecessary. Any violation should be reported in the CCR as distributed to the public. There is a great deal of misunderstanding in the public on how a running annual average works; generally the public sees any exceedance as a problem even if the RAA is under the MCL. As EPA has unwisely stated that "No level of PFOS/PFOA" is acceptable, this has placed water providers into an untenable position.

EPA Response: Please see section 9.1 of the EPA response in this *Response to Comments* document on CCR requirements and section 9.2 of the EPA response in this *Response to Comments* document on PN requirements. The EPA notes that PN is only required when there is a violation and for PFAS this is based on a RAA. The EPA uses RAAs for many other chemical contaminants, including Synthetic Organic Contaminants (SOCs), and in those scenarios the RAA, not a single sample result, determines whether there is a violation. For further discussion of use of RAAs, please see section 8.2 of the EPA response in this *Response to Comments* document and section VIII.B of the Federal Register Notice for this action. The EPA has not stated that "no level of PFOS/PFOS is acceptable." Rather, the EPA has followed long-standing agency practice of establishing the MCLG at zero for PFOA and PFOS based on the determination that these two contaminants are *Likely to be Carcinogenic to Humans* (please see section IV of the preamble for this action). The EPA simultaneously set enforceable MCLs, levels below which systems are in compliance with the EPA's enforceable drinking water standards and do not require PN under this rule. The MCL, not the MCLG, determines which levels of PFOA and PFOS are "acceptable" in drinking water. See section V of the preamble for this action for further discussion.

Environmental Protection Network (EPN) (Doc. #1773, SBC-043875)

Public Notification

EPA proposes that violations of any one or more of the three MCLs would be designated as Tier 2. As a result, the PWS must notify the public of the violation as soon as practicable but no later than 30 days after the system learns of the violation. EPN recommends that EPA clarify that public notification must occur whenever there is a violation at any one distribution point. EPN further recommends that the public notification should remain in place until the public water system returns to compliance, as required.

EPA Response: Please see section 9.2 of the EPA response in this *Response to Comments* document for discussion of PN requirements. In response to the commenter's recommendation that "the public notification should remain in place until the PWS returns to compliance," the EPA notes that the form and manner of PN delivery is beyond the scope of this

rulemaking. Additionally, in response to the commenter's request that the EPA "clarify that public notification must occur whenever there is a violation at any one distribution point", the EPA has determined in the final rule that the regulated PFAS contaminants require Tier 2 PN to be issued in the event of an MCL violation. As stated in Section 141.905(b) of the final rule, if any entry point has a violation, then the system is in violation. The EPA does not agree with the commenter that there should be a violation (and therefore PN required) whenever there is an exceedance of the MCL at any one distribution point because PFAS are chronic contaminants and an MCL violation is based on a RAA of four quarterly samples to evaluate the persistence of the contamination, consistent with the compliance approach for other chronic contaminants in the NPDWRs. However, the EPA does note that CWSs will need to report in their CCR all detected results, which would include results that exceed the MCL. For further discussion of use of RAAs, please see section 8.2 of the EPA response in this *Response to Comments* document and section VIII.B of the Federal Register Notice for this action.

Earthjustice et al. (Doc. #1808, SBC-046121)

D. EPA's Proposed Tier 2 Designation for Violations of its PFAS MCLs Does Not Account for Acute Toxicity and Must be Amended

To "ensure[] that consumers will know if there is a problem with their drinking water," the SDWA requires "each owner or operator of a public water system" to give notice to consumers of all violations of a NPDWR through public notice. [FN216: Proposed Rule, 88 Fed. Reg. at 18,684; 40 C.F.R. § 141.201(a), (c).] "The public notice requirements for each violation or situation," "are determined by the tier to which [the violation or situation] is assigned." [FN217: 40 C.F.R. § 141.201(b).]

Tier 1 notice is required for violations and situations "with significant potential to have serious adverse effects on human health as a result of short-term exposure" and must be provided as soon as practical but no later than 24 hours after the system learns of the violation. [FN218: Id. §§ 141.202(a)(9), 141.202(b)(1).] Tier 2 notice applies to all violations and situations not designated as Tier 1 but which have the "potential to have serious adverse effects on human health" and must be provided as soon as practical but no later than 30 days after the system learns of the violation. [FN219: Id. §§ 141.201(b), 141.203(b).] Finally, Tier 3 notice is required for all NPDWR violations and situations not included in Tier 1 and Tier 2 and must be provided "not later than one year after the public water system learns of the violation or situation or begins operating under a variance or exemption." [FN220: Id. § 141.204(b).]

In the Proposed Rule, EPA proposes designating violations of the MCLs for the Six PFAS as requiring "Tier 2" public notice. [FN221: Proposed Rule, 88 Fed. Reg. at 18,684.] This proposal ignores the acute toxicity of the Six PFAS, and EPA must modify its proposal to require Tier 1 public notice for violations of all the proposed MCLs so consumers can be informed of the potential for significant harm in a timely manner.

EPA's proposal "that violations of the three MCLs . . . be designated as Tier 2" for purposes of the public notification rule ignores scientific evidence establishing a link between serious adverse health effects and short-term exposure to the Six PFAS. [FN222: Id. "The proposed rule also designates monitoring and testing procedure violations as Tier 3[.]" Id. at 18,699.] EPA acknowledges that exposure to PFOA and PFOS "may have an adverse effect on the health of persons" and that PFHxS, GenX, PFNA, and PFBS "may individually and in a mixture each result in adverse health effects, including disrupting multiple biological pathways that result in common adverse effects on several biological systems including the endocrine, cardiovascular, developmental, immune, and hepatic systems." [FN223: Id. at 18,644–45.] However, while EPA acknowledges that these PFAS can cause serious harms, its analysis focuses significantly on chronic harms at the expense of a careful analysis of the harms these PFAS pose in the short-term. [FN224: Id. at 18,645–46 (citing studies of mice dosed for 42–44 days or 53–64 days, for example).] As a result of the short shrift EPA gave to acute toxicity studies, it has mis-designated the violation of the proposed MCLs for public notification purposes.

The Six PFAS all pose short-term health harms. Acute and short-term health effects for PFOA, PFOS, PFHxS, and PFNA are summarized in ATSDR's Toxicological Profile for Perfluoroalkyls. [FN225: ATSDR 2021 at 62, 84, 88-99.] Acute PFOA exposure is associated with liver, immunological, reproductive, and developmental effects. [FN226: Id. at 62.] Acute PFOS exposure is associated with liver, immunological, and developmental effects. [FN227: Id. at 84.] Acute PFNA exposure is associated with liver and immunological effects as well as changes in body weight. [FN228: Id. at 88-90.]

Acute exposure to PFOS has also been found to affect the plasticity of brain synapses, creating neurotoxic harm, [FN229: Qian Zhang et al., Effects Of Perfluorooctane Sulfonate and its Alternatives on Long-Term Potentiation in The Hippocampus CA1 Region if Adult Rats in vivo, 5 Toxicology Rsch. 539, 539–546 (2016), doi: 10.1039/c5tx00184f.] and damage the liver. [FN230: Jiali Xing, Toxicity Assessment Of Perfluorooctane Sulfonate Using Acute and Subchronic Male C57BL/6J Mouse Models, 210 Env't Pollution 388–96 (2016), https://pubmed.ncbi.nlm.nih.gov/26807985/.] For PFOA, one study found that "cellular effects exerted after 24 h[our] exposure to perfluorooctanoic acid are non-reversible after a 48 h[our] recovery period." [FN231: Peropadre et al., An Acute Exposure to Perfluorooctanoic Acid Causes Non-Reversible Plasma Membrane Injury in Hela Cells, 260 Env't Pollution Art. No. 11400 (2020), https://pubmed.ncbi.nlm.nih.gov/31995777/.] Another study found that acute exposure to PFOA can "disrupt[] key hormones in the pancreas" and "induce[] lipid accumulation in the liver." [FN232: Xinmou Wu et al., Effect of Acute Exposure to PFOA On Mouse Liver Cells In Vivo And In Vitro, 24 Env't Sci and Pollution Rsch. Int'l 24201, 24203 (2017), https://pubmed.ncbi.nlm.nih.gov/28887612/.] Acute exposure to PFNA has been found to impair reproductive health, [FN233: Shilpi Singh & Shio Kumar Singh, Acute Exposure To Perfluorononanoic Acid in Prepubertal Mice: Effect on Germ Cell Dynamics and an Insight into the Possible Mechanisms of its Inhibitory Action on Testicular Functions, 183 Ecotoxicology Env't Safety Art No.109499, 1667 (2019), https://pubmed.ncbi.nlm.nih.gov/31398581/; Shilpi Singh & Shio Kumar Singh, Prepubertal Exposure to Perfluorononanoic Acid Interferes with

Spermatogenesis and Steroidogenesis in Male Mice, 170 Ecotoxicology Env't Safety 590, 598 (2019), https://pubmed.ncbi.nlm.nih.gov/30576894/; Shilpi Singh & Shio Kumar Singh, Effect of Gestational Exposure to Perfluorononanoic Acid On Neonatal Mice Testes, 39 J. of Applied Toxicology 1663, 1665 (2019), https://pubmed.ncbi.nlm.nih.gov/31389053/; Yixing Feng et al., Effects of PFNA Exposure on Expression of Junction-Associated Molecules and Secretory Function in Rat Sertoli Cells, 30 Reprod. Toxicology 429–37 (2010), https://pubmed.ncbi.nlm.nih.gov/20580666/.] and negatively impact liver functionality in diabetic mice. [FN234: Fang X, Perfluorononanoic Acid Disturbed the Metabolism of Lipid in the Liver of Streptozotocin-Induced Diabetic Rats, 25 Toxicology Mechanisms & Methods 622, 626 (2015), https://pubmed.ncbi.nlm.nih.gov/26056853/.] A study on PFHxS found that "a single neonatal exposure to PFHxS can cause irreversible neurotoxic effects in mice." [FN235: Henrick Viberg et al., Adult Dose-Dependent Behavioral and Cognitive Disturbances After a Single Neonatal PFHXS Dose, 304 Toxicology 185–91 (2013) https://pubmed.ncbi.nlm.nih.gov/23287389/.] PFHxS has also been found to pose similar brain development concerns as PFOS in response to acute exposure. [FN236: Qian Zhang et al., Effects of Perfluorooctane Sulfonate and its Alternatives on Long-Term Potentiation in The Hippocampus CA1 Region if Adult Rats, at 539 ("In addition, PFHxS and Cl- PFAES exhibited comparable potential to PFOS in disturbing LTP.").] PFBS has been found to have an effect on the liver which "may represent an acute response to the chemical at a high dose." [FN237: Lau et al., Pharmacokinetic Profile of Perfluorobutane Sulfonate and Activation of Hepatic Nuclear Receptor Target Genes in Mice, 441 Toxicology 152522 (2020), https://pubmed.ncbi.nlm.nih.gov/32534104/.] Additional acute studies of PFBS are identified in the Toxicity Assessment for PFBS. [FN238: EPA, Human Health Toxicity Values for Perfluorobutane Sulfonic Acid (CASRN 375-73-5) and Related Compound Potassium Perfluorobutane Sulfonate (CASRN 29420-49-3) (2021) at 50–51.]

EPA's Toxicity Assessment for GenX reviews 10 studies for acute toxicity and four studies for short term toxicity (seven-day dosing). [FN239: EPA, Human Health Toxicity Values for Hexafluoropropylene Oxide (HFPO) Dimer Acid and Its Ammonium Salt (CASRN 13252-13-6 and CASRN 62037-80-3) Also Known as 'GenX Chemicals' at 35-37.] Since the publication of that assessment, additional acute and short-term toxicity studies have been published. For example, Cannon et al. found that a single dose of GenX administered by oral gavage caused decreases in P- glycoprotein (P-gp) transport activity and breast cancer resistance protein (BCRP) transport activity in the brain capillaries of exposed rats. [FN240: Cannon et al., Effect of GenX on P-Glycoprotein, Breast Cancer Resistance Protein, and Multidrug Resistance-Associated Protein 2 at the Blood-Brain Barrier, 128 Env't Health Persp. 37002 (March 2020), https://doi.org/10.1289/EHP5884.] Further, a pair of studies by Conley et al. exposed rats from gestation day 14–18 or gestation day 17–21 respectively (i.e., 5 days of exposure) and found effects in both the dosed mothers and developing fetuses. [FN241: Conley et al., Adverse Maternal, Fetal, and Postnatal Effects of Hexafluoropropylene Oxide Dimer Acid (GenX) from Oral Gestational Exposure in Sprague-Dawley Rats, 127 Env't Health Persp. 037008 (Mar 2019), https://doi.org/10.1289/EHP4372 ("Conley 2019"); Conley et al., Hexafluoropropylene

Oxide-Dimer Acid (HFPO-DA or GenX) Alters Maternal and Fetal Glucose and Lipid Metabolism and Produces Neonatal Mortality, Low Birthweight, and Hepatomegaly in the Sprague-Dawley Rat, 146 Env't Int't 106204 (Jan. 2021) https://doi.org/10.1016/j.envint.2020.106204 ("Conley 2021").] In animals exposed from gestation day 14–18, fetal and maternal livers had increased expression of genes in the PPAR signaling pathway, and rats exposed to GenX gained less weight during their pregnancy and had larger livers than unexposed animals. [FN242: Conley 2019 at 037008-6 to 037008-8.] Results were similar for animals exposed from gestation day 17–21. [FN243: Conley 2021 at 106204-4 to 106204-10.] Additionally, Blake et al. (2023) exposed CD-1 mice from gestation day 1.5 to 11.5 or 17.5 (i.e. 10 days or 17 days of exposure) and found that exposed mothers gained more weight during the dosing period, had larger livers that showed "abnormal ultrastructure with enlarged hepatocytes," had larger kidneys and altered blood clinical chemistry, including increased cholesterol, HDL, and ALT levels. [FN244: Blake et al., Evaluation of Maternal, Embryo, and Placental Effects in CD-1 Mice Following Gestational Exposure to Perfluorooctanoic Acid (PFOA) or Hexafluoropropylene Oxide Dimer Acid (HFPO-DA or GenX), 128 Env't Health Persp. 128 (Feb. 2020), https://doi.org/10.1289/EHP6233.] GenX exposed fetuses had a larger embryo:placenta weight ratio and increased placental lesions. [FN245: Id.]

These health risks are significant and require swift public notice so consumers can take immediate action to protect themselves from exposure. Accordingly, EPA should adjust the proposed public notice designation for violations of the PFAS MCLs from Tier 2 to Tier 1 in the final rule.

EPA Response: The EPA disagrees with the commenter that the agency should adjust public notification tiering for MCL violations from Tier 2 to Tier 1; please see section 9.2 of the EPA response in this *Response to Comments* document for discussion of PN requirements, including PN tiering. The EPA acknowledges that developmental exposure can result in health effects occurring in less than lifetime scenarios which is why the mandatory health effects language for regulated PFAS to be included in PN and CCRs includes language such as the following (with PFOA used as an example here): "In addition, there may be increased risks of developmental and immune effects for people who drink water containing PFOA in excess of the MCL following repeated exposure during pregnancy and/or childhood." Additionally, as described in section 9.2 of the EPA response in this *Response to Comments* document, the EPA acknowledges that there may be instances in which it is appropriate to elevate the tiering of PN on a case-by-case basis. Under the existing PN Rule in 40 CFR 141.202(a), a violation that routinely requires a Tier 2 notice but poses elevated risk from short-term exposure, as determined by the primacy agency, may be elevated to Tier 1.

The EPA also disagrees that the analysis does not carefully consider harms PFAS pose after developmental exposure. The Health Based Water Concentrations (HBWCs) and/or MCLGs for PFNA, HFPO-DA, and PFBS were all based on reproductive or developmental studies that used less-than-chronic exposure designs targeting sensitive lifestages (please see section III.B of the

federal register notice for this action and section 3 of the EPA response in this *Response to Comments* document). The commenter cites the ATSDR Toxicological Profile for Perfluoroalkyls (ATSDR, 2021) to support this claim, while ignoring that the EPA relied on that same assessment as the source of reference values for PFNA and PFHxS. Similarly, the EPA considered less-than-chronic exposure studies when developing the final toxicity assessments for PFOA and PFOS (USEPA, 2024a; USEPA, 2024b), particularly studies of developmental, reproductive, immunological, and neurological toxicity. Subsequently, the Reference Doses (RfDs) for PFOA and PFOS are based in part on developmental effects.

Wisconsin Department of Health Services (Doc. #1823, SBC-044279)

May 25, 2023

Jennifer McLain, Director

Office of Ground Water and Drinking Water

U.S. Environmental Protection Agency 1200 Pennsylvania Avenue, NW Washington, DC 20460

Subject: Comments on National Primary Drinking Water Regulations: Per- and poly- fluoroalkyl substances (PFAS) Rules Promulgation (88 FR 18638, EPA-HQ-OW- 2022-0114)

Dear Dr. McLain,

As Wisconsin's lead public health agency, the Wisconsin Department of Health Services (WDHS) works closely with the Wisconsin Department of Natural Resources (WDNR) to address environmental health concerns statewide. We appreciate EPA's actions to set drinking water standards for several PFAS, something heavily needed as we continue to discover and respond to contamination by these substances in Wisconsin drinking water supplies. We concur with comments on the proposed PFAS rules that were submitted by WDNR and, in this letter, we are submitting an additional comment.

While the proposed rules include public notification requirements, sole reliance on the conventional public notice framework and use of consumer confidence reports is not responsive to situations involving substances with known risks from shorter than chronic exposures, including PFAS. As a result, sensitive sub-populations do not receive clear, actionable information in time to make meaningful personal risk management decisions about their water. WDHS recommends that EPA consider public notification requirements that reflect sound risk communication strategies to support community members at greatest risk from unsafe exposures to PFAS in drinking water.

PFAS have been shown to have health impacts on timescales shorter than chronic exposure, and timely communication of elevated PFAS levels can equip individuals to make informed risk management decisions; delaying that notification puts individuals at unnecessary risk.

EPA Response: Please see section 9.2 of the EPA response in this *Response to Comments* document.

Wisconsin Department of Health Services (Doc. #1823, SBC-044281)

We know that shorter term exposures to PFAS are meaningful for sensitive subpopulations, such as pregnant individuals and young children. The ATSDR Exposure Assessment studies found that interruption of PFAS exposures has a demonstrated impact on lowering PFAS body burden. However, with respect to drinking water exposures, this risk reduction behavior is predicated on an individual's awareness of PFAS sampling results. Under the current notification guidelines, several quarters of results that marginally exceed the proposed MCL can be collected, which may result in many months going by without public notification of levels of PFAS that are known to cause adverse health impacts.

EPA Response: Please see section 9.2 of the EPA response in this *Response to Comments* document.

Plymouth Village Water & Sewer District (Doc. #1827, SBC-044563)

[Please carefully consider the following points to help inform the pending rulemaking on this class of pervasive and persistent PFAS chemicals:]

• Hundreds of systems are likely to be in a continuous public notification cycle for years. This will initially cause public alarm, followed by desensitization and resistance to increasing water rates for necessary funding, overall eroding public trust in public water supplies.

EPA Response: Please see section 9.2 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1576, SBC-042456 in section 9.2 in this *Response to Comments* document for discussion of PN requirements for repeat notice.

Wisconsin Department of Natural Resources (Doc. #1828, SBC-044802)

Public Notice

WDNR agrees with comment from ASDWA and recommends EPA clarify the health effects language proposed to be included in the public notification requirements. The public notice language referencing both chronic and acute health effects is confusing.

EPA Response: Please see section 9.2 of the EPA response in this *Response to Comments* document.

Corix Infrastructure Inc. (Doc. #1834, SBC-045372)

[With regards to the specific items EPA has requested comment on, Corix provides below:]

• We support the designation of violations of the proposed MCLs as Tier 2.

EPA Response: Please see section 9.2 of the EPA response in this *Response to Comments* document. The EPA acknowledges the commenter's support of Tier 2 public notification for this action.

Little Hocking Water Association (Doc. #1835, SBC-045519)

Comment on public notification requirements.

EPA is proposing to require water suppliers to comply with the Consumer Confidence Report (CCR) requirements of 40 CFR 141 Subpart O and inform customers if PFAS are detected in the CCR and the public notification rule. LHWA supports these public notification requirements.

EPA Response: Please see section 9.1 of the EPA response in this *Response to Comments* document for discussion of CCR requirements and section 9.2 of the EPA response in this *Response to Comments* document for discussion of PN requirements. The EPA acknowledges the commenter's support for the agency's public notification requirements for this action.

Little Hocking Water Association (Doc. #1835, SBC-045520)

However, EPA proposes that violations of the proposed PFAS MCLs be designated as Tier 2, which requires notification as soon as practicable but no later than 30 days after the system learns of the violation. LHWA does not support the Tier 2 designation. Instead, violations of the proposed PFAS MCLs should be designated as Tier 1 violations, requiring public notice as soon as practical but no later than 24 hours after the system learns of the violation. As stated above, people have been unknowingly dosed with PFAS for over 60 years. We do not know which dose is the one that will a person sick. As such, EPA should be using the "nth dose" policy as the most protective of human health.

EPA Response: Please see section 9.2 of the EPA response in this *Response to Comments* document. In response to the commenter's assertion that "we do not know which dose is the one that will a person sick", the EPA disagrees. For the four Hazard Index PFAS regulated under this action, the agency has identified doses below which adverse effects are unlikely to occur based on the best available science (i.e., RfDs), which have been used to establish the

MCLGs and/or HBWCs. For PFOA and PFOS, the agency has determined that there is no dose below which adverse effects are unlikely to occur and, as such, has followed long-standing agency practice of establishing the MCLG at zero for PFOA and PFOS based on the determination that these two contaminants are *Likely to be Carcinogenic to Humans.* Additionally, the EPA notes that the commenter does not provide a description of the "nth dose policy" in their comment letter and therefore the agency cannot directly respond to the commenter's recommendation.

New England Water Works Association (Doc. #1836, SBC-045392)

Communication:

EPA proposes that a PWS must repeat public outreach to its consumers every 3 months if a violation or situation persists unless the primacy agency determines otherwise, but that at a minimum, systems must give repeat notice at least once per year. Because it will take time for a PWS to design and construct treatment, we do not find quarterly Public Notice to have added value (in fact, it would most likely cause confusion for consumers). NEWWA recommends that EPA allow a Tier III notice to be utilized if a violation persists.

EPA Response: Please see section 9.2 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1576, SBC-042456 in section 9.2 in this *Response to Comments* document.

Midwest Environmental Advocates +more (Doc. #1846, SBC-045838)

In Wisconsin, there have been recent examples of water systems failing to adequately warn and educate their consumers about PFAS pollution when asked by citizens or required by the WDNR and the Wisconsin Department of Health Services. For instance, in 2019, the water system from the City of Wausau learned that all its municipal wells exceeded recommended state standards, yet the water system provided false or misleading information to consumers when asked by a resident in 2021. [FN40: WSAW-TV, Wausau public works director explains response to citizen email causing PFAS misinformation concerns (Feb. 10, 2022),] Despite knowing that the results showed detections higher than recommended state limits for about two years, the system's highest official assured the consumer that the system's drinking water didn't have a PFAS water quality issue. The response stated:

"Wausau Water Works has been and will continue to be proactive on the PFAS/PFOA discussions and upcoming health risk analysis by USEPA and WDNR requirements. We have tested our source water for these compounds in the past and the latest round of sampling was in 2019. USEPA has a limit of 70 parts per trillion and WDNR is considering a 20 parts per trillion limit. We are well below either of these." [FN 41: Wausau Pilot & Review, Wausau email shows Public Works director appears to have misled mayor on water toxicity (Feb. 10, 2022) (emphasis added), https://wausaupilotandreview.com/2022/02/10/wausau-email-shows-public-works-director-appears-to-have-misled-mayor-on-water-toxicity/]

Similarly, the water system from the City of West Bend failed to act when high levels of PFAS were discovered in its drinking water in January of 2020. More than two years later, when one the Commenters learned of the results through a public records request and alerted WDNR of the issue, the water utility was forced to publish a public notification. [FN42: Wisconsin Examiner, Water utilities must act quickly and transparently to address PFAS contamination: Commentary by Jorge Roman-Romero (July 5, 2022), https://wisconsinexaminer.com/2022/07/05/water-utilities-must-act-quickly-and-transparently-to-address-pfas-contamination/] However, the public notification was framed more as a public relations document than a warning, titled: "City of West Bend Water Utility Proactively Conducts Voluntary Municipal Well Sampling for PFAS." [FN43: City of West Bend, City of West Bend Water Utility Proactively Conducts Voluntary Municipal Well Sampling for PFAS (June 7, 2022), https://www.ci.west-bend.wi.us/news_detail_T41_R205.php] Additionally, the notification contained misleading statements about the timing of the protective actions taken by the utility:

"Three wells … detected PFAS. Well #4 was the only well to indicate levels above the Wisconsin Department of Health Services and U.S. Environmental Protection Agency's non-regulatory health advisory levels in drinking water. It was immediately shut down."

Contrary to an immediate response, it took a public records request and extensive back-and-forth between the water system and WDNR for the notification to be issued and the protective action to be taken.

EPA Response: The EPA acknowledges the commenters' submission of information about challenges faced in Wausau and West Bend, Wisconsin with respect to disseminating information on PFAS contamination and the implementation of state PFAS requirements. Following the compliance dates for the final PFAS NPDWR, water systems will be required to implement the public notification requirements summarized in section IX.B.3 of the preamble for this action which will eliminate the need for a public records request or an extensive back and forth with the state for the notification to be issued. These PN requirements will apply to water systems that supply finished drinking water treated by PWSs.

Midwest Environmental Advocates +more (Doc. #1846, SBC-045836)

III. EPA Should Issue a Right-to-Know Guidance for Water Systems to Use When Required to Notify the Public About PFAS Detections.

Commenters urge EPA to issue guidance for water systems to use when informing their consumers about health risks posed by PFAS detections in their drinking water. Recognizing the public's right-to-know as an integral principle of public health protection, the SDWA contains provisions [FN36: 42 U.S.C. 300g-3(c).] aimed at "educat[ing] the American people about the risks they face from a particular contaminant" because "[p]ublic notification is a powerful force for prevention." [FN37: See also Senate Environment and Public Works Committee (104th Congress), Senate Report on S. 1316, Safe Drinking Water Amendments Act of 1995 (Nov. 7, 1995), https://www.congress.gov/congressional-report/104th-congress/senate-report/169] To this

end, EPA should use its authority to urge water systems to communicate effectively about PFAS detections and their risks.

EPA Response: Please see section 9.1 of the EPA response in this *Response to Comments* document for discussion of CCR requirements and section 9.2 of the EPA response in this *Response to Comments* document for discussion of PN requirements. Additionally, as the EPA develops implementation materials following final rule promulgation, the agency will consider additional resources to support states and water systems for notifying their customers.

10 Treatment Technologies

10.1 Best Available Treatment Technology Identification and Evaluation

Summary of Major Public Comments and EPA Responses

The vast majority of comments germane to the Best Available Treatment Technology (BAT) designations support the EPA's designation of granular activated carbon (GAC), anion exchange resin (AIX), and high-pressure membranes (such as nanofiltration [NF] and reverse osmosis [RO]) as BATs that are technologically feasible for treating drinking water to the proposed standards or below. Many commenters shared practical experience with installed treatment including successes, costs, implementation considerations, challenges, and other areas. The EPA agrees that GAC, AIX, RO, and NF are BATs and consistent with the criteria outlined in the *Best Available Technologies and Small System Compliance Technologies for PFAS in Drinking Water (BAT/SSCT)* document (USEPA, 2024a) for identifying "feasible" treatment for PFAS in this rule, and the comments providing information on practical full-scale experience with these technologies further support this finding.

A few commenters suggested either that the designated BATs could not treat to or below the Maximum Contaminant Level (MCL) or that not enough data was available to support the conclusion that the BATs could treat to at or below the designated MCL. The EPA disagrees with these commenters based on the history of full-scale use as documented in the BAT/SSCT document, the information in the proposed and final rule preambles, as well as in the comments that provided full-scale data as well as case studies. For example, commenters highlighted more than 45 military installations that have treated PFAS, including those in this rule, successfully for more than 15 years, a major water treatment company provided information on over 150 successful installations they had performed, and comments supported that there are significant numbers of industrial users successfully treating PFAS, including those in this rule. One commenter noted the example of the Chemours Fayetteville facility, which used GAC to eliminate PFAS, including those in this rule, as high as 345,000 ng/L and has reduced PFAS in effluent to non-detect levels for several PFAS. Finally, the Water Quality Association (WQA) reviewed proprietary performance data from its accredited laboratory, which demonstrates that this standard is feasible for the BATs selected to effectively remove the PFAS regulated in this rule from drinking water.

Many commenters pointed out site-specific issues with particular BATs. The EPA acknowledges that not every BAT represents the best treatment option for an individual system and site-specific considerations can limit BAT selection. For instance, residuals management considerations can limit the choice of RO/NF, particularly in states with limited water resources. While many commenters agreed that high pressure membranes such as RO and NF can remove the six PFAS in the final National Primary Drinking Water Regulation (NPDWR), many commenters also suggested that high pressure membranes may not be the most feasible treatment option for some systems because of residual management considerations, which are discussed in the residuals

management section below. There are, however, documented RO/NF facilities for treating PFAS in California, Illinois, North Carolina, and Alabama (USEPA, 2024a). In response to public comment and residual management concerns surrounding high pressure membrane technologies, the EPA has adjusted RO/NF's technology projection compliance forecast to 0 percent in the Economic Analysis (EA). While the EPA is not including any water systems selecting RO/NF installation to comply with the PFAS NPDWR, it remains a BAT for water systems to consider. For additional details on the EPA's EA, please see section XIII.

The EPA also acknowledges that due to technical site-specific considerations, some BATs may not be the best choice for particular water types. The final NPDWR does not require the use of any specific BAT and systems may choose other treatment or non-treatment approaches (e.g., connecting to new source waters) to comply with the rule. PFAS treatment option selection should consider conditions for a given utility, including water quality, available space, disposal options, local rules, and currently installed unit operations. For example, AIX may be the preferred technology for some utilities based on expected treatment needs, while others may select GAC or other technologies. However, as many commenters indicated, the BAT designations are appropriate for all public water systems (PWSs) across the country.

Several commenters pointed out that GAC may release arsenic at levels exceeding arsenic's MCL temporarily when installed and upon changing media, deleteriously impacting finished water quality. While the EPA has documented challenges surrounding GAC and arsenic (USEPA, 2024a), the EPA disagrees that the arsenic release poses an exposure concern so long as appropriate procedures are followed. Those procedures include discarding the initial bed volumes (BVs) after installation or replacement of media. The quantity of treated water discarded can be significant (e.g., as high as 350 BVs as one commenter noted). However, this amount of discarded water is low in comparison to the normal service life between GAC replacement, which is approximately 84,000 BVs or approximately about 0.5 percent of the total treated volume. The total water volume discarded is also low in comparison to water loss through leaks across the United States, which account for about 15 percent of treated water or what would be approximately 12,600 BV equivalents for this system. While conserving water is a significant issue, the water discarded due to GAC applications is relatively low. Systems can reduce water discard associated with BAT implementation by using acid washed and/or prerinsed GAC or using buffered/pre-flushed resins for AIX. Any treatment technology can create problems if improperly maintained and operated. Finally, GAC has been statutorily designated as "feasible for the control of synthetic organic chemicals," such as PFAS, in the Safe Drinking Water Act (SDWA) Section 1412(b)(5).

Many commenters pointed out the need for increased research, technological innovation, and guidance in treating drinking water for PFAS. The EPA's final rule represents data-driven drinking water standards that are based on the best available science and meet the requirements of the SDWA. For the six PFAS, the EPA considered PFAS health effects information, evidence supporting dose-additive health effects from co-occurring PFAS, as well as national and state data for the levels of multiple PFAS in finished drinking water. SDWA provides a framework for

the EPA to regulate emerging contaminants of concern in drinking water. Under the statute, the EPA may act based on the "best available" science and information 42 U.S. Cod § 300g–1(3)(A)(i). Thus, the statute recognizes that the EPA may act in the face of imperfect information and provides a mechanism for the EPA to update standards as more science becomes available. The available information is sufficient to finalize the BATs as proposed but EPA agrees that more research may be beneficial (USEPA, 2022a). With respect to the EPA's request for public comment on additional guidance materials that would be helpful to support successful technical implementation of the rule, the EPA received many comments related to the need for technical materials to support rule implementation. The agency plans to look to suggestions from states, technical assistance providers, industry associations, and interested stakeholders following the rule promulgation to provide technical materials that can assist water systems in complying with the regulations, which is further discussed in section 1.2 of the EPA's response in this *Response to Comments* document. The EPA is currently funding many technical assistance efforts associated with PFAS, including supporting treatment infrastructure projects through the Drinking Water State Revolving Fund (DWSRF) and the Emerging Contaminant in Small or Disadvantaged Communities (EC-SDC) grant program as designated and funded through the Bipartisan Infrastructure Law (BIL). Please see section 2.4 of the EPA's response in this *Response to Comments* document for further discussion on funding.

Many commenters stated that permitting needs to be streamlined and that more assistance should be proffered to primacy agencies, utilities, and other interested stakeholders. While SDWA does not require permits, state and local authorities often require permits for the installation of treatment facilities at water systems. The EPA has developed supporting documents such as the *Best Available Technologies and Small System Compliance for Per- and Polyfluoroalkyl Substances (PFAS) in Drinking Water* document (USEPA, 2024a) that can be used to help permitting authorities develop more familiarity with these technologies over time. The agency plans to look to suggestions from states, technical assistance providers, industry associations, and interested stakeholders following the rule promulgation to provide technical materials that can assist water systems in complying with the regulations.

Many commenters questioned how the BATs were identified, evaluated, and selected in the final rule. Additionally, some of these commenters expressed concern with the costs of implementing and operating these technologies. Section 1412(b)(4) of SDWA requires that the agency "list the technology, treatment techniques, and other means which the Administrator finds to be feasible for purposes of meeting [the MCL]," which are referred to as BATs. The EPA used the following criteria for identifying "feasible" BATs: (1) The capability of a high removal efficiency; (2) a history of full-scale operation; (3) general geographic applicability; (4) reasonable cost based on large and metropolitan water systems; (5) reasonable service life; (6) compatibility with other water treatment processes; and (7) the ability to bring all the water in a system into compliance. As part of this analysis, the agency considered costs of BATs that have been demonstrated under field conditions to be effective at removing the PFAS regulated by the NPDWR and determined that the costs of complying with the MCLs are reasonable for large and metropolitan water systems at a system and national level as described in section 4 of the EPA response in this

Response to Comments document (see *A Legislative History of the Safe Drinking Water Act*, Committee Print, 97th Cong., 2d Sess. (1982) at 550). Pursuant to SDWA § 1412(b)(4)(ii), the agency also evaluated "technolog[ies], treatment technique[s], or other means that [are] affordable" for small PWSs. In this evaluation, described further in section 10.5, the agency determined that the costs of SSCTs are affordable for households served by small drinking water systems. Therefore, the EPA disagrees with commenter concerns that the agency did not adequately consider costs in establishing the final MCLs with respect to treatment feasibility. The EPA's final rule represents data-driven drinking water standards that are based on the best available science and meet the requirements of SDWA. In the final rule, the EPA is codifying GAC, AIX, NF, and RO as BATs. For additional discussion on MCLs, please see section 5 of the EPA response in this *Response to Comments* document.

Many commenters requested or recommended additional guidance to support implementation of the final NPDWR, including technical materials related to treatment technologies. After finalization of the PFAS NPDWR, the EPA also intends to provide support to utilities, primacy agencies, and other interested parties to ensure successful rule implementation and plans to consider the topics suggested by the commenter as the agency develops implementation materials for the final NPDWR.

Individual Public Comments

Richard Kinch (Doc. #1503, SBC-042572)

As an ex-EPA employee that worked for decades on assessing technology performance, I have concerns regard the rigor of data gathering associated with technology performance, especially the lack of EPA sampling at full scale operations. Without better data, there is little means to judge whether EPA's conclusions have merit. EPA should expedite a sampling program and notice the data and further analyses, and reopen the comment period. Further details are provided in the attached file.

See attached file(s)

Comments on EPA's Proposed PFAS National Primary Drinking Water Regulations

By Richard Kinch

As an ex-EPA employee of 41 years, I have some general comments regarding treatment technologies as addressed in the proposal. (While I have engaged in consulting activities, these comments are simply my personal opinion, as I am currently not engaged in consulting.)

As a general matter, I expected to see much more in the way of information in Section XI. Treatment Technologies of the preamble. The sparce information seems to reflect that project managers were focused on the risk assessment, and did little work on treatment technologies – perhaps just quickly throwing together a minor literature search to get the proposal out as scheduled, or not looking at the treatment technology section as important. The treatment

technology section, however, is of significant importance, as it determines whether the risk based criteria can be met, and whether the cost can be justified. As with addressing Lead in drinking water, the Agency needed to look at what treatment technology could reasonably do to set an achievable requirement. Over time, I have seen risk criteria get lower and lower. As that happens, EPA will more frequently encounter circumstances where intended risk-based regulations must make treatment technology-based compromises. When dealing with parts per trillion for PFAS, the treatment technology work should clearly be robust.

Stepping back in the project's timeline, it is easy to identify a set of steps that should have been taken which are common to the Agency's regulations assessing treatment technologies – for water, air, and solid waste. EPA should have conducted their own sampling and analysis of full-scale treatment operations, and collected whatever long-term self-monitoring data is available at the full-scale treatment operations (long-term performance data would be most helpful in assessing treatment variability, and is commonly assessed in treatment technology assessments by the Agency). I must admit a significant degree of surprise to find no reference to EPA actually going out and doing some basic sampling and analysis (or gathering long-term self-monitoring). The Agency's "suppositions" regarding treatment technologies maybe correct, but in providing comment I simply cannot made a sound conclusion in the absence of appropriate data. The importance of this rule makes doing the basic and appropriate data development essential. Publishing a proposal and asking for comment is not an adequate substitute for EPA's responsibility to gather appropriate data. My overarching comment, therefore, is that EPA did not develop adequate treatment technology data, and should expedite going out to full-scale treatment operations and conducting sampling and analysis, and should also gather long-term self-monitoring from full-scale treatment operations. The additional information should then be provided to the public in a notice of data availability with an opportunity for public comment.

Below are some additional points of concerns which follow the basic framework the Agency's provided:

The Agency identifies the BATs as those meeting the following criteria:

(1) The capability of a high removal efficiency;

(2) a history of full-scale operation;

(3) general geographic applicability;

(4) reasonable cost based on large and metropolitan water systems;

(5) reasonable service life;

(6) compatibility with other water treatment processes; and

(7) the ability to bring all the water in a system into compliance.

• The threshold issue with regard to treatment technologies is whether the Agency can adequately assess technology performance, as it would occur on a full-scale and long-term basis,

by solely doing a literature search. The essence of the issue is that the literature tends to be research studies trying to estimate what the treatment technologies can achieve, while sampling and analyses of the actually full-scale operations by EPA would give the actual performance. This is a bit like the difference between looking at political polls, versus counting the votes. Maybe in some cases the polls are so clear that the vote counting seems unnecessary, but largely, it is an essential part of the process. I worked on technology-based regulations in the Effluent Guidelines program in the Office of Water, and technology-based regulations for hazardous wastes and air emissions. None of my experiences would have supported the trivial effort provided in the proposal with regard to the PFAS technology-based assessment with no actual EPA sampling program of real-world performance. The literature search provides useful information to better understand and interpret full-scale and long-term data that EPA should directly gather (including self-monitoring data), but is not a justification for EPA avoiding directly gathering of such information.

• As a general matter I suspect it is easier for literature research projects to show better results. One can only speculate on the causes for such outcomes, but somethings that come to mind are: where the literature is not full-scale, it is just easier to refine the setup; for literature from treatment manufacturers (or funded by) the selection of what gets tested and published can be subject to self-interests (if a manufacturer has two case studies, one of which has much better results, it would not be surprising that they only publish the good one); if a manufacture of treatment media knows that a literature research project maybe particularly important to their financial future, they might make extra efforts to provide the highest quality product for the short-term testing (when I was addressing wastewaters for the automotive industry, I learned of a case where the corporate quality control checkers uncovered a problem – the inspection date was known and the facility to store a collection of the highest quality parts, so that all the cars coming off the assembly line on inspection day, were of the highest quality and did not represent overall production); there may also be some differences when those with doctorates publishing research articles are involved versus normal facility staff.

• In a similar manner there can be temptations and bias by EPA's in the selection of which literature to reference and which pieces of data to use in the selected references. There is no acknowledgement of data not achieving the limit or explanation for such dismissal. Typically, robust data gathering and analyses presents complexities that need to be addressed. By avoiding an EPA sampling effort, and apparently focusing the data selection on what was desired, the need to address complexities just never appears. When EPA properly conducts sampling of full-scale long-term treatment technologies, there is more appropriate performance data, and the opportunity to obscure how data maybe skewed is greatly diminished. Strange things may or may not happen, but they are a possibility (like a political poll that is flat out wrong). The necessary way to insure EPA as well as public understands the actual treatment performance in a production setting is to get into the field and do the sampling and analyses work to obtain that information (including getting whatever long-term self-monitoring data is available).

• Each regulated parameter should be addressed individually for each of the 7 BAT criteria. There appears to be reasonable references in literature that these types of chemicals do not behave in an identical manner during treatment, and thus there is a need for parameter specific support. This should include identification of actual data supporting conclusions (summary information in the Preamble and details in supporting documents).

• There is an inference that there is a "history of full-scale operations". The preamble should provide summary data on the known full-scale treatment operations, with the facilities and their treatment technologies identified in supporting documents, along with what parameters they are treating. Full-scale treatment technology data should be weighed far more heavily than lab-scale information. The lack of information presented in this area opens up the speculation that the "history of full-scale operations" may be weaker than implied. The problem with inferences, instead of full disclosure of data, is if an inference is found to be wrong, it undermines trust.

• The assessment of the various technologies expresses a common theme – the technology "can" or "may" achieve >99% removal and meet the 4 ng/L limit. The "ability to bring all the water in a system into compliance" is a determination that warrants far more than what appears to be using blinders to focus only on the data that supports a desired outcome. In July 2022 GAO issued a TECHNOLOGY ASSESSMENT (Persistent Chemicals, Technologies for PFAS Assessment, Detection, and Treatment) that was provided to Congress, which stated: "The currently available technologies for removal of PFAS from water vary in effectiveness, but all can remove up to 90 percent or more of certain PFAS (see table 4), which are easier to remove from water than other PFAS." The GAO characterization (which I also find lacks detail), acknowledges some complexities, appears to reach conclusions which differ from EPA's conclusions, signals the need for some significant work on treatment technologies in EPA's regulatory effort.

• There are certifications such as NSF/ANSI 53, which cover drinking water treatment devices, and include consideration of PFOA and PFOS. They have been certifying the ability to meet 70 ng/L. In conducting their tests, they may have results on performance of various systems. They may have a major trove of data on PFOA and PFOS for drinking water treatment devices. There seems to be no reference to that data – if such certifications apply to full-scale systems, perhaps that is another source of data EPA could gather.

• In conducting assessments of treatment technologies, data should be provided on the range of influent concentrations for each parameter. Of course, treatment of a parameter that starts below the regulatory level is largely meaningless, while, in general, the higher concentrations are more meaningful in assessing the ability of technologies to fully meet the target. Clear disclosure should be provided that demonstrates that the high-end influent concentration will be successfully treated to achieve the regulatory criteria.

• Treatment System do not operate at a single performance level. With time there are changes in the influent characterization and maybe the treatment system itself. In addition, the simple matter of taking a sample, splitting it, and having it analyzed two or more time can result in somewhat

different answers. In all technology-based regulatory efforts at EPA for which I was involved there would be an assessment of variability (i.e., how much higher a maximum daily value is versus the long-term average – such variability factors vary significantly depending on the treatment and parameter. During my work in EPA's Effluent Guidelines programs variability factors were often in the 3.5X to 4.5X.) For the PFAS proposal, the whole consideration of variability of treatment performance appears to be missing. This is where efforts are needed by EPA to gather long-term self-monitoring data, conduct the appropriate analyses, and provide notice and comment.

• If the thought process by the Agency is that these types of technologies can just be run with more media or longer detention times to achieve whatever result is desired, even if it is outside the realm of normal design, EPA maybe moving outside the scope of systems that have historic full-scale systems, and the cost of such treatment. I suggest the proper process is more in line with getting the performance data on full-scale systems in operation.

• With such a minimal treatment technology presentation in the proposal, it does raise fundamental concerns that a robust presentation of data might not support the proposal. Sometimes giving an issue a minimal presentation helps make the issue go unnoticed, with commenters focusing on the items EPA focuses on, and a critical issue can be missed during the review and even in litigation. (While sometimes effective, if intentional, such actions are inconsistent with good governance.) The Agency may have the right conclusion with regard to treatment technologies, but the proposal does not present adequate support. After adequate data are gathered and fully assessed, then one can determine if the criteria can be met using the identified technologies and assess the appropriate costs. If there is not sufficient treatment technology support for each of the regulated parameters, then a structure along the lines of the drinking water requirements for Lead would be worth considering.

While I care about helping to get this issue dealt with correctly, I devoted a very limited time to providing these comments. I appreciate the importance of the issue, and hope you will deal with doing the significant and necessary work and making the appropriate changes.

One ancillary thought… EPA regulations tend to be divided into 2 paths. The development of some regulations follows a risk-based path (what do we need to be protective), while the others a technology-based path (what can technology achieve). In addressing PFAS, the Agency was essentially following the risk-based path. The problem is that in the end, the Agency needs a finding that there is treatment technology has the ability to bring all the water in a system into compliance (with some accompanying cost and economic impact work). This brings about the need to essentially perform a typical technology-based assessment. The Agency could do a very minimal technology-based assessment if it is clear that the treatment technology would bring the Agency to an even lower level. Based on the information provided with the proposal, EPA has not provided adequate support on the treatment technologies being able to bring all the water in a system into compliance with the proposed criteria. The Agency doesn't necessarily need to do a full technology-based assessment to get the answer, but the nature of the many decades of technology-based project studies by EPA provide good guidance on what to do. An appropriately

meaningful path was just not taken for this proposal, but as stated earlier, EPA can and should expedite appropriate data development and analyses, and provide additional notice and comment.

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document. Additionally, the EPA disagrees with many of the comments leveled here. In particular, the EPA disagrees that the agency did not appropriately evaluate technology performance when establishing the final standards. The EPA assessed feasibility in accordance with the SDWA when setting the MCL. Under current law and as described in the proposed rule (USEPA, 2023a), the EPA establishes drinking water standards through a multi-step process. *See* S. Rep. No. 169, 104th Cong., 1st Sess. (1995) at 3. First, the agency establishes a non-enforceable Maximum Contaminant Level Goal (MCLG) for the contaminant in drinking water at a level which no known or anticipated adverse effects to the health of persons will occur and which allow for an adequate margin of safety. Second, the agency generally sets an enforceable MCL as close to that public health goal as feasible, taking costs into consideration. In this second step, consistent with the definition of "feasible" in Section 1412(b)(4)(D), the EPA evaluates the availability and performance of BATs for treating water to minimize the presence of the contaminant consistent with the MCLG as well as the costs of applying those BATs to large and metropolitan water systems when treating to that level (1412(b)(4)(E) and (5)). [1] The definition of "feasible" means feasible with the use of the best technology "which includes consideration of the analytical limits of the best available treatment technology." (Emphasis added); *see also* Section 1401(1)(C)(i) stating that a NPDWR includes an MCL only "if, in the judgment of the Administrator, it is economically and technologically feasible to ascertain the level of such contaminant in water in public water systems." The EPA disagrees that the agency should not rely upon peer-reviewed literature to assess the effectiveness of technologies and should use and perform sampling itself as SDWA section 1412(b)(3)(A) requires that the agency use "(i) the best available peer reviewed science and studies conducted in accordance with sound and objective scientific practices; and (ii) data collected by accepted methods or best available methods." As a result of these analyses and in consideration of these factors, the agency has determined that multiple treatment technologies (e.g., GAC, AIX, NF, and RO) "examined for efficacy under field conditions and not solely under laboratory conditions" are found to be both effective and available to treat the six PFAS to the standards and below.

The commenter states that they expected "much more in the way of information in Section XI. Treatment Technologies of the preamble," The EPA conducted an extensive analysis of the best available peer reviewed science and studies conducted in accordance with sound and objective scientific practice to identify these BATs. The agency's evaluation of that scientific information is summarized in three documents supporting the final NPDWR: the *Best Available Technologies and Small System Compliance Technologies for PFAS in Drinking Water* document, the *Technologies and Costs for Removing Per- and Polyfluoroalkyl Substances from Drinking Water*

[1]Based on legislative history, the EPA interprets "taking cost into consideration" in Section 1412(b)(4)(D) to be limited to "reasonable cost based on large and metropolitan drinking water systems;" (see A Legislative History of the Safe Drinking Water Act, Committee Print, 97th Cong., 2d Sess. (1982) at 550).

document, and the *Drinking Water Treatability Database*. As this information is already publicly available in the EPA publications that were referenced in the docket at proposal, there is no need to duplicate already freely accessible tables and figures. The proposed and final rules were written clearly and concisely, which ensured that information was comprehensive, informative, and understandable, and ensured that supporting documents contained more explanatory information and data. The *Technologies and Costs for Removing Per- and Polyfluoroalkyl Substances from Drinking Water* document covers 321 pages by itself, not all details could be covered in the preamble to the proposed and final rules. For example, table 4 in the BAT/SSCT document provides a breakdown of perfluoroalkyl carboxylic acids treated by GAC detailing compound name, backbone length, number of bench, pilot, and full-scale studies with maximum removal efficiency and provides the data sources for this information. Analogous tables exist for other kinds of PFAS, such as perfluoroalkyl sulfonate acids, and treatment technologies such as AIX. The BAT designations were supported by a number of commenters that described practical, real-world, full-scale experience with these treatment technologies.

The EPA disagrees with the commenter's assertion that the agency's data on treatment performance was biased toward data that technologies were effective. The EPA considered all data that met applicable requirements, including data that showed poor removal. The EPA agrees with the commenter that technology performance can be variable. The rule proposal mentioned that the effectiveness of media-dependent processes decreases as the media is used or with specific water quality considerations. As noted in the *Drinking Water Treatability Database,* some full-scale studies found PFAS concentration in treated water equaled or exceeded that of the raw water where the media had been in service for a long period (e.g., at least 12 months up to more than 6 years) without regeneration or replacement. The negative removal efficiency was attributed to desorption of previously adsorbed PFAS. Full-scale studies with more frequent replacement showed successful contaminant removal.

The commenter also references the National Sanitation Foundation/American National Standards institute (NSF/ANSI) standard 53 as a potential information source on treatment. These NSF/ANSI standards apply to point of use (POU) and point of entry (POE) devices, not full-scale treatment. That information is not publicly available and treated as confidential business information by the certification organizations. EPA further notes that technologies can work differently at different scales, which is part of the justification for why the SDWA requires technologies to have a history field use 42 U.S. Cod § 300g–1(b)(4)(D). The testing is often done by third parties such as the WQA, who submitted comment Doc. #1694, SBC-044986 in section 10.5 stating "product performance data produced by the WQA's accredited laboratory suggests that the POU/POE water treatment industry may already have multiple products that can reduce PFAS chemicals to near or below the proposed MCL."

In promulgating this NPDWR, the EPA followed applicable procedures and requirements described in SDWA, including those related to the use of the best available, peer-reviewed science and supporting studies as well as data collected by accepted methods. EPA also points out that the SDWA does not require the collection of treatment performance data by the EPA.

When developing technology-based standards under the Clean Water Act (CWA), the agency relies on industry-supplied data and samples are not always collected by the agency. Potable water, which is governed by the SDWA, has a much narrower band of influent characteristics than effluent from industrial processes, which are governed by the CWA. As noted, SDWA section 1412(b)(3)(A) requires that Agency use "(i) the best available peer reviewed science and studies conducted in accordance with sound and objective scientific practices; and (ii) data collected by accepted methods or best available methods." The commenter is also incorrect in stating that the rule is solely a risk-based rule; as explained above and in the preambles to the proposed and final rule, as well as required by 42 U.S. Cod § 300g–1(b)(4)(B), feasibility and performance of treatment technologies were taken into account. More information on the MCL can be found in section 5.

Maine Water Utilities Association (MWUA) (Doc. #1567, SBC-042734)

Treatment Considerations:

EPA is proposing MCLs for PFOA and PFOS at 4 ppt and a Hazard Index approach for four other PFAS compounds: perfluorohexane sulfonic acid (PFHxS), hexafluoropropylene oxide dimer acid (HFPO-DA) and its ammonium salt (also known as a GenX chemicals), perfluorononanoic acid (PFNA), and perfluorobutane sulfonic acid (PFBS) with a MCLG of 1.0. NEWWA is unfamiliar with the Hazard Index approach. While perhaps common in the Superfund program, it has never been used under the Safe Drinking Water Act before. We are concerned that a cumulative regulatory approach ignores the complexities of selecting, implementing, and operating the appropriate and affordable PFAS treatment solutions.

There are a limited number of drinking water treatment technologies that are currently known to be effective for PFAS removal. However, there is no one-size-fits-all solution. Depending on several site-specific factors, such as the concentrations and types of PFAS present in the source water(s), general water quality characteristics, and existing treatment processes, treatment technologies may show different removal effectiveness for the varying carbon chain lengths and attached functional groups. EPA needs to provide flexibility within this regulation to allow for expansion of treatment options as technology progresses. Advancement in Best Available Technologies (BATs) will be made, and EPA and primacy states need to be positioned to swiftly approve new BATs.

EPA Response: Please see sections 10.1 and 10.3 of the EPA response in this *Response to Comments* document. The EPA agrees that there are several site-specific factors that will dictate the appropriate strategy for distinct locations and referenced this in the rule proposal preamble, which in section VI.B states for example "PFAS are well documented to co-occur, the exact chemical composition is often site-specific in nature." The EPA also agrees that each technology works differently depending on the factors the commenter enumerated, which were also stated in the proposed rule preamble in section XI.B. The *Best Available Technologies and Small System Compliance Technologies for PFAS in Drinking Water* document as well as other

available guidance recommend pilot testing to aid in determining the best solution for a given location and acknowledge that sometimes external factors such as limited space may dictate a different treatment train than the optimal engineering approach. The EPA also agrees that there will be advances made in BATs. It is important to note that flexibilities requested already exist as water systems may use any technology or practice to meet the PFAS MCLs and are not limited to the BATs in this rule. Other technologies may be chosen in lieu of BAT because they may be more cost effective or better suited to the specific operating conditions of the particular site to meet the MCL.

Regarding the commenter's concern that a "cumulative regulatory approach ignores the complexities of selecting, implementing, and operating...PFAS treatment solutions," the Hazard Index approach does not ignore these complexities. The Hazard Index imposes no burdens or restrictions on selection of treatment technology by itself, which would differ from individual MCLs for these chemicals, for example. The BATs discussed above have all been demonstrated to be effective in removing all six PFAS finalized for regulation as part of this rulemaking albeit to differing degrees. Additionally, the process integration for all BATs is similar. While sites may wish to choose differing integrations, it is likely that most will be post traditional media filters; BATs may also require some post treatment adjustment. Further, since these same technologies also remove other long-chain and higher carbon/higher molecular weight PFAS, the EPA expects this rulemaking will provide additional public health benefits and protection by removing unregulated PFAS that may have adverse health effects, which is discussed further in section 10.3.

Minnesota Pollution Control Agency (MPCA) (Doc. #1569, SBC-042494)

Section XI – Treatment technologies

Topic: Part A, best available technologies or BATs, includes non-treatment options such as finding an alternate source of drinking water (e.g. drilling a new well) or purchasing water from another facility.

MPCA comments: It is important to note that compliance with SDWA for PFAS contamination using alternative drinking water sources (other aquifers or water systems) may pose longer term risks to the drinking water supplies due to hydrogeologic principles of interconnectivity between aquifers and reliance on these other sources may in fact, exacerbate the spread of PFAS in the subsurface due to water well pumping influence. This potentially poses a risk to future generations drinking water resources.

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document. The EPA encourages water utilities to carefully consider all options and identify risks associated with the various alternatives for MCL compliance (such as non-treatment options). Water systems should consider the impacts of new source water wells on existing PFAS contamination plumes before selecting this option.

Association of State and Territorial Solid Waste Management Officials (ASTSWMO) (Doc. #1583, SBC-042403)

[Overall, as movement is made toward better regulation and oversight of these contaminants, ASTSWMO's membership recognizes a corresponding need for research, communication, and improved understanding within the following areas:]

• drinking water, soil, and wastewater treatment technologies;

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document. The science is currently sufficient to finalize the NPDWR as documented in sections 4 and 5 of the EPA response in this *Response to Comments* document. The EPA is currently funding many technical assistance efforts associated with PFAS, including supporting treatment infrastructure projects through the DWSRF and the Emerging Contaminant grant program as designated and funded through the BIL. The agency has been collaborating with states, technical assistance providers, industry associations, and interested stakeholders to provide technical materials that can assist water systems in complying with the regulations, as well as outreach efforts to help develop technical and operator capacities. As outlined in the PFAS Strategic Roadmap, the EPA is committed to addressing PFAS. The Office of Research and Development (ORD) is also evaluating and developing technologies for reducing PFAS in the environment to inform decisions on drinking water and wastewater treatment, contaminated site cleanup and remediation, air emission controls, and end-of-life materials management.

Washington Suburban Sanitary Commission (WSSC Water) (Doc. #1585, SBC-042778)

Feasibility of NF/RO:

WSSC Water concurs with EPA's assessment that the disposal of PFAS-contaminated reject water presents a challenge for the viability of NF/RO treatment for many water systems. Additionally, we agree that the operational costs of NF/RO are likely to be higher than those of GAC due to the handling of the reject water. If water systems are unable to dispose of the concentrated reject waste to a brackish water or a sanitary sewer, NF/RO may not be a feasible option. We urge EPA to consider these technological constraints when determining the practicality of regulating PFAS at the proposed MCLs.

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document. For additional information on disposal concerns including how they were considered when setting the MCL, please see sections 10.4 and 5.1 of the EPA response in this *Response to Comments* document. Not every BAT represents the best treatment option for an individual system and site-specific considerations can limit BAT selection. Indeed, the EPA states that the reject water "will require disposal or additional treatment" in the rule proposal section XI.A.3. Additionally, the *Best Available Technologies and Small System Compliance Technologies for PFAS in Drinking Water* document contains more information on reject water disposal. However, there may be water systems where disposal of the reject water is feasible,

therefore, the agency has listed NF and RO as BATs and expects that water systems will consider their site-specific decisions when deciding between these BATs and other BATs such as GAC and AIX that do not require disposal of reject water.

Cape Fear Public Utility Authority (CFPUA) (Doc. #1588, SBC-042378)

May 26, 2023

Via U.S. Mail and online submission at Regulations.gov

U.S. Environmental Protection Agency

EPA Docket Center

Docket ID No. EPA-HQ-OW-2022-0114, PFAS: PFOA and PFOS NPDWR

Mail Code 28221T

1200 Pennsylvania Avenue, NW

Washington, DC 20460

Re: Comments on Docket ID No. EPA-HQ-OW-2022-0114, PFAS: PFOA and PFOS NPDWR

Cape Fear Public Utility Authority (CFPUA) provides drinking water to approximately 200,000 people in the City of Wilmington and unincorporated New Hanover County in North Carolina. About 80 percent of CFPUA's drinking water is sourced from the Cape Fear River. In 2017, our community learned chemical manufacturer Chemours (and its predecessor, DuPont) had for many years been discharging per- and polyfluoroalkyl substances (PFAS), including GenX, into the Cape Fear River upstream from our raw water intakes. CFPUA's Sweeney Water Treatment Plant, which treats raw water sourced from the Cape Fear River, is considered among North Carolina's most sophisticated water treatment plants. At the time, however, it was unable to treat for PFAS, so Chemours' PFAS in the river also was in our community's finished drinking water.

In the five years since this revelation, CFPUA:

• Conducted pilot testing to compare granular activated carbon (GAC), ion exchange resin, and reverse-osmosis as potential permanent PFAS-removal options at Sweeney, with GAC emerging as the best solution;

• Began more frequent exchanges of GAC in existing biological filters as an interim step to provide some immediate PFAS removal in finished water; and

• Spent $46 million to design and construct eight new deep-bed GAC contactors, which began operating in fall 2022 and now effectively and consistently remove PFAS from finished drinking water to levels at or near non-detection.

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document. The EPA appreciates the commenter for providing their experience with installing a listed BAT as well as pilot testing other BATs to remove PFAS to levels at or near non-detection and some cost information.

New York Section American Water Works Association (NYSAWWA) (Doc. #1591, SBC-042372)

Has EPA conducted performance evaluations of current Best Available Technologies (BATs) to verify they can treat to levels below the proposed PQL of 4 ppt? It is critically important when suggesting BATs for future compliance, that adequate performance data available to assure systems that the use of a BAT will provide compliance.

EPA Response: Yes, please see section 10.1 of the EPA response in this *Response to Comments* document and supporting documentation such as the *Best Available Technologies and Small System Compliance Technologies for PFAS in Drinking Water* document and the *Drinking Water Treatability Database*.

Michigan Department of Environment, Great Lakes, and Energy (EGLE) Drinking Water and Environmental Health Division (DWEHD) (Doc. #1597, SBC-042989)

F. Treatment Technologies

Having reviewed Section XI of the proposed NPDWR, EGLE DWEHD agrees with EPA's proposed list of best available treatment technologies for PFAS removal in drinking water. These are largely consistent with those included in Michigan's SDWA for PFAS.

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document.

Water Works Board of the City of Birmingham (BWWB) (Doc. #1602, SBC-043647)

C. The EPA's Best Available Technologies (BATs) including GAC, IX, and NF/RO have inherent differences in the degrees to which they remove various PFAS species.

i. Liu et al (2022) evaluated the efficiency of NF and RO membranes for the removal of PFAS from water. While rejections of various species by RO membranes was high (>96%) and consistent across membrane types, rejection by NF membranes ranged from 25-100% for various species. The degree of analyte rejection is a function of the membrane type/product selected—therefore, it is possible that a product selected to effectively remove regulated contaminants today, may not be suitable for future regulated PFAS species.

ii. PFAS species/classes could be preferentially removed by one treatment versus another: Hayman et al (2023) assessed the efficacy of PFAS removal by several types of GAC (Calgon F400, Blacklite Pure Biochar) and IX products (Purolite PFA694E, Amberlite IRA958) and

found that IX was more effective than GAC at removing PFBS, PFHxS, and PFOS (the perfluoroalkyl sulfonic acids), whereas GAC was more effective as removing PFBA, PFHxA, and PFOA (the perfluorocarboxylic acids). This is another important consideration if additional PFAS are perhaps added to the regulation in the future. Analogous to membrane product selection discussed above, PFAS removal efficacy can vary between carbon and resin types (Zeng et al 2020; Dixit et al 2021).

iii. There are a reasonable number of full-scale GAC treatment studies investigating PFAS removal for several, but not all, of the species in the proposed PFAS rule. For instance, there is only 1 full scale study investigating GenX (HFPO-DA) removal by GAC (Table 6). If EPA is to consider regulation of additional PFAS compounds in the future, a similar lack of full-scale data is likely to be a challenge. It is recommended that additional full-scale studies be conducted to better understand treatment efficacy and variables that impact it.

Table 6: Number of Full-Scale GAC Treatment Studies in the Literature for UCMR3 PFAS Species that are in the Proposed PFAS Rule, adapted from USEPA.

[Table 6: See Docket ID EPA-HQ-OW-2022-0114-1602]

iv. Shorter chain PFAS are commonly more difficult to remove; Zeng et al (2020) demonstrated that shorter chain PFAS (specifically perfluorocarboxylic acid or perfluorosulfonic acid classes) always broke through before longer-chain species. If additional short-chain PFAS are added to the regulation, this could introduce new treatment challenges for systems sized to remove longer chain compounds.

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document. The EPA agrees that different technologies have different removal efficacies depending on site-specific conditions to include specific PFAS fingerprint at the site, water quality characteristics, and other considerations as well as specific operational conditions such as contact time, type of media used, time between media changeouts and other factors. The EPA stated these same facts in the rule proposal. The EPA also agrees, and also stated in the proposed rule, that shorter-chained PFAS tend to break through before longer-chained PFAS of the same family. For the specific case of RO/NF, unlike low pressure membranes, NF and RO systems are not manufactured as proprietary equipment and membranes from one manufacturer are typically interchangeable with those from others.

The EPA agrees that more research can help and is sponsoring this research in accordance with the comment. The EPA's final rule represents data-driven drinking water standards that are based on the best available science and meet SDWA requirements. Under the statute, the EPA may act based on the "best available" science and information. Thus, the statute recognizes that the EPA may act in the face of imperfect information and provides a mechanism for the EPA to update standards as more science becomes available. While there is only one full-scale study for HFPO-DA removal using GAC, as long as a technology been tested beyond the laboratory under full-scale conditions for other contaminants and the performance of the technology may reasonably be projected based upon other available treatment data, such as pilot data, it may be deemed a

BAT. There is no requirement for the application of a BAT to be demonstrated at full scale for each individual contaminant. The BAT must show effectiveness for the contaminant at least at bench or pilot scale, the technology is reasonably be expected to perform in a similar manner under field conditions regardless of aberrations due to scale-up factors is the requirement, and the technology has been demonstrated during field conditions. As GAC for HFPO-DA has been demonstrated at full-scale already *and* several pilot studies have been completed *and* this technology is well established in general as well as specifically for PFAS, changing the BAT designation or delaying the final rule for more data is not necessary.

American Water Works Company Inc. (Doc. #1608, SBC-043991)

Best Available Technology (BAT)

American Water agrees with the U.S. EPA's identification of granular activated carbon (GAC), anion exchange (AIX), and high-pressure membranes (reverse osmosis and nanofiltration (RO/NF)) as technologies that should be able to effectively treat PFOA and PFOS to 4.0 ppt or lower. We note, however, that while all three are discussed in the preamble, only GAC is listed as BAT in the rule language at 141.61(b). We also have concerns related to the cost and application of the different treatments as outlined in these comments.

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document. The EPA thanks American Water Works Company Inc. for its assessment that GAC, AIX, RO, and NF can treat PFOA and PFOS to 4.0 ppt or lower. *The Best Available Technologies and Small System Compliance for Per- and Polyfluoroalkyl Substances (PFAS) in Drinking Water* document delineates the BATs for this rule, the table in the Code of Federal Regulations at 141.61(b) is not a complete listing of BATs for the contaminants listed. The EPA amended § 141.61 by adding paragraphs (d) and table 5 to paragraph (d) to make clear the BATs for PFAS regulated by the NPDWR.

American Water Works Company Inc. (Doc. #1608, SBC-043994)

AIX Challenges in Surface Water Applications

To American Water's knowledge, there are not currently any non-regenerable AIX treatment systems being used in surface water treatment applications. American Water owns and operates one regenerable AIX nitrate removal system treating combined filter effluent in a surface water plant and is aware that some other large surface water treatment plants in the U.S. are equipped with this technology. However, regenerable AIX systems in surface water treatment plants may only operate seasonally and/or may only treat a portion of the plant flow. More importantly, regenerable AIX systems typically include a brief media backwash during each brine regeneration cycle, which may significantly reduce the risks posed by particulate fouling in a non-regenerable AIX treatment system that cannot be backwashed.

AIX resin manufacturers may not warrant their media systems unless water systems include upstream bag or cartridge filtration, which could add significant capital and operating expense and may be impractical to operate and maintain in large-scale applications. Presumably, the requirement for upstream cartridge filtration is to avoid the potential for the AIX media bed to become fouled or clogged with particulate matter that may increase pressure drop and lead to channeling, short-circuiting, or risk damaging the synthetic resin beads. As a point of reference, American Water operates several groundwater treatment facilities with inline bag or cartridge filters upstream of the resin and has found that moderate levels of iron and manganese, even as low as 0.3 ppm for iron or 0.05 ppm for manganese, can lead to frequent replacement of expensive filter cartridges.

American Water is currently pilot testing multiple non-regenerable AIX media for PFAS treatment in parallel with GAC and a proprietary absorbent media treating combined filter effluent at a surface water plant. At this installation, we have experienced several incidences of severe media fouling and associated high head loss with the AIX media despite having a 5-micron cartridge filter installed upstream of the pilot columns. It is currently unknown what is causing this fouling, but based on this limited experience, American Water has significant concerns with the viability of AIX in surface water treatment applications. Similarly, there is currently insufficient experience with proprietary media to know how they will operate over time. Accordingly, GAC may be the only practical treatment for the removal of PFAS in surface water treatment plants at this time. If so, this could put added pressure on the GAC supply and reactivation service industry. It also creates a challenge for drinking water utilities that may select a more expensive treatment approach because insufficient information is available to know if a seemingly lower cost technology will offer adequate reliability and operability.

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document. The EPA thanks the commenter for providing their experience with operating AIX treatment systems. The agency is aware of several systems that have chosen AIX as the most effective choice for that site; other commenters such as the New Jersey Department of Environmental Protection (NJDEP) have also provided experience of this. The EPA also acknowledges that due to technical site-specific considerations, some BATs may not be the best choice for particular water types. Both GAC and AIX treatment processes rely on adequate pretreatment to reduce any constituents that may accelerate contaminant breakthrough. Generally, AIX resin pretreatment should include influent pH adjustment to avoid scaling and optimize performance, total organic carbon reduction to prevent fouling, and control of influent total suspended solids. Additionally, other processes such as aeration may be employed to oxidize transition metals such an iron and manganese for removal by filtration prior to AIX or GAC treatment in groundwater. These pretreatment as well as pilot study/engineering costs are included in the EA, for more information on costs please see section 13. The EPA is aware and acknowledged in the proposed rule as well as in the *Best Available Technologies and Small System Compliance Technologies for PFAS in Drinking Water* document that costs for each technology will vary based on site-specific conditions, so what is affordable for one site may not make economic sense for another site. Please see section 10.6 of the EPA response in this

Response to Comments document for additional discussion on treatment technology availability and capacity. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions.

Colorado Water Utility Council (CWUC) (Doc. #1622, SBC-044045)

26. EPA requests comment on whether PWSs can feasibly treat to 4.0 ppt or below.

a. Treatment technologies exist to reduce PFOA and PFOS to 4.0 ppt or below. However other constituents are unknown at this time as they may not have been the target compounds in pilots or other studies. The main issue is the exorbitant costs that EPA has grossly underestimated. EPA needs to realistically consider the availability of treatment technology, treatment materials, labor, and timelines necessary to make appropriate changes at a treatment facility.

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions and 10.6. For discussion of the basis for EPA's cost estimates in the Health Risk Reduction and Cost Analysis (HRRCA), please see section 13 of the EPA response in this *Response to Comments* document.

Village of Woodbury (Doc. #1629, SBC-042959)

Additionally, it is not clear what treatment technologies effectively remove these PFAS to maintain compliance with the new rule.

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1608, SBC-043991 in section 10.1 in this *Response to Comments* document.

Village of Woodbury (Doc. #1629, SBC-042956)

10. The "EPA requests comment on whether PWSs can feasibly treat to 4.0 ppt or below"; in our view, this should be known with certainty prior to adoption of the proposed rule if only based on the potential economic impacts related to initiating engineering design and potentially construction efforts pre-maturely to avoid the potential of non-compliance in the face of defined source water allocation and availability constraints.

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document. In the final rule, the EPA had evaluated and presented full scale data of systems that treated to 4.0 ppt or below as discussed in the *Best Available Technologies and Small System Compliance Technologies for PFAS in Drinking Water, Technologies and Costs for Removing Per- and Polyfluoroalkyl Substances from Drinking Water,* and in the Drinking

Water Treatability Database. For additional discussion on how the agency considers analytic feasibility when establishing the MCL, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

Village of Woodbury (Doc. #1629, SBC-042950)

4. EPA has identified Granular Activated Carbon (GAC), Anion Exchange (AIX) Resins, and Nanofiltration (NF) and Reverse Osmosis (RO) as available technologies with effective removal capabilities. According to the information provided by the EPA, these are capable of treatment to concentrations below the analytical detection limits. This information is based on lab studies, pilot scale, and full-scale applications. In our view, the EPA should summarize the information studied and include: length of the study, detected levels, treated levels, technology used including equipment, media, etc., length of time needed to purchase and install equipment, cost of purchasing and installing equipment, cost to maintain equipment/media, and useful life. We note the references section of the promulgation approximates three (3) to six (6) studies for any one of the treatment technologies, this does not appear to be a sufficient amount of data to ensure eventual compliance to proposed levels imposed by the promulgation.

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document. The EPA disagrees with the commenter that the agency did not consider a sufficient amount of data in how the EPA evaluated feasible treatment technologies and affordable technologies for small systems. Specifically, the EPA refers the commenter to the *Best Available Technologies and Small System Compliance Technologies for PFAS in Drinking Water* documents supporting the final NPDWR, which contain lab, pilot, and full-scale summary data as well as the *Technologies and Costs for Removing Per- and Polyfluoroalkyl Substances from Drinking Water* supporting document that contains information on operation as well as installation. As an example, the BAT support document summarized information from 57 studies for GAC and removal of PFOA and PFOS alone. Additionally, the EPA directs the commenter to the Drinking Water Treatability Database cited in the rulemaking docket, which contains tabular summaries of studies of different treatment technologies.

North Carolina Division of Water Resources (NCDEQ) (Doc. #1652, SBC-044192)

2. NCDEQ recommends that EPA develop guidance and in-depth training for state agencies and water systems on PFAS treatment technologies, including guidance that addresses simultaneous compliance concerns. NCDEQ recommends that EPA invest funding into evaluations of the PFAS treatment technologies (especially for small systems) to support states.

As outlined in the rule proposal, each of the BAT, in most cases, has the technical capability of treating below the detection limit for PFAS; NCDEQ has limited experience with some of the BAT for PFAS or other contaminants. In-depth training will help ensure state agencies are comfortable approving these technologies for the removal of PFAS at their water systems. Additionally, because each of the available treatment technologies may require a pilot test to

ensure treatment efficacy, NCDEQ recommends that EPA develop specific guidance on what should be required and the optimal meline for a pilot for each of the technologies at differently sized systems. This guidance should also include BAT design criteria recommendations and best practices (e.g., redundant treatment vessels, intermediate sample taps, etc.). NCDEQ strongly recommends that EPA invest funding into evaluations of these technologies by ORD. Investment should focus on treatment technologies at small water systems.

Other state agencies have noted that the initiation of granular activated carbon (GAC) treatment may release arsenic at levels that may exceed the arsenic MCL. Even if the released arsenic exceeds the MCL, state agencies want to ensure that treatment for one contaminant does not pose exposure risks for other regulated contaminants. NCDEQ recommends that EPA develop additional guidance on GAC start-up and conditions that may be utilized to ensure the safe startup of GAC. Additionally, GAC is not optimal for every PFAS. EPA should continually release the most up-to-date guidance and research to state agencies that show what treatment media is most effective depending on what PFAS analytes are being addressed on an individual water system basis.

NCDEQ also encourages EPA to consider the effects of reverse osmosis (RO) treatment, as well as nanofiltration (NF), on the corrosion chemistry of the system. NCDEQ does a treatment change evaluation that may require a corrosion control treatment (CCT) evaluation ahead of the installation of RO/NF/Ion Exchange. NCDEQ recommends that EPA provide additional clarification on this issue in the final rule.

NCDEQ recommends that EPA develop guidance for water systems considering their options to address the PFAS MCLs, both treatment and non-treatment. EPA should include some of the above considerations in that guidance material to ensure systems fully evaluate their options and understand the challenges associated with each. EPA should include considerations for regionalization/consolidation and utilize the opportunity to encourage systems that are currently not viable to connect to viable water systems. Guidance should include Information related to corrosion control concerns when consolidating systems and changing sources.

Additionally, NCDEQ recommends that EPA develop updated, in-depth simultaneous compliance guidance for state agencies. Simultaneous compliance guidance will help to ensure that compliance with one contaminant is not being traded for another, similar to the past water quality problems in Washington, DC, in which elevated lead levels were caused due to a change in disinfectant to address disinfection by-product concerns. Drinking water chemistry is very complex, and state agencies want to ensure treatment is protecting consumers from all NPDWR contaminants.

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document. The EPA has developed supporting rule documents such as *the Best Available Technologies and Small System Compliance for Per- and Polyfluoroalkyl Substances (PFAS) in Drinking Water* document (USEPA, 2024a) that can be used to help primacy agencies develop more familiarity with these technologies over time. After finalization of the PFAS

NPDWR, the EPA also intends to work to provide support to utilities, primacy agencies, and other interested parties to ensure successful rule implementation and will consider the topics suggested by the commenter as the agency develops implementation materials for the final NPDWR. Sections 3.5.1 and 4.5.1 of the *Best Available Technologies and Small System Compliance for Per- and Polyfluoroalkyl Substances (PFAS) in Drinking Water* document (USEPA, 2024a) contain corrosion control and other process integration information for AIX and NF/RO, respectively.

Cleveland Water, City of Cleveland, Ohio (Doc. #1672, SBC-044922)

Section 7: Treatment Technologies

EPA has identified three possible treatment technologies readily available that are successful in removing the proposed PFAS from drinking water. These three treatment techniques, identified as the BATs, are granular activated carbon (GAC), anion exchange (AIX), or high-pressure membranes such as reverse osmosis (RO) and nanofiltration (NF). Research and advancements in technology have greatly improved our understanding of PFAS, such as new developments in treatment techniques and detection limits, and new information is becoming available at an incredible pace. Cleveland Water agrees with EPA's assessment that the proposed MCLs are technologically feasible, but also would like to urge EPA to further explore the economic feasibility of these treatment techniques.

PWSs have significant differences in the composition of their source waters, as well as different environmental factors, which can influence a system's water quality. For example, source water composition is different depending on climate, region of the country, and type of water source, among other issues, including climate change impacts. These differences are what drive decisions utilities must make when new treatment is required. These decisions are rarely obvious and require time and research to make the best choice with minimal negative effects, which is why an extended compliance timeline is so critical.

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document. The EPA agrees that decisions to implement and operate new treatment technologies can pose challenges due to site-specific factors such as composition of source waters and other environmental factors as the commenter notes. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions. Additionally, the EPA seeks to continue its research as well as outreach efforts to help develop technical and operator capacities.

Cleveland Water, City of Cleveland, Ohio (Doc. #1672, SBC-044905)

EPA creates confusion when it states in the preamble, "Measuring PFOA and PFOS results below the practical quantitation limit (PQLs) may not be achievable from all laboratories and may not have the same precision as higher-level measurements, nor does EPA believe it is

appropriate to make potentially costly compliance decisions based on such lower-level measurements." However, EPA also states that it assumes water systems will treat to 80% of the proposed MCL to include "a margin of safety." Installing these treatment techniques will take several years, so a utility risks being in noncompliance at any moment if it is approaching detection at the proposed 4.0 ppt MCL, even though EPA has expressed that it is not "appropriate" to make costly decisions on these low-level measurements. Therefore, water systems with 3.2-4.0 ppt samples whose running annual average (RAA) is below 4.0 ppt will have to make the decision to install treatment in case there is seasonal variability or spikes that may put them out of compliance, potentially costing them and their ratepayers, millions of dollars to get below this margin of safety that cannot be reliably measured.

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document. The 80 percent assumption was used to aid in modeling the economic impact of the rule. Systems will not be in violation if their results are less than or equal to the MCL. Systems that collect additional samples for operational assistance are not penalized under the rule. Compliance samples with results under 4.0 ppt for PFOA or PFOS are counted as a zero under the running annual average calculation, roughly meaning one sample under four would need a sample at eight to counteract it. Systems will be able to make operational decisions using the methods' available abilities to detect PFAS. For additional discussion on laboratory considerations and practical quantitation limits, please see section 5.1.2 of the EPA response in this *Response to Comments* document; for additional discussion on monitoring and compliance requirements, please see section 8 of the EPA response in this *Response to Comments* document; and for additional discussion on cost modeling and its assumptions, please see section 13 of the EPA response in this *Response to Comments* document.

A. O. Smith Corporation (Doc. #1674, SBC-043699)

4. Treatment Technologies

In the Company's experience granulated-activated-carbon (GAC), ion-exchange (IX), and reverse osmosis (RO) technologies are all effective in removing the targeted PFAS compounds in the proposed PFAS NPDWS with the caveat that the removal efficiency and capacity can vary from technology to technology and among different PFAS compounds.

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document.

Horsham Water & Sewer Authority (HWSA) (Doc. #1686, SBC-043815)

Secondly, EPA disregards and therefore completely underestimates the impact of the temporary leaching of metals, in particular arsenic, from GAC. EPA states in the Technologies and Costs for Removing Per- and Polyfluorinated Substances (PFAS) from Drinking Water document that the arsenic can be "readily managed by using pre-treated GAC media or diverting the first few bed volumes of treated water to waste and not typically require post-treatment". EPA is incorrect

in both cases. As background, the PADEP inserted the following language into our GAC operating permits:

For operation of bituminous coal Granular Activated Carbon (GAC), the permittee shall, prior to operation of any new GAC Unit or after any GAC media change out:

a. Backwash the GAC Unit per the manufacture's recommendation.

b. Filter-to-waste the GAC Unit per the manufacture's recommendation.

c. Sample for arsenic in the raw water and on the effluent line after the filter-to-waste is complete. The sample shall be analyzed by a laboratory accredited by DEP for arsenic. The accredited laboratory shall report the sample results to DEP using Code "S" for Special Monitoring. The GAC Unit cannot be placed into service until the arsenic results are received and are less than 10.0 µg/l and no greater than 1.0 g/l above the raw water sample result.

D. Repeat steps "a" through "c" until the arsenic results are less than 10.0 ug/l and no greater than 1.0 ug/l above the raw water sample result.

HWSA worked with our manufacturer to test their acid rinsed pre-treated GAC and found that we were still not able to meet these conditions. As all 8 of our permanent installations have background levels of naturally occurring arsenic ranging from non-detect (below the method reporting limit of 1.0 WI) to 3.5 1.1/1, both the raw water samples and "acceptable" post-GAC samples are going to be extremely low arsenic values, well below the SDWA drinking water standard for arsenic of 10 µg/l. Looking for a difference less than or equal to the method reporting limit in two environmental samples of extremely low values themselves is analytically challenging to say the least. Numerous times, HWSA has initially flushed well over 100,000 gallons of GAC treated water to waste (~45 bed volumes for a Model 8 Calgon GAC vessel) only to find that the arsenic levels have not met condition "c." above when the laboratory report was sent and therefore had to perform additional flushing. In one case seven (7) rounds of flushing and sampling were performed over almost 2 months of time. Over 800,000 gallons of SDWA compliant water (~350 bed volumes) were flushed to waste in this case. The graph below shows the amount of water flushed versus the difference in raw water arsenic levels to post GAC levels. Note the "apparent backsliding of arsenic removal" shown in the graph due to the not unexpected analytical error in looking at two environmental samples of extremely low values well below the SDWA arsenic MCL value.

[Figure: see docket ID EPA-HQ-OW-2022-0114-1686]

This is not just a "few bed volumes" as EPA has cavalierly stated. This is a significant volume of treated water being wasted and that has a cost. But it is not just the cost for the water lost to waste, as the loss of time the unit is unavailable while performing flushing and arsenic testing means that an alternate supply has to be used to account for the loss of production. In our case that is purchased water from a neighboring utility using surface water at a higher cost than producing our own.

A neighboring ground water utility began using coconut-based GAC rather than bituminous coal-based GAC to avoid this very expensive and time-consuming process. Of course, their bed volumes dramatically decreased since coconut-based GAC does not perform as well as bituminous coal-based GAC for PFAS removal and their operating costs increased dramatically as well but they did avoid the lost production time. Either way, this is a situation that EPA is not accurately accounting for. It is our understanding that PADEP is still planning on adding this special condition to all new GAC installations in the state, and it is most likely that it will be copied by other states over time if not already, If EPA is not going to address the appropriateness of this special arsenic condition in GAC permits under the SDWA with the states, then EPA needs to at least account for this in their cost analysis.

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document specifically on concerns related to arsenic release and GAC. The EPA notes that use of a BAT is not required by the rule; if site-specific conditions indicate that GAC is not the best technology to meet the rule (due to water wasting concerns or otherwise), a system is free to choose a different treatment or non-treatment option to comply with the NPDWR. For a discussion of how the EPA accounted for disposal considerations in establishing the MCL, please see sections 5.1.3 and 10.4 of the EPA response in this *Response to Comments* document. For discussion related to cost estimates as well as the assumptions used to develop them, please see section 13 of the EPA response in this *Response to Comments* document.

New Jersey Department of Environmental Protection (NJDEP) (Doc. #1699, SBC-045040)

NJDEP recommends that EPA review the need for additional monitoring after installation of GAC, including for arsenic. NJDEP requires systems that have proposed to install GAC to sample for arsenic following initial installation and media changeouts, as some studies have indicated this as a potential concern. To ensure that these protections are available to customers of public water nationwide, NJDEP recommends EPA considers standards for this practice.

NJDEP recommends that EPA evaluate the need for monitoring backwash water. NJDEP is aware of concerns from various sewer authorities on the discharge of PFAS from GAC filter media backwashing into sanitary sewer collection systems. NJDEP therefore advises EPA to support research or evaluation of the potential for PFAS release to the waste stream when backwashing.

NJDEP recommends that EPA include language specific to carbon regeneration. Under New Jersey's Safe Drinking Water Act rules at N.J.A.C. 7:10-11.15(h)8, regenerated carbon is only permitted if it was in use at a potable water treatment plant and regenerated in facilities that only handle drinking water treatment plant media.

Anion Exchange:

An analysis of the 102 samples submitted by the thirteen facilities with AIX treatment shows only four detections of PFOA ranging from 2.2 ppt to 8.6 ppt and two detections of PFOS

ranging from 2.0 ppt to 3.2 ppt. Based on these data, the facilities that utilized AIX treatment for removal of PFAS were able to remove PFOA and PFOS to below detectable levels in 92% to 96% of all finished water samples. Detection limits for these samples ranged from 2 ppt to 5 ppt.

NJDEP advises EPA to consider challenges that may be posed by nitrosamine production which can occur in anion exchange treatment systems. This situation is believed to occur because of a reaction between free chlorine and the anion exchange. This unique chemical reaction could pose issues for systems that may have pre-chlorination for Fe/Mn removal prior to the PFAS treatment and may have other public health implications if not adequately addressed by the water system utilizing this treatment technology.

Reverse Osmosis:

EPA noted in its proposal that Reverse Osmosis is a viable treatment technology for the removal of PFAS for public water systems. NJDEP acknowledges the technical feasibility of this treatment technology. However, based on treatment permits submitted by public water systems to NJDEP, this treatment technology is infrequently selected by systems for removal of PFAS. NJDEP's understanding is that reverse osmosis presents a major challenge for waste stream management, particularly for non- community water systems. In New Jersey, non-community water systems frequently do not have municipal sewer connections and may be left with the option of discharging waste streams to a septic system or onsite waste storage tank.

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document. The EPA thanks the NJDEP for its comment and insight related to the BATs, particularly experience indicating their ability to treat to or below the PFAS MCLs. After finalization of the PFAS NPDWR, the EPA also intends to provide support to utilities, primacy agencies, and other interested parties to ensure successful rule implementation and will consider the topics suggested by the commenter as the agency develops implementation materials for the final NPDWR.

Arsenic release from GAC has been addressed in the final rule preamble, as well as the *Best Available Technologies and Small System Compliance for Per- and Polyfluoroalkyl Substances (PFAS) in Drinking Water* document (USEPA, 2024a). Additionally, an MCL already exists for arsenic and regulated entities must sample at each entry point to the distribution system (EPTDS), meaning post GAC treatment. The EPA would also like to point out that typically, deep bed GAC does not require backwashing because the particulates in the water are removed ahead of the GAC system, but there may be instances where particulates deposit onto the GAC, creating a head loss that may be resolved through backwashing. If so, the backwash water may contain a PFAS foam that may be managed according to appropriate guidance such as the *Interim Guidance on the Destruction and Disposal of Perfluoroalkyl and Polyfluoroalkyl Substances and Materials Containing Perfluoroalkyl and Polyfluoroalkyl Substances*.

The EPA appreciates NJDEP's insight to carbon reactivation. The EPA points out that standards such as the American Water Works Association (AWWA) and NSF/ANSI Standard 61 can help and that even carbon reactivation at a dedicated food-grade facility can lead to unanticipated

problems if the carbon is not segregated and traceable from the time it leaves the specific treatment point's location, through the receiving, storage, and reactivation at the reactivation facility, and until it is delivered back to the site because of changes in chemistry.

The EPA is aware of nitrosamine production in AIX systems. The EPA notes that pre-chlorination is not the only method to treat transition metal precipitation across contactors; aeration, for instance, or other practices may be best on a site-specific basis.

The EPA agrees and acknowledges, as well as has acknowledged in other areas such as the final rule preamble, the *Interim Guidance on the Destruction and Disposal of Perfluoroalkyl and Polyfluoroalkyl Substances and Materials Containing Perfluoroalkyl and Polyfluoroalkyl Substances*, and the *Best Available Technologies and Small System Compliance for Per- and Polyfluoroalkyl Substances (PFAS) in Drinking Water*, that there can be difficulties in managing RO concentrate. The EPA lowered the forecasted uptake of RO/NF for compliance in its EA for the rule based on comments such as this. The EPA notes that concentrate may require additional treatment such as with GAC or AIX prior to discharge. Please see section 10.5 of the EPA response in this *Response to Comments* document for additional information on small system compliance technologies (SSCTs) and POU devices.

State of Vermont Agency of Natural Resources and Department of Health (Doc. #1708, SBC-045119)

7) EPA requests comment on whether PWSs can feasibly treat to 4.0 ppt or below.

This can be accomplished with a lead/lag treatment configuration and midpoint sampling to measure breakthrough of one treatment device before the PFAS reaches finished water. While this increases the cost of treatment, it is feasible as long as there are available methods to detect PFAS at these concentrations.

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document.

State of Vermont Agency of Natural Resources and Department of Health (Doc. #1708, SBC-045097)

g. Monitoring framework with treatment:

Because the proposed regulation does not speak to the topic, the final regulation must include a minimum on-going sampling requirement for when systems install treatment that is protective of public health. It cannot be reduced to once every 3-year monitoring under the proposed framework. What happens if there is treatment breakthrough in year 2? How will we know when the media is "spent"? It can be theorized but without individual piloting, at an added cost and increased timeline, we won't know how the GAC responds to other materials in the water and what the longevity of the filters will be. There need to be clear sampling protocols, be it at mid-point locations that will signal vessel changeout, or more frequently in the finished

water/effluent. It is not protective of public health to require 3- year sampling based on the proposed regulation for a filter that actually requires annual re- bedding. Leaving it up to the States will create disparity and added regulatory processes in state rules. Creating some other arbitrary calendar-based filter changeout regime would place an undue burden on the small systems, especially those with varied seasonal flow, who would not load the filters to the extent other systems might. Our experience to date can give us a sense of how long filters can last, but that is when systems are removing 20+ppt of PFAS. The longevity of a filter removing, for example, 4 ppt is untested in our state and many others. Since the proposed regulation essentially regulates to the reporting level, there will be no allowable amount of "breakthrough" with the public and user base, many of whom will see their regular water bills increase due to the need to pay for the treatment and on-going expenses. It will also erode consumer confidence in the Water System to have levels up and down and not caught before levels approach the MCL(s). This is why the regulation must have a sampling protocol to assess efficacy and longevity of the filter vessels/media and not to leave it up to the standard framework or State-specific regulations.

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document. The EPA understands that some systems who install treatment may regularly sample finished water to ensure the efficacy of their treatment media (e.g., filters), above and beyond what they would do for compliance monitoring. For further information on the agency's responses to these concerns, please see section 8.1.2 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions.

Philadelphia Water Department (PWD) (Doc. #1709, SBC-045732)

Regarding the sixth feasibility criterion of the BATs having "compatibility with other water treatment processes: The information cited in USEPA 2023g does not accurately reflect the necessary level of site-specific research that is needed for implementation to account for impacts to other treatment processes and downstream water quality. For all three BATs, the EPA states that "[a]dditional research will not be required" to determine the compatibility with other treatment processes. This statement is overly broad and does not account for the varied water quality, particularly in drinking water treatment facilities that use surface water as a source. This statement also does not account for the potential impacts to other treatment processes or downstream water quality. Specifically, IX and RO/NF are noted to increase corrosivity of finished water in Section 3.4.1 and Section 4.5.1, respectively, which would require investigation with pipe loop studies using harvested pipes. Impacts on corrosivity and its deleterious effects on compliance with the existing lead and copper rule (LCR) and future LCR Revisions or LCR Improvements (LCRR/LCRI) are not properly accounted for. Additionally, for high-pressure membranes, the EPA notes in Sections 4.4.1 and 4.5.1 that adverse effects may occur during operation of these technologies, but that additional research is not required. Pilot-scale and phased full-scale evaluations are vital to understanding these impacts and should not be dismissed.

Given the issues detailed above regarding the first, second, fourth, and sixth criteria of assessing feasibility of BATs for all three of the proposed BATs, especially in large, surface water PWSs, PWD believes that the criteria for determining feasibility were not met. EPA should re-assess the feasibility of achieving the proposed MCLs for PFOA, PFOS, and the HI through BATs, especially in large surface water systems (population over 50,000 people) which serve over 50% of the population in the United States (see Table 4-4 in rulemaking reference USEPA 2023j).

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document. The EPA disagrees with the commenter's statement that the criteria for determining feasibility were not met and notes that no verifiable information was provided by the commenter as it relates to the first, second, fourth, or sixth criteria identified in this comment. These criteria have high removal efficacy, history of full-scale operation, compatibility with other treatment processes, and reasonable cost basis for large and medium systems. The EPA agrees that site-specific circumstances will require attention and investigation, such as through pilot studies, however, that is not new research but rather an engineering problem and application, which are already well understood. There is extensive supporting evidence supporting the final determinations regarding the technologies in the *Best Available Technologies and Small System Compliance for Per- and Polyfluoroalkyl Substances (PFAS) in Drinking Water*, the *Drinking Water Treatability Database*, the *Technologies and Costs for Removing Per- and Polyfluoroalkyl Substances (PFAS) from Drinking Water* documents. The conclusions outlined in the record provide a clear indication of high removal efficacy, history of full-scale operation, compatibility with other treatment processes, and reasonable cost basis for large and medium systems.

The EPA notes that implementation timing associated with this PFAS NPDWR and the proposed Lead and Copper Rule Improvements (LCRI) has the potential to overlap. To the extent implementation overlaps, some rule start-up, administrative, and sampling/service line (SL) inventory costs associated with both rules could affect a large number of PWSs and states. The more significant costs of installing and operating PFAS treatment technology in a similar time frame with installing and operating corrosion control treatment (CCT) and/or conducting service line replacement are expected to fall on some systems. The EPA does not have sufficiently detailed PFAS occurrence, and lead service line (LSL)/galvanized requiring replacement (GRR) service line and 90th percentile lead tap sample data to explore the potential treatment cost interactions of the two rules. The EPA further notes that SDWA Section 1412(b)(3)(C)(i)(III) requires that the EPA include quantifiable and non-quantifiable costs that are likely to occur solely as a result of compliance with the rule, including monitoring, treatment and other costs and excluding costs resulting from compliance with other proposed or promulgated regulations. As explained in the preamble to the proposed and final rules and in these responses to comments, it is feasible for water systems to comply with both regulations and address impacts that PFAS treatment may have on CCT and to take appropriate mitigations, potentially similar to the ones outlined in the BAT/SSCT document or the summary of major public comments for this section. This is especially in light of increased funding under the BIL, which is discussed further in

section 2.4. Please see section 13 of the EPA response in this *Response to Comments* document for additional discussion on the EPA's HRRCA.

Philadelphia Water Department (PWD) (Doc. #1709, SBC-045730)

EPA should reevaluate the proposed MCL values for PFOA and PFAS and must consider more factors in evaluating technical and economic feasibility. The EPA has not demonstrated the feasibility of the BATs for large systems to achieve the proposed MCL of 4 ppt for PFOA and PFOS.

In Section VI.D, EPA states that its "proposal is based upon its proposed finding that an MCL of 4.0 ppt for PFOA and PFOS and an HI of 1.0 for perfluorohexane sulfonate (PFHxS), hexafluoropropylene oxide-dimer acid (HFPO-DA), perfluorononanoic acid (PFNA), and perfluorobutanesulfonic acid (PFBS) are feasible because treatment technologies are available that treat to below these levels and there are analytical methods that can reliably quantify at these levels". Similarly, in Section VI.A, EPA states that it "has determined that 4.0 ppt represents what is achievable for BATs given the standard of 'reasonable cost based on large and metropolitan water systems.'" EPA determines feasibility for treatment techniques based on seven conditions including the capability of a high removal efficiency, the history of full-scale operation, the reasonable cost on large and metropolitan water systems, and the compatibility with other water systems (criteria 1, 2, 4, and 6). However, PWD believes that EPA's assessment of the three proposed BATs falls short of these four criteria, especially in the case of large metropolitan water systems that have a surface water source. PWD strongly recommends that EPA revisit its determination for the application of the proposed MCLs at large surface water treatment plants or release additional data that supports the ability of the BATs to achieve the MCLs at these types of water treatment plants.

In the EPA's "Best Available Technologies and Small System Compliance for Per- and Polyfluoroalkyl Substances (PFAS) in Drinking Water" document (Reference USEPA, 2023g in the Proposed rulemaking), EPA provides more information to discuss the proposed BATs and whether they meet the five criteria to determine feasibility.

Regarding the first feasibility criterion of the BATs having "the capability of a high removal efficiency": In USEPA 2023g, when assessing whether the technology is reliable enough to continuously meet a drinking water MCL, EPA states "Yes. Numerous full-scale drinking water facilities are using Granularly Activated Carbon (GAC) to meet current state drinking water requirements for PFAS". While PWD does not dispute this statement, the assessment of whether these BATs can effectively treat to various state MCLs is not relevant to this rulemaking as the EPA's proposed MCLs are lower than all state MCLs. Even in instances where GAC has been shown to effectively remove PFAS to comply with higher MCLs, the lower MCLs proposed in the draft NPDWR will affect the overall feasibility in terms of operational and maintenance costs, logistics of GAC replacement, and GAC availability. It is unclear how effective these

BATs will be at meeting this stricter MCL when it only appears to have been assessed to the state required MCLs.

Regarding the second feasibility criterion of the BATs having a "history of full-scale operation": For GAC, while there are many examples of GAC being implemented for PFAS treatment, the vast majority are referencing small groundwater sources. Of the two examples of full-scale implementation in a large, surface water Public Water System (PWS), both have questionable references without a comprehensive or cursory review of their implementation. For the first example, in Ann Arbor, Michigan, the source cited in USEPA 2023g is a non-scientific digital news article. Even so, the article, which gives a single data point on removal, clearly states that the PWS attributed the decreases observed in finished water PFAS levels to a combination of the GAC system and drastically reduced source water concentrations. For the second example cited in USEPA 2023g, a PWS in North Carolina installed GAC at one of their treatment facilities. The citation used for this example was from a non-peer-reviewed article published in Journal AWWA that discussed the decision- making process to implement GAC and the design and piloting steps taken. This article was published in October 2020 and construction on the full-scale implementation was not expected to be finished until February of 2022. No addition al information about operations at the North Carolina PWS was provided. PWD recommends that EPA release any additional information available demonstrating the successful application of GAC at large, surface water treatment plants.

This lack of evidence relating to implementation in surface water sources is compounded by the observation by EPA that increased levels of Natural Organic Matter (NOM) can reduce the efficacy of GAC. Surface water sources are likely to experience far higher levels of NOM with greater ranges in concentration than groundwater sources. Higher levels of NOM have a high potential to compete with PFAS for sorption sites. EPA does not present clear evidence that this technology can effectively remove PFAS with varying levels of NOM at full-scale. While EPA states in USEPA 2023g, "it should be possible to reliably manage the impact of natural organic matter through piloting, selection of design parameters, and operational monitoring," PWD questions whether EPA's belief in the "possible" demonstrates what is technical and feasible. For Ion Exchange (IX), EPA cites a limited number of full-scale implementation examples in USEPA 2023g; however, they are all groundwater sources and at low flow rates. There is no evidence presented that this technology will be scalable for a large, surface water PWS. For Reverse Osmosis and Nano Filtration (RO/NF), EPA does not provide any examples of RO/NF being implemented at full- scale for PFAS removal with performance data available. Overall, the full-scale feasibility of the three BATs has not been demonstrated for surface water PWSs within USEPA 2023g and additional investigation is warranted.

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document. The EPA notes that the preponderance of evidence documented in NPDWR supporting materials, such as the *Best Available Technologies and Small System Compliance for Per- and Polyfluoroalkyl Substances (PFAS) in Drinking Water*, the Drinking Water Treatability Database, the *Technologies and Costs for Removing Per- and Polyfluoroalkyl*

Substances (PFAS) from Drinking Water, and *HRRCA* supports the EPA's assertion that this rule is feasible for large water systems. The public record also demonstrates large surface water systems that have shown that treatment to at or below 4.0 ppt is feasible such as Cape Fear Public Utility Authority, who also submitted a comment and is referenced indirectly in the comment as a PWS in North Carolina. While the EPA has reviewed data from large metropolitan systems such as Cape Fear, the EPA is not obligated to take this step. The EPA establishes drinking water standards through a formal multi-step process. *See* S. Rep. No. 169, 104th Cong., 1st Sess. (1995) at 3. As part of that process the agency generally sets an enforceable MCL as close to the MCLG as feasible, taking costs into consideration. In this second step, consistent with the definition of "feasible" in Section 1412(b)(4)(D), the EPA evaluates the availability and performance of (BATs for treating water to minimize the presence of the contaminant consistent with the MCLG as well as the costs of applying those BATs to large and metropolitan water systems when treating to that level (1412(b)(4)(E) and (5)). [2] There is no requirement that a large metropolitan system already treat only that the cost for such an entity is considered. Additionally, SDWA section 1412(b)(3)(A) requires that Agency use "(i) the best available peer reviewed science and studies conducted in accordance with sound and objective scientific practices: and (ii) data collected by accepted methods or best available methods." The data in question was collected by accepted methods although it is not necessarily peer reviewed. For additional discussion on the SDWA rulemaking process please see section 1 of the EPA response in this *Response to Comments* document, for additional information on how the agency set the MCLGs please see section 4 of the EPA response in this *Response to Comments* document, for information on how the agency considers analytic feasibility when establishing the MCL, please see 5.1.2 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions. For additional information on how large metropolitan systems were incorporated into the cost analysis please see section 13 of the EPA response in this *Response to Comments* document.

Philadelphia Water Department (PWD) (Doc. #1709, SBC-045731)

Regarding the fourth feasibility criterion of the BATs having "reasonable cost based on large and metropolitan water systems": For many large and metropolitan PWSs, the population is served by a surface water source. Given the lack of evidence in USEPA 2023g on full-scale implementation of the proposed BAT in large, surface water PWSs, it is unclear how EPA can accurately estimate the costs associated with these BATs in large and metropolitan sources. Given the high percentage of large PWSs that are expected to exceed one of the three proposed MCLs (estimated at ~25% in rulemaking reference USEPA 2023j), a slight underestimation of cost when extrapolating costs from small and medium PWS implementations could result in a

[2]Based on legislative history, the EPA interprets "taking cost into consideration" in Section 1412(b)(4)(D) to be limited to "reasonable cost based on large and metropolitan drinking water systems (A Legislative History of the Safe Drinking Water Act, Committee Print, 97th Cong., 2d Sess. (1982) at 550).

severe underestimation in the overall cost of this rulemaking. Given the fact that a large portion of the cost associated with this rulemaking will be passed along to the PWS ratepayers, PWD believes that EPA should not underestimate the possible costs of this rulemaking. Additionally, in USEPA 2023g, when evaluating the fourth feasibility study, EPA assessed the "reasonable cost basis for large and medium systems" rather than "large and metropolitan" systems as stated in the rulemaking. As a result, EPA uses examples of implementation in medium systems (defined in USEPA 2023g as flow rate greater than 1 MGD and less than 10 MGD) to support this criterion. For GAC, the two large system examples are detailed above as having questionable citations and for RO/NF, they cite two large systems that have started implementation but do not have performance data available to assess their success. Additionally, the largest example facility has a rated capacity (50 MGD) that is significantly smaller than the smallest of PWD's three WTPs (86 MGD). These issues make it difficult to accurately assess both capital and operation and maintenance costs associated with these technologies in large and metropolitan water systems. This issue is further compounded by the lack of nationwide occurrence data to accurately assess the economic impact that this rulemaking will have especially on large PWSs, which are stated to serve over 200 million people across this country (rulemaking reference USEPA 2023j). PWD would also like to note that the capital cost estimates using the cost equations for large PWS for RO/NF place this technology as requiring lower capital investment than GAC or IX pressure vessels, which does not align with the experience PWD has with cost estimation for these technologies. There are several unknowns that could significantly impact capital costs that do not appear to be accounted for in these cost equations, such as utility requirements (e.g., electrical connections), land acquisition, land availability, and ancillary infrastructure needs to mitigate unintended consequences. PWD believes that EPA's implementation cost estimates significantly underestimate total capital costs for large and metropolitan surface water systems and these costs cannot be extrapolated from small and medium systems for large PWSs.

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document, as well as the previous two responses to the Philadelphia Water Department. Land availability will be a factor in selecting the appropriate compliance technology as differing options have varying footprints. While "ancillary infrastructure needs" is unspecified, all work breakdown structure (WBS) models include ancillary costs, including land and permitting, as well as indirect capital costs, including electrical infrastructure, architectural fees for treatment building, sitework, among other costs. Additionally, there are contingency and miscellaneous allowances to account for unforeseen factors such as mitigating unintended consequences. For more information see the *Technologies and Costs for Removing Per- and Polyfluoroalkyl Substances (PFAS) from Drinking Water* document.

Citizens Campaign for the Environment (CCE) (Doc. #1710, SBC-045128)

We have the tools available to protect drinking water from PFAS, and it is time to use them. Activated carbon treatment systems, which have been shown to be effective and readily available, are the most studied and commonly used filtration for PFAS removal. This filtration

method has been shown to effectively remove PFAS from drinking water. [FN1: Reducing PFAS in Drinking Water with Treatment Technologies. U.S. EPA, August 2018. https://www.epa.gov/sciencematters/reducing-pfas-drinking-water-treatment-technologies] Once a water supplier installs an activated carbon treatment system for one PFAS chemical it will filter out additional PFAS chemicals. This is good news for public health protection since achieving the proposed drinking water standards is clearly realistic for water suppliers.

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document; for additional information on co-removal of additional PFAS compounds, please see section 10.3 of the EPA response in this *Response to Comments* document.

Environmental Working Group (EWG) (Doc. #1721, SBC-045413)

Granular activated carbon, or GAC, is effective at reducing PFAS to the levels in the proposed rule. For example, GAC has been used at the Chemours Fayetteville facility to nearly eliminate PFAS as high as 345,000 parts per trillion (ppt) and has reduced PFAS in effluent to non-detect levels for several PFAS. [FN49: See Southern Env't Law Ctr. Et al., Comments on Advanced Notice of Proposed Rulemaking Clean Water Act Effluent Limitations Guidelines and Standards for the Organic Chemicals, Plastics and Synthetic Fibers Point Source Category, EPA-HQ-OW-202-0582, at 13.] Chemours' own testing through pilot studies shows that GAC is capable of removing more than 99 percent of 20 PFAS. [FN50: Id.] EPA researchers have found that, "GAC can be 100 percent effective for a period of time, depending on the type of carbon used, the depth of the bed of carbon, the flow rate of the water, the specific PFAS you need to remove, temperature, and the degree and type of organic matter as well as other contaminants, or constituents, in the water."[FN51: Env't Prot. Agency, Reducing PFAS in Drinking Water with Treatment Technologies, (Aug. 23, 2018), https://www.epa.gov/sciencematters/reducing-pfas-drinking-water-treatment-technologies.] A 2018 report found that GAC has been used to remove PFAS "for over 15 years at more than 45 military installations, as well as several industrial sites and publicly owned treatment works."[FN52: Interstate Technology Regulatory Council, PFAS – Per- and Polyfluoroalkyl Substances: 12. Treatment Technologies, (Updated Sept. 2020) (citing E. Forrester and J. Matthis, "Treatment Solutions for PFAS Removal: Evaluating Total Cost" (2018)) at https://pfas-1.itrcweb.org/12-treatment-technologies/.] In Michigan, several industrial dischargers saw 99 percent reductions of PFOS in effluent after installing GAC through an industrial pretreatment program for PFAS. [FN53: Michigan PFAS Action Response Team, "Wastewater Treatment Plants/Industrial Pretreatment Program," https://www.michigan.gov/pfasresponse/0,9038,7-365-88059_91299---,00.html (last updated March 2023).]

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document.

Connecticut Department of Public Health (CT DPH) (Doc. #1745, SBC-045233)

3. EPA is seeking comment on the benefits from using treatment technologies (such as reverse osmosis and GAC) that have been demonstrated to co-remove other types of contaminants found in drinking water and whether employing these treatment technologies are sound strategies to address PFAS and other regulated or unregulated contaminants that may cooccur in drinking water.

CT DPH notes that reverse osmosis is becoming a non-viable treatment method for PWSs due to increased operation and maintenance for reverse osmosis membranes to prevent fouling, increases in operator training, and assurance that operator is onsite daily to inspect.

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document.

Connecticut Department of Public Health (CT DPH) (Doc. #1745, SBC-045231)

Treatment

EPA estimates granular activated carbon (GAC) treatment will be sufficiently available to support cost-effective compliance with this proposed regulation, and requests comment on whether additional guidance on applicable circumstances for GAC treatment is needed.

Although GAC and ion exchange resins (IX) are shown to be effective in removing certain PFAS, GAC is not optimal for short chain PFAS (Riegel, Haist-Gulde, and Sacher 2023). EPA should provide additional guidance when recommending either GAC or IX usage based on each PWS's PFAS results and not recommend GAC for short chain PFAS to avoid future issues if additional short chain PFAS become regulated. EPA should also note the referenced GAC and IX studies in the proposed rule are from 2020 and are based on EPA's previous health advisory of 70 ppt for PFOA, PFOS or the sum of both PFAS.

Effective GAC implementation will also rely on source water quality parameters and the availability of appropriate treatment vessels Due to supply chain issues, there is currently substantial lead time to procure treatment vessels with six to twelve months given as a delivery time frame.

EPA should provide additional guidance on type of GAC to implement (coal over coconut) and when a PWS should optimally implement GAC instead of IX or implement both depending on a PWS's PFAS results. Implementation of coal-based GAC requires an acid pre-wash to prevent residual arsenic issues which increases operator time and training.

Installing GAC and IX treatment at PWSs increases the overall footprint of the PWS and will add increased construction costs and the amount of time a certified operator is needed onsite (increase in training/education costs, staff costs). Workforce challenges for qualified water system operators for treatment systems will be an area that consistently needs to be addressed.

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document. The EPA agrees that different BATs have differing efficacies depending on site-specific conditions (such as PFAS composition, water chemistry, and many others) and water systems are free to choose technologies that best fit their circumstances. After finalization of the PFAS NPDWR, the EPA also intends to provide support to utilities, primacy agencies, and other interested parties to ensure successful rule implementation and plans to consider the topics suggested by the commenter as the agency develops implementation materials for the final NPDWR. While acid pre-washing is one way to lower arsenic, it is not the only option. The best option should be determined on a site-specific basis.

The EPA notes that while the GAC and AIX studies date from prior to the 2022 interim updated PFOA and PFOS health advisories, the treatment data from that time shows that GAC and AIX can treat to at or below the MCLs. The EPA also points out that pre-built contactors are not the only option and there are multiple designs and configurations, for example, a gravity contactor, which may also meet rule requirements. The EPA also agrees that installing GAC and AIX will increase costs for PWSs and has described these costs in, among other areas, the *Technologies and Costs for Removing Per- and Polyfluoroalkyl Substances (PFAS) from Drinking Water*, the individual WBS documents for the specific technologies such as the *Work Breakdown Structure-Based Cost Model for Granular Activated Carbon Drinking Water Treatment*, the EA materials, and section 13 of the this *Response to Comments* document.

Las Cruces Utilities (LCU) (Doc. #1753, SBC-043912)

In response to Section XI-Treatment Technologies, EPA requests comment on whether PWSs can feasibly treat to 4.0 ppt or below.

• The feasibility of treatment depends on PFAS concentrations and the water system configuration. In situations where PFAS concentrations are very high, multiple treatment systems may be needed in series, and would then likely become financially infeasible. The number of impacted EPTDS may also render this infeasible from a cost standpoint. In situations where the water system is configured such that centralized treatment cannot be provided, treatment would then be needed at each source (e.g., groundwater well) and this would likely become financially infeasible.

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document. The EPA agrees that site-specific conditions can affect engineering design and that that specific BATs may not be appropriate at specific sites. As discussed in the final rule preamble, systems are free to choose the technology that works best to achieve compliance for that system. The EPA, however, disagrees that this is financially infeasible and refers the commenter to the *Technologies and Costs for Removing Per- and Polyfluoroalkyl Substances (PFAS) from Drinking Water*, the individual WBS documents for the specific technologies such as the *Work Breakdown Structure-Based Cost Model for Granular Activated Carbon Drinking Water Treatment*, the EA materials, and the HRRCA section of the response to comment. These

documents show that vessel configuration and the other factors mentioned were considered in the cost analysis. For additional discussion on how the agency considers analytic feasibility when establishing the MCL, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For additional discussion on the EPA's HRRCA, please see section 13 of the EPA response in this *Response to Comments* document.

Las Cruces Utilities (LCU) (Doc. #1753, SBC-043919)

In response to Section XIII. Health Risk Reduction and Cost Analysis, EPA requests comment on Table 26 which provides the initial treatment technology compliance forecast, presented in percentages of systems adopting GAC, PFAS-selective IX, centralized RO, system interconnection, and use new wells across system design flows and TOC levels. This information is used in EPA's cost and benefit modeling. Please also comment on the potential for point-of-use devices, including those using RO or activated carbon as a compliance option.

• Table 26 generally is accurate for the parameters included. EPA should also consider very high concentrations of PFAS, such as greater than 400 ppt. Most of the systems can achieve greater than 99% removal, but remaining concentration would be greater than the MCL of 4.0 ppt if concentrations are greater than 400 ppt.

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document. Systems with very high concentrations of PFAS were included in the analysis and may have additional considerations, and alternative options to treatment include interconnection with another system or drilling new wells to replace a contaminated source. For more information on PFAS occurrence, please see section 6 of the EPA response in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-046156)

3.3 Reverse Osmosis and Nanofiltration

RO and NF are membrane-based water treatment processes in which a semi-permeable barrier removes dissolved contaminants from water. This capability is attractive when considering the need to remove total dissolved solids (TDS), specific ions such as calcium, magnesium, sodium, chloride, sulfate, and hardness; DBP precursors; and T&O causing compounds as well as high levels of PFAS. RO/NF processes are commonly applied in water treatment plants and have applications ranging from desalination of brackish water, softening, and the removal of nitrate, agricultural chemicals (e.g., atrazine), color, total organic carbon (TOC), DBP precursors, and PFAS. Both RO and NF processes are capable of a high rejection of PFAS. While RO/NF systems are more expensive than GAC or IX systems, they are most viable when the GAC/IX replacement frequency requirements are cost-prohibitive because of high concentrations of influent PFAS.

The key differences between RO and NF are salt passage and feed pressure. RO membranes reject a higher percentage of dissolved ions in the feed water and require a greater feed pressure than NF membranes. NF membranes preferentially remove larger divalent ions or molecules compared to monovalent ions. Thus, NF systems generally exhibit lower energy use and lower operating cost than RO systems. The lower feed pressure required for NF generally translates to a slightly favorable capital cost in relation to RO systems treating the same flow rate. However, the benefits of higher salt rejection and flexibility of systems designed for RO to utilize either NF or RO membranes typically results in utilities favoring RO over marginally lower cost NF systems.

For a typical RO/NF system, membrane elements are mounted into pressure vessels that are arranged in stages, banks, or arrays. The number of stages required depends on specified recovery. Two stages are typically used for recovery less than 80 percent, and three stages are required for higher recovery. RO/NF is a cross flow filtration method, in which only a portion of the feedwater becomes permeate (finished water). The remainder leaves the system as concentrate (brine) that carries away the concentrated material before precipitation or scaling forms on the membrane surface or in the device. Antiscalant is used to control the precipitation of sparingly soluble salts such as calcium carbonate, calcium sulphate, barium sulfate, calcium fluoride, silicon dioxide, etc.

3.3.1 Implementation and Operational Considerations

The recovery of the RO/NF treatment systems depends on the concentrations of the sparingly soluble salts and typically ranges from 75 to 85 percent. Pretreatment requirements include pH depression, antiscalant chemical products to reduce scaling, and cartridge filters to protect the RO/NF membranes from particulates.

The combination of pH depression in the feedwater and the removal of alkalinity through the process results in a low pH (acidic) finished water. Gases pass through NF/RO membranes, resulting in the potential need for removal of hydrogen sulfide and carbon dioxide from the treated water. Post- treatment generally consists of gas stripping through a decarbonation tower and chemical conditioning by addition of a base such as lime or sodium hydroxide (caustic) to raise pH, alkalinity, and hardness to render the water less corrosive. Sometimes a corrosion inhibitor is also added to prevent distribution system corrosion.

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document. The EPA thanks the commenter for providing information about these treatment processes.

Environmental Protection Network (EPN) (Doc. #1773, SBC-043850)

While EPA has presented excellent references to support the designation of these technologies as BAT, EPN notes that EPA has omitted some key references. EPA should cite two reports by the New Jersey Drinking Water Quality Institute documenting seven different GAC treatment plants

operating for years in the U.S. that removed PFOA, PFOS, and other PFAS chemicals to non-detectable levels. [FN1: New Jersey Drinking Water Quality Institute. June 2015. Recommendations on Perfluorinated Compound Treatment Options for Drinking Water; FN2: New Jersey Drinking Water Quality Institute. November 2017. Second Addendum to Appendix C: Recommendations on Perfluorinated Compound Treatment Options for Drinking Water.] EPA should also cite the New Jersey Drinking Water Watch data which documents that seven GAC plants and five AIX plants in the state have been achieving non-detectable levels of PFOA and PFOS since 2019, with detection limits ranging from 0.53 to 5 ppt. [FN3: New Jersey Department of Environmental Protection. Drinking Water Watch.]

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document. The EPA acknowledges the additional data submitted by the commenter and notes that it corroborates with the findings for the BATs identified and selected for the final NPDWR, presented in the *Best Available Technologies and Small System Compliance for Per- and Polyfluoroalkyl Substances (PFAS) in Drinking Water*.

Environmental Protection Network (EPN) (Doc. #1773, SBC-043847)

PFOA and PFOS MCLs

Under SDWA section 1412(b)(4)(B), EPA must generally establish an enforceable MCL as close to the MCLG as feasible. Section 1412(b)(4)(d) defines feasibility as "feasible with the use of the best technology, treatment techniques, or other means which the Administrator finds, after examination for efficacy under field conditions and not solely under laboratory conditions, are available (taking cost into consideration)." EPN agrees that EPA has appropriately identified Best Available Treatment (BAT) as granulated activated carbon (GAC), anion exchange (AIX), reverse osmosis (RO), and nanofiltration (NF).

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document.

Northwest Biosolids Association et al. (Doc. #1783, SBC-043804)

Limited Treatment Options. Technologies do not yet exist that are proven effective for PFAS removal and destruction as part of a current treatment train. When they do become available, systems will be expensive and likely difficult to operate and maintain.

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document. The EPA disagrees that there are not proven technologies for the removal and destruction of PFAS. While the BATs identified for the final NPDWR are separative processes rather than destructive processes, they have been demonstrated to be effective in PFAS removal. For additional discussion of residuals management, please see section 10.4 of the EPA response in this *Response to Comments* document.

Northwest Biosolids Association et al. (Doc. #1783, SBC-043796)

[We recommend that drinking water regulations for PFAS include actions that support scientific understanding and exploring implementation solutions that would include actions such as:]

• Facility-specific evaluations to examine PFAS removal technologies, effectiveness and costs including societal impacts such as affordability, equity, energy use and greenhouse gas emissions.

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document for discussion of EPA's consideration of greenhouse gas emissions. Please see section 14 of the EPA response in this *Response to Comments* document for additional discussion on affordability and equity, and for the EPA's HRRCA, please see section 13 of the EPA response in this *Response to Comments* document. Individual sites will have to incorporate these decisions in their particular sites for their unique circumstances.

West Virginia Municipal Water Quality Association (Doc. #1816, SBC-044673)

III. Technologies may not be available depending on EPA's overall PFAS-related regulatory actions.

EPA states "there are technologies currently available that effectively remove [PFOS, PFOA, PFNA, PFHxS, or HFPO-DA] and other PFAS." 88 Fed. Reg. 18638, 18684 (Mar. 29, 2023). See also 88 Fed. Reg. at 18685-86 ("GAC can be a cost-effective treatment option despite needing to dispose of contaminated carbon."; "AIX can be a cost-effective treatment option"; "The three technologies discussed [GAC, AIX, and RO] have all been demonstrated to be effective in removing all six PFAS proposed for regulation as part of this rulemaking.") EPA needs to further investigate whether technologies are as available as they perceive.

In particular, the degree of removal of long-chain and short-chain PFAS varies with the type of technology employed. Has EPA determined that all six of the PFAS being regulated can be removed with each individual technology evaluated by EPA? We question whether the technologies evaluated can be counted on to remove all six of these chemicals (comprising both short and long chain PFAS) below the proposed MCL levels.

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document. Yes, the EPA had determined that all six regulated PFAS can be removed by the BATs, please see the EPA response to comment Doc. #1503, SBC-042572 from Richard Kinch in section 10.1 in this *Response to Comments* document for more information on that determination. Section 10.2 of the EPA response in this *Response to Comments* document also contains information on co-removal and should be helpful for the commenter. For information on availability, please see section 10.6 of the EPA response in this *Response to Comments* document.

NORTH CAROLINA WATER QUALITY ASSOCIATION (Doc. #1818, SBC-044629)

III. Technologies may not be available depending on EPA's overall PFAS-related regulatory actions.

EPA states "there are technologies currently available that effectively remove [PFOS, PFOA, PFNA, PFHxS, or HFPO-DA] and other PFAS." 88 Fed. Reg. 18638, 18684 (Mar. 29, 2023). See also 88 Fed. Reg. at 18685-86 ("GAC can be a cost-effective treatment option despite needing to dispose of contaminated carbon."; "AIX can be a cost-effective treatment option"; "The three technologies discussed [GAC, AIX, and RO] have all been demonstrated to be effective in removing all six PFAS proposed for regulation as part of this rulemaking.") EPA needs to further investigate whether technologies are as available as they perceive.

In particular, the degree of removal of long-chain and short-chain PFAS varies with the type of technology employed. Has EPA determined that all six of the PFAS being regulated can be removed with each individual technology evaluated by EPA? We question whether the technologies evaluated can be counted on to remove all six of these chemicals (comprising both short and long chain PFAS) below the proposed MCL levels.

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1816, SBC-044673 in section 10.1 in this *Response to Comments* document.

South Carolina Water Quality Association (Doc. #1819, SBC-044607)

III. Technologies may not be available depending on EPA's overall PFAS-related regulatory actions.

EPA states "there are technologies currently available that effectively remove [PFOS, PFOA, PFNA, PFHxS, or HFPO-DA] and other PFAS." 88 Fed. Reg. 18638, 18684 (Mar. 29, 2023). See also 88 Fed. Reg. at 18685-86 ("GAC can be a cost-effective treatment option despite needing to dispose of contaminated carbon."; "AIX can be a cost-effective treatment option"; "The three technologies discussed [GAC, AIX, and RO] have all been demonstrated to be effective in removing all six PFAS proposed for regulation as part of this rulemaking.") EPA needs to further investigate whether technologies are as available as they perceive.

In particular, the degree of removal of long-chain and short-chain PFAS varies with the type of technology employed. New England Water Works Association (Doc. #1836, SBC-045386)

Treatment Considerations:

EPA is proposing MCLs for PFOA and PFOS at 4 ppt and a Hazard Index approach for four other PFAS compounds: PFHxS, HFPO-DA/GenX, PFNA, and PFBS with a MCLG of 1.0 (unitless) Hazard Index. NEWWA members are unfamiliar with the Hazard Index approach as it has never been used under the Safe Drinking Water Act before. We are concerned that a cumulative regulatory approach ignores the complexities of selecting, implementing, and operating the appropriate and affordable PFAS treatment solutions.

There are a limited number of drinking water treatment technologies that are currently known to be effective for PFAS removal. However, there is no one-size-fits-all solution. Depending on several site- specific factors, such as the concentrations and types of PFAS present in the source water(s), general water quality characteristics, and existing treatment processes, treatment technologies may show different removal effectiveness for the varying carbon chain lengths and attached functional groups. EPA needs to provide flexibility within this regulation to allow for expansion of treatment options as technology progresses. Advancement in Best Available Technologies (BATs) will be made, and EPA and primacy states need to be positioned to swiftly approve new BATs.

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document. The EPA agrees that not every BAT represents the best treatment option for an individual system and site-specific considerations can inform BAT selection. The EPA notes that water systems may choose any treatment or non-treatment options to comply with the MCL and that it does not necessarily need to be a BAT identified in the final NPDWR. For more information on co-removal, please see section 10.2 of the EPA response in this *Response to Comments* document. For information on the cumulative regulatory approach, please see the EPA response to comment Doc. #1567, SBC-042734 in section 10.1 in this *Response to Comments* document.

New England Water Works Association (Doc. #1836, SBC-045388)

There is significant engineering effort and cost that goes into selection of the appropriate treatment technologies for a given water system. Site-specific testing, either bench-scale or pilot-scale, that evaluates the effectiveness of the treatment technologies with the actual contaminated water and the follow-up cost analysis is critical for:

1) Identifying the appropriate treatment solution for that specific water and existing treatment process;

2) Selecting the cost-effective alternative; and

3) Identifying and avoiding any potential unintended consequences that are inherently possible when any new water treatment process is added (e.g., although this is a very infrequent occurrence, coal- based carbon has been observed to release arsenic under certain water conditions).

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document. The EPA agrees that effort should go into selecting the appropriate treatment technology for a particular treatment site. The EPA also agrees that bench testing (which may reduce the cost of pilot testing) and pilot testing are important costs that are considered in the final NPDWR. Please see section 13 of the EPA response in this *Response to Comments* document for additional discussion on the EPA's HRRCA.

Anna Trujillo (Doc. #1959, SBC-047297)

Reverse osmosis, activated carbon treatments, and ion exchange treatments can all be used to remove PFAs from water. Each therapy has a unique result, and some are more successful than others, but generally, the therapies are advancing human health, the environment, and the well-being of our animals.

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document.

Brittney Johansen (Doc. #2750, SBC-047419)

The technologies on the EPA's own website published in January 2022 show promise for removing PFAS from water at different scales. These methods need to be applied to the appropriate scales and accessible nationally for all income levels at the expense of companies holding CBI's for any form of PFAS chemical.

I also request a hard stop to all forms of current and future PFAS manufacturing.

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document. For additional discussion on comments outside the scope of the current NPDWR, please see section 15.1 of the EPA response in this *Response to Comments* document. For more information on the HRRCA please see section 13 of the EPA response in this *Response to Comments* document.

Nick Fitzgerald (Doc. #3072-94, SBC-047406)

Next, I'm convinced that bold, passive American-made solutions can be achieved to begin removing PFAS from the environment on the scale necessitated. Wherever PFAS contaminated groundwater seeps into larger bodies of water, we should be installing bioswales with granular activated carbon, GAC, amended soils or burying GAC in fine bags or gabion baskets for passive subsurface water remediation and periodic disposal to proper sites. We should be studying if our wildfire ravaged forest can be harvested while replanted to produce GAC locally for pennies on the dollar. Are we studying how GAC from native species such as Douglas fir, Maple, or Aspen work to remove PFAS? Are we studying which climate change ready native plant species can effectively draw up and remove PFAS from contaminated areas? Likely contaminated groundwater seeps from the west plains into the Spokane River, present a perfect opportunity for proof of concept because this is unfortunately coming down to costs and the scale of the issue could readily put Fortune 500 companies into bankruptcy. We may just have to bootstrap this with community planting projects, give us plant starts, we can organize and help achieve this shared dire goal. If this issue could be around for centuries, we will do best to act quickly to remove PFAS in bulk from the environment such that it's largely persistent on a time scale of decades or years. With talented engineers and constructors and federal level scientific support, this problem could be meaningfully reduced in real time. A designed and built water sampling devices for pesticide studies for the USGS that were in order of magnitude less costly than alternatives. I am a build your own laboratory type of guy, and there are plenty more like me out there who could be sourced to actually address this problem on a scale that begins to approach the magnitude of the issue at hand. What I hear is people asking for the government to do something, anything, in response to the issue, not hand waving or vouchers for laboratory-grown livers. We are years past knowing this is a big concern. They want to fish their historic waterways and not get cancer. Have you fixed the problem that you should have protected the nation from in the first place? I hear folks talking about government mistrust. Meaningfully addressing environmental PFAS without further bankrupting the youth would go miles in

restoring faith in government. Nicholas B Fitzgerald, Spokane, Washington. Thank you. I yield back.

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document. For additional discussion on comments outside the scope of the current NPDWR, please see section 15.1 of the EPA response in this *Response to Comments* document. The EPA also notes that research is an important part of the PFAS Strategic Roadmap and EPA has looked into phytoremediation such as the October 1, 2018, through March 31, 2019, Small Business Innovation Research (SBIR) – Phase I grant Phytoremediation of PFAS via phytoextraction among others as well as funding research into different sorbents through the Innovative Water Technology Micropollutants request for application mechanism.

Robert Hollander (Doc. #1516, SBC-042713)

6. 88 FR 18688, 1st paragraph

Does reactivation of GAC and incineration of resin destroy any PFAS residues contained in them?

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comment*s document. The EPA refers the commenter to section three of the *Interim Guidance on the Destruction and Disposal of Perfluoroalkyl and Polyfluoroalkyl Substances and Materials Containing Perfluoroalkyl and Polyfluoroalkyl Substances* available on the internet at: https://www.epa.gov/system/files/documents/2021-11/epa-hq-olem-2020-0527-0002_content.pdf for a thorough discussion of this question.

Massachusetts Water Works Association (MWWA) (Doc. #1601, SBC-042885)

Treatment Considerations:

EPA is proposing MCLs for PFOA and PFOS at 4 ppt and a Hazard Index approach for four other PFAS compounds: PFHxS, HFPO-DA/GenX, PFNA, PFBS with a MCL of 1.0 (unitless) Hazard Index. MWWA is unfamiliar with the Hazard Index approach. While perhaps common in the EPA's CERCLA program and the Massachusetts Waste-Site Clean-up program, it has never been used before under the SDWA. We are concerned that a cumulative regulatory approach ignores the complexities of selecting, implementing, and operating the appropriate and affordable PFAS treatment solutions. We are also concerned about the uncertainties that exist if EPA decides to regulate more PFAS compounds in the future under the Hazard Index.

There are a limited number of drinking water treatment technologies that are currently known to be effective for PFAS removal. However, there is no one-size-fits-all solution. Depending on several site-specific factors, such as the concentrations and types of PFAS present in the source water(s), general water quality characteristics, and existing treatment processes, treatment technologies may show different removal effectiveness for the varying carbon chain lengths and attached functional groups. EPA needs to provide flexibility within this regulation to allow for

expansion of treatment options as technology progresses. Advancement in Best Available Technologies (BATs) will be made, and EPA and primacy states need to be positioned to swiftly approve new BATs. It is recommended that EPA and primacy states streamline their new technology review process to grant approvals more quickly. In Massachusetts, MassDEP required new technology approval for Granulated Activated Carbon (GAC) which required manufacturers, consultants, and PWS to jump through hoops that MWWA believes were unnecessary given that GAC has been widely used in water treatment and is one of only a few proven technologies for removing PFAS.

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document, it describes how water systems may use technologies other than BATs to meet the MCLs. Some primacy agencies may require permits and approval of technologies. The EPA has provided materials such as the *Best Available Technologies and Small System Compliance for Per- and Polyfluoroalkyl Substances (PFAS) in Drinking Water* document to assist primacy agencies that may require permitting. For information on the cumulative regulatory approach, please see the EPA response to comment Doc. #1567, SBC-042734 in section 10.1 in this *Response to Comments* document, as well as section 10.4 of the EPA response in this *Response to Comments* document.

American Water Works Company Inc. (Doc. #1608, SBC-043995)

Reverse Osmosis/Nanofiltration

American Water believes that RO/NF are not practical treatment technologies for most utilities. RO/NF membrane processes are extremely energy-intensive, very susceptible to fouling, and produce a voluminous waste stream that poses an additional treatment/disposal challenge because of dissolved solids and PFAS content. RO/NF treatment will likely only be appropriate for utilities whose only available sources of supply contain elevated total dissolved solids that cannot be removed via another more cost-effective or environmentally friendly treatment process.

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document.

Association of State Drinking Water Administrators (ASDWA) (Doc. #1628, SBC-044118)

ASDWA recommends that EPA provide guidance on the BAT options offered that would be effective on a small enough scale to be used at these small water systems.

Numerous primacy agencies have indicated that they do not have experience with very small treatment units for PFAS treatment. However, primacy agencies have expressed the importance of ensuring treatment units are correctly sized for the water system.

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document. After finalization of the PFAS NPDWR, the EPA also intends to work to

provide support to utilities, primacy agencies, and other interested parties to ensure successful rule implementation and plans to consider the topics suggested by the commenter as the agency develops implementation materials for the final NPDWR. More information on SSCTs can be found in section 10.5 of the EPA response in this *Response to Comments* document.

Association of State Drinking Water Administrators (ASDWA) (Doc. #1628, SBC-044108)

Primacy agencies have also highlighted concerns regarding the use of reverse osmosis (RO). While in some circumstances, RO may be the best option, this technology has many challenges that may not be able to be overcome and would make RO infeasible for some water systems. The cost to install and operate over time due to energy usage, waste disposal, and operator costs make the technology infeasible for many small water systems. RO is very difficult to operate and requires a highly trained and certified operator—primacy agencies have seen water systems with RO installed that fail to properly maintain the treatment, prematurely foul the membrane, or even enter enforcement due to operational concerns. Additionally, systems in states with limited water resources may experience water rights conflicts because of the amount of water used for brine disposal. Water systems in these states may also have limited disposal options for RO brine since there is limited dilution in the waterways. Primacy agencies have noted that these systems are left with limited options of deep well injection or evaporation ponds. One final concern regarding RO, as well as nanofiltration (NF), is the effect on the corrosion chemistry of the system. Some primacy agencies require a corrosion control treatment (CCT) evaluation before installing RO/NF/IX. ASDWA recommends that EPA provide additional clarification on these issues in the final rule.

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document. The EPA agrees that RO may be the best option in some circumstances and may not be appropriate in others, based on are site-specific concerns. More information about handling RO brine is provided in the *Interim PFAS Destruction and Disposal Guidance*. In acknowledgement of these potential issues for RO and NF, the EPA has adjusted RO/NF's technology projection compliance forecast to 0 percent in the final rule's EA. Additionally, the EPA has published guidance on corrosivity concerns in various places, for example, the *Best Available Technologies and Small System Compliance Technologies for PFAS in Drinking Water* in sections 3.4.1 and 4.5.1 for AIX and RO/NF, respectively.

Washington County Department of Public Health and Environment (Doc. #1739, SBC-043573)

Available technologies

• In the discussion of best available technologies or BATs in Part A, Section XI, Treatment Technologies, a non-treatment option such as finding an alternate source of drinking water (i.e. drilling a new well) or purchase water from another facility is included.

o The use of alternative drinking water sources, such as drilling new wells in deeper aquifers, may involve risks over the long term to community water supplies, due to the interconnectivity

of groundwater sources. The Twin Cities East Metro area of PFAS contamination is a example of the interconnectedness of water resources.

o EPA should consider adding a discussion of emerging destruction and separation technology types that may provide future treatment efficacy at the small and large scale.

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document. After finalization of the PFAS NPDWR, the EPA also intends to work to provide support to utilities, primacy agencies, and other interested parties to ensure successful rule implementation and plans to consider the topics suggested by the commenter as the agency develops implementation materials for the final NPDWR. The final NPDWR does not require the use of any specific BAT and systems may choose other treatment or non-treatment approaches (e.g., connecting to new source waters) to comply with the rule based on site-specific conditions for a given utility, including water quality, available space, disposal options, local rules, and currently installed unit operations.

National Ground Water Association (NGWA) (Doc. #1804, SBC-045473)

[The steps identified in that letter include:]

• accelerating research on water treatment and health effects to support future decision making and contaminant prioritization, and

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document.

Association of Missouri Cleanwater Agencies (Doc. #1817, SBC-044651)

III. Technologies may not be available depending on EPA's overall PFAS-related regulatory actions.

EPA states "there are technologies currently available that effectively remove [PFOS, PFOA, PFNA, PFHxS, or HFPO-DA] and other PFAS." 88 Fed. Reg. 18638, 18684 (Mar. 29, 2023). See also 88 Fed. Reg. at 18685-86 ("GAC can be a cost-effective treatment option despite needing to dispose of contaminated carbon."; "AIX can be a cost-effective treatment option"; "The three technologies discussed [GAC, AIX, and RO] have all been demonstrated to be effective in removing all six PFAS proposed for regulation as part of this rulemaking.") EPA needs to further investigate whether technologies are as available as they perceive.

In particular, the degree of removal of long-chain and short-chain PFAS varies with the type of technology employed. Has EPA determined that all six of the PFAS being regulated can be removed with each individual technology evaluated by EPA? We question whether the technologies evaluated can be counted on to remove all six of these chemicals (comprising both short and long chain PFAS) below the proposed MCL levels.

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document and the EPA response to comment Doc. #1816, SBC-044673 in section 10.1 in this *Response to Comments* document.

Professor Emeritus of Geophysics (Doc. #3072-90, SBC-046398)

My name is George Jiracek. I am a Professor Emeritus of Geophysics living in San Diego. I've studied our planet from pole to pole and on every continent. It's just over five years ago since famous physicist Stephen Hawking died after publishing a book for public consumption, where he warned that there are three ways within a thousand years that we may not survive on planet Earth. They are: (1) runaway climate change; (2) nuclear Armageddon; and (3) an asteroid impact. As a scientist, I must add one more, PFAS. This is because as mentioned by others, PFAS affect reproductive organs, both male and female, and if we can't have children, we will not survive. So since 99% of us have PFAS in our bloodstreams and we remove PFAS through waste products which continue to have PFAS, we must develop methods that destroy, not just filter, PFAS at absolute levels of 100% and at scale. Treatments such as ion exchange, granular activated carbon, and reverse osmosis are only 90% effective. Recycling drinking water programs do not remove 100% of PFAS. I think what we really need is a national, international moonshot program now aimed at how to best break carbon-fluorine bonds so we can destroy 100% of all dangerous PFAS, not only in drinking water, but in all sources. As a veteran, I know that we now spend $81 billion on defense each year. Surely, we can spend what it takes to save human life on our planet. Thank you.

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document. The EPA's final rule represents data-driven drinking water standards that are based on the best available science, meet the requirements of SDWA, and that regulation of the PFAS covered by the NPDWR is vital toward protecting public health by removing these contaminants from our nation's drinking water.

Water and Wastewater Equipment Manufacturers Association (WWEMA) (Doc. #1727, SBC-043525)

[Please see our comments below.]

Comment #2: PFAS Liability Shield Needed for Technology Solution Providers

To take full advantage of the historic $50 billion in BIL funding of which $10 billion is dedicated to PFAS remediation, it will be critical to ensure liability protections for technology solution providers. As a passive receiver, WWEMA is asking for state and Federal policymakers to protect technology solution providers who are actively working to address our country's PFAS contamination crisis from future liability. In order to fully utilize the current BATs listed by EPA and to promote early adoption and technology evolution for PFAS removal, solution providers should be encouraged to bring current and innovative technologies to bear and be shielded from third party litigation and liability lawsuits. Without policy makers shielding technology providers

from lawsuits outside of acceptable liability scope, this could seriously impact the ability of these solution providers to address these issues at the state and local levels. Without such assurances, companies may be reluctant to provide technologies to the water marketplace or to further invest in innovation and new technologies for PFAS removal.

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document. SDWA does not provide EPA with the liability protection authority requested by the commenter.

This study was a collaborative effort; many individuals and utilities spent time compiling data, answering questions, and making contacts. We wish to thank the following utilities for sharing data and Steering Committee Members for their time and insight:

Partner Utilities:

• Cape Fear Public Utility Authority (CFPUA)

• City of Ann Arbor

• Greater Cincinnati Water Works

• Plainfield Charter Township

• City of North Miami Beach

• Miami-Dade County Water and Sewer Department

• Tucson Water

• Steering Committee Members:

• Amy Stoffer – Northern Kentucky Water District

• Cynthia Lane – Platte Canyon

• Carel Vandermeyden – CFPUA

• Robert Cheng – Coachella Valley Water District

• Zaid Chowdhury – Garver USA

• Chuck Hertz – Retired

2.0 Introduction

Known as "forever chemicals" because they do not easily biodegrade, per- and polyfluoroalkyl substances (PFAS) are drawing increased scrutiny from health agencies, water utilities, and the public for their presence in drinking water and their effects on human and environmental health. They have quickly become contaminants of great concern in drinking water.

Six PFAS compounds were monitored in finished drinking water as part of the Third Unregulated Contaminant Monitoring Rule (UCMR 3) between 2013 and 2015 to quantify their prevalence across the United States. The UCMR program provides the U.S. Environmental Protection Agency (EPA) with nationally representative occurrence data to inform drinking water regulations. Using the results from UCMR 3, in February 2021, the EPA published a final determination to regulate perfluorooctanoic acid (PFOA) and perfluorooctane sulfonic acid (PFOS) and signaled an interest in considering the regulation of additional PFAS. On March 14, 2023 the EPA announced the first proposed National Primary Drinking Water Regulation (NPDWR) for six PFAS compounds, including PFOA, PFOS, perfluorononanoic acid (PFNA), hexafluoropropylene oxide dimer acid (HFPO-DA, commonly known as GenX Chemicals), perfluorohexane sulfonic acid (PFHxS), and perfluorobutane sulfonic acid (PFBS). The deadline for public comment on this proposed regulation is May 30th, 2023 and the EPA has publicly committed to promulgate the PFAS NPDWR by the end of 2023.

U.S. federal laws and executive orders stipulate that the U.S. EPA estimate the cost of compliance for this new primary drinking water regulation. Black & Veatch was selected by the

American Water Works Association (AWWA) to develop a national cost estimate for water systems to remove PFAS from drinking water to better understand the financial impacts to communities and the costs to comply with a national primary drinking water regulation, a policy that could impact each of the more than 66,500 public water systems.

The project was funded by the Water Industry Technical Action Fund (WITAF), which is managed by the AWWA's Water Utility Council to support projects, studies, analyses, reports, and presentations in support of the organization's legislative and regulatory agenda. The national cost estimate and its cost models, developed under WITAF 056, are intended to support to AWWA's engagement with the U.S. EPA and Congress on the differences in financial impacts of treating drinking water to various PFAS regulatory limits. WITAF funded a separate project (WITAF 057) to generate a national PFAS occurrence database using data from state monitoring and UCMR3. This national database was used as an input for the WITAF 057 project.

The national cost modeling tool programmatically evaluates each public water system (PWS) with occurrence data from WITAF 057 to generate a dataset of the most probable capital and operating costs. Those costs are then scaled up nationally to account for the PWSs without data captured in WITAF 057 to quantify the national cost of compliance of a proposed regulation, bringing flexibility for data-driven responses to EPA cost assessments. This project brought together occurrence data, cost data, and best practice design methodology to help ensure the U.S. EPA's proposed national primary drinking water regulations for PFAS accurately reflect cost estimates for drinking water treatment.

3.0 PFAS Treatment Technologies

Treatment strategies for PFAS in drinking water include proven, commercially available technologies as well as emerging technologies. Many of these developing technologies have been demonstrated on the bench scale but have not yet been proven at the full scale or are not yet commercially available.

Commercially available technologies that have been demonstrated at full scale in the field to reduce concentrations of PFAS in drinking water are limited to the following:

- Granular activated carbon (GAC).
- Ion exchange (IX).
- Nanofiltration (NF) and reverse osmosis (RO).

Treatment considerations for the application of each of these technologies are described in the following subsections.

3.1 Granular Activated Carbon

GAC media is a well-known adsorbent for organics and has been widely applied in water treatment. GAC is produced from carbon-based materials such as coal, coconut shells, peat, or wood that has been "activated" to produce a highly porous media with adsorptive properties. The

pores contain sites on which organic compounds become attached and are adsorbed onto the activated carbon matrix.

GAC treatment applications include removal of organics, such as color, disinfection byproducts (DBP) and their precursors, taste and odor (T&O) causing compounds, industrial chemicals, and emerging contaminants such as PFAS, endocrine disrupting compounds, and pharmaceuticals and personal care products. Each of these contaminants compete for adsorption sites on GAC media with targeted PFAS if present. In some cases, co-adsorption can be viewed as a benefit for using GAC as the co-contaminants are simultaneously removed. Cost analyses and removal performance models must balance competitive adsorption of co-contaminants and its associated detrimental performance impact on PFAS removal.

GAC has a finite capacity for adsorbing compounds. High concentrations of organics or high flow rates will lead to more frequent media replacement. In general, short-chained PFAS are less readily adsorbed and less strongly bound than long chain compounds. The overall efficacy of GAC removal of PFAS highly dependent on the water matrix, the water treatment goals, and the design of the system. One of the most important design parameters is the empty bed contact time (EBCT), or the time during which the water is in contact with the media bed (also the duration at which adsorption can occur), assuming the water flows through the entire bed at a constant velocity. A desired EBCT will result in breakthrough when the adsorptive capacity of the media has been exhausted. The media must be either replaced or reactivated at that time.

3.1.1 Implementation and Operational Considerations

GAC applied for PFAS removal is most effective when used solely as an adsorbent. Conventional granular media filters containing GAC are typically designed for short EBCTs and must be frequently backwashed for removal of particulate material that is retained in the media. Such backwashing disrupts the adsorption front. Short EBCTs and backwashing lead to fast breakthrough of contaminants and underutilization of GAC media. If a water treatment facility contains conventional filters, contactors for GAC adsorption are typically located downstream.

Process selection (including GAC media selection) is typically confirmed through demonstration testing (bench-, pilot- or full-scale studies) to account for the unique characteristics of the source water.

GAC adsorption treatment systems installed for PFAS removal typically provide a 10 to 20 minute EBCT and a surface loading rate of 4 to 10 gallon per minute (gpm) per square foot of media (gpm/sf). PFAS adsorbers are applied in two main configurations: pressure vessels or gravity basins.

• Pressure vessel configurations are more common in small systems (less than approximately 10 million gallons per day [mgd]). Pre-engineered pressure-vessel type GAC treatment systems are widely available. Vessels are typically carbon steel or fiberglass reinforced plastic (FRP). Pressure vessels may be installed in single (parallel) or dual stage (series/lead-lag) arrangements.

o The single stage arrangement allows for columns to be operated in various stages of breakthrough or exhaustion, resulting in an overall effluent below the treatment target. This arrangement can result in better media utilization, produce a more consistent product water quality, and lessen impact of potential overruns on individual vessels. Single stage systems typically include N+1 redundancy.

o The dual stage arrangement allows for simultaneous production during media replacement, and sampling between vessels ensures that lag vessel effluent always meets treatment targets. The lead vessel can be in service until the media is completely exhausted, leading to higher utilization of the adsorbent media. The dual stage arrangement includes built-in redundancy as either the lead or lag vessel can be removed from service without reducing the treatment flow rate. Thus, no dedicated redundant vessels are typically provided.

• To avoid an excessive number of pressure vessels, gravity basin configurations are typically applied by large systems with design flows greater than approximately 10 mgd. Gravity basins are typically single stage and operated at various stages of breakthrough, similar to a single stage pressure vessel arrangement. The basins themselves are typically constructed of concrete with an N+1 redundancy because of the single stage arrangement.

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document. The EPA acknowledges the information referenced by the commenter and has considered the information in updating the cost estimates for the final NPDWR. For additional discussion on the EPA's cost analysis, please see section 13.3 of the EPA response in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-046153)

3.2 Ion Exchange

IX is an adsorptive water treatment process that involves the selective exchange of ions in solution with ions bound to a resin matrix. IX has a long history in water treatment, and resins are manufactured for a variety of contaminants, including PFAS. Several manufacturers provide specific IX resins designed to be selective for PFAS as the market has expanded for their use. Some resins originally intended for removal of other contaminants (such as perchlorate) have shown a high degree of selectivity and capacity for PFAS as well.

IX resins, like GAC, have a limited capacity for adsorption. The adsorptive capacity of IX resins is affected by contaminant concentrations and flow rates in the same manner as GAC. However, the IX resins surveyed have proven to be highly selective toward PFAS removal, exhibiting minimal removal of other contaminants. This may result in a greater adsorptive capacity for PFAS compared to GAC, without, however, the co-contaminant removal benefits of other technologies. In general, short-chained PFAS are less readily adsorbed and less strongly bound than long chain compounds. The overall efficacy of IX for PFAS removal is highly individual to the water matrix, the water treatment goals, and the design of the system.

An IX treatment process does not result in a fixed percentage removal of a contaminant over time, as there is a variable degree of contaminant removal and gradual or sharp contaminant breakthrough. Although it is selective to certain contaminant groups, the resin can experience interference from other compounds in the water matrix. The most preferred compound will tend to exhibit long runs and sharp breakthroughs; less preferred compounds will have earlier, more gradual breakthroughs.

Exhaustion of the media is determined (in a fashion similar to that for GAC) through the measure of the contaminant in the effluent (breakthrough). When the adsorptive capacity has been exhausted, the resins require replacement or regeneration. Because of the proposed CERCLA hazardous substance designations for PFOA and PFOS as discussed in Subsection 3.1.1, single use (fixed-bed) systems are currently being considered for IX, requiring disposal of spent media and replacement with new resin when exhausted. PFAS destruction technologies are currently in research and development that may be able to destroy PFAS in the brine stream, although that technology is not yet matured enough for full- scale implementation.

Fixed-bed IX has been demonstrated at full scale in the field as a proven PFAS removal technology. Fixed-bed ion exchangers applied for PFAS removal consist of carbon steel or FRP pressure vessels and typically 1.5 to 3 minutes of EBCT (as compared to 10 to 20 minutes for GAC). IX can be favorable because of the smaller footprint required.

3.2.1 Implementation and Operational Considerations

The efficacy of an IX treatment system will likely be improved by a pretreatment step to remove interferences such as suspended solids, particulate natural organic matter, and colloidal compounds. Commercially available filters can be selected depending on the pretreatment needs to improve the treatment capacity of the IX system. This prefiltration step can prevent deposition of fine particles on the resin, reduce pressure drop across a column, and increase run time.

Process selection (including resin selection) is typically confirmed through demonstration testing (bench-, pilot- or full-scale studies) to account for the unique characteristics of the source water.

Ion exchange treatment systems are conventionally installed in pressure filters in lieu of gravity basins. As with GAC, the pressure vessels can be implemented in single or dual stage arrangements.

Considerations for the single or dual stage arrangements are summarized in Subsection 3.1.1.

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document. For information on the cumulative regulatory approach, please see the EPA response to comment Doc. #1567, SBC-042734 in section 10.1 in this *Response to Comments* document, as well as section 10.4 of the EPA response in this *Response to Comments* document. The EPA acknowledges the information referenced by the commenter.

Environmental Protection Network (EPN) (Doc. #1773, SBC-043865)

EPN agrees that EPA has appropriately identified BAT achieving this HI of one as GAC, AIX, RO, and NF. EPA asks for public comment on whether these technologies will also remove other PFAS not included in the rule. Studies cited in this rule and EPA's Drinking Water Treatability database show that GAC and AIX removal efficiencies generally increase as PFAS chain length increases. RO and NF have higher removal efficiencies than GAC and AIX for short chain PFAS. EPN recommends that EPA review drinking water treatment data from Massachusetts, Vermont, and Michigan because these states have MCLs for PFAS not included in this rule (PFHxA, PFHpA, PFDA). They should have monitoring data indicating removal efficiencies for these three additional PFAS.

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document. The SDWA regulates contaminants that meet specific regulatory criteria as outlined in section 3; the EPA appreciates data sources for other PFAS. For more information on treatment efficacy in relation to chain length, please see section 10.3 of the EPA response in this *Response to Comments* document.

Environmental Working Group (EWG) (Doc. #1721, SBC-045414)

There are also additional highly effective technologies that treat PFAS in drinking water. In North Carolina, the Fayetteville Chemours Plant is using a reverse osmosis treatment system, coupled with GAC and IX, to treat the wastewater from its manufacturing processes. Pilot tests for an RO system at Northwest Water Treatment Plant in North Carolina found that it was expected to remove 90 percent or more of PFAS compounds, including GenX. [FN54: See Anna Reade, Tracy Quinn, & Judith S. Schreiber, Scientific & Policy Assessment for Per- and Polyfluoroalkyl Substances in Drinking Water, NAT. RES. DEF. COUNCIL at 55 (April 12, 2019), https://www.nrdc.org/sites/default/files/media-uploads/nrdc_pfas_report.pdf.] RO is considered the most robust technology for protecting against unidentified contaminants and does not require media change out nearly as often as GAC. [FN55:Id.] Although less common than GAC systems, RO systems are being used nationwide to remove PFAS. For example, the West Morgan-East Lawrence Water Authority serving Decatur, Alabama, is installing an RO system to remove PFAS. [FN56: Alabama Dep't of Env't Mgmt., Per- and Polyfluoroalkyl Substances (PFAS) in Drinking Water, http://adem.alabama.gov/programs/water/drinkingwater/pfaspage.cnt (last visited May 29, 2023).]

IX or IX resins specified to perform to the same standard as GAC have also been shown to be effective in some cases. [FN57: Tasha Stoiber et al., PFAS in Drinking Water: An Emergent Water Quality Threat, WATER SOLS. (2020), https://www.ewg.org/sites/default/files/u352/Stoiber_Evans_WaterSolutions_2020.pdf.]

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document for more information on co-removal. The EPA thanks the commenter for providing examples of systems employing RO at full scale and acknowledges that site-specific

conditions can make technologies perform to different levels. The EPA agrees that the BATs chosen are appropriate and notes that RO systems do not use media but may need to change membranes.

Environmental Council of the States (ECOS) (Doc. #1752, SBC-044506)

Treatment Technology Review

As water systems plan to comply with the NPDWR, they will look to states and EPA for help identifying effective and reliable treatment technologies. While several treatment options exist, water systems will need support and information to evaluate the challenges and benefits of different technology options. ECOS recommends that EPA support evaluations of PFAS treatment technologies by the Office of Research and Development, with particular focus on treatment options for smaller systems, and that EPA develop additional information and guidance for systems about various PFAS treatment options. Additionally, ECOS acknowledges that treatment technology improvements will require technical and operational training for public water system operators and encourages EPA to provide resources to address this need.

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document. The EPA has developed supporting rule documents such as the *Best Available Technologies and Small System Compliance for Per- and Polyfluoroalkyl Substances (PFAS) in Drinking Water* document that can be used to help develop familiarity with proven drinking water PFAS technologies. After finalization of the PFAS NPDWR, the EPA also intends to work to provide support to utilities, primacy agencies, and other interested parties to ensure successful rule implementation. The EPA is currently funding many technical assistance efforts associated with PFAS, including supporting treatment infrastructure projects through the DWSRF and the Emerging Contaminant grant program as designated and funded through the BIL. As outlined in the PFAS Strategic Roadmap, the EPA is committed to addressing PFAS. The ORD is also evaluating and developing technologies for reducing PFAS in the environment to inform decisions on drinking water and wastewater treatment, contaminated site cleanup and remediation, air emission controls, and end-of-life materials management.

New York State Department of Health (NYS DOH) (Doc. #1677, SBC-044950)

12. In quantifying the benefits realized through the use of RO, GAC and ion exchange resins to treat PFAS, EPA does not consider the potential health impacts associated with microbiological, organic and inorganic constituents that may leach or be released from the treatment media, potentially offsetting a portion of the benefits. Carbon used for PFAS removal is typically either bituminous or coconut shell-based coals, All coals contain some arsenic (USGS, 2005). While coconut shell-based coals can have lower arsenic levels than their bituminous competitors, many of the largest producers of GAC for PFAS removal use bituminous based coals for PFAS removal. To compensate, many GAC manufacturers have developed acid washed coal to reduce levels of contaminants. Nonetheless, based on our observations in full scale carbon treatment

systems, the New York State Department of Health has developed guidance that recommends three consecutive results be provided that show decreasing arsenic concentrations as the forward rinse to waste progresses and for which the last sample concentration is below the arsenic MCL [FN2: https://www.health.ny.gov/environmental/water/drinking/docs/interim_recommendationszfor_granular_activated_carbon_installations_v_l.pdf].

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document.

Eastern Municipal Water District (EMWD) (Doc. #1780, SBC-043822)

EMWD has a unique situation where we treat brackish groundwater that is too salty to drink, through a reverse osmosis (RO) system, and then utilize a bypass to blend a small portion of the salty groundwater with the RO water before placing the water in the distribution system. This practice of adding back a reasonable amount of total dissolved solids (TDS) and alkalinity back to the water is important because makes the water more palatable, and helps prevent corrosion of the potable water distribution system. Once this MCL is in place, EMWD would nesed to manage this system differently, in a manner that treats 100 percent of the groundwater to ensure PFAS removal, and then add the necessary TDS and alkalinity through a source that is not salty groundwater. This additional treatment will incur construction costs, additional operation and maintenance costs, as well as the cost of chemicals to adjust the alkalinity.

During a meeting with EPA last week, we expressed concerns regarding the cost of PFAS clean-up, and EPA staff directed us to SRF, WIFIA, and other loan opportunities. Loans are not a reasonable answer to the cost challenge. Even though loans can extend the repayment period, the cost of PFAS cleanup is ultimately and unfairly shouldered by drinking water customers.

EPA Response: Please see section 10.1 of the EPA response in this *Response to Comments* document. For more information treatment considerations related to MCLs, please see section 5.1.4 of the EPA response in this *Response to Comments* document. Regarding funding considerations, please see section 2.4 of the EPA response in this *Response to Comments* document.

10.2 Other PFAS Removal Treatment Technologies

Summary of Major Public Comments and EPA Responses

The EPA received many suggestions for additional BATs including powdered activated carbon (PAC), alternative sorbents, and new destructive technologies. However, these alternative BATs proposed, except for PAC, currently lack demonstrated full-scale removal of the six PFAS under consideration. The EPA notes that there are some reports of PAC use on a temporary basis and that it can reduce PFAS concentrations in drinking water. PAC may be an appropriate choice of technology in certain circumstances; however, its efficacy for trace removal tends to be variable due to factors such as carbon particle size, background organics, and plant efficiency. Therefore,

PAC is not as effective as GAC overall, and the agency has not designated it as a BAT. The EPA periodically reevaluates treatment technologies and may add additional technologies based on updated information. It is important to note that water systems may use any technology or practice to meet the PFAS MCLs and are not limited to the BATs in this rule. Other technologies may be chosen in lieu of BAT because they may be more cost effective or better suited to the specific operating conditions of the particular site to meet the MCL.

Individual Public Comments

Pennsylvania Department of Environmental Protection (Doc. #1626, SBC-044895)

Treatment Considerations

• DEP recommends that EPA reestablish the national Environmental Treatment Verification (ETV) program to streamline and improve efficiencies regarding review and approval of new treatment technologies. Without this national program, states must approve treatment technologies at the state level, which is neither streamlined nor efficient, and creates an unnecessary burden on limited resources for states, water systems, and treatment technology manufacturers.

EPA Response: Please see section 10.2 of the EPA response in this *Response to Comments* document. The EPA's Environmental Technology Verification Program (ETV) concluded operations in early 2014 and reestablishing the ETV is outside the scope of this NPDWR. More information on permitting can be found in section 10.1 of the EPA response in this *Response to Comments* document.

Orange County Water District (OCWD), California (Doc. #1634, SBC-043239)

Alternative Treatment Technologies

EPA requested additional information on PFAS removal treatment technologies not identified in the proposed rule that have been shown to reduce levels of PFAS to the proposed standard. OCWD's ongoing pilot testing program has identified at least one alternative adsorbent, comprised of a proprietary surface-modified clay mineral, which shows promising performance as compared to the more established granular activated carbon (GAC) and ion exchange (IX) technologies. These types of emerging technologies offer potentially lower operating costs via selectivity and/or enhanced PFAS sorption capacity. OCWD recommends EPA tailor the final rule such that these types of alternative treatment technologies can be more easily approved by state primacy agencies for use in PFAS water treatment. This would help spur research, innovation, and development for additional cost-effective options for treatment media, thereby helping to meet the significant increase in demand associated with the final rule.

EPA Response: Please see section 10.2 of the EPA response in this *Response to Comments* document. The EPA thanks the commenter for providing anecdotal information on emerging technologies for treating PFAS in drinking water to at or below the MCLs. The EPA

agrees with commenter that alternative technologies may have adequate removal efficacy and affordable costs. The EPA points out that SDWA does not require permits nor does SDWA require approval for technology use. The EPA is also funding the development of these alternative technologies directly through, for example, the Innovative Water Technology Grant Program for next generation adsorbents and SBIR grants. More information on permitting can be found in section 10.1 of the EPA response in this *Response to Comments* document.

Park City Municipal Corporation (Doc. #2793, SBC-046610)

Park City Municipal Corporation, water system number UTAH22011, is a 8,500 population public water system that has PFAS detections in all three of its groundwater wells. We attribute the source of PFAS to be from Fluoro Ski Wax, and have prohibited it in our Source Protection Ordinance and implemented a successful ski wax take back program to reduce further environmental impact. Please consider the following comment regarding EPA's proposed PFAS Drinking Water Rule.

We request that the Proposed PFAS Rule specifically identifies the ability to utilize a blending plan as a non-treatment MCL compliance option. There is nothing in the proposed rule that prevents us from using blending as long as we do it before the Entry Point to the Distribution System. However, we think many State regulators shy away from agreeing to anything that is not specifically stated in the EPA rule. So, we do think that it is important for blending to be mentioned as an option, even if in passing, just to make sure that States are comfortable approving a water system blending strategy.

PFOS and PFOA concentrations in our wells range from 4-7 parts per trillion (ppt). We have the ability to blend other sources that do not have detectable PFAS concentrations to below the proposed MCLs. Our consultant, Water Quality and Treatment Solutions, Inc (WQTS) developed Conceptual Design and Probable Cost of PFAS Treatment Systems for the City's Groundwater Wells. Conceptual level cost estimates (–30% / +50%) to treat all three wells with ion exchange, one of the PFAS best available technology treatment options range from $6.8 - $14.7 Million in capital costs and $250K-$550K per year in operation and maintenance costs. Blending costs are less than $40k and operational requirements are minimal in comparison with treatment requirements.

EPA identifies blending as a viable compliance option in the documents found at the following links.

- Help for Small Systems in Complying with Drinking Water Regulations, identifies Blending Source Waters as a non-treatment compliance option, https://www.epa.gov/dwcapacity/help-small-systems-complying-drinking-water-regulations#non-treatment, -Systems that have multiple sources may be able to mix, or blend, these waters prior to distribution to their customers. Blending source water can help to lower contaminant concentrations."

- The Arsenic Rule has supporting compliance documents that identify blending as a viable compliance option.

- Complying With the Revised Drinking Water Standard for Arsenic: Small Entity Compliance Guide, https://www.epa.gov/sites/default/files/2015-09/documents/2005_11_10_arsenic_ars_final_app_f_1.pdf, STEP #5 – If a Problem Exists, What Are My Options? Source Water Changes: If arsenic levels in your existing water source exceed the MCL, you may want to consider blending water from a source with low arsenic levels with your current source. The level of arsenic in the blended water may be low enough to comply with the Arsenic Rule.

- Arsenic Treatment Technology Evaluation Handbook for Small Systems: https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=200026IH.txt, Arsenic Mitigation Checklist, 3. Determine if a non-treatment mitigation strategy such as source abandonment or blending can be implemented. Description of Arsenic Mitigation Strategies: Blending - The combination of multiple water sources to produce a stream with an arsenic concentration below the MCL.

Affordability has become a significant challenge in Park City where we have had to establish some of the higher water rates in the Country due to CWA and SDWA compliance orders and requirements for removal of metals from Park City's mine tunnel drinking water sources. We have bonded $140M to pay for a new, compliance ordered metals removal water treatment plant and associated infrastructure, which required significant rate increases over the last decade. We did not anticipate the cost of treating to remove PFAS in our financial models, and will have to implement additional rate increases if we have to treat to remove PFAS rather than achieve compliance through blending. The State of Utah Drinking Water Board has preliminarily reviewed and is not supportive of the potential for Park City to receive grant funding for PFAS Treatment; therefore, compliance costs would need to paid by rate payers.

EPA Response: Please see section 10.2 of the EPA response in this *Response to Comments* document. The EPA notes that no specific technology, technique, or process is required under this rule to meet the MCLs and that all options have potential tradeoffs. The EPA recommends that utilities and primacy agencies evaluate all options according to their site-specific needs and circumstances. The EPA thanks the commenter for providing data related to its projected compliance costs; more information on the EPA cost models can be found in section 13 HRRCA. As noted in the final rule preamble, section II.E, funding under the Infrastructure Investment and Jobs Act (IIJA), often referred to as the BIL, will assist many disadvantaged communities, small systems, and others with the costs of addressing emerging contaminants, like PFAS, when it might otherwise be cost-challenging. More information on BIL may be found in section 2.4 of the EPA response in this *Response to Comments* document. Additionally, to support BIL implementation, the EPA is offering water technical assistance (WaterTA) to help communities identify water challenges and solutions, build capacity, and develop application materials to access water infrastructure funding (USEPA, 2023b).

New Jersey Department of Environmental Protection (NJDEP) (Doc. #1699, SBC-045043)

In addition, NJDEP requests clarification on whether EPA would support blending as an option to achieve compliance with the proposed MCLs.

EPA Response: Please see section 10.2 of the EPA response in this *Response to Comments* document. The EPA notes no specific technology, technique, or process is required under this rule to meet the MCLs and that all options have potential tradeoffs. The EPA recommends that utilities and primacy agencies evaluate all options according to their site-specific needs and circumstances.

New Jersey Department of Environmental Protection (NJDEP) (Doc. #1699, SBC-045042)

Additional Treatment Technologies:

EPA requested additional information on PFAS removal treatment technologies that were not identified in the proposed rule that have been shown to reduce levels of PFAS. NJDEP is currently anticipating a permit proposal for a system to use reverse osmosis to isolate PFAS, then remove PFAS from the concentrate stream using an aqueous electrostatic contactor. The technology proposed by the water system completed a study under the EPA's Small Business Innovation Research (SBIR) Phase 1 (2019).

In terms of treatment technologies not identified in the proposed rule, NJDEP notes that it has conditionally approved for use an adsorptive media that works in a similar way to GAC that does not require backwash. The systems that have received approval for use of this media have not installed the treatment at this time. Additional information about this media is available at https://www.mineralstech.com/business-segments/performance-materials/cetco/environmental-products/products/fluoro-sorb.

Additional Considerations:

EPA's proposal does not note any recommendations for a lead-lag configuration for anion exchange and GAC treatment. Considering the potential public health impacts and delays between sampling and receipt of analysis results, EPA should consider whether systems should implement a lead-lag configuration to reduce public health impacts in the event of breakthrough in the lead media vessel. Depending on the frequency with which a system is sampling, breakthrough may not be noticed for a significant period.

EPA Response: Please see section 10.2 of the EPA response in this *Response to Comments* document. The EPA thanks the commenter for providing an example of a treatment train consisting of RO (an identified BAT) and a novel concentration technology (an aqueous electrostatic contactor) as well as an example of a novel adsorptive media. The EPA welcomes any data, observations, and comments that NJDEP can provide surrounding the treatment trains and novel technology. The EPA reevaluates BATs and may add additional technologies based on updated information. The EPA believes that each system in consultation with their primacy

agency will appropriately adjust to site-specific considerations. The final rule is not proscriptive in how water systems achieve compliance with the MCLs and agrees that lead-lag configurations may be appropriate in many situations.

State of Vermont Agency of Natural Resources and Department of Health (Doc. #1708, SBC-045114)

4) Are there additional technologies which are viable for PFAS removal to the proposed MCLs as well as any additional costs which may be associated with non-treatment options such as water rights procurement:

a. Foam fractionation: We would appreciate an evaluation of foam fractionation - is this actually feasible and it is a viable option?

EPA Response: Please see section 10.2 of the EPA response in this *Response to Comments* document. The EPA notes that foam fractionation has had success according to limited research; however, this technology has not met all criteria to be a BAT. Specifically, most studies on foam fractionation were performed with detection limits too high to be relevant for this regulation, many PFAS included in the rule were missing from the studies, the EPA is unaware of any full-scale drinking water applications, nor at the current time is there enough understanding to understand and interpret smaller scale studies to full-scale, and questions remain about the mass-balance for the process that may oxidatively transform PFAS precursors; therefore, the EPA lacks the data to conclude whether this technology is a feasible and viable option for water systems and based on this lack of understanding cannot designate foam fractionation as a PFAS BAT at this time. The EPA notes that innovation is important, and a pilot study may help determine the viability of foam fractionation for a specific site.

Louisville Water Company (Doc. #1720, SBC-043557)

[In that regard, we are providing the following comments on key issues that we think require consideration.]

7. Louisville Water is mildly concerned that although the agency has discussed granulated activated carbon (GAC), it has been largely silent on the use of powdered activated carbon (PAC) as a treatment technology. In fact, Louisville Water has been conducting research on the efficacy of PAC to remove various PFAS in Louisville Water conditions and we are confident that PAC will be a feasible alternative to attain compliance. PAC is effective for treating the PFAS of concern (PFOA and other long-chain PFAS) for Louisville Water sources, dosage can be based on water-quality conditions (for PFAS and other water quality issues), will have less impact on current treatment processes, and the capital and operating costs of PAC will be substantially lower than alternatives. Additionally, PAC has other water quality benefits, including reduced disinfection by-product precursors (TOCs), reduced microcontaminants, improved taste and odor control, and improved operational flexibility.

EPA Response: Please see section 10.2 of the EPA response in this *Response to Comments* document. The EPA appreciates the commenter's research and encourages Louisville Water Company to use the best technology in consultation with the primacy agency to comply with the MCLs, considering site-specific conditions. The EPA also notes that information about treating specific PFAS, such as HFPO-DA, with PAC is included in the Drinking Water Treatability Database, which is available online at https://tdb.epa.gov/tdb/home.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-045980)

Section 7.2: Alternative treatment technology

EPA requested additional information on PFAS removal treatment technologies not identified in the proposed rule that have been shown to reduce levels of PFAS to the proposed standard. Several AMWA members are currently undergoing testing of some emerging alternative absorbance media, like clay, specifically for PFAS removal. Because clay media does not co-remove TOC, it would be beneficial for utilities that have raw water TOC levels that could interfere with other PFAS-removing media. AMWA recommends EPA consider additional treatment techniques once they have been fully tested and shown they meet PFAS removal targets. More options for media would decrease demand for others, like GAC, where there may be a struggle to meet demand.

PWSs testing alternative absorbance media technology have seen initial signs of adequate removal efficacy and have found initial costs to be comparable to AIX and GAC. These alternative media even have the potential to require lower operation and maintenance costs over their lifetimes. As evident with the other technologies EPA lists, there is still uncertainty over the disposal options of the media. AMWA requests that EPA keep additional absorbance technologies in mind and consider their use when possible.

EPA Response: Please see section 10.2 of the EPA response in this *Response to Comments* document. The EPA appreciates and thanks the Association of Metropolitan Water Agencies (AMWA) for providing an example of a novel adsorptive media. The EPA reevaluates treatment technologies and may add additional BATs based on updated information.

Connecticut Department of Public Health (CT DPH) (Doc. #1745, SBC-045232)

2. EPA requests additional information on PFAS removal treatment technologies not identified in the proposed rule that have been shown to reduce levels of PFAS to the proposed regulatory standard.

CT DPH would encourage EPA to look at the wide range of PFAS treatment and prevention technologies currently in use or in study and not limited to drinking water treatment. This includes an update on the PFAS Innovative Treatment Team (PITT) studies on electrochemical oxidation and super critical water oxidation.

For waste generation reduction, technologies such as surface-active foam fractionalization (SAFF) are encouraging and similar technology and practicality for PWS implementation could be further researched.

EPA Response: Please see section 10.2 of the EPA response in this *Response to Comments* document. The EPA appreciates the examples cited by the Connecticut Department of Public Health. The EPA considers research as a key pillar of the PFAS Strategic Roadmap. Destructive technologies are discussed in the *Interim Guidance on the Destruction and Disposal of Perfluoroalkyl and Polyfluoroalkyl Substances and Materials Containing Perfluoroalkyl and Polyfluoroalkyl Substances* available on the internet at: https://www.epa.gov/system/files/documents/2021-11/epa-hq-olem-2020-0527-0002_content.pdf

Aclarity (Doc. #1755, SBC-044510)

Ensuring Best Available Solutions are Utilized

The federal government has a responsibility to use all available resources to eliminate pollution, safeguard public health, and develop laws that reinforce public health safeguards particularly in underserved communities and provide all communities with safe drinking water. Equitable access to clean water is a basic human right, essential for survival and well-being. It encompasses safe water for drinking, hygiene, agriculture, and daily life. It requires improving infrastructure, water management, and pollution control. Collaboration among governments, organizations, and along with adequate resources, education, and advocacy for marginalized communities are imperative. By recognizing water as a human right, we can create a just and sustainable future, ensuring equal access for all. Removing dangerous chemicals from our water, such as PFAS, is critical and ensuring the PFAS cycle ends is the only way to ensure this.

There are known and reliable technologies available today to safely remove and destroy PFAS from drinking water. We urge the federal government to use all available resources in addressing PFAS. It is imperative, when evaluating use of funds for future infrastructure, to include innovative technologies such as electrochemical processes (EOx) in any technological planning. EOx is a reliable process that has been in use in the water industry for decades.

PFAS destruction technologies, such as Electrochemical Oxidation, Supercritical Water Oxidation, and others are a viable improvement to the current removal methods used for PFAS such as Granular Activated Carbon or Ion Exchange which merely remove PFAS. PFAS destruction technologies can be partnered with removal technologies in a cost effective manner to ensure PFAS are destroyed forever and do not remain in our environment, moving through constant removal and disposal cycles.

EPA Response: Please see section 10.2 of the EPA response in this *Response to Comments* document. The EPA appreciates the commenter's examples of emerging PFAS destruction technologies. The EPA agrees that in some circumstances on-site destruction can be more effective than utilization of an off-site destruction and disposal vendor. Destructive

technologies are discussed in the *Interim Guidance on the Destruction and Disposal of Perfluoroalkyl and Polyfluoroalkyl Substances and Materials Containing Perfluoroalkyl and Polyfluoroalkyl Substances* available on the internet at: https://www.epa.gov/system/files/documents/2021-11/epa-hq-olem-2020-0527-0002_content.pdf. While no electrochemical oxidation (EOx) process was selected as a BAT for drinking water treatment, these processes may be considered in the future. No EOx processes were chosen because there are no full-scale studies available on these processes and these processes are not currently understood well enough to scale up PFAS data to full scale. Removal efficiencies have also not been demonstrated well enough in the required ranges for this regulation and there are some concerns related to partial defluoridation of longer compounds creating more short-chained PFAS in some circumstances; There is also not enough data available in the literature at this time surrounding PFAS mixtures or costs associated with using these technologies at scale. The PFAS Innovative Treatment Team (PITT) has published research briefs on additional non-traditional destruction and disposal methods, including electrochemical oxidation, mechanochemical degradation, pyrolysis and gasification, as well as supercritical water oxidation.

Aclarity (Doc. #1755, SBC-044512)

There are currently numerous companies with field deployed technology that destroy PFAS: Aclarity, Aquagga, 374Water, AECOM, and Batelle. There are others under rapid development including but not limited to Purafide, Enspired Solutions, OnVector, Axine, Xyvant, and Claros Technologies. These destruction technologies need to be considered to permanently eliminate PFAS.

Who We Are

Aclarity is a venture-backed, woman owned and founded water technology company based in Massachusetts. Aclarity's low energy, electrochemical process quickly and safely destroys dangerous contaminants in water at the industrial scale and makes it easy to destroy unwanted contaminants such as PFAS in landfill leachate and other highly concentrated PFAS streams. Aclarity's mission is to destroy PFAS forever. Our Aclarity electrochemical oxidation system destroys PFAS chemicals in water and liquid waste for pennies per gallon today. We pass concentrated PFAS streams, like raw landfill leachate, through our fully skidded and modular electrochemical oxidation system and destroy PFAS compounds to greater than 99%. Full-scale PFAS destruction has been demonstrated at steady-state for weeks in the field.

Aclarity greatly appreciates the opportunity to respond to this rulemaking. We would be happy to provide more information or schedule a meeting to discuss our views in greater detail if that would be helpful.

Sincerely,

Julie Bliss Mullen

Aclarity Founder and Chief Executive Officer www.aclaritywater.com

EPA Response: Please see section 10.2 of the EPA response in this *Response to Comments* document. The EPA thanks the commenter for sharing examples of PFAS destruction technologies and vendors and invites commenter to send in data, particularly the full-scale data, information on how complete defluoridation was measured, and other pertinent experiment details. More information on why electrochemical oxidation was not selected as a BAT is provided in the EPA response to comment Doc. #1755, SBC-044510 from Aclarity in section 10.2 in this *Response to Comments* document.

Connecticut Section of the AWWA (CTAWWA) and Connecticut Water Works Association (CWWA) (Doc. #1763, SBC-044233)

We are encouraged that ongoing research is pursuing destructive treatment technologies as an alternative to the traditional PFAS treatment methods that include granular activated carbon, reverse osmosis, and ion exchange. These destructive technologies have the potential to provide a benefit to utilities, to their ratepayers, and to the environment. We encourage the EPA to invest in accelerating the research on these technologies, thereby avoiding a situation where utilities are 'forced' into today's treatment options even though superior options are on the horizon.

EPA Response: Please see sections 10.1 and 10.2 of the EPA response in this *Response to Comments* document. The EPA refers the commenter to the EPA response to comment Doc. #1634, SBC-043239 in section 10.2 in this *Response to Comments* document. Please see section 12 of the EPA response in this *Response to Comments* document for more information about implementation timelines. Rules could be deferred indefinitely waiting for technological improvement; in light of available information on health effects, occurrence, currently available analytical methods, and currently feasible treatment technologies, deferring this rule is not in line with the EPA mission to protect human health.

Northwest Biosolids Association et al. (Doc. #1783, SBC-043797)

[We recommend that drinking water regulations for PFAS include actions that support scientific understanding and exploring implementation solutions that would include actions such as:]

• Examination of flexible compliance actions with thresholds that can be achieved through current available technologies.

EPA Response: Please see sections 10.1 and 10.2 of the EPA response in this *Response to Comments* document. The EPA, and the public comment record, has shown that the MCLs are achievable through currently available technologies. The EPA also does not dictate specific methods to achieve compliance with MCLs. Please see section 5 of the EPA response in this *Response to Comments* document for more information on how the agency evaluated feasibility of the MCLs. Section 10 of the EPA response in this *Response to Comments* document contains information on how BATs were evaluated.

Anonymous (Doc. #2373, SBC-047426)

I would also like to comment on the best available technologies for treating contaminated sources of PFAS and disposal options of the residuals. While further research likely needs to occur, there appears to be some promising treatments that could chemically breakdown PFAS into safe byproducts, meaning disposal will not be an issue (Morris, 2022).

Morris, A. (2022, August 18). "Forever chemicals" destroyed by simple new method. News.northwestern.edu. https://news.northwestern.edu/stories/2022/08/forever-chemicals-destroyed-by-simple-new-method/

EPA Response: Please see section 10.2 of the EPA response in this *Response to Comments* document. The EPA appreciates an example of a destructive technology and agrees that significant research needs to occur before this could be viable. The *Interim PFAS Destruction and Disposal Guidance* contains information on judging the readiness level of disposal and destruction processes.

Orange Water and Sewer Authority (OWASA) (Doc. #1524, SBC-042614)

Our comments around the rule focus primarily on the timeline for compliance and the associated supply chain issues with construction.

PFAS Regulation Comments

• Treatment

*OWASA's water treatment plant is already optimized for current rules and regulations (and the WTP has been involved with the AWWA and EPA supported Partnership for Safe Water program and has received numerous awards) yet the addition of treatment for PFAS removal provides very little ancillary benefit for our water quality (beyond the required removal of PFAS compounds). This is a large investment for a singular benefit.

*Treatment has yet to be determined and PFAS removal treatment may require post treatment chemical additions to return the water to a more palatable state.

EPA Response: Please see sections 10.1, 10.2 and 10.3 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions. The EPA agrees that each BAT may require post-treatment steps depending on site-specific circumstances. The EPA disagrees that PFAS treatment provides a singular benefit with very little ancillary benefit; surface water systems like Orange Water and Sewer Authority (OWASA) can particularly benefit through disinfection byproducts (DBP) precursor reduction or removal of non-targeted PFAS as described in section 10.3 of the EPA response in this *Response to Comments* document.

10.3 PFAS Co-Removal

Summary of Major Public Comments and EPA Responses

A significant majority of commenters supported the EPA's position that treatment technologies that remove PFAS provide ancillary benefits by removing other known or potential contaminants. One commenter disputed the ability of these technologies to provide ancillary benefits, and others suggested that the EPA's proposed regulation would provide only limited protection against the many PFAS not under consideration in the rule. The EPA disagrees with the commenters who state that the proposed regulation would not result in a reduction in co-occurring PFAS and other contaminants. Burkhardt et al. (2023) estimates that 30 of 31 PFAS that are quantified by EPA Methods 533 and 537.1 can be economically removed by GAC in typical water qualities and that of 428 PFAS evaluated, 76-87 percent are economically treatable. The co-removal benefits are well documented in the scientific literature and in the evidence submitted by public comment. The Best Available Technologies and Technologies and Cost support documents summarize literature demonstrating the co-removal capabilities of treatment technologies.

Some commenters stated that treatment for one PFAS does not inherently imply removal of other PFAS. The EPA agrees, as discussed in the proposed rule preamble. In general, there is an inverse relationship between treatability and toxicity, which is tied to the carbon backbone (Bellia et al., 2023). Generally, the longer the carbon backbone length, the more easily the PFAS is removed by a given treatment technology. For example, if PFOA (C8) is targeted for removal by the water system, perfluorodecanoic acid (PFDA, C10) would most likely be removed as well. However, the converse would not be true (i.e., a system targeting PFNA (C9) removal would reduce perfluorohexanoic acid [PFHxA] (C6) to a lesser extent).

Some commenters suggested that co-removal would decrease the removal efficiency of GAC or AIX and that removal efficiency of non-target contaminants is lower than it could otherwise be. The EPA agrees that the removal of non-targeted contaminants by GAC or AIX can lower the PFAS removal efficiency; the agency has accounted for this uncertainty in Appendix N of the EA (USEPA, 2024b). The EPA also agrees that targeting contaminants for removal will be more effective than relying on other non-targeted removal. For example, a GAC facility designed to remove PFAS will not be as effective at removing DBP precursors as a facility designed for that; however, there will still be co-removal of DBP precursors, which may lead to a reduction in DBPs. Ultimately, treatment facilities operate best when tailored to specific contaminants or mixture of contaminants unique to that location. For additional information on the EPA's co-benefit analysis, please see section XII in the final rule preamble.

Some commenters expressed concern about co-removal taking beneficial ions from water, specifically fluoride ions, and suggested that would be an added cost to the rule. The EPA notes that fluoride has a legally enforceable MCL of 4.0 mg/L, and a non-enforceable secondary standard of 2.0 mg/L to prevent mild or moderate dental fluorosis. The EPA also notes that while some PFAS contain organic fluorine bound to carbon, fluorine and fluoride are not the same. The

BATs identified for the removal of PFAS for drinking water are not optimized for the removal of fluoride and do not necessarily provide effective removal of naturally occurring fluoride. For example, GAC is ineffective for fluoride removal at environmentally relevant pHs.

Some commenters suggested that co-removal may make it more difficult to dispose of materials left over from the drinking water treatment processes, known as treatment residuals. For example, GAC may remove and concentrate radon or other contaminants to such an extent that the spent media is considered hazardous. The EPA believes that removing hazardous constituents from drinking water is generally beneficial even though it could complicate residual management. More details on treatment residuals are discussed in part C of this section below.

Some commenters also suggest more research may be beneficial to understanding co-removal. The EPA agrees (USEPA, 2022a).

Individual Public Comments

Alliance of Nurses for Healthy Environments (Doc. #1544, SBC-042671)

Under EPA's proposal, drinking water utilities will be required to test water for PFOA, PFOS, GenX, PFBS, PFNA, and PFHxS and install treatment technologies to reduce the concentrations of these chemicals to the level of EPA's proposed "maximum contaminant levels" or lower. Fortunately, proven technology is available that will not only reduce the presence of the six PFAS in EPA's proposal, but will also improve protection against other PFAS compounds and common contaminants.

EPA Response: Please see section 10.3 of the EPA response in this *Response to Comments* document. The EPA agrees that proven technology is available that will improve protection against these regulated PFAS and other contaminants and notes that non-treatment options are also available for compliance.

Virginia Health Catalyst (Doc. #1556, SBC-042866)

While it is critical to address the dangers of PFAS contamination in our water supply, we urge EPA to not take any action that unintentionally bans, removes, or restricts other chemicals essential to public health. Fluoride, for example, is a chemical that has been added to public water supplies for decades to help prevent tooth decay, particularly in low-income communities. It is crucial that any regulations aimed at reducing PFAS contamination do not inadvertently limit or eliminate the use of fluoride or other public health interventions.

We urge the EPA to carefully consider the potential unintended consequences of any proposed regulations, and to work with public health experts and stakeholders to develop solutions that effectively address PFAS contamination while preserving access to safe and effective interventions like fluoride.

Thank you for your continued efforts to protect the health and safety of our communities. Please do not hesitate to contact me at sholland@vahealthcatalyst.org or 804-269-8721 should you have any questions.

Sincerely,

Sarah Bedard Holland

Chief Executive Officer

Virginia Health Catalyst

EPA Response: Please see section 10.3 of the EPA response in this *Response to Comments* document.

Colorado Water Utility Council (CWUC) (Doc. #1622, SBC-044046)

27. EPA requests comment on the co-removal of the HI chemicals (PFHxS, PFBS, PFNA, and HFPO-DA) when GAC, IX, or RO are used in the treatment of PFOA and/or PFOS.

a. Treatments used for PFOA/PFOS don't necessarily remove (efficiently) the four other compounds, particularly PFHxS.

EPA Response: Please see sections 10.1 and 10.3 of the EPA response in this *Response to Comments* document. The EPA agrees that treatment processes should account for site-specific circumstances and that a treatment optimized for one chemical may not be as effective for another chemical.

Colorado Water Utility Council (CWUC) (Doc. #1622, SBC-044018)

2. EPA requests comment on its evaluation that regulation of PFHxS, HFPO-DA, PFNA, PFBS, and their mixtures, in addition to PFOA and PFOS, will provide protection from PFAS that will not be regulated under this proposed rule.

a. CWUC is unsure if there is enough data and evidence to answer this question at this time. There is a high likelihood that many other PFAS compounds will be removed using the same treatment technologies installed to remove these six, but the full spectrum of removal capabilities is currently unknown.

EPA Response: Please see sections 10.1 and 10.3 of the EPA response in this *Response to Comments* document.

New England Interstate Water Pollution Control Commission (NEIWPCC) (Doc. #1650, SBC-043150)

Furthermore, our member states are concerned with the effect of treatment technologies on beneficial fluoride present in the water. Over 12 million people are served by water systems with

naturally occurring fluoride at or above optimal levels. [FN8: https://www.cdc.gov/fluoridation/statistics/2018stats.htm] Certain treatment technologies, such as activated carbon [FN9: https://www.watertechonline.com/wastewater/article/15549902/the-basics-of-activated-carbon-adsorption], could remove this fluoride, leading to negative impacts on the oral and general health of the public. We urge EPA to consider the costs associated with ensuring those systems are able to continue to supply consumers with beneficial fluoride, the public health impact if fluoride is no longer present, and to support the development of treatment technologies that encourage the persistence of beneficial fluoride.

EPA Response: Please see section 10.3 of the EPA response in this *Response to Comments* document.

American Dental Association (ADA) (Doc. #1671, SBC-043689)

EPA is proposing to reduce the maximum allowable concentration of these PFAS in public drinking water—from 4.0 nanograms per liter (ng/L) to 1.0 ng/L—based on a determination that no adverse effects are known or anticipated to occur at that exposure level. This goal would be achieved, in part, by requiring water control authorities to install new filtration technologies at their public water distribution system's point of entry.

EPA has identified "compatibility with other water treatment processes" as one of its criteria for recognizing the best available PFAS removal technologies. [FN1: 88 FR 18684] However, the PFAS-removing technologies EPA is currently proposing [FN*: EPA has identified granular activated carbon (GAC), anion exchange resin (AIX), reverse osmosis (RO), and nanofiltration (NF) as the best available technologies to achieve a PFAS concentration level of 1.0 ng/L or less in public drinking water.] have the potential to undermine a water treatment process that has advanced the public's oral health for more than 75 years: community water fluoridation.

Community water fluoridation is the controlled adjustment of the natural fluoride content in water to 0.7 mg/L, which is the level recommended by the U.S. Public Health Service to help prevent tooth decay. [FN2: U.S. Department of Health and Human Services. Federal Panel on Community Water Fluoridation. U.S. Public Health Service recommendation for fluoride concentration in drinking water for the prevention of dental caries. Public Health Rep. 2015 Jul-Aug; 130(4): 318–331. doi:10.1177/003335491513000408] For more than 75 years, it has been a safe and inexpensive way to reduce tooth decay in children and adults by at least 25 percent. [FN3: American Dental Association, Fluoridation Facts, 2018. Available at www.ada.org/resources/ community-initiatives/fluoride-in-water/fluoridation-facts (accessed May 30, 2023)] In fact, the CDC hailed it as one of ten great public health achievements of the 20th century. [FN4: 4 Centers for Disease Control and Prevention. Ten Great Public Health Achievements – United States, 1900-1999. MMWR 1999; 48 (12): 241-243. Available at: www.cdc.gov/mmwr/preview/ mmwrhtml/00056796.htm (accessed May 30, 2023)]

In 2018, 73 percent of the U.S. population on community water systems—207,426,535 people—had access to fluoridated water. [FN5: Based on water system data reported by states to the CDC

Water Fluoridation Reporting System as of December 31, 2018. Available at www.cdc.gov/fluoridation/statistics/2018stats.htm (accessed May 30, 2023)] The national health objectives in Healthy People 2030 aim to increase that number to over 77 percent. [FN6: Office of Disease Prevention and Health Promotion. (n.d.). Oral Conditios. Healthy People 2030. U.S. Department of Health and Human Services. Available at www.health.gov/healthypeople/objectives-and-data/browse-objectives/oral-conditions (accessed May 30, 2023)]

As you continue exploring the best available PFAS removal technologies, we urge you to consider equipment location and laboratory certification standards that will not inadvertently remove fluoride from public water systems. It may be valuable to speak with the Centers for Disease Control and Prevention about options for removing PFAS from drinking water without removing fluoride in the process.

Thank you for providing us the opportunity to comment. If you have any questions, please contact Mr. Robert J. Burns at 202-789-5176 or burnsr@ada.org.

Sincerely,

George R. Shepley

President

Raymond A. Cohlmia, D.D.S.

Executive Director

GRS:RAC:rjb

EPA Response: Please see section 10.3 of the EPA response in this *Response to Comments* document. The EPA notes that the commenter has incorrectly characterized the proposed MCLs and that the agency is not specifying the location of any PFAS treatment in the water system's overall treatment processes. Water systems should work with their primacy agency to determine the most appropriate location and EPA anticipates added fluoride typically would be placed after (downstream from) where PFAS treatment unit processes would be located. The EPA has consulted with the Centers for Disease Control and Prevention as a part of the agency's consultation with the Secretary of Health and Human Services regarding this regulation.

American Dental Association (ADA) (Doc. #1671, SBC-043687)

The American Dental Association is pleased to submit the attached comments regarding EPA's proposal to reduce exposure to several per- and polyfluoroalkyl substances (PFAS) in drinking water. In sum, we urge EPA to consider equipment location and laboratory certification standards that will not inadvertently remove fluoride from public water systems. It may be valuable to speak with the Centers for Disease Control and Prevention about options for removing PFAS from drinking water without removing fluoride in the process.

EPA Response: Please see section 10.3 of the EPA response in this *Response to Comments* document. The agency is not specifying the location of any PFAS treatment in the water system's overall treatment processes. Water systems should work with their primacy agency to determine the most appropriate location and the EPA anticipates added fluoride typically would be placed after (downstream from) where PFAS treatment unit processes would be located. The EPA has consulted with the Centers for Disease Control and Prevention as a part of the agency's consultation with the Secretary of Health and Human Services regarding this regulation. The approved methods for this regulation measure for specific PFAS using high resolution mass spectrometry after solid phase extractions; the inorganic fluoride would not be measured as part of this process. For more information on analytical methods, please see section 7 of the EPA response in this *Response to Comments* document.

A. O. Smith Corporation (Doc. #1674, SBC-043700)

Moreover, the Company agrees that there are co-benefits from using the aforementioned treatment technologies as any non-selective treatment technology (e.g., RO, GAC, IX, etc.) has the potential to remove co-contaminants and as a result should be encouraged. For example, a POU RO system that is certified to remove PFAS also removes arsenic, lead, and nitrate/nitrite. Another example are the resins used in IX systems to treat perchlorate are similarly effective to remove PFAS compounds.

EPA Response: Please see section 10.3 of the EPA response in this *Response to Comments* document. The EPA agrees that each BAT (RO, NF, GAC, AIX) has the potential to remove co-contaminants. The EPA notes that there are currently no POU devices that are certified to meet the MCL; please see section 10.5 of the EPA response in this *Response to Comments* document for additional discussion on SSCTs.

New York State Department of Health (NYS DOH) (Doc. #1677, SBC-044956)

18. EPA is seeking comment on the benefits of treatment technologies such as Reverse Osmosis to co-remove other contaminants. To date New York State has not approved large scale use of reverse osmosis (RO) treatment to address issues associated with PFAS. We recognize the appeal of RO to address co-occurrence of PFAS with organic and inorganic contaminants. However, we caution that any decision to proceed with RO be accompanied by a science-based evaluation of simultaneous compliance with the Lead and Copper Rule and its successors at each public water system proposing its use. We recognize that RO may be suitable for some challenging water quality issues as well as at very small water systems and is an important tool in the regulatory toolbox. At this time, we do not believe that widespread application is practical with current technologies. We anticipate that membrane technologies will continue to evolve with time, and the Department will consider health protective treatment proposals that are supported by site specific engineering evaluations.

EPA Response: Please see sections 10.1 and 10.3 of the EPA response in this *Response to Comments* document. The EPA agrees with the commenter's assessment that RO can remove co-occurring contaminants and may be suitable for select sites. In acknowledgement of potential issues surrounding RO, the EPA has adjusted RO/NF's technology projection compliance forecast to 0 percent in the EA. The EPA has published guidance on corrosivity concerns in various places, for example, the *Best Available Technologies and Small System Compliance Technologies for PFAS in Drinking Water* in section 4.5.1.

State of Vermont Agency of Natural Resources and Department of Health (Doc. #1708, SBC-045117)

5) Benefits from using treatment technologies (such as reverse osmosis and GAC) that have been demonstrated to co-remove other types of contaminants found in drinking water and whether employing these treatment technologies are sound strategies to address PFAS and other regulated or unregulated contaminants that may co-occur in drinking water:

a. Radon is currently not included under EPAs National Primary Drinking Water Regulations. GAC treatment would co-treat radon, which could affect disposal costs of spent carbon. Constituents that can currently be discharged to a drywell (or other onsite disposal or discharged to municipal sanitary sewer), such as those exempt from Underground Injection Control Rules, could not be discharged into a dry well if co-treated with PFAS, which may reduce the lifespan of the treatment and increase the complexity of the treatment, counteracting any benefit gained from co-treatment.

b. Vermont does not currently have any surface water system treatment plants treating PFAS; however, the costs associated with disposal of media used to treat PFAS would counteract any benefit gained by co-treating non-hazardous constituents, such as DBPs.

EPA Response: Please see section 10.3 of the EPA response in this *Response to Comments* document. For information on residuals management the EPA refers commenter to section 10.4 of the EPA response in this *Response to Comments* document, however, the EPA notes that destruction and disposal of PFAS-containing materials is currently not subject to certain hazardous waste regulation and therefore the materials may be managed in non-hazardous as well as hazardous waste treatment and disposal systems. A PFAS-containing waste, however, may meet the regulatory definition of hazardous waste if PFAS is mixed with a listed hazardous waste or if a PFAS-containing mixture exhibits a hazardous characteristic (e.g., corrosivity or another characteristic stemming from the material that is mixed with PFAS). For more information on the HRRCA the EPA used, please see section 13 of the EPA response in this *Response to Comments* document.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-045981)

Section 7.3: Co-removal of contaminants

EPA is seeking comments on the utilization of the proposed BATs as sound strategies for addressing PFAS and other regulated and unregulated contaminants that occur in drinking water. Specifically, EPA seeks further comment on the co-removal of HI chemicals and the usefulness of GAC in removing other regulated and unregulated contaminants, like precursors to disinfection byproducts (DBPs). EPA states several times in the preamble that GAC will be effective in removing DBP precursors, something currently being discussed in the National Drinking Water Advisory Council (NDWAC) Microbial and DBP (MDBP) Rule Revision Working Group process.

AMWA cautions EPA in assuming that a treatment technique like GAC will universally co-remove other contaminants. A GAC facility specifically designed to remove PFAS may not be as efficient at removing DBP precursors or other contaminants, as the size and components of the facility were not designed for that purpose. Similarly, current GAC facilities in use for TOC removal may not be removing PFAS to levels required for this proposed rule. These "co-removing" contaminants must also compete for adsorption sites on GAC, further reducing media life and diminishing the effectiveness of PFAS removal. Any changes to these treatment facilities currently in place may require more construction, increased capacity, and further testing to assess other risk trade-offs.

AMWA would also like to point out that different PFAS mobilize differently through filter columns or beds, indicating that treatment techniques may not universally co-remove contaminants. Shorter chain PFAS tend to move faster through filter media and can be more difficult to remove, often driving the treatment design. If a water system is coming into compliance with an MCL for a longer chain PFAS, there may not be as much co-removal of shorter chain PFAS. Ultimately, treatment facilities need to be tailored to the contaminant of interest. A PWS having a treatment facility in place does not inherently mean the system can be easily adjusted to address more or different contaminants without compromising compliance elsewhere.

EPA Response: Please see sections 10.1 and 10.3 of the EPA response in this *Response to Comments* document. The EPA further notes that the agency did not claim universal co-removal of other contaminants.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-045993)

Section 8.8: Cost of co-occurring PFAS

In section 7.3 of these comments, AMWA responds to EPA's request for comment regarding the co-removal of contaminants with this rulemaking. While BATs described in this proposal can co-remove other PFAS, EPA should consider co-removal consequences on overall removal effectiveness. With treatment techniques like GAC, various contaminants compete for adsorption sites, which can diminish the effectiveness of PFAS removal. GAC would have to be replaced or reactivated more often to account for this co-removal. Additionally, media will need to be

replaced more often if the PFOA and PFOS MCLs are finalized at 4 ppt rather than 10 ppt, thus increasing annual costs of treatment.

EPA Response: Please see section 10.3 and 10.4 of the EPA response in this *Response to Comments* document. Information on the cost analysis used may be found in section 13 of the EPA response in this *Response to Comments* document.

Connecticut Department of Public Health (CT DPH) (Doc. #1745, SBC-045242)

General Comments on Proposed National Primary Drinking Water Regulation

EPA requests comment on its evaluation that regulation of PFHxS, HFPO–DA, PFNA, PFBS, and their mixtures, in addition to PFOA and PFOS, will provide protection from PFAS that will not be regulated under this proposed rule.

EPA's proposed regulation of PFHxS, HFPO–DA, PFNA, PFBS, and their mixtures, in addition to PFOA and PFOS would provide some level of protection against PFBA, PFHxA and PFDA exposure if the three unregulated PFAS are found around concentrations similar or lower than that of the PFAS to be regulated. However, if PFBA, PFHxA and/or PFDA are the only PFAS of significant amount in the drinking water, the proposed regulation may not provide sufficient protection from them.

EPA Response: Please see section 10.3 of the EPA response in this *Response to Comments* document. The EPA agrees that the regulation would provide some level of protection against other unregulated PFAS.

Las Cruces Utilities (LCU) (Doc. #1753, SBC-043915)

In response to Section XI-Treatment Technologies, EPA is seeking comment on the benefits from using treatment technologies (such as reverse osmosis and GAC) that have been demonstrated to co-remove other types of contaminants found in drinking water and whether employing these treatment technologies are sound strategies to address PFAS and other regulated or unregulated contaminants that may co-occur in drinking water.

• PFAS treatment could conflict with current chemical dosing practices for red water control.

EPA Response: Please see sections 10.1 and 10.3 of the EPA response in this *Response to Comments* document. The EPA acknowledges the information submitted by the commenter and notes that transition metal precipitation can be controlled without phosphate dosing, for example, through aeration and filtration. The best solution will likely be site-specific, and the EPA recommends pilot studies to delineate potential process integration issues as well as test solutions to any discovered problems.

Arizona Water Company (Doc. #1758, SBC-044537)

Many of the required PFAS removal facilities will be treating water sources that are already being treated for other contaminants. Many wells in the Company's water systems are already being treated for arsenic, nitrate, and other contaminants. These treatment facilities have already been constructed at considerable cost to the Company and its customers. Additionally, these treatment facilities often use similar technologies as those the EPA currently lists as known treatment technologies for PFAS removal, yet the efficacy of these technologies to treat various forms of PFAS, and any additional costs of doing so, have not been comprehensively studied. The Company recommends the EPA conduct research and provide information on treatment technologies that can simultaneously remove PFAS and other contaminants.

EPA Response: Please see section 10.1 and 10.3 of the EPA response in this *Response to Comments* document.

American Fluoridation Society, Inc. (Doc. #1776, SBC-043831)

As the EPA explores methods to remove PFAS chemicals whether through point of removal being at the water plant, Point of Entry, or Point of Use, it is critical that the method(s)/technology(ies) determined to be the most effective to do so not undermine the public health measure of community water fluoridation. Filtration methods and points of placement of the PFAS removal technologies have the potential to inadvertently remove the public health benefits by removing the fluoride ion from the water.

The American Fluoridation Society recommends the pursuit of PFAS removal technologies that will be highly effective in removal of PFAS chemicals while at the same time not removing the fluoride ion. One public health benefit cannot be made at the expense of another public health benefit. Both must occur simultaneously to benefit our country's residents to protect their health and well-being. To this end, it may be valuable to consult the Centers for Disease Control and Prevention about options for removing PFAS from drinking water without removing the fluoride ion in the process.

Thank you for the opportunity to provide comment. If you have any questions, please contact Dr. Johnny Johnson, Jr. at 727-409-1770 or DrJohnny@AmericanFluoridationSociety.org.

Warm regards,

Johnny Johnson, Jr., DMD, MS

Pediatric Dentist

Diplomate, American Board of Pediatric Dentistry

Life Fellow, American Academy of Pediatric Dentistry

President, American Fluoridation Society

Web: AmericanFluoridationSociety.org

Cell: 727-409- 1770

Email: DrJohnny@AmericanFluoridationSociety.org

EPA Response: Please see section 10.3 of the EPA response in this *Response to Comments* document. Water systems should work with their primacy agency to determine the most appropriate location and the EPA anticipates added fluoride typically would be placed after (downstream from) where PFAS treatment unit processes would be located. The EPA has consulted with the Centers for Disease Control and Prevention as a part of the agency's consultation with the Secretary of Health and Human Services regarding this regulation.

Ohio Environmental Council (Doc. #1794, SBC-045326)

Under EPA's proposal, drinking water utilities will be required to test water for PFOA, PFOS, GenX, PFBS, PFNA, and PFHxS and install treatment technologies to reduce the concentrations of these chemicals to the level of EPA's proposed "maximum contaminant levels" or lower. Fortunately, proven technology is available that will not only reduce the presence of the six PFAS in EPA's proposal, but will also improve protection against other PFAS compounds and common contaminants.

EPA Response: Please see section 10.3 of the EPA response in this *Response to Comments* document. The EPA agrees that the BAT technologies identified in the final NPDWR should also remove other PFAS compounds.

Little Hocking Water Association (Doc. #1835, SBC-045514)

Data on the removal of HI chemicals when GAC is used to remove PFOA and/or PFOS.

EPA requested information on co-removal of the HI chemicals PFHxS, PFBS, PFNA and HFPO-DA when, inter alia, GAC is used in the treatment of PFOA and/or PFOS. The Little Hocking Water Association provides the following comments and data with regard to co- removal of HI chemicals:

1. LHWA has had a GAC treatment system (two lead/lag configurations with 20,000 pounds of food-grade carbon in each vessel) to remove PFOA since November 2007. For the time period from November 2007 to February 2018, Dupont/Chemours (the responsible party for monitoring for PFAS) only reported concentrations of PFOA. Carbon changeouts are based on a trigger concentration of 15 ppt of PFOA in the lead beds. As of May 2023, the carbon has been replaced in the lead beds 70 times since November 2007. The average time between carbon changeout varies from 52 days to 132 days, but averages 82 days.

2. Since February 2018, data is available for co-removal of HFPO-DA. The graphs below show the concentrations of PFOA and HFPO-DA in the GAC treatment lead beds immediately prior to

changing carbon on the East and West Beds, respectively, in the GAC system for Little Hocking (data source, Chemours, 2023a):

[Figure 4: see docket ID EPA-HQ-OQ-2022-0114-1835]

[Figure 5: see docket ID EPA-HQ-OQ-2022-0114-1835]

These graphs show that the GAC is less effective in removal of HFPO-DA than PFOA because there are instances where the concentration of HFPO-DA is higher than the concentration of PFOA in the lead beds (even though the concentration of PFOA in the raw water is an order of magnitude higher than the concentration of HFPO-DA (see Attachments 1 and 3).

3. Until May 2022, the reporting limit for both PFOA and HFPO-DA, as requested of the laboratory by Chemours, was 10 ppt. Since May 2022, the reporting limit has been <2.0 ppt. There have been no detections of either PFOA or HFPO-DA in the lag beds since the GAC treatment system went online in November 2007.

4. As of March 27, 2023, Chemours has directed the laboratory to report concentrations for all 18 PFAS using Method 537.1. LHWA has no reported concentrations of other HI PFAS in the raw water, but detection levels are elevated to approximately 10 ppt due to dilution because of the elevated concentrations of PFOA and HFPO-DA.

5. A one-point dataset is also available for Belpre, Ohio's public water system. Belpre also has a GAC system to remove PFOA that has been in operation since February 2006. The system consists of two lead and lag beds with 20,000 pounds of carbon per vessel. The criteria for carbon changeout are different from the LHWA. Carbon is changed out when the lead beds exceed 500 ppt or when the lag beds exceed a detectable level of 5 ppt, whichever occurs first (Ohio EPA, 2007). According to Chemours (2023b), carbon was last changed on November 26, 2022. The table below shows the raw water concentrations of PFAS and the concentrations of HI PFAS in the Belpre raw water and the lead beds of the GAC system on March 20, 2023 (source of data, Chemours, 2023b).

[Table 7: see docket ID EPA-HQ-OQ-2022-0114-1835]

Similar to LHWA, Belpre only received results for PFOA from 2006 until March 2023, when reporting was changed to the 18 PFAS using Method 537.1. As of March 2023, there are no detections of any of the reported PFAS in the lag beds.

While LHWA agrees that GAC will remove PFOA, PFOS, and some other PFAS, the chain length of the PFAS matters. Generally, the shorter the carbon chain length, the less effective GAC is at removing those chemicals. In LHWA's experience and in reviewing other systems' data, the operation of the GAC makes a difference on co-removal. There are two operational parameters that affect co-removal: which chemical is used as the trigger for carbon changeout and when carbon changeout is done. The chemical at the highest concentration in pretreated water should be the chemical concentration that dictates when the carbon is changed. But, this can change. See above data on LHWA's East and West Lead Beds where the PFOA and HFPO-

DA "take turns" being detected at the highest concentrations. Second, LHWA has observed that when carbon changeouts are performed can greatly effect removal.

Data on the co-removal of other PFAS when GAC is used to remove PFOA and/or PFOS.

"EPA is seeking comment on the benefits from using treatment technologies (such as reverse osmosis and GAC) that have been demonstrated to co-remove other types of contaminants found in drinking water and whether employing these treatment technologies are sound strategies to address PFAS and other regulated or unregulated contaminants that may co- occur in drinking water." LHWA provides the following comments/data with regard to co- removal of other PFAS by GAC that are currently not proposed to be regulated.

As of March 27, 2023 when Chemours directed the laboratory to report results for all 18 PFAS under Method 537.1, LHWA now has data (see below table, data source, Chemours, 2023a) that shows additional PFAS that are not currently proposed to be regulated (PFHxA and PFHpA) are present in their raw water:

[Table 8: see docket ID EPA-HQ-OQ-2022-0114-1835]

With regard to removal by GAC of these additional PFAS, the below table (data source, Chemours, 2023a) shows that sampling confirmed the presence of these two PFAS in the east lead bed on May 8, 2023.

[Table 9: see docket ID EPA-HQ-OQ-2022-0114-1835]

No detections were found in the west lead bed or in either of the lag beds. The carbon was replaced on May 10, 2023.

This indicates from this one small dataset, that GAC seems to have the potential to provide protection from exposure to other known PFAS and that GAC treatment can be beneficial in the removal of some additional PFAS. However, the full load of PFAS and PFAS precursors are not known and the effectiveness of GAC for these unsampled constituents is unknown.

EPA Response: Please see sections 10.1 and 10.3 of the EPA response in this *Response to Comments* document. The EPA acknowledges the information submitted by the commenter and agrees that GAC has the potential to provide removal of additional PFAS.

Julie Reynolds (Doc. #2040, SBC-046313)

I applaud and welcome the EPA's action to regulate forever chemicals in drinking water, and agree with the proposed actions. I am concerned, however, that the filters used to remove these chemicals will also remove fluoride ions from the water that have been added for optimal community water fluoridation. Water fluoridation is a safe, cost effective population health approach to reducing tooth decay and improving oral health. It would be a crisis if this successful public health approach were to be negatively affected by the proposed regulations. As a board-certified specialist in public health dentistry, I have seen the negative effects firsthand, both in

my patients and in my research, of the lack of access to preventive interventions. I urge the EPA to evaluate options for removal of forever chemicals that do not negatively affect the many decades of successful community water fluoridation in this country.

EPA Response: Please see section 10.3 of the EPA response in this *Response to Comments* document.

10.4 Management of Treatment Residuals

10.4.1 General

Summary of Major Public Comments and EPA Responses

While some commenters stated that more research can be beneficial to further our understanding of managing PFAS treatment residuals, others urged the EPA to proceed with this rulemaking as expeditiously as possible in the interest of public health. Others argued that the EPA should delay this action until the PFAS Destruction and Disposal Guidance is updated. The National Defense Authorization Act for Fiscal Year 2020, Public Law No: 116-92 Section 7361 directs the EPA to revise the PFAS Destruction and Disposal Guidance triennially; the new destruction and disposal guidance is anticipated to be released approximately concurrently with this rule and further revisions may be expected before the effective dates for this rule. For these reasons, the EPA disagrees that the projected significant and direct public health protections for drinking water consumers in this rule should be delayed for the revision of guidance on management of PFAS waste streams.

Many commenters expressed concern that not enough was being done to manage spent drinking water treatment residuals containing PFAS at the end of their useful working life and that residual management amounted to media shifting (i.e., taking PFAS from water via sorption media then landfilling that media does nothing to reduce the overall amount of PFAS). Many commenters stated that landfills and thermal treatment facilities can potentially be PFAS sources as the BATs in this rule are separative as opposed to destructive technologies. The EPA notes that from a mass balance perspective, PFAS removal from drinking water is generally anticipated to result in lower concentrations of PFAS in the environment. With appropriate controls, landfills and thermal treatment of PFAS contaminated media can minimize PFAS releases to the environment (USEPA, 2020). Sorptive media can be incinerated or reactivated. There is also ongoing research into destructive and sequestration technologies that may help quantify the extent to which PFAS may be destroyed, some of which is funded by the EPA (USEPA, 2022a). Furthermore, it is also important to distinguish between a potential environmental release and a direct exposure. A PFAS release does not inherently imply human exposure and a release is not inherently risky to specific populations. From a risk management perspective, while the EPA acknowledges that while each destruction and disposal technology has limitations, a potential environmental release under point source management is anticipated to be a more health protective alternative than human exposure through drinking water.

Some commenters suggested that reactivation was not permissible under the 2020 Interim PFAS Destruction and Disposal Guidance or that interim storage was required. Commenters are incorrect in their interpretation of the plain language in that guidance. The guidance does not state that reactivation or thermal treatment are prohibited. The guidance acknowledges a need for further refinement and research and that interim storage may be an option if the immediate dispensation of PFAS-containing materials is not imperative. However, nowhere does that guidance mandate interim storage or prohibit other forms of PFAS destruction and disposal.

Some commenters recommended the EPA consider additional destruction and disposal technologies. The EPA notes that disposal and destruction technologies are currently available to manage drinking water residuals. The EPA appreciates the example destructive technologies, and while beyond the scope of finalizing this NPDWR, the agency intends to consider additional destruction and disposal technologies in future destruction and disposal guidance. As part of the PFAS Strategic Roadmap, the ORD is evaluating and developing end-of-life materials management technologies, including disposal and destruction technologies to further reduce PFAS in the environment, in addition to their work on drinking water and wastewater treatment, contaminated site cleanup and remediation, air emission controls, and health effects.

Many commenters suggested that high pressure membranes, which separate PFAS from one stream and concentrate it in another stream, may not be feasible as a BAT because utilities treating and discharging reject water from high pressure membranes typically require a National Pollutant Discharge Elimination System (NPDES) permit. The EPA disagrees because there are currently full-scale facilities that use this technology to treat PFAS and high-pressure membranes may be the best viable option in a multi-contaminant setting. The brine may undergo further pre-treatment as part of a process train to enable discharge, such as GAC or AIX treatment. Some RO/NF applications discharge directly to surface water or through an interconnection to a wastewater treatment plant. The EPA, however, agrees that brine treatment or disposal may be challenging and in 2022, the EPA issued memoranda that recommended NPDES and publicly owned treatment works (POTW) pretreatment program permitting conditions for PFAS discharges (USEPA, 2022b; USEPA, 2022c). In conclusion, in limited applications, high pressure membranes may still serve as a viable treatment strategy, such as for facilities with access to brine treatment or disposal.

Individual Public Comments

North Penn Water Authority (NPWA) (Doc. #1470, SBC-043295)

And, very importantly, there is concern about how the disposal of all this used carbon material, after it has been saturated with PFAS removed from the water, can be accomplished within the new stringent regulations. Will incineration or land application of this waste material continue to be considered acceptable? The overall environmental impact of spent carbon needs to be thought out thoroughly and planned for.

EPA Response: Please see section 10.4.1 of the EPA response in this *Response to Comments* document.

Orange Water and Sewer Authority (OWASA) (Doc. #1524, SBC-042620)

• GAC/IX regeneration

o There are only a few regeneration facilities in the US – how will this impact our ability to regenerate our media and then return it to our facility?

o Will the limited regeneration options impact cost and timeline to receive media?

EPA Response: Please see sections 10.4.1 and 10.4.2 of the EPA response in this *Response to Comments* document. For additional discussion on treatment technology availability and capacity, please see section 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions.

Water Environment Federation (WEF) (Doc. #1529, SBC-043317)

• One Water: In a one-water world, PFAS removed is PFAS reallocated to another media. For example, GAC will concentrate PFAS, which will then be transferred to an accepting receiving landfill, and landfill leachate routed to a water resource recovery facility. Another example is "reject" water from water reuse operations, which may also concentrate PFAS.

• Technology: Destruction technologies must be proven with subsidized funding identified in order to install and maintain these systems.

EPA Response: Please see sections 10.4.1 and 10.4.2 of the EPA response in this *Response to Comments* document.

Washington Suburban Sanitary Commission (WSSC Water) (Doc. #1585, SBC-042774)

4. Treatment technologies

Waste management costs:

The EPA has identified three treatment methods, granular activated carbon (GAC), ion exchange (IX), and nanofiltration/reverse osmosis (NF/RO), as the Best Available Technologies (BAT) for removing PFAS. WSSC Water agrees with EPA's assessment of technological feasibility and the agency's conclusion that compliance can be accomplished at the MCL of 4 ppt utilizing these treatment processes. However, all of these BATs generate waste streams or spent media, which require reactivation, waste treatment, and disposal. Taking a holistic view of the fate of PFAS, these treatment processes simply shift PFAS from drinking water to another media, which could be subject to further regulation and require additional treatment. As such, the EPA must carefully

consider lifecycle waste management needs for the holistic reduction of PFAS in the environment when evaluating the technological feasibility and associated compliance costs of these treatment methods.

EPA Response: Please see section 10.4.1 and 10.4.2 of the EPA response in this *Response to Comments* document.

Washington Suburban Sanitary Commission (WSSC Water) (Doc. #1585, SBC-047711)

We are also concerned that EPA's annualized cost proposal does not include the costs associated with disposing of spent media as hazardous waste, on the basis that PFAS-contaminated waste is not currently classified as hazardous waste. This approach contradicts EPA's Action Plan to potentially regulate municipal treatment discharge under CERCLA, and we urge the agency to revise its cost assumptions in line with its future rulemaking directions.

EPA Response: Please see sections 10.4.1 and 10.4.2 of the EPA response in this *Response to Comments* document. The designation does not require waste to be treated in any particular fashion, nor disposed of at any particular type of landfill. The designation also does not restrict, change, or recommend any specific activity or type of waste at landfills. The EPA took the unusual step of including a supplemental analysis where PFAS is considered a hazardous waste in the proposed rule preamble and supporting documents. For more information on the EPA modeled costs such as what was included, please see section 13 of the EPA response in this *Response to Comments* document.

Security Water District, Security Water and Sanitation Districts/Enterprises (Doc. #1587, SBC-042783)

Lastly, we have grave concerns with the lack of understanding and guidance regarding the disposal of spent pre-filters, resin and carbon, and ultimately the destruction of the PFAS contained in those materials. Why are we forcing water systems to capture PFAS if we don't know what to do with it once captured? It seems foolhardy to simply move PFAS around in the environment.

EPA Response: Please see section 10.4.1 of the EPA response in this *Response to Comments* document.

Water Works Board of the City of Birmingham (BWWB) (Doc. #1602, SBC-043648)

2. The USEPA recommended best available technologies (BATs) for PFAS removal are essentially separation technologies rather than destruction technologies. Thus, PFAS removed from drinking water supplies are simply shifted to other environment vectors for public exposure via the residuals management process. It is recommended that USEPA provide a longer-term direction for PFAS management in the environment.

There are currently only a few options for PFAS-containing wastes, including landfilling and incineration. Each disposal approach can return either the original PFAS or their degradation products back into the environment, demonstrating the cyclical PFAS challenge (Stoiber et al. 2020).

Since some classes of PFAS are semi-volatile, it is possible for landfilled PFAS-laden materials to volatilize or leach over time (Coffin et al. 2022; Smallwood et al. 2023). Certain PFAS species have been measured in ambient air samples from wastewater treatment plants and landfills (Coffin et al. 2022).

Landfill leachate is commonly sent to a wastewater treatment plant where the PFAS is often carried over to sludge and effluent – only shifting the PFAS contamination from site to site (Stoiber et al. 2020). Incineration of PFAS-containing wastes can emit harmful air pollutants (such as fluorinated greenhouse gasses) (Stoiber et al. 2020).

There are a limited number of full-scale studies investigating the fate of PFAS in the GAC reactivation process. Reactivation can cause some PFAS compounds to be transformed, volatilized, or defluorinated. Several studies suggest that the fate of PFAS in GAC reactivation is a function of PFAS chain length, reactivation temperature, and combustion atmosphere. Additional full-scale studies are necessary to better understand and manage PFAS air emissions form GAC reactivation facilities (EPA 2023).

EPA Response: Please see section 10.4.1 of the EPA response in this *Response to Comments* document.

Prince William County Service Authority (Doc. #1609, SBC-042835)

Water utilities need clarity on the additional regulatory actions EPA is considering with respect to PFAS in residual streams created during the water treatment process.

Utilities that exceed the proposed MCLs and/or HI must evaluate treatment alternatives to achieve compliance. Each alternative will generate residual streams. EPA has suggested granular activated carbon (GAC), ion exchange (IX), and reverse osmosis (RO) as treatment alternatives. None of these alternatives actually remove PFAS from the environment, they simply move it from one media (source water) to another (filter media or membrane filtrate). The regulatory framework for discharging or disposing of PFAS laden membrane filtrate is uncertain. Spent GAC and IX media must be regenerated and/or disposed of properly. The capacity of the marketplace to regenerate or dispose of the quantities of these materials resulting from the proposed rule is unknown. The availability and capacity of landfills willing and/or certified to accept PFAS contaminated filter media is unknown. If the demand for these landfills increases significantly, disposal costs will also increase, adding further burden to utility ratepayers.

EPA Response: Please see section 10.4.1 of the EPA response in this *Response to Comments* document, as well as the *Interim PFAS Destruction and Disposal Guidance*

document. For more information on utility rate payers please see section 2.4 of the EPA response in this *Response to Comments* document.

Savannah River Nuclear Solutions LLC (Doc. #1647, SBC-043338)

Comment 5

Section X.I.C. Management of Treatment Residuals (pg. 18686)

The proposed rule and accompanying support documents do not provide a complete picture of the management of the residuals produced by the designated BAT.

The technologies designated as BAT for removing PFAS from drinking water are treatment technologies, designed to transfer the PFAS into another media (or in the case of RO/NF, the same media in a more concentrated form). According to EPA's own support document, Best Available Technologies and Small Systems Compliance Technologies for PFAS in Drinking Water, EPA- 833-P-23-009 (February 2023) "additional research might be needed to better understand and manage PFAS air emissions from GAC reactivation facilities. The results of this research might necessitate changes to spent GAC management practices." Further, there may be circumstances when reactivating spent GAC may not make economic or operational sense. In these circumstances, GAC may be disposed of after use, such as in a landfill, and then replaced with completely new GAC. This would likely generate additional liquid leachate that would also require treatment. Future Resource Conservation and Recovery Act (RCRA) hazardous waste regulations could also limit the available management options.

Similarly, spent AIX resins are currently incinerated as a preferred method of disposal, which would potentially transfer PFAS combustion products to the air. EPA indicates that "[T]he literature is inconclusive regarding the fate of PFAS during incineration in general (USEPA, 2020) and there are no studies specific to incineration of IX resin. Additional full-scale research might be needed to better understand and manage PFAS air emissions from incineration facilities. The results of this research might necessitate changes to spent resin management practices." (Best Available Technologies and Small System Compliance Technologies for Per- and Polyfluoroalkyl Substances (PFAS) in Drinking Water, EPA Document EPA-822-P-23-009, pg. 22). AIX resins could be land disposed; however, this would likely transfer PFAS constituents to the liquid leachate which would require additional treatment. Has research been conducted on the leachability of PFAS constituents from spent AIX resins as future RCRA hazardous waste regulations, including Land Disposal Restrictions could also limit the available management options?

EPA Response: Please see sections 10.4.1 and 10.4.2 of the EPA response in this *Response to Comments* document, as well as the *Interim PFAS Destruction and Disposal Guidance* document.

Virginia Municipal Drinking Water Association (VMDWA) (Doc. #1657, SBC-043166)

In addition, another key component of a valid national cost assessment is the cost of how residuals from PFAS removal by the use of the assumed technologies (GAC and RO) will be disposed. This is especially critical in light of EPA's proposed hazardous waste designation under CERCLA for PFOA and PFOS. EPA's proposal identifies a 4-5% increase for the need for hazardous rather than non-hazardous waste disposal methods, 88 Fed. Reg. at 18686, but VMDWA is concerned that the availability and feasibility of such disposal and the associated costs will be significantly worse than assumed in the proposal. These concerns are based on past experience with hazardous waste disposal facility availability challenges and the widespread, increased need for hazardous waste disposal of PFAS treatment residuals driven by the combination of EPA's MCLs and EPA's CERCLA designation.

EPA Response: Please see sections 10.4.1 and 10.4.2 of the EPA response in this *Response to Comments* document, as well as the *Interim PFAS Destruction and Disposal Guidance* document. The designation does not require waste to be treated in any particular fashion., nor disposed of at any particular type of landfill. The designation also does not restrict, change, or recommend any specific activity or type of waste at landfills.

Maryland Association of Municipal Wastewater Agencies (MAMWA) (Doc. #1658, SBC-043401)

In addition, another key component of a valid national cost assessment is the cost of how residuals from PFAS removal by the use of the assumed technologies (GAC and RO) will be disposed. This is especially critical in light of EPA's proposed hazardous waste designation under CERCLA for PFOA and PFOS. EPA's proposal identifies a 4-5% increase for the need for hazardous rather than non-hazardous waste disposal methods, 88 Fed. Reg. at 18686, but MAMWA is concerned that the availability and feasibility of such disposal and the associated costs will be significantly worse than assumed in the proposal. These concerns are based on past experience with hazardous waste disposal facility availability challenges and the widespread, increased need for hazardous waste disposal of PFAS treatment residuals driven by the combination of EPA's MCLs and EPA's CERCLA designation.

EPA Response: Please see sections 10.4.1 and 10.4.2 of the EPA response in this *Response to Comments* document, as well as the *Interim PFAS Destruction and Disposal Guidance* document. The designation does not require waste to be treated in any particular fashion., nor disposed of at any particular type of landfill. The designation also does not restrict, change, or recommend any specific activity or type of waste at landfills.

California Farm Bureau Federation (Doc. #1704, SBC-045078)

Disposal

EPA is obligated by statute to issue periodic guidance, every four years, on the destruction and disposal of PFAS compounds. EPA's initial guidance document submitted to Congress reported on various technologies that have been utilized as well as those under evaluation for use in the management of PFAS and PFAS-contaminated media. The lack of clear guidance and standards for the management, treatment, and destruction of PFAS compounds continues to present significant challenges for those parties managing PFAS compounds and contaminated media. Because of this, much of this material is being stored in anticipation of EPA issuing more definitive guidance.

EPA Response: Please see sections 10.4.1 and 10.4.2 of the EPA response in this *Response to Comments* document, as well as the *Interim PFAS Destruction and Disposal Guidance* document.

Protecting Our Water, Environment, and Ratepayers (POWER) (Doc. #1714, SBC-045930)

DETAILED COMMENTS:

COMMENT 1 — EPA SHOULD FINALIZE TECHNOLOGICAL STANDARDS FOR THE DISPOSAL AND DESTRUCTION OF TREATMENT BYPRODUCTS PRIOR TO FINALIZING THE MCLS.

In order to adhere to the MCLs, it will be necessary for public water systems to have EPA approved technological standards for the disposal and destruction of treatment byproducts. Failure to have these in place prior to finalizing the MCL will result in public water systems potentially having inconsistent treatment and disposal standards. EPA last issued Interim Guidance on disposal and destruction of PFAS in December 2020. In the two years and five months since the Interim Guidance was issued, EPA has failed to promulgate a final standard for the treatment and disposal of PFAS. Instead, it has pursued proposed rules, such as this one, whose efficacy and costs are dependent on the treatment and disposal standards. [FN2: EPA, Interim Guidance on the Destruction and Disposal of Perfluoroalkyl and Polyfluoroalkyl Substances and Materials Containing Perfluoroalkyl and Polyfluoroalkyl Substances at 7 (Dec. 18, 2020) (https://www.epa.gov/system/files/documents/2021-11/epa-hq-olem-2020-0527-0002_content.pdf).] If the rule is now finalized as proposed, such a cart-before-the-horse approach will render the final rule arbitrary and capricious.

Treatment and disposal technologies for PFAS are still being developed and costs vary significantly based on geographic location. [FN3: EPA, Economic Assessment (EA) of the Potential Costs and Other Impacts of the Proposed Rulemaking to Designate Perfluorooctanoic Acid and Perfluorooctanesulfonic Acid as Hazardous Substances (Aug. 2022) (https://www.regulations.gov/document/EPA-HQ-OLEM-2019-0341-0035).] POWER! members provide critical public health services by providing clean drinking water and wastewater. Drinking water is generated 24 hours a day, every day of the year, for every person in the United States. There is no possible way to halt the flow of drinking water and the by-products of the cleanup process. As such, the disposal and destruction processes for the treatment byproducts

need to be clearly understood prior to implementation of the proposed rule. It is imperative that the science and technology for handling, cleanup, and disposal be developed and implemented prior to finalizing the proposed MCLs.

EPA has acknowledged that there are currently technological deficiencies and uncertainties regarding the destruction of PFAS. [FN4: EPA, Interim Guidance on the Destruction and Disposal of Perfluoroalkyl and Polyfluoroalkyl Substances and Materials Containing Perfluoroalkyl and Polyfluoroalkyl Substances at 7 (Dec. 18, 2020) (https://www.epa.gov/system/files/documents/2021-11/epa-hq-olem-2020-0527-0002_content.pdf).] Setting MCLs for PFOA, PFOS, PFNA, PFHxS, PFBS, and GenX compounds before reliable methods of destruction have been finalized is a recipe for confusion and litigation. The science and conclusive methods of destruction and/or disposal are not yet settled and EPA has acknowledged that time is needed to bridge this gap. [FN5: EPA, Interim Guidance on the Destruction and Disposal of Perfluoroalkyl and Polyfluoroalkyl Substances and Materials Containing Perfluoroalkyl and Polyfluoroalkyl Substances at 91 (Dec. 18, 2020) (https://www.epa.gov/system/files/documents/2021-11/epa-hq-olem-2020-0527-0002_content.pdf).]

POWER! respectfully requests that EPA delay implementing this proposed rule until EPA finalizes the standards for PFAS disposal and destruction.

EPA Response: Please see section 10.4.1 of the EPA response in this *Response to Comments* document.

Clean Air Council, et al. (Doc. #1731, SBC-043863)

d. Treatment of contaminated drinking water to achieve the proposed MCLs and HBWC is technically feasible for national implementation of the proposed PFAS regulations. However, EPA must facilitate the development of safe technologies for the disposal of PFAS waste created by water treatment to avoid re-release of PFAS to the environment.

EPA Response: Please see section 10.4.1 of the EPA response in this *Response to Comments* document, as well as the *Interim PFAS Destruction and Disposal Guidance* document.

Clean Air Council, et al. (Doc. #1731, SBC-043849)

A critical issue that EPA must address if the proposed NPDWR is to be truly effective in protecting public health and the environment is the safe disposal of the PFAS water treatment waste products: All current technologies for the removal of PFAS from water produce solid and/or liquid waste containing high levels of these pollutants. However, methodologies for the safe disposal of these materials are lacking and risk either re-introducing PFAS into the environment (such as by leaching from landfills) or producing toxic fumes (from thermal processes). Commenters understand that developing such technologies is outside the scope of

this proposed drinking water rule, but urge EPA to expedite solutions to PFAS waste to coincide with the scheduled national implementation of the NPDWR.

EPA Response: Please see section 10.4.1 of the EPA response in this *Response to Comments* document, as well as the *Interim PFAS Destruction and Disposal Guidance* document.

Clean Air Council, et al. (Doc. #1731, SBC-043886)

More problematic, however, are the PFAS waste streams from the water treatment facilities. All processes recommended by EPA to remove PFAS species from drinking water transfer and sequester the PFAS in a different medium. In the case of GAC, PFAS adsorbs onto the charcoal particles forming a solid waste of GAC/PFAS. In ion exchange processes, the waste is a brine solution from resin regeneration that contains high concentrations of PFAS (as well as salt and other organic compounds), and at the end of a resin lifecycle, ion-exchange resin is saturated with PFAS. In RO/nanofiltration, the waste stream is an aqueous solution that contains high concentrations of the rejected PFAS compounds [FN75: See, e.g., Thomas Speth, Session 3: PFAS Treatment in Drinking Water and Wastewater - State of the Science, EPA (Sept. 16, 2020), https://www.epa.gov/sites/default/files/2020-09/documents/r1-pfas_webinar_day_1_session_3_speth.pdf; Craig Patterson, Managing PFAS in Spent Adsorption Media, EPA (May 28, 2020), https://cfpub.epa.gov/si/si_public_file_download.cfm?p_download_id=540623&Lab=CESER.]

Safe disposal of these PFAS waste products is essential, posing challenges that have not been adequately addressed to date [FN76: See, e.g., Jay N. Meegoda, et al., A Review of PFAS Destruction Technologies, 19 INT'L J. OF ENVMTL. RES. & PUB. HEALTH 16397 (Dec. 7, 2022), available at https://doi.org/10.3390/ijerph192416397.] This issue will become acute once the NPDWR is enacted due to the large quantities that will be produced by the PWS.

EPA published in 2020 an interim guide for the destruction and disposal of PFAS-containing waste that reviews current approaches [FN77: EPA, Section on PFOA, PFOS & Other PFAS, Interim Guidance on Destroying and Disposing of Certain PFAS and PFAS-Containing Materials That Are Not Consumer Products, https://www. epa.gov/pfas/interim-guidance-destroying-and-disposing-certain-pfas-and-pfas-containing-materials-are-not (last updated Nov. 21, 2022).] Reactivating GAC for re-use occurs via combustion. For other solid phases such as spent GAC or the ion exchange resin, landfill disposal or thermal treatment are cited. Aqueous solutions such as those resulting from ion-exchange resin regeneration or RO/nanofiltration separations may be disposed of by underground injection or thermal treatment.

Unfortunately, as clearly stated in the report, these methodologies pose substantial challenges. For example, although high temperature combustion can break down PFAS, there is insufficient data characterizing the emissions from such processes and the nature and prevalence of toxic fluorinated products of incomplete combustion. The results may be severe air pollution by reactive fluorinated species. Leaching from underground injection or landfills can re-introduce

PFAS species into soil and, in particular, groundwater. Some new technologies such as plasma treatment are under development, but it is not clear that, even if effective, they could address the large volumes needed [FN78: See, e.g., Raj Kamal Singh, et al., Breakdown Products from Perfluorinated Alkyl Substances (PFAS) Degradation in a Plasma-Based Water Treatment Process, 53 ENVMTL. SCI. & TECH. 2731 (Feb. 15, 2019), available at https://doi.org/10.1021/acs.est.8b07031.] The proposed NPDWR rule discusses some of these issues in Section XI.C, committing to expand and accelerate research on PFAS destruction and disposal technologies in tandem with stricter regulations such as the CERCLA, the Resource Conservation and Recovery Act ("RCRA"), or the Toxic Substances Control Act ("TSCA"). However, all it can offer PWSs is, "At present, the most likely management option for spent material containing PFAS is reactivation for GAC and incineration for spent IX resin. For disposal of RO/NF membrane concentrate, most systems use surface water discharge or discharge to sanitary sewer."[FN79: 88 Fed. Reg. 18686.] The potential harm to the environment, as well as to human health from these disposal methods which risk reintroducing the PFAS into the environment may well undo the benefits of the NPDWR.

Commenters understand that developing safe disposal methods for the PFAS-infused waste produced by water treatment under the proposed rule is outside the scope of the NPDWR. However, while the proposed NPDWR is a crucial step to protecting human health and the environment from the significant harms caused by PFAS, to be effective and prevent re-introduction of the PFAS to groundwater and soil, or stop the release of toxic fluorinated emissions to air, EPA must address the next step: Providing effective and safe disposal methods of the waste material from PFAS removal.

EPA Response: Please see section 10.4.1 of the EPA response in this *Response to Comments* document and note that the *Interim PFAS Destruction and Disposal Guidance* document provides guidance on the destruction and disposal of PFAS-laden materials. The EPA is also evaluating and developing technologies for reducing PFAS in the environment to inform decisions on drinking water and wastewater treatment, contaminated site cleanup and remediation, air emission controls, and end-of-life materials management.

U.S Conference of Mayors, National League of Cities and National Association of Counties (Doc. #1733, SBC-043897)

Moreover, given that both technologies only remove but do not destroy PFOS and PFOA, local governments will have to find a way of disposing of the spent carbon and membranes. Considering that EPA is also moving forward to declare both chemicals as hazardous substances under CERCLA, local governments will be forced to use either hazardous waste landfills or hazardous waste incinerators. Unfortunately, there are very few of either of these facilities and will necessitate expensive long-hauling of material. Given the increase in energy usage associated with these treatments and the additional costs associated with appropriate disposal, EPA should focus more attention on an effective means of destroying these chemicals.

EPA Response: Please see sections 10.4.1 and 10.4.2 of the EPA response in this *Response to Comments* document. The designation does not require waste to be treated in any particular fashion, nor disposed of at any particular type of landfill. The designation also does not restrict, change, or recommend any specific activity or type of waste at landfills.

Connecticut Department of Public Health (CT DPH) (Doc. #1745, SBC-045203)

4. CT DPH recommends financial and logistical support be provided for the disposal of used PFAS remediation media. As a relatively small and intensively developed state with limited capacity for disposal, Connecticut currently faces significant waste management challenges for drinking water treatment media. This is especially true of hazardous waste. Consequently, costs incurred for the safe management of used PFAS remediation media will be considerable as most if not all such waste will need to be exported out of state for proper disposal.

EPA Response: Please see section 10.4.1 of the EPA response in this *Response to Comments* document. The EPA notes that PFAS, nor specific PFAS, are not currently a listed hazardous waste. The passage of the IIJA, also referred to as the BIL, invests over $11.7 billion in the DWSRF; $4 billion to the DWSRF for Emerging Contaminants; and $5 billion in EC-SDC grants. These funds will assist many disadvantaged communities, small systems, and others with the costs of installation of treatment when it might otherwise be cost-challenging. These funds can also be used to address emerging contaminants like PFAS in drinking water through actions such as technical assistance, certain water quality testing, and contractor training, which will allow communities supplemental funding to meet their obligations under this proposed regulation and help ensure protection from PFAS contamination of drinking water. The EPA seeks to continue developing implementation assistance. More information on these monies may be found in section 2.4 of the EPA response in this *Response to Comments* document.

West Virginia Rivers Coalition et al. (Doc. #1746, SBC-045255)

In the same way, it is critical that disposal options permanently remove PFAS from the PFAS cycle. The disposal options identified in EPA's 2020 Interim Guidance on the Destruction and Disposal of Perfluoroalkyl and Polyfluoroalkyl Substances and Materials Containing Perfluoroalkyl and Polyfluoroalkyl Substances are landfill disposal and thermal treatment. In anticipation of the updated version to be released in 2023, we ask EPA to ensure that PFAS residuals from drinking water treatment are not simply being moved from media to media, as that would continue to endanger public health.

EPA Response: Please see section 10.4.1 of the EPA response in this *Response to Comments* document.

Environmental Council of the States (ECOS) (Doc. #1752, SBC-044507)

PFAS Destruction and Disposal

In addition to providing resources related to treatment technologies, more research and information is needed around various technical and cost-effective approaches to destroying and disposing of PFAS and PFAS-containing wastes. ECOS encourages the Office of Water to coordinate with the Office of Land and Emergency Management and others to clarify PFAS disposal options, and to research and communicate with states and stakeholders about destruction and disposal options as they are developed. States request that EPA finalize its Interim Guidance on the Destruction and Disposal of Perfluoroalkyl and Polyfluoroalkyl Substances and Materials Containing Perfluoroalkyl and Polyfluoroalkyl Substances as soon as possible so that this guidance can be incorporated in planning for the final rule.

EPA Response: Please see section 10.4.1 of the EPA response in this *Response to Comments* document. The EPA Office of Water (OW) is coordinating with the Office of Land and Emergency Management (OLEM) on the *PFAS Destruction and Disposal Guidance* as well as other Agency actions to address PFAS through the PFAS Council.

Los Angeles County Sanitation Districts (Doc. #1756, SBC-044514)

Treatment residuals could impose a significant burden and will promote environmental cycling of PFAS. Most of the accepted PFAS treatment technologies do not cause the destruction of PFAS, rather they involve the separation of PFAS from the source into PFAS-laden treatment residuals that must also be managed appropriately. Accordingly, the proposed MCLs are likely to require the deployment and operation of thousands of new drinking water treatment systems and will generate significant quantities of PFAS-laden treatment residuals (e.g., filter concentrates, spent absorbent media). In many cases, these residuals will need to be safely handled at municipal or hazardous waste landfills (depending on the promulgation by EPA of other waste-related regulations under the Resource Conservation and Recovery Act and the Comprehensive Environmental Response, Compensation and Liability Act) and wastewater treatment plants. However, these facilities often do not have emission controls or treatment processes in place to prevent PFAS from re-entering the environment, and, when required to implement treatment themselves to meet impending PFAS regulations under other statutes, these facilities will also generate treatment residuals. The absence of clear guidance from the EPA regarding appropriate disposal and handling practices for PFAS treatment residuals, as well as the absence of mandates or recommendations to reactivate or reuse treatment materials where feasible, suggest that substantial quantities of residuals would impact waste and wastewater facilities that will already be impacted by treatment requirements to address existing PFAS sources. The Sanitation Districts strongly urge the EPA to develop policies, programs, and regulations that govern the safe disposal and destruction of PFAS and PFAS-containing materials prior to promulgating the proposed MCLs. These policies should seek to limit the environmental cycling of PFAS and specify available and feasible treatment technologies and practices for the management of treatment residuals.

EPA Response: Please see sections 10.4.1 and 10.4.2 of the EPA response in this *Response to Comments* document, as well as the *Interim PFAS Destruction and Disposal Guidance* document.

PFAS Regulatory Coalition (Doc. #1761, SBC-046086)

f) How did EPA choose 200 miles as its transportation distance for hazardous waste shipments? In the appendix "Economic Analysis for the Proposed Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation," EPA uses a 200-mile distance in its sensitivity analysis for hazardous versus non-hazardous waste disposal. EPA-822-P-23-001. However, small systems and non-transient, noncommunity systems are likely much farther away from an available hazardous waste disposal facility. EPA should include a more realistic distance in its analysis.

g) Did EPA consider the increases in social costs resulting from increased energy use required treatment? It appears that energy costs were considered only as part of O&M costs for lighting, ventilation and pump operations. But treatment for PFAS involves fairly energy-intensive activities. Therefore, EPA's energy cost estimates seem low EPA's analysis also needs to include increased social costs associated with that required increase of energy use.

EPA Response: Please see section 10.4.1 of the EPA response in this *Response to Comments* document. The total area of the United States is approximately 3,800,000 square miles, meaning on average each state is around 76,000 square miles. The square root of this is about 275 miles and each state has at least one hazardous waste disposal site, so 200 miles was chosen as a baseline national average as a conservative estimate. The EPA considered social costs to carbon, please see section 14 of the EPA response in this *Response to Comments* document. For more information on the EPA cost model, please see section 13 of the EPA response in this *Response to Comments* document.

PFAS Regulatory Coalition (Doc. #1761, SBC-046084)

d) Did EPA review how treatment media are being handled by waste disposal facility today? In our members' experience, PFAS-impacted media, including treatment media, are often being refused at regular landfills and only being accepted at hazardous waste landfills. EPA's approach, in which these costs are looked at only as part of a sensitivity analysis, ignores the true costs that are being experienced today, regardless of the regulatory status of the material being handled.

EPA Response: Please see sections 10.4.1 and 10.4.2 of the EPA response in this *Response to Comments* document. The EPA refers commenter to the summary of major public comments for this section. The designation does not require waste to be treated in any particular fashion, nor disposed of at any particular type of landfill. The designation also does not restrict, change, or recommend any specific activity or type of waste at landfills. Without data the EPA cannot generalize the experience of the PFAS Regulatory Coalition nationally and encourages

the coalition to submit data supporting its claims. For more information on the EPA cost model please see section 13 of the EPA response in this *Response to Comments* document.

Bowling Green Municipal Utilities (Doc. #1767, SBC-043935)

Collateral Impacts: There is no guidance on what to do with spent treatment chemicals after use in removing PFOS/PFOA. This is problematic of developing a rule piece-meal without considering the full long-term implications.

EPA Response: Please see section 10.4.1 of the EPA response in this *Response to Comments* document. The EPA disagrees that the long-term implications, including disposal of treatment materials, have not been considered and has published *PFAS Destruction and Disposal Guidance*. The EPA refers commenter to the summary of major public comments for this section.

Western Urban Water Coalition (WUWC) (Doc. #1768, SBC-043940)

II. Unavoidable Obstacles Threaten to Make Implementing the Proposed Rule Practically or Legally Infeasible

Treatment Options and Disposal of Residuals

WUWC has serious concerns with EPA's assumptions and conclusions regarding the feasibility of proposed treatment methods and the disposal of drinking water treatment residuals containing PFAS. [FN11: 88 Fed. Reg. at 18686 (discussing "management of treatment residuals"); 88 Fed. Reg. at 18731 (requesting comment on EPA's estimates for drinking water treatment residuals, regeneration, and capacity of disposal sites).] EPA states that treatment technologies using GAC and IX resin are the best available technologies for PFAS treatment based on several factors including efficiency and cost. [FN12: Id. At 18684.]

EPA Response: Please see sections 10.1 and 10.4.1 of the EPA response in this *Response to Comments* document.

City of Tulsa Water and Sewer Department (CoT WSD) (Doc. #1785, SBC-043789)

In addition, EPA significantly downplayed the effect of the possibility of GAC, ion exchange (IX) resin, or RO/NF concentrate waste stream being designated as hazardous waste. In the previously referenced AWWA study [FN1: Black & Veatch, prepared for American Water Works Association. (2023). WITAF 56 Technical Memorandum, PFAS National Cost Model Report (B&V Project No. 409850). https://www.awwa.org/Portals/0/AWWA/Government/2023030756BVFinalTechnicalMemoradum.pdf?ver=202303-14-102450-257] typical GAC reactivation temperatures are not appropriate for PFAS removal (pg. 4). EPA states that conventional regeneration solutions are not effective in restoring PFAS-selective IX resins (88 FR 18685). If spent GAC is designated as hazardous

substance, the GAC supplier may refuse to accept it. There are limited hazardous waste landfills; there is only one in Oklahoma. Replacement and disposal costs of GAC and the other BAT media could increase exponentially if this occurs.

(This space intentionally left blank)

The City of Tulsa Water and Sewer Department values the opportunity to comment on the preliminary regulatory determination and proposed rule for per- and polyfluoroalkyl substances (PFAS) National Primary Drinking Water Regulation, and appreciates EPA's consideration of the expressed questions, opinions, and comments in this letter. Please contact me if you have any questions.

Sincerely,

Eric Lee, Director

City of Tulsa Water and Sewer Department

EPA Response: Please see sections 10.4.1 and 10.4.2 of the EPA response in this *Response to Comments* document, as well as the *Interim PFAS Destruction and Disposal Guidance* document.

Fairfax Water (Doc. #1789, SBC-045303)

Utilities that exceed the proposed MCLs and/or HI must evaluate treatment alternatives to achieve compliance. Each alternative will generate residual streams. EPA has suggested granular activated carbon (GAC), ion exchange (IX), and reverse osmosis (RO) as treatment alternatives. None of these alternatives actually remove PFAS from the environment, they simply move it from one media (source water) to another (filter media or membrane filtrate). The regulatory framework for discharging or disposing of PFAS laden membrane filtrate is uncertain. Spent GAC and IX media must be regenerated and/or disposed of properly. The capacity of the marketplace to regenerate or dispose of the quantities of these materials resulting from the proposed rule is unknown. The availability and capacity of landfills willing and/or certified to accept PFAS contaminated filter media is unknown. If the demand for these landfills increases significantly, disposal costs will also increase, adding further burden to utility ratepayers. Fairfax Water currently land applies residuals (solid) from its Potomac water treatment plant to farmland

at a cost of $32/ton. Disposal of those residuals in a landfill would cost $117/ton, before accounting for additional costs due to the presence of PFAS.

The proposed rule states that other PFAS compounds may be added to the proposed HI in the future. EPA also indicates that the MCLs for PFOA and PFOS could be lowered in future regulatory actions. EPA is moving forward with actions such as designating certain PFAS compounds as hazardous waste under CERCLA, which further introduces risk to utility ratepayers. EPA should provide water utilities clarity on the additional regulatory actions being considered with respect to PFAS in treatment residuals in order to support cost effective decision making on behalf of our ratepaying public.

EPA Response: Please see sections 10.4.1, 10.4.2, 10.6 of the EPA response in this *Response to Comments* document, and the *Interim PFAS Destruction and Disposal Guidance.* The designation does not require waste to be treated in any particular fashion, nor disposed of at any particular type of landfill. The designation also does not restrict, change, or recommend any specific activity or type of waste at landfills. More information on ratepayers is in section 2.4 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions.

Massachusetts Municipal Association (MMA) (Doc. #1800, SBC-043766)

Additionally, the disposal options for PFAS-related waste must be addressed. A responsible waste management policy for contaminated materials will be necessary to prevent PFAS from re-entering the environment, whether through landfill leachate or otherwise. The management of these environmental contaminants will require a holistic approach that anticipates future problems, including a dwindling supply of landfill capacity that New England states are experiencing. Should further regulations complicate the waste management landscape, states could become reliant on transporting waste across state and federal borders to those willing to handle contaminated waste. This is not only a costly solution for municipal budgets to handle, but an environmental detriment when considering the greenhouse gas emissions associated with shipping waste out of state via truck or rail.

EPA Response: Please see section 10.4.1 of the EPA response in this *Response to Comments* document and the *Interim PFAS Destruction and Disposal Guidance.* The EPA has published guidance that if followed minimizes risk from the destruction or disposal of PFAS-laden materials. The EPA considered social costs to carbon, please see section 14 of the EPA response in this *Response to Comments* document, and the EPA cost models in general are discussed in section 13 of the EPA response in this *Response to Comments* document.

Millie Garcia-Serrano (Doc. #1803, SBC-044286)

2. PFAS Disposal and Destruction: ASTSWMO is concerned with the increase in the volume of PFAS-contaminated materials and waste streams that will result from this rulemaking. As EPA is

aware, there are many existing challenges associated with the lack and/or limitations of destruction and disposal technologies for PFAS-containing materials and waste streams, including the outright prohibition of PFAS-containing materials destruction in some jurisdictions. Sending PFAS-containing materials to landfills is problematic, due to capacity issues and the lack of proven solidification and stabilization technologies to minimize PFAS in landfill leachate. Further, there remains uncertainty in the acceptable levels of PFAS in compost, biosolids, and industrial byproducts that are otherwise suitable for land application. ASTSWMO recommends that EPA prioritize the identification of effective treatment and disposal options and associated PFAS destruction research to ensure that PFAS contamination is safely disposed of, including finalization of EPA's interim Guidance on the Destruction of and Disposal of Perfluoroalkyl and Polyfluoroalkyl Substances and Materials Containing Perfluoroalkyl and Polyfuoroalkyl Substances.

EPA Response: Please see section 10.4.1 of the EPA response in this *Response to Comments* document. The EPA disagrees that a capacity issue exists and refers the commenter to the summary of major public comments for this section. The EPA has prioritized research; the ORD is evaluating and developing technologies for reducing PFAS in the environment to inform decisions on drinking water and wastewater treatment, contaminated site cleanup and remediation, air emission controls, and end-of-life materials management.

Earthjustice et al. (Doc. #1808, SBC-047716)

Fifth, EPA should develop an estimate of the benefits of managing spent filtration materials as hazardous waste, which would reduce environmental releases of PFAS and associated human exposures. In assessing the Proposed Rule's costs in the Draft EA, EPA correctly excludes the incremental costs to water systems from potential future requirements to manage spent filtration materials as hazardous waste, electing instead to calculate such costs as part of an illustrative sensitivity analysis because these costs are not attributable to the rule under consideration. [FN140: Id. at 4–5.] While EPA's inclusion of this sensitivity analysis enhances the transparency value of the EA, it improperly considers only the costs of potential hazardous waste management requirements, without accounting for the benefits. [FN141: Id. at 5.] If EPA maintains this illustrative analysis as part of the final EA, it also must include a benefits estimate to ensure that its analysis is comprehensive and balanced. [FN142: Id.]

EPA Response: Please see section 10.4.1 of the EPA response in this *Response to Comments* document. The EPA agrees that it is correct to exclude costs from potential future requirements not under consideration in the current rule. In acknowledgement of the commenter's request, the EPA has updated the EA to include a statement about the existence of non-quantified benefits that could result from managing PFAS-laden residuals from water treatment as hazardous waste. For more information on the EPA cost and benefit models, please see section 13 of the EPA response in this *Response to Comments* document.

Groundwater Resources Association of California (Doc. #1831, SBC-045355)

Finally, we also recommend that EPA take into consideration the impact on groundwater resources from the disposal of waste-media from PFAS treatment systems. EPA should highlight options for destructive treatment (e.g.. Hydrothermal alkaline treatment [HALT] or electrochemical oxidation [ECO]) over treatment technologies that create concentrated PFAS waste streams to better protect groundwater quality.

[Figure 1: see docket ID EPA-HQ-OQ-2022-0114-1831]

EPA Response: Please see sections 10.1, 10.2, 10.3, and 10.4.1 of the EPA response in this *Response to Comments* document. The EPA has published the *Interim PFAS Destruction and Disposal Guidance* and the PITT has published research briefs on additional non-traditional destruction and disposal methods, including electrochemical oxidation, mechanochemical degradation, pyrolysis and gasification, as well as supercritical water oxidation.

Kevin Rolfes (Doc. #2802, SBC-047440)

Treatment of contaminated drinking water to achieve the proposed MCLs and HI is technically feasible for national implementation of the proposed PFAS regulations. However, the treatment processes produce waste that needs to be disposed of safely. This issue will become acute once the NPDWR is enacted due to the large quantities that will be produced.

I understand that developing safe disposal methods for the PFAS-infused waste produced by water treatment under the proposed rule is outside the scope of the NPDWR. However, while the proposed NPDWR is a crucial step to protecting human health and the environment from the significant harms caused by PFAS, to be ultimately effective, prevent the re-introduction of PFAS to groundwater and soil, and stop the release of toxic fluorinated emissions to air, EPA should expeditiously address the next step: Facilitating effective and safe disposal methods of the waste material from PFAS removal.

In sum, I firmly support the proposed NPDWR and look forward to seeing it implemented as a vital part of an overall strategy to protect public health from PFAS.

EPA Response: Please see sections 10.4.1 of the EPA response in this *Response to Comments* document. The EPA agrees that drinking water treatment to at or below the MCLs is technically feasible as well as that this treatment will generate residuals that require proper management. The EPA has facilitated safe and effective disposal methods for these materials through, among other ways, the *PFAS Destruction and Disposal Guidance*, the PITT briefs, technical briefs such as incineration to manage PFAS waste streams, and the EPA research on PFAS homepage.

Savannah River Nuclear Solutions LLC (Doc. #1647, SBC-043340)

Finally, while RO/NF has been shown to achieve high removal efficiency for PFAS, large volumes of residual concentrate (15-30% of the feed stream) containing high levels of PFAS are produced from these systems which must be managed. Neither the proposed rule nor support documents provide a clear disposal path for these residual streams besides treatment in a wastewater treatment plant, discharge to non-potable water body (e.g., ocean or brackish estuary), or other methods that are reportedly used (deepwell injection, evaporation ponds, etc.; Technologies and Costs for Removing Per- and Polyfluoroalkyl Substances (PFAS) from Drinking Water, EPA Document EPA-822-P-23-011, pg. 53). These methods only transfers PFAS constituents to other water bodies or media.

Additional research is needed on all of these technologies and the full implications of their use, including cross-media effects and residual management before they can be designated as BAT.

EPA Response: Please see sections 10.1 and 10.4.1 of the EPA response in this *Response to Comments* document. The EPA refers the commenter to the *Interim Guidance on the Destruction and Disposal* for management of treatment residuals including RO/NF concentrate. Sites with reject water from RO/NF membranes typically have a NPDES Permit; drinking water treatment utilities using membranes must follow all applicable NPDES permit or pretreatment program requirements for any permit or control mechanism issued for their facility. While the EPA agrees that more research could be beneficial, and is sponsoring research, the EPA believes that this technology is mature, well understood, and should be listed as a BAT as outlined in the in the *Best Available Technologies and Small System Compliance Technologies for PFAS in Drinking Water* (BAT/SSCT) document (USEPA, 2024a).

Philadelphia Water Department (PWD) (Doc. #1709, SBC-053309)

Third, the operational costs do not account for the potential change to the designation of spent media as hazardous substances under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) or hazardous waste under the Resource Conservation and Recovery Act (RCRA). In September 2022, the EPA proposed a Draft Rule to designate PFOA and PFOS as hazardous substances under CERCLA, creating liability concerns for any waste streams containing these substances. Additionally, EPA is in the process of evaluating changes to RCRA that would designate certain PFAS compounds as a hazardous waste, making disposal of contaminated material like spent media both more difficult and costly. In Appendix N, Section N.2 of the Economic Analysis, the EPA estimates that this change in designation from a non-hazardous waste to a hazardous waste would result in a 4-6% increase in annualized costs. PWD requests that EPA share their supporting calculations to verify these cost assumptions. PWD recommends that these elevated operational costs should be included in the Economic Analysis to account for future challenges for disposal of PFAS-laden media and the diminishing available landfill volume. Additionally, the increased costs of media disposal would not be equally distributed, as the disposals costs are regional and the distances PWSs may need

to transport these wastes will vary greatly, and thus some facilities will bear a more significant financial strain to dispose of spent media.

EPA Response: Please see section 10.4 of the EPA response in this *Response to Comments* document. The EPA has published the requested information in the *Technologies and Costs for Removing Per- and Polyfluoroalkyl Substances from Drinking Water* document. The WBS used to generate cost curves are also freely available on the EPA website at https://www.epa.gov/sdwa/drinking-water-treatment-technology-unit-cost-models. For more information on the EPA cost and benefit models, please see section 13 of the EPA response in this *Response to Comments* document.

10.4.2 Disposal of spent drinking water materials under possible future regulatory actions under other statutes and costs

Summary of Major Public Comments and EPA Responses

Many commenters, including destruction and disposal trade associations, stated there would be difficulties managing spent residuals containing PFAS generated from drinking water treatment. In contrast, other commenters stated that there was existing national capacity and at least one company stated they were actively evaluating investment for additional capacity to handle residuals. The record demonstrates that there is existing national capacity to handle spent drinking water residuals containing PFAS in a manner that minimizes risk to human health. Destruction and disposal of PFAS-containing materials is currently not subject to certain hazardous waste regulation and therefore the materials may be managed in non-hazardous and hazardous waste treatment and disposal systems (USEPA, 2020). Hazardous waste is regulated pursuant to the Resource Conservation and Recovery Act (RCRA) authority 42 U.S.C. 6921-6939 (also known as RCRA "Subtitle C"). The regulatory definition of hazardous waste is found in 40 CFR 261.3. PFAS are currently not a listed hazardous waste or characterized as a hazardous waste, but a PFAS-containing waste may meet the regulatory definition of hazardous waste if PFAS is mixed with a listed hazardous waste or if a PFAS-containing mixture exhibits a hazardous characteristic (e.g., corrosivity or another characteristic stemming from the material that is mixed with PFAS). PFAS that are commingled with hazardous substances and/or hazardous wastes will be subject to the appropriate rules and regulations and may be included as Applicable or Relevant and Appropriate Requirements on a site-specific basis. Not all disposal sites may be appropriate for spent drinking water treatment residuals containing PFAS and the EPA encourages owners and operators of treatment facilities use appropriate guidance on treatment residual management such as the 2020 Interim Guidance on the Destruction and Disposal of Perfluoroalkyl and Polyfluoroalkyl Substances and Materials Containing Perfluoroalkyl and Polyfluoroalkyl Substances (USEPA, 2020) and subsequent updates.

Regarding commenter concerns on disposal capacity, the EPA believes that there is existing national capacity to dispose of PFAS treatment residuals that would be generated as detailed in the following paragraph. There is also sufficient national capacity to handle non-hazardous waste as detailed below. The EPA acknowledges that there may be short-term increases in demand for

disposal facilities, but market forces are anticipated to result in additional suppliers and increased capacity in the long term. Again, it is worth reiterating that under current federal regulations, PFAS is not designated as a hazardous waste on its own. However, if PFAS were to be designated as hazardous waste in the future, EPA believes there is currently sufficient national capacity to handle waste generated from the treatment of drinking water to remove PFAS as also detailed below.

The EPA anticipates approximately 226,500 short tons of spent drinking water media such as activated carbon and AIX resin to be generated annually as a result of this rule; in calendar year 2018 alone, the US generated about 290 million short tons of waste (USEPA, 2022d). The increase in total waste caused by this final rule is approximately 0.08 percent of the total US waste produced. This is a minor change in aggregate waste produced; the same amount as a pound contributes to a ton. Further, approximately 212,500 short tons of the 226,500 are anticipated to be GAC, which Is expected to be reactivated, and therefore not incinerated or landfilled. Even if PFAS were to be designated in the future as regulatory hazardous waste, there is existing capacity to handle these waste streams through existing hazardous waste facilities in every state (see discussion below). Some water systems may have to ship hazardous wastes significant distances; however, the main cost driver is disposal fees not transportation. The EPA rejects the assertion that it has not evaluated if sufficient capacity exists for disposal and storage of PFOA and PFOS contaminated materials. The EPA also acknowledges that the Comprehensive Environmental Response Compensation and Liability Act (CERCLA) section 104(c)(9) does not allow the agency to initiate a remedial action, unless the state first enters into a state Superfund State Contract or Cooperative Agreement (CA) that assures the availability of adequate capacity to manage hazardous wastes generated in the state for 20 years following the date of the response agreement. This final rule, however, does not impose any capacity concerns that require further action under section 104(c)(9). The EPA is considering designating PFOA and PFOS as CERCLA hazardous substances. No PFAS are currently listed as hazardous wastes under RCRA. The 2021 Biennial Report Summary Results indicate about 18 million tons of hazardous wastes are normally generated annually. Drinking water treatment materials then would constitute about a 1.26 percent increase in hazardous wastes generated annually. Since there is over twenty years' capacity, the relatively small magnitude of the increase indicates that waste management capacity is sufficient in the short term should PFAS be designated as regulatory hazardous wastes.

A few commenters suggest the EPA did not appropriately consider disposal concerns for spent treatment media as part of the agency's feasibility determination. These commenters state that they believe disposal options are currently limited for liquid brine, reject waters resulting from RO, or solid waste from GAC treatment and that disposal capacity will be further limited should the EPA designate PFAS waste as hazardous. These commenters contend that these limitations increase operating expenses for utilities and should be factored in the establishment of the PFOA and PFOS MCLs. The EPA disagrees with these commenters that the agency did not adequately consider disposal of spent treatment media in the rule. First, disposal options for PFAS are currently available. These destruction and disposal options include landfills, thermal treatment,

and underground injection. Systems are currently disposing of spent media, such as activated carbon, through thermal treatment, to include reactivation, and at landfills. While precautions should be taken to minimize PFAS release to the environment from spent media, current disposal options allow these precautions to be taken as appropriate. See USEPA (2024c) and section X of the final rule preamble for further discussion. Furthermore, the EPA has provided guidance for pretreatment and wastewater disposal to manage PFAS that enters the sanitary sewer system and must be managed by POTWs (USEPA, 2022b; USEPA, 2022c).

Many commenters further conveyed concern over the cost of drinking water residuals management resulting from finalizing this rule. Many commenters suggested that regulations under other statutes, particularly a potential CERCLA hazardous substance designation, would increase disposal costs. The EPA disagrees that, if finalized, the CERCLA hazardous substance designation for PFOA and PFOS would increase disposal costs for water treatment facilities. The designation of PFOA and PFOS as CERCLA hazardous substances would not require waste (e.g., biosolids, treatment residuals, etc.) to be treated in any particular fashion, nor disposed of at any specific particular type of landfill. The designation also would not restrict, change, or recommend any specific activity or type of waste at landfills. Along with other release notification requirements, CERCLA designation would require that any person in charge of a vessel or facility report a release of PFOA and/or PFOS of one pound or more within a 24-hour period. The EPA does not expect spent drinking water treatment residuals containing PFAS to be released into the environment at or above the reportable quantity as a part of standard residuals management practices used by water systems. This is because the PFAS loading onto sorptive media is very small. The weight percent of PFAS onto GAC under normal treating scenarios should vary widely; however, a reasonable order of magnitude estimate is $1x10^{-5}$ grams PFAS per gram of sorbent in full-scale applications. High pressure membranes split water into a treated stream and concentrated waste stream. The concentrated waste stream should contain about 5-12 times more PFAS than the influent, which is likely to still be in the ng/L scale. A drinking water facility that takes reasonable precautions is unlikely to release enough low concentration residuals to release one pound of PFOA and/or PFOS within a 24-hour period. At the concentrations discussed above, to exceed a one-pound threshold, a facility using sorptive techniques would have to improperly dispose of approximately 50 tons of sorbent. A one-pound uncontrolled release from RO or NF facilities, assuming 500 ng/L of PFAS in the reject water, would require approximately 240 million gallons of high-pressure membrane concentrate to be released within 24 hours. Additionally, neither a release nor a report of a release automatically requires any response action under CERCLA. The EPA makes CERCLA response decisions based on site-specific information, which includes evaluating the nature, extent, and risk to human health and/or the environment from the release. Hazardous substance designations do not automatically result in CERCLA liability for any specific release. Whether an entity may be subject to litigation or held liable under CERCLA are site-specific and fact-dependent inquiries. Likewise, CERCLA affords the federal government broad discretion as to whether or how to respond to a release. For those reasons, the EPA cannot assess with reasonable certainty what litigation or liability outcomes could indirectly result from such a designation since those

outcomes are often linked to the EPA's discretionary decisions with respect to CERCLA response actions as well as site-specific and fact-dependent court rulings.

While no PFAS are currently listed as regulatory hazardous wastes under RCRA, in response to stakeholder feedback, the EPA included a sensitivity analysis to determine the impact on water systems should they be required to handle and dispose of PFAS treatment materials as hazardous waste in the future. The results of this analysis can be found in the EA for this rule (USEPA, 2024d). Some commenters suggested that accounting for future potential regulations is uncommon, and trying to account for all potential future contingencies would make economic analyses impossible. The EPA strongly agrees and has not attempted to do so here; this analysis was limited to looking at a hypothetical future hazardous waste listing situation because that has been of particular concern in this rulemaking. Some commenters stated that the EPA should account for the public health benefits of treating PFAS as hazardous wastes, not just additional costs incurred. The EPA agrees and has modified the analysis to include a qualitative statement about the public health benefits that could arise from treating PFAS as hazardous wastes. Many commenters stated that the EPA hazardous waste cost would drive the total cost higher than the 3-5 percent estimated by the EPA. After considering public comment, the EPA has revised the final cost estimates in this rule. The estimated increased cost would be approximately $99M at the two percent discount rate. The increased cost was driven by updating the dollar year of cost curves from 2021 to 2022, which increased waste management unit costs by approximately 12 percent; implementing a cap on media life even if not indicated; changes in technology compliance forecast eliminating RO/NF while increasing GAC and AIX (thereby increasing spent media volume); and increasing occurrence estimates for the final rule compared to the proposed rule, triggering more systems into treatment. The increased costs were not driven by changes to unit cost estimates for hazardous waste management. The total cost encompasses capital costs, maintenance, design, and operations, including waste management. Waste management costs are thus a subset of operational cost, which in turn is a subset of total costs; generally, changes in the cost of one subcomponent would not significantly influence total costs, and the record does not reflect that a change in waste disposal costs would have a significant impact on total costs under this rule. These estimates are discussed in greater detail in the HRRCA section of this rulemaking and in Appendix N of the EA (USEPA, 2024b).

Some commenters suggest that the EPA failed to consider the costs and impacts of the proposed MCLs in non-drinking water contexts, such as its potential uses as CERCLA clean-up standards. As required by SDWA, this rulemaking and analyses supporting the rulemaking only includes costs that "are likely to occur solely as a result of compliance with the [MCL]." Thus, the EPA's cost analyses focused on the compliance costs of meeting the MCL to PWSs that are directly subject to this regulation. The same provision expressly directs the EPA to exclude "costs resulting from compliance with other proposed or promulgated regulations." Thus, the EPA cannot consider the costs of use of the MCLs under other EPA statutes (such as CERCLA) as part of its EA because SDWA specifically excludes such consideration (42 U.S.C. § 300g-1(b)(3)(C)(i)(III)). See also *City of Waukesha v. EPA*, 320 F.3d 228, 243-244 (D.C. Cir. 2003) (finding that SDWA excludes consideration of the costs of, for example, CERCLA compliance,

as part of the required cost/benefit analysis). In addition, whether and how MCLs might be used in any particular clean-up is very site-specific and, thus, as a practical matter cannot be evaluated in this rulemaking. Many commenters suggested that EPA should remove water system liability if the agency promulgates a PFAS hazardous substance designation or hazardous waste listing. Water system liability is outside the scope of this regulatory action. Other comments that are outside the scope of this rule making are in section 15.1.

Individual Public Comments

Orange Water and Sewer Authority (OWASA) (Doc. #1524, SBC-042622)

• Hazardous Waste generation/Impacts to treatment plant solids disposal options

o As of right now OWASA's WTP solids would not qualify as hazardous waste, but in the future if the limits become more stringent or if our composting facility decides not to accept waste that has PFAS, there will be impacts to our utility (money and disposal options)

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document. For information on the EPA cost models, please see section 13 of the EPA response in this *Response to Comments* document.

Maine Water Utilities Association (MWUA) (Doc. #1567, SBC-042742)

Liability Concerns:

Disposal concerns are currently centered around pending updates to the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) on regulating PFOA and PFOS as hazardous substances, which may impact the available media disposal methods such as landfilling. EPA's current proposal includes setting the default reportable quantity (RQ) at 1.0 pound in a 24-hour period for PFOA and PFOS, and any release at or above RQ must be reported. Granular activated carbon (GAC), anion exchange (AIX) and novel adsorbents all would concentrate PFAS on the media. Disposal considerations are currently most important for anion exchange or novel adsorbents as, currently, major GAC manufacturers offer reactivation services that indicate thermal destruction of PFAS while no resin or novel adsorbent manufacturers offer regeneration services presently. With the ongoing CERCLA update efforts, once PFOA and PFOS are designated as hazardous substances, it will limit the disposal options and sites willing to accept spent media such as resin and novel adsorbents. The draft CERCLA proposal still needs to be finalized, and no industry exemptions have been included for water and wastewater systems. Even though GAC manufacturers provide reactivation, there is indication that regenerated GAC does not fully remove PFAS; with this knowledge, there is a possibility that only virgin media would be permitted for use in PFAS removal systems, not regenerated GAC. The concerns with disposal of PFAS containing media stresses the need for significant focus on advancing destruction technologies.

MWUA, and other New England state water associations made comments on dockets EPA-HQ-OLEM-2019-0341 and EPA-HQ-OLEM-2022-0922-0001 dealing with regulating PFAS under CERCLA. EPA should not move forward with any proposed CERCLA designation until exemptions are granted to water utilities who are passive receivers of PFAS substances. We understand that EPA is separately considering a CERCLA enforcement discretion policy to make it clear that EPA may choose not to take CERCLA enforcement actions against certain entities, but we believe the exemption for water utilities and publicly owned treatment works should be embedded in the regulation. Policies are subject to interpretation and change, whereas regulations have a specified public process. We are therefore requesting that in whatever CERCLA rulemaking EPA moves forward with, EPA provide PWS with an exemption from liability if any or all PFAS compounds are designated as hazardous substances under CERLCA. Doing so would keep CERCLA liability on the industries that created the pollution and/or utilized the substances in the first place.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

Minnesota Pollution Control Agency (MPCA) (Doc. #1569, SBC-042495)

Topic: Part C, Management of treatment residuals includes this statement: "For disposal of Reverse Osmosis (RO)/Nano Filtration (NF) membrane concentrate, most systems use surface water discharge or discharge to sanitary sewer. The large volume of residuals is a well-known obstacle to adoption of membrane separation technology in general."

MPCA comments: A discharge of RO/NF membrane treatment residuals to a surface water or to a sanitary sewer system which ultimately discharges to a surface water, recirculates the PFAS into the environment posing risks to human and ecological receptors. Either type of discharge may also represent a violation of other state or federal water quality standards and/or NPDES permit conditions.

EPA should consider a hazardous waste disposal exclusion for nominally sized or Point of Use / Point of Entry filtration systems (POU/POEs) and may want to consider adding a discussion of emerging destruction and separation technology types that may provide future treatment efficacy at the small and large scale.

EPA Response: Please see sections 10.1, 10.4.1 and 10.4.2 of the EPA response in this *Response to Comments* document.

San Antonio Water System (SAWS) (Doc. #1570, SBC-042485)

o EPA is simultaneously proposing the inclusion of nine (9) PFAS compounds to be designated as hazardous substances under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) as the regulations pertaining to PFAS are being proposed under the Safe Drinking Water Act.

o PWSs face the possible imposition of liability for the presence of designated PFAS compounds, deemed hazardous substances, even though they are passive recipients of these compounds. Requiring testing and disclosure of the presence of PFAS compounds while facing this potential liability is contrary to the interest of every PWS and could lead to litigation that makes compliance with PFAS regulations virtually impossible.

o As a practical matter, PWSs will not know the best treatment methods to implement without understanding hazardous waste disposal regulations. For a PWS to reach compliance under the proposed drinking water rule, they will be creating hazardous waste under the anticipated CERCLA regulations. EPA needs to clearly define approved disposal options available for treatment biproducts, laboratory analytical waste, etc.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

Sammamish Plateau Water and Sewer District (Doc. #1573, SBC-042463)

Since water utilities are not the responsible party for PFAS contamination, but may be required to implement PFAS treatment/removal as mandated under the rule, USEPA should recognize that spent treatment media will become a byproduct of the proposed rule. As such, USEPA should acknowledge the need for corresponding Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) exemption/immunity for agencies mandated to treat for PFAS removal. In addition, any MCL which would require a water utility to treat for PFAS should be applied as the same standard for parties responsible contaminating potable groundwater with PFAS who will be required to conduct remediation activities.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document. The EPA agrees that removing PFAS from drinking water using the proposed BATs generates residual materials which must be appropriately managed and has pointed out in the rule proposal as well as guidance documents including the *Best Available Technologies and Small System Compliance Technologies for PFAS in Drinking Water*, the *Technologies and Costs for Removing Per- and Polyfluoroalkyl Substances from Drinking Water*, and the *PFAS Destruction and Disposal Guidance* documents. Comments on other rules should be made on those dockets. Comments on CERCLA liability are outside SDWA, please see section 15.1 of the EPA response in this *Response to Comments* document for other comments outside SDWA.

COMM Water Department (Doc. #1577, SBC-042445)

EPA must address the water sector's concerns about potential liability under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA). EPA is proposing to regulate PFOA and PFOS as hazardous substances, which may impact the available media disposal methods such as landfilling. EPA should not move forward with any proposed CERCLA designation until exemptions are granted to water utilities who are passive receivers of

PFAS substances. The requested exemption needs to be embedded in law or regulation, and not just through an enforcement discretion policy. In whatever CERCLA rulemaking EPA moves forward with, EPA must provide PWS with an exemption from liability, including CERCLA third-party liability, if any or all PFAS compounds are designated as hazardous substances under CERLCA. Doing so would keep CERCLA liability on the industries that created the pollution and/or utilized the substances in the first place.

EPA Response: Please see sections 10.4.2 and 10.6 of the EPA response in this *Response to Comments* document. Designation does not require facilities to take any specific response actions, such as sampling, treatment, or disposal. Designation does not require any response action by a private party and does not determine liability for hazardous substance release response costs. Response actions are contingent, discretionary, and site-specific decisions made after a hazardous substance release or threatened release. The designation does not require waste to be treated in any particular fashion., nor disposed of at any particular type of landfill. The designation also does not restrict, change, or recommend any specific activity or type of waste at landfills. The EPA would also like to clarify that neither the designation, nor CERCLA, require any prospective monitoring. Any potential monitoring that may be necessary for a given release is to be determined on a site-specific basis. Comments on other rules should be made on those dockets. Comments on CERCLA liability are outside the scope of this SDWA rulemaking action, please see section 15.1 of the EPA response in this *Response to Comments* document for other comments outside the scope of this SDWA rulemaking action.

Santa Clarita Valley Water Agency (SCVWA) (Doc. #1578, SBC-042432)

Other PFAS Chemicals rule making efforts, like the U.S. Environmental Protection Agency's (EPA) Proposed Rule – Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) Hazardous Substances: Designation of Perfluorooctanoic Acid and Perfluorooctanoic Acid (PFAS Chemicals) have further cost and liability considerations. The proposed rule will have additional significant cost impacts as it proceeds through the nation's water and wastewater regulatory framework. The rulemaking process would benefit from a consolidated approach when considering the total cost impacts of the new rule.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document. More information about EPA cost analysis can be found in section 13 of the EPA response in this *Response to Comments* document.

San Gabriel Valley Water Association (SGVWA) (Doc. #1580, SBC-042422)

Upside-down Implementation with CERCLA Let's Polluters off the Hook: In September 2022, EPA issued a Notice of Proposed Rulemaking (NPRM) designating PFOA and PFOS as hazardous substances under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA). In April 2023, EPA issued an Advance Notice of Proposed Rulemaking (ANPRM) about possible future designations of PFAS under CERCLA.

If such designations happen before setting an MCL, it may lead to lawsuits between drinking water suppliers and wastewater agencies detecting PFAS substances. This could cause billions of dollars in local mitigation efforts to go to waste, and responsible parties may not be held accountable to remediate the contamination they caused. However, giving exemptions to wastewater agencies and water suppliers under CERCLA requires congressional approval while the regulatory process is ongoing. This creates a race against time as the litigation time bomb counts down.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document. Comments on CERCLA liability are outside the scope of this SDWA rulemaking action, please see section 15.1 of the EPA response in this *Response to Comments* document for other comments outside of this SDWA rulemaking action.

San Gabriel Valley Water Association (SGVWA) (Doc. #1580, SBC-042417)

Hazardous Waste Disposal: The economic analysis does not include the expenses related to transporting and disposing of hazardous waste, also known as PFAS residuals, to certified disposal facilities located in other states. These additional costs can potentially double the total cost of meeting the MCL requirements.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document. The EPA refers the commenter to the EPA response to comment Doc. #1761, SBC-046086 in section 10.4.1 in this *Response to Comments* document for details on how the 200-mile waste disposal distance was selected. More information on the EPA cost analysis can be found in section 13 of the EPA response in this *Response to Comments* document.

Association of State and Territorial Solid Waste Management Officials (ASTSWMO) (Doc. #1583, SBC-042398)

PFAS Disposal and Destruction: ASTSWMO is concerned with the increase in the volume of PFAS-contaminated materials and waste streams that will result from this rulemaking. As EPA is aware, there are many existing challenges associated with the lack and/or limitations of destruction and disposal technologies for PFAS-containing materials and waste streams, including the outright prohibition of PFAS-containing materials destruction in some jurisdictions. Sending PFAS-containing materials to landfills is problematic, due to capacity issues and the lack of proven solidification and stabilization technologies to minimize PFAS in landfill leachate. Further, there remains uncertainty in the acceptable levels of PFAS in compost, biosolids, and industrial byproducts that are otherwise suitable for land application. ASTSWMO recommends that EPA prioritize the identification of effective treatment and disposal options and associated PFAS destruction research to ensure that PFAS contamination is safely disposed of, including finalization of EPA's interim Guidance on the Destruction of and Disposal of Perfluoroalkyl and Polyfluoroalkyl Substances and Materials Containing Perfluoroalkyl and Polyfuoroalkyl Substances.

EPA Response: Please see sections 10.4.1, 10.4.2, and 10.6 of the EPA response in this *Response to Comments* document.

Pennsylvania Chamber of Business and Industry (Doc. #1592, SBC-042797)

The PA Chamber Reiterates Our Concern with Listing These Substances Under

CERCLA

In a joint letter with other state chambers filed with the EPA last November [FN1: https://www.pachamber.org/wp-content/uploads/2022/11/State-Chamber-Coalition-Comments-on-CERCLADesignation-OLEM.pdf], the PA Chamber expressed its concern adding these compounds to CERCLA, given the costs and uncertainties with respect to storage and disposal, as well as the fact that the World Health Organization's report on PFOS and PFOA in drinking water calls into question EPA's approach on this matter. This move would also impose significant liability for domestic manufacturers, again in conflict with the stated policy goals of this administration and Congress on shoring up supply chains.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document. The EPA notes that the draft World Health Organization (WHO) report referenced by the commenter was postponed based on negative public comment based on not using the best available science and that it referenced 2016 EPA Health Advisory levels for PFOA and PFOS. More information may be found online at https://cdn.who.int/media/docs/default-source/wash-documents/wash-chemicals/pfos-and-pfoa-in-dw-comments-responses-21.11.23.pdf?sfvrsn=71261026_1or https://www.who.int/teams/environment-climate-change-and-health/water-sanitation-and-health/chemical-hazards-in-drinking-water/per-and-polyfluoroalkyl-substances Comments on CERCLA liability are outside the scope of this SDWA rulemaking action, please see section 15.1 of the EPA response in this *Response to Comments* document for other comments outside the scope of this SDWA rulemaking action.

Massachusetts Water Works Association (MWWA) (Doc. #1601, SBC-042894)

Liability Concerns:

Disposal concerns are currently centered around pending updates to the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) on regulating PFOA and PFOS as hazardous substances, which may impact the available media disposal methods such as landfilling. EPA's current proposal includes setting the default reportable quantity (RQ) at 1.0 pound in a 24-hour period for PFOA and PFOS, and any release at or above RQ must be reported. Granular activated carbon (GAC), anion exchange (AIX) and novel adsorbents concentrate PFAS on the media. Disposal considerations are currently most important for anion exchange or novel adsorbents since, currently, major GAC manufacturers offer reactivation services that indicate thermal destruction of PFAS, while no resin or novel adsorbent

manufacturers offer regeneration services. With the ongoing CERCLA update efforts, once PFOA and PFOS are designated as hazardous substances, it will limit the disposal options and sites willing to accept spent media such as resin and novel adsorbents. The draft CERCLA proposal still needs to be finalized, and no industry exemptions have been included for water and wastewater systems. Even though GAC manufacturers provide reactivation, there is indication that regenerated GAC does not fully remove PFAS; with this knowledge, there is a possibility that only virgin media would be permitted for use in PFAS removal systems, not regenerated GAC.

MWWA made comments on dockets EPA-HQ-OLEM-2019-0341 and EPA-HQ-OLEM2022-0922-0001 dealing with regulating PFAS under CERCLA. EPA should not move forward with any proposed CERCLA designation until exemptions are granted to water utilities who are passive receivers of PFAS substances. We understand that EPA is separately considering a CERCLA "enforcement discretion policy" to clarify that EPA may choose not to take CERCLA enforcement actions against certain entities. However, we vigorously advocate the exemption for water utilities and publicly owned treatment works be explicitly provided in the regulation. Policies are subject to interpretation and change, whereas regulations have a specified public process. We are therefore requesting that in whatever CERCLA rulemaking EPA advances, EPA provide PWS with an exemption from liability, including CERCLA third-party liability, if any or all PFAS compounds are designated as hazardous substances under CERLCA. Doing so would keep CERCLA liability on the industries that created the pollution and/or utilized the substances in the first place.

There are challenges associated with disposal of spent media and treatment residuals, beyond just the increased costs if no exemptions are granted to water (and wastewater) utilities under CERCLA. Massachusetts drinking water and wastewater facilities face a biosolids management and disposal crisis as PFAS chemicals are causing land application bans and restrictions, and dwindling landfill space reduces disposal capacity. We need EPA to rapidly work toward finding permanent destruction technologies or we will continue to face the prospect of a never-ending cycle of moving PFAS around our environment.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document. Designation does not require facilities to take any specific response actions, such as sampling, treatment, or disposal. Designation does not require any response action by a private party and does not determine liability for hazardous substance release response costs. Response actions are contingent, discretionary, and site-specific decisions made after a hazardous substance release or threatened release. The designation does not require waste to be treated in any particular fashion, nor disposed of at any particular type of landfill. The designation also does not restrict, change, or recommend any specific activity or type of waste at landfills. The EPA would also like to clarify that neither the designation, nor CERCLA, require any prospective monitoring. Any potential monitoring that may be necessary for a given release is to be determined on a site-specific basis. Comments on CERCLA liability are outside the scope of this SDWA rulemaking action, please see section 15.1 of the EPA response in this

Response to Comments document for other comments outside the scope of this SDWA rulemaking action.

Regarding enforcement discretion, existing liability limitations in CERCLA coupled with existing CERCLA enforcement policies are sufficient to mitigate concerns about liability that may arise after designation. No additional action is necessary to ensure that those limitations and policies continue to operate as they have for decades. Nonetheless, the EPA intends to develop a policy, consistent with those limitations and policies, that explains EPA's priorities for enforcement in the context of PFOA and PFOS releases. As the EPA states in the fiscal year (FY) 2024-2027 National Enforcement and Compliance Initiates (NECI), the agency expects to "focus on implementing EPA's PFAS Strategic Roadmap and holding responsible those who significantly contribute to the release of PFAS into the environment …." The NECI also clarifies that "OECA does not intend to pursue entities where equitable factors do not support CERCLA responsibility, such as farmers, water utilities, airports, or local fire departments, much as OECA exercises CERCLA enforcement discretion in other areas." The EPA will make enforcement decisions on a site-by-site basis informed by site-specific circumstances.

Water Works Board of the City of Birmingham (BWWB) (Doc. #1602, SBC-043632)

6. The USEPA recommended BATs for PFAS removal are essentially separation technologies rather than destruction technologies. Thus, PFAS removed from drinking water supplies are shifted to other environmental vectors for public exposure via the residuals management process. Depending on the BAT selected, residuals handling could require landfilling, incineration, or deep well injection-- further reallocating PFAS contamination to air, surface water and groundwater, ocean water etc.

7. It is likely that the USEPA significantly underestimated the national cost impacts of residual management if PFAS-contaminated wastes are regulated as hazardous waste in the future. If/when the USEPA designates one or more species of PFAS as "hazards substances" under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) or "hazardous constituents" under the Resource Conservation and Recovery Act (RCRA), there is potential for a significant escalation in residuals management costs. Similarly, regulatory action under the Clean Water Act (CWA) to control PFAS discharges could also result in escalated residuals management costs for water treatment systems. USEPA estimated costs for two spent GAC management scenarios: 1) Off-site reactivation under current RCRA non-hazardous waste regulations; 2) Off-site disposal as a hazardous waste and replacement with virgin GAC. USEPA stated that there will only be a 6% ($61 million) increase in the national annual PFAS treatment cost when spent GAC is regulated as hazardous waste. However, BWWB conducted a preliminary cost estimate for the same scenarios and the hazardous-waste scenario resulted in approximately 38% higher disposal costs than the non-hazardous waste scenario, which results in an increase in the annual O&M cost for an 80 MGD filter plant of $1.5 million. USEPA's assessment of the influence of these regulations on residuals management is clearly underestimated.

Please refer to Attachment 1 for further comments on the proposed PFAS Rule.

EPA Response: Please see sections 10.4.1 and 10.4.2 of the EPA response in this *Response to Comments* document. The EPA appreciates the commenter sharing a data point but points out that a national average can vary drastically from specific scenarios and refers the commenter to section 13 of the EPA response in this *Response to Comments* document for more information on the cost models. Comments on CERCLA liability are outside the scope of this action, please see section 15.1 of the EPA response in this *Response to Comments* document for other comments outside this scope.

American Water Works Company Inc. (Doc. #1608, SBC-043996)

Waste and Waste Disposal

American Water believes that the U.S. EPA should clearly establish acceptable means of disposal or reactivation/regeneration of PFAS-bearing treatment media. Additionally, if the number and location of approved disposal or treatment outlets is very limited, then increased hauling, disposal, and/or media reactivation costs pose a significant threat to the accuracy of the U.S. EPA's cost assumptions. Further, water utilities that provide a critical community service should not be liable for the fate of PFAS contaminants if residuals are disposed of or treated using an approved waste management practice. American Water firmly believes that the ultimate responsibility for the cleanup of these contaminants should fall to those who created the problem. Drinking water and wastewater utilities are not responsible for the presence of PFAS contaminants in sources of supply and customer wastewater discharges. Protecting water and wastewater utilities from liability associated with handling and disposing of PFAS-contaminated residuals according to USEPA-approved methods is important for minimizing legal risks and associated cost burdens to utilities and their customers.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document. The EPA has provided clear destruction and disposal guidance for example in the *Interim PFAS Destruction and Disposal Guidance* document. For discussion on costs, please see the EA and the HRRCA section.

American Water Works Company Inc. (Doc. #1608, SBC-044004)

American Water joins other water organizations in urging the U.S. EPA, Congress, and other decision-makers to implement policies that will:

• keep harmful PFAS out of our drinking water supplies and our communities;

• exempt all water and wastewater systems from financial liability for PFAS under CERCLA;

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document. The EPA agrees that reducing PFAS in drinking water is an important policy objective. Comments on CERCLA liability are outside the scope of this action, please see

section 15.1 of the EPA response in this *Response to Comments* document for other comments outside such scope.

Marlene Ladderbush (Doc. #1612, SBC-042921)

EPA must address the water sector's concerns about potential liability under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA). EPA is proposing to regulate PFOA and PFOS as hazardous substances, which may impact the available media disposal methods such as landfilling. EPA should not move forward with any proposed CERCLA designation until exemptions are granted to water utilities who are passive receivers of PFAS substances. The requested exemption needs to be embedded in law or regulation, and not just through an enforcement discretion policy. In whatever CERCLA rulemaking EPA moves forward with, EPA must provide PWS with an exemption from liability, including CERCLA third-party liability, if any or all PFAS compounds are designated as hazardous substances under CERLCA. Doing so would keep CERCLA liability on the industries that created the pollution and/or utilized the substances in the first place.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document. Comments on CERCLA liability are outside the scope of this action, please see section 15.1 of the EPA response in this *Response to Comments* document for other comments outside the scope.

Town of Lincoln Water Department (Doc. #1613, SBC-043033)

EPA must address the water sector's concerns about potential liability under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA). EPA is proposing to regulate PFOA and PFOS as hazardous substances, which may impact the available media disposal methods such as landfilling. EPA should not move forward with any proposed CERCLA designation until exemptions are granted to water utilities who are passive receivers of PFAS substances. The requested exemption needs to be embedded in law or regulation, and not just through an enforcement discretion policy. In whatever CERCLA rulemaking EPA moves forward with, EPA must provide PWS with an exemption from liability, including CERCLA third-party liability, if any or all PFAS compounds are designated as hazardous substances under CERLCA. Doing so would keep CERCLA liability on the industries that created the pollution and/or utilized the substances in the first place.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document. Comments on CERCLA liability are outside the scope of this action, please see section 15.1 of the EPA response in this *Response to Comments* document for other comments outside this scope.

Oklahoma Department of Environmental Quality (DEQ) (Doc. #1616, SBC-043051)

PFAS Treatment and Related Waste Disposal

EPA should prioritize research on waste disposal methods and move to address PFAS waste disposal to ensure that PFAS contamination is not being moved from one media type to another. DEQ recommends that EPA finalize the Agency's Interim Guidance on the Destruction and Disposal of Perfluoroalkyl and Polyfluoroalkyl Substances and Materials Containing Perfluoroalkyl and Polyfluoroalkyl Substances ahead of the final rule.

All of the Best Available Technologies listed for complying with the PFAS MCL's have waste streams that will need to be appropriately addressed. Some states have reported water systems being unable to dispose of their PFAS-containing media, as some waste disposal sites are refusing to accept the material. PFAS is only included in a limited number of NPDES permits, and so PFAS containing reject water from RO applications going to waste water treatment facilities may not be removed and may be returned to source water locations. As waste disposal options are developed and regulated, EPA should ensure that water systems are able to reasonably comply with the options.

EPA Response: Please see sections 10.4.1 and 10.4.2 of the EPA response in this *Response to Comments* document.

Water One - Water District No. 1 of Johnson County, Kansas (Doc. #1627, SBC-042331)

Residuals Disposal and CERCLA Exemption

The proposed PFAS regulation does not address associated water treatment facility discharges (or similarly, wastewater treatment plant discharges) or disposal of the compounds once removed. Residual disposal will further increase implementation costs and possibly even the ability to operate a treatment facility. There must be action taken to create an exemption from liability under CERCLA for water systems acting in accordance with all applicable laws and regulations in the event of PFAS contamination. EPA proposed to designate two PFAS hazardous substances. This allows EPA to hold “potentially responsible parties" financially liable for any required remediation at contaminated sites. Although the designation is intended to target polluters, water treatment providers may be at risk without an explicit exemption.

We appreciate the opportunity to review and provide comment on the proposed PFAS NPDWR and hope the EPA will consider the significant implications of this proposed regulation and pause implementation until further scientific data is collected, costs and logistical implications are addressed, and a CERCLA exemption is established. If you have additional questions, please fill free to contact us.

Sincerely,

Eric R. Arner

Acting General Manager

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document. Comments on CERCLA liability are outside the scope of this action, please see section 15.1 of the EPA response in this *Response to Comments* document for other comments outside the scope.

Association of State Drinking Water Administrators (ASDWA) (Doc. #1628, SBC-044111)

Waste Disposal

ASDWA recommends that EPA prioritize research on waste disposal methods and move to address PFAS waste disposal utilizing a regulatory mechanism as soon as possible to ensure that PFAS contamination is not being moved from one media type to another. ASDWA recommends that EPA finalize the Agency's Interim Guidance on the Destruction and Disposal of Perfluoroalkyl and Polyfluoroalkyl Substances and Materials Containing Perfluoroalkyl and Polyfluoroalkyl Substances ahead of the final rule.

The current information on other environmental impacts of PFAS disposal is limited, and all of the BAT listed for complying with the MCL have waste streams that will need to be appropriately addressed, including spent GAC media or ion exchange (IX) resin, RO brine water, and spent POU/POE devices. PFAS has not yet been designated under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) as a hazardous substance, but some primacy agencies have already reported water systems being unable to dispose of their PFAS-containing media as some waste disposal sites are refusing to accept the material.

PFAS is only included in a limited number of NPDES permits, so PFAS in the reject water from RO applications going to wastewater treatment facilities may not be removed, returning to source water locations. Research is limited on using underground injection control wells for RO reject water. Research is also limited on thermal regeneration of GAC and the release of PFAS into the atmosphere. ASDWA strongly recommends that EPA continue to pursue research on waste disposal options for PFAS to ensure long-term mitigation. As these waste disposal options are developed and regulated, EPA should ensure that water systems are able to reasonably comply with those options.

ASDWA recommends that EPA update and finalize the Agency's Interim Guidance on the

Destruction and Disposal of Perfluoroalkyl and Polyfluoroalkyl Substances and Materials Containing Perfluoroalkyl and Polyfluoroalkyl Substances ahead of the final rule. Additionally, guidance about PFAS contaminated waste should be outlined in Resource and Conservation Recovery Act (RCRA) policies and procedures.

EPA Response: Please see sections 10.4.1 and 10.4.2 of the EPA response in this *Response to Comments* document.

Village of Woodbury (Doc. #1629, SBC-042951)

5. Some of the proposed treatment options require media change-outs and disposal for effective treatment of PFAS. EPA acknowledges that disposal of media could create conflict with other regulations including Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) because spent media may be designated as hazardous waste. It is noted [FN1: Proposed PFAS National Primary Drinking Water Regulation" presentation, dated March 29, 2023, prepared by the US EPA Office of Water.] the EPA is still researching this issue; in our view until viable options for media disposal are identified, the promulgation should be stayed.

Additionally, processes requiring backwash and disposal of the same should be evaluated. Guidance on acceptable disposal of backwash for any process requiring the same, as well as, cost considerations for frequency should be established for public water suppliers and EPA to consider as part of the proposed rule.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document. The EPA disagrees that there are no viable options for media disposal and has presented viable options for media disposal for example in the *Interim PFAS Destruction and Disposal Guidance* document.

Texas Commission on Environmental Quality (TCEQ) (Doc. #1632, SBC-044137)

PFAS Destruction and Disposal

TCEQ urges EPA to provide additional information on PFAS destruction and disposal and finalize EPA's Interim Guidance on the Destruction and Disposal of Perfluoroalkyl and Polyfluoroalkyl Substances and Materials Containing Perfluoroalkyl and Polyfluoroalkyl Substances as soon as possible so that this guidance can be incorporated in implementation planning for the final rule.

EPA Response: Please see sections 10.4.1 and 10.4.2 of the EPA response in this *Response to Comments* document. The EPA is updating the *Interim PFAS Destruction and Disposal Guidance* document. After finalization of the PFAS NPDWR, the EPA plans to provide support to utilities, primacy agencies, and other interested parties to ensure successful rule implementation.

Town of Tewksbury, Massachusetts (Doc. #1637, SBC-043250)

EPA must address the water sector's concerns about potential liability under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA). EPA is proposing to regulate PFOA and PFOS as hazardous substances, which may impact the available media disposal methods such as landfilling. EPA should not move forward with any proposed CERCLA designation until exemptions are granted to water utilities who are passive receivers of PFAS substances. The requested exemption needs to be embedded in law or regulation, and not

just through an enforcement discretion policy. In whatever CERCLA rulemaking EPA moves forward with, EPA must provide PWS with an exemption from liability, including CERCLA third-party liability, if any or all PFAS compounds are designated as hazardous substances under CERLCA. Doing so would keep CERCLA liability on the industries that created the pollution and/or utilized the substances in the first place.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document. Comments on CERCLA liability are outside the scope of this action, please see section 15.1 of the EPA response in this *Response to Comments* document for other comments outside this scope.

Citizens Against Ruining the Environment (CARE) (Doc. #1638, SBC-043447)

CARE Comment 3 – The Current Residual PFAS Waste Disposal Requirements Will Allow PFAS to Reenter the Environment Following Disposal and Urges EPA to Develop Disposal Requirements That Fully Neutralize or Destroy PFAS Contamination.

CARE strongly encourages EPA to develop clear requirements for PWS to dispose of PFAS waste from water treatment with methods that fully neutralize or destroy PFAS contaminants. CARE is very concerned with current disposal requirements for residual PFAS waste collected at water systems. EPA's own data shows that PFAS may be able to harm human health and the environment through other means than just water, including swallowing contaminated soil or dust, and breathing air containing PFAS. [FN37: Our Current Understanding of the Human Health and Environmental Risks of PFAS, EPA, https://www.epa.gov/pfas/our-current-understanding-human-health-and-environmental-risks-pfas (March 16, 2023).] According to EPA, the most likely management option for spent material containing PFAS is reactivation for GAC and incineration for spent IX resin. [FN38: PFAS National Primary Drinking Water Regulation Rulemaking, 88 Fed. Reg. at 18686.] Reactivated carbon can become totally exhausted with contaminants not removed during reactivation and must eventually be replaced. [FN39: Id. at 18685.] For disposal of RO/NF membrane concentrate, most systems use surface water discharge or discharge to sanitary sewer. [FN40: Id. at 18686.] The large volume of residuals is a well-known obstacle to adoption of membrane separation technology in general.

Additionally, despite the possibility of some PFAS being designated as hazardous substances under CERCLA or hazardous constituents under RCRA, EPA states it does not believe those actions should limit disposal options and how PFAS containing waste is required to be managed. [FN41: Id. at 18688.]

EPA Response: Please see sections 10.4.1 and 10.4.2 of the EPA response in this *Response to Comments* document.

California Municipal Utilities Association (CMUA) (Doc. #1639, SBC-043257)

Additionally, the Regulation may impact public water agency hazardous substance disposal practices and agency liability. If one or more PFAS are designated as hazardous substances under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), the removal of PFAS from agencies' water supplies will result in treatment residuals that are deemed hazardous substances, and the public agency is under additional obligations to dispose of the hazardous substances properly. Even with proper disposal, the public agency is still subject to potential liability. Because CERCLA imposes strict, joint and several, and retroactive liability, public water agencies that dispose of water treatment residuals with any concentration of PFAS that are designated CERCLA hazardous substances may be required to clean up all the contamination from the disposal site if no other viable potentially responsible party (PRP) is identified. In addition, public water agencies may be sued by other PRPs to recover at least some, if not all, the costs for cleanup. It is also possible that wastewater effluent that contains PFAS will be considered a hazardous substance. More certainty as to the characterization of PFAS as hazardous substances and the resulting consequences for public water agencies is needed before the EPA can require compliance with the Regulation.

Lastly, certainty regarding the impacts an agency may face under the drinking water discharge permit system is needed. The permitting scheme allows agencies to discharge into the waters of the U.S.; it is unclear whether the discharge of PFAS fits into the existing permitting scheme or if agencies will need to apply for a different permit to cover those types of discharges. It is also unclear whether such discharges of PFAS could subject agencies to potential CERCLA liability.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document. Comments on CERCLA liability are outside the scope of this action, please see section 15.1 of the EPA response in this *Response to Comments* document for other comments outside this scope.

American Farm Bureau Federation et al. (Doc. #1642, SBC-043497)

The absence of regulatory requirements or at least clear guidance on management, treatment, disposal, and destruction guidelines hampers the ability of drinking water utilities to develop the management infrastructure needed to address PFOA and PFOS contamination. State regulators look to EPA for guidance on this topic for the purpose of reviewing and approving cleanup plans.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document. The EPA has provided guidance on management, treatment, disposal, and destruction, for example, in the *Best Available Technologies and Small System Compliance Technologies for PFAS in Drinking Water* and the *Technologies and Costs for Removing Per- and Polyfluoroalkyl Substances from Drinking Water* documents. The EPA has been collaborating and will continue to collaborate with states, technical assistance providers, industry

associations, and interested stakeholders to provide technical materials that can assist water systems in complying with the regulations.

American Farm Bureau Federation et al. (Doc. #1642, SBC-043495)

Disposal: EPA is obligated by statute to issue periodic (every four years) guidance on the destruction and disposal of PFAS compounds. EPA's initial guidance document submitted to Congress basically reported on the various technologies that have been used or that are under evaluation for use in the management of PFAS and PFAS-contaminated media. The lack of clear guidance and standards for the management, treatment, and destruction of PFAS compounds continues to present a significant challenge to the array of parties managing PFAS compounds and contaminated media. Much of this material is being stored in anticipation of EPA issuing more definitive guidance

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document. The EPA notes that the *Interim PFAS Destruction and Disposal Guidance* document contains clear guidance and standards for the management of PFAS-laden treatment residuals.

New England Interstate Water Pollution Control Commission (NEIWPCC) (Doc. #1650, SBC-043149)

Given our member states existing concerns, we urge EPA to consider the cost and availability of disposal options for spent media. In light of the potential CERCLA-designation of such disposal sites and the RCRA listing of certain PFAS compounds, our member states are concerned that future disposal options will be quite limited. Our experience in the northeast region [FN7: https://www.pressherald.com/2023/02/28/landfill-instability-has-maine-sewer-plants-in-a-bind/] suggest such regulatory changes may have a significant impact on the availability of disposal sites.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

North Carolina Division of Water Resources (NCDEQ) (Doc. #1652, SBC-044194)

4. NCDEQ recommends that EPA prioritizes research on waste disposal methods and move to address PFAS waste disposal utilizing a regulatory mechanism as soon as possible to ensure that PFAS contamination is not being moved from one media type to another. NCDEQ recommends that EPA finalize the Agency's Interim Guidance on the Destruction and Disposal of Perfluoroalkyl and Polyfluoroalkyl Substances and Materials Containing Perfluoroalkyl and Polyfluoroalkyl Substances.

The current Information on other environmental impacts of PFAS disposal is limited, and all of the BAT listed for complying with the MCL have waste streams that will need to be

appropriately addressed, including spent GAC media or ion exchange (IX) resin, RO brine water, and spent POU/POE devices. EPA is working on designing PFAS under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) as a hazardous substance, but some state agencies have already reported water systems being unable to dispose of their PFAS-containing media as some waste disposal sites are refusing to accept the material. In North Carolina, PFAS monitoring is being added to NPDES permits issued by NCDEQ at permit renewal and permit modification stages, so PFAS-containing reject water from RO applications going to wastewater treatment facilities may not be removed, returning to source water locations. There is also limited research on thermal regeneration of GAC and the release of PFAS into the atmosphere. NCDEQ strongly recommends that EPA continue to pursue research on waste disposal options for PFAS to ensure long-term mitigation. As these waste disposal options are developed and regulated, EPA should ensure that water systems are able to reasonably comply with those options. Additionally, NCDEQ recommends that EPA update and finalize the Agency's Interim Guidance on the Destruction and Disposal of Perfluoroalkyl and Polyfluoroalkyl Substances and Materials Containing Perfluoroalkyl and Polyfluoroalkyl Substances ahead of the final rule.

EPA Response: Please see sections 10.4.1 and 10.4.2 of the EPA response in this *Response to Comments* document.

National Association of Clean Water Agencies (NACWA) (Doc. #1659, SBC-043157)

Notably, virgin GAC has a limited life span and PWSs will continually need to replace their spent-GAC by either disposing these materials in certain hazardous waste landfills or hauling it out for regeneration or recycling. These processes have considerable indirect climate impacts including increased carbon footprints to transport GAC to disposal or regeneration sites, greater quantities of waste disposed in landfills, and tremendous energy needs to regenerate spent GAC.

The same can be true for PWSs opting to install expensive reverse osmosis or anion exchange as treatment techniques to remove PFAS chemicals from drinking water. The spent resin and concentrated PFAS liquid post-filtration will have to be dealt with—only continuing to pass the PFAS contamination burden to another entity and often making its way full circle to wastewater utilities to deal with. EPA should have considered these indirect impacts.

Conclusion

NACWA appreciates the opportunity to file these comments and hopes EPA takes time to carefully review and consider these. If EPA has any questions, please do not hesitate to contact me at 202/533-1839 or eremmel@nacwa.org.

Emily Remmel

Director, Regulatory Affairs

EPA Response: Please see sections 10.4.1 and 10.4.2 of the EPA response in this *Response to Comments* document. With respect to commenter concerns on the social cost of carbon, please see section 13.11 of the EPA response in this *Response to Comments* document.

Water Supply District of Acton (Doc. #1662, SBC-043666)

EPA must address the water sector's concerns about potential liability under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA). EPA is proposing to regulate PFOA and PFOS as hazardous substances, which may impact the available media disposal methods such as landfilling. EPA should not move forward with any proposed CERCLA designation until exemptions are granted to water utilities who are passive receivers of PFAS substances. The requested exemption must be embedded in law or regulation, not just through an enforcement discretion policy. Managing backwash and media disposal poses financial and sustainability concerns in a market that is already constrained.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document. Comments on CERCLA liability are outside the scope of this SDWA rulemaking action, please see section 15.1 of the EPA response in this *Response to Comments* document for other comments outside the scope of this SDWA rulemaking action.

Washington State Department of Health (DOH) (Doc. #1665, SBC-044428)

Page 18731. Section XI – Treatment Technologies

This section combines treatment technologies with generation and disposal of PFAS waste. Recommend further separation of these two topics to further clarify and address each topic in greater detail.

• DOH does not have enough data to provide meaningful comments on treatment technologies for PFAS in drinking water.

EPA requests comment on the estimates for disposing of drinking water treatment residuals or regenerating drinking water treatment media including assumptions related to the transport distance to disposal sites and other costs that arise out of disposal of PFAS contaminated drinking water treatment residuals.

• This response was prepared by the Washington State Department of Ecology. In Washington State, water treatment residuals might be designated as Washington State Only Dangerous Waste if the concentration of persistent PFAS compounds exceeds state only designation criteria. If it does, then that waste stream must be diverted to a Subtitle C landfill designed to manage PFAS waste. All subtitle C landfills are out of state (closest are in Idaho and Oregon), making transportation and treatment costs high.

• This response was prepared by the Washington State Department of Ecology. PFAS waste disposal in Washington State is governed by Washington Administrative Code 173-303.

Appropriate disposal of PFAS waste generated from removal from drinking water depends upon the specific waste category designation. Thresholds have been established by the Washington State Department of Ecology that designate appropriate disposal approaches and locations depending upon concentrations of PFAS within environmental media.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document. The EPA thanks the commenter for providing state-specific legal clarification and data.

City of Hillsboro, Oregon (Doc. #1668, SBC-043123)

4. Interim guidance for Utilities for PFAS Disposal

Most of the advanced treatment solutions suggested by EPA generate PFAS "residuals" from the filters or other by-products of media that have been used in the treatment process to capture PFAS and remove it from drinking water. Currently the EPA has interim guidance for PFAS disposal, however this places additional strain on water utilities for additional compliance measures related to disposal of PFAS. Water utilities are not the original sources of PFAS, and yet are now tasked with the burden of removal from drinking water sources. Water utilities should be exempt from the disposal requirements under CERCLA, as they are now burdened with the PFAS residuals through treatment.

Hillsboro Water hopes that our comments help EPA develop sound rule options that further reduce risks posed by PFAS, recognizing the realities of local budgets and infrastructure renewal needs. If EPA has any questions regarding these comments, please contact Sarah Honious, Water Quality Program Coordinator at 503-615-6540, Sarah.Honious@Hillsboro-Oregon.gov.

Sincerely,

Jessica Dorsey

Water Resources Manager City of Hillsboro

503-615-6579

jessica.dorsey@hillsboro-oregon.gov

Black and Veatch (2023). WITAF 56 Technical Memorandum: PFAS National Cost Model Report (B&V Project No. 409850). American Water Works Association.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document. Comments on CERCLA liability are outside the scope of this SDWA rulemaking action, please see section 15.1 of the EPA response in this *Response to Comments* document for other comments outside the scope.

National Association of Water Companies (NAWC) (Doc. #1670, SBC-044166)

NAWC urges EPA to develop a residuals management plan that addresses disposal capacity, standardized analytical methodology, and establishing a CERCLA exemption for drinking water systems before finalizing the rule to ensure additional liability and expense is not incurred by the public and ratepayers.

EPA Response: Please see sections 10.4.2 and 10.6 of the EPA response in this *Response to Comments* document. Comments on CERCLA liability are outside the scope of this SDWA rulemaking action, please see section 15.1 of the EPA response in this *Response to Comments* document for other comments outside the scope.

National Association of Water Companies (NAWC) (Doc. #1670, SBC-044164)

Compounding timeline feasibility concerns, EPA has not provided communities and public water systems with a clear plan to manage the water treatment residuals that will be produced as a result of the requirement in the proposed rule. Without a residuals management plan that addresses disposal coordination and capacity, analytical methodology and standardized waste characterization, and CERCLA liability, residuals disposal poses an almost insurmountable logistical obstacle for all drinking water systems, and it raises the significant issue of potential liability for communities related to the transport and the final disposition of treatment residuals.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document. To address timeline feasibility concerns, the EPA has provided compliance flexibility through a two-year capital improvements extension of the MCL compliance deadline allowed by Section 1412(b)(10) of SDWA in response to challenges raised by commenters surrounding capital improvement.

Cleveland Water, City of Cleveland, Ohio (Doc. #1672, SBC-044924)

Section 7.2: Disposal and reactivation

EPA requests comment on the availability of facilities to dispose of or reactivate drinking water treatment media containing PFAS. Specifically, EPA seeks comment of whether there is sufficient capacity to address increased demand for disposal options. Typically, spent GAC and AIX media need to either be disposed of in a landfill, reactivated (GAC), or incinerated. Looking at the PFAS issue holistically, disposing of media simply takes the PFAS from one area and moves it to another. This is not a long-term solution for PFAS management, and Cleveland Water requests that EPA prioritize and invest in better solutions for PFAS disposal and destruction. As EPA has mentioned, PFAS are extremely persistent, therefore, moving PFAS around will only increase the stockpile of the chemical, increasing the likelihood of localized contamination events. As polluters continue to pour PFAS into the environment, there needs to be a solution to break down PFAS so communities near disposal sites are not put at risk due to the actions of polluters.

PWSs do not have capacity on site to temporarily store spent media, therefore it is crucial that there be availability for disposal or reactivation with no delay. Cleveland Water is very concerned about the ability to transport and dispose of media containing PFAS as the agency moves forward with designation PFOA and PFOS as hazardous substances under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA). If EPA takes this action, wastes of these substances would no longer be allowed to be disposed of in industrial solid waste or municipal landfills. Instead, these waste streams would have to be sent to specified hazardous waste landfills. Additionally, this media would need to be transported by individuals with the qualifications to transport hazardous waste. EPA is also in the process of soliciting comment on the possibility of designating more PFAS as CERCLA hazardous substances, further hindering the capacity for disposal space. This would increase the cost of disposal of media containing PFAS, with the financial burdens likely falling on ratepayers rather than those directly responsible for the pollution.

Any such hazardous substance designation for PFAS must be accompanied by targeted liability protections for water systems. In the case of drinking water systems that filter PFAS from their water supplies, a hazardous substance designation without liability protections would put these systems at risk after they dispose of water treatment byproducts at an appropriate landfill. Should that landfill ever be the subject of a CERCLA cleanup because of PFAS contamination, the water system could be held liable as a potentially responsible party even if it followed all legal requirements when disposing of the byproducts. EPA has discussed an "enforcement discretion" policy under which it would not pursue this type of PFAS-related CERCLA claim against water systems, but this would do nothing to prevent a polluter from undertaking a private right of action claim against a water system, to attempt to reduce its own liability exposure. The cost analysis of this rulemaking cannot be accurately calculated without taking these potential CERCLA cleanup costs into account. EPA needs to address this issue holistically, not separately by different Offices within the Agency.

EPA also requests comments on the impacts the disposal of PFAS contaminated media will have on communities adjacent to disposal communities. This is a huge environmental justice issue. EPA's proposal involves removing PFAS from communities and essentially storing and disposing of it near others, which are in many cases underserved and disadvantaged communities. EPA needs to prioritize research into better destruction techniques that do not harm historically underserved communities. Disposing of media containing PFAS near these communities compromises the agency's goal of protecting public health.

EPA Response: Please see sections 10.4.1 and 10.4.2 of the EPA response in this *Response to Comments* document. The EPA has added a qualitative discussion of the potential impacts of PFAS disposal on overburdened communities to section 8.2 of its environmental justice (EJ) analysis for the final rule, found in Chapter 8 of the EA (USEPA, 2024d). Additional disposal costs are discussed in the EA appendices. Comments on CERCLA liability are outside the scope of this SDWA rulemaking action, please see section 15.1 of the EPA response in this *Response to Comments* document for other comments outside the scope.

Association of California Water Agencies (ACWA) (Doc. #1675, SBC-044932)

COMMENT 2 – CERCLA COSTS – EPA's drinking water proposal raises CERCLA cleanup cost concerns for our members.

In this proposed rule, EPA acknowledges stakeholder concerns that a PFAS hazardous designation under CERCLA may limit drinking water treatment residuals disposal options and increase costs [FN10: 88 Fed. Reg. at 18,686.]. EPA asserts that designating certain PFAS as hazardous substances under CERCLA generally should not result in limits on disposal of PFAS drinking water treatment residuals and that treatment costs may increase "marginally." [FN11: 88 Fed. Reg. at 18,686] ACWA disagrees with the assertion that the potential cost increases under a CERCLA PFAS designation would be marginal.

The agency argues that the increase in public water systems costs "are not significant enough to change the determination that benefits of the rulemaking justify the costs." [FN12: 88 Fed. Reg. at 18,686.] Specifically, EPA determined that the annual costs would increase by $30- $61 million per year if water systems are required to dispose of PFAS treatment as hazardous waste. [FN13: 88 Fed. Reg. at 18,729.]

ACWA previously raised our CERCLA costs concerns directly with EPA and the Office of Management and Budget (OMB) and asked that financial impacts to the water and wastewater sectors be considered in its previous CERCLA proposal [FN14: Office of Information and Regulatory Affairs, View EO 12866 Meeting 2050-AH09 (Mar. 2, 2022), click here. [Link: https://www.reginfo.gov/public/do/viewEO12866Meeting?viewRule=true&rin=2050-AH09&meetingId=121873&acronym=2050-EPA/OLEM]]. ACWA also submitted extensive comments on EPA's proposal to designate PFOA and PFOS as CERCLA hazardous substances [FN15: ACWA, Designation of PFOA and PFOS as CERCLA Hazardous Substances (Nov. 7, 2022), click here. [Link: https://www.acwa.com/resources/designation-of-pfoa-and-pfos-as-cercla-hazardous-substances/]].

CERCLA is designed to remediate contaminated sites and hold parties that caused the contamination financially responsible for cleanup costs through its "polluter pays" model. ACWA strongly supports the "polluter pays" principle of CERCLA. Unfortunately, under EPA's current regulatory efforts, our members and their ratepayers will be facing a "community pays" outcome that unfairly shifts the clean-up and liability costs onto municipalities and the public they serve.

When drinking water or water reuse agencies remove PFAS from source water via filtration media, they are responsible for the disposal of these potentially PFAS-laden filter media. The media will typically be recycled or disposed of in accordance with applicable law. Should that disposal location ever become a "facility" where there is a release or threatened release of hazardous substances, the water agency could be held liable for cleanup under CERCLA and/or analogous state law due to its lawful disposal of this necessary byproduct of a vital public health

service. This outcome would force local ratepayers to cover the cleanup costs after they already paid to remove the PFAS from their source water.

As water agencies establish treatment systems for PFAS, a hazardous substance designation will increase the cost of treatment and disposing of the media and materials remaining after treatment because of the stringent disposal requirements for CERCLA hazardous substances. [FN16: U.S. Chamber of Commerce, PFOS and PFOA Private Cleanup Costs at Non-Federal Sites (Jun. 2022), click here. [Link: https://www.uschamber.com/assets/documents/PFOS-and-PFOA-Private-Cleanup-Costs-at-Superfund-Sites-6.8.22.pdf] Several ACWA members have already invested millions of dollars in capital costs as well as operation and maintenance to treat PFAS contamination.

Moreover, regulatory agencies can use MCLs as de facto CERCLA cleanup standards at PFAS contaminated sites, which could further increase costs for responsible parties [FN17: Perkins Coie, EPA Proposes Stringent National Drinking Water Standard for Six PFAS (Mar. 16, 2023), click here. [Link: https://www.perkinscoie.com/en/news-insights/epa-proposes-stringent-national-drinking-water-standards-for-six-pfas.html#10]]. Last year, the U.S. Chamber of Commerce released a study on the cost implications of a PFAS CERCLA designation. The study found that just the annual private party cleanup costs for PFOA and PFOS under CERCLA at non-federal sites are estimated to be $700-$800 million annually [FN18: U.S. Chamber of Commerce, PFOS and PFOA Private Cleanup Costs at Non-Federal Sites (Jun. 2022), click here.[Link: https://www.perkinscoie.com/en/news-insights/epa-proposes-stringent-national-drinking-water-standards-for-six-pfas.html#10]].

The Chamber of Commerce further emphasized to OMB that "the rulemaking cost estimates are expected to be much higher as private party costs at Superfund sites are just one element of the total costs borne by communities from a proposed hazardous substance designation." [FN19: U.S. Chamber of Commerce, U.S. Chamber Letter to OMB Director Young on EPA's Proposed rule, "Designating PFOA and PFOS as CERCLA Hazardous Substances" (Jun. 8, 2022), click here. [Link: https://www.uschamber.com/environment/u-s-chamber-letter-to-omb-director-young-on-epas-proposed-rule-designating-pfoa-and-pfos-as-cercla-hazardous-substances]]. Specifically, municipalities responsible for community water systems, landfills, and publicly owned treatment works would incur significant additional costs for cleanup [FN20: U.S. Chamber of Commerce, PFOS and PFOA Private Cleanup Costs at Non-Federal Sites at 3-4.].

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document. Comments on CERCLA liability are outside the scope of this SDWA rulemaking action, please see section 15.1 of the EPA response in this *Response to Comments* document for other comments outside this scope.

Horsham Water & Sewer Authority (HWSA) (Doc. #1686, SBC-043817)

We also have serious concerns regarding the costs for disposal of PFAS treatment residuals. As EPA is aware, actions resulting from other environmental statutes, such as the Comprehensive

Environmental Response, Compensation, and Liability Act (CERCLA) may impact future disposal practices. While EPA has stated it is prioritizing research on PFAS disposal options, this only adds to the uncertainty of future options and costs. That future costs may well exceed EPA's current estimates is a distinct possibility. HWSA supports and concurs with the American Water Works Association's (AWWA) compliance cost analysis presented in their comments. We believe the AWWA Model, and the Case Study information presented in their comments reflect a more accurate picture of the likely costs of this rule than that presented by the EPA Model. We believe that it is important that the costs be presented accurately and believe EPA should update its Technologies and Costs for Removing Per- and Polyfluorinated Substances (PFAS) from Drinking Water document using available real world full-scale cost and treatment performance data before finalizing the rule.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document. The EPA has replied to AWWA's cost compliance in the HRRCA section and refers readers to that as well as the summary of responses to major comments for this section.

State of Vermont Agency of Natural Resources and Department of Health (Doc. #1708, SBC-045096)

f. Unknown determination on PFAS-waste and hazard distinction, associated costs; going into this not knowing future costs:

There have been discussions about exempting water treatment residuals from the various hazard determinations with respect to PFAS as it is treated more broadly. We need a clear understanding of the residuals and how they will be managed and the associated costs.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

Philadelphia Water Department (PWD) (Doc. #1709, SBC-045735)

Additionally, water utilities that implement technologies to remove PFAS will have to manage PFAS-containing treatment residuals or spent treatment media. If EPA's proposal to classify PFAS as hazardous substance under the CERCLA is finalized, operating costs to manage treatment residuals will place additional financial burden on water utilities and could make finding outlets for PFAS contaminated media difficult. These impacts will be compounded should EPA follow through with their evaluation to make changes to RCRA that would designate certain PFAS compounds as a hazardous waste. As has been seen in Maine, the ban on biosolids land application due to PFAS concerns has created a crisis for utilities, with landfills increasingly refusing to take this waste, forcing sludge to be transported into Canada for ultimate disposal. If the proposed CERCLA changes become final, this will result in significant increases to the implementation time and cost of these BATs. The higher costs will ultimately be borne by the utilities and ratepayers and the increased implementation time will impact PWSs' compliance

status. EPA should include this consideration in its cost assessments and its proposed compliance timeline.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

U.S. Chamber of Commerce et al. (Doc. #1713, SBC-045912)

B. Costs will be compounded with potential costs of PFOA and PFOS hazardous substance designations under CERCLA

One direct, additional cost of this rulemaking establishing an MCL for the six PFAS is the cost of cleanup under CERCLA. EPA fails to consider the use of MCLs and MCLGs as cleanup standards. Section 121(d) of CERCLA requires remedial actions to meet a standard of control that "at least attains Maximum Contaminant Level Goals established under the Safe Drinking Water Act and water quality criteria established under section 304 or 303 of the Clean Water Act, where such goals or criteria are relevant and appropriate under the circumstances of the release or threatened release."[FN155: 42 U.S.C. [sec] 9621(d)(2)(A)(ii).] EPA acknowledges that MCLs are "relevant and appropriate as in situ cleanup standards where either surface water or ground water is or may be used for drinking water. When no promulgated standard exists for a given contaminant, proposed MCLs are to be given greater consideration among the to-be-considered advisories."[FN156: U.S. EPA CERCLA Compliance with Other Laws Manual at 195 (August 1988): https://nepis.epa.gov/Exe/ZyNET.exe/10001VMG.TXT?ZyActionD=ZyDocument&Client=EPA&Index=1986+Thru+1990&Docs=&Query=&Time=&EndTime=&SearchMethod=1&TocRestrict=n&Toc=&TocEntry=&QField=&QFieldYear=&QFieldMonth=&QFieldDay=&IntQFieldOp=0&ExtQFieldOp=0&XmlQuery=&File=D%3A%5Czyfiles%5CIndex%20Data%5C86thru90%5CTxt%5C00000003%5C10001VMG.txt&User=ANONYMOUS&Password=anonymous&SortMethod=h%7C-&MaximumDocuments=1&FuzzyDegree=0&ImageQuality=r75g8/r75g8/x150y150g16/i425&Display=hpfr&DefSeekPage=x&SearchBack=ZyActionL&Back=ZyActionS&BackDesc=Results%20page&MaximumPages=1&ZyEntry=1&SeekPage=x&ZyPURL#.] With a potential CERCLA designation for PFOA and PFOS, surface water-sourced systems will have to treat all grit (filtered solids from raw surface water) as containing a hazardous substance.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

U.S. Chamber of Commerce et al. (Doc. #1713, SBC-045908)

A. EPA does not appropriately analyze costs associated with hazardous waste disposal

EPA has publicly committed to initiating rulemaking to address PFOA, PFOS, PFBS, and GenX as RCRA hazardous constituents [FN150: See EPA response to Governor Michelle Lujan

Grisham of New Mexico's petition to identify PFAS as hazardous waste under RCRA: https://www.epa.gov/newsreleases/epa-responds-new-mexico-governor-and-acts-address-pfas-under-hazardous-waste-law.]. As EPA acknowledges, costs will be even higher if residuals from the treatment of PFAS-contaminated water must be sent to hazardous waste disposal facilities. Despite that recognition, EPA claims that it did not address these costs in its national annualized costs because such wastes "are not currently" regulated as hazardous wastes [FN151: 88 Fed. Reg. at 18701. EPA indicates that the national annualized costs do not reflect costs of hazardous waste disposal for GAC and IX media.]. EPA acknowledges, given the pending CERCLA rulemaking, solid waste facilities may refuse to accept these wastes whether or not such wastes are regulated as hazardous waste [FN152: 88 Fed. Reg. at 18688.]. In the experience of the Chamber and its coalition, this outcome is likely.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

Protecting Our Water, Environment, and Ratepayers (POWER) (Doc. #1714, SBC-045932)

Although EPA discussed the cost of disposal of treatment byproduct, it has failed to adequately consider the disposal cost of this byproduct once EPA designates all six PFAS as hazardous under CERCLA and RCRA.

In the proposed NPDWR, EPA concedes that there are concerns from stakeholders regarding the designation of PFOA and PFOS as hazardous under CERCLA. [FN11: Proposed Rule, 88 Fed. Reg. at 18686.] At the same time, EPA is considering designating additional PFAS compounds as hazardous substances under CERCLA. [FN12: EPA, Addressing PFAS in the Environment, 88 Fed. Reg. 22399, 22399 (proposed April 13, 2023).] Given that other EPA actions indicate that the EPA intends to consider PFAS as a hazardous substance, the EPA should consider the costs of hazardous waste disposal for the residual media.

The designation as hazardous under CERCLA and RCRA would change the method in which byproducts are disposed. In the context of the proposed MCLs, the costs of the disposal of hazardous byproducts are not known because the technology needed to dispose of PFAS are still being developed. However, the minimum disposal requirements would require the byproducts to be disposed at hazardous waste management facilities. Hazardous waste sites (e.g. landfills) are more costly because there are strict environmental controls required, there are fewer locations to put the byproduct, and these locations are generally farther away from each agency than a typical municipal solid waste disposal site. Until the technology to dispose PFAS is identified and the EPA decides whether some or all PFAS are going to be designated as hazardous under CERCLA and RCRA, the costs of byproduct disposal cannot be fully or accurately understood.

As such, EPA's assumption that the costs would only increase marginally compared to costs for disposing byproducts that are not hazardous is misguided and inadequate. [FN13: Proposed Rule, 88 Fed. Reg. at 18688.]

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

Loudoun Water (Doc. #1717, SBC-043519)

Loudoun Water uses GAC and membrane technologies in the operation of our water treatment facilities, and we are concerned about the cumulative effects of availability and cost of GAC materials and residuals management and disposal. This is especially uncertain considering EPA's proposed hazardous waste designation under CERCLA for PFOA and PFOS.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document for a discussion of residuals disposal and section 10.6 of the EPA response in this *Response to Comments* document on treatment technology availability and capacity. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions.

Massachusetts Department of Environmental Protection (MassDEP) (Doc. #1726, SBC-045143)

Waste Disposal

MassDEP recommends that EPA prioritize research on waste disposal methods and move to regulate PFAS waste disposal as soon as possible to ensure that PFAS contamination is not being moved from one media type to another. EPA should finalize its Interim Guidance on the Destruction and Disposal of Perfluoroalkyl and Polyfluoroalkyl Substances and Materials Containing Perfluoroalkyl and Polyfluoroalkyl Substances ahead of the final rule.

The current information on other environmental impacts of PFAS disposal is limited, and the Best Available Technologies (BATs) listed for complying with the Maximum Contaminant Level (MCL) have waste streams that will need to be appropriately addressed, including spent Granular Activated Carbon (GAC) media or ion exchange resin, Nanofiltration (NF) and Reverse Osmosis (RO) brine water, and spent Point of Use/Point of Entry (POU/POE) devices. Although PFAS has not yet been designated under the Comprehensive Environmental Response, Compensation, and Liability Act as a hazardous substance, some systems have already reported being unable to dispose of their PFAS-containing media as some waste disposal sites are refusing to accept the material. PFAS is only included in a limited number of NPDES permits, and so PFAS-containing reject water from NF/RO applications going to wastewater treatment facilities may not be removed, returning to source water locations. There is limited research on using underground injection control wells for NF/RO reject water. There is also limited research on thermal regeneration of GAC and the release of PFAS to the atmosphere. MassDEP strongly recommends that EPA continue to pursue research on waste disposal options for PFAS to ensure long-term mitigation. As these waste disposal options are developed and regulated, EPA should ensure that systems are able to reasonably comply with those options. Additionally, MassDEP recommends that EPA update and finalize the Agency's Interim Guidance on the Destruction and

Disposal of Perfluoroalkyl and Polyfluoroalkyl Substances and Materials Containing Perfluoroalkyl and Polyfluoroalkyl Substances in advance of the final rule.

EPA Response: Please see sections 10.4.1 and 10.4.2 of the EPA response in this *Response to Comments* document.

Water and Wastewater Equipment Manufacturers Association (WWEMA) (Doc. #1727, SBC-043526)

[Please see our comments below.]

Comment #3: Requesting Industry Involvement in Updated Disposal Guidance

Disposal of PFAS contaminated residuals or regenerating drinking water treatment media will have significantly different costs depending on if PFAS are deemed hazardous materials under CERCLA. Since a number of PFAS treatment providers engage in this service for their clients (the utilities), direct industry involvement in the development of updated disposal guidance development, which is expected before the end of the calendar year, is absolutely critical. We ask that WWEMA and its technology leaders be a part of the process in developing updated disposal guidance .

Thank you for the opportunity to comment on the proposed rulemaking. If you have any questions, please feel free to contact me at vanessa@wwema.org or at (703) 444-1777.

Vanessa M. Leiby

Executive Director

WWEMA

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

Arizona Corporation Commission (ACC) (Doc. #1735, SBC-045186)

DISPOSAL OF MEDIA RESIDUALS

The EPA's paper lacks sufficient detail regarding the disposal of PFAS saturated media or residual(s). Presently, the most effective disposal method for PFAS saturated ion exchange resins and granular activated charcoal is incineration. The ACC has been informed that proper high-temperature incineration is not currently available in Arizona. Further, there is some concern on the ACC's part that this method of disposal results in the possibility that the contaminants may become airborne and end up back in the aquifer.

There is also a lack of knowledge regarding safe disposal practices for PFAS-containing residual(s) generated during the reverse osmosis remediation process. Due to the lack of

available information, Arizona utilities considering reverse osmosis for PFAS remediation have expressed concerns about safe disposal.

The ACC urges the EPA to provide guidance on the best practices for disposing of waste produced by different remediation technologies. If proper disposal is not addressed, there is a potential for PFAS to return to the water supply or spread the contamination to additional systems.

EPA Response: Please see sections 10.1 and 10.4.2 of the EPA response in this *Response to Comments* document.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-045983)

PWSs do not have the capacity on site to temporarily store spent media. Therefore, there must be availability for spent PFAS media disposal or reactivation with no delay. AMWA is very concerned about the ability to transport and dispose of media containing PFAS as the agency moves forward with designation of PFOA and PFOS as hazardous substances under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA). If EPA takes this action, wastes of these substances would no longer be allowed to be disposed of in industrial solid waste or municipal landfills. Instead, these waste streams would have to be sent to specified hazardous waste landfills. Additionally, this media would need to be transported by individuals and vehicles with the qualifications to transport hazardous waste. EPA is also in the process of soliciting comment on the possibility of designating more PFAS as CERCLA hazardous substances, further hindering the capacity for disposal space. This would increase the cost of disposal of media containing PFAS, with the financial burdens likely falling on ratepayers rather than those directly responsible for the pollution.

AMWA and other drinking water and wastewater organizations have consistently asserted that any such hazardous substance designation for PFAS must be accompanied by targeted liability protections for water systems. In the case of drinking water systems that filter PFAS from their water supplies, a hazardous substance designation without liability protections would put these systems at risk after they dispose of water treatment byproducts at an appropriate landfill. Should that landfill ever be the subject of a CERCLA cleanup because of PFAS contamination, the water system could be held liable as a potentially responsible party even if it followed all legal requirements when disposing of the byproducts. EPA has discussed an "enforcement discretion" policy under which it would not pursue this type of PFAS-related CERCLA claim against water systems, but this would be administration-dependent and do nothing to prevent a polluter from undertaking a private right of action claim against a water system to attempt to reduce its liability exposure. The cost analysis of this rulemaking cannot be accurately calculated without taking these potential CERCLA cleanup costs into account.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document. Comments on CERCLA liability are outside the scope of this SDWA

rulemaking action, please see section 15.1 of the EPA response in this *Response to Comments* document for other comments outside the scope.

Connecticut Department of Public Health (CT DPH) (Doc. #1745, SBC-045234)

5. EPA requests comment on the availability of facilities to dispose of or regenerate drinking water treatment media that contains PFAS. EPA requests comment on whether there will be sufficient capacity to address the increased demand for disposal of drinking water treatment residuals or to regenerate media for reuse by drinking water treatment facilities.

EPA should consider the amount of PFAS generated waste from these best available treatment (BAT) methods. This could possibly overwhelm landfills. EPA should also consider the possible pending CERCLA hazardous waste designation for PFAS which would further complicate the disposal process by

a. Increasing disposal costs,

b. Limiting the number of landfills which can accept PFAS waste unless specific CERCLA exemption is given, and

c. Limiting the reactivation and reuse of GAC

As a relatively small and intensively developed state with limited capacity for disposal, Connecticut currently faces significant waste management challenges. This is especially true of hazardous waste. Consequently, costs incurred for the safe management of used PFAS drinking water remediation media will be considerable as most if not all such waste will need to be exported out of state for proper disposal.

Reactivation of GAC treatment media also presents concerns as thermal temperatures must be high enough to achieve PFAS degradation. Improper reactivation of GAC could lead to the dispersal of PFAS contamination through the air emissions from reactivation facilities.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document. Comments on CERCLA liability are outside the scope of this SDWA rulemaking action, please see section 15.1 of the EPA response in this *Response to Comments* document for other comments outside the scope.

City of Thornton, Colorado (Doc. #1748, SBC-044788)

Thornton suggests that the EPA prioritizes the regeneration of treatment media, assist in providing infrastructure and transportation options to ensure sustainability of resources, and provide exemption from CERCLA and RCRA rules for WTP utilities as these could lead to additional costs that are not captured in the EPA's analysis.

EPA Response: Please see sections 10.4.1 and 10.4.2 of the EPA response in this *Response to Comments* document. Comments on CERCLA liability are outside the scope of this

SDWA rulemaking action, please see section 15.1 of the EPA response in this *Response to Comments* document for other comments outside the scope.

Arizona Water Company (Doc. #1758, SBC-044538)

Handling waste from PFAS removal facilities results in considerable O&M costs. The Company is anticipating using IX to remove PFAS from drinking water due to a combination of cost and PFAS removal capability. The only allowable disposal methods for PFAS-impregnated IX media are landfill disposal or high-temperature incineration. The Company recommends the EPA provide clarification on whether spent media will be considered hazardous waste due to the presence of PFAS. The Company anticipates that a considerable portion of O&M costs for PFAS treatment will be the additional expenses of handling and disposing of PFAS-impregnated removal media according to hazardous materials standards. The Company recommends that the EPA assist water utilities with funding to offset the costs of hazardous waste disposal and provide standards to dispose of hazardous waste extracted during PFAS removal.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document. Information on funding is provided in section 2.4 of the EPA response in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-046157)

A major challenge to implementing centralized NF/RO treatment for PFAS removal is in dealing with the concentrated waste stream generated by the treatment process. Contaminants are rejected into a waste brine stream that is typically around 15 percent by volume of the feedwater (for low salinity feed waters) and 4 to 7 times more concentrated than the raw water fed to the membranes. As a result, additional raw water is required to achieve the desired finished water capacity, and the waste stream requires disposal. Traditional alternatives for disposal include sending the stream to a downstream water reclamation facility, discharging to surface water, or injection into underground deep wells.

However, because of the CERCLA regulations for PFOA and PFOS as discussed in Subsection 3.1.1 and pending effluent limit goals for PFAS, concentrate treatment may be required before disposal using these methods.

EPA Response: Please see sections 10.1 and 10.4.2 of the EPA response in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-045617)

Shifting Landscape of Residual Management Practices

During the stakeholder engagement in advance of publishing the proposal, EPA was encouraged to consider the impacts of new regulatory actions that would impact disposal of GAC, IX, and

RO waste streams with PFAS. In September 2022, EPA proposed to designate PFOA and PFOS as hazardous substances under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA); a broader action was proposed for additional PFAS in April 2023 (EPA, 2022i; EPA, 2023h). Separately, EPA is also preparing to list PFOA, PFOS, PFBS, and HFPO-DA as hazardous constituents (EPA, 2022c).

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-046151)

Exhausted GAC filter media will be saturated with PFAS. Bulk GAC can be reactivated by the media supplier through thermal treatment at high temperatures (up to 1800 [deg] F) to remove and destroy adsorbed contaminants (Rebecca DiStefano, 2022). This reactivation process restores the media's adsorptive capacity, allowing the media to be returned for reuse. GAC is sometimes regenerated by heating the media to temperatures typically less than 400 [deg] F to remove a portion of the adsorbed contaminants. However, this process will not remove all the compounds and will not destroy the PFAS compounds; therefore, it is not appropriate for GAC utilized for PFAS removal. Media suppliers may not accept the low volumes of GAC required by small systems for reactivation, forcing them to dispose of spent GAC and replace it with new (virgin) material.

Disposal alternatives for exhausted GAC that will not be reactivated for municipal reuse include disposal by reactivation for industrial reuse, incineration, and landfilling. The cost of each disposal method depends on proximity to disposal sites, hazardous waste classification, and volume of material. Disposal costs can be a significant operational cost for GAC treatment systems.

The EPA proposed to designate PFOS and PFOA as hazardous substances under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) in August of 2022. This designation is expected to limit the disposal sites willing to accept spent GAC media. Additionally, the practice of reactivating GAC media contaminated with PFAS is expected to be more limited in drinking water applications.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

California-Nevada Section American Water Works Association (CA-NV AWWA) (Doc. #1775, SBC-045276)

EPA has also not adequately considered in its economic feasibility assessment the difficulty and the ensuing high cost for compliance that community water systems will encounter to manage and dispose of PFAS-containing treatment residuals. Many letters and public testimony raise a concern, recognized by EPA, that designating PFOA and PFOS as hazardous substances under

CERCLA will restrict the facilities willing to accept wastes from water treatment. When options are limited or even nonexistent, the cost to water systems for disposal will be high. If landfill disposal becomes impossible, the only option would be destruction of the PFAS contaminants.

However, the feasibility and cost of incineration or thermal treatment of spent treatment media is questionable. These restrictions, costs, and uncertainties must be factored into a better economic feasibility assessment.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

Metropolitan Water District of Southern California (Doc. #1777, SBC-045436)

5. EPA should fully consider the economic impacts and feasibility of the proposed regulations

Under section 1412(b)(4)(B) of the SDWA, EPA must generally establish an enforceable MCL as close to the MCLG as feasible, considering costs. EPA acknowledges in this NPDWR Rulemaking: "Stakeholders have expressed concern to EPA that a hazardous substance designation for certain PFAS may limit their disposal options for drinking water treatment residuals (e.g., spent media, concentrated waste streams) and/or potentially increase costs."[FN20: 88 Fed. Reg. at 18686.] Thus, EPA has specifically requested comment on "the availability of facilities to dispose of or regenerate drinking water treatment media that contains PFAS" and "whether there will be sufficient capacity to address the increased demand for disposal of drinking water treatment residuals or to regenerate media for reuse by drinking water treatment facilities."[FN21: 88 Fed. Reg. at 18731.] If landfills refuse to accept treatment residuals containing PFAS due to concerns regarding potential liability under CERCLA or analogous state laws, disposal of treatment residuals is no longer realistic, directly affecting the feasibility analysis.

Also, Metropolitan has significant concerns regarding the feasibility and cost of incineration as a disposal option for the Best Available Technologies. EPA proposes anion exchange (AIX) and Granular Activated Carbon (GAC) as the Best Available Technology to treat PFAS-contaminated water. [FN22: 88 Fed. Reg. at 18684.] Both treatment technologies result in residuals that must be destroyed or disposed. [FN23: 88 Fed. Reg. at 18686.] For AIX, once a contaminant breaks through the resin, EPA recognizes that the exhausted resin must also be disposed. [FN24: 88 Fed. Reg. at 18686.] Typically, spent IX resin is incinerated. [FN25: 88 Fed. Reg. at 18688.] Similarly, facilities reactivate spent GAC through thermal treatment. [FN26: EPA, Interim Guidance on the Destruction and Disposal of Perfluoroalkyl and Polyfluoroalkyl Substances and Materials Containing Perfluoroalkyl and Polyfluoroalkyl Substances (Dec. 2020) (Interim Guidance) at pp. 36-37.] However, there are several issues with incineration. For example, the Department of Defense has placed a temporary ban on the incineration of PFAS;[FN27: Memorandum from Assistant Secretary of Defense for Energy, Installations, and Environment Paul Cramer to Assistant Secretary of the Army, Assistant Secretary of the Navy, Assistant Secretary of the Air Force, and Director, Defense Logistics Agency (2022).] Illinois

enacted a ban on the incineration of PFAS;[FN28: H.B. 4818, 102d Gen. Assemb., (Ill. 2022).] and EPA itself has raised concerns over the uncertainties associated with incineration. [FN29: EPA, Technical Support Document - Technologies and Cost for Removing Per- and Polyfluoroalkyl Substances (PFAS) from Drinking Water, at pp. 18-19, 39 (Feb. 2023)] Also, restricting or banning PFAS waste incineration and thermal treatment methods would further raise the cost of Superfund site cleanup and affect EPA's economic feasibility analysis. An assessment by the U.S. Chamber of Commerce shows that prohibiting thermal treatment of PFAS contaminated soil would raise costs at a single National Priorities List (NPL) site by up to $1 million and that approximately 25% of the existing NPL sites would find onsite incineration more cost effective than disposal at a Subtitle C landfill. [FN30: U.S. Chamber of Commerce, PFOS and PFOA Private Cleanup Costs at Non-Federal Sites (June 2022) ("Chamber Study") at p. 10, available at PFOS-and-PFOA-Private-Cleanup-Costs-at-Superfund-Sites-6.8.22.pdf (uschamber.com).]

Due to these uncertainties, EPA's interim guidance manual recommends interim storage over incineration. [FN31: EPA, Interim Guidance, at p. 5.] However, this recommendation conflicts with EPA's acknowledgement in the proposed rule that "large volumes of spent GAC and ion exchange resin must be removed which does not lend itself to on-site storage over time."[FN32: 88 Fed. Reg. at 18686.] Thus, EPA should reconsider its economic feasibility analysis in light of these issues and this additional information. EPA should specifically consider the economic feasibility of and provide guidance for media disposal.

Lastly, Metropolitan is concerned that EPA's proposal to designate certain PFAS as CERCLA hazardous substances will substantially increase treatment and disposal costs incurred by water and wastewater utilities[FN33: On September 6, 2022, EPA proposed designating PFOA and PFOS as CERCLA hazardous substances. (87 Fed. Reg. 54415 (Sept. 6, 2022).) More recently, on April 13, 2023, EPA requested input and data regarding potentially designating in the future seven other PFAS and their salts and structural isomers; precursors to PFOA, PFOS, and the seven other PFAS; and/or categories of PFAS as CERCLA hazardous substances. (88 Fed. Reg. 22399 (Apr. 13, 2023).)] and lawsuits against water and wastewater systems. [FN34: Under CERCLA's strict, joint and several, and retroactive liability scheme, water systems that dispose of water treatment residuals with any concentration of PFOA and PFOS may be required to clean up all the contamination from the disposal site if no other viable PRP is identified. Additionally, water and wastewater agencies may be sued by other PRPs to recover at least some, if not all, of the costs for cleanup. So many PFAS contamination lawsuits have already been filed (more than 2,500 cases) that these cases have been consolidated in a nationwide multidistrict litigation (MDL) in a South Carolina federal district court. In re: Aqueous Film-Forming Foams Products Liability Litigation, MDL No. 2873.] In prior comments on EPA's proposal to designate PFOA and PFOS as CERCLA hazardous substances, Metropolitan explained that potentially responsible parties may be compelled to compensate the oversight agency and/or other parties for costs incurred in responding to any release or threatened release of CERCLA hazardous substances. [FN35: Metropolitan, Designation of PFOA and PFOS as CERCLA Hazardous Substances (Nov. 7, 2022) [See attached]]

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

Earthjustice et al. (Doc. #1808, SBC-046132)

11. EPA provides a supplemental, illustrative analysis of the costs of compliance with the proposed NPDWS if spent filtration materials were regulated as hazardous waste, but to be fully objective, this illustrative analysis should also demonstrate the benefits of such an action.

As noted in comment #3 in the above section, in the main analysis EPA correctly excludes any incremental increase in PWS disposal costs that are specific to hazardous materials. The Agency does, however, provide an illustrative analysis of the disposal costs if PFAS were regulated as a hazardous material.

In my professional opinion, it is misleading to present this illustrative exercise for just the costs, without also discussing the benefits. To be fully transparent and balanced, it would be informative to provide a companion illustrative analysis of the corresponding environmental and health benefits that would result from treating spent filtration materials as a hazardous waste.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

West Virginia Municipal Water Quality Association (Doc. #1816, SBC-044674)

Also, EPA fails to distinguish between non-destructive technologies and destructive technologies, whose development has been on different trajectories. Non-destructive technologies such as granular activated carbon (GAC) and reverse osmosis (RO) may not be feasible depending on how EPA regulates residuals (such as concentrated RO brine). Notably, EPA has currently proposed listing PFOA and PFOS hazardous substances under the federal Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA). EPA details how it included a potential hazardous designation in its calculation:

EPA assessed the potential impact on PWS treatment costs associated with hazardous residual management requirements in a sensitivity analysis on the proposed option. Relative to the national analysis for the proposed option assuming nonhazardous disposal, the hazardous waste disposal assumption would increase PWS costs by 4% ($30 million annually) at the 3% discount rate and 5% ($61 million annually) at the 7% discount rate should spent media need to be disposed of as hazardous waste in the future because of separate EPA or State regulatory action. EPA's sensitivity analysis demonstrates that potential hazardous waste disposal requirements may increase PWS treatment costs marginally, however the increase in PWS costs are not significant enough to change the determination that benefits of the rulemaking justify the costs.

88 Fed. Reg. at 18686.

We think this is completely incorrect. In general, asserting that the disposal cost of a hazardous waste versus non-hazardous waste is only 4-5% higher defied common experience and logic. Such an estimate is shockingly optimistic. EPA has no basis for this hypothetical assumption. Moreover, EPA understates the volumes of spent GAC material that will have to be addressed nationally. Our members have seen reuse/disposal vendors abandon prior offers to manage these wastes and those who remain willing to accept such wastes are doing so at much higher rates than they indicated to our members just a few years ago.

A PFAS CERCLA designation will surely have a significant increase in reuse/disposal costs. We have previously shared with EPA that such a CERCLA designation for PFOA/PFOS will in fact likely prevent the regeneration of granulated activated carbon media used by water treatment facilities and others to reduce PFAS levels in finished drinking water and other media. It would also create numerous difficulties for addressing RO brine. Additionally, if there are limits on spent carbon regeneration, it will also greatly impact the prices and availability of virgin carbon. Has EPA considered this effect?

EPA must revisit its clearly erroneous conclusion that a hazardous waste designation for PFOA/PFOS will have only a 4-5 percent increase in PFAS reuse/disposal costs. That conclusion seems illogical to us. EPA should clarify the basis for its $30-61M additional annual cost impact if PFOA/PFOS are designated as hazardous wastes. Across 3,000 water systems, that would be just an additional $30,000 per system per year – an amount that seems impossibly small to dispose of significant quantities of hazardous waste from these 24/7 utility operations.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document. For comments and additional information related to the EPA's cost analysis, please see section 13 of the EPA response in this *Response to Comments* document.

Association of Missouri Cleanwater Agencies (Doc. #1817, SBC-044652)

Also, EPA fails to distinguish between non-destructive technologies and destructive technologies, whose development has been on different trajectories. Non-destructive technologies such as granular activated carbon (GAC) and reverse osmosis (RO) may not be feasible depending on how EPA regulates residuals (such as concentrated RO brine). Notably, EPA has currently proposed listing PFOA and PFOS hazardous substances under the federal Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA). EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

Mississippi Farm Bureau Federation (Doc. #1826, SBC-044270)

MFBF is also concerned that this proposed rule has come forward before EPA has published a Final Rule on labeling PFAS as a hazardous substance under CERCLA. Before any testing program moves forward, our farmers need assurances that they will not be considered potentially responsible parties for the land application of solid waste found to contain PFAS.

Sincerely,

Andy Whittington, Environmental Programs Coordinator

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document. Comments on CERCLA liability are outside the scope of this SDWA rulemaking action, please see section 15.1 of the EPA response in this *Response to Comments* document for other comments outside the scope.

Corix Infrastructure Inc. (Doc. #1834, SBC-045373)

[With regards to the specific items EPA has requested comment on, Corix provides below:]

• With regards to the request for comment on the disposal of treatment residual or media, we reiterate our comment above that the testing method of disposal media has not been completed. Many of the PFAS testing methods are still being developed, including for solid waste. This poses an almost insurmountable logistical issue for all drinking water systems. In addition, this raises the significant issue of potential liability to drinking water systems for the impact of the final disposition of the media used. Corix strongly implores EPA to determine the testing method and finalize a CERCLA exemption for drinking water systems before finalizing the rule to ensure additional liability and expense is not incurred by the public and ratepayers.

Conclusion

Corix appreciates EPA's efforts to protect public health and the environment from the harmful PFAS chemicals that pose a risk to many. We support EPA's efforts to better understand PFAS sources, take measured and practical approaches in gathering data and assessing the risks of PFAS to public health and the environment and urge EPA to consider these comments to ensure that the agency produces a rule that is protective, feasible and affordable.

Sincerely,

Kendra Rose

Director, Health, Safety & Environment

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document. The six PFAS in this rule have testing methods available. The EPA refers commenter to the *Interim PFAS Destruction and Disposal Guidance* document and section 7 of the EPA response in this *Response to Comments* document.

New England Water Works Association (Doc. #1836, SBC-045394)

Liability Concerns:

Disposal concerns are currently centered around pending updates to the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) on regulating PFOA and PFOS as hazardous substances, which may impact the available media disposal methods such as landfilling. EPA's current proposal includes setting the default reportable quantity (RQ) at 1.0 pound in a 24-hour period for PFOA and PFOS, and any release at or above RQ must be reported. Granular activated carbon (GAC), anion exchange (AIX) and novel adsorbents all would concentrate PFAS on the media. Disposal considerations are currently most important for anion exchange or novel adsorbents as, at this time, major GAC manufacturers offer reactivation services that indicate thermal destruction of PFAS while no resin or novel adsorbent manufacturers offer regeneration services presently. With the ongoing CERCLA update efforts, once PFOA and PFOS are designated as hazardous substances, it will limit the disposal options and sites willing to accept spent media such as resin and novel adsorbents. This will certainly drive the cost of spent media even higher, with those costs again landing unfairly upon the PWS and its ratepayers. The draft CERCLA proposal still needs to be finalized, and no industry exemptions have been included for water and wastewater systems. Even though GAC manufacturers provide reactivation, there is indication that regenerated GAC does not fully remove PFAS. With this knowledge, there is a possibility that only virgin media would be permitted for use in PFAS removal systems, not regenerated GAC. The concerns with disposal of PFAS-containing media stresses the need for significant focus on advancing destruction technologies.

NEWWA, and the other New England state water associations made comments on dockets EPA-HQ-OLEM- 2019-0341 and EPA-HQ-OLEM-2022-0922-0001 dealing with regulating PFAS under CERCLA. EPA should not move forward with any proposed CERCLA designation until exemptions are granted to water utilities who are passive receivers of PFAS substances. We understand that EPA is separately considering a CERCLA enforcement discretion policy to make it clear that EPA may choose not to take CERCLA enforcement actions against certain entities, but we believe the exemption for water utilities and publicly owned treatment works should be embedded in the regulation. Policies are subject to interpretation and change, whereas regulations have a specified public process. We are therefore requesting that in whatever CERCLA rulemaking EPA moves forward with, EPA provide PWS with an exemption from liability if any or all PFAS compounds are designated as hazardous substances under CERLCA. Doing so would keep CERCLA liability on the industries that created the pollution and/or utilized the substances in the first place.

EPA Response: Please see sections 10.4.2 and 10.1 of the EPA response in this *Response to Comments* document. Comments on CERCLA liability are outside the scope of this SDWA rulemaking action, please see section 15.1 of the EPA response in this *Response to Comments* document for other comments outside the scope.

Citizens Energy Group (Doc. #1838, SBC-044871)

Cost of Managing Process Byproducts as Solid Wastes

One additional aspect of this rule that Citizens would like to highlight is the assumption made by EPA regarding the costs of managing treatment plant process byproducts under the solid waste regulatory framework in the future. While EPA has not solicited specific comment on this area, Citizens believes that it is appropriate to offer this comment considering EPA's discussion in the preamble to the proposed rule.

There is a discussion at 88 Fed. Reg. 18686 that starts, "Stakeholders have expressed concern to EPA that a hazardous substance designation for certain PFAS may limit their disposal options for drinking water treatment residuals…." Later in the paragraph, EPA offers that "[a]lthough EPA anticipates that designation chemicals as hazardous substances under CERCLA should not result in limits on for (sic) disposal of PFAS drinking water treatment residuals, EPA has estimated the treatment costs for systems both with the use of hazardous waste disposal and non-hazardous disposal options to assess the effects of potentially increased disposal costs."

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

Citizens Energy Group (Doc. #1838, SBC-044872)

In late 2021, EPA granted (in part) a petition from the State of New Mexico to list certain PFAS compounds as hazardous waste constituents under RCRA. So, regardless of whether the CERCLA designation as a hazardous substance moves forward, the agency has already indicated its intent to undertake rulemaking under RCRA that (absent a specific carve out exemption for water and wastewater utilities) would have an impact on the management of process byproducts generated. Indeed, on 88 Fed. Reg. 18688, EPA acknowledges that there is a rulemaking proposal is in queue to designate PFAS as a hazardous constituent under RCRA.

Why does this matter? EPA's cost estimates vastly underestimate the impact on water systems in a "regulated under RCRA" future. Here is an example that illustrates that.

Citizens completed a project in its utility system where the materials removed had to be managed under RCRA as a hazardous waste because the constituents in the material were listed (not because the waste was characteristic). The materials were managed at a Subtitle C landfill facility in Michigan – Citizens' cost of disposal was $320 per ton plus transportation to the facility. On the other hand, Citizens has a project that generated materials that were managed as a non-hazardous waste at a local Subtitle D landfill. Citizens paid $350 for the triaxle load of residuals (somewhere in the 6-8 ton range per triaxle load). Summarized concisely: disposal as a RCRA hazardous waste is almost 10x the cost of managing as a non-hazardous waste.

In the economic impact analysis that goes with the rule, EPA has the following table that suggests the annualized costs to a PWS will increase is only about 5% under the RCRA

hazardous waste scenario. Because the RCRA listing is in the future (probably farther out than the applicability of the MCLs), water systems and their customers won't experience the impacts until this economic impact analysis is long forgotten – it will just come as another stressor on O&M expenses that results in rate increases to the customer.

[Table 1: See Docket ID EPA-HQ-OW-2022-0114-1838]

Citizens requests that as EPA considers a path forward for managing PFAS under the RCRA program that it remains mindful of the affordability impacts of its regulations and ultimately, "who pays". Specifically, Citizens requests that EPA ensure that residuals and byproducts from water systems are exempted from classification as a hazardous waste under RCRA to avoid a shift of the expenses associated with managing PFAS in the environment to utility customers through higher costs of disposal.

Conclusion

Citizens appreciates the opportunity to offer these comments on the proposed rule and stands ready to assist EPA as may be appropriate. Please do not hesitate to contact me via e-mail at amciver@citizensenergygroup.com or by telephone at (317) 927-4393 should you have questions or need additional information.

Sincerely,

Ann W. McIver, QEP

Director, Environmental Stewardship

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document. The EPA thanks commenter for providing data on waste disposal.

North American Meat Institute (Doc. #1839, SBC-047720)

An additional likely burden of meeting these extremely low levels will relate to disposal of treatment residuals. EPA states that the Agency has evaluatesd options and developed interim guidance for the destruction and disposal of PFAS and PFAS-containing materials from some products, including spent drinking water treatment media. However, there are open questions as to whether the media might be considered a hazardous substance and the implications that could have under other environmental statutes such as CERCLA. Against this looming complication, EPA has stated that it is "prioritizing research on PFAS disposal options in different environmental media and best management practices." This lack of a clear path forward introduces uncertainty for all stakeholders.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

American Chemistry Council (ACC) (Doc. #1841, SBC-044842)

The baseline assumption in EPA's economic analysis is that the residuals and spent media from the water treatment systems (i.e., spent GAC, IX resins, and waste streams from RO and nanofiltration) will be disposed of as nonhazardous wastes. Although the Agency estimates increased annual costs of the MCL proposal of $30 to $61 million in light of the Agency's proposal to designate PFOA and PFOS as hazardous substances under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), [FN170: 88 Fed. Reg. 18686] this estimates likely understates the impact of CERCLA designation considerably, in light of the following considerations –

• Current uncertainty over the acceptable approaches to dispose of materials contaminated with PFOA and PFOS resulting from the Agency's 2000 Interim Guidance has resulted in considerable confusion – resulting in a reduction of disposal options and increased costs,

• The costs associated with hazardous waste management are often an order of magnitude more than non-hazardous waste management. It is not clear whether EPA's sensitivity analysis as presented in the economic analysis reflects this level of increase, and

• EPA estimate does noy consider the increase in costs to dispose of waste streams from RO and nanofiltration systems if they must be managed as hazardous waste.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

Washington Association of Sewer and Water Districts (Doc. #1842, SBC-044773)

Recognizing Need for CERCLA Exemption

Water utilities are mandated to implement PFAS treatment/removal under the rule, while not the responsible party for the contamination. For this reason, EPA should acknowledge that spent treatment media will become a byproduct of the proposed rule and advocate for agencies mandated to treat for PFAS removal to be exempt from Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA). As safe drinking water agencies, our member utilities recognize the importance of this public health issue. But since it is not caused by the utilities, they should not be liable under CERCLA for any byproducts of the treatment. EPA needs to support utilities in their effort to obtain this exemption.

We appreciate your consideration of our comments along with those of our members, Lakewood Water District and Sammamish Plateau Water, who have on the ground experience with PFAS contamination and cleanup of their drinking water sources.

Sincerely,

Judi Gladstone Executive Director

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document. Comments on CERCLA liability are outside the scope of this SDWA rulemaking action, please see section 15.1 of the EPA response in this *Response to Comments* document for other comments outside the scope.

Amigos Bravos (Doc. #1844, SBC-045400)

Amigos Bravos also supports the EPA's proposal to require public water systems to dispose of treatment residuals that contain any combination of PFHxS, PFNA, PFBS, and GenX Chemicals that meet or exceed the Hazard Index, at the local level, under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA).

EPA Response: Please see sections 10.4.1 and 10.4.2 of the EPA response in this *Response to Comments* document.

Colorado Water Utility Council (CWUC) (Doc. #1622, SBC-044050)

30. EPA requests comment on the availability of facilities to dispose of or regenerate drinking water treatment media that contains PFAS. EPA requests comment on whether there will be sufficient capacity to address the increased demand for disposal of drinking water treatment residuals or to regenerate media for reuse by drinking water treatment facilities.

a. CWUC is concerned there will not be enough disposal/regeneration sites in the state to support the increase in GAC use/disposal required to meet this proposed rule. At this time, CWUC front-range members are only aware of one regeneration site in the Denver metro area that can take PFAS-containing treatment residuals. Regeneration of materials may not be a desirable method for drinking water facilities.

EPA Response: Please see sections 10.4.2 and 10.6 of the EPA response in this *Response to Comments* document.

American Farm Bureau Federation et al. (Doc. #1642, SBC-043498)

Responsible parties lack places to send contaminated materials for appropriate management and disposal.

[Table 1: See Docket ID EPA-HQ-OW-2022-0114-1642]

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

Massachusetts Water Resources Authority (Doc. #1645, SBC-043289)

f. Summary

EPA's proposed PFAS NPDWR will result in thousands of PWSs across the country needing to install treatment. This treatment will come at a significant cost to their ratepayers, create a significant demand on treatment resources required to remove PFAS from water, likely resulting in an overall increase in the cost of these treatment products for all users; and, will result in increased demands for disposal of spent filters/media, creating an unsustainable burden on landfills and incineration facilities nationwide.

EPA Response: Please see sections 10.4.2 and 10.6 of the EPA response in this *Response to Comments* document.

Savannah River Nuclear Solutions LLC (Doc. #1647, SBC-043339)

Further, has EPA determined that sufficient landfill capacity (whether Subtitle D solid waste landfills, or Subtitle C hazardous waste landfills) exists for the potential disposal of large volumes of spent GAC as well as spent IX resins? Land disposal was specifically identified as a management option for these residuals which do not lend themselves to long-term storage or thermal treatment in EPA's 2020 Interim Guidance on the Destruction and Disposal of Perfluoroalkyl and Polyfluoroalkyl Substances and Materials Containing Perfluoroalkyl and Polyfluoroalkyl Substances and it does not appear that landfill capacity was evaluated in any of the proposed rule support documents.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

Washington State Department of Health (DOH) (Doc. #1665, SBC-044429)

EPA requests comments on the availability of facilities to dispose of or regenerate drinking water treatment media that contains PFAS. EPA requests comment on whether there will be sufficient capacity to address the increased demand for disposal of drinking water treatment residuals or to regenerate media for reuse by drinking water treatment facilities.

• This response was prepared by the Washington State Department of Ecology. Currently, waste disposal facilities are not engineered to manage PFAS waste streams. There are questions around how effective and appropriate disposal methods are in either destroying PFAS or storing it indefinitely in a landfill. Although most landfills take this waste currently (e.g., there are a lot of available landfills to send this waste too), that is only because it is not regulated.

• This response was prepared by the Washington State Department of Ecology. Washington State Department of Ecology is currently developing an EIS to research and determine the least impactful disposal method. A draft EIS is due later the summer of 2023.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

Aurora Water, City of Aurora, Colorado (Doc. #1669, SBC-043722)

Additionally, Aurora Water is concerned with the availability of disposal or regeneration sites. Currently, there is only one regeneration facility in our area, and we expect that they will be overwhelmed with utilities requiring materials to be regenerated. Additional costs could be incurred due to potential construction of new regeneration facilities or additional disposal sites.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

State of Vermont Agency of Natural Resources and Department of Health (Doc. #1708, SBC-045121)

8) EPA requests comment on the estimates for disposing of drinking water treatment residuals or regenerating drinking water treatment media including assumptions related to the transport distance to disposal sites and other costs that arise out of disposal of PFAS contaminated drinking water treatment residuals.

Costs may rise as a result of this change, as more Water Systems will be looking to dispose of spent GAC and some disposal facilities will have limited capacity to take PFAS-heavy filter media. The likelihood is that certain states with the capacity to accept this waste will become targets of public scrutiny and be seen as taking "other states' waste" which could limit small states like Vermont, with only a single in-state landfill, from being able to responsibly dispose of the media.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

State of Vermont Agency of Natural Resources and Department of Health (Doc. #1708, SBC-045122)

9) EPA requests comment on the availability of facilities to dispose of or regenerate drinking water treatment media that contains PFAS. EPA requests comment on whether there will be sufficient capacity to address the increased demand for disposal of drinking water treatment residuals or to regenerate media for reuse by drinking water treatment facilities.

As stated in previous comments, availability is limited, some wastewater facilities will not accept PFAS in backwash disposal if another solution exists.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

U.S. Chamber of Commerce et al. (Doc. #1713, SBC-045910)

Landfills will likely require dewatering or containerization to accept the material and already strained capacity at waste incinerators capable of destroying PFAS will be further reduced. Further, EPA fails to address landfill capacity limitation. EPA must clarify how it expects thousands of water systems to properly dispose of PFAS waste and the costs for disposal. EPA also needs to finalize its PFAS disposal guidance before it can reasonably complete a cost analysis [FN153: In fact, the Interim Disposal Guidance demonstrates that hazardous waste management costs are an order of magnitude greater than non-hazardous waste management costs. See EPA Interim Guidance on Destroying and Disposing of Certain PFAS and PFAS-Containing Materials that Are Not Consumer Products at 56 Tables 3-1 and 3-2 (December 18, 2020): https://www.epa.gov/pfas/interim-guidance-destroying-and-disposing-certain-pfas-and-pfas-containing-materials-are-not.].

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

Loudoun Water (Doc. #1717, SBC-043520)

Loudoun Water expects that the availability and feasibility of such disposal and the associated costs will be significantly worse than assumed in the proposal, and that the expanded need for these services will significantly increase the operational costs of current water and wastewater treatment facilities that are not otherwise affected by this rule.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-045982)

Section 7.4: Disposal and reactivation

EPA requests comment on the availability of facilities to dispose of or reactivate drinking water treatment media containing PFAS. Specifically, EPA seeks comment on whether there is sufficient capacity to address the increased demand for disposal options. Typically, spent GAC and AIX media need to either be disposed of in a landfill, reactivated (for GAC only), or incinerated. Looking at the PFAS issue holistically, disposing of media simply takes the PFAS from one area and moves it to another. This is not a long-term solution for PFAS management, and AMWA requests that EPA prioritize and invest in better solutions for PFAS disposal and destruction. As EPA has mentioned, PFAS are extremely persistent; therefore, moving PFAS around will only increase the stockpile of the chemical, increasing the likelihood of localized contamination events. As polluters continue to release PFAS into the environment, there needs to be a solution to safely eliminate it to ensure that communities near disposal sites are not put at risk due to the actions of polluters.

EPA Response: Please see sections 10.4.1 and 10.4.2 of the EPA response in this *Response to Comments* document.

LSP Association (LSPA) (Doc. #1742, SBC-043607)

Public and private sector organizations in Massachusetts are experiencing a severe remediation waste disposal capacity crisis for all contaminants, not just PFAS. No new landfills are currently in the planning stages in Massachusetts, the hurdle of local municipal approval is daunting, and facility siting is a highly sensitive public issue. All of these factors would make it exceedingly difficult and expensive to find the additional capacity needed for disposal of the high volume of spent treatment media that would be generated by the proposed regulations. Again, the LSPA concurs with the challenges as presented in the MWWA May 26, 2023 comment letter (pp. 13-14).

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document. The EPA notes that commenter's assessment contradicts the National Capacity Assessment Reports required under CERCLA Section 104(c)(9), which indicates that Massachusetts has existing capacity though at least the next 20-year period.

Las Cruces Utilities (LCU) (Doc. #1753, SBC-043917)

In response to Section XI-Treatment Technologies, EPA requests comment on the availability of facilities to dispose of or regenerate drinking water treatment media that contains PFAS. EPA requests comment on whether there will be sufficient capacity to address the increased demand for disposal of drinking water treatment residuals or to regenerate media for reuse by drinking water treatment facilities.

• If the media will be categorized as hazardous waste, there are only a few facilities in the U.S. that would accept it. Transportation costs to deliver this material would be significant.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

PFAS Regulatory Coalition (Doc. #1761, SBC-046085)

e) Did EPA consider landfill capacity in its costs of waste disposal? There is going to be greater demand for PFAS disposal options. Treatment media is only one aspect, but our members also have to deal with impacted biosolids, soils, and construction debris. As has been recently experienced in Maine with biosolids, landfill capacities are stressed – which of course affects costs. EPA should include these factors in its analysis.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

Western Urban Water Coalition (WUWC) (Doc. #1768, SBC-043946)

Last, to the extent that the Proposed Rule assumes incineration is an available disposal option, EPA has failed to account for significant risk of legal infeasibility. The U.S. Department of Defense has placed a temporary ban on the incineration of PFAS. [FN18: Off. of the Assistant Sec'y of Def. for Energy, Installations, and Env't, Department of Defense Incineration Moratorium Report to Congress (Feb. 2023).] The state of Illinois has also enacted an outright ban on PFAS incineration. [FN19: 415 ILCS 5/22/62 (2022).] EPA itself has raised concerns over the uncertainties associated with incineration. [FN20: See e.g., U.S. EPA, Technical Support Document -Technologies and Cost for Removing Per- and Polyfluoroalkyl Substances (PFAS) from Drinking Water 18-19, 39 (Feb. 2023); U.S. EPA, Best Available Technologies and Small System Compliance Technologies for Per- and Polyfluoroalkyl Substances (PFAS) in Drinking Water 15 (2023).] If restrictions upon PFAS waste incineration become more widespread, the typical costs of cleanup of PFAS-impacted sites would also increase as a foreseeable consequence of the Proposed Rule [FN21: U.S. Chamber of Commerce, PFOS and PFOA Private Cleanup Costs at Non-Federal Sites 10 (June 2022) (finding that prohibiting thermal treatment of PFAS contaminated soil would raise costs at a single National Priorities List (NPL) site by up to $1 million and that approximately 25 percent of existing NPL sites would find onsite incineration more cost effective than disposal at a Subtitle C landfill)] Nothing in the Proposed Rule explains how EPA has concluded the selected MCLs are feasible given existing or prospective future legal prohibitions on one of the two "most likely management options" that EPA identified. For the foregoing reasons, WUWC has significant concerns about the feasibility assessment supporting the Proposed Rule.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

Western Urban Water Coalition (WUWC) (Doc. #1768, SBC-043944)

EPA has substituted its cost-benefit judgment for the feasibility determination required by SDWA. Nothing in existing law requires the owner or operator of a hazardous waste landfill to accept PFAS-containing residuals for disposal. The basis for EPA's assumption that at least some landfills will be available for disposal has not been supported.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

U.S. Chamber of Commerce (Doc. #1537, SBC-042645)

However, there are substantial questions with EPA's current proposal. It is critical that EPA gets this right, as the costs that the proposed rule would impose are significant, and likely underestimated, leading to several challenges to the water utilities and other industries. For example, the proposed rule does not consider that maximum contaminant levels (MCLs) set in

this regulation would have direct relationship to the costs of Superfund cleanups, given the pending CERCLA hazardous substance designation for PFOA and PFOS. SDWA sets the standard for using the "best available peer-review science." The proposed MCL must be changed to properly balance these costs and benefits, as the statute requires and EPA has done in setting prior MCLs.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document. The EPA further notes that the agency has considered the health risk reduction costs and benefits in accordance with SDWA, more information on the HRRCA is in section 13 of the EPA response in this *Response to Comments* document.

Association of State and Territorial Solid Waste Management Officials (ASTSWMO) (Doc. #1583, SBC-042397)

EPA needs to consider implementation of the proposed regulation, which poses financial, technological, logistical, and communication challenges that are of significant concern to the ASTSWMO membership, as follows:

1. Cost Concerns: EPA's cost analysis does not include costs that will be incurred under CERCLA or other remediation programs, which are likely to be significant. For example, for Superfund-financed sites, where there are no viable responsible parties, States will be responsible for cost-sharing obligations for remedial actions as well as 100% of the costs for long-term operation and maintenance of the remedies in perpetuity. Additionally, with this proposed regulation, the number of sites to be remediated is likely to increase significantly, requiring additional resources for States to perform and/or oversee the remedial activities.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

New York Section American Water Works Association (NYSAWWA) (Doc. #1591, SBC-042375)

We note that EPA's cost estimates fail to consider the impacts that potential waste disposal regulations may have on water suppliers. In the event that spent GAC, PAC backwash residuals or ion exchange resins with PFOA/PFAS in them are designated as hazardous materials, it will dramatically increase operational costs for treatment. These costs cannot be accurately predicted until all regulatory entities have finalized their own rules.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

Water Works Board of the City of Birmingham (BWWB) (Doc. #1602, SBC-043636)

B. PFAS-contaminated GAC and IX media are not considered hazardous wastes in the national cost analysis-- although potential regulation for designating PFAS species as "hazardous substances" under CERCLA or "hazardous constituents" under RCRA has been proposed. For GAC, EPA currently assumes that the spent media is reactivated off- site under current RCRA non-hazardous waste regulations. However, residual disposal as hazardous waste may cause a considerable increase in the O&M costs. For instance, based on EPA's WBS Cost Model for GAC, the spent media disposal costs are $112.16/ton as non-hazardous waste versus $551.86/ton as hazardous waste. BWWB conducted a preliminary cost estimate for the hazardous-waste scenario resulted in approximately 38% higher disposal costs than the non-hazardous waste scenario, which results in an increase in the annual O&M cost for an 80MGD filter plant of $1.5 million. Please refer to Table A1 in Appendix A for additional supporting data.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

Water Works Board of the City of Birmingham (BWWB) (Doc. #1602, SBC-043651)

5. Hazardous residuals: If/when the USEPA designates one or more species of PFAS as "hazards substances" under CERCLA or "hazardous constituents" under RCRA, there is potential for a significant escalation in residuals management costs. Similarly, regulatory action under CWA to control PFAS discharges could also result in escalated residuals management costs for water treatment systems. It is likely that the USEPA's assessment of the influence of these regulations on residuals management substantially underestimates the challenges to feasibility and affordability.

USEPA's national cost analysis reflects the assumption that PFAS-contaminated wastes are not considered hazardous wastes. A hazardous substance designation on PFAS species could limit disposal options for drinking water treatment residuals (i.e., spent media, concentrated waste streams). EPA has acknowledged that if PFAS-contaminated wastes require handling as hazardous wastes, the residuals management costs are expected to be higher.

EPA assessed the cost impact under the assumption of hazardous waste disposal and estimated that the increase in cost due to hazardous disposal is, on average) $30M assuming a 3% discount rate, and $61M assuming a 7% discount rate (EPA 2023).

The PFAS Regulatory Coalition (comprised of a group of industrial companies, municipal entities, agricultural parties, aviation representatives and trade associations) submitted a request to the USEPA for an extension of the comment period on the proposal to designate PFOA and PFOS as CERCLA Hazardous Substance—in their letter, the Coalition mentions that, while EPA states that the Proposed Designation is "economically significant", the economic assessment does not quantify indirect costs, which the Coalition feels could run into the millions or even billions of dollars, across the spectrum of impact.

Numerous utilities submitted comments on the proposed designation, echoing the sentiment that costs are underestimated and could overwhelm water and wastewater utilities. Based on BWWB's preliminary cost estimates comparing hazardous and non-hazardous disposal of spent GAC, it is likely that the EPA's assessment underestimates the costs of residuals handling.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

American Water Works Company Inc. (Doc. #1608, SBC-043998)

American Water is also concerned about the ultimate disposal of PFAS-contaminated AIX or GAC that will not be reactivated/regenerated. Disposal volumes represented by AIX or GAC may more than double the current mass of material being disposed in hazardous waste landfills. If EPA classifies PFAS-laden AIX resin or GAC hazardous, then supply and demand principals would suggest that such an increase in demand could trigger a substantial increase in cost. Lack of certainty over the long-term suitability, viability, and availability of disposal options puts undue risk on utilities' ability to select a treatment process that will minimize long-term cost impacts to customers from this proposed regulation.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

Aquarion Water Company (Doc. #1617, SBC-043373)

Significant operating and maintenance costs, including the uncertain cost of disposing of PFAS-laden filter media, will add to this annual cost.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

Beaufort-Jasper Water & Sewer Authority (BJWSA) (Doc. #1618, SBC-042933)

How will residual disposal add to the cost of operation?

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

Colorado Water Utility Council (CWUC) (Doc. #1622, SBC-044049)

29. EPA requests comment on the estimates for disposing of drinking water treatment residuals or regenerating drinking water treatment media including assumptions related to the transport distance to disposal sites and other costs that arise out of disposal of PFAS contaminated drinking water treatment residuals.

a. Costs of disposal may continue to increase as the use of treatment residuals increase, particularly with CERCLA designations. As more utilities start using GAC and are required to replace more often to meet the proposed MCLs, disposal/regeneration sites will likely increase fees for use of their facilities. Further, CWUC is concerned that incineration may be ineffective and/or banned in the future.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

Citizens Against Ruining the Environment (CARE) (Doc. #1638, SBC-043448)

EPA only estimates that relative to the national analysis for the proposed options, a hazardous waste disposal would increase PWS costs between 4-7% should spent media need to be disposed of as hazardous waste. [FN42: Id. at 18686.] CARE is deeply concerned with such a determination.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

Savannah River Nuclear Solutions LLC (Doc. #1647, SBC-043341)

Comment 6

Section X.I.C. Management of Treatment Residuals (pg. 18686)

EPA is also requesting comment on the estimates for disposing of drinking water treatment residuals or regenerating drinking water treatment media including assumptions related to the transport distance to disposal sites and other costs that arise out of disposal of PFAS contaminated drinking water treatment residuals. These costs are difficult to quantify as they are dependent upon the type of treatment/disposal sites utilized and whether the residuals would be considered RCRA hazardous wastes. While Subtitle D solid waste landfills are generally more ubiquitous and are more evenly spread throughout the country, the number of RCRA landfill facilities are limited and generally are located in the mid-west and west coast, making RCRA disposal more expensive for east-coast generators. Similarly, the number of hazardous waste incineration facilities are also limited and are not geographically spread throughout the country. In some cases, transportation costs of residuals may outweigh the costs for actual disposal.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

Santa Clara Valley Water District (Valley Water) (Doc. #1664, SBC-043126)

Comment 2 – The NPDWR Raises CERCLA Cost Concerns and Threatens the Feasibility of Projects that Help Address Climate Change

The EPA acknowledges stakeholder concerns that a PFAS hazardous designation under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) may limit drinking water treatment residual disposal options and increase costs. Given that regulatory agencies may rely on Maximum Contaminant Levels as CERCLA cleanup standards, Valley Water does not agree with the EPA conclusion that treatment costs may increase "marginally" or that the increase in public water systems' costs "are not significant enough to change the determination that benefits of the rulemaking justify the costs."

Valley Water currently operates three drinking water treatment plants and an advanced water purification facility and is planning additional purification facilities to support and expand potable reuse. Valley Water has been proactive in pursuing potable reuse as a locally controlled and drought resilient water supply as a key strategy to address climate change. As part of the water purification process, reverse osmosis removes PFAS, which end up in the reverse osmosis concentrate (ROC). Due to the large cost needed to advance potable reuse, Valley Water is extremely concerned with the disposal costs and liability that could be incurred related to disposal of the ROC. These potential cleanup and disposal costs could place an undue burden on the "non-polluting" water agencies and local ratepayers and go against the "polluter pays" principle of CERCLA. Valley Water is concerned that the EPA's proposed regulation may result in a "community pays" outcome that unfairly shifts the cleanup and liability costs onto municipalities and the public they serve. In essence, public agencies like Valley Water could be disincentivized from pursuing the creation of climate adaptive, drought resilient water supplies. This disincentive may leave local communities without sustainable, drought proof supplies in the face of climate change, the effects of which are observed now and are likely to be more pronounced in the future.

EPA Response: Please see sections 10.1 and 10.4.2 of the EPA response in this *Response to Comments* document.

Washington State Department of Health (DOH) (Doc. #1665, SBC-044432)

EPA requests comment on the costs associated with the storage, transportation and underground injection of the brine concentrate residuals from the RO/NF process.

• This response was prepared by the Washington State Department of Ecology. Ecology does not have readily available cost data for storage, transport and underground injection of brine concentrate residuals from the RO/NF process.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

Aurora Water, City of Aurora, Colorado (Doc. #1669, SBC-043721)

Not only will there be increased costs for treatment, but also increased costs for disposal of treatment residuals. To remove PFAS to the levels in the proposed rule, Aurora Water will be

forced to replace their granular activated carbon (GAC) materials seven times more per year than previously planned.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document. The EPA thanks the commenter for information about their expected treatment system impacts.

New York State Department of Health (NYS DOH) (Doc. #1677, SBC-044965)

26. EPA is requesting comment on a drinking water proposal when it is still unknown what the impacts will be on water treatment plant residuals and wastewater treatment plants. EPA assessed residuals costs in its economic analysis and concluded no significant impact. There will not be agreement on this conclusion, particularly for small systems. Clean Water Act regulations, if ultimately promulgated, may restrict water treatment plant discharges to water bodies forcing wastewater treatment plants to look upstream and preclude WTP discharges to the collections system. In addition, a hazardous substance designation under the Resource Conservation Recovery Act (RCRA) will increase costs and a hazardous constituent designation under the Comprehensive Environmental Response, Compensation and Recovery Act may create liability for both water and wastewater treatment plants.

27. As noted above, there are significant variabilities surrounding disposal costs of treatment residuals such as spent activated carbon. In New York, some water treatment facilities are landfilling all residuals while other residuals are being regenerated and reused, resulting in very different costs. Evaluating the cost of managing these residuals is complicated by potential liability, perceived or actual, if PFAS from these residuals end up in landfill leachate or air discharge from thermal treatment facilities. The possibility of a RCRA Hazardous Waste designation for some PFAS-wastes adds even more uncertainty, with much higher costs. Development of a cost-effective solution for treatment or disposal of PFAS-wastes is critical to many aspects of New York's response to PFAS contamination, and we urge EPA to make this a priority.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

State of Vermont Agency of Natural Resources and Department of Health (Doc. #1708, SBC-045118)

6) Residual disposal: There are challenges with current available options to manage spent PFAS treatment media, such as disposal at certified disposal facilities or regeneration. With the likely increase in treatment with the proposed MCL, it is likely that the cost of managing or disposing spent treatment media will increase.

a. If EPA wants to include membrane technologies as a solution, there needs to be more discussions and consideration about advanced treatment of the concentrate and how it will be

managed or disposed. Disposal into surface water or sanitary sewers is not a solution in many states, including Vermont. Disposing of RO/NF membrane concentrate into a surface water or sanitary sewer should not be considered an acceptable standard.

b. Regeneration of pretreatment (e.g., softening) would need to be treated water because PFAS can't be discharged into the sewer. This may add more costs to systems that would need to add or modify treatment or storage facilities. This cost was not identified in the analysis.

EPA Response: Please see sections 10.4.1 and 10.4.2 of the EPA response in this *Response to Comments* document.

U.S. Chamber of Commerce et al. (Doc. #1713, SBC-045909)

While EPA assessed the potential impact on PWS treatment costs associated with hazardous residual management requirements in a sensitivity analysis on the proposed option, EPA underestimates these costs. EPA expects annual costs to increase by $30 - $61 million if water systems are required to dispose hazardous waste (spent GAC and resin) but does not explain how regulated entities will handle PFAS waste and the additional costs of managing PFAS waste as a direct result of this rulemaking.

EPA Response: Please see section 10.4 2 of the EPA response in this *Response to Comments* document.

U.S. Chamber of Commerce et al. (Doc. #1713, SBC-045913)

C. EPA assumes direct discharge of RO/NF concentrate to the environment

EPA assumes 5% of Public Water Systems that require treatment will elect to utilize reverse osmosis (RO) or nanofiltration (NF). These membrane-based treatment options will concentrate the PFAS and other constituents present in the source water that are removed from the treated water into a reject stream. EPA assumes that the reject stream will be 15-30% of the total flow to the treatment unit.

EPA states that the RO/NF cost model included an assumption that the reject stream from Reverse Osmosis and Nanofiltration units would be direct discharged via NPDES permitted outfalls to non-potable receiving streams (ocean or brackish estuaries). [FN157: 88 Fed. Reg at 18696.] The ability to discharge concentrated streams of PFAS material to the natural environment via a permitted outfall is not a reasonable assumption for this cost model, nor is it aligned with EPA's roadmap for regulation of PFAS. EPA's cost estimate would be higher if it included a cost estimate for disposal of brine concentrate as a RCRA hazardous waste.

EPA further notes two full-scale applications of RO to treat PFAS in drinking water systems [FN158: See EPA Technical Support Document - Technologies and Cost for Removing Per- and Polyfluoroalkyl Substances (PFAS) from Drinking Water, 2023, EPA-822-P-23-011.]. In addition to those installations, the industrial facilities that the Chamber represents have

experience using Reverse Osmosis units in their facilities. From this experience, EPA has not adequately addressed costs associated with the need for remineralization of RO permeate to make it non-corrosive to downstream piping and to make it suitable for consumption as a drinking water. The coalition also suggests EPA has underestimated the reject quantities that would be expected with the proposed pretreatment units identified by EPA. EPA should assume rejection rates of 25-30% when developing disposal costs for RO units.

EPA Response: Please see sections 10.4.1, 10.4.2, and 13 of the EPA response in this *Response to Comments* document. The EPA has adjusted RO/NF's technology projection compliance forecast to 0 percent in the EA.

Protecting Our Water, Environment, and Ratepayers (POWER) (Doc. #1714, SBC-045935)

The proposed rule does not clearly indicate if other non-regulated PFAS were considered in the byproduct disposal rate.

Besides the issue with disposal, the EPA's estimate on byproduct disposal rate does not adequately consider other non-regulated PFAS. There are thousands of different PFAS compounds. Many of these compounds have little sampling data and the general background concentrations of these compounds are unknown. Given the prevalence and co-occurrence of well-studied PFAS compounds, one can assume that the other thousands of PFAS compounds will co-occur with the regulated PFAS compounds.

As such, it is likely that the drinking water treatment mechanisms required to catch the six PFAS compounds regulated by this rule will also capture many of the thousands of other PFAS compounds, especially if the molecular chains of the unregulated compounds are the same size or larger. Because the cleanup mechanisms will likely capture these additional compounds, the estimated lifetime of the treatment media is likely overestimated. If the treatment media lifetimes are shorter than predicted, maintenance costs will be higher than EPA estimated.

POWER! requests that EPA ensure that all reasonably foreseeable impacts and costs are considered – as required by the SDWA, Executive Order 12866 and OMB Circular A-4 – before proceeding to finalize the proposed rule. A revised analysis should include disposal costs if all six PFAS substances are hazardous substances under CERCLA, the financing costs of historic investments in new treatment infrastructure in a three-year window, and a more accurate estimate of treatment media life and costs.

EPA Response: Please see sections 10.4.2 and 10.3 of the EPA response in this *Response to Comments* document. More information on costs may be found in section 13. While there can be significant quantities of non-quantified PFAS in specific waters, this is accounted for by using a statistical approach in the national cost modeling and helps to explain why some utilities have significant differences in changeout frequency despite being relatively similar in other respects. The three-year timeline was expanded with a two-year capital improvements window. The designation does not require waste to be treated in any particular fashion., nor disposed of at any

particular type of landfill. The designation also does not restrict, change, or recommend any specific activity or type of waste at landfills. The EPA took the unusual and non-required step of providing a supplemental analysis in the hypothetical future RCRA hazardous wastes scenario, which is in the appendix to the cost analysis.

HRSD (Doc. #1719, SBC-043547)

Spent media management becomes even more complex under the proposed CERCLA rule in which PFOA, PFOS and other PFAS compounds are designated as hazardous substances. The transport and disposal of spent media as hazardous wastes is expected to be much more costly than what is estimated by EPA. HRSD's own estimates indicate that the cost of spent media disposal will nearly double if managed as a hazardous waste, with disposal costs of nearly $1.6 million annually. This doesn't even factor in the challenges with increased reliance on hazardous waste landfills and the practical limitation of landfill capacity and availability to manage what are anticipated to be significant volumes of spent media. HRSD alone is anticipating that we could generate more than 6,000 tons of spent media annually.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document. Designation has no impact on RCRA's list of "hazardous wastes." PFAS, including PFOA and PFOS, are not currently listed, or being proposed to be listed, as RCRA hazardous wastes, and designation of PFOA and PFOS as CERCLA hazardous substances does not automatically require that PFOA- and/or PFOS-contaminated waste be treated or disposed of at RCRA Subtitle C facilities. The CERCLA designation does not result in any specific RCRA requirements, nor does designation impose additional costs for waste management facilities. Designation does not impose any specific landfill operation or management requirements.

City of Thornton, Colorado (Doc. #1748, SBC-044787)

Also, Thornton is highly concerned about disposal costs associated with GAC media and other treatment residuals.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

Las Cruces Utilities (LCU) (Doc. #1753, SBC-043922)

In response to Section XIII. Health Risk Reduction and Cost Analysis, EPA requests comment on the costs associated with the storage, transportation and underground injection of the brine concentrate residuals from the RO/NF process.

• Inland management of RO brine would be the significant cost of the whole treatment system. Coastal disposal would be more feasible (assuming coastal PFAS impacts would be acceptable), but for LCU this would be non-feasible. Deep well injection would be 3,000-4,000 feet and has

associated costs and risks. Transporting liquid would be by truck or train, pipelines would not be feasible.

EPA Response: Please see sections 10.4.1 and 10.4.2 of the EPA response in this *Response to Comments* document.

Las Cruces Utilities (LCU) (Doc. #1753, SBC-043916)

In response to Section XI-Treatment Technologies, EPA requests comment on the estimates for disposing of drinking water treatment residuals or regenerating drinking water treatment media including assumptions related to the transport distance to disposal sites and other costs that arise out of disposal of PFAS contaminated drinking water treatment residuals.

• At a large scale, transportation costs and disposal fees for regenerating large amounts of media may not be financially feasible.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-046165)

5.4.1 Estimation of Media Life and Disposal

The generalized logistic function of the Clark model (Clark, 1987), represented in Equation 2, was the basis for calculations for estimation of media life for both GAC and IX. While more rigorous techniques exist for modeling adsorption, Clark's model was utilized for its relative simplicity and accuracy.

[Equation 2: Docket ID: EPA-HQ-OW-2022-0114-1759]

r' and B can be solved for from the slope and intercept of the plot of ln[(Co/C)^1/n-1] versus time. If a constant flow is assumed, the number of bed volumes becomes directly proportional to time, allowing these relationships to be expressed as a function of bed volumes treated rather than time. B, n, and r' values utilized for GAC and IX are expressed in Table 5-9. The values utilized for GAC were derived from data collected during a Black & Veatch GAC pilot study for CFPUA. The values utilized for IX were derived partially from data collected during a Black & Veatch IX pilot study for CFPUA and partially from data collected during an IX pilot study for La Habra Height County Water District (LHHCWD).

Table 5-9 Values Variables in Modeled Bed Life

[Table 5-9: Docket ID: EPA-HQ-OW-2022-0114-1759]

For each system with occurrence data, C was calculated for each PFAS compound at a specified bed volume increment. Increments of 250 bed volumes up to a maximum of 40,000 were calculated for GAC. Increments of 5,000 bed volumes up to a maximum of 800,000 were

calculated for IX. The number of bed volumes at which C exceeded the specified target replacement concentration was determined, and the number of bed volumes for the first contaminant to breach its target concentration was used to calculate media replacement frequency. The number of bed volumes treated before the first contaminant exceeded the target concentration was subjected to Monte Carlo variability as described in Section 5.2.

EPA Response: Please see sections 10.1, 10.4.2, and 13 of the EPA response in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-045618)

EPA considers these actions as part of the economic analysis, particularly through a sensitivity analysis. As noted above, the quantity of GAC and IX that EPA estimates will be disposed of annually is not reported in the supporting information. As noted above, the demand for GAC may exceed 100,000 tons annually. EPA has recently estimated that the costs to incinerate hazardous waste ranges from $400 to $1,700 per ton depending on the type of waste (EPA, 2020). At a minimum, the annual costs to incinerate GAC and IX as hazardous waste will exceed $40 million and are likely to be beyond $100 million. Just the costs of incineration significantly exceeds the $30 million estimate, which EPA describes as including hazard waste disposal and associated costs (e.g., transportation and handling).

While EPA notes that hazard waste disposal costs are excluded from the estimate of annual costs, these costs should not be ignored. EPA's current commitment is to finalize the PFOA and PFOS hazardous substance designations under CERCLA this summer. Furthermore, as these actions are advanced, waste management practices are shifting and leading to increased disposal prices for water systems and, in some cases, facilities are refusing to accept water treatment residuals (AWWA, 2022).

AWWA recommends that the EPA (i) more closely look at the costs associated with hazardous waste disposal, including available guidance from Office of Land and Emergency Management (OLEM) and (ii) include the cost of hazard waste disposal of spent media. The current EPA regulatory agenda will drive impacts the cost of treatment options for removing PFAS from drinking water and will be legally binding by the time water systems must comply with any PFAS rule.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-046154)

Exhausted IX resin will be saturated with PFAS. Disposal alternatives for exhausted IX resins include incineration and landfilling. The cost of each disposal method depends on proximity to disposal sites, hazardous waste classification, and volume of material. Disposal costs can be a significant operational cost for IX treatment systems.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

PFAS Regulatory Coalition (Doc. #1761, SBC-046087)

h) Did EPA consider the costs associated with RO reject disposal? It appears that EPA assumed that reject streams would be directly discharged via NPDES permitted outfalls to non-potable receiving streams (oceans or brackish estuaries). However, EPA needs to recognize that discharging concentrated streams of PFAS-containing material to the environment via a permitted outfall may not be feasible, due to Whole Effluent Toxicity testing and other CWA-based requirements. Nor would that approach align well with EPA's overall strategy for regulation of PFAS.

EPA Response: Please see sections 10.4.1 and 10.4.2 of the EPA response in this *Response to Comments* document. The EPA has adjusted RO/NF's technology projection compliance forecast to 0 percent in the EA.

Western Urban Water Coalition (WUWC) (Doc. #1768, SBC-043943)

EPA also does not properly address the disposal of spent treatment media. Based upon its 2020 Interim Guidance,[FN13: Id. at 18686(citing EPA, Interim Guidance on the Destruction and Disposal of Perfluoroalkyl and Polyfluoroalkyl Substances and Materials Containing Perfluoroalkyl and Polyfluoroalkyl Substances (2020)).] EPA states that "the most likely management option for spent material containing PFAS is reactivation for GAC and incineration for spent IX resin."[FN14:Id.] EPA acknowledges that the "large volume of residuals is a well-known obstacle" and that "large volumes of spent GAC and ion exchange resin must be removed which does not lend itself to onsite storage over time."[FN15: Id.] EPA further acknowledged the potential for PFAS-containing residuals to be characterized as hazardous waste subject to heightened disposal restrictions, and estimated the incremental costs of disposal to utilities. Nevertheless, EPA concluded that "costs are limited to the disposal of the PFAS contaminated residuals and wastes," and found that the "increase in [public water systems] costs are not significant enough to change the determination that the benefits of the rulemaking justify the costs."[FN16:Id.]

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

Western Urban Water Coalition (WUWC) (Doc. #1768, SBC-043945)

By its own admission, EPA has also undercounted the costs if treatment residuals must be managed as hazardous. Under the Resource Conservation and Recovery Act (RCRA) and analogous state laws, water systems cannot lawfully accumulate and store hazardous waste without a permit. [FN17: The default maximum unpermitted accumulation period under RCRA

is 180 days. 40 C.F.R. § 262.16(b).] Neither the Proposed Rule nor the supporting EA appear to account for RCRA permit processing and compliance burdens that would apply to the storage of treatment residuals prior to offsite disposal.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

Environmental Protection Network (EPN) (Doc. #1773, SBC-043852)

EPN agrees with EPA's finding that potential hazardous waste disposal requirements for spent GAC and AIX resins would increase water system costs marginally but not enough to change the determination that the benefits of the rule justify the costs.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

Laurens County Water and Sewer Commission (LCWSC) (Doc. #1805, SBC-043744)

Of course, a key component of a cost assessment is the costs for how GAC residuals will be disposed of/reused. This is especially critical in light of the proposed hazardous waste designation under CERCLA for PFOA and PFOS. We are perplexed by the desire to concentrate a contaminant that has no economically feasible destruction techniques for a rural water system. For example, will utilities be able to regenerate GAC media? If we cannot, the annual O&M costs will be significantly higher. Moreover, if GAC media are hazardous wastes, the disposal costs will be enormous. Uncertainty over whether spent GAC media will be hazardous wastes will force water utilities to delay their selection of PFAS barrier installations due to the uncertainty over materially significant life-cycle costs.

EPA Response: Please see sections 10.4.1 and 10.4.2 of the EPA response in this *Response to Comments* document.

Florida Rural Water Association (FRWA) (Doc. #1806, SBC-044696)

In addition, supply chain issues, skyrocketing construction and transportation costs, and unknown media (lack of availability of disposal facilities) disposal fees have been increasing the actual cost of remediation far exceeding preliminary estimates. In some situations, the GAC is only lasting 6 months with much higher Operation and Maintenance, disposal and logistics fee's to truck to Texas for approved disposal.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

Office of Advocacy at the U.S. Small Business Administration (Doc. #1807, SBC-045483)

Advocacy is also concerned about the significant increases in disposal costs if these PFAS are required to be managed as hazardous substances under the Comprehensive Environmental Response, Compensation, and Liability Act [FN10: Designation of Perfluorooctanoic Acid (PFOA) and Perfluorooctanesulfonic Acid (PFOS) as CERCLA Hazardous Substances, 87 Fed. Reg. 54415, (Sept. 6, 2022)] or designated as hazardous constituents under Resource Conservation and Recovery Act [FN11: Introduction to the Unified Agenda of Federal Regulatory and Deregulatory Actions-Fall 2022, 88 Fed. Reg.1066, 1150.]. Because these actions are not yet final, the agency did not include these costs as part of the rule compliance costs [FN12: EPA did provide a separate sensitivity analysis based on the hazardous waste disposal assumption which demonstrates that costs would increase for public water systems by 4% ($30 million annually) at the 3% discount rate and 5% ($61 million annually) at the 7% discount rate. See, Economic Analysis for the Proposed Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation, [Economic Analysis] (March, 2023), Appendix N.].

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

Earthjustice et al. (Doc. #1808, SBC-046126)

3. EPA correctly excludes any incremental costs to PWSs that would result from the need to dispose of spent filtration materials as hazardous waste.

The PFAS addressed by EPA's proposed NPDWRs—PFOS, PFOA, PFHxS, HFPO-DA and its ammonium salt, PFNA, and PFBS—are not currently regulated as hazardous materials under federal law, and therefore additional disposal costs that would be required by federal law for the disposal of hazardous materials should not be applied in this EA of the proposed NPDWS. In my professional experience, it is standard practice to only account for other regulations in the baseline if those regulations have been promulgated as of the time of the EA. Accounting for future potential regulations in the baseline is uncommon, and trying to account for all potential future contingencies in this regard would quickly make any EA unmanageable. If EPA later determines that PFOS, PFOA, and other regulated PFAS are hazardous materials, then any incremental increase in disposal costs for such materials over normal spent filtration material disposal costs would be a cost of that future regulation, and not of the currently proposed NPDWS.

Overall, EPA's choice to not incorporate in its cost analysis the expense of treating spent filtration materials as hazardous waste is well-grounded in economic theory and common practice. Nonetheless, in response to stakeholder comments EPA did include such costs in an illustrative sensitivity analysis. Although beyond standard practice, this illustrative exercise demonstrates the Agency's responsiveness and desire for full transparency in the regulatory development process. As discussed in comment #11 in the next section of this memorandum, if

EPA maintains this illustrative cost analysis, then the Agency should also estimate the corresponding health and environmental benefits of treating spent filtration materials as hazardous waste. This is necessary in order to make this sensitivity analysis comprehensive and balanced.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

West Virginia Municipal Water Quality Association (Doc. #1816, SBC-044669)

Of course, a key component of a valid national cost assessment is the cost for how barrier technology (GAC, RO) residuals will be disposed of/reused. This is especially critical in light of the proposed hazardous waste designation under CERCLA for PFOA and PFOS.

For example, will utilities be able to regenerate GAC media? If we can't, the annual O&M costs will be significantly higher for the 3-6 thousand affected facilities. Moreover, if GAC media (and/or Reverse Osmosis residuals) are hazardous wastes, the disposal costs will be enormous. We are shocked at EPA's estimate that residuals from PFAS barrier technology will only cost an additional $30-61 million annually to dispose of if PFOA/PFOS are designated as hazardous substances. We think there will be an incredible volume of material requiring disposal that will dwarf EPA's cost estimate. Also, many facilities have assumed they will be able to regenerate their GAC, for example, and EPA must address whether regeneration will be an option under a hazardous waste designation. Further, EPA must address whether it accounted for a loss of regeneration as part of its $30-61 million additional annual cost.

Uncertainty over whether spent GAC media will be hazardous wastes will force water utilities to delay their selection of PFAS barrier installations due to the uncertainty over materially significant life-cycle costs. If spent GAC media (and RO residuals) are hazardous wastes, that may further cause water utilities to defer technology selection until there are PFAS treatment options that avoid hazardous waste residuals.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

Association of Missouri Cleanwater Agencies (Doc. #1817, SBC-044647)

Of course, a key component of a valid national cost assessment is the cost for how barrier technology (GAC, RO) residuals will be disposed of/reused. This is especially critical in light of the proposed hazardous waste designation under CERCLA for PFOA and PFOS.

For example, will utilities be able to regenerate GAC media? If we can't, the annual O&M costs will be significantly higher for the 3-6 thousand affected facilities. Moreover, if GAC media (and/or Reverse Osmosis residuals) are hazardous wastes, the disposal costs will be enormous. We are shocked at EPA's estimate that residuals from PFAS barrier technology will only cost an additional $30-61 million annually to dispose of if PFOA/PFOS are designated as hazardous

substances. We think there will be an incredible volume of material requiring disposal that will dwarf EPA's cost estimate. Also, many facilities have assumed they will be able to regenerate their GAC, for example, and EPA must address whether regeneration will be an option under a hazardous waste designation. Further, EPA must address whether it accounted for a loss of regeneration as part of its $30-61 million additional annual cost.

Uncertainty over whether spent GAC media will be hazardous wastes will force water utilities to delay their selection of PFAS barrier installations due to the uncertainty over materially significant life-cycle costs. If spent GAC media (and RO residuals) are hazardous wastes, that may further cause water utilities to defer technology selection until there are PFAS treatment options that avoid hazardous waste residuals.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

NORTH CAROLINA WATER QUALITY ASSOCIATION (Doc. #1818, SBC-044625)

Of course, a key component of a valid national cost assessment is the cost for how barrier technology (GAC, RO) residuals will be disposed of/reused. This is especially critical in light of the proposed hazardous waste designation under CERCLA for PFOA and PFOS.

For example, will utilities be able to regenerate GAC media? If we can't, the annual O&M costs will be significantly higher for the 3-6 thousand affected facilities. Moreover, if GAC media (and/or Reverse Osmosis residuals) are hazardous wastes, the disposal costs will be enormous. We are shocked at EPA's estimate that residuals from PFAS barrier technology will only cost an additional $30-61 million annually to dispose of if PFOA/PFOS are designated as hazardous substances. We think there will be an incredible volume of material requiring disposal that will dwarf EPA's cost estimate. Also, many facilities have assumed they will be able to regenerate their GAC, for example, and EPA must address whether regeneration will be an option under a hazardous waste designation. Further, EPA must address whether it accounted for a loss of regeneration as part of its $30-61 million additional annual cost.

Uncertainty over whether spent GAC media will be hazardous wastes will force water utilities to delay their selection of PFAS barrier installations due to the uncertainty over materially significant life-cycle costs. If spent GAC media (and RO residuals) are hazardous wastes, that may further cause water utilities to defer technology selection until there are PFAS treatment options that avoid hazardous waste residuals.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

South Carolina Water Quality Association (Doc. #1819, SBC-044603)

Of course, a key component of a valid national cost assessment is the cost for how barrier technology (GAC, RO) residuals will be disposed of/reused. This is especially critical in light of the proposed hazardous waste designation under CERCLA for PFOA and PFOS.

For example, will utilities be able to regenerate GAC media? If we can't, the annual O&M costs will be significantly higher for the 3-6 thousand affected facilities. Moreover, if GAC media (and/or Reverse Osmosis residuals) are hazardous wastes, the disposal costs will be enormous. We are shocked at EPA's estimate that residuals from PFAS barrier technology will only cost an additional $30-61 million annually to dispose of if PFOA/PFOS are designated as hazardous substances. We think there will be an incredible volume of material requiring disposal that will dwarf EPA's cost estimate. Also, many facilities have assumed they will be able to regenerate their GAC, for example, and EPA must address whether regeneration will be an option under a hazardous waste designation. Further, EPA must address whether it accounted for a loss of regeneration as part of its $30-61 million additional annual cost.

Uncertainty over whether spent GAC media will be hazardous wastes will force water utilities to delay their selection of PFAS barrier installations due to the uncertainty over materially significant life-cycle costs. If spent GAC media (and RO residuals) are hazardous wastes, that may further cause water utilities to defer technology selection until there are PFAS treatment options that avoid hazardous waste residuals.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

Wet Weather Partnership (Doc. #1820, SBC-044581)

Of course, a key component of a valid national cost assessment is the cost for how barrier technology (GAC, RO) residuals will be disposed of/reused. This is especially critical in light of the proposed hazardous waste designation under CERCLA for PFOA and PFOS.

For example, will utilities be able to regenerate GAC media? If we can't, the annual O&M costs will be significantly higher for the 3-6 thousand affected facilities. Moreover, if GAC media (and/or Reverse Osmosis residuals) are hazardous wastes, the disposal costs will be enormous. We are shocked at EPA's estimate that residuals from PFAS barrier technology will only cost an additional $30-61 million annually to dispose of if PFOA/PFOS are designated as hazardous substances. We think there will be an incredible volume of material requiring disposal that will dwarf EPA's cost estimate. Also, many facilities have assumed they will be able to regenerate their GAC, for example, and EPA must address whether regeneration will be an option under a hazardous waste designation. Further, EPA must address whether it accounted for a loss of regeneration as part of its $30-61 million additional annual cost.

Uncertainty over whether spent GAC media will be hazardous wastes will force water utilities to delay their selection of PFAS barrier installations due to the uncertainty over materially

significant life-cycle costs. If spent GAC media (and RO residuals) are hazardous wastes, that may further cause water utilities to defer technology selection until there are PFAS treatment options that avoid hazardous waste residuals.

EPA Response: Please see section 10.4.2 of the EPA response in this *Response to Comments* document.

Oneida Nation (Doc. #1825, SBC-044272)

Comments on proposed rule

PFAS Treatment residuals and disposal options:

EPA wants to designate some PFAS as hazardous substance which could affect disposal options. There is a cost to disposing hazardous waste; EPA estimates a couple of hundred annually per household. The Oneida Nation has tested our water to be PFAS and PFOS free/undetectable. Thus, one would anticipate no hazardous waste generation. Therefore, we cannot estimate the concentration and amount of generation. Also, EPA is only listing four PFAS as hazardous materials. Without filters to remove these materials, they would most likely end up in our WWTP biosolids which are currently taken to landfill.

At this point we cannot estimate the annual cost of disposal or when it would occur. Possibly a more substantial concern would be the cost to add filters to our wells. If we are required to add filters, the cost would likely exceed two hundred thousand dollars. Additionally, it would be estimated the installation would be two to three years to design and build the filter into our current housing site water system. Since our wells share the same water source if PFAS showed up in one well it would likely show up in all of them (we do not have a known source of PFAS/PFOS on the Reservation). The cost may run into the millions of dollars if we needed to add more wells and filters. There are options that need to be considered for continued improvements in our water systems in the coming years.

EPA Response: Please see sections 10.4.2 and 13 of the EPA response in this *Response to Comments* document.

10.4.3 Impacts on disposal of PFAS contaminated treatment residuals on communities adjacent to the disposal facilities

Summary of Major Public Comments and EPA Responses

Some commenters stated that more research can be beneficial to further our understanding of PFAS-contaminated treatment residuals on adjacent communities. The EPA agrees that research can be beneficial and is sponsoring research as a key pillar of the PFAS Strategic Roadmap. The ORD is evaluating and developing technologies for reducing PFAS in the environment to inform decisions on drinking water and wastewater treatment, contaminated site cleanup and remediation, air emission controls, and end-of-life materials management.

Some commenters were concerned about impacts from managing treatment residuals on communities adjacent to disposal facilities. Appropriate controls, such as those outlined in the *Interim PFAS Destruction and Disposal Guidance* document, can minimize environmental PFAS releases from PFAS-laden drinking water residuals. This guidance is updated every three years according to section 7361 of The National Defense Authorization Act for Fiscal Year 2020, Public Law No: 116-92. The EPA also notes that, as previously described in the summary of major comments for section 10.4, it is important to distinguish between a potential environmental release and a direct exposure. A PFAS release does not inherently imply human exposure and a release is not inherently risky to specific populations. From a risk management perspective, the EPA acknowledges that while each destruction and disposal technology has limitations, a potential environmental release under point source management is anticipated to be a more health protective alternative than human exposure through drinking water.

Some commenters were especially concerned about EJ and that disposal of PFAS-containing wastes has the potential to impact adjacent communities. The EPA believes that these potential impacts can be minimized with careful management of the disposal and/or destruction approaches as described in the *Interim PFAS Destruction and Disposal Guidance* document. The agency also notes that there are uncertainties associated with the potential pathways of exposure for communities with potential EJ concerns regarding the destruction and disposal of PFAS in drinking water. The EPA has added a qualitative discussion of the potential impacts of PFAS disposal on overburdened communities to Section 8.2 of its EJ analysis for the final rule. For more information on the findings of the EPA's EJ analysis, please see Chapter 8 of the EA (USEPA, 2024d). Through this action, the EPA reaffirms the importance of EJ considerations in agency activities, including rulemaking. The EPA's EJ analysis for the final rule demonstrates that communities of color are anticipated to experience elevated baseline PFAS drinking water exposures compared to the entire sample population in this analysis. However, the EPA believes that this action is likely to reduce existing disproportionate and adverse effects on people of color, low-income populations and/or Indigenous populations.

Individual Public Comments

Washington State Department of Health (DOH) (Doc. #1665, SBC-044430)

EPA requests comment on the impacts that the disposal of PFAS contaminated treatment residuals may have in communities adjacent to the disposal facilities.

• This response was prepared by the Washington State Department of Ecology. With regards to Subtitle D landfills, impacts to adjacent communities would be minor as long as non-dangerous PFAS waste goes to a modern-day lined landfill. Many solid waste landfills capture leachate in lined leachate lagoons that do not discharge. Many also discharge to wastewater treatment plants, which is where any impact would occur in terms of their discharge of treated wastewater or management of biosolids.

• This response was prepared by the Washington State Department of Ecology. Regarding disposal options for high concentration PFAS dangerous waste, there are unknowns on how they could affect adjacent communities. Permitted Subtitle C landfills are preferred if they are designed to manage PFAS. Incineration has shown to destroy the PFAS molecule at prescribed temperature and residence time, but Ecology has not come across environmental data to show no PFAS is being emitted. PFAS would also likely outlive the life of a Subtitle C landfill in the future, so we hesitate to recommend this option for high concentration PFAS wastes because we do not fully understand the effect it could have on adjacent communities.

EPA Response: Please see section 10.4.3 of the EPA response in this *Response to Comments* document. The EPA appreciates the commenter's analysis and notes that PFAS-laden drinking water residuals typically have relatively low PFAS concentrations as outlined in the summary of major comments for section 10.4 of the EPA response in this *Response to Comments* document. The EPA agrees that appropriate controls, such as those outlined in the *Interim PFAS Destruction and Disposal Guidance* document, can minimize environmental PFAS releases from PFAS-laden drinking water residuals.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-045991)

Furthermore, given the increased association between communities of color and water systems contaminated with PFAS [FN19: Liddie, Schaider, and Sunderland. (15 May 2023). Sociodemographic Factors Are Associated with the Abundance of PFAS Sources and Detection in U.S. Community Water Systems. Environmental Science & Technology. DOI:10.1021/acs.est.2c07255], AMWA asks EPA to examine the impacts of disposal of PFAS-contaminated media on communities near disposal sites. Specifically, in the final rulemaking and implementation, EPA should examine how to support PWSs and fence-line communities in equitably distributing risks from PFAS disposal. EPA's proposal involves removing PFAS from drinking water to protect communities, but this will require storing and disposing PFAS near other communities until implementing destruction technologies are readily available. EPA needs to prioritize research into better destruction techniques that do not harm communities that have already been historically underserved. Without proper consideration and community support, disposing of media containing PFAS near communities compromises the agency's goal of protecting public health. Prior to finalizing this NPDWR, EPA should plan for further evaluation and cooperation with PWSs to equitably remove and dispose of PFAS.

EPA Response: Please see section 10.4.3 of the EPA response in this *Response to Comments* document. Appropriate controls, such as those outlined in the *Interim PFAS Destruction and Disposal Guidance* document, can minimize environmental PFAS releases from PFAS-laden drinking water residuals.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-045984)

EPA also requests comments on the impacts the disposal of PFAS-contaminated media will have on communities adjacent to disposal communities. EPA's proposal involves removing PFAS from communities and essentially storing and disposing of it near others, which are in many cases underserved and disadvantaged communities. EPA needs to prioritize research into better destruction techniques that do not harm communities that have already been historically underserved. Disposing of media containing PFAS near these communities compromises the agency's goal of protecting public health.

EPA Response: Please see section 10.4.3 of the EPA response in this *Response to Comments* document. Appropriate controls, such as those outlined in the *Interim PFAS Destruction and Disposal Guidance* document, can minimize environmental PFAS releases from PFAS-laden drinking water residuals.

Connecticut Department of Public Health (CT DPH) (Doc. #1745, SBC-045235)

6. EPA requests comment on the impacts that the disposal of PFAS contaminated treatment residuals may have in communities adjacent to the disposal facilities.

For states that allow incineration as a disposal method, there are little data on PFAS emissions from incineration. This disposal method could lead to possible health effects from exposure during incineration and/or reintroduction of PFAS not fully destroyed during incineration. There are similar concerns with leachate from spent carbon or resins for those that end up at landfills as their final disposal destination. CTDPH seeks assistance from EPA to work to identify and address appropriate and safe disposal methods.

EPA Response: Please see section 10.4.3 of the EPA response in this *Response to Comments* document. The EPA appreciates the commenter's direction as to the type of assistance that will be best for it and EPA notes that the *Interim PFAS Destruction and Disposal Guidance* document contains guidance for the disposal of PFAS-laden drinking water materials.

Aclarity (Doc. #1755, SBC-044511)

The current cycle leaves communities vulnerable and at risk of PFAS related health concerns as PFAS laden materials are often disposed of in landfills, incinerated or injected deep into wells, allowing PFAS to continue to contaminate through landfill leachate or aerosols created through incineration. We urge the federal government to address this PFAS cycle.

Furthermore, any entity who is currently utilizing these subpar "disposal" methods should be held accountable in proving they are not exacerbating the problem and spreading PFAS contamination.

EPA Response: Please see sections 10.4.1 and 10.4.3 of the EPA response in this *Response to Comments* document. The EPA disagrees that appropriately managed destruction

and disposal methods pose health concerns and has published guidance that can help minimize releases in the *Interim PFAS Destruction and Disposal Guidance* document.

Bailey Smith (Doc. #1787, SBC-045813)

Regarding EPA's request for comment as to the "impacts that the disposal of PFAS contaminated treatment residuals may have in communities adjacent to the disposal facilities,"[FN46: Proposed Rule, supra note 3 at 18731.] this comment provides an example of two families who have suffered due to lack of PFAS regulation. Disposal of PFAS contaminated treatment may have horrific impacts on communities adjacent to treatment facilities. [FN47: See e.g., Hayes & Faber, supra note 2; Perkins, supra note 2.] EPA should take care to address this in its final rule. Treatment facilities should make sure to dispose of PFAS contaminated treatment residue as far away from people's homes or drinking water sites as possible.

EPA Response: Please see section 10.4.3 of the EPA response in this *Response to Comments* document. The examples cited by the commenter relate to industrial facility discharges rather than problems stemming from PFAS-laden drinking water treatment residual discharges. Provided that guidance the EPA has published is followed, for example in the *Interim PFAS Destruction and Disposal Guidance* document, environmental PFAS releases should be minimized.

Anonymous (Doc. #1944, SBC-047322)

The United Nations believes a safe, clean, healthy, and sustainable environment is a right for ALL humans. How can we say this is true for the United States when our government allows low-income communities with a high population of people of color, continue to be disproportionately affected by chemical pollutants in their water, air, and the overall environment they are unknowingly subjected to? The EPA shows that Black individuals in America, in comparison with other groups, are 54% more likely to live near hazardous facilities, something that is not brought up enough (Desikan, 2019).

EPA Response: Please see section 10.4.3 of the EPA response in this *Response to Comments* document. Through this action, the EPA reaffirms the importance of EJ considerations in agency activities, including rulemaking. The EPA's EJ analysis for the final rule demonstrates that communities of color are anticipated to experience elevated baseline PFAS drinking water exposures compared to the entire sample population in this analysis. The EPA notes Desikan et al. (2019) is cited in the EPA's EJ analysis for this rule, which can be found in Section 8.2 of the EA (USEPA, 2024d).

10.5 Small System Compliance Technologies identification and evaluation

Summary of Major Public Comments and EPA Responses

Many commenters stated that the POU/ POE water treatment industry may already have multiple products that can reduce PFAS chemicals to below the final MCLs. Additionally, some commenters stated that the influent used (i.e., the challenge water) to test these POU/POE products often contains much higher concentrations of PFAS than would normally be found in most source waters. Commenters also pointed out that under NSF/ANSI, 53 and 58 certifications exist for total PFAS (PFOA, PFOS, PFHxS, PFHxA, and PFDA), as well as perfluoroheptanoic acid (PFHpA), PFHxS, and PFNA individually. However, SDWA Section 1412(b)(4)(E)(ii) requires that SSCTs achieve compliance with the MCL or treatment technique. While devices certified to the NSF/ANSI standards must be demonstrated to significantly reduce PFAS concentrations and, in many cases, can reasonably be expected to treat below this rule's MCLs, the current standards and certification procedures do not assure compliance with this rule. In particular, PFBS and HFPO-DA have no certification standards at this time and the certification standards for PFOA, PFOS, and PFHxS are above this rule's MCL. The certification standards for PFOA, PFOS, and PFHxS are 20 ng/L, compared to the MCLs of 4.0 ng/L for PFOA and PFOS, as well as 10 ng/L for PFHxS; the total PFAS certification standard is 20 ng/L effluent comprised of PFOA, PFOS, PFHxS, PFHxA, and PFDA compared to an Hazard Index of 1 for mixtures of PFHxS, PFNA, HFPO-DA and PFBS. Since the NPDWR has standards that NSF/ANSI is currently unable to verify, POE/POU technologies could potentially not achieve compliance contrary to SDWA Section 1412(b)(4)(E)(ii), which requires that SSCTs achieve compliance with the MCL. While POU/POE technologies may provide significant levels of protection, and the EPA anticipates they will eventually comply with the NPDWR, there is not yet a systematic verification process in place for the level of protection provided by these devices. As mentioned in the proposal, the EPA is aware that the NSF/ANSI Drinking Water Treatment Unit Joint Committee Task Group is in the process of updating their standards; should these future standards meet the NPDWR, the EPA could revise the SSCT list to include POE/POU.

Many commenters also pointed out numerous challenges surrounding POU/POE as a compliance option for some PWSs such as resident cooperation, operation and maintenance, monitoring, and implementation of distributed treatment approaches. The EPA agrees that implementation of POU/POE as a compliance option for any NPDWR can be challenging for some PWSs but also agrees with commenters who noted that POU/POE can provide flexibility and compliance options to small water systems or certain non-transient non-community water systems (NTNCWS) such as schools, factories, office buildings, and hospitals that provide their own water.

The EPA received many comments that other POU devices other than RO/NF should be acceptable ways to meet the MCLs for small systems. For instance, commenters noted that a combination GAC/AIX device with filters could reduce PFAS concentrations to below the MCL

values. The EPA agrees and has changed wording in the final rule preamble and related supporting documents that implied that only RO/NF POU devices would be able to meet a future certification standard. The EPA notes that for small systems, as long as the proposed POU/POE devices are certified by an appropriate third-party certifier (e.g., ANSI/NSF), they would meet the requirements of this regulation. The EPA also received many requests to change the way data was displayed in tables 20 and 22 in the final rule, which summarized proposed SSCTs for PFAS removal and total annual cost per household for candidate technologies. In the proposal, the EPA wrote that this data was "Not Applicable" because of the economies of scale for centralized treatment. The EPA has changed the way this is displayed by replacing the term "Not Applicable" with "Data Unavailable." The EPA notes that neither of these changes imposes nor relieves any rule requirements and only serve to recharacterize the way the EPA reports available technologies.

The EPA asked for comment on the national level analysis of affordability of SSCTs and specifically on the potential methodologies presented in the EA. A couple of commenters recommended the EPA not use median household income (MHI) in the affordability analysis. The EPA decided to retain the MHI measure of income in its primary national level SSCT affordability methodology given the value is easily understandable and available, providing a central tendency for income that is representative of a whole community's ability to pay and is not unduly influenced by outlier values. However, in this rulemaking, the EPA recognizes the value in examining alternative measures of a community's ability to afford an SSCT, so the agency chose to include supplemental analyses that use alternative metrics, specifically 1 percent of MHI, 2.5 percent of lowest quintile income (LQI), and an analysis accounting for financial assistance. These supplemental analyses help to characterize affordability when considering the marginal impact, disadvantaged community groups, and subsidization.

Some commenters stated that the data the EPA used to inform current water rates from the 2006 Community Water System Survey (CWSS) is outdated. While dated, the data from the 2006 CWSS remains the best available dataset for this national level analysis and affordability determination for the following reasons: (1) the CWSS survey used a stratified random sample design to ensure the sample was representative, and (2) these responses can be extrapolated to national estimates since the survey has a known sampling framework, and the data can be organized by system size, source, and ownership (USEPA, 2020).

Some commenters recommended the EPA extend the affordability analysis to medium and large systems. The EPA disagrees with this recommendation, as the purpose of this analysis is to determine if available SSCTs are affordable, per SDWA Section 1412(b)(4)C(ii) Additionally, the water sector has significant economies of scale so if a centralized technology is affordable for small systems, it will be for medium and large systems as well. Therefore, the EPA chose to continue to analyze small system technologies rather than include medium and large systems.

Some commenters specifically disagreed with one of the EPA's supplemental affordability analyses that examined the impact of the rule when accounting for the financial assistance through BIL and other sources that are generally available to small systems. These commenters

stated that the EPA should not assume that this funding will be available or enough to cover the small system capital costs associated with the rule. The EPA conducted this supplemental analysis in response to the recommendations of the Science Advisory Board (SAB), which stated, "[i]f this funding is readily available to many or most systems facing affordability problems, it seems appropriate to take the availability of this funding into account in determining national level affordability. (USEPA, 2002)." The EPA disagrees with these commenters as this significant funding should be generally available, and the EPA continues its efforts to help PWSs access it. It is therefore reasonable to consider the burden reduction in the supplemental affordability analysis.

Some commenters disagreed with the EPA's affordability determination because they stated it was based on inaccurate treatment cost information. A couple of commenters presented their own estimates for small system household costs and compared these estimates to the EPA's affordability threshold and concluded the rule is unaffordable. The EPA disagrees with many of the underlying assumptions in the commenters' cost estimates that, on whole, result in overestimated household costs. These commenters cited cost information that is not representative of the range of treatment costs nationally, and the EPA disagrees with the commenter's cost model that systematically overestimates capital operation and treatment costs. The EPA updated the affordability analysis for the national affordability determination using the updated treatment cost curves (discussed in section XII.D) and found for systems serving between 25 and 500 people, that the upper bound estimated annual household treatment costs for GAC exceed the expenditure margin. Lower bound estimated annual household treatment costs for GAC do not exceed the expenditure margin; for more information please see section XII. These exceedances are primarily driven by capital costs and attributable to the use of high-cost materials (e.g., stainless steel) in the upper bound estimates. Systems using low-cost materials, but with source water characteristics otherwise set to the upper bound (e.g., influent PFAS at approximately 7,000 ng/L, influent total organic carbon [TOC] at 2 mg/L), would fall below the expenditure margin. Although costs increase in some scenarios, the increases are not significant enough to change the conclusions about affordability. Technologies are affordable for all small systems when the technologies do not use the high-end materials. Technologies that do not use high end materials are available for small systems. For more information on the EPA's response to comments on treatment costs please see section XII. The EPA also disagrees that there are no affordable compliance technologies for small systems as the EPA has demonstrated that SCCTs are available below the affordability threshold using the best available peer reviewed information to support the agency's cost estimates.

Individual Public Comments

New Jersey Department of Environmental Protection (NJDEP) (Doc. #1699, SBC-045044)

Regarding small system compliance technologies (SSCTs), NJDEP has primarily observed anion exchange proposed due to the additional backwashing required for operating GAC vessels and

discharge concerns with reverse osmosis. Of the 24 permits issued by NJDEP for systems with capacity less than one MGD, 17 were for anion exchange and seven were for GAC.

EPA Response: Please see section 10.5 of the EPA response in this *Response to Comments* document. The EPA thanks NJDEP for sharing their observations with regard to SSCTs.

Wyoming Department of Environmental Quality (WDEQ) (Doc. #1716, SBC-044761)

WDEQ recommends that EPA (1) provide an analysis of the operational costs for lesser-quality source waters, specifically higher Total Dissolved Solids and Total Suspended Solids content, which lessen the effectiveness of PFAS BATs, (2) provide further information as to whether the cost of Small System Compliance Technologies (SSCTs) would be affected, and (3) determine whether this analysis changes EPA's findings that the identified candidate technologies meet SSCT affordability criterion.

EPA Response: Please see section 10.5 of the EPA response in this *Response to Comments* document. The EPA evaluated the concerns raised by the commenter in the proposed and final rule. For instance, influent TOC levels, pre-treatment prior to BATs to remove for example for total suspended solids (TSS), and effects on small systems were considered (for additional information, please see the *Technologies and Costs for Removing Per- and Polyfluoroalkyl Substances from Drinking Water* supporting document as well as the discussion in the final rule preamble, Section X).

Connecticut Department of Public Health (CT DPH) (Doc. #1745, SBC-045236)

7. EPA requests comment on the type of assistance that would help small public water systems identify laboratories that can perform the required monitoring, evaluate treatment technologies, and determine the most appropriate way to dispose of PFAS contaminated residuals and waste the systems may generate when implementing the rule.

CT DPH recommends that EPA provide a table or chart with evaluation of treatment technologies for removal of PFAS, including up to date information on when to use or not use GAC, IX, or both in series. For instance, if a particular PWS has higher concentrations of short chain PFAS, EPA might recommend using IX instead of GAC. Further, there is a wide range of IX media available. Guidance on which types to use and when would be beneficial. EPA should also be aware of current supply chain issues for GAC and IX vessel production which could delay implementation by six to twelve months. For assistance with residual PFAS waste going to landfills this is going to rely on the still to be determined CERCLA hazardous waste designation for PFAS and any CERCLA exemptions for landfills.

EPA Response: Please see section 10.5 of the EPA response in this *Response to Comments* document. An evaluation of treatment technologies was published in the *Best Available Technologies and Small System Compliance Technologies for PFAS in Drinking Water*

document. The EPA notes that site-specific considerations, such as water chemistry, will dictate the choice of BAT and pilot studies are recommended. In consideration of potential problems surrounding capital improvement timeframes, the EPA has provided compliance flexibility by providing a two-year capital improvements extension of the MCL compliance deadline allowed by Section 1412(b)(10) of SDWA. A CERCLA designation does not require waste to be treated in any particular fashion, nor disposed of at any particular type of landfill. The designation also does not restrict, change, or recommend any specific activity or type of waste at landfills. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions.

Environmental Protection Network (EPN) (Doc. #1773, SBC-043848)

We further agree that EPA has appropriately identified small system compliance technologies as GAC and AIX for all small systems serving 25 to 10,000 people, with RO and NF also being BAT for systems serving 3,300 to 10,000 people.

EPA Response: Please see section 10.5 of the EPA response in this *Response to Comments* document.

Oklahoma Department of Environmental Quality (DEQ) (Doc. #1616, SBC-043050)

Concerns with POU/POE Treatment Devices

POU/POE devices should not be considered a compliance option for the PFAS MCL's until removal standards meet the MCL's.

Even if standards would align with the final MCL's, many states would still be hesitant to approve POU/POE devices as a compliance option. While this option might seem like an economical alternative, the POU/POE option has sometimes been reported as more expensive over time as compared to other alternatives available. Factors such as ongoing operation and maintenance, monitoring, testing, and replacement drive these costs. Concerns have been raised that these devices may not be properly maintained. Additionally, the POU/POE compliance option requires 100% participation from the community, which is difficult to maintain.

EPA Response: Please see section 10.5 of the EPA response in this *Response to Comments* document.

Association of State Drinking Water Administrators (ASDWA) (Doc. #1628, SBC-044110)

Point of Use and Point of Entry Devices

ASDWA recommends that POU/POE devices not be considered a compliance option for the

PFAS MCL until PFAS removal standards meet the MCL. Once standards align with the MCLs, ASDWA recommends limiting the compliance option for using POU/POE to very small systems serving 250 or fewer persons.

The final PFAS NPDWR should clearly outline that point-of-use (POU) and point-of-entry (POE) devices may not be a viable option for many systems. Additionally, the final rule should clearly state that the POU/POE option can only be pursued if the standards for the devices can reliably and consistently meet the MCL. Currently, POU/POE devices are not a viable or feasible option for compliance with the proposed PFAS MCLs. Current standards for POU/POE devices include NSF/ANSI 53: Drinking Water Treatment Units – Health Effects and NSF/ANSI 58: Reverse Osmosis Drinking Water Treatment Systems. The current standards for these treatment units allow a maximum effluent concentration of 20 ppt for total PFAS, 20 ppt for PFHpA, 20 ppt for PFHxS, 20 ppt for PFOA, 20 ppt for PFOS, and 6 ppt for PFNA. Additionally, current standards do not have reference concentrations for PFBS or GenX. While NSF has indicated it plans to incorporate additional PFAS and require treatment to levels designated by EPA's final MCL values, until such time that these standards are updated, POU/POE devices should not be considered a compliance option for the PFAS MCL.

Once removal standards align with the final MCL, many primacy agencies will still be hesitant to approve POU/POE devices as a compliance option. Recently published research found that resident cooperation, operation and maintenance, monitoring, and the actual implementation of distributed treatment approaches were repeatedly listed as the greatest compliance concerns [FN1: Alfredo, K., Wilson, M., and Roberson, A. Management of point-of-use and point-of-entry for regulatory compliance: Survey of state administrators. https://doi.org/10.1002/aws2.1334].

While some primacy agencies allow and encourage the use of POU/POE devices as a compliance mechanism for small systems, others do not allow POU/POE in any circumstance. The same study mentioned above found that most primacy agencies and utilities described systems of approximately 30–50 connections as the most successful. Most survey respondents indicated restricting the use of POU/POE to water systems with less than 500 connections (this number is likely on the high side). ASDWA recommends that the compliance option for using POU/POE be limited to very small systems serving 250 or fewer connections.

The final rule should include language that while POU/POE devices are an option, these devices are not a viable option in many circumstances. While this option may seem like an economical alternative, several primacy agencies have reported that when implemented for other contaminants, the POU/POE option becomes more expensive over time compared to other available alternatives. Factors such as device approval, ongoing operation and maintenance in perpetuity, monitoring, testing, and replacement drive these costs. Sampling to ensure the devices are working is a specific concern due to the cost of PFAS sampling and the access to homes for sampling locations. Primacy agencies have reported that maintaining compliance on POU systems can take significant staff resources. Primacy agencies have also raised concerns regarding biofilm growth should the devices be improperly maintained. Additionally, the POU/POE compliance option requires 100% participation from the community, which is difficult

to maintain in perpetuity in most communities and would not be possible in systems serving more than 250 connections. The installation of POU devices often requires overtime work after hours to gain access to the customer's homes, and for the tracking of these devices and their monitoring results. Additionally, maintenance becomes increasingly difficult as more POU devices are installed.

EPA Response: Please see section 10.5 of the EPA response in this *Response to Comments* document. The agency acknowledges the study by Alfredo et al. (2023) referenced in the comment and plans to consider this information when considering POU and POE devices as SSCTs in the future.

North Carolina Division of Water Resources (NCDEQ) (Doc. #1652, SBC-044193)

3. NCDEQ recommends that POU/POE devices should not be considered a compliance option for the PFAS MCL until PFAS removal standards meet the MCL. Once standards align with the MCLs, NCDEQ recommends that the compliance option for using POU/POE be limited to very small systems serving 250 or fewer persons who have unrestricted access to each POU/POE

The final PFAS NPDWR should clearly outline that point-of-use (POU) and point-of-entry (POE) devices may not be a viable option for many systems. Additionally, the final rule should clearly state that the POU/POE option can only be pursued if the standards for the devices can reliably and consistently meet the MCL. Currently, POU/POE devices are not a viable or feasible option for compliance with the proposed PFAS MCLs. Current standards for POU/POE devices include NSF/ANSI 53: Drinking Water Treatment Units – Health Effects and NSF/ANSI 58: Reverse Osmosis Drinking Water Treatment Systems. The current standards for these treatment units allow a maximum effluent concentration of 20 ppt for total PFAS, 20 ppt for PFHpA, 20 ppt for PFHxS, 20 ppt for PFOA, 20 ppt for PFOS, and 6 ppt for PFNA. Additionally, current standards do not have reference concentrations for PFBS or GenX. While NSF has indicated it plans to incorporate additional PFAS and require treatment to levels designated by EPA's final MCL values, until such time that these standards are updated, POU/POE devices should not be considered a compliance option for the PFAS MCL.

Once removal standards align with the final MCL, NCDEQ will still be hesitant to approve POU/POE devices as a compliance option. Recently published research found that resident cooperation, operation and maintenance, monitoring, and the actual implementation of distributed treatment approaches were repeatedly listed as the greatest compliance concerns [FN2: Alfredo, K., Wilson, M., and Roberson, A. Management of point-of-use and point-of-entry for regulatory compliance: Survey of state administrators. https://doi.org/10.1002/aws2.1334]. The same study mentioned above found that most state agencies and utilities described systems of approximately 30–50 connections as the most successful. NCDEQ recommends that the compliance option for using POU/POE be limited to very small systems serving 250 or fewer persons where the system has unrestricted access to the POU/POE.

The final rule should include language that while POU/POE devices are an option, these devices are not a viable option in many circumstances. While this option may seem like an economical alternative the POU/POE option becomes more expensive over time as compared to other alternatives available. Factors such as device approval, ongoing operation and maintenance in perpetuity, monitoring, testing, and replacement drive these costs. Sampling to ensure the devices are working is a specific concern due to the cost of PFAS sampling and the access to sampling locations. Determining compliance on POU systems can take significant staff resources. Biofilm growth is a concern with this option should the devices be improperly maintained. Additionally, the POU/POE compliance option requires 100% participation from the community, which is difficult to maintain in perpetuity in most communities and would not be viable in systems serving more than 250 persons. The tracking of these devices and their monitoring results, in addition to the maintenance, becomes increasingly difficult as more POU devices are installed.

EPA Response: Please see section 10.5 of the EPA response in this *Response to Comments* document. The agency acknowledges the study by Alfredo et al. (2023) referenced in the comment and plans to consider this information when considering POU and POE devices as SSCTs in the future.

A. O. Smith Corporation (Doc. #1674, SBC-043701)

5. Small System Compliance Technologies

A. O. Smith is encouraged that the EPA recognizes the key role that POU and POE technologies play in assisting small water systems with a cost-effective approach for SDWA compliance. POU and POE systems that treat drinking water "at the tap" or whole household level, have the additional value of removing (or significantly reducing) contaminants below a prescribed MCL, which results in further lowering the risk from exposure to potentially harmful substances, and thus lowers the risk of an adverse health outcome. This is especially acute when the drinking source is a private well. However, even households that receive their drinking water from a public water system or supply can benefit from these technologies considering that drinking water that has been treated centrally traverses through distribution pipes where recontamination can occur. Therefore, POU and POE systems provide additional protection to sensitive populations where exposures to drinking water contaminants are more likely to result in adverse health outcomes including increased mortality. These populations include newborns, children, pregnant mothers, immunocompromised individuals, and the elderly. [FN14: COST BENEFITS OF POINT-OF-USE DEVICES IN REDUCTION OF HEALTH RISKS FROM DRINKING WATER, Marc Verhougstraete, Ph.D., Kelly Reynolds, Ph.D., Akrum Tamimi, Ph.D., Charles Gerba, Ph.D., Water Quality Research Foundation, November 16, 2016.]

a. Technologies and Implementation Strategies

As it relates to small system compliance technologies and implementation strategies in the context of meeting a prescribed MCL, the SDWA controls and the EPA has provided long-

standing guidance and requirements for small systems that chose to use POU and/or POE technologies for MCL compliance. [FN15: Safe Drinking Water Act § 1412(b)(4)(E)(ii); see also, Point-of-Use or Point-of-Entry Treatment Options for Small Drinking Water Systems, United States Environmental Protection Agency, Office of Water, 4607, EPA 815-R-06-010, April 2006.] A prerequisite requirement is that only POU or POE units that have been independently certified in accordance with American National Standards Institute (ANSI) product standards can be used as part of a compliance strategy. [FN16: Id.] In that regard the Company concurs with this requirement and currently has POU and POE products that are third-party certified to the industry's current standards for PFOA and PFOS. [FN17: NSF/ANSI 53: Drinking Water Treatment Units – Health Effects and NSF/ANSI 58: Reverse Osmosis Drinking Water Treatment Systems.] The Company further recognizes that while the PFAS NPDWS recognizes the potential for these products to be utilized by small systems for MCL compliance, it did not include POU devices as a current compliance option "because the regulatory options under consideration require treatment to concentrations below 70 ppt total of PFOA and PFOS… and the affordability conclusions for POU RO should be considered preliminary because they reflect the costs of devices certified under the current standard, not a future standard." [FN18: 88 FR 18688 (Footnote 5).]

First, EPA only considered POU RO systems in its analysis. As discussed earlier, a wide array of POU and POE technologies can remove PFAS chemicals. POU technologies currently used for this purpose include Filters and RO systems. POU Filters often contain activated carbon, but typically other types of media (e.g., anion exchange media) are also added to improve the removal efficacy of PFAS. POE treatment for PFAS can be accomplished using anion-exchange systems, whole-house filtration, and whole-house RO systems. Many of these POU and POE systems are capable of PFAS reduction, and some have been certified for PFOA and PFOS reduction to ANSI standards and A. O. Smith recommends that these technology methods of POU filtration and POE options be added to Table 20 as eligible product categories. [FN19: 88 FR 18686-18687 (see Table 20)]

Second, as the EPA is aware, and for accuracy, NSF/ANSI 53 and 58 have been amended to reflect concentrations below 20 ppt for PFOA and PFOS, which is a significant step in protecting consumers. The NSF/ANSI testing procedures to certify products to the standard utilize a "challenge" or influent water that meets or exceeds 95% of the concentration levels found in drinking water. In practice this means that if the delivered water to a home has a concentration of 70 ppt of PFOA and PFOS the certified device will remove 95% leaving 3.5 ppt, which would meet the proposed MCL.

Notwithstanding the operative effect of products certified to the current NSF/ANSI 53 and 58 standards for PFOA and PFOS, those bodies, as well as other stakeholders that sit on the NSF/ANSI Drinking Water Treatment Unit Joint Committee Task Group are actively reviewing updates to both standards based on the EPA's proposed PFAS NPDWS to ascertain the feasibility and practicality of amending the standards to a 4 ppt concentration level.

Lastly, A. O. Smith recommends that the EPA revisit its regulatory recognition of POU and POE devices that are certified to NSF/ANSI 53 and 58 in its PFAS NPDWS Final Rule, including allowing small systems to use currently certified NSF/ANSI devices for MCL compliance.

EPA Response: Please see section 10.5 of the EPA response in this *Response to Comments* document. The EPA has also amended language to include all types of POU/POE systems that meet standards as opposed to only RO systems.

A. O. Smith Corporation (Doc. #1674, SBC-043703)

Lastly, and as a cited previously, SDWA allows small public water systems serving 10,000 or less connections to use POU and POE treatment systems for MCL compliance consistent with EPA regulations and guidance, as well as state-specific approvals. [FN22: See, Arsenic SSCT - 40 CFR Section 141.62(d), Radionuclides SSCT - 40 CFR Section 141.66(h), and Point-of-Use or Point-of-Entry Treatment Options for Small Drinking Water Systems - EPA 815-R-06-010).]That said, the proposed PFAS NPDWS only contemplates small public water systems with less than 3,300 connections utilizing POU or POE systems for MCL compliance. While the EPA based its assumption due to the limits of the WBS Model, A. O. Smith recommends – and consistent with SDWA and preexisting guidance for systems serving 10,000 or less connections – that Tables 20 and 22 be expanded to allow small systems to consider these options for populations up to 10,000 by replacing the term "Not Applicable" with "Data Unavailable", which will help clarify that small water systems should conduct their analysis to determine the feasibility of this technology for any project size within that range and allow them to choose the best solution available. [FN23: 88 FR 18687.]

EPA Response: Please see section 10.5 of the EPA response in this *Response to Comments* document. In response to commenter's request, the EPA changed the way information was displayed; the EPA notes that neither of these changes imposes nor relieves any rule requirements and only serve to recharacterize the way the EPA reports available technologies.

Water Quality Association (WQA) (Doc. #1694, SBC-044982)

• The EPA has always allowed consideration of both POU and POE as a Small Systems Compliance Technology (SSCT) for all size categories. However, Table 22 suggests that this technology should be limited to communities of 3,300 or less as it says POU RO systems are "Not Applicable" for systems that serve between 3,300 and 10,000 people. This is based on an EPA assumption due to the limits of the WBS Model. WQA requests that Tables 20 and 22 [FN2: Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation, 2023, Table 20 & Table 22. EPA-HQ-OW-2022-0114-0027.] clarify this gap by stating in the table "Data Unavailable" and encourage small water systems to conduct an analysis to determine the feasibility of this technology for any project size within that range.

• There are two existing national standards for testing and certifying POU and POE water filtration systems that offer elective claims to reduce PFAS chemicals, including PFOS and PFOA, to a cumulative 20 ppt. These standards are NSF/ANSI 53: Drinking Water Treatment Units – Health Effects and NSF/ANSI 58: Reverse Osmosis Drinking Water Treatment Systems. These standards also cover claims for several other water-related contaminants and are "reasonably anticipated" to meet parameters set by the EPA's final rule on PFAS, considering all NSF/ANSI standards either meet or exceed the EPA's MCLs set for other contaminants. [FN3: NSF/ANSI 53 and 58 meet or exceed EPA's maximum contaminant levels or action levels for several contaminants such as Lead, Copper, Arsenic, Nitrates, Chromium (total), and Mercury.]

o There is already an active NSF/ANSI Drinking Water Treatment Unit Joint Committee Task Group reviewing updates to both standards based on the EPA's proposed rule and health index approach.

EPA Response: Please see section 10.5 of the EPA response in this *Response to Comments* document. In response to commenter's request, the EPA changed the way information was displayed; the EPA notes that neither of these changes imposes nor relieves any rule requirements and only serve to recharacterize the way the EPA reports available technologies.

Water Quality Association (WQA) (Doc. #1694, SBC-044986)

Treatment Technologies: POU/POE Strategies to Reduce PFAS in Drinking Water

Treatment technologies of RO, AIX, and those that utilize carbon have all been available for contaminant reduction applications in POU and POE for decades, as they have been for larger public water system applications. The EPA requested input specifically on the use of Granular Activated Carbon Filters (GAC Filters), which is one type of POU Filter, but often the POU Filters which are used for PFAS removal use a carbon-block technology. WQA feels that a more inclusive term to describe this technology category is "POU Filter" or "POU Filtration," and all of our comments relative to this carbon technology category should be taken in that context.

The EPA only considered POU RO systems in its analysis, but a wide array of POU and POE technologies can remove PFAS chemicals. POU technologies currently used for this purpose include Filters and RO systems. POU Filters often contain activated carbon, but typically other types of media (e.g., anion exchange media) are also added to improve the removal efficacy of PFAS. POE treatment for PFAS can be accomplished using anion-exchange systems, whole-house filtration, and whole-house RO systems.

Many of these POU and POE systems are capable of PFAS reduction, and some have been certified for PFOA and PFOS reduction to American National Standards. All should be recognized as available solutions for public water system compliance. The determination of the best solution should be made by the public water system provider. Costs and other considerations, such as influent levels, will vary widely, as with any technology solution, whether treatment is provided at the source, tap, or some combination. Proven technologies exist,

and the available options should not be unreasonably restricted by regulation. WQA recommends that various methods of POU filtration and POE (e.g., Anion Exchange) options be added to Table 20 as product categories. [FN5: EPA-HQ-OW-2022-0114-0027, Table 20] These technologies should be referred to as best available technologies (BATs) in addition to POU RO, which is already included throughout the proposed regulation.

POU and POE products also allow leveraging of multiple technologies in a solitary product. This will enable manufacturers to maximize synergies between treatment approaches, providing a more comprehensive and longer-lasting solution. This can be accomplished while maintaining a simple installation and user experience as it is being provided in a single product. One example of this would be the addition of an activated carbon post filter to an RO-based product.

As stated previously, a review of product performance data produced by WQA's accredited laboratory suggests that the POU/POE water treatment industry may already have multiple products available that can reduce PFAS chemicals to near or below the proposed MCL. Detection limits in place at the time of testing were at 5 ppt for PFOA, HFPO-DA, PFDA, PFHpA, and PFNA and 10 ppt for PFOS, PFBS, and PFHxS, respectively. The availability and efficacy of these systems are expected to increase by the enforcement date.

EPA Response: Please see section 10.5 of the EPA response in this *Response to Comments* document. The EPA has amended language to include all types of POU/POE systems that meet standards as opposed to only RO systems.

Water Quality Association (WQA) (Doc. #1694, SBC-044980)

• A review of product performance data produced by WQA's accredited laboratory suggests that the POU/POE water treatment industry may already have multiple products that can reduce PFAS chemicals to near or below the proposed MCL.

o It should be noted that these products are tested using an extremely high influent challenge level of a combined 500 ng/L PFOA and 1000 ng/L PFOS, demonstrating their ability to reduce PFAS at very high concentrations. For comparison, the EPA's cost analysis uses significantly lower influent concentrations for small water systems, 70 ng/L and 264 ng/L. [FN1: Best Available Technologies and Small System Compliance Technologies for PFAS in Drinking Water, EPA-822P-23-009, p. 36. 2023g.] It's conceivable that POU/POE products could reduce to even lower levels and possibly with larger treatment capacities if tested using lower influent concentrations.

• Treatment of PFAS to the proposed levels will introduce significant new challenges for small community water systems, and POU/POE options should remain fully available for consideration as a viable treatment solution in the final rule.

o POU Reverse Osmosis (RO) systems, as mentioned in the proposed rulemaking, are effective in reducing PFAS. However, the EPA should also indicate that other POU and POE filtration systems, such as carbon blocks, Granular Activated Carbon Matrixes (GAC), and Anion

Exchange (AIX), can also treat these contaminants. Treatment technologies used on a large-scale application are generally the same as those used in POU and POE applications.

EPA Response: Please see section 10.5 of the EPA response in this *Response to Comments* document. The EPA has amended language to include all types of POU/POE systems that meet standards as opposed to only RO systems.

Water Quality Association (WQA) (Doc. #1694, SBC-044984)

*Supporting information for WQA's comment can be found in the attached analysis.

In summary, WQA and its members are dedicated to reducing PFAS in drinking water by continuing to develop cost-effective certified POU and POE technologies. These treatment solutions are critically important to assisting small community water systems with compliance. By implementing final barrier POU and POE technologies tailored to the specific needs of a community along with other proposed solutions, the EPA and water treatment industry, in partnership, can help ensure healthier and safer drinking water for all Americans.

Thank you in advance for considering these comments, and we welcome any opportunity to meet with you to discuss these recommendations in greater detail.

Sincerely,

Jeremy Pollack

Director of Government Affairs

Water Quality Association JPollack@WQA.org

WQA Analysis

Proposed National Primary Drinking Water Regulation Rulemaking for PFAS

Docket ID No. EPA-HQ-OW-2022-0114

Water treatment systems, such as POU and POE, can assist with reducing PFAS in drinking water. Many households and businesses currently utilize these final barrier technologies to improve their drinking water quality. Therefore, it is vital for the EPA to incorporate and afford public water systems the flexibility to potentially deploy these water treatment systems to address their compliance obligations under any final NPDWR for PFAS.

Industry Standards

WQA recognizes that the EPA encourages using third-party certified products to ensure that these systems function as intended to remove specific contaminants of concern. WQA offers the following information to ensure the EPA is aligned with WQA on how current industry standards compare to the proposed regulatory goals.

There are currently two existing standards for testing and certifying water filtration systems that offer elective claims to reduce PFOA and PFOS in addition to other PFAS chemicals: NSF/ANSI 53: Drinking Water Treatment Units – Health Effects and NSF/ANSI 58: Reverse Osmosis Drinking Water Treatment Systems. It's important to note that the NSF/ANSI testing procedures utilize a "challenge" or influent water that meets or exceeds 95% of the concentration levels previously found in drinking water based on a dataset compiled from the UCMR 3 data and an additional dataset from the Environmental Working Group (EWG). The challenge levels currently used in the NSF/ANSI testing procedure are:

[Table 1: See Docket ID EPA-HQ-OW-2022-0114-1694]

Supporting documentation states that the "EPA generated costs assuming [community water], systems must meet MCLs for PFOA and PFOS of 4 nanograms per liter (ng/L) each, with initial influent concentrations of 70 ng/L and 264 ng/L, respectively." [FN4: Best Available Technologies and Small System Compliance Technologies for PFAS in Drinking Water, EPA-822P-23-009, p. 36. 2023g.] This Influent Challenge Level is significantly less challenging than the levels used in the standards for POU/POE water treatment systems. The standards allow for testing of a mixture of the seven contaminants listed in the table above at a total PFAS challenge level of 2,160 ppt; a mixture of PFOA and PFOS at a challenge level of 1,500 ppt, or for individual claims to be made for PFHpA, PFHxS, PFNA, PFOA, and PFOS at the influent challenge levels noted in the table above. Two PFAS compounds, PFBS and PFDA, were excluded from the individual contaminant reductions because their occurrence levels in the dataset mentioned above were found to be less than their health advisory levels at that time.

It should be noted that both standards are under continuous maintenance and are expected to be updated in advance of the EPA's promulgated regulation for PFAS. However, three gaps exist between the current standards and the EPA's proposed rule, all of which will be reviewed and expected to be revised in accordance with the final rule:

1. The current NSF/ANSI standards set the maximum effluent at 20 ppt for the total PFAS claim, for PFOA and PFOS combined, and for individual claims for PFHpA and PFHxS. PFNA's maximum effluent level is set at 6 ppt.

2. The current NSF/ANSI standards do not address GenX. The selection of 20 ppt was made based on State level activity at the time, and the exclusion of GenX was decided upon by the Joint Committee due to the lack of available occurrence data, which is needed to establish a conservative challenge level, and also because the EPA shared information with the NSF Task Group indicating that they were reviewing GenX. This data is expected to be available with the release of the UCMR 5 data. The EPA should provide ample time after the publishing of that information for water systems to review and respond in addition to working with above-standard committees and other stakeholders such as WQA to adapt accordingly.

3. The current NSF/ANSI standards include requirements for the maximum levels of certain PFAS chemicals detected during material safety/extraction testing, NSF/ANSI 53 and 58 redirects to NSF/ANSI/CAN 600: Health Effects Evaluation and Criteria for Chemicals in

Drinking Water. This standard is currently using the 2016 EPA Health Advisory of 70 ppt, which requires the summation of PFOA and PFOS for materials that extract these compounds. The Task Group that maintains the health effects criteria has indicated that any EPA PFAS regulations will be proposed to the Joint Committee to supersede the existing Health Advisory for material safety/extraction evaluations.

These standards are "reasonably anticipated" to meet parameters set by the EPA's final rule considering all NSF/ANSI standards either meet or exceed the EPA's MCLs set for other contaminants. Additionally, there is already an active NSF/ANSI Drinking Water Treatment Unit Joint Committee Task Group that will be reviewing updates to both standards based on the EPA's rule and health index approach. Their recommendations will be brought to the full Joint Committee for review and approval.

Furthermore, standards developed through the American National Standards Institute (ANSI) consensus-based process are established with the representation of all interested and affected stakeholders, including manufacturers, non-profits, advocacy organizations, government representatives (such as the EPA), and academia. The development process weighs scientific research and the feasibility of treatment technology in relation to potential health and environmental risks. At this time, all NSF/ANSI Standards meet or exceed established POU and POE effluent criteria at EPA-regulated levels for all drinking water health contaminants.

EPA Response: Please see section 10.5 of the EPA response in this *Response to Comments* document. The EPA has amended language to include all types of POU/POE systems that meet standards as opposed to only RO systems. The EPA has provided compliance flexibility by providing a two-year capital improvements extension of the MCL compliance deadline allowed by Section 1412(b)(10) of SDWA. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions.

Water Quality Association (WQA) (Doc. #1694, SBC-044988)

Moreover, under the Safe Drinking Water Act (SDWA), POU/POE water treatment systems can only be used for compliance in small water systems (10,000 people or less), although their use is contingent on state-specific guidelines. The EPA has always allowed consideration of POU and POE as a Small Systems Compliance Technology (SSCT) for all size categories served by small systems (e.g., Arsenic SSCT - 40 CFR Section 141.62(d), Radionuclides SSCT - 40 CFR Section 141.66(h), Point-of-Use or Point-of-Entry Treatment Options for Small Drinking Water Systems - EPA 815-R-06-010). WQA recommends that Tables 20 and 22 be expanded to allow small systems to consider these options for populations up to 10,000 by replacing the term "Not Applicable" with "Data Unavailable."[FN7: EPA-HQ-OW-2022-0114-0027, Table 20 & 22] This will help clarify that small water systems should conduct their analysis to determine the feasibility of this technology for any project size within that range and allow them to choose the best solution available.

Considering ongoing issues with compliance for other contaminants and some of the complications and limitations associated with the treatment of PFAS chemicals, these water systems are more likely to utilize POU/POE going forward. According to the EPA's Safe Drinking Water Information System (SDWIS) data, between 2008 and 2018, 2720 small community water systems experienced at least one MCL violation, with a total of 31,127 MCL violations reported. Of those, 68% were very small systems providing water to less than five people, many of which were chronic violations. [FN8: Lane, K., Reckhow, D., Tobiason, J., & Kumpel, E. (2023). Triple-bottom-line approach for comparing point-of-use/point-of-entry to centralized water treatment. AWWA Water Science, e1320. https://doi.org/10.1002/aws2.1320 Page 5.] WQA would welcome the opportunity to work with the EPA on guidance for systems that elect to use POU/POE technology.

EPA Response: Please see section 10.5 of the EPA response in this *Response to Comments* document. In response to the commenter's request, the EPA changed the way information was displayed; the EPA notes that neither of these changes imposes nor relieves any rule requirements and only serve to recharacterize the way the EPA reports available technologies.

Water Quality Association (WQA) (Doc. #1694, SBC-044985)

Lab Capabilities

WQA, like other testing and certification agencies, has a laboratory fully accredited by the American National Standards Institute's National Accreditation Board (ANAB) and Standards Council of Canada (SCC). The laboratory provides certification of products and indicates that a third-party organization has monitored the manufacturer's operations to ensure they meet guidelines for manufacturing processes and materials used. Products are tested to ensure compliance with industry standards, performance, and certification requirements. Although current industry standards test to 20 ppt for PFAS chemicals, WQA's Laboratory has been able to review existing performance testing data to 5 ppt (PFOA, HFPO-DA, PFDA, PFHpA, PFNA) and 10 ppt (PFOS, PFBS, PFHxS). WQA can currently evaluate product testing to a reporting limit of 1 ppt for PFAS, which will increase the precision in determining the POU/POE industry's ability to assist with addressing this public health issue.

Certification of products, processes, or services provides assurance that they comply with specified requirements in standards and other normative documents. In the case of certified POU/POE products, accredited Certification Bodies (CBs) develop certification schemes that include initial product testing, initial factory inspection, and compliance with the applicable health and safety product standards, including marking and labeling requirements. CBs also require annual surveillance inspections that consider the quality management system, retesting requirements, and frequency, modifications to certified products, and revisions to product standards.

EPA Response: Please see sections 10.1 and 10.5 of the EPA response in this *Response to Comments* document.

New Jersey Department of Environmental Protection (NJDEP) (Doc. #1699, SBC-045041)

Point-of-Use Treatment:

NJDEP recommends that EPA provide clarification on if Point-of-Use (POU) GAC, reverse osmosis, and anion exchange systems meet the definition of Best Available Technologies (BAT)s under Section A of its proposal. EPA would require that the BATs bring all water in a system into compliance. However, POU treatment units inherently can only treat water at a single line, or sample location in the system, and would not effectively treat all water in the system.

EPA Response: Please see sections 10.5 and 10.1 of the EPA response in this *Response to Comments* document.

State of Vermont Agency of Natural Resources and Department of Health (Doc. #1708, SBC-045116)

c. The feasibility of POU filters should be considered for non-community systems as discussed elsewhere in these comments.

EPA Response: Please see section 10.5 of the EPA response in this *Response to Comments* document.

State of Vermont Agency of Natural Resources and Department of Health (Doc. #1708, SBC-045092)

Reliance on Point of Use (POU) treatment, while well-intentioned may not always be small system friendly, especially for systems near the 3,300 population "cut-off" identified in the proposed regulation. We support the consideration of POU treatment in the right application, however, it is necessary that EPA provide additional information about how to establish representative sampling protocols following POU installation and guardrails on how to implement a POU program. The existing POU guidance from EPA predates PFAS and does not provide adequate support to states weighing their options; it also provides broad authority pertaining to creating "representative" sampling protocols post-POU installation. Given that there are no or limited NSF/ANSI standards for the reduction of PFAS, either that certification will need to happen, or EPA will need to provide treatment specifications to ensure it truly is Best Available Technology (BAT). We are concerned that lower income citizens are unable to afford to replace their own filters when needed and would otherwise be at the mercy of the water system to provide replacement filters/cartridges based on, at times, an assumption that the treatment has worked effectively up to the point of replacement.

EPA should consider limiting the POU aspect of the rule to NTNC systems and limited community systems. There are concerns with the regulation as currently drafted whereby it would mean a water system would be attempting to manage upwards of 1,000 tap filters which may not be achievable. The post-installation framework must be set in regulation and be uniform. The regulation needs to actively and thoughtfully guard against a scenario where a system installs treatment, demonstrates PFAS reduction, transitions to 3-year monitoring, to find out 2.5 years later that they are breaking through and exceeding the Heath Advisory, MCLG, and MCL based on unmaintained POU devices.

EPA Response: Please see section 10.5 of the EPA response in this *Response to Comments* document. The EPA appreciates the commenter's feedback on what kind of guidance to provide. POU/POE devices are rated for treated volumes as well as time; these may come with indicators or must show the device is capable of exceeding a margin of safety for the rating. The EPA notes that POU/POE devices must be maintained by the water system if it is using them for compliance purposes. The EPA is not proscriptive in the chosen method to meet the regulation provided that the system is in fact meeting the regulation.

National Ground Water Association (NGWA) (Doc. #1804, SBC-045460)

1. POE and POU water treatment products, with tested efficacy to a third party NSF/ANSI standard, should be incorporated as approved methodology for small systems to meet compliance.

2. NSF/ANSI 53 as well as NSF/ANSI 58 are current standards that test efficacy to a 70 ng/L endpoint. Currently the ANSI process has incorporated changes to a 20 ng/L endpoint, but will need time to update the standards to meet any new MCL. There should be a grandfathering of such products until the standards are updated.

EPA should provide time in implementation for National Sanitation Foundation (NSF) and American National Standards Institute (ANSI) processes to catch up with regulatory health protection requirements. Third-party certified products protect the consumer.

EPA Response: Please see section 10.5 of the EPA response in this *Response to Comments* document. The EPA agrees that POU RO devices may be a cost-effective option for small systems in some circumstances and should the NSF/ANSI standards change to be at least as stringent as the MCL they may be listed as a SSCT option.

John Mayo (Doc. #2707, SBC-046317)

Regarding the EPA proposed action on PFAS, my comment is 'out of the box', and is the result of 7 years of intensive 'research and investigation' of our local water utility, which is a 'poster child' for the majority of American water utilities, i.e., they are old, outdated, and the cost of bringing them up to par is massive, resulting in many/most not being able to generate the funds required, therefore, something more 'personal' in nature, that is also more cost effective appears

to be the better option. Reverse Osmosis filters eliminate the majority of chemicals, and if necessasry, the EPA could develop one that removes PFAS more efficiently, and then provide each user, such a filter. Filters would allow bother the EPA and more importantly, the consumer, to get, and stay ahead of harmful contaminants; those we know about today, as well as any that may 'graduate' onto the harmful to health list. Less expensive than bringing an antique system up to date, while providing 'immediate' trust and confidence in a 'purer product'.

EPA Response: Please see section 10.5 of the EPA response in this *Response to Comments* document. The EPA agrees that POU RO devices may be a cost-effective option for small systems in some circumstances and should the NSF/ANSI standards change to be at least as stringent as the MCL they may be listed as a SSCT option.

Breast Cancer Prevention Partners (Doc. #2743, SBC-047290)

We also urge you to provide activated carbon filters at the household level to filter contaminants as they are being regulated and mitigated.

EPA Response: Please see section 10.5 of the EPA response in this *Response to Comments* document. The best compliance option for a particular system is a site-specific determination. Should POU activated carbon filters be deemed the best compliance option for a particular system, then that particular system would be responsible for providing and maintaining those devices.

California Association of Mutual Water Companies (Doc. #3072-25, SBC-047372)

My name is Susan Allen, and I am the managing member services director for the California Association of Mutual Water Companies, which is a professional association that helps small and very small systems with connections between 15 and 3,000 throughout the state of California. We would like to raise concerns that are unique to these very small systems that we don't believe the EPA proposal has fully addressed. The first is in the treatment technologies that have been identified. We wanted to make you aware that for other contaminants, the State of California's Division of Drinking Water, which is part of the California State Water Resources Control Board, has identified that the kinds of treatment that you've proposal which are best available technologies are not economically feasible for systems with less than 200 connections, and they're moving toward having very small systems use point of use and point of entry devices. So, we would like to have point of use and point of entry be included as technologies that are available for resources and knowing that the costs include things like pilot testing and a lot of other compliance requirements, those costs would be challenging for small systems to face. We ultimately would also appreciate help in finding options that are scalable to the tiny systems and welcome any work that EPA could do on that front as well.

EPA Response: Please see section 10.5 of the EPA response in this *Response to Comments* document. The EPA agrees that small systems may benefit from compliance technologies that are different from larger water systems. The EPA has published an analysis to

this effect, which is summarized in section 10.4 in the preamble; small systems costs were evaluated in the *Best Available Technologies and Small System Compliance Technologies for PFAS in Drinking Water* document section 6 as well as the *Technologies and Costs for Removing Per- and Polyfluoroalkyl Substances from Drinking Water* document.

Nebraska Department of Environment and Energy (NDEE) (Doc. #1653, SBC-043210)

The identification of POUs (RO/NF) as viable treatment options ignores the difficulty that small systems and their operators encounter in managing treatment technologies. Only the smallest systems with no other option should consider POU devices.

EPA Response: Please see section 10.5 of the EPA response in this *Response to Comments* document. The EPA thanks the commenter for providing its prospective and notes that so long as the rule is being met EPA is not prescriptive on the technology used to meet it. The EPA allows individual systems, provided there are not additional state, local, territorial, or Tribal, rules to consider, to determine the best ways to comply in individual circumstances.

Wyoming Department of Environmental Quality (WDEQ) (Doc. #1716, SBC-044762)

11. WDEQ Has Concerns with Point-of-Use and Point-of-Entry Filtration Devices/or PFAS Treatment and MCL Compliance of Small Systems

WDEQ is concerned with the proposed use of Point-of-Use (POU) and Point-of-Entry (POE) devices for the removal of PFAS from drinking water, while recognizing they may be an appropriate solution in certain circumstances. Manufacturers of these devices have not demonstrated the ability to meet the proposed MCL of 4.0 ppt. Currently, these devices can only remove PFAS down to 20 ppt. POU/POE devices are not regulated by the WDEQ, and it has been WDEQ's experience that homeowners tend to either discontinue use of the POU/POE devices or not maintain them over time. States may not have adequate or sustainable resources to assist homeowners with these devices over time, and the burden would shift to homeowners, who, particularly in overburdened communities, would likely be unable to sustain them in the long term.

WDEQ recommends that EPA reevaluate accepting POU/POE devices regardless of third-party certification achieving standards equal to EPA's PFAS MCLs due to the lack of oversight and accountability inherent in POU device maintenance and operation. If this option is retained in the final rule, EPA needs to recognize the additional burden placed on states to consider and develop appropriate oversight measures.

EPA Response: Please see section 10.5 of the EPA response in this *Response to Comments* document. The EPA thanks commenter for providing its perspective.

Steve Sears (Doc. #2383, SBC-047498)

Dear Michael Regan,

I got tired of waiting and added a Reverse Osmosis Filtration system with ACTIVE CARBON FILTERS. My research found that the ACTIVE CARBON was a major eliminator of the PFAS chemicals in our drinking water. I would like to suggest that the EPA provide funds for the installing of a similar system by homeowners since getting companies like AQUA to do the filtration seems impossible!!

EPA Response: Please see section 10.5 of the EPA response in this *Response to Comments* document. The EPA refers commenter to the summary of major comments for this section. The EPA also notes that POU/POE devices may not be the best solution for every system. The passage of the IIJA, also referred to as the BIL, invests over $11.7 billion in the DWSRF; $4 billion to the DWSRF for Emerging Contaminants; and $5 billion in EC-SDC grants. These funds will be available to assist PWSs with the costs of installation of treatment when it might otherwise be cost-challenging. These funds can also be used to address emerging contaminants like PFAS in drinking water. More information on BIL can be found in section 2.4 of the EPA response in this *Response to Comments* document.

California Association of Mutual Water Companies (Doc. #1676, SBC-043775)

Affordability vs. Economic Feasibility of Treatment Systems

The proposal identifies three treatment technologies available to remove PFAS and advances an assessment that the technologies are affordable based on federal funding allocations to provide support and assistance to small systems and systems serving disadvantaged communities. However, economic feasibility and affordability are two different concepts.

CalMutuals would like to call attention to the fact that the Division of Drinking Water (DDW) of the California State Water Resources Control Board has determined that for other contaminants similar treatment technologies are not economically feasible options for systems with less than 200 connections. As a result, DDW has recommended the use of Point of Use and Point of Entry Devices (POU/POE) for systems with less than 200 connections despite manufacturer disclaimers that these devices are not intended to bring water systems into compliance with official contaminant standards. CalMutuals welcomes EPA engagement in identifying realistic and economically feasible treatment technologies for very small systems and further requests that guidelines for allocation of available funding includes all technologies, including POU/POE if very small systems are required to implement this inferior option. Resources to provide technical support and address costs of devices, installation, monitoring and regulatory compliance are critical to facilitating compliance by very small systems with the proposed MCL.

EPA Response: Please see section 10.5 of the EPA response in this *Response to Comments* document. The EPA found affordable and economical BATs for all system sizes; the

previously mentioned section, as well as the EA and the EPA response to comments on the EA can provide more information.

Anonymous (Doc. #2312, SBC-047307)

Another public commenter, Catherine Buchanan, suggested the use of activated carbon filters while water treatment facilities are updated to treat for PFAs and was baffled by the reluctance of the panel to inform the public of their effectiveness. Upon further research, I found that even the official EPA website has an article titled "Reducing PFAS in Drinking Water with Treatment Technologies" which lists "Activated Carbon Treatment" as an effective adsorbent method for PFAS. Additionally, the article states that the granular activated carbon "has been shown to effectively remove PFAS from drinking water when it is used in a flow through filter mode after particulates have already been removed". I agree with Catherine Buchanan's opinion that the information should be spread more widely. If EPA believes that these filters are not effective enough, then I believe the EPA should suggest alternatives for civilians to better filter their water of these contaminants. While the proposed rule is still being discussed, people every day are drinking water with PFAS, and if/when the final rule is passed, it will take time for the treatment facilities to update. Additionally, information about PFAS should be more widespread since I believe that not many people even know about the existence of these chemicals. Overall, it is crucial that the public is informed to ensure the safety of the public.

EPA Response: Please see section 10.5 of the EPA response in this *Response to Comments* document. The EPA agrees that informed stakeholders make better decisions and plans to continue to communicate information to aid the public in their understanding of PFAS risks. Please see section 1.2 of the EPA response in this *Response to Comments* document regarding risk communication and anticipated materials. The EPA refers commenter to the summary of major comments for section 10.5 of the EPA response in this *Response to Comments* document for information on POU devices and why they are not currently a compliance option but may be in the future.

North Carolina Division of Water Resources (NCDEQ) (Doc. #1652, SBC-044199)

9. NCDEQ recommends that EPA provide guidance on the BAT options offered that would be effective on a small enough scale to be used at these small water systems.

NCDEQ does not have experience with very small treatment units for PFAS treatment. However, we understand the importance of ensuring treatment units are correctly sized for the water system.

EPA Response: Please see section 10.5 of the EPA response in this *Response to Comments* document. After finalization of the PFAS NPDWR, the EPA also intends to provide support to utilities, primacy agencies, and other interested parties to ensure successful rule implementation and plans to consider the topics suggested by the commenter as the agency develops implementation materials for the final NPDWR.

National Ground Water Association (NGWA) (Doc. #1804, SBC-045468)

Small Water Systems and Private Wellowner Consideration – EPA should consider the implication of setting MCLs for these PFAS on the protectiveness of small water system consumers and private well owners which would choose decentralized point-of-entry/point-of-use treatment technologies. EPA should support research in decentralized PFAS treatment systems.

EPA Response: Please see section 10.5 of the EPA response in this *Response to Comments* document. The EPA has considered the implication of setting MCLs on small water systems and refers commenter to the *Best Available Technologies and Small System Compliance for Per- and Polyfluoroalkyl Substances (PFAS) in Drinking Water* document. The EPA notes that the SDWA applies to PWSs that regularly serve a minimum of 25 people or 15 service connections for at least 60 days a year. The EPA is sponsoring research for PFAS treatment systems, some of which may support decentralized treatment.

National Ground Water Association (NGWA) (Doc. #1804, SBC-045455)

Treatment technology - There are proven technologies to remove PFAS to below these limits, but designing, procuring, and constructing treatment takes time and money. EPA should direct research to support technologies that can be applied to small water systems and individual residences in the cases of applying alternative treatment technology. Are treatment technologies robust enough to maintain the level of performance to the MCL?

EPA Response: Please see sections 10.1 and 10.5 of the EPA response in this *Response to Comments* document. The *Best Available Technologies and Small System Compliance Technologies for PFAS in Drinking Water* document contains a list of technologies that can feasibly meet the MCLs for each small system size category listed in Section 1412(b)(4)(E)(ii) of SDWA. This includes small systems serving a population of 25-500 people. The EPA has provided compliance flexibility by providing a two-year capital improvements extension of the MCL compliance deadline allowed by Section 1412(b)(10) of SDWA in response to challenges raised by commenters surrounding capital improvement. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions. The EPA also requests the commenter to see the EPA response to comment Doc. #1634, SBC-043239 in section 10.2 in this *Response to Comments* document.

10.6 Treatment technology availability and capacity

Summary of Major Public Comments and EPA Responses

Many comments pointed to potential supply chain issues in both material and technical capacity such as qualified personnel, including certified operators. While there may be some supply chain issues in the short-term, comments from BAT suppliers indicate excess capacity as well as

investment in production. Furthermore, while there may be temporary difficulties in supply chain and technical capacity, the structural demand increase should lead to supply increases as well as innovation, such as proposed technologies that were not designated as BATs. This has been historically demonstrated multiple times in prior drinking water rules. For example, activated alumina was listed as one of the BATs and a SSCT for arsenic removal in the Arsenic Rule (USEPA, 2001), and EPA acknowledged granular ferric hydroxide media as a developing technology. While the granular ferric hydroxide media was not selected as a BAT/SSCT at the time due to lack of full-scale demonstration, these media became the predominant approach to addressing arsenic: Rubel (2003) stated that new iron-based materials could be "employed economically on a spent media basis without the incorporation of pH adjustment chemicals and equipment." McCullough et al. (2005) cited over a dozen demonstration sites across the US implementing granular iron media treatment technologies, providing further supporting evidence that new technologies evolved in the wake of the Arsenic rule to provide more efficient and economical treatment systems. Additionally, the present statutory standard for "best available technology" under 1412(b)(4)(D) represents a change from the provision prior to 1986, which required the EPA to judge feasibility on the basis of "best technologies generally available" (BTGA). The 1986 Amendments to the SDWA changed BTGA to BAT and added the requirement that BAT must be tested for efficacy under field conditions, not just under laboratory conditions. The legislative history explains that Congress removed the term "generally" to assure that MCLs "reflect the full extent of current technology capability" [S. Rep. No. 56, 99th Cong., 1st Sess. at 6 (1985)]. Read together with the legislative history, the EPA has concluded that the statutory term "best available technology" is a broader standard than "best technology generally available," and that this standard allows the EPA to select a technology that is not necessarily in widespread use, as long as its performance has been validated in a reliable manner. Indeed, the 1991 Lead and Copper Rule stated, "as long as it has been tested beyond the laboratory under full-scale conditions for other contaminants, and the performance of the technology for lead and copper may reasonably be projected based upon other available treatment data (i.e., laboratory or pilot scale), the EPA believes the technology can be established as BAT." For additional discussion on how the agency considers analytic feasibility and cost when establishing the MCL, please see section 5 of the EPA response in this *Response to Comments* document.

Several commenters provided comment on market capacity and demand for GAC and other treatment media. The EPA notes that a major manufacturer of municipal activated carbon submitted a comment on the draft PFAS NPDWR that stated they were prepared for the significant increase in market demand (see Calgon Comment Document #1620). Additionally, the ability to reactivate GAC media for continued PFAS removal takes pressure off the carbon market by providing additional capacity in the US. There are also many US manufacturers of AIX resin, contrary to some ascertains. Some commenters stated that requirements under Build America, Buy America Act (BABA) can make acquisition of treatment materials difficult. BABA does not apply if systems are not seeking funding through the DWSRF/BIL funding programs; more information on BABA is in section 2.4.

With respect to the challenges raised by commenters surrounding capital improvement, the EPA has provided compliance flexibility by providing a two-year capital improvements extension of the MCL compliance deadline allowed by Section 1412(b)(10) of SDWA. The EPA finds that the evidence submitted by commenters strongly supports that a significant number of systems covered by this rule will need two additional years to make capital improvements to meet the MCL. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions. Additionally, the EPA plans to continue its research as well as outreach efforts to help develop technical and operator capacities.

Individual Public Comments

North Penn Water Authority (NPWA) (Doc. #1470, SBC-043294)

Since Granular Activated Carbon treatment is effective at removing PFAS from water, it is certain that demand for this material around the country will increase, and most likely the cost will grow proportionately. Can an already stressed supply chain keep up with the added demand for this material?

EPA Response: Please see section 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions. The EPA notes there are other technologies and non-treatment options available to meet the final NPDWR, such as AIX.

Orange Water and Sewer Authority (OWASA) (Doc. #1524, SBC-042617)

• Supply Chain

o GAC Media

* Will there be enough GAC media available when it is needed to start up treatment and then replace spent media?

o Pressure Vessels

* Will supply chain impact the ability to get pressure vessels on order and installed by the compliance date

o Ion Exchange media

* Will there be enough IX media available when it is needed to start up treatment and then replace spent media?

EPA Response: Please see section 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may

affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions.

Water Environment Federation (WEF) (Doc. #1529, SBC-043307)

Supplies: Granular Activated Carbon (GAC) will face supply chain issues if the proposed regulation is approved. The waiting period for a supply of GAC has been reported to be as high as 9-24 months. IX resin lead times will be delayed as these are manufactured overseas.

EPA Response: Please see section 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions. The EPA notes that not all AIX resin is manufactured overseas.

Greater Cincinnati Water Works (GCWW) (Doc. #1550, SBC-042691)

We are also concerned that the EPA estimates do not account for the increase in demand for granular activated carbon and other treatment materials and reactivation services which will result from the sudden need for similar treatment at many facilities across the country. Based on conversations with our GAC supplier, one of the largest in the country, they are already very near their production capacity. Even with additional capacity coming online, we are concerned the availability of GAC will not meet the demand in the short timeframe given for compliance.

EPA Response: Please see section 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions.

Maine Water Utilities Association (MWUA) (Doc. #1567, SBC-042743)

Supply Chain/Procurement/Costs:

MWUA is also concerned that PWSs may face even greater procurement challenges when new national drinking water standards for PFAS are put in place. At times, carbon vessels have been delayed for months due to supply chain issues and increased demand. Different states also have different procurement laws that may need to be followed for design and construction services which add time to the overall project implementation schedule. EPA should be thinking ahead to authorities that exist, such as the Defense Production Act, to compel the quicker manufacturing of treatment components for PFAS treatment if necessary.

EPA Response: Please see section 10.6 of the EPA response in this *Response to Comments* document. The EPA has provided processes for a PWS unable to secure critical resources necessary for water treatment (see https://www.epa.gov/waterutilityresponse/how-use-

defense-production-act#Steps). For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions.

San Gabriel Valley Water Association (SGVWA) (Doc. #1580, SBC-042419)

Considerable Supply Chain Challenges: The number of advanced treatment systems that will be required is significant and will need to be expedited. These challenges also apply to the supply of the media required, treatment vessels, etc., for the construction of the treatment.

EPA Response: Please see section 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions.

Missouri River Public Water Supplies Association (MRPWSA) (Doc. #1581, SBC-042411)

Treatment — MRPWSA agrees that granular activated carbon and anion exchange should be effective to treat PFOA and PFOS to 4.0 ppt or lower but have concerns about the availability of treatment given the anticipated increase in demand, challenges with use of anion exchange in surface water applications, and waste disposal.

EPA Response: Please see section 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions. Concerns regarding BATs such as AIX, are addressed in section 10.1 of the EPA response in this *Response to Comments* document. For concerns related to waste disposal, please see section 10.4 of the EPA response in this *Response to Comments* document.

Washington Suburban Sanitary Commission (WSSC Water) (Doc. #1585, SBC-042775)

Supply of adsorbents:

Due to the challenges of adsorbent regeneration, many utilities that have implemented PFAS treatment already have selected to replace adsorbents with virgin GAC or IX media. The EPA should evaluate the sufficiency of the national supply of GAC and IX adsorbents as well as sustainability and PFAS destruction effectiveness of disposal services in the determination of cost feasibility and implementation timeline.

EPA Response: Please see section 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to*

Comments document on extensions and exemptions. For concerns related to disposal, please see section 10.4 of the EPA response in this *Response to Comments* document.

New York Section American Water Works Association (NYSAWWA) (Doc. #1591, SBC-042376)

12. The Rule fails to address supply chain challenges. It has been our observation that since 2020, granular activated carbon costs have doubled. Is there a market cap for Granular Activated Carbon (GAC) or Ion Exchange (IX), and does the proposed rule move the nation's water supplies closer to fighting that market limitation? As supply reaches availability, price escalation and supply chain issues are to be expected. These supply chain issues must be considered in the cost impact evaluation.

13. Many utilities rely on GAC for treatment processes unrelated to this proposed regulation. The increased demand for GAC and resulting cost and supply chain impacts will be significant for water supplies that do not have to treat for perfluorinated compounds. This cost impact is not considered in the EPA's analysis and could be more significant than the direct impact of the rule itself.

EPA Response: Please see section 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions. More information on the EA can be found in section 13 of the EPA response in this *Response to Comments* document.

Lehigh County Authority (LCA) (Doc. #1600, SBC-042821)

3. Materials & Equipment Delays – Granulated activated carbon, one of the most common treatment technologies for PFAS, has been reported to have waiting periods of 9-24 months. Ion exchange resin is manufactured overseas, which will also delay delivery times. The current economic and supply-chain environment has also been causing long delays in the delivery of treatment equipment such as pumps, control systems, electrical components, and more. With a significant increase in demand for these specific types of materials and equipment to support utilities striving to achieve compliance with this rule, it is expected the problem to worsen and delays to be lengthened over the course of the compliance period.

EPA Response: Please see section 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions.

Massachusetts Water Works Association (MWWA) (Doc. #1601, SBC-042896)

Supply Chain/Procurement:

MWWA is also concerned that PWSs will face even greater procurement challenges when new national drinking water standards for PFAS are put in place. At times, carbon vessels have been delayed for months due to supply chain issues and increased demand. Different states also have different procurement laws that must be followed for design and construction services, which add time to the overall project implementation schedule. EPA should communicate with existing authorities, such as the Defense Production Act, to compel quicker manufacturing of treatment components for PFAS if necessary. We also note that Build America/Buy America provisions under BIL add complexity to securing water treatment components and appurtenances. EPA should communicate with Congress to remove this added burden, or EPA should provide a waiver for PFAS treatment components.

EPA Response: Please see section 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions. The EPA has provided processes for a PWS unable to secure critical resources necessary for water treatment (see https://www.epa.gov/waterutilityresponse/how-use-defense-production-act#Steps). Please note that there are significant US manufacturers including Purolite, Graver Technologies, Resin Tech Inc., AmeriWater LLC, etc.

Water Works Board of the City of Birmingham (BWWB) (Doc. #1602, SBC-043654)

8. Supply chain issues: With thousands of systems potentially needing to install treatment, the concerns are numerous and include: scarcity of GAC and IX media; vessels; other appurtenant equipment, and carbon reactivation service. It is unclear whether these concerns were appropriately taken into account in EPA's economic analysis.

EPA Response: Please see section 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions. More information on the EA can be found in section 13 of the EPA response in this *Response to Comments* document.

American Water Works Company Inc. (Doc. #1608, SBC-043993)

We are also concerned with the ability of the industry to increase GAC supply and reactivation service capacity in a timely fashion to meet the anticipated surge in demand for such services.

EPA Response: Please see section 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions.

American Water Works Company Inc. (Doc. #1608, SBC-043997)

American Water has concerns about the capacity of U.S. vendors to reactivate GAC, given the significant increase in demand from drinking water utilities as a result of this rule. Based on the number of facilities that we expect to be impacted by the proposed MCL, American Water projects that our added demand alone for GAC reactivation services could be in the range of 20 million to 50 million pounds per year, depending on actual bed volume capacities achieved. Based on a preliminary discussion with a major GAC supplier in the U.S., this volume may represent up to 30% of its total current annual reactivation capacity, which indicates that if other drinking water utilities have a similar demand for GAC reactivation services, there will be inadequate U.S. capacity. If American Water's projected needs are representative of the rest of the drinking water utility industry, and if utilities rely more heavily on GAC technology because of the additional benefits it provides or the challenges of using AIX in surface water applications, the demand for GAC supply and reactivation services may increase more than 10-fold over current capacity.

EPA Response: Please see section 10.6 of the EPA response in this *Response to Comments* document. The EPA notes that the choice of BAT depends on site-specific conditions, and the available data is not sufficient to support the generalization that surface waters may benefit more from GAC than AIX or draw any other broad conclusions. Please see section 10.1 of the EPA response in this *Response to Comments* document regarding BAT identification and evaluation and section 10.3 of the EPA response in this *Response to Comments* document regarding PFAS co-removal for more information about this topic. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions.

American Water Works Company Inc. (Doc. #1608, SBC-043984)

Treatment – American Water agrees that granular activated carbon and anion exchange should be effective to treat PFOA and PFOS to 4.0 ppt or lower but has concerns about the availability of treatment given the anticipated increase in demand, challenges with the use of anion exchange in surface water applications, and waste disposal.

EPA Response: Please see section 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions. Concerns regarding BATs such as AIX are addressed in section 10.1 of the EPA response in this *Response to Comments* document. For concerns related to waste disposal, please see section 10.4 of the EPA response in this *Response to Comments* document.

Beaufort-Jasper Water & Sewer Authority (BJWSA) (Doc. #1618, SBC-042932)

The proposed rule will result in an unprecedented demand not only on the construction industry, but also on the materials and resources needed to construct and operate the new facilities. It is not clear how the demand for PFAS removal technologies will be addressed nationwide. For example, GAC is a proven PFAS barrier. Is there enough capacity in the GAC market to supply and reactivat!:! the amount of carbon needed to remove PFAS below required levels nationwide?

EPA Response: Please see section 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions.

Calgon Carbon Corporation (Doc. #1620, SBC-042939)

May 26, 2023

Michael S. Regan Administrator

Environmental Protection Agency 1200 Pennsylvania Avenue, N.S. Mail Code: 4607M

Washington, DC 20460

Re: Preparedness to Provide Water Treatment Systems and Services for Compliance to the EPA's Proposed Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation (Docket ID: EPA-HG-OW-2022-0114)

Administrator Regan,

As a manufacturer, Calgon Carbon Corporation (Calgon Carbon) typically refrains from offering comment on regulatory matters. In our opinion, as water and air treatment experts, it would not be appropriate for us to opine on the merit of regulation nor the limits proposed. However, since the proposed limits were announced, concern about industry preparedness has been raised at industry conferences and trade shows, by the media, and even by customers. The intent of this letter is to inform you that Calgon Carbon has been preparing and will continue to prepare to meet the market needs to achieve compliance. Specifically:

• Our products are proven capable of achieving the proposed regulatory limits.

o For over 20 years, Calgon Carbon has supplied proven solutions for PFAS treatment of both drinking water and wastewater. Today, we have over 150 full scale systems (designed for PFAS removal and averaging over 1500 gpm each in treatment capacity) installed across the United States. Calgon Carbon's U.S. produced granular activated carbon removes PFAS from drinking water to at or below the draft MCLs as evidenced by full scale data, pilot data, and laboratory data.1,2 [FN1: Westreich, P, Mimna, R, Brewer, J, Forrester, F. The removal of short-chain and long-chain perfluoroalkyl acids and sulfonates via granular activated carbons: A comparative

column study. Remediation. 2018; 29: 19– 26. https://doi.org/10.1002/rem.21579], [FN2: McNamara, J.D., Franco, R., Mimna, R. and Zappa, L. (2018), Comparison of Activated Carbons for Removal of Perfluorinated Compounds From Drinking Water. Journal - American Water Works Association, 110: E2-E14. https://doi.org/10.5942/jawwa.2018.110.0003] With a well-designed carbon adsorption system, utilities can effectively and consistently meet the limits recently proposed by the U.S. EPA.

• We have invested a significant amount of capital to increase existing capacity in several areas.

o Granular Activated Carbon: In 2019, Calgon Carbon made the decision to invest ~$185MM to significantly expand the production of our reagglomerated, bituminous coal based granular activated carbon in Pearl River, Mississippi. Reagglomerated, bituminous coal based granular activated carbon (specifically Filtrasorb® 400) has consistently demonstrated superior removal of PFAS compared to other types of activated carbon. The new production line is slated to start-up in 2023, just a few months from now, and will be capable of making this high performing product.

o Carbon Adsorber Equipment: Calgon Carbon fabricates carbon adsorption equipment in Pittsburgh, Pennsylvania. This equipment facilitates the efficient use of granular activated carbon at treatment sites. In 2020, Calgon Carbon invested capital to expand our production by 25% and, through optimization efforts, we expect to increase capacity by another 15% within the next year. In addition, we are actively working with third party partners to secure equipment capacity and further expand our fabrication footprint.

o Reactivation: Calgon Carbon operates five reactivation facilities across the United States. For background, reactivation is a high temperature thermal process that restores granular activated carbon to near-original state and, through the process, destroys the contaminants adsorbed onto the media. In 2019, we expanded our reactivation capacity in Pittsburgh, Pennsylvania, and we are actively evaluating investment for additional capacity in the USA.

o Compliance to Build American, Buy American Act (BABAA): Our coal based activated carbon products and carbon adsorption equipment are sourced from and produced in the USA. We are fully capable of offering solutions compliant to the requirements set forth in BABAA.

• Our reactivation technology can effectively be deployed to remove and destroy PFAS to > 99.99% efficiency.

o The effectiveness of thermal destruction has been a question posed by industry for some period of time and more recently seeing a greater level of inquiry due to nature of PFAS chemistry. Scientific research and laboratory work supported the ability to destroy PFAS through reactivation. However, in 2021, Calgon Carbon invested in a full-scale demonstration of reactivation. The results of this study, which are detailed in a peer reviewed article in the September 2022 edition of the Remediation Journal, proved the effectiveness of the technology. This essentially ends PFAS's reign as a "Forever Chemical" at a much lower life-cycle cost than landfilling or incineration.3 [FN3: DiStefano, R., Feliciano, T., Mimna, R., Redding, A, and

Matthis, J. (2022), Thermal destruction of PFAS during full-scale reactivation of PFAS-laden granular activated carbon. Remediation. 2022; 32: 231-238. https://doi.org/10.1002/rem.21735]

EPA Response: Please see section 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions. The EPA appreciates the detailed information on Calgon Carbon's expanding capacity as well as treatment expertise.

Colorado Water Utility Council (CWUC) (Doc. #1622, SBC-044047)

28. EPA estimates GAC treatment will be sufficiently available to support cost-effective compliance with this proposed regulation, and requests comment on whether additional guidance on applicable circumstances for GAC treatment is needed.

a. CWUC is concerned whether there is enough manufacturing capacity to supply all water systems nationwide with the GAC they need.

EPA Response: Please see section 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions.

Aqua America, an Essential Utilities Company (Doc. #1623, SBC-043069)

Implementation will Further Strain the Supply Chain

Since the COVID-19 Pandemic, water systems have been faced with a strained supply chain. This strain has led to increased purchasing costs, longer lead times for equipment or materials, and limitations on the products that are available. Lead times for key equipment (e.g., vessels, carbon or resin media, electrical components, etc.) have already increased to beyond 12 months, depending on the equipment and the degree of specialization it requires. GAC media and IX resins are not widely available from more than a few suppliers. The current expectation is that orders for replacement GAC media should be made at least 6 months in advance of when the replacement is needed and for new customers the lead time is upwards of 12-18 months. IX resin supplies may face similar issues, given that the resin is not manufactured domestically and with the increase in demand much of the GAC required to treat PFAS will need to be acquired from suppliers in China and India. Additionally, there are presently only five manufacturing facilities across the U.S. and Canada for GAC vessels. These facilities will be heavily relied upon to provide most vessels for GAC. These issues are also impacting major ancillary equipment like electrical panels, motor control centers, etc. In Aqua's experience constructing several PFAS treatment systems since 2017, lead times for key equipment to construct PFAS treatment have only increased.

EPA Response: Please see section 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions. The EPA notes that there are AIX resins that are manufactured in the United States.

WaterPIO (Doc. #1624, SBC-043463)

4. There simply won't be enough water treatment systems or filtration media available for public water systems to use to meet the proposed MCLs and HI.

EPA Response: Please see section 10.6 of the EPA response in this *Response to Comments* document.

Water One - Water District No. 1 of Johnson County, Kansas (Doc. #1627, SBC-042329)

Operations and Supply Chain Challenges

From an operational perspective, water utilities will essentially need to implement water treatment that has a 100% removal rate of PFAS compounds to achieve compliance under the proposed regulation. At this time, the technologies and available supplies for this are currently not available at the scale needed to achieve this standard nationwide and it would likely take years for the already-taxed supply chains to catch up. GAC, ion exchange, and appropriate membranes are all either in short supply or extremely hard to implement at the scale needed. Currently, GAC vessels have lead times of over 18 months in the US and this expecting to get worse.

EPA Response: Please see section 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions. The EPA disagrees that a 100 percent removal rate is required by all utilities. For example, if a utility has influent water containing PFOS at a level of 15 ppt, it will need to remove approximately 11 ppt for compliance which is about a 75 percent removal rate. For more information on this topic, please see section 6 of the EPA response in this *Response to Comments* document.

Association of State Drinking Water Administrators (ASDWA) (Doc. #1628, SBC-044112)

Resource Concerns

ASDWA recommends that EPA continue funding PFAS research on treatment and mitigation at water systems to help offset the cost increases affecting capital costs for these projects.

As a result of the COVID-19 pandemic and ongoing geopolitical conflicts, primacy agencies and water systems have already experienced ongoing effects on the global supply chain. Primacy

agencies have reported that systems have had to delay the installation of treatment technologies due to supply shortages. Specifically, one primacy agency identified that the lead time needed for a granular activated carbon (GAC) treatment vessel was over 18 months for one installation of PFAS treatment. Additionally, primacy agencies have reported media and other equipment shortages. In conjunction with inflation, these shortages have caused project costs to increase across the board. These global supply chain and treatment shortage issues are significant feasibility concerns with rule implementation.

EPA Response: Please see section 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions.

Village of Woodbury (Doc. #1629, SBC-042957)

11. It is stated, the "EPA estimates GAC treatment will be sufficiently available to support cost-effective compliance with this proposed regulation, and requests comment on whether additional guidance on applicable circumstances for GAC treatment is needed". The rule should consider supply chain challenges and costs of inflation due to availability of media. Additionally, water suppliers using this technology for other purposes are at a disadvantage if this is the only sufficiently available treatment technology.

EPA Response: Please see section 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions. For information on inflation impact, please see section 13.4 of the EPA response in this *Response to Comments* document. While GAC is anticipated to be the most widely used technology, and a major GAC supplier as well as reactivator has provided information on expanded capacity, facilities, and efficiency, it is not the only treatment technology. The EPA anticipates AIX as well as high pressure membranes will also be in sufficient capacity as further described in this section of the EPA response in this *Response to Comments* document .

Association of Environmental Authorities (AEA) (Doc. #1635, SBC-042965)

Adopting the NPDWR is also likely to result in higher demand for granulated activated carbon. Availability and supply chain problems could interfere with utilities' ability to comply.

EPA Response: Please see section 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions.

National Rural Water Association (NRWA) (Doc. #1641, SBC-043266)

Capacity is limited. There are limited entities that construct and install the necessary equipment. In Kentucky, water systems using GAC are already experiencing uncertain and timely deliveries for material replenishment and regeneration orders.

EPA Response: Please see section 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions.

American Farm Bureau Federation et al. (Doc. #1642, SBC-043491)

Specific to rural drinking water utilities, we are concerned about the availability of these technologies, especially since drinking water utilities will only have three years to obtain, install and get these systems up and running. We have already heard that supply chain issues are impacting technologies like granular activated carbon, and it will only be further squeezed as the 66,560 water systems in our country all work to meet the implementation deadline. Small, rural facilities will undoubtably face more challenges in obtaining these technologies, as the priority will be placed on large, metropolitan systems.

EPA Response: Please see section 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions. While there are many PWSs in the United States, approximately 4,100 to 6,700 systems, or about 6-10 percent, are anticipated to require installed treatment, not all systems, more information on how many water systems may be drawn into treatment may be found in section 6 of the EPA response in this *Response to Comments* document.

Savannah River Nuclear Solutions LLC (Doc. #1647, SBC-043326)

Comment 2

Has EPA considered potential supply chain issues if the proposed rule is approved? The current waiting period for a supply of GAC has been reported to be as high as 9-24 months. AIX resin lead times could be significantly delayed as many of these are manufactured overseas.

EPA Response: Please see section 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions.

New England Interstate Water Pollution Control Commission (NEIWPCC) (Doc. #1650, SBC-043148)

Treatment Technologies

Our member states are also concerned by the effects the rule will have on the availability and cost of treatment technologies. The rising demand for granular activated carbon (GAC), combined with ongoing supply chain issues, have already led to increased costs and lead time to acquire treatment media. As the rule is implemented, without coordinated efforts, we expect those costs, and the cost of disposal of spent media, to further increase.

EPA Response: Please see section 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions. For information on costs related to disposal, please see section 10.4.2 of the EPA response in this *Response to Comments* document.

National Association of Clean Water Agencies (NACWA) (Doc. #1659, SBC-043156)

Without a PFAS Destruction Technology Readily Available, EPA's Reliance on Treatment Technique Fails to Consider Indirect Impacts

EPA's proposed rule points to granulated activated carbon (GAC), anion exchange, and reverse osmosis as possible advanced treatment techniques PWSs should consider to remove PFAS from drinking water. Outside the direct costs associated with installing these advanced treatment techniques, each raises other concerns and indirect impacts that should be more thoroughly considered by EPA.

For example, PWSs selecting GAC technology will need millions of pounds of GAC to comply with EPA's proposed regulation. Currently, there are considerable supply chain issues and long waiting periods to purchase virgin GAC.

EPA Response: The EPA is not prescribing a particular treatment technique in this regulation; rather, the agency has identified Best Available Technologies (please see section 10.1 of the EPA response in this *Response to Comments* document) for treatment to comply with the rule. Please see section 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions. Information on the EPA cost analysis, including outside direct costs, is in section 13 of the EPA response in this *Response to Comments* document.

City of Allentown and Lehigh County Authority (LCA), Pennsylvania (Doc. #1667, SBC-043681)

2. Materials & Equipment Delays – Granulated activated carbon, one of the most common treatment technologies for PFAS, has been reported to have waiting periods of 9-24 months. Ion exchange resin is manufactured overseas, which will also delay delivery times. The current economic and supply-chain environment has also been causing prolonged delays in the delivery of treatment equipment such as pumps, control systems, electrical components, and more. With a significant increase in demand for these specific types of materials and equipment to support utilities striving to achieve compliance with this rule, it is expected the problem to worsen and delays to be lengthened over the course of the compliance period.

EPA Response: The EPA notes that there are AIX resins that are manufactured in the United States. Please see section 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions.

Aurora Water, City of Aurora, Colorado (Doc. #1669, SBC-043724)

EPA should also consider additional environmental impacts that will come from this proposal. There will be a significant increase in demand for GAC from water systems working to comply with this rule.

EPA Response: Please see section 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions. Please see section 14.1 of the EPA response in this *Response to Comments* document for how the EPA considered the social cost of carbon from this rule.

Aurora Water, City of Aurora, Colorado (Doc. #1669, SBC-043727)

Treatment Technologies

Aurora Water is also concerned about the increased demand for GAC and whether it will be sufficiently available to support cost-effective compliance with the proposed rule. After speaking with GAC suppliers, Aurora Water is very concerned with the ability to obtain GAC materials for PFAS treatment. With every water system in the area likely considering GAC treatment for their drinking water system demand is only going to rise. Considering the raw material availability and supply chain issues most manufacturers are facing, it is doubtful they will be able to keep up. Aurora Water suggests the EPA considers GAC availability for water systems when reconsidering the MCLs and implementation timeline for the proposed rule.

EPA Response: Please see section 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions.

Cleveland Water, City of Cleveland, Ohio (Doc. #1672, SBC-044923)

Section 7.1: Sufficiently available and Cost-effective

EPA specifically states in the preamble that it estimates GAC treatment will be sufficiently available to support cost-effective compliance with this proposed regulation. As mentioned earlier, water systems are already seeing approximately 18-month lead times on GAC vessels for PFAS treatment. This does not seem to be sufficiently available when that is half of EPA's proposed compliance timeline of three years. Should the rule be finalized in its current form, thus spurring additional nationwide demand for these products, one could assume these lead times will only get worse.

There is concern over who will get priority for new GAC as well. Those who already have existing contracts, whether the system is using GAC for TOC removal or compliance with a state PFAS MCL, are concerned new contracts may receive priority based on new prices or agreements. Another alternative, new contracts may not be awarded if demand is already too high to meet with existing contracts. Due to costs and other factors, GAC will likely be a top choice for many utilities required to apply treatment, therefore it is imperative the capacity of suppliers be thoroughly reviewed to ensure availability.

Another aspect of these technologies is that media does not maintain performance of PFAS removal forever. GAC can be reactivated, but only a finite number of times as some is lost each time. With levels proposed at the PQL, 4.0 ppt, even water systems that have already implemented one of these technologies for PFAS treatment will see increased costs and must revise treatment plans. Reliably treating down to this proposed level, which is half the level of the lowest state MCL, will require much more frequent replacement of media. This will significantly increase operation and maintenance costs. With only a select few GAC reactivation facilities in the country, significant transport costs, often time across state lines, will be required.

Cleveland Water wants to reiterate that EPA and water utilities are all working toward the same goal of protecting public health by providing clean, safe and affordable drinking water to the public. Affordability is a key term here and many utilities across the United States are struggling with the ability to maintain affordable rates in light of required capital and regulatory projects. It is crucial that regulations do not put unnecessary or significant financial burdens on ratepayers. As we saw during the COVID-19 pandemic, any economic hardship can cause individuals to have to make difficult choices like choosing between paying water bills and buying groceries. Access to safe, clean drinking water is a necessity, and we should be working to ensure this access is affordable and equitable.

EPA Response: Please see sections 10.1 and 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions. The frequency of media changeout was considered in the HRRCA section and details can be found in the *Technologies and Costs for Removing Per- and Polyfluoroalkyl Substances from Drinking Water* document.

A. O. Smith Corporation (Doc. #1674, SBC-043704)

6. Supply Chain

Given the Company's position as a global manufacturer and seller of third-party certified POU and POE systems that remove up to ninety-nine different health-based contaminants from drinking water, we felt it prudent to raise awareness around the global supply of certain carbons. As the EPA may be aware certain carbons – most notably coconut-based GAC – are sourced outside of the United States with the majority coming from the Asian sub-continent. While there are domestic sources such as bituminous coal, most GAC, and some other resins, among other treatment media will be sourced at a premium (i.e., higher cost) if carbon manufacturers and suppliers do not increase capacity as market dynamics change (e.g., public water system demand), not to mention having to deal with potential supply chain disruptions due to geo-political challenges.

Conclusion

Once again, A. O. Smith appreciates the opportunity to submit these comments to the U.S. Environmental Protection Agency regarding its request for comment on its PFAS National Primary Drinking Water Regulation Rulemaking. The proposed PFAS NPDWS raises a series of complex questions and challenges for the EPA and public water systems moving forward. A. O. Smith, and the broader water treatment industry, can play a vital role in mitigating adverse human health impacts posed by elevated levels of PFAS in the nation's drinking water. Along those lines the Company stands ready to be a resource to the EPA as it completes its work on the PFAS NPDWS. In the interim, A. O. Smith would welcome the opportunity to answer any questions the EPA may have with the respect to the Company's submission or other areas that the EPA would like to engage further on related to the PFAS NPDWS. Best Regards,

Joshua C. Greene, Esq.

Corporate Vice President, Government and Industry Affairs

A. O. Smith Corporation

Global Headquarters

11270 West Park Place Milwaukee, WI 53224

jcgreene@aosmith.com

EPA Response: The EPA thanks the commenter for its willingness to serve as a resource and invites the commenter to provide any data as well as other experiences and comments. Please see section 10.6 of the EPA response in this *Response to Comments* document.

Massachusetts Coalition for Water Resources Stewardship (MCWRS) (Doc. #1691, SBC-044328)

[The proposed MCLs raise the specter of serious unintended consequences that could pose public health risks for water consumers. Some of these are:]

d. As most water systems opt for GAC as the treatment of choice for PFAS, having thousands of new systems demanding GAC and GAC regeneration services will likely put a strain on suppliers and GAC services. The ability of the GAC industry to meet this new demand must be closely assessed before an MCL is finalized. Failure to do so will not only create higher costs for GAC but also jeopardize its availability for existing facilities that depend on this material for current public health protection.

EPA Response: Please see section 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions.

New Jersey Department of Environmental Protection (NJDEP) (Doc. #1699, SBC-045039)

Current supply-chain issues are leading to additional challenges for systems when trying to plan for and schedule media change-outs. This may pose an even greater challenge at the low levels proposed by EPA.

EPA Response: Please see section 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions.

New Jersey Department of Environmental Protection (NJDEP) (Doc. #1699, SBC-045037)

NJDEP has observed quite substantial lead-times on materials such as carbon, anion exchange media, media vessels, electronic components, and various other supply chain issues ranging from months to over a year. It is NJDEP's understanding that these supply chain issues have recently affected the timeframe for PFAS treatment installation for nearly every public water system, even those with expansive supply networks.

Granular Activated Carbon (GAC):

EPA estimates that GAC treatment will be sufficiently available to support cost-effective compliance.

EPA Response: Please see section 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions.

California Farm Bureau Federation (Doc. #1704, SBC-045074)

Specific to rural drinking water utilities, we are additionally concerned about the availability of these technologies, especially since drinking water utilities will be required no more than three years to obtain, install, and implement such systems. Further, we have been advised that supply chain issues are impacting technologies such as granular activated carbon, creating additional concern that supplies will be further limited. Historically, priority is often given to large, metropolitan systems, meaning rural facilities will undoubtably face more challenges in obtaining high-demand technologies.

EPA Response: Please see section 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions.

Wyoming Department of Environmental Quality (WDEQ) (Doc. #1716, SBC-044757)

8. Further Analysis Is Needed to Determine Whether the Increased Demand of PFAS Treatment Technology and Infrastructure Can Be Met by Industry in the Proposed Compliance Timeframe

Section XIII of the proposed PFAS NPDW rule does not provide information regarding analysis of whether the industries that supply PFAS treatment and remediation technology will be able to sustain the increased demand from PWSs once the PFAS NPDW rule is in effect; specifically, no analysis is provided as to whether a three-year timeline for compliance is achievable for PWSs that will need to implement PFAS treatment technology or source water replacement. Due to the extremely low concentrations proposed for PFAS MCLs, in addition to the proposed Rule Trigger Level of one-third the PFOA and PFOS MCLs and one-third the PFAS HI values, a significant percentage of PWSs may need to implement some measure of PFAS treatment technology. Many of the small and rural PWSs requiring treatment will choose granular activated carbon (GAC) for treatment due to lower relative cost and ease of operation. The EPA should consider developing more analysis on whether the industry can meet that anticipated demand. Many small and rural systems may be forced into more expensive treatment technologies, such as Reverse Osmosis (RO) or ion exchange, to meet the proposed compliance deadline as increased demand on GAC will reduce availability and increase costs. Such analysis should consider feasible disposal options for treatment media.

EPA Response: Please see sections 10.1 and 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to*

Comments document on extensions and exemptions. For concerns related to disposal options for treatment media, please see section 10.4.1 of the EPA response in this *Response to Comments* document as well as the Management of Treatment Residuals section as well as the *Interim PFAS Destruction and Disposal Guidance* document.

Water and Wastewater Equipment Manufacturers Association (WWEMA) (Doc. #1727, SBC-043524)

May 30, 2023

U.S. Environmental Protection Agency EPA Docket Center

Office of Ground Water and Drinking Water Docket

Mail Code 28221T

1200 Pennsylvania Ave., NW

Washington DC 20460

Submitted Electronically: htt ps: // www.requlat ions.gov; and via email: PFASNPD WR@epa.gov

RE: Docket ID No. EPA-HQ-OW-2022-0114

Attn: Alexis Lan

The Water and Wastewater Equipment Manufacturers Association (WWEMA) is pleased to submit the following comments on the U.S. Environmental Protection Agency's (EPA's) PFAS National Primary Drinking Water Regulation Rulemaking as published in the March 29, 2023 Federal Register. As the Association that represents PFAS technology solution providers to the water sector, we are providing comments focused on the treatment aspects of the proposed rule.

WWEMA and its members stand ready to support the water sector in removing PFAS compounds from drinking water and to work with EPA to ensure the adequate availability of PFAS removal treatment technologies. To accomplish this, it is critical to ensure that technology solution providers do not face barriers and unintended consequences in their efforts to provide safe drinking water to consumers across the country. Please see our comments below.

Comment #1: Product Waivers Required to Ensure BAT Capacity to Meet Demand

WWEMA agrees with EPA that the Best Available Technologies (BATs) for the removal of PFAS contaminants are granular activated carbon (GAC), anion exchange (AIX), and high-pressure membranes such as reverse osmosis (RO) and nanofiltration (NF). WWEMA disagrees, however, with EPA's assessment that GAC treatment will be sufficiently available in sufficient quantities to support cost effective compliance with the proposed regulation. As EPA is aware, the Bipartisan Infrastructure Law (BIL) signed by President Biden on November 15, 2021 requires that all infrastructure projects funded using Federal dollars must comply with the new

Build America, Buy America (BABA) requirements. The BIL specifically provided Federal funding to be directed to removal of PFAS and other emerging contaminants in addition to increased funding through the traditional state revolving loan fund (SRF) programs for infrastructure improvements. Although there are a number of carbon manufacturers that provide treatment to U.S. utilities and municipalities, we are currently aware of only one company that sources their carbon in the U.S. for PFAS removal. That means that resources available to provide this BAT will be limited if even one dollar of Federal funding is used for the project unless a waiver is provided.

This situation is similar for companies that provide RO and NF as well as those that provide ultrafiltration (UF) and microfiltration (MF) as pretreatment for PFAS removal. None of the current large-scale membrane manufacturers that provide membrane BAT to the U.S. water market currently manufacture their products domestically or in sufficient quantity to meet current projected needs. While WWEMA has not done extensive outreach to anion exchange manufacturers, our general understanding is that they may be in the same predicament. A number of companies are evaluating the options to produce their products domestically, but it will require several years and a sizeable investment to create or expand sufficient manufacturing capacity to meet the demand for current and future PFAS treatment. To ensure adequate access to these critical BAT technologies, WWEMA requests a National Public Interest Waiver for these PFAS removal technologies while the market adapts to close this gap. This will be particularly important for small and disadvantaged communities that will need ready access to these technologies.

EPA Response: As acknowledged in the comment, there are US suppliers for all BATs identified. Please see section 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions. More on BABA and public interest waivers can be found in section 2.4.

Clean Air Council, et al. (Doc. #1731, SBC-043885)

d. Treatment of contaminated drinking water to achieve the proposed MCLs and HBWC is technically feasible for national implementation of the proposed PFAS regulations. However, EPA must facilitate the development of safe technologies for the disposal of PFAS waste created by water treatment to avoid re-release of PFAS to the environment.

EPA has identified several methods that can effectively remove the PFAS compounds down to non-detectable levels [FN69: EPA states that these methods remove up to 99% of PFAS. EPA, Per- and Polyfluoroalkyl Substances, https://tdb.epa.gov/tdb/contaminant?id=11020 (select "Treatment Processes" under "Contaminant Navigation") (last visited May 30, 2023). That level is judged to be "non-detectable." See, e.g., EPA, EPA Researchers Investigate the Effectiveness of Point-of-use/Point-of-entry Systems to Remove Per- and Polyfluoroalkyl Substances from

Drinking Water (Jan. 22, 2020), https://www.epa.gov/sciencematters/epa-researchers-investigate-effectiveness-point-usepoint-entry-systems-remove-and.] These methods have been extensively tested and validated (see for example studies by Erica Gagliano, et al, and by Caihong Liu, et al. [FN70: Erica Gagliano, et al., Removal of Poly- and Perfluoroalkyl Substances (PFAS) from Water by Adsorption: Role of PFAS Chain Length, Effect of Organic Matter and Challenges in Adsorbent Regeneration, 171 WATER RES. 115381 (Mar. 15, 2020), available at https://doi.org/10.1016/ j.watres.2019.115381; Caihong Liu, et al., Evaluating the Efficiency of Nanofiltration and Reverse Osmosis Membrane Processes for the Removal of Per- and Polyfluoroalkyl Substances from Water: A Critical Review, 302 SEPARATION & PURIFICATION TECH. 122161 (Dec. 1, 2022), available at https://doi.org/10.1016/j.seppur.2022.122161.]) and are also the methods of choice for drinking water treatment in the states that enacted PFAS drinking water regulations.

Current water treatment facilities cannot address PFAS contamination [FN71: See, e.g., Shui Cheung Edgar Leung, et al., Emerging Technologies for PFOS/PFOA Degradation and Removal: A Review, 827 SCI. OF THE TOTAL ENVMT. 153669 (June 25, 2022), available at https://doi.org/10.1016/j.scitotenv.2022.153669.] Therefore, EPs where PFAS levels exceed the proposed NPDWR MCLs and/or HI will need to add a dedicated PFAS treatment unit. However, the methods used for removal of PFAS from water (Granulated Activated Carbon—GAC, ion exchange, Reverse Osmosis—RO/nanofiltration membranes) are similar to technologies currently used in drinking water facilities to address contamination by other types of compounds. For example, GAC units are frequently used for removal of volatile organic compounds ("VOCs"), taste or odor-producing compounds, or other types of contaminants. Ion exchange, which is used for removal of arsenic, nitrate, perchlorate, sulfate, or uranium, is most often applied for water 'softening' by removing calcium and magnesium [FN72: EPA, Overview of Drinking Water Treatment Technologies, https://www.epa.gov/sdwa/overview-drinking-water-treatment-technologies#GAC (last updated Apr. 13, 2023).] PFAS-removal units use these technologies, but are designed to specifically address PFAS contamination. The prevalence and familiarity of these processes means that once a PFAS treatment unit is constructed, facility personnel will have the required expertise to operate it effectively.

A few challenges will need to be considered, however, due to the large number of PWSs that are expected to exceed the proposed limits and require implementation of water treatment. First is supply availability: There will be a very large need for GAC, ion-exchange resin and/or RO/nanofiltration membranes during the facility construction stage [FN73: See, e.g., Global Ind. Analysts, Inc., Global Activated Carbon Market to Reach 3.9 Million Tons by 2026, CISION (Mar. 23, 2022), https://www.prnewswire.com/news-releases/global-activated-carbon-market-to-reach-3-9-million-tons-by-2026--301506731.html.] Even after the initial implementation stage, there will be a constant, albeit lower, demand for these materials: GAC materials saturate and need to be regenerated or replaced; ion exchange resins lose efficacy after a given number of regeneration cycles; RO/nanofiltration membranes also degrade with time, [FN74: See, e.g., S. J. Chow, et al, Comparative Investigation of PFAS Adsorption onto Activated Carbon and Anion Exchange Resins During Long-Term Operation of a Pilot Treatment Plant, 226 WATER RES.

Article No. 119198 (Nov. 1, 2022), available at https://doi.org/10.1016/j.watres.2022.119198.] although the exact rate of replacement will depend on the contaminant concentrations and operation procedures. To ensure compliance under the proposed rule's timeline and schedule, the federal government should examine whether there is a need to develop new facilities producing PFAS treatment materials to address the national need.

EPA Response: Please see section 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions. For more information on disposal please see the *Interim PFAS Destruction and Disposal Guidance* document as well as the Management of Treatment Residuals section.

U.S Conference of Mayors, National League of Cities and National Association of Counties (Doc. #1733, SBC-043896)

c. Supply Chain, Disposal and Workforce Challenges

The technologies used to remove PFOS and PFOA from drinking water include Granulated Activated Carbon (GAC) or reverse osmosis membranes. Supply chain disruptions are already apparent at the local level, with over a year wait for replacement carbon, and in many cases the cost of needed supplies has also increased. These factors will be further exacerbated if more water utilities add GAC to their systems as a treatment technique. Establishing a higher initial MCL would allow those public water systems with the highest PFOA or PFOS levels, and therefore also the highest public health risks, to be prioritized first. A rapid increase in demand resulting from detection-level MCL levels would only exacerbate the amount of time it takes to obtain and install necessary treatment.

EPA Response: Please see section 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions. For additional discussion on how the agency considers analytic feasibility and cost when establishing the MCL, please see section 5 of the EPA response in this *Response to Comments* document.

Florida Section American Water Works Association - Water Utility Council (FSAWWA WUC) (Doc. #1737, SBC-044487)

• Global Supply Chain Issues:

EPA is aware of supply chain issues for the Water and Wastewater Sectors and thankfully published a Supply Chain Resilience Guide for Water and Wastewater Utilities as well as provided case studies (please see https://www.epa.gov/waterutilityresponse/water-and-wastewater-sector-supply-chain-resilience). Through the global pandemic and other mechanisms,

utilities across the country are facing increased wait times and price increases for numerous products and supplies. We recommend EPA consider how future supply and demand will affect both the cost and timelines to meet the proposed NPDWR. For example, one of our members reports a 9- month wait for Granular Activated Carbon (GAC) supplies, one of EPA's recommended treatment methodologies.

EPA Response: Please see section 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-045978)

Section 7.1: Sufficiently available and cost-effective

EPA specifically states in the preamble that it estimates GAC treatment will be sufficiently available to support cost-effective compliance with this proposed regulation. As discussed, water systems at this time are seeing approximately 18-month lead times on GAC vessels for PFAS treatment. This timing does not seem to be sufficiently available when that is half of EPA's proposed compliance timeline of three years. Should the rule be finalized in its current form, spurring additional nationwide demand for these products, it is likely lead times will increase.

There are considerable concerns over which systems will get priority for the new GAC as well. Systems that already have existing contracts, whether the system is using GAC for total organic carbon (TOC) removal or compliance with a state PFAS MCL, are concerned new contracts may receive priority based on new prices or agreements. Conversely, treatment technology suppliers may not prioritize issuing new contracts if demand is already high with existing contracts. Due to costs, EPA's recommendation, and other factors, GAC will likely be a top choice for many utilities required to apply treatment; therefore, it is imperative EPA thoroughly assess the capacity of suppliers to ensure availability of GAC filtration.

PWSs will likely encounter difficulties implementing any treatment techniques due to increased demands on the supply chain and other regulatory requirements. Similar to GAC, PWSs considering AIX may find it both more difficult and more expensive once the final rule triggers higher demand. Furthermore, other requirements imposed on water systems, like Build America, Buy America (BABA) requirements, can make acquiring certain materials difficult and prolong acquisition timelines.

EPA Response: Please see section 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions.

LSP Association (LSPA) (Doc. #1742, SBC-043606)

Slide 30: EPA estimated annualized costs per year for water systems that treat or change water source: Costs of system capital, operation, and maintenance are annualized.

• The LSPA estimates that granular activated carbon (GAC) use will increase exponentially if the proposed MCLs are implemented. Adequate source materials (coal, coconut, sugarcane bagasse, soybean hulls, nutshell) are not available to meet the resulting demand; therefore, costs will increase accordingly. Did EPA consider the supply/demand issues and escalating costs associated with GAC?

• Communities that can least afford it, such as minority, low-income, and environmental justice populations will be disadvantaged if required to compete with more affluent communities and public water supply systems for dwindling resources.

• The LSPA concurs with the MWWA in their May 26, 2023 comment letter regarding supply chain and procurement challenges (pp.14-15).

EPA Response: Please see section 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions. With respect to the commenter's concern about impacts to "minority, low-income, and environmental justice populations," the EPA conducted an EJ analysis for the final rule that assessed the demographic distribution of baseline PFAS exposure in drinking water as well as the anticipated distribution of benefits and costs that will result from the rule. For more information on the EPA's EJ analysis, please see Chapter 8 of the EA (USEPA, 2024d).

There may be opportunities for many communities to utilize external funding streams to address such challenges. The BIL, the Low-Income Water Household Assistance Program through the American Rescue Plan, and other funding sources may be able to provide financial assistance for addressing emerging contaminants. In particular, the BIL funding has specific allocations for disadvantaged and/or small communities to address emerging contaminants, including PFAS. For example, the *Emerging Contaminants in Small or Disadvantaged Communities grant program* will provide states and territories with $5 billion to provide grants to PWSs in small or disadvantaged communities to address emerging contaminants, including PFAS. Grants will be awarded non-competitively to states and territories. For more information on funding available through BIL, please see section 2.4 of the EPA response in this *Response to Comments* document. For more information on the cost analysis please see section 13 of the EPA response in this *Response to Comments* document.

LSP Association (LSPA) (Doc. #1742, SBC-043608)

The LSPA asserts that the resource capacity, supply chain availability of GAC and other treatment supplies, and laboratory capacity for undertaking compliance to these low MCLs has been greatly overestimated by USEPA.

EPA Response: Please see section 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions.

Liberty (Doc. #1747, SBC-043625)

Regarding the proposed regulation, as the demand for treatment vessels and the treatment materials they house (such as GAC and IX resin) increases exponentially, even approved and shovel-ready projects may be necessarily postponed due to supply chain limitations.

EPA Response: Please see section 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions.

Las Cruces Utilities (LCU) (Doc. #1753, SBC-043914)

In response to Section XI-Treatment Technologies, EPA estimates GAC treatment will be sufficiently available to support cost-effective compliance with this proposed regulation, and requests comment on whether additional guidance on applicable circumstances for GAC treatment is needed.

• EPA should provide additional guidance as to when GAC treatment is not appropriate or viable. Water demand for these systems and the required GAC media will increase, and therefore become more expensive. Increased demand will also lead to longer lead times and may make it difficult to meet the compliance deadlines.

EPA Response: Please see sections 10.1 and 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions. After finalization of the PFAS NPDWR, the EPA also seeks to provide support to utilities, primacy agencies, and other interested parties to ensure successful rule implementation and plans to consider the topics suggested by the commenter as the agency develops implementation materials for the final NPDWR.

PFAS Regulatory Coalition (Doc. #1761, SBC-046083)

c) Did EPA consider the costs/availability of treatment media? The demand for treatment media is greatly increasing for remediation projects and will increase further due to this Proposal. EPA should consider how market demand will affect price and availability of the different treatment media.

EPA Response: Please see section 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions. Please see section 5 of the EPA response in this *Response to Comments* document for additional discussion on cost considerations when establishing the MCLs. The EPA also refers commenter to the *Technologies and Costs for Removing Per- and Polyfluoroalkyl Substances from Drinking Water* document. For more information on the cost analysis, please see section 13 of the EPA response in this *Response to Comments* document.

Western Urban Water Coalition (WUWC) (Doc. #1768, SBC-043941)

However, the Proposed Rule does not consider significant supply chain challenges that have impacted the availability of GAC and IX resin, or whether there is a sufficient supply of these materials to meet the increase in demand that would result from the Proposed Rule.

EPA Response: Please see section 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions.

City of Tulsa Water and Sewer Department (CoT WSD) (Doc. #1785, SBC-043786)

CoT WSD believes that EPA's estimate regarding availability of GAC is grossly understated. Many water systems, including CoT WSD, currently use GAC filters in their conventional treatment train. For our system, GAC is replaced with virgin material in 8 of the 24 filters (total, in two WTPs) each year at a cost of about $2.5M. It must be assumed that many systems operate a similar replacement schedule, plus or minus months, and some may use reactivated GAC, but it doesn't appear that EPA accounted for this usage in the proposed rule or in supporting documents. In the supporting document, Technologies and Cost for Removing Per- and Polyfluoroalkyl Substances (PFAS) from Drinking Water (EPA-822-P-23-011), EPA discusses GAC in regard to deep-bed contactors. EPA states that support for GAC effectiveness is "evident form the number of full-scale facilities that are currently using the technology," but this is only 30 systems out of the thousands of systems across the country (pg. 15). It can be surmised that to achieve compliance with this rule, there will be many systems that will 1) install new conventional GAC filters, 2) increase frequency of GAC replacement in conventional filters, or

3) install new deep-bed GAC contactors for specific removal of PFAS. With any or all of these scenarios, the demand for GAC will be significant, supply chain could be challenged, delivery times extended, and costs could increase significantly.

EPA Response: Please see section 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions. Please see section 13 of the EPA response in this *Response to Comments* document for the EPA cost analysis.

Pennsylvania Municipal Authorities Association (Doc. #1832, SBC-045790)

[PMAA's specific comments on the Proposal are as follows:]

14. The supply of Granular Activated Carbon (GAC) (and possibly other treatment-related products) may be subject to supply chain issues if the Proposal is ultimately promulgated as a final PFAS regulation. Anecdotal information suggests that the wait time for Granular Activated Carbon will increase substantially as a result of the mandates in the Proposal. How does EPA suggest that municipal entities address this potential problem?

EPA Response: Please see section 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions.

New England Water Works Association (Doc. #1836, SBC-045396)

Supply Chain/Procurement:

NEWWA is also concerned that PWSs may face even greater procurement challenges when new national drinking water standards for PFAS are put in place. At times, carbon vessels have been delayed for months due to supply-chain issues and increased demand. Different states also have different procurement laws that may need to be followed for design and construction services, which add time to the overall project implementation schedule. EPA should be thinking ahead to authorities that exist, such as the Defense Production Act, to compel the quicker manufacturing of treatment components for PFAS treatment if necessary. Build America, Buy America (BABA) provisions required for BIL funding provide an added layer of complexity and delay when trying to quickly source materials and components needed for PFAS treatment systems. PWS in New England trying to build treatment systems and meet BABA and AIS requirements are already facing months-long delays. When the rest of the nation begins the same process, the wave of demand will be overwhelming. EPA must provide flexibility and relief for drinking water PFAS projects and streamline the waiver review process, which takes months to complete.

EPA Response: Please see section 10.6 of the EPA response in this *Response to Comments* document. For additional discussion on supply chain and labor challenges that may

affect the compliance timeline, please see section 12 of the EPA response in this *Response to Comments* document on extensions and exemptions. The EPA has provided processes for a PWS unable to secure critical resources necessary for water treatment (see https://www.epa.gov/waterutilityresponse/how-use-defense-production-act#Steps).

11 Rule Implementation and Enforcement

11.1 Requirements for Primacy

Summary of Major Public Comments and EPA Responses

The EPA received one comment that most of the initial monitoring may occur before primacy applications will be submitted, which are not due until two years after final rule promulgation. A couple of commenters assert that it is unclear why states are required to include an initial monitoring plan in their primacy application and that states will not be able to implement and demonstrate that this monitoring plan is enforceable under state law until state regulations have been promulgated. The EPA notes that some comments related to the requirements for primacy are also contained within sections 5 and 12 of this *Response to Comments* document. The EPA recognizes that some initial monitoring by water systems may occur prior to a state, territory, or Tribe receiving EPA approval for primacy and agrees with the commentor that for states to develop a monitoring plan that addresses when systems will be scheduled to conduct initial monitoring is not a necessary requirement for a primacy application. However, where states are approved for primacy before the compliance date for the water systems, primacy agencies should have procedures for evaluating whether data that a community water system (CWS) or non-transient non-community water system (NTNCWS) submits to satisfy the initial monitoring requirements are acceptable. It is therefore appropriate to require primacy agencies to include in their primacy application a description of their procedures for reviewing water system's use of pre-existing data to meet initial monitoring requirements, including the criteria that will be used to determine if the data are acceptable and the primacy agency's procedures for ensuring water system compliance within the required timeframes. The compliance deadline for this initial monitoring by systems is three-years from promulgation, in which case primacy agencies should have primacy or interim primacy at the time of the initial monitoring deadline. To address the possibility that a state, Tribe, or territory may get an extension to apply for primacy, the final rule provides that these special primacy requirements are not applicable after the initial monitoring deadline (i.e., three years after publication of the rule in the Federal Register). When a primacy agency does not yet have primacy for a new drinking water rule, a National Primary Drinking Water Regulation (NPDWR) is nonetheless applicable to water systems and may be enforced by the EPA following the compliance dates specified in § 141.900(b).

Individual Public Comments

Massachusetts Department of Environmental Protection (MassDEP) (Doc. #1726, SBC-045165)

Monitoring and special primacy requirements

Given that initial monitoring may occur anytime between final rule promulgation and the compliance date (three years later), it is unclear why states are required to include an initial monitoring plan in their primacy application. Primacy applications wouldn't normally be due

until two years after final rule promulgation. Two-thirds of the initial monitoring period would have already passed by that date. Moreover, states will not be able to demonstrate that this monitoring plan is enforceable under state law until state regulations have been promulgated which, again, will likely occur well into the initial monitoring period.

EPA Response: Please see section 11.1 of the EPA response, as well as the EPA response to comment Doc. #1626, SBC-044880 in section 16.5 and Doc. #1708, SBC-045100 in section 5.1.2, in this *Response to Comments* document.

11.2 Record Keeping Requirements

Summary of Major Public Comments and EPA Responses

The EPA received a few comments about the record keeping that primacy agencies must maintain for compliance determinations and reporting, storing public water system (PWS) facility data, tracking monitoring schedules, and keeping the public informed of the quality of their drinking water. As noted in the comments, most primacy agencies rely on the Safe Drinking Water Information System (SDWIS), developed by the EPA, to support this record keeping requirement. It was recommended that the EPA develop a data system, either SDWIS or a replacement, that is capable of fully managing the data associated with the proposed rule. Further, it was recommended that the EPA develop data management solutions such as a mechanism for migrating Unregulated Contaminant Monitoring Rule (UCMR) data into SDWIS State to reduce or eliminate the burden of ensuring compliance with the initial monitoring and identify systems eligible for reduced monitoring frequency when compliance monitoring begins. The EPA agrees that appropriate data management solutions are needed to effectively comply with Safe Drinking Water Act (SDWA) requirements; however, the agency does not believe these systems must be available at the time of rule promulgation. Additionally, while beyond the scope of this rulemaking itself, the EPA is actively working on PFAS data management solutions, including Drinking Water State-Federal-Tribal Information Exchange System (DW-SFTIES) support and potentially updating the SDWIS suite of applications to manage data reported from this rule.

The primacy agency record keeping requirements in 40 CFR 142.14 remain unchanged and would apply to PFAS as with any other regulated contaminants. Water system recordkeeping requirements are referenced within Subpart Z in § 141.904. In the final rule, the EPA updated this regulatory text to cross-reference the record retention provisions in § 141.33. The EPA is developing the DW-SFTIES that will support all SDWA drinking water rules. The EPA plans to continue to provide support for necessary updates to SDWIS State, including for reporting requirements for new rules, until the DW-SFTIES is in production and in use by primacy agencies. SDWIS State support and updates will continue until the DW-SFTIES Board recommends a sunset date after DW-SFTIES is in production and in use by primacy agencies. The EPA will evaluate the migration of UCMR data into the suite of SDWIS applications, including the technical considerations raised by commenters for data migration from the Safe

Drinking Water Accession and Review System (SDWARS) to SDWIS (e.g., incorporation of field reagent blanks (FRBs)).

The EPA also received a few comments requesting the agency develop a tool that would calculate the Hazard Index, and some of these commenters suggested that such a tool be integrated into the EPA's SDWIS application. The EPA agrees creating an online tool to facilitate checking the Hazard Index calculation will be beneficial for various stakeholders and is developing a Hazard Index Calculator to assist drinking water systems and primacy agencies in calculating the Hazard Index, as discussed in section 1.2 of the EPA response in this *Response to Comments* document. While beyond the scope of this rulemaking itself, the EPA is actively working on PFAS data management solutions, including DW-SFTIES support and potentially updating the SDWIS suite of applications to manage data reported from this rule, to include integrated calculation of the Hazard Index.

Individual Public Comments

Association of State Drinking Water Administrators (ASDWA) (Doc. #1628, SBC-044078)

Data Management

ASDWA recommends EPA ensure DW-SFTIES is capable of fully managing the data of the proposed rule.

The importance of data management in effectively implementing any rule cannot be understated. The Safe Drinking Water Information System (SDWIS) is used by most primacy agencies for compliance determinations and reporting, storing public water system facility data, tracking monitoring schedules, and keeping the public informed of the quality of their drinking water. Several primacy agencies do not use SDWIS and instead have developed custom data systems in use by their program - known as "SDWIS Free." Currently, SDWIS cannot effectively manage PFAS data, so most primacy agencies engaged with early data tracking and collection for PFAS do so outside of that data system. Many primacy agencies will need to migrate this data into SDWIS, which presents several challenges. SDWIS is undergoing a modernization effort that will span the next few years. Once the modernized system is released, known as Drinking Water State Federal and Tribal Information Exchange System or DW-SFTIES, additional time will be needed before state primacy agencies put it in production. Given these timelines, primacy agencies will need to manage PFAS-related data across multiple systems. Eventually, primacy agencies will need to migrate PFAS data into DW-SFTIES, which is presumed to fully support the data management of the proposed rule. These essential primacy agency functions increase the cost of rule implementation.

ASDWA recommends EPA develop a mechanism for migrating UCMR data into SDWIS State to reduce or eliminate the burden imposed on primacy agencies who would otherwise need to perform this work manually.

Managing PFAS data across multiple systems further challenges water systems that request reduced monitoring and have submitted UCMR 5 data to EPA through the Safe Drinking Water Accession and Review System (SDWARS). No automated process exists to migrate these data into SDWIS, and this gap is significant. Additionally, some missing data elements (Laboratory IDs, Minimum Reporting Levels, etc.) and the inability to download quality control data, which must be viewed in SDWARS one analyte at a time, may complicate developing a simple solution. Still, as the requirements for reduced monitoring depend on these data, resolving the data migration issue is a priority concern.

EPA Response: Please see section 11.2 of the EPA response in this *Response to Comments* document. Comments related to SDWIS or other data management systems used by primacy agencies are beyond the scope of this rulemaking.

Texas Commission on Environmental Quality (TCEQ) (Doc. #1632, SBC-044127)

Lack of Data Tools to Implement the Proposed Rule

Existing EPA data tools do not have the functionality to implement the proposed rule and additional tools are needed to facilitate the Fifth Unregulated Contaminant Monitoring Rule (UCMR5) for PFAS data sharing and compliance determinations. The current version of the Safe Drinking Water Information System-State (SDWIS/State) database does not have the functionality to calculate compliance reliably and consistently for the HI or differentiate usage of sample results below the PQL for separate methodologies (i.e., health-based standards and monitoring requirements) concurrently. EPA's modernization of SDWIS/State has been in the process for more than a decade and primacy agencies still do not have a reliable database to be able to implement the requirements of several newly promulgated NPDWRs. SDWIS/State often requires TCEQ to divert limited resources to develop reliable workarounds and other extensive and costly data management solutions to perform basic business functions.

TCEQ recommends EPA provide timely data entry instructions and update database applications with required logic to ensure accurate compliance values and the ability to make reliable compliance determinations. If EPA cannot provide the necessary updates to SDWIS/State before finalizing the PFAS NPDWR, TCEQ recommends the Drinking Water State Federal Tribal Information Exchange System (DW-SFTIES) hosts an adequate structure to accommodate compliance determination requirements. If EPA cannot provide the necessary updates to either SDWIS/State or DW-SFTIES, TCEQ recommends EPA extend the compliance date of the rule to allow adequate time for primacy agencies to develop data management solutions. Without time to develop a data management solution, primacy agencies would have to perform manual compliance determinations which would increase the potential for errors and delays in timely compliance determinations and communications to the public, impacting public health.

Managing PFAS data across multiple systems further presents a challenge for water systems that request reduced monitoring and have submitted UCMR5 data to EPA through the Safe Drinking Water Accession and Review System (SDWARS). No automated process exists to migrate these

data into SDWIS/State. This creates a significant data gap. TCEQ urges EPA to develop a mechanism for migrating UCMR5 data from SDWARS into SDWIS/State to reduce or eliminate the burden imposed on primacy agencies that will otherwise need to perform this work manually or develop tools to accomplish this function.

EPA Response: Please see section 11.2 of the EPA response in this *Response to Comments* document for discussion of the aspects of the comment related to data management platforms; for the response to the element of the comment related to data entry instructions, please see section 11.3 of the EPA response in this *Response to Comments* document. As noted in section 11.2 of the EPA response in this *Response to Comments* document, the EPA plans to continue to provide data management support either through updates to SDWIS State, including for reporting requirements for new rules, or through DW-SFTIES when available for use by primacy agencies. For further information about compliance timelines, please see section 12.1 of the EPA response in this *Response to Comments* document.

North Carolina Division of Water Resources (NCDEQ) (Doc. #1652, SBC-044173)

D. Data Management

1. NCDEQ recommends EPA ensure DW-SFTIES is capable of fully managing the data of the proposed rule.

The importance of data management in effectively implementing any rule cannot be understated. The Safe Drinking Water Information System (SDWIS) is used by NCDEQ for compliance determinations and reporting, storing public water system facility data, tracking monitoring schedules, and keeping the public informed of the quality of their drinking water. Currently, SDWIS cannot manage PFAS data, so NCDEQ has had to manage early data tracking and collection for PFAS outside of that data system. NCDEQ will need to migrate this data into SDWIS, which presents several challenges. SDWIS is undergoing a modernization effort that will span the next few years. Once the modernized system called DW-SFTIES (Drinking Water State Federal and Tribal Information Exchange System) is released, it will take additional time before it is in production at NCDEQ. Given these timelines, NCDEQ will need to manage PFAS-related data on its own across multiple systems. Eventually, NCDEQ will need to migrate PFAS data into DWSFTIES, which is presumed to fully support the data management of the proposed rule. NCDEQ would like to work with EPA and other affected states to implement an effective solution that addresses near term and long-term data management requirements.

2. NCDEQ recommends EPA develop a mechanism for migrating the Unregulated Contaminant Monitoring Rule 5 (UCMR 5) data into SDWIS State to reduce or eliminate the burden imposed on state agencies who would otherwise need to perform this work manually.

Managing PFAS data across multiple systems further presents a challenge for water systems that request reduced monitoring and have submitted UCMR 5 data to EPA through the Safe Drinking Water Accession and Review System (SDWARS). No automated process exists to migrate these

data into SDWIS, and this is a significant gap. Additionally, some missing data elements (Laboratory IDs, Minimum Reporting Levels, etc.) and the inability to download quality control data, which must be viewed in SDWARS one analyte at a me, may complicate the process of developing a solution. This is particularly important as the requirements for reduced monitoring depend on these data. NCDEQ would like to work with EPA and other affected states to implement an effective solution that enables efficient and timely migration of UCMR 5 data.

EPA Response: Please see section 11.2 of the EPA response in this *Response to Comments* document.

New Jersey Department of Environmental Protection (NJDEP) (Doc. #1699, SBC-045045)

State Implementation & Enforcement

Section 1413 of the federal Safe Drinking Water Act establishes requirements that primacy entities must meet to maintain primacy including: adopting and implementing adequate procedures for enforcement and keeping records and making reports available on activities that EPA requires by regulations. The current version of the Safe Drinking Water Information System (SDWIS) does not allow states to track and enforce the requirements of the proposed MCLs. The SOC framework requires systems serving less than 3,300 customers to collect two (2) quarterly samples in one year triennially. The current release of SDWIS does not facilitate these schedules and New Jersey has had to improvise by utilizing dual schedules to enable compliance determinations. Additionally, the calculation of the Hazard Index is not supported by SDWIS. EPA has stated that states will be provided with a calculator but without integration into SDWIS its use may be limited and time consuming.

These modifications will create challenges for States with limited staffing or technology constraints as they implement these requirements, along with potentially transitioning to a new database. As the next version of SDWIS, DW-SFTIES: Drinking Water State-Federal-Tribal Information Exchange System, is in development, EPA needs to make sure any new requirements are integrated into the new system.

EPA Response: Please see section 11.2 of the EPA response in this *Response to Comments* document. Please see section 13.3.1 of the EPA response in this *Response to Comments* document for a discussion of estimating primacy agency costs (including regulatory start-up costs).

Massachusetts Department of Environmental Protection (MassDEP) (Doc. #1726, SBC-045146)

4. Data Management

EPA should take steps to ensure that DW-SFTIES is capable of fully managing the data of the proposed rule.

The importance of data management in the effective implementation of any rule cannot be understated. Massachusetts currently uses a database developed in-house, the Water Quality Testing System (WQTS), to store system inventory, system staffing, monitoring schedules, water quality results, inspections, rule milestones, violations and enforcements. WQTS records are used to meet our primacy agency reporting obligations and to keep the public informed of the quality of their drinking water. WQTS has been modified to implement the Massachusetts PFAS rule but will likely need additional changes to reflect EPA's PFAS NPDWR and its new reporting requirements. MassDEP intends to transition into EPA's modernized system, the Drinking Water State Federal and Tribal Information Exchange System (DW- SFTIES) after its anticipated release date of January 1, 2025. DW-SFTIES must include all the fields and functions necessary to manage the new PFAS rule.

EPA should develop a mechanism for migrating UCMR5 data into state data systems to reduce or eliminate state burden.

Managing PFAS data across multiple systems presents a challenge for water systems that have submitted Unregulated Contaminant Monitoring Rule (UCMR5) data to EPA through the Safe Drinking Water Accession and Review System (SDWARS) and that request reduced monitoring based on those data. No process exists to migrate these data into state data systems. The existing SDWARS data download option is missing key data elements (Laboratory IDs, Minimum Reporting Levels (MRLs), Date Extracted, Date Analyzed, etc.) necessary to determine its applicability to substitute for initial monitoring. Furthermore, the inability to download quality control data, which must be viewed in SDWARS one analyte at a time, may complicate the process. Full electronic data packages of UCMR5 samples which include the results of field reagent blanks (FRBs) required by the method are needed for states to consider using these results for compliance. Absent this capability, MassDEP may not be in a position to offer public water systems the opportunity to substitute UCMR5 data for initial monitoring.

EPA must provide Data Entry Instructions (DEIs) within six months of the promulgation of the rule to allow primacy agencies, particularly "SDWIS Free" programs, to prepare their systems.

MassDEP will need time to prepare its current database, WQTS, to meet the new requirements. To ensure WQTS is prepared to manage the data and to ensure timely reporting to EPA, access to the Data Entry Instructions (DEIs) within at least six months of promulgation of the rule is critical. This need is especially great as MassDEP is a "SDWIS Free" program that cannot begin this work without a final DEI.

EPA Response: Please see section 11.2 of the EPA response in this *Response to Comments* document for discussion of the aspects of the comment related to data management platforms; the response on the element of the comment related to data entry instructions can be found in section 11.3 of the EPA response in this *Response to Comments* document. Please see section 8.7 of the EPA response in this *Response to Comments* document for discussion of the analysis of FRBs, for quality control (QC) purposes, when PFAS are detected.

Washington State Department of Health (DOH) (Doc. #1665, SBC-044393)

DOH requests that EPA develop tools to aid with implementing the Hazard Index (HI) calculations for different state data systems. Multiple calculations for determining a HI result introduce a level of complexity for our data system. Also, as additional PFAS substances are evaluated and potentially regulated, it is important to consider how this will impact the current proposed HI calculations and allow for provision of additional PFAS to the proposed HI methodology.

EPA Response: Please see section 11.2 of the EPA response in this *Response to Comments* document for discussion of primacy agency record keeping requirements, including data management infrastructure necessary to implement the rule and tools for calculating the Hazard Index. Regarding regulation of additional PFAS in the future, the EPA would follow the regulatory development process outlined under SDWA and determine if additional PFAS are appropriate for inclusion in the Hazard Index. For further discussion of adding additional PFAS to the Hazard Index in the future, please see section 5.2.1 of the EPA response in this *Response to Comments* document.

Nebraska Department of Environment and Energy (NDEE) (Doc. #1653, SBC-043213)

• The proposed rule is expected to be finalized in 2024 prior to needed SDWIS updates including the ability to calculate the HI.

o States will be expected to calculate the HI manually which introduces human error, allows for inconsistent implementation from state to state and among EPA regions, and will require additional staff time. The Department would prefer EPA create a standardized assessment tool within SDWIS for calculating the HI.

EPA Response: Please see section 11.2 of the EPA response in this *Response to Comments* document for discussion of primacy agency record keeping requirements, including data management tools necessary to implement the rule. Please see section 1.2 of the EPA response in this *Response to Comments* document for further discussion of tools for calculation of the Hazard Index to avoid manual calculation.

Thurston Public Utility District (PUD), WA (Doc. #1729, SBC-043584)

3. That EPA develop tools to aid with implementing the Hazard Index (HI) calculations for different state data systems. Multiple calculations for determining a HI result introduce a level of complexity for any data system. Also, as additional PFAS substances are evaluated and potentially regulated, it is important to consider how this will impact the current proposed HI calculations and allow for provision of additional PFAS to the proposed HI methodology.

EPA Response: Please see the EPA response to comment Doc. #1665, SBC-044393 in section 11.2 in this *Response to Comments* document.

11.3 Reporting Requirements

Summary of Major Public Comments and EPA Responses

A few commenters recommended that the EPA provide Data Entry Instructions within six months of the promulgation of the rule to allow primacy agencies, particularly those that do not use SDWIS State, to implement their data systems for reporting to the EPA, prepare their PWS, and train staff. The EPA acknowledges this comment and will work to develop Data Entry Instructions as soon as possible. One commentor recommended that the EPA provide separate tracking of reporting and monitoring violations. The EPA acknowledges this comment and will consider this as data reporting tools are developed. A couple of commentors recommended that the reporting and recordkeeping requirements for compliance within the rule should provide an option for not requiring the running annual average (RAA) to be reported by the laboratories if the primacy agency performs the RAA calculations for the water system. In addition, one commenter requested that the primacy agency calculate the RAA and another commentor inquired whether the EPA intended to allow the water systems not to perform the RAA calculations if the primacy agency performs the RAA calculations. The EPA disagrees with these four comments and notes that two of them are contained within sections 8 and 16 of this *Response to Comments* document. Laboratories, under the proposed and final rule are not required to conduct an RAA calculation. To ensure that the water system has immediate knowledge of their compliance status, the final rule requires that water systems calculate the RAA and report this to the primacy agency. Primacy agencies or laboratories may also calculate the RAA, to confirm the results from the water system, but it is not a required reporting element under this regulation. Lastly, another commentor suggested that utilities be required to report the occurrence and concentration of other PFAS listed in the method (preferably 533) to facilitate data collection and to better inform water treatment objectives. The EPA disagrees with this comment, as it is outside the scope of this action, but does note that many water systems are currently collecting samples and reporting monitoring data for 29 PFAS that can be measured with EPA Methods 533 and 537.1 under UCMR 5 where the EPA has the regulatory authority; the majority of these PFAS compounds are not subject to any requirements under this Subpart.

The reporting requirements for primacy agencies under 40 CFR 142.15 remain unchanged and apply to PFAS as with any other regulated contaminant. The EPA intends to develop and provide access to Data Entry Instructions within one year after rule publication. The EPA will follow the usual protocol of engaging with a state-EPA workgroup for drafting the Data Entry Instructions. In this process, the EPA will consider the use of separate monitoring and reporting violation codes, like is used for the Revised Total Coliform Rule (RTCR). In this final regulation, the cross-reference to the water system reporting timeframes and provisions in § 141.31 at the start of § 141.904 is retained, and, at 40 CFR 141.904(b) Table 2, the EPA requires water systems to report PFAS RAAs to their primacy agency. As a general process, the laboratory will conduct the analysis of the sample and the system will use the result to calculate their RAA; the RAA

calculation may subsequently be completed by the primacy agency as a compliance check. The EPA does recognize that state laboratories often directly report results to the state as allowed in 40 CFR 141.31(c) and that electronic reporting tools, such as the Compliance Monitoring Data Portal (CMDP), may be used by systems to comply with this reporting requirement.

Individual Public Comments

Michigan Department of Environment, Great Lakes, and Energy (EGLE) Drinking Water and Environmental Health Division (DWEHD) (Doc. #1597, SBC-042990)

G. Rule Implementation and Enforcement

Having reviewed Section XII of the proposed NPDWR, EGLE DWEHD generally agrees with EPA's summary of requirements for primacy, record keeping, reporting, exemptions, and extensions. Regarding Table 1 of 141.904: EGLE DWEHD requests that EPA allow state agencies to calculate items 2, 3, and 4, rather than have supply report these values. Compliance calculations are complex, and our experience is that water supplies may calculate incorrectly and take (or not take) action based on incorrectly calculated values. There is precedent in some other rules to allow states to calculate values.

EPA Response: Please see section 11.3 of the EPA response in this *Response to Comments* document; see also the EPA response to comment Doc. #1626, SBC-044880 in section 16.5 in this *Response to Comments* document.

Michigan Department of Environment, Great Lakes, and Energy (EGLE) Drinking Water and Environmental Health Division (DWEHD) (Doc. #1597, SBC-042991)

EGLE DWEHD requests that EPA, when developing agency data reporting obligations, separate tracking and reporting of monitoring violations from reporting violations. This prevents confusion within state agencies and for the public by providing clarity about what type of violation has occurred.

EPA Response: Please see section 11.3 of the EPA response in this *Response to Comments* document; see also the EPA response to comment Doc. #1652, SBC-044185 in section 8.2 in this *Response to Comments* document.

Association of State Drinking Water Administrators (ASDWA) (Doc. #1628, SBC-044100)

Additionally, the reporting and recordkeeping requirements for compliance within the rule should provide an option for not requiring the RAA to be reported by the laboratories if the primacy agency performs the RAA calculations for the water system.

EPA Response: Please see section 11.3 of the EPA response in this *Response to Comments* document.

Association of State Drinking Water Administrators (ASDWA) (Doc. #1628, SBC-044079)

ASDWA recommends that EPA provide Data Entry Instructions (DEIs) within six months of the promulgation of the rule to allow primacy agencies, particularly "SDWIS Free" programs, to prepare their systems.

All primacy agencies will need time to prepare their existing data systems to meet the new requirements. To ensure data systems are prepared to manage the data required and ensure timely reporting to EPA, access to the Data Entry Instructions (DEIs) is critical. This need is especially great for "SDWIS Free" programs which require additional lead times to update their custom data systems and rely on the DEIs to ensure the reporting and recordkeeping requirements are met.

EPA Response: Please see section 11.3 of the EPA response in this *Response to Comments* document.

North Carolina Division of Water Resources (NCDEQ) (Doc. #1652, SBC-044174)

D. Data Management

…

3. NCDEQ recommends that EPA provide Data Entry Instructions (DEIs) within six months of the promulgation of the rule to allow NCDEQ to prepare their systems and train staff.

NCDEQ will need time to prepare our existing data entry processes to meet the new requirements. To ensure timely reporting to EPA, access to the Data Entry Instructions (DEIs) is critical.

4. NCDEQ recommends that EPA coordinate between its programs, regions, and headquarters to ensure the Agency is not creating duplicative reporting requirements on the states.

EPA headquarters and regional staff often request duplicate data from the state. As a coregulator, NCDEQ wants to work with EPA and be helpful, but these additional data collections take significant staff me. NCDEQ recommends that EPA improve coordination between its programs, regions, and headquarters to ensure the Agency is not creating redundant reporting requirements for state agencies.

EPA Response: Please see section 11.3 of the EPA response in this *Response to Comments* document for commenter's item #D3 discussed in this comment. For item #D4 discussed in this comment, the EPA appreciates the cooperation of primacy agency co-regulators. The EPA works to limit the data collection requests but makes information requests as needed to support its oversight role.

American Council of Independent Laboratories (ACIL) (Doc. #1692, SBC-044745)

8. List of Reported PFAS Analytes

ACIL recommends that while the NPRM only requires monitoring only 6 PFAS analytes, ACIL recommends that utilities be required to report the occurrence and concentration of other PFAS listed in the method (preferably 533) in order to facilitate data collection and to better inform water treatment objectives

If you have any questions about any of our comments or would like further information, please contact Judy Morgan, Chair, ACIL Environmental Sciences Section (ESS) at judy.morgan@pacelabs.com, 615-347-5418 or David Friedman, ACIL ESS Technical Advisor at friedmanconsulting@outlook.com, 703-389-3821.

Sincerely yours,

Judith R. Morgan, MS, REM

11.4 Enforcement and Other Issues

Summary of Major Public Comments and EPA Responses

The EPA received a few comments related to enforcement actions, including concerning topics such as penalties against systems that are in the process of installing treatment. The EPA notes that one of these comments about financial penalties appears in section 12.1 of this *Response to Comments* document. Below, the EPA addresses a couple of other comments related to enforcement and also shares additional information on its websites, including those listed below, such as the SDWA Enforcement Response Policy. The EPA notes that comments about the cost, including to primacy agencies, of enforcement-related activities may be found in section 13.3.1 of this *Response to Comments* document.

Individual Public Comments

Lakewood Water District (LWD) (Doc. #1574, SBC-042755)

Monitoring Penalties Counterproductive

As proposed, the regulations would seem to penalize water purveyors like LWD that have proactively and aggressively addressed PFAS contamination of their systems. LWD has been monitoring its wells for PFAS and reporting those results for many years. Under EPA's proposed rules, LWD now runs the risk of being classified (once EPA's MCLs are adopted) in violation of PFAS MCLs even though the regulatory framework in our state (Washington) will not have had time to be stood up.

EPA, instead, should postpone enforcement of PFAS MCLs until after state compliance systems and programs have been formally established.

EPA Response: The EPA disagrees that systems will be "penalized" for having proactively, previously collected PFAS data, as these data will not be used for compliance monitoring. This data can be only used to satisfy initial monitoring requirements; the EPA requires the most recent monitoring data that meet the criteria established under the NPDWR or for a system to collect and submit new data within 3 years of rule promulgation. The EPA does not agree that it should postpone enforcement of PFAS Maximum Contaminant Levels (MCLs) until after state compliance systems and programs have been formally established. This PFAS regulation sets a national standard; any state, such as Washington, can also be more stringent. SDWA § 1412(b)(10) requires that a "NPDWR shall take effect "3 years after the date on which the regulation is promulgated unless the administrator determines that an earlier date is practicable." Section 1412(b)(10) also authorizes "the Administrator, or a State (in the case of an individual system), may allow up 2 additional years to comply with a maximum contaminant level…if the Administrator or the State…determines that additional time is necessary for capital improvements." As described in section 12.1 of the EPA response in this *Response to Comments* document, under the final rule, systems have 5 years from promulgation of the rule for MCL

compliance to allow time for capital improvements. States will have time to obtain primacy and stand up their programs in light of the two-year primacy deadlines; where a state does not have primacy or interim primacy for a rule, the EPA would be the primacy agency. Therefore, a regulatory framework will be in place in any event when the water systems must comply with the NPDWR. Please see also the EPA response to comment Doc. #1708, SBC-045094 in section 12.1 in this *Response to Comments* document.

Bob Johnson (Doc. #3072-99, SBC-046403)

Hi, good evening. I appreciate the second go round. There's a point I wanted to make that I did not have time before. I would highly, very highly, recommend that Congress or EPA, if possible, make it mandatory for these laws to be obeyed, mandatory financial penalties and fines, if not, politics tend to get involved. And I can say this with full conscience, that next door to my house is a regional landfill, which has not been in compliance in two and a half years and the state of North Carolina will not bring it under control, EPA will not get involved. They have been issued seven notices of violation in the last two and a half years. They have been warned that they were going to be fined $75,000 per day per occurrence. And at times they have six notices of violations at one time. So far, they have not been fined anything whatsoever, but the North Carolina DEQ has furnished some grant money to them. So, if this is not made mandatory, my guess is that 20 years from now we still will not see it done here. The only thing it seems that the state politicians look for in North Carolina is the cost. And without mandatory penalties, I think we're wasting our time. I appreciate the conference. You've done an excellent job, and I hope you have a good day. Thank you.

EPA Response: Compliance with statutes by local entities (in this case, a landfill) is outside the scope of this regulatory action; however, note that the EPA offers a portal where anyone can report possible violations of environmental laws and regulations at https://echo.epa.gov/report-environmental-violations. Compliance with the MCLs for PFAS for PWSs is mandatory beginning 5 years from the date of rule promulgation. The establishment of mandatory penalties is beyond the scope of this rulemaking; Section SDWA 1414 governs the imposition of civil penalties for violations in federal enforcement actions. Therefore, the EPA is not establishing new penalties for PFAS specifically in this NPDWR. If the EPA decides in a case to seek penalties for a water system's noncompliance with an applicable requirement such as the PFAS MCL in this new NPDWR, then the EPA would rely on its statutory authorities, including SDWA Section 1414, to impose the penalty. The EPA's SDWA Enforcement Response Policy (USEPA, 2009) explains how the EPA typically pursues enforcement cases involving a water system's violations of the SDWA. Primacy agencies must have the authority to take enforcement actions and assess civil penalties (40 CFR 142.10(b)(6)). As provided in SDWA Section 1413, nothing in SDWA precludes a state from establishing requirements that are more stringent than the final NPDWR, including enforcement provisions.

The EPA is initiating actions under multiple environmental authorities—the Resource Conservation and Recovery Act (RCRA), Toxic Substances Control Act (TSCA), Clean Water

Act (CWA), SDWA and Comprehensive Environmental Response Compensation and Liability Act (CERCLA)—to identify past and ongoing releases of PFAS into the environment at facilities where PFAS has been used, manufactured, discharged, disposed of, released, and/or spilled. The EPA is conducting inspections, issuing information requests, and collecting data to understand the level of contamination and current risks posed by PFAS to surrounding communities and will seek to address threats to human health with all its available tools. The EPA works with its federal, state and Tribal regulatory partners through a comprehensive SDWA compliance monitoring program (https://www.epa.gov/compliance/safe-drinking-water-act-sdwa-compliance-monitoring) to protect human health and the environment by ensuring that the regulated community obeys environmental laws/regulations through on-site visits by qualified inspectors, and a review of the information the EPA or a state/Tribe requires to be submitted.

Delores Kirkwood (Doc. #2772, SBC-046497)

In the upper 1/3 of INDIANA it is clear that they are falsifying the numbers. Ask a statistician what are the chances of the numbers being either exactly as the last testing (right at the edge of the permitable range) or exactly the same as the previous testing for (9?) harmful substances that would harm you?

The EPA should be the ones testing the water, NOT a political person working for that city. We are being poisoned unless we have the money to buy Distilled (doctor recommended) water, and not bottled when some merely fill bottles with tap water. PLEASE, protect a child's future.

EPA Response: Concerns about the accuracy of certain data already collected and reported are outside the scope of these regulations. However, the EPA is initiating actions under multiple environmental authorities—the RCRA, TSCA, CWA, SDWA and CERCLA—to identify past and ongoing releases of PFAS into the environment at facilities where PFAS has been used, manufactured, discharged, disposed of, released, and/or spilled. The EPA is conducting inspections, issuing information requests, and collecting data to understand the level of contamination and current risks posed by PFAS to surrounding communities and will seek to address threats to human health with all its available tools. Additionally, due to the toxicity and persistence of PFAS chemicals, and the breadth and scope of PFAS contamination throughout the country, the EPA selected Addressing Exposure to PFAS as a new National Enforcement and Compliance Initiative (NECI) for Fiscal Years 2024-2027. PFAS contamination is a significant priority for the EPA and, while the regulatory framework for PFAS continues to develop across multiple statutes, the EPA has already taken a number of enforcement actions to ensure compliance with existing statutes, including action to address an imminent and substantial endangerment to communities. The EPA will increase those efforts, particularly where necessary to protect drinking water supplies, as part of this new initiative. The EPA works with its federal, state and Tribal regulatory partners through a comprehensive SDWA compliance monitoring program (https://www.epa.gov/compliance/safe-drinking-water-act-sdwa-compliance-monitoring) to protect human health and the environment by ensuring that the regulated

community obeys environmental laws/regulations through on-site visits by qualified inspectors, and a review of the information the EPA or a state/Tribe requires to be submitted.

The EPA also offers a portal where anyone can report possible violations of environmental laws and regulations at https://echo.epa.gov/report-environmental-violations. Systems are required to maintain records that document compliance with SDWA requirements, including documentation of the results received from a laboratory analyzing water samples. Regarding the suggestion that the EPA collect all samples, rather than allowing the PWSs to collect the samples, this is not a practical approach. Rather, under the PFAS regulation and other NPDWRs, water systems are responsible for collecting compliance samples and reporting this information to the state that has received primary enforcement authority (primacy) for implementing SDWA. The EPA also maintains oversight responsibility of the primacy agencies. The EPA and states operate in partnership to administer and implement safe drinking water programs, including to oversee adherence to the requirements of NPDWRs.

12 Exemptions and Extensions

12.1 Requirements

Summary of Major Public Comments and EPA Responses

The nearly uniform sentiment of commenters, including utilities and state primacy Agencies, was their concern over the ability of water systems to meet the three-year compliance deadline. Commenters expressed that it will be very challenging to both conduct initial monitoring and take actions (e.g., installing treatment) to comply with the Maximum Contaminant Level (MCL) within three years. Many of these commenters shared their on-the-ground experience in managing facilities that required capital improvements and provided evidence that additional time is needed to procure, design, pilot, permit, and ultimately construct treatment systems. Additionally, several commenters provided evidence of on-going labor and workforce challenges as well as recent experience with supply chain difficulties to obtain materials necessary to design and construct treatment facilities, which many attributed as a direct or indirect result of the COVID-pandemic residual impacts (AWWA, 2023).

The agency has evaluated the data and information shared by commenters regarding their experience with the time it takes to implement capital improvement projects. The EPA estimates that approximately 4,100 – 6,700 systems will be impacted by the MCLs in this final rule. Based on the EPA's initial compliance forecast, the agency anticipates that many of these systems will be installing advanced treatment technologies to meet the final PFAS standards (for additional discussion on the compliance forecast, please see section XII). The treatment technologies listed as best available technologies (BATs) for the final rule include granular activated carbon (GAC), ion exchange resins, and centralized reverse osmosis/nanofiltration (RO/NF) (please see section X of the final rule preamble for more information). To ensure cost effective compliance with the PFAS MCLs, systems often need to evaluate their treatment technology options as a first step. Several commenters have noted that this planning step may include pilot studies with potential treatment systems, or it may be limited to an evaluation of the raw water characteristics. Further, some commenters have submitted data and project management plans for systems choosing to conduct pilot testing, indicating that it may take a year or more to contract with vendors and to perform pilot testing. Once the planning step is completed, systems must design and construct the treatment systems. Several commenters submitted information to the EPA indicating that the design and permitting of the treatment systems can take an additional year or longer, and construction of the treatment system can take another year or longer. Because systems will also need time to obtain funding, obtain local government approval of the project, or acquire the land necessary to construct these technologies, many commenters contend that systems will need additional time beyond the three-year effective date to comply with the MCLs.

While the EPA stated in the proposed rule that the agency did not intend to provide a two-year extension nationwide necessary for capital improvements, the EPA finds that the evidence submitted by commenters strongly supports that a significant number of systems covered by this

rule will need two additional years to make capital improvements to meet the MCL. Specifically, the EPA reviewed data from applicants seeking Drinking Water State Revolving Fund (DWSRF) funding for capital improvement projects (e.g., installation of advanced treatment technologies such as GAC or ion exchange (IX)) and confirmed that these projects, on average, take about three or more years to complete (which excludes the time and activities that may occur to ensure these capital improvement projects are implemented successfully, such as the time it may take to secure funding or to conduct pilot testing) (USEPA, 2024a). This evidence along with the breadth of practicable experience shared by utilities and primacy agencies demonstrate that additional time is necessary for a significant number of system sizes and types located throughout the country to make capital improvements. Additionally, the EPA notes that the number of systems estimated to be impacted by the MCLs are greater than what the agency anticipated in the proposal (i.e., an increase from 3,400 - 6,300 systems to 4,100 – 6,700 systems nationally). This increase provides further evidence that a capital improvement extension is warranted as the agency expects that many of these systems will be installing advanced treatment technologies to meet the final PFAS standards. The agency also agrees with commenters that on-going labor and workforce challenges exist and can limit the ability to design, construct and operate treatment facilities. These workforce challenges facing water utilities and other sector organizations support the need for a capital improvement extension as a sufficient availability of qualified personnel is necessary to implement and sustain capital improvement projects. These issues may be attributed as a direct or indirect result of the recent COVID-19 pandemic and are clearly documented in data submitted to the agency as part of the public comment process (AWWA, 2023). Based upon these considerations, the EPA determined, in accordance with section 1412(b)(10) of the Safe Drinking Water Act (SDWA), that the compliance date for the PFAS MCLs, regardless of system size, will be 5 years from the date of promulgation of the standard.

Some commenters recommend the EPA to follow a staggered implementation timeframe similar to what was done in some previous National Primary Drinking Water Regulations (NPDWRs) where compliance deadlines were staggered based on system size (USEPA, 2001; 2006). In these prior examples, larger systems typically conducted their monitoring and implemented the MCL first, followed by smaller systems. Upon consideration of information submitted by commenters, particularly issues related to supply chain complications that are directly or indirectly related to the COVID-19 pandemic residual challenges, the EPA has determined that a significant number of systems subject to the rule, including large systems, will require two additional years to complete the capital improvements necessary to comply with the MCLs for PFAS regulated under this action. For this reason, the EPA disagrees with commenters that staggered implementation based on system size is warranted for this rule. While large systems may have greater resources to implement capital improvements (e.g., engineering and construction management staff to manage the projects), they still require time to design, pilot, permit, and construct treatment facilities.

Some commenters note that it will be challenging for systems to conduct their initial monitoring and install treatment within three years, particularly for those systems not conducting the fifth

Unregulated Contaminant Monitoring Regulation (UCMR 5) monitoring that is ongoing until 2026. The EPA notes that the agency is finalizing a flexibility for systems to use previously acquired monitoring data from UCMR 5 or an equivalent state-led monitoring program for their initial monitoring which is intended to alleviate the burden placed on water systems in collecting additional data (see section VIII for additional information on monitoring). While the agency agrees that systems need an additional two years to make capital improvements, the EPA finds that it is practicable for most systems to complete their initial monitoring within three years because all systems serving greater than 3,300 people will have appropriate monitoring data from UCMR 5. Many systems smaller than 3,300 people will also have appropriate monitoring data from state-led monitoring programs that may be eligible to meet the rule's initial monitoring requirements, and some will have UCMR 5 or other data. If systems find elevated levels of PFAS, these systems have an additional two years to comply with the MCL. If a system does not have eligible previously collected monitoring data and are concerned about insufficient time to install capital improvements, the EPA encourages these facilities to collect monitoring data as soon as possible after rule promulgation, allowing them the bulk of the five-year period to plan for and install any capital improvements if necessary.

Some commenters point to concerns regarding laboratory capability and capacity in supporting the proposed three-year compliance timeline. Additionally, a couple of commenters noted that if additional time were allowed, water systems that are close to the MCL may have time to identify and address sources of PFAS in their watersheds rather than investing resources on treatment initially. Finally, a couple of commenters recommend the EPA consider implementation flexibilities for small and rural water systems and suggest that these types of utilities may not have staff capacity nor expertise to compete for funding to implement the rule. While the agency acknowledges these commenter concerns, these issues are not directly related to capital improvements and thus were not the basis for the EPA's decision to extend the compliance date for the PFAS MCLs. However, the agency believes that extending the compliance date will also provide ancillary benefits toward addressing laboratory capability and capacity issues and may provide opportunities for systems who are close to exceeding the MCLs to investigate sources of contamination. Additionally, the extended compliance deadline may give smaller and rural water utilities more time to apply for funding under the Bipartisan Infrastructure Investment and Jobs Act (IIJA), also referred to as the Bipartisan Infrastructure Law (BIL) (please see section II of the final rule preamble for a discussion on BIL).

SDWA § 1416(a) and (b)(2)(C) describe how the EPA or states may also grant an exemption for systems meeting specified criteria that provides an additional period for compliance. These exemptions are issued on a case-by-case basis at the discretion of the primacy agency. Public water systems (PWSs) that meet the minimum criteria outlined in the SDWA may be eligible for an exemption of up to three years. For smaller water systems (≤3,300 population), exemptions can provide up to six additional years to achieve compliance. States exercising primacy enforcement responsibility must have adopted the 1998 Variance and Exemption Regulation (USEPA, 1998) for water systems in those jurisdictions to be able to provide exemptions.

The EPA requested comment as to whether there are specific conditions, in addition to the statutory conditions, that should be mandated for systems to be eligible for exemptions from the PFAS NPDWR under SDWA § 1416. Several commenters requested the EPA provide additional guidance to primacy Agencies on when exemptions are appropriate under SDWA § 1416 similar to what was done for the final Arsenic NPDWR (USEPA, 2002), which provided additional guidance on prioritizing systems for case-by-case extensions of the compliance deadline (beyond the 5 years provided in this rule) consistent with the requirement that an exemption not create an "unreasonable risk to health." Because relatively few states choose to issue exemptions, the EPA is not issuing additional guidance around implementation of SDWA § 1416 at this time but may reconsider the need for such guidance based on information developed during the initial compliance period. Furthermore, the EPA cannot issue exemptions as part of the NPDWR, as suggested by some commenters; exemptions under SDWA Section 1416 are issued by the primacy agency on a case-by-case basis and must meet the criteria under that provision.

Some commenters note simultaneous compliance issues with other final or proposed rules, such as the proposed Lead and Copper Rule Improvements. To the extent that implementation overlaps with other rules, the Health Risk Reduction and Cost Analysis (HRRCA) required by SDWA excludes costs that result from compliance with other regulations. Specifically, the agency notes that SDWA Section 1412(b)(3)(C)(i)(III) requires that EPA include quantifiable and non-quantifiable costs that are likely to occur solely as a result of compliance with the rule including monitoring, treatment and other costs and excluding costs resulting from compliance with other proposed or promulgated regulations. Nonetheless, the EPA has not identified any other drinking water regulations or requirements that will inhibit compliance with this regulation, nor should this regulation significantly impair compliance with other regulations such as the lead and copper rules (e.g., installing a treatment technology to comply with the MCLs for the PFAS NPDWR does not inhibit a system from taking action to meet corrosion control requirements under the lead and copper rule). With respect to the proposed Lead and Copper Rule Improvements, should the agency finalize that NPDWR, the EPA notes that operational adjustments may be necessary if treatment is installed to meet the MCLs under this NPDWR. Ion exchange resins or RO, for instance, may make water more corrosive if post-treatment stabilization (e.g., pH adjustment) is not performed. However, increases in corrosivity is short-lived after an ion exchange media change-out (please see the *Best Available Technologies and Small System Compliance Technologies Support Document*, USEPA 2024b). Systems using RO would likely need post-treatment stabilization to address corrosivity. While the EPA is not aware of many systems treating source waters for lead and copper (USEPA, 2019 – see FRN Vol. 84, No. 219, at page 61706), post-treatment stabilization and corrosion control will depend upon the treatment selected for lead or copper source water treatment. Nevertheless, the EPA recommends utilities to evaluate all treatment (and non-treatment) options for their site-specific needs and to carefully examine their operational plans to meet the requirements of this and other final NPDWRs. Finally, while the agency has not identified any other drinking water regulations or requirements that will inhibit compliance with this regulation, nor should this regulation significantly impact compliance with other regulations, the EPA's decision to extend the

compliance date for the PFAS MCLs may provide benefits for those systems to the extent that any such simultaneous compliance challenges exist.

SDWA § 1412(b)(10) requires that a NPDWR shall take effect "3 years after the date on which the regulation is promulgated unless the administrator determines that an earlier date is practicable." Section 1412(b)(2) also authorizes "the Administrator, or a State (in the case of an individual system), may allow up 2 additional years to *comply with a maximum contaminant level*…if the Administrator or the State…determines that additional time is necessary for capital improvements" (emphasis added). Congress intended the extension under this provision to allow for a total of five years to comply with the MCL. Thus, if the EPA provides a two-year extension of the MCL compliance deadline for all systems based on the need for capital improvements, a state cannot provide an additional two-year extension under Section 1412(b)(10) for capital improvements but may grant exemptions under Section 1416 consistent with applicable requirements.

Pursuant to SDWA § 1412(b)(10), the final PFAS NPDWR is effective 60 days after promulgation. The compliance date for the PFAS NPDWR, other than the MCLs, is 3 years after promulgation. As discussed above and upon consideration of information submitted by commenters, the EPA is exercising its authority under SDWA § 1412(b)(10) to implement a nationwide capital improvement extension to comply with the MCLs. All systems must comply with the MCLs by 5 years after the promulgation date.

Systems must comply with initial monitoring requirements within three years of rule promulgation and will be required to summarize PFAS monitoring results and applicable information beginning with Consumer Confidence Reports (CCRs) delivered in 2027. As the MCL compliance date is set at five years from rule promulgation, systems must report MCL violations in the CCR, accompanied by the required health effects language and information about violations, starting in 2029. Monitoring and testing procedure violations require Tier 3 notification: systems must provide notice no later than one year after the system learns of the violation. Systems must repeat the notice annually for as long as the violation persists. Systems must comply with initial monitoring requirements within three years of rule promulgation and systems must provide Tier 3 notification for monitoring and testing procedure violations starting in 2027. As the MCL compliance date is set at five years from rule promulgation, systems must provide Tier 2 notification for MCL violations, starting in 2029. For more information on SDWA Right-to-Know requirements, please see section IX of the final rule preamble.

Some commenters recommend a different regulatory framework than what the EPA proposed to alleviate perceived implementation concerns (e.g., reduce the potential of inundating laboratories or providing more time to plan and identify opportunities for source water reduction). For example, a few commenters suggest a phased-in MCL, where systems demonstrating higher concentrations are addressed first in the NPDWR, or MCL approaches where interim targets are set for compliance. While the agency has implemented a phased-in MCL in other NPDWRs, it is neither necessary or appropriate to do so here. The monitoring and compliance requirements finalized in the PFAS NPDWR address high-risk systems (i.e., systems with elevated

concentrations will require more frequent monitoring whereas systems without contamination or low levels of contamination will monitor less frequently). Based on these monitoring results, water systems may then be required to change their monitoring frequency if the results suggest increasing or decreasing concentrations (for additional discussion on monitoring and compliance requirements for the rule, please see section 8 of the EPA response in this *Response to Comments* document). In scenarios where elevated levels of PFAS are found in presumably "lower-risk" systems, a phased-in approach is not public health protective as these are systems that may experience spikes in PFAS concentrations. These fluctuations have been demonstrated in the agency's evaluation of PFAS occurrence in drinking water. The agency does not believe a phased-in approach that would delay compliance for such systems is warranted given the likely occurrence, co-occurrence, and public health concerns of the PFAS regulated by the NPDWR. The development of such a phase-in would also require additional resources both to develop the phase-in and to implement it, and is likely to be challenging to implement.

However, upon consideration of information submitted by commenters, particularly issues related to supply chain complications that are directly or indirectly related to the COVID-19 pandemic residual challenges, the EPA has determined that a significant number of systems subject to the rule will require an additional 2 years to complete the capital improvements necessary to comply with the MCLs for PFAS regulated under this action. The EPA expects that the additional 2 years are necessary for capital improvements to meet the MCL. Because EPA has provided a 2 year extension based on the need for capital improvements, EPA has addressed the concerns of many commenters about the need for additional time to comply with the rule, and therefore a phased schedule for rule implementation based on the concentrations of PFAS detected is unnecessary.

Individual Public Comments

Orange Water and Sewer Authority (OWASA) (Doc. #1524, SBC-042621)

• Treatment Support

o Start up and commissioning teams may be at a premium (especially if you go with a vendor supplied pressure vessel). This could impact the OWASA team's understanding of the new system as well as overall operation of the new system

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Orange Water and Sewer Authority (OWASA) (Doc. #1524, SBC-042619)

• Engineer Availability

o Current labor market it making it difficult to find engineers

o All of our current consultants are busy and not everyone is suited to design advanced treatment so those that are will be carrying a heavy load of work

• Contractor Availability

o Contractors are busy and are also being influenced by the difficult labor market

o Paying a premium for contractor availability

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Orange Water and Sewer Authority (OWASA) (Doc. #1524, SBC-042616)

• Timeline

o Regulatory Compliance deadline

o Because of the magnitude of costs involved, there are certain alternatives (e.g., new water treatment facility) that may represent the best overall solution for the utility for which the compliance timeline doesn't allow enough time to properly evaluate, design, and implement. Instead we have to quickly pick a technology that we know will work and that we can possibly get running prior to the compliance deadline plus the extension.

o There is a lot of new research and development of new treatment options/technologies is ongoing with PFAS and the current timeline precludes us from evaluating and potentially implementing some of these newer technologies and approaches.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

City of Dayton, Ohio (Doc. #1528, SBC-042632)

Attached are the comments for the City of Dayton, Ohio.

COMMENTS OF THE CITY OF DAYTON, OHIO

U.S. EPA's March 14, 2023, Proposed National Primary Drinking Water Regulation (NPDWR) for the Following Per- and Polyfluoroalkyl Substances (PFAS): [PFOA, PFOS, PFNA, Hr-PO-DA (GenX), PFHxS, and PFBSI

Public Docket ID: EPA-HQ-OW-2022-0114

Submitted Electronically (www.regulations.gov)

April 20, 2023

The City of Dayton, Ohio ("Dayton" or "the City") submits these comments on the above referenced proposed NPDWR.

Dayton is requesting that PWSs be given sufficient time to comply with the final MCLs and that funding for compliance be provided through avenues with no effect on ratepayers.

Dayton supplies 400,000 customers with treated groundwater, at an average daily flow of 60 million gallons per day (MGD), sourced from two well fields, the Mad River and the Miami Well Fields. The Mad River Well Field supplies approximately two-thirds of the treated water and directly adjoins Wright-Patterson Air Force Base's (WPAFB) southwestern boundary. Dayton's source water is 100% groundwater under the direct influence of surface water pumped from one of the largest Safe Water Drinking Act (SDWA) designated sole source aquifers in the U.S.

The City of Dayton has a significant interest in the proposed NPDWR due to the detection of per- and poly-fluoroalkyl substances (PFAS) in its early detection monitoring wells since 2016. The PFAS, primarily perfluorooctanoic acid (PFOA) and perfluorooctane sulfonate (PFOS), were detected at levels consistently above the 2016 PFAS health advisory level (HAL) of 70 parts per trillion (ppt) and as high as 150 ppt. The PFAS contamination is resultant of both surface water and groundwater flow from WPAFB.

In response, eight production wells closest to WPAFB, accounting for nearly 35% of the Mad

River Well Field's pumping capacity, were removed from service since 2017 at the request of Ohio EPA.

Treated water from the Ottawa Water Treatment Plant, which receives water from the Mad River Well Field has elevated PFAS levels that consistently range between 5-12 ppt, and sometimes as high as 18 ppt, considerably above U.S. EPA's 2022 revised SDWA HAL for PFAS, and the draft maximum contaminant levels (MCLs) of 4 ppt.

The City has requested WPAFB to fund the installation of a treatment system to remove the PFAS from the finished water produced at the Ottawa Water Treatment Plant; to date, the request has been denied.

Since 2016, the City of Dayton has been working closely with both Ohio and U.S. EPA to develop a comprehensive PFAS Strategy. This strategy includes the development of an alternate

water supply, conveyance of water to the Ottawa Water Treatment Plant, and treatment of finished drinking water to remove any remaining PFAS. However, the estimated cost of implementing this strategy is over $300 million.

The City of Dayton has several concerns regarding the proposed NPDWR, including:

• the amount of time to be afforded to public water systems (PWSs) to meet the final MCLs;

• the action steps that would be triggered based on an exceedance of the final MCLs;

• the enforcement discretion to be afforded to PWSs like Dayton that are likely to have difficulty meeting applicable deadlines to consistently comply with final MCLs;

[The City of Dayton has several concerns regarding the proposed NPDWR, including:]

• and the potential sources of funding to be made available to PWSs like Dayton that have contaminated raw water coming from sources outside of the City's control.

Dayton is requesting that PWSs be given sufficient time to comply with the final MCLs and that funding for compliance be provided through avenues with no effect on ratepayers.

The City of Dayton appreciates the opportunity to submit these comments and would welcome an opportunity to discuss them with U.S. EPA's staff whenever convenient.

Respectfully submitted,

CITY OF DAYTON, OHIO

By:

Michael Powell, Director

Department of Water

City of Dayton, Ohio

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. For funding concerns, the agency notes that funds are also available through the passage of the BIL to assist many disadvantaged communities, small systems, and others with the costs of installation of treatment when it might otherwise be cost-challenging. Please see section 2.4 of the EPA response in this *Response to Comments* document for more discussion about currently available funding.

Water Environment Federation (WEF) (Doc. #1529, SBC-043309)

Implementation: With 5,000 – 10,000 systems being required to treat for PFAS, contractor availability will be limited. Pilot testing can also take from 12-18 months.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Greater Cincinnati Water Works (GCWW) (Doc. #1550, SBC-042690)

Aside from the high cost of retrofitting our ground water treatment plant, Greater Cincinnati Water Works is very concerned about the timing of this regulation as well as the compliance schedule. EPA has a goal of finalizing this rule by the end of 2023 after which water systems will have three years to come into compliance. An option for a two-year extension is available for systems needing capital improvements, but this extension is not automatic. Typically projects of this magnitude for large utilities are multi-year projects. Piloting, design, regulatory approval, procurement, and construction can easily exceed three, and even five years. The current compliance schedule is far too aggressive to implement on a national basis.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Greater Cincinnati Water Works (GCWW) (Doc. #1550, SBC-042692)

The timing of this regulation is especially challenging for utilities as they muster resources to simultaneously comply with the recently promulgated Lead and Copper Rule soon to be followed by the Lead and Copper Rule Improvements. As utilities continue to put significant financial and personnel resources toward removal of lead lines and optimizing water quality for corrosion control, compliance with the PFAS rule will stress our limited resources even further. Although significant federal funding has been made available, it is not nearly enough to cover the costs of both programs. Concurrent implementation of these programs will place a significant burden on all our rate payers and make it more difficult for us to fund these two programs, aging infrastructure improvements, and programs for disadvantaged customers all at the same time.

We request this compliance period include a significantly longer compliance schedule for facilities requiring capital improvements. This will allow for additional time to plan treatment processes carefully, ensure simultaneous compliance with multiple regulations, and for costs to be spread over a longer time period.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline as well as simultaneous compliance challenges. For funding concerns, the agency notes that funds are also available through the passage of the BIL to assist many disadvantaged communities, small systems, and others with the costs of installation of treatment when it might otherwise be cost-challenging. Please see section 2.4 of the EPA response in this *Response to Comments* document for more discussion about currently available funding.

Ross Renick (Doc. #1553, SBC-042560)

May 10, 2023

Dr. Jennifer McLain,

Director

Office of Ground Water and Drinking Water (OGWDW)

United States Environmental Protection Agency (E.S. EPA)

1201 Constitution Ave NW

Washington DC, 20004

Re: Docket ID No. EPA-HQ-OW-2022-0114 Per- and Polyfluoroalkyl Substances National Primary Drinking Water Regulation

Dear Dr. McLain,

Thank you for the opportunity to comment on the upcoming proposal regarding Per- and Polyfluoroalkyl Substances and the National Primary Drinking Water Regulation (NPDWR). This comment is in general support of the proposed regulation and the need for swift action regarding the emerging contaminants that threaten our drinking water supplies. According to the EPA's definition of "emergent contaminants, a chemical or material characterized by a perceived, potential, or real threat to human health or the environments or by a lack of published health standards", the determinations of the two contaminants PFOA and PFOS, and the concurrent four (PFHxS, PFNA, Genx Chemicals, and PFBS seems appropriate as these contaminants are rapidly being detected in drinking water supplies across the country. However, there are parts of the proposal I do find concerning and would like to address for your consideration.

The first concern is the timeline of events. Per the CDC, many PFAS including PFOS and PFOA are a concern because they do not break down in the environment, can move through soils and contaminate drinking water sources, and are a bioaccumulate in fish and wildlife (CDC n.d.). In many places throughout the country these fish and wildlife sources are harvested as a main

source of protein and concern over the consumption of these food sources should be a concern. The effective enforceable date of this regulation of 2026 should be moved up. Even though this proposal is specifically addressing drinking water, there are other sources of PFAS in the environment that will affect human health and I feel as if we should limit those that we can as soon as possible. To that point, technology available (GAC, AIX, RO, and NF) presented by Mr. Lan is greater than 99% effective at achieving concentrations below analytical detection limits (EPA n.d.). If these technologies are available currently, we should implement them as soon as possible. Another issue with the proposed timeline is the Maximum Contaminant Level Goals (MCLGs) are non-enforceable (EPA n.d.). Meanwhile, with sooner implementation of the NPDWR, Maximum Contaminant Levels (MCLs) would be enforceable, and violations could be enforced sooner, ensuring safe drinking water. There are already enough non-enforced regulations within the Safe Water Drinking Act (SWDA) and PFAS should not be one of those due to the adverse human health effects. The Science Advisory Board has already recommended strengthening the rationale for PFAS from "suggestive" to "likely" in relation to various cancers and there should be swift action to reduce these risks (EPA, n.d.). A national standard for PFAS in drinking water should be a priority as there are currently 31 states with no PFAS regulations in place and several states have regulations that are less stringent than the current EPA Lifetime Drinking Water Health Advisory Level of 70 ppt for PFOS and PFOA guidance (Leighton, 2023).

EPA Response: The agency agrees with the commenter on the health concerns posed by PFAS and that establishing a national PFAS NPDWR as expeditiously as possible is needed to protect public health and the environment. SDWA § 1412(b)(10) requires that a "NPDWR shall take effect "3 years after the date on which the regulation is promulgated unless the administrator determines that an earlier date is practicable." For the same reasons discussed in section 12.1 of the EPA response in this *Response to Comments* document concerning the challenges water systems face in meeting the three-year statutory timeline for compliance provided in SDWA, EPA has determined that it is not "practicable" for water systems to comply with the rule prior to the three-year date set in the statute. However, under the statute, states can set more stringent requirements, including setting earlier compliance dates pursuant to SDWA Section 1414(e). Section 1412(b)(2) also authorizes "the Administrator, or a State (in the case of an individual system), may allow up 2 additional years to comply with a maximum contaminant level…if the Administrator or the State…determines that additional time is necessary for capital improvements. Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Michigan Farm Bureau (MFB) (Doc. #1562, SBC-043359)

Small and rural water suppliers face additional challenges: many assistance programs listed above are competitive and rely on a complex application process that smaller utilities have neither the staff capacity nor expertise to compete for limited dollars. Additionally, those federal

assistance programs are primarily in the form of low- or no-interest loans instead of grants, so many communities already struggling with asset management cannot afford the payback on such loans even at beneficial rates. Staff shortages even for the existing work required to safely operate and maintain drinking water systems are widespread: AWWA conducted a survey in 2021 on staffing and supply chain needs, [FN17: American Water Works Association. 2021. Covid Water Sector Impact Survey 5 (Oct 2021). Retrieved from: https://www.awwa.org/Portals/0/AWWA/Communications/COVID19Impact5thSurveyPublicSummary.pdf] and found that 40 percent of drinking water utilities of all sizes are struggling to fill positions at their facilities, and employee turnover has doubled. While in part due to Covid-19 labor shortages, the survey notes this challenge is also reflective of long-term trends that have not eased as return to work increased after initial shutdowns and pandemic-related restrictions were lifted. This shortage will worsen as additional contractors, permanent staff, laboratory capability, and treatment operators are needed to implement the additional regulatory requirements of complying with PFAS MCLs.

Worst, many agricultural businesses, such as farms with on-site worker housing for part of the year, packers and processors with enough employees to qualify as a public supply while not being a public utility, dairy and other farms with specific drinking water requirements that must meet public water supply standards, and other agricultural water users are not eligible at all for many federal or state assistance programs, or suffer similar problems with capacity to compete for that money in the programs they may participate in. Those agricultural businesses do not have rate payers to spread costs to; they must simply absorb the costs to their business with no means of increasing prices on goods to compensate for those costs since farms are not price makers but price takers competing in global markets with complex pricing and purchase scenarios.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. For funding concerns, the agency notes that funds are also available through the passage of the BIL to assist many disadvantaged communities, small systems, and others with the costs of installation of treatment when it might otherwise be cost-challenging. Please see section 2.4 of the EPA response in this *Response to Comments* document for more discussion about currently available funding.

Missouri Department of Natural Resources (Doc. #1563, SBC-042511)

The proposed regulation is unclear on how it applies to secondary systems. It seems unnecessary to require systems who purchase all of their water from another system to monitor for PFAS. The Department recommends that EPA include an exemption from the monitoring requirements for purchasing systems within the final rule. The producing systems would control the levels in the purchasing system, and there should not be an instance where the purchasing system would

exceed the MCL if the producing system does not. Requiring purchasing systems to test for PFAS would be a waste of water system resources, and will exacerbate existing laboratory capacity issues.

EPA Response: The agency has clarified the applicability of the NPDWR for secondary (i.e., consecutive systems that buys or otherwise receives some or all its finished water from a wholesale system) in the final rule (see section I of the final rule preamble). The EPA has defined in Title 40, Chapter 1, Subchapter D, Part 141.2 a wholesale system as a PWS that supplies finished PWSs and a consecutive system as a PWS that buys or otherwise receives some or all its finished water from a wholesale system. In the final NPDWR, the EPA reiterates that all community water systems (CWSs) and non-transient non-community water systems (NTNCWSs) must comply with this regulation. This includes consecutive CWSs and NTNCWSs; however, the requirements these consecutive systems must implement to comply with the regulation may be, and often are, much less extensive. For finished water that is provided through a system interconnection, the wholesale systems will be responsible for conducting the monitoring requirements at the entry point to the distribution system (EPTDS). The final regulation does not require that any monitoring be conducted at a system interconnection point. Where a violation does occur, the wholesale system must notify any consecutive systems of this violation and it is the responsibility of the consecutive system to provide Public Notification (PN) to their customers pursuant to § 141.201(c)(1). In addition, wholesale systems must also provide information in Subpart O to consecutive systems for developing CCRs (§ 141.201(c)(1)). Consecutive systems are responsible for providing their customers with the reports (§ 141.153(a)).

Maine Water Utilities Association (MWUA) (Doc. #1567, SBC-042738)

If a PWS must install treatment to address PFAS in their drinking water, it may cause the classification of their system to change, necessitating higher-grade licensed operators. In many states, operators sitting for higher-grade licenses have course requirements before they can even sit for the exams. EPA and primacy states must recognize that this will cause staffing issues and will need to provide compliance forbearance and flexibility for the operators to obtain the necessary licenses. As many PWS are already struggling to attract and retain appropriately licensed staff and the industry expects to lose many operators to retirement in the next 5 years, this is a significant concern.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. The EPA acknowledges that in some states, operation of advanced treatment processes may necessitate higher-level operating licenses. These exams may be offered multiple times a year depending on the level being sought. While operator training or certification is not explicitly captured in the EPA's cost estimates, the cost models include a 10

percent miscellaneous allowance on both capital and operating costs which may capture some systems that may need additional training or cost of that training. The EPA recommends utilities evaluate all treatment (and non-treatment options) for their site-specific needs, carefully examine operator certification requirements within their state, and to carefully plan their workforce needs to meet the requirements of the final NPDWR. In addition, States can use the DWSRF set-asides to support operator certification programs. Set-asides are different than the loan portion of the program in that the funds don't go directly to the utility but are supporting the overall goals of the DWSRF. The set-asides can assist the state in ensuring that water systems have properly trained operators to operate and maintain drinking water infrastructure to supply safe water to consumers. This set-aside can, for example, fund state operator certification staff and the development of operator certification databases and data management programs to track operators' certification status. For more information, please visit: https://www.epa.gov/dwcapacity/about-drinking-water-state-revolving-fund-dwsrf-set-asides#overview

Maine Water Utilities Association (MWUA) (Doc. #1567, SBC-042736)

There is significant engineering effort and cost that goes into selection of the appropriate treatment technologies for a given water system. Site-specific testing, either bench-scale or pilot-scale, that evaluates the effectiveness of the treatment technologies with the actual contaminated water and the follow-up cost analysis is critical for 1) identifying the appropriate treatment solution for that specific water and existing treatment processes; 2) selecting the cost-effective alternative; and 3) identifying and avoiding any potential unintended consequences that are inherently possible when any new water treatment process is added (e.g. although this is a very infrequent occurrence, coal-based carbon has been observed to release arsenic under certain water conditions). While such testing provides critical design parameters and potentially cost-saving measures, it takes time. Designing and building permanent PFAS treatment facilities – assuming timely approval from primacy agencies, and local permitting – can be a lengthy process. [FN1: See Appendix C] Renting temporary treatment equipment is not only very costly but also takes time. These challenges should be considered in EPA's timeframe for enforcing PFAS standards in drinking water.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Maine Water Utilities Association (MWUA) (Doc. #1567, SBC-042745)

Closing:

Thank you for the opportunity to provide these comments. As mentioned previously and throughout this letter, public water suppliers understand the importance of ensuring that the drinking water that reaches their customers meets Safe Drinking Water Act requirements and protects the public's health. Water suppliers work hard each day to meet these goals and satisfy their customers' expectations. As we have all come to be keenly aware, the issue of emerging contaminants is a huge challenge. Our members will be tasked with meeting all regulatory requirements and standards; therefore, EPA has an obligation to address our implementation concerns prior to finalizing the regulations. We look forward to working collaboratively with EPA and the state primacy agencies to ensure our PWS can meet their mandate of continued protection of public health.

Sincerely,

Brian McGuire

President

Maine Water Utilities Association

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

San Antonio Water System (SAWS) (Doc. #1570, SBC-042487)

• This proposed rule has been released while PWSs across the country are working toward compliance under the substantial Lead and Copper Rule Revised (LCRR). EPA references the feasibility of these proposed PFAS regulations. However, it's unclear if any evaluation has occurred that looks at the feasibility of this proposed regulation from the standpoint of the PWS dealing with both these regulations at the same time.

o The staff working towards compliance on LCRR will likely be the same staff required to work toward PFAS compliance. This is causing PWSs to be overextended.

o It does not appear that there has been coordination within EPA as these LCRR and PFAS rules have been developed. This is further substantiated by the upcoming release of the Lead and Copper Rule Improvements (LCRI), which are slated to be released in early 2024, requiring further action on the PWS.

o For LCRR, LCRI and PFAS, third party consultants, engineering firms, and laboratory capacity are needed to reach compliance. This is causing a scarcity in industry expertise for the PWSs as well as the supporting consultants.

SAWS values the effort that EPA has put into this proposed rule and encourages EPA to reevaluate these regulations based on the most current science available to PWSs and our ratepayers. These national regulations will be pivotal throughout the country and therefore must be attainable and feasible. Thank you for your time and consideration of these comments.

Sincerely,

Scott R. Halty

Director

Resource Protection and Compliance

San Antonio Water System

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges, as well as simultaneous compliance challenges, that may affect the compliance timeline.

San Antonio Water System (SAWS) (Doc. #1570, SBC-042481)

PWSs are looking at significant capital improvements. The demand on firms able to provide engineering and construction will be high and may not meet the needs required across the country. Three years will not be enough time for systems to sample, design and implement capital improvements. A longer compliance timeframe should be considered.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

National Special Districts Coalition (NSDC) (Doc. #1571, SBC-043002)

As EPA works toward finalizing this rule for the safety and protection of public health, NSDC requests the agency providing realistic timelines and deadlines for compliance with any final rule. Sufficient time should be granted to water agencies to conduct necessary studies, develop treatment plans, and implement changes without compromising the uninterrupted delivery of safe drinking water to the community.

All in all, NSDC encourages EPA to continue offering and enhancing its collaborative approach that involves active engagement with water agencies and stakeholders to mitigate burdensome regulatory compliance issues that could arise and to collectively address challenges and ensure the successful implementation of the proposed standards.

We believe that a comprehensive and collaborative approach, which considers the aforementioned concerns, will lead to a more effective and successful implementation of the proposed NPDWR.

Thank you for considering the National Special Districts Coalition's comments on the NPDWR. We look forward to continued collaboration and working together to protect the health and well-being of the thousands of communities special districts serve across the nation.

Sincerely,

Cole Arreola-Karr

Federal Advocacy Director

National Special Districts Coalition

1112 I St., Suite 200

Sacramento, CA 95814

colek@nationalspecialdistricts.org

(417) 861-7418

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

City of Wilmington, Ohio (Doc. #1572, SBC-042467)

Even though the City of Wilmington has been proactive in addressing the PFAS contamination by already employing the consulting engineering firm Hazen & Sawyer for a PFAS planning study, the timeframe for meeting the proposed MCLs will be difficult to meet in the current construction climate. Right now, many water and wastewater infrastructure projects are receiving no bids, or just one bid. Many additional projects will be hitting the street at the same time due to this proposed MCL, further stressing the construction market.

The City of Wilmington requests that the timeline for compliance includes additional, automatic flexibility to account for the tight construction market, and that funding is guaranteed to be available so that the additional treatment needed to meet the proposed MCLs does not require rate increases.

Respectfully submitted,

Rick Schaffer

Public Works Director

City of Wilmington, Ohio

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Lakewood Water District (LWD) (Doc. #1574, SBC-042756)

Timeline to Implement

The three-year timeline proposed to complete 12 months of sampling and then to put any mitigation steps into place is not feasible. With recent experience, an aggressive design schedule for a treatment facility is 12 months.

In addition, many regulatory agencies will require pilot testing for treatment systems, which will further add to the time required to implement system improvements. With many jurisdictions and engineering firms being understaffed, the perming and design schedule can extend significantly. A typical bid advertisement and award timeframe can easily be two months. It is not unreasonable to expect an 18-month timeframe before construction is ready to begin. This is before any treatment equipment is ordered as well. Currently, we see about a 6–12-month lead me for pumps and upwards of 12 months lead me for pressure filter vessels used in our GAC system. In addition, it would be safe to assume other utilities across the United States would also select GAC systems which will undoubtedly increase lead times.

We have seen similarly long lead times for GAC media for new installations. Even with 12 months of sampling data, the design, budding, equipment procurement, and construction may take up to three years under typical practices. This is even before the anticipated significant increase in demand for engineering, equipment, and construction created by water systems throughout the country, requiring goods from a limited pool of qualified engineers, manufacturers, and construction contractors. A timeline of at least five years would still be an aggressive schedule but at least somewhat more realistic.

Funding timelines further exacerbate the ability to meet the proposed timeline for the rule. As an example, LWD was fortunate to receive direct appropriations to help offset costs for two new wells through Senator Murray's office in May 2021 and still has not been able to receive a contract from the EPA program charged with administering the funding. With the federal funds described in the rule, the timeline for systems fortunate to receive funds is further extended past the proposed rule's effective date.

Sincerely,

Randall M. Black

General Manager

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

New Hampshire Water Works Association, Inc. (NHWWA) (Doc. #1576, SBC-042454)

The three-year implementation timeline for PFAS detection and remediation is unreasonable given real constraints such as the number of impacted systems, manufacturing and supply chain constraints (including treatment media), analytical methods and laboratory capacity, widespread professional labor and certified water Operator shortages, residual disposal issues, and system owner liability concerns. Systemic failures to meet an unrealistic timeframe will result in numerous, unnecessary enforcement documents and action that will consume regulatory time and erode public trust. These systemic constraints must be factored into a realistic implementation schedule.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. For additional discussion on residual disposal issues, please see section 10.4.2 of the EPA response in this *Response to Comments* document. For additional discussion on how the agency considers analytic feasibility when establishing the MCL, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

COMM Water Department (Doc. #1577, SBC-042442)

EPA's timeline for compliance with the rule is not reasonable, and likely not even achievable, given the work that goes into designing, constructing, and funding new treatment systems. The water sector, including operators, design engineers, and construction workers, is challenged with workforce issues like many other sectors of our society. More sophisticated treatment will likely cause a change in PWS classification and may require a higher-grade operator license. In Massachusetts, it takes time to get through the required training to be able to sit for a higher-grade exam. EPA does not appear to have given any thought to issues such as this when they crafted the rule and its three-year implementation timeframe. EPA must adjust the compliance timeframe to be more realistic.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the

compliance timeline. For concerns regarding operator certification, please see the EPA response to comment Doc. #1567, SBC-042738 in section 12.1 in this *Response to Comments* document.

COMM Water Department (Doc. #1577, SBC-042447)

Thank you for the opportunity to provide these comments. As a water professional, I work hard to always follow the laws and regulations put forth by our regulatory agencies. I am sounding the alarm that I do not think this rule is reasonable, nor easily achievable. EPA has an obligation to address the water sector's implementation concerns and craft a final rule that is more realistic in its expectations of implementation and schedule and comes with the requisite funding to ensure PWS can comply.

Sincerely,

Craig Crocker

Superintendent, COMM Water Department

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Santa Clarita Valley Water Agency (SCVWA) (Doc. #1578, SBC-042430)

Based upon our experience it will be critical to ensure adequate time for compliance with the proposed rule. As mentioned, we are currently observing supply chain difficulties with the construction of recent PFAS facilities. Specifically, specialized equipment has exceptionally long lead times, and in one case we have received a lead time notice of over 70 weeks for the Motor Control Center. In addition, we have started to receive notice of delay from the resin provider (in this case Evoqua) having 9 scheduled resin fills with another water agency. We believe the two most recent projects reflect the current timing conditions for project design, construction and delivery. The project delivery time for the Valley Center Well facility was 3.5 years and is projected to be 4 years for the Santa Clara and Honby Wells facility. As the scope and magnitude of complying with the proposed rule are realized, the competition for the same resources will be further magnified and delays will be compounded.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

San Gabriel Valley Water Association (SGVWA) (Doc. #1580, SBC-042420)

Scarce Workforce: One problem associated with implementing advanced treatment systems for MCLs is the shortage of available workers. This will lead to a significant demand for more water operators in thousands of communities across the country. This demand may result in disparities in the availability of qualified operators between larger, wealthier water suppliers and those with fewer resources. Additionally, current operators may need to obtain higher levels of certification to manage and maintain the new systems, which will require additional staff time and resources. This poses a challenge to the sustainability of many small water systems.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. For funding concerns, the agency notes that funds are also available through the passage of the BIL to assist many disadvantaged communities, small systems, and others with the costs of installation of treatment when it might otherwise be cost-challenging. Please see section 2.4 of the EPA response in this *Response to Comments* document for more discussion about currently available funding. Regarding concerns on operator certification licenses, please see the EPA response to comment Doc. #1567, SBC-042738 in section 12.1 in this *Response to Comments* document.

Missouri River Public Water Supplies Association (MRPWSA) (Doc. #1581, SBC-042414)

Effective Date — MRPWSA strongly urges U.S. EPA to adopt an Effective Date for the final rule that accounts for the time for the regulatory review process with the States and to construct the facilities necessary to meet the part per trillion proposed regulations.

Sincerely,

Tim Ganz

President

Missouri River Public Water Supplies Association

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Washington Suburban Sanitary Commission (WSSC Water) (Doc. #1585, SBC-042770)

2. Implementation Timeline

Initial monitoring period:

Under the proposed rule, water systems are required to achieve full compliance beginning three years after the promulgation of the final rule. If initial monitoring results exceed the MCL, mitigation measures, which often require capital improvements, must be implemented within the same three-year period. This timeline is significantly shorter than the usual minimum duration of 10 years needed to complete capital improvements. In WSSC Water, bench testing, pilot testing, design, budget allocations, procurement, site acquisition, and permitting and construction for a treatment process of this complexity has historically required 9 to 11 years. WSSC Water acknowledges that delaying rule compliance for 10 years may adversely impact public health protection. As such, we suggest that EPA consider extending the compliance timeline to a total of eight years, with a standard three-year compliance timeline, a nationwide blanket two-year extension, and another three-year extension at the discretion of the primacy agency, in accordance with SDWA *1416. EPA may also consider providing states with specific guidance tailored for PFAS to assist states determining which systems would qualify for additional 3-year extension. While a total of 8 years is still insufficient for water systems to adopt necessary mitigation measures in order to comply with the rule, when combined with the phased MCL approach recommended above and an initial MCL set at 10 ppt, water systems would have more appropriate opportunities to prepare for the required capital improvement measures.

Alternatively, EPA may consider a risk-based approach, where water systems with low levels of PFAS during the initial monitoring period may be granted an extended implementation schedule before beginning compliance. This approach would have minimal impact on public health protection, considering the demonstrated low risk. EPA has successfully adopted this approach with its arsenic rule, where systems demonstrating low level of risk are eligible for an exemption from compliance for a certain period depending on the levels found. EPA could also explore a similar risk-based implementation framework that has been successfully adopted in the Long Term 2 Enhanced Surface Water Treatment Rule. Under this framework, water systems conducted two rounds of two-year source water monitoring, with a six-year interval between each round, to assess the level of risk. Based on the identified risk, water systems would then be subject to Bin Placement, a tiered mitigation measure consistent with the level of risk detected.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. Regarding exemptions, the EPA notes that, as suggested by the commenter, primacy agencies who have adopted the 1998 *Variance and Exemptions Regulation* (USEPA, 1998) may choose to grant exemptions on a case-by-case basis.. Primacy agencies who choose to issue such exemptions can consider the kind of prioritizing based on risk that is suggested by the commenter; this would be consistent with the arsenic guidance and the statutory requirement that granting an exemption will not result in an unreasonable risk to health. SDWA Section 1416(a)(3). See section 12.1 of the EPA response in this *Response to Comments* document. For

additional discussion on how the agency considers analytic feasibility when establishing the MCL, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

Security Water District, Security Water and Sanitation Districts/Enterprises (Doc. #1587, SBC-042782)

It was January, 2016 when we first shut down wells due to PFAS contamination, and the Ion Exchange facility was not fully-functional until May, 2022 — more than 6 years later. Consequently, we are concerned that the 3-year implementation time line is insufficient. We have many other concerns with regard to implementation and the time allowed to implement, including:

• Increasing laboratory testing turn-around time due to higher demand

• Supply chain issues that have become common

• Workforce shortages and the need for operators to be certified at higher levels

due to increased treatment requirements

• Longer turn-around time for SRF funding due to higher demand and more stringent federal requirements

• The need for piloting, which will extend the time to implement treatment

• Post-treatment requirements, such as increased LCR sampling

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Security Water District, Security Water and Sanitation Districts/Enterprises (Doc. #1587, SBC-042780)

May 26, 2023

United States Environmental Protection Agency 1200 Pennsylvania Avenue, N.W.

Washington D.C. 20460

Delivered via EPA website

Thank you for providing the opportunity to comment on the proposed National Primary Drinking Water Regulation (NPDWR) for six PFAS chemicals. As the General Manager of the Security Water and Sanitation Districts, located just south of Colorado Springs, Colorado, I am keenly aware of the impact that PFAS chemicals, as well as EPA actions, can have on a community.

Since early 2016, It's been a bit of a whirlwind for the customers, elected officials, staff, consultants and others involved in the issues of PFAS well contamination in the Security Water District.

With the issuance of the new Lifetime Health Advisory in May, 2016, the advisory levels for PFOA and PFOS went from a combined 600 parts per trillion to a combined 70 parts per trillion overnight. This caused some members of our community to consider the drinking water supply in Security to be poisoned, rendering our 24 groundwater wells virtually unusable. As a result:

• A local non-profit brought in a semi-truck load of bottled water on a weekly basis. The line of cars waiting to pick up their weekly allocation of bottled water was a mile long.

• Customers called us to find out how to dispose of all of their empty single-use water bottles.

• The local fire department refused to use the community water supply during their annual 4th of July pancake breakfast, opting instead to use bottled water to make pancake batter.

• A community swimming pool demanded that we pay to replace the water in their swimming pool (with what?)

I fear that an inadequate or hasty implementation of the proposed PFAS Rule will result in similar outcomes for water systems across the country.

EPA Response: The EPA's final rule represents data-driven drinking water standards that are based on the best available science and meet the requirements of SDWA; regulation of the PFAS covered by the NPDWR is vital toward protecting public health by removing these contaminants from our nation's drinking water. After finalization of the PFAS NPDWR, the EPA also intends to work with stakeholders to provide support to utilities, primacy agencies, and other interested parties to ensure successful rule implementation. For additional discussion on risk communication issues for the final PFAS NPDWR, please see section 1.2 of the EPA response in this *Response to Comments* document. Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Cape Fear Public Utility Authority (CFPUA) (Doc. #1588, SBC-042382)

Potential impacts of EPA's proposed compliance deadline

EPA states that it "assumes promulgation of the regulations by the end of 2023, followed by a three-year window for utilities who exceed the MCLs or hazard index to identify, design, fund, and construct treatment necessary to achieve compliance." While this timeline may be achievable for some affected water systems, we note the pilot testing, design, and construction of CFPUA's treatment took almost five years.

Certainly, CFPUA's work occurred amid numerous challenges, most notably operational, labor-market, and supply-chain bottlenecks resulting from the worldwide COVID-19 pandemic. One challenge we did not face was competition from thousands of other water utilities seeking to accomplish the same goal by the same deadline. EPA's proposed implementation timeline will spark a scramble by water systems to secure limited, specialized resources: consulting expertise, experienced and qualified construction contractors, materials essential to building and operating treatment, and laboratory analysis, just to name the most obvious. Already inflated costs and lengthy equipment, material, and service lead times will increase even further – not only for those adding new treatment to comply with the proposed NPDWR but also for CFPUA and others who already have effective treatment but require regular services such as GAC regeneration and laboratory analysis. The mismatch between supply and demand will further widen the gap between available federal funding and the number of water systems that need federal funding. It will further add to the financial burdens inevitably borne by individual utilities and their customers. Extending the compliance window from three years from promulgation to five years or more, with a tiered structure based on utility size and for water systems installing capital improvements would reduce the workforce and supply chain challenges.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Suffolk County Water Authority (SCWA) (Doc. #1589, SBC-043370)

6. Supply Chain Limitations for Treatment Installation and Media Procurement Will Present Significant Challenges

As indicated above, the SCWA has been installing new GAC treatment systems to address PFAS over the last four to five years, and it is purchasing additional systems as fast as they can be manufactured. The current lead time for purchase of new GAC systems is in excess of 12 months. The SCWA's GAC filter media contractor has given notice to SCWA that it may not be able to fulfill all of SCWA's filter media needs over the summer months of this year. These supply chain issues are real and significant. They will only get worse after the proposed federal PFAS regulation is finalized because there will be a substantial increase in demand for both treatment systems and filter media.

7. Time Frame for Implementation Should be Extended to the Greatest Extent Practicable

Finally, SCWA again commends the EPA for proposing National Primary Drinking Water Regulations for these six PFAS because they will improve the health of public water supply customers across the nation. However, in SCWA's experience, there will be significant obstacles, including high costs, inadequate laboratory capacity, and supply chain issues that will make compliance with the final rule difficult and time consuming. Thus, the SCWA recommends

allowing the maximum time permissible for the implementation of the rule under the Safe Drinking Water Act.

Respectfully submitted,

Timothy J. Hopkins

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Lehigh County Authority (LCA) (Doc. #1600, SBC-042820)

2. Workforce Impacts – Across the nation, the story at every utility and supporting organization is the same: there are simply not enough applicants for the jobs we have available. Utilities are struggling to maintain full staffing, and engineering firms are feeling the same constraints. This will make compliance with the proposed rule in a relatively short period of time very difficult. If the data are accurate, a significant number of utilities will be facing the need to evaluate treatment alternatives for PFAS at the same time, creating a wave of projects and demand for engineering services that the current workforce conditions will not support.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Lehigh County Authority (LCA) (Doc. #1600, SBC-042822)

4. Compounding Compliance Pressures – The proposed PFAS requirements are coming at a time when water systems are already deeply engaged in a variety of other new regulatory compliance efforts, such as the efforts to meet new requirements laid out in the Lead & Copper Rule Revision (LCRR). Significant capital expenses will be incurred over the next several years as utilities work to remove lead service lines and implement corrosion control systems to achieve LCRR compliance. This effort will draw on the same limited resources (workforce, materials, engineering support, and funding) that are needed to achieve PFAS compliance.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges, as well as simultaneous compliance challenges, that may affect the compliance timeline

Lehigh County Authority (LCA) (Doc. #1600, SBC-042824)

Based on these significant compliance and implementation challenges, LCA believes the standard implementation timeline is not appropriate for the proposed PFAS rule. The need to plan, design, pilot, and construct facilities will take much longer than the three-year timeline given the challenges described above. EPA should consider extending the effective date of compliance by two years to ease the burden on water systems that must install capital improvements to achieve compliance.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Massachusetts Water Works Association (MWWA) (Doc. #1601, SBC-042887)

There is significant engineering effort and cost that goes into selection of the appropriate treatment technologies for a given water system. Site-specific testing, either bench-scale or pilot-scale, that evaluates the effectiveness of the treatment technologies for the actual contaminated water and an associated cost analysis are critical for 1) identifying the appropriate treatment solution for that specific water and existing treatment processes; 2) selecting the cost-effective alternative; and 3) identifying and avoiding any potential unintended consequences that are inherently possible when any new water treatment process is added (e.g. although this is a very infrequent occurrence, coal-based carbon has been observed to release arsenic under certain water conditions) [FN18: https://doi.org/10.1002/awwa.1959]. While such testing provides critical design parameters and potential cost-saving measures, it takes significant time. Designing and building permanent PFAS treatment facilities – assuming timely approval from MassDEP, and local permitting – is a lengthy process [FN19: See Appendix A which MWWA believes captures the typical timeline for brining treatment online under normal circumstances.]. Renting temporary treatment equipment similarly is costly and time-consuming. These challenges should be considered in EPA's timeframe for enforcing PFAS standards in drinking water. It will be very difficult for PWS to come into compliance with this rule within the three-year window EPA is proposing.

If a PWS must install treatment to address PFAS in their drinking water, it may cause the classification of their system to change, necessitating higher-grade licensed operators. In Massachusetts and other states, operators sitting for higher-grade licenses have course requirements before they can even sit for the exams. EPA and primacy states must recognize that this will cause staffing issues and will need to provide compliance forbearance and flexibility for the operators to obtain the necessary licenses. Many PWS are already struggling to attract and retain appropriately licensed staff and the industry expects to lose many operators to retirement in the next five years. Some PWS in wealthier communities may, through higher salaries, be able

to lure currently licensed operators from other systems that cannot compete with higher wages. These less wealthy PWS often have significant Environmental Justice populations that could be put at risk due to lack of certified water treatment operators. PWS are already struggling to maintain staffing levels and that problem will be exacerbated by this proposed PFAS MCL.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. Regarding concerns on operator certification licenses, please see the EPA response to comment Doc. #1567, SBC-042738 in section 12.1 in this *Response to Comments* document.

Water Works Board of the City of Birmingham (BWWB) (Doc. #1602, SBC-043652)

6. Compliance time and high demand drive cost increase: The proposed rule allows three years for systems to come into compliance with the Rule, including initial monitoring. States are authorized to grant a two-year extension, but this is not guaranteed. Associated concerns include insufficient time, availability of qualified contractors, and surge in construction prices based on demand. It is recommended that USEPA extend the implementation timeframe for compliance with the proposed PFAS Rule to 2029 in order to reflect the time needed to complete source water characterization, piloting of technologies, design, and construction of treatment solutions.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Arlington County Virginia (Doc. #1603, SBC-043006)

2. The regulation as proposed cannot be implemented by the industry

EPA Response: The EPA's final rule represents data-driven drinking water standards that are based on a thorough analysis of feasibility consistent with requirements under SDWA. For additional discussion on the EPA's feasibility analysis, please see section 5.1.2 of the EPA response in this *Response to Comments* document. For discussion on treatment technologies, please see section 10 of the EPA response in this *Response to Comments* document. Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Arlington County Virginia (Doc. #1603, SBC-043010)

Proposed Implementation Timeline & Limits

As proposed, the regulation would provide a 3-year window for water utilities across the country to achieve treatment levels which are at the limits of current technology. The regulations would be implemented while we still have limited knowledge regarding the transmission and behavior of PFAS in the built and natural environment and water utility systems.

Our limited knowledge of PFAS prevalence and behavior combined with such a severe and aggressive enforceable level will drive many water utilities to initiate costly and complicated treatment upgrades to ensure future compliance, even though existing testing has not exceeded the proposed MCL.

By establishing such an aggressive implementation level and timeline, the proposed regulation will compel reactive upgrades and investments at hundreds or thousands of utilities – many of which will ultimately be demonstrated to have been unnecessary or imprudent. In addition to diverting investment from more impactful upgrades (infrastructure renewal, corrosion control, source water supply & protection, infrastructure security, etc.), the aggressive level and schedule will serve to distort and likely overwhelm several sectors of the utility engineering and consulting industry.

Alternatively, a graduated approach to drinking water levels combined with source control research and regulation would enable more informed and responsible management of PFAS exposure. Instead of racing to a regulatory limit at the threshold of technology and drastically below other nations, EPA should focus immediate resources on those systems with excessive exposures, and on researching and regulating sources of PFAS. Such an approach would steer limited resources to the greatest needs and would demonstrate some adherence to the "polluter should pay" principle.

Finally, a 3-year (or even 5-year process if a 2-year extension is assumed) implementation is infeasible to implement the necessary capital improvements at most large drinking water plants. Such upgrades typically require capital planning to include extensive public engagement and legislative actions around rate increases. Further, new treatment processes at large drinking water plants require extensive planning, design, and importantly bench-scale piloting. Failure to adequately analyze process impacts and water chemistry changes through such pilot studies can have calamitous side effects – as occurred in Flint Michigan. In addition to the extensive planning, design, testing, and financial processes, water treatment plants are subject to extensive State and local regulatory requirements, including local land-use regulations. In an urban area such as the National Capital region, local permitting requirements alone will require several years of process.

EPA Response: The EPA disagrees with the commenter that knowledge is limited on PFAS sources, exposure, and human health effects that would preclude regulation at this time. The EPA's final rule represents data-driven drinking water standards that are based on the best

available science and meet the requirements of SDWA; regulation of the PFAS covered by the NPDWR is vital toward protecting public health by removing these contaminants from our nation's drinking water. Regarding actions the EPA is taking to research and address PFAS through other environmental statutes, the agency notes that these actions are outside the scope of the current rulemaking but directs the commenter's attention to the EPA PFAS Strategic Roadmap that outlines the whole-of-agency approach to "further the science and research, to restrict these dangerous chemicals from getting into the environment, and to immediately move to remediate the problem in communities across the country" (USEPA, 2022). Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Arlington County Virginia (Doc. #1603, SBC-043014)

Third, implementation of the rule will exceed the capacity of the engineering, construction, and material markets – generating unpredictable inflation.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. The commenter also provides no verifiable information regarding "unpredictable inflation;" for treatment technology availability and capacity considerations, please see section 10.6 of the EPA response in this *Response to Comments* document.

Arlington County Virginia (Doc. #1603, SBC-043017)

3. It seems unlikely that sufficient consulting engineers, utility contractors, equipment and material suppliers, and State regulators exist or can grow to meet the demand to shepherd the thousands of major capital upgrade projects which will be triggered by the proposed regulation to completion within the proposed 3-year timeframe. Such distortion of the market will presumably instigate concentrated and excessive inflation far exceeding general benchmarks. We do not see any consideration of focused and acute inflationary impacts in the economic analysis.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). This will provide the maximum amount of time that EPA can provide by regulation to address concerns about compliance timeframes. This extension will provide time for supply, where lacking, to meet demand for treatment technologies and associated contracting and engineering services. Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. Regarding rising costs in the drinking water sector and the effects of

inflation, as recommended by commenters, the EPA adjusted the cost estimates by escalating unit costs using indices including the Bureau of Labor Statistics producer price indices. For more information see section 13.3.3 of the EPA response in this *Response to Comments* document. The commenter also provides no verifiable information regarding "excessive inflation far exceeding general benchmarks" and the EPA disagrees that treatment capital, operation and maintenance costs and other rule associated costs are likely to increase significantly as a result of heightened demand.

American Water Works Company Inc. (Doc. #1608, SBC-043987)

Effective Date – American Water strongly urges the U.S. EPA to adopt an Effective Date for the final rule that is five years from the promulgation date, similar to the approach used under the Arsenic Rule.

EPA Response: Consistent with the commenter's request, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

American Water Works Company Inc. (Doc. #1608, SBC-043976)

The implementation timing should also consider the available capacity of engineers, contractors, and suppliers to build the required treatment and the available capacity of vendors to supply ion exchange resin, granular activated carbon, and media reactivation/waste disposal services on an ongoing basis.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. For treatment technology availability and capacity considerations, please see section 10.6 of the EPA response in this *Response to Comments* document.

American Water Works Company Inc. (Doc. #1608, SBC-044008)

Effective Date

American Water strongly urges the U.S. EPA to adopt an Effective Date for the final rule that is five years from the promulgation date, similar to the approach used under the Arsenic Rule. We believe that the same rationale applies to this rule and that the implementation timing should consider the available capacity of engineers, contractors, and suppliers to obtain the necessary approvals and permits and build the required treatment; and also the available capacity of vendors to supply ion exchange resin and supply/reactivate granular activated carbon used for treatment on an ongoing basis. We believe the capacities of those resources will be challenged if

the Effective Date for the final rule is set at three years from the promulgation date, which will further drive up both capital and ongoing operational expenses associated with PFAS treatment.

Furthermore, establishing an Effective Date of five years from the promulgation date will allow drinking water utilities more time to adequately sample and ultimately assess their risk of compliance, as well as to analyze/pilot treatment options to make prudent decisions on very significant capital investment for treatment which will affect customer rates. This is especially true for surface water supplies that tend to have higher overall and seasonal variability of PFAS concentrations; and which will require significantly higher capital investment and operational expenditure on a per gallon basis for PFAS treatment.

The following comes from the preamble to the final Arsenic Rule (66 FR 6992-2993):

"M. What is the Effective Date and Compliance Date for the Rule?

In the proposed rule, EPA made a finding that all small systems (i.e., systems serving 10,000 people or less) would be granted a 2-year capital improvement extension which extends the MCL effective date for purposes of compliance with the new MCL to January 23, 2006. EPA proposed the 2- year capital improvement extension for small systems because of the time required for systems to plan, finance, design and construct new treatment systems.

Large systems were not provided this additional time because of the greater resources these systems have to perform capital improvements in a timely manner. However, upon consideration of information submitted by commenters, EPA has determined that large systems will also require an additional 2 years to complete the capital improvements necessary to comply with the arsenic MCL. While large systems (i.e., systems serving more than 10,000 people) do have greater resources to implement capital improvements, (e.g., engineering and construction management staff to manage the projects), these systems generally also have more entry points to the distribution system that will require treatment.

A number of treatment technologies are listed as BAT for the proposed rule: ion exchange, activated alumina, reverse osmosis, modified coagulation/ filtration, modified lime softening and electrodialysis reversal. There are also several emerging technologies for arsenic removal, such as nanofiltration and granular ferric hydroxide. To ensure cost effective compliance with the arsenic MCL, systems will need to evaluate their treatment technology options as a first step. This planning step may include pilot studies with potential treatment systems, or it may be limited to an evaluation of the raw water characteristics. Systems choosing to conduct pilot testing may take a year or more to contract with vendors and to perform pilot testing.

Once the planning step is completed systems must design and construct the treatment systems. Design and permitting of the treatment systems can take an additional year, and construction of the treatment system can take another year. Because systems will also need time to: obtain funding, obtain local government approval of the project, or acquire the land necessary to construct these technologies, it is likely that most large systems will need additional time beyond the three-year effective date for compliance with the new MCL that EPA proposed.

Based upon these considerations, EPA determined, in accordance with section 1412(b)(10) of SDWA, that the compliance date for the new arsenic MCL, regardless of system size, will be 5 years from the date of promulgation of the standard. See section I.H. for more information regarding variance and exemptions."

EPA Response: Consistent with this comment and for reasons similar to those provided in the arsenic rule quoted by the commenter, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Prince William County Service Authority (Doc. #1609, SBC-042836)

Timeframe for Compliance is Unrealistic

The proposed rule provides only three years for compliance from final rulemaking. While utilities can apply for a two-year extension from their primacy agency, extensions are not guaranteed. Even a five-year period to comply ignores the realities of implementing capital projects such as the addition of GAC, ion exchange (IX), or reverse osmosis (RO) to existing treatment plants. Any of these treatment alternatives would need to be piloted for at least one year to capture seasonal variations in source water quality. Depending on the alternative being studied, pipe loop studies may also be required to ensure that multiple competing regulations do not result in non-compliance. Certainly, any utility contemplating a change in source water to achieve PFAS compliance would need to undertake both of these studies to avoid unintended consequences in the distribution system. Additionally, utilities will have to develop the financial capacity to implement these capital projects. Utilities will have to increase rates, issue bonds, secure grants and/or loans, or a combination of these. All of these efforts take time, but funds have to be in hand before design and construction can proceed.

At the proposed MCL and HI levels, the rule will place significant demand on a limited pool of resources to achieve compliance. Too many utilities will be competing for the same consulting engineers, construction contractors, and suppliers at the same time making it difficult for utilities to meet unrealistic compliance deadlines This will lead to further cost increases and rampant noncompliance which would be contrary to the objective of the regulation. Additionally, there will be significant impacts on the limited resources of primacy agencies to support utilities in the compliance process. These limitations will invariably lead to additional costs beyond what EPA currently estimates. The pool for construction contractors for water infrastructure projects is already stressed. Utilities are seeing fewer bidders, sometimes only one bidder, and bids are consistently higher than engineers' estimates. Utilities, consulting engineers, and contractors are all facing workforce challenges. Cost increases due to competition for limited resources will further strain the ratepaying public and drinking water affordability.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA

1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Prince William County Service Authority (Doc. #1609, SBC-042844)

4. The underestimation of utilities impacted by the proposed rule and the unrealistic compliance deadline will place significant demand on limited resources for consulting engineers, contractors, suppliers, and primacy agency support to achieve compliance. This will lead to further cost increases and rampant noncompliance which would be contrary to the objective of the regulation.

EPA Response: After finalization of the PFAS NPDWR, the EPA also intends to work with stakeholders to provide support to utilities, primacy agencies, and other interested parties to ensure successful rule implementation. For additional discussion on risk communication issues for the final PFAS NPDWR, please see section 1.2 of the EPA response in this *Response to Comments* document. Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Prince William County Service Authority (Doc. #1609, SBC-042837)

While the Service Authority supports the goal of the proposed PFAS rule, a compliance deadline that is not achievable could ultimately lead to thousands of utilities being out of compliance. Rampant noncompliance places an unnecessary burden on primacy agencies and EPA and undermines the confidence of the public in its drinking water. The public would be better served by knowing the path to compliance is achievable rather than by being routinely notified that their drinking water fails to meet standards. Repeated notices of noncompliance will only drive more people to drink bottled water under the false impression that it is safer when it is actually not regulated by the same EPA PFAS standard. Many who choose bottled water may be people who can least afford to do so.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Marlene Ladderbush (Doc. #1612, SBC-042918)

EPA's timeline for compliance with the rule is not reasonable, and likely not even achievable, given the work that goes into designing, constructing, and funding new treatment systems. The water sector, including operators, design engineers, and construction workers, is challenged with

workforce issues like many other sectors of our society. More sophisticated treatment will likely cause a change in PWS classification and may require a higher-grade operator license. In Massachusetts, it takes time to get through the required training to be able to sit for a higher-grade exam. EPA does not appear to have given any thought to issues such as this when they crafted the rule and its three-year implementation timeframe. EPA must adjust the compliance timeframe to be more realistic.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. Regarding concerns on operator certification licenses, please see the EPA response to comment Doc. #1567, SBC-042738 in section 12.1 in this *Response to Comments* document.

Town of Lincoln Water Department (Doc. #1613, SBC-043030)

EPA's timeline for compliance with the rule is not reasonable, and likely not even achievable, given the work that goes into designing, constructing, and funding new treatment systems. The water sector, including operators, design engineers, and construction workers, is challenged with workforce issues like many other sectors of our society. More sophisticated treatment will likely cause a change in PWS classification and may require a higher-grade operator license. In Massachusetts, it takes time to get through the required training to be able to sit for a higher-grade exam. EPA does not appear to have given any thought to issues such as this when they crafted the rule and its three-year implementation timeframe. EPA must adjust the compliance timeframe to be more realistic.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. Regarding concerns on operator certification licenses, please see the EPA response to comment Doc. #1567, SBC-042738 in section 12.1 in this *Response to Comments* document.

Aquarion Water Company (Doc. #1617, SBC-043376)

2. With the requirement to comply with the regulation three years after promulgation, there will be a rush of planning, design, pilot testing, permitting, financing, procurement, and construction activity across the U.S. water industry. This rush of activity will drive up costs as utilities compete for resources (e.g., filter vessels, GAC, IX media) and as utilities make decisions based on relatively limited experience addressing PFAS. The allowance for two additional years to comply in cases where capital improvements are needed will provide limited relief.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension for all water systems pursuant to SDWA 1412(b)(10). Based on the public comments provided and record for this rulemaking, the two additional years to comply should provide significant relief. Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Beaufort-Jasper Water & Sewer Authority (BJWSA) (Doc. #1618, SBC-042931)

The proposed maximum contaminant levels of PFAS in drinking water will require that a significant number of water utilities across the country install additional treatment to remove these compounds. Based on current inflationary pressures and recent escalations in construction bid prices, we believe EPA has significantly underestimated the nationwide cost to address PFAS contamination in drinking water. Furthermore, the compliance timeframe provided in the proposal (three years from rule finalization) is simply not feasible given the demand on the construction industry, lingering supply chain issues, and significant labor shortages. Projects of the magnitude required for PFAS removal normally take five years or more to implement, and include multiple steps such as study of appropriate technology, pilot testing, detailed design, bid, construction, and startup. Regulatory review is also required throughout the process. Such an aggressive implementation timeline for so many utilities will have the likely impact of driving construction prices up even higher for all projects (not just those associated with PFAS).

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10) to provide the five years suggested by the commenter. Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline and section 13 of the EPA response in this *Response to Comments* document with respect to concerns about underestimating costs.

Beaufort-Jasper Water & Sewer Authority (BJWSA) (Doc. #1618, SBC-042936)

In conjunction with a more reasonable implementation schedule, the time to plan and construct new PFAS removal facilities needs to be broadened beyond the proposed 3-year timeframe. At a minimum, utilities should be given five years to properly plan, design and construct facilities. For example, a thoughtful and logical sequence for performing the necessary due diligence and facility construction could be as follows.

Year 1: Perform PFAS Treatability Study - evaluate alternative technologies, removal efficiencies, operation and maintenance considerations; evaluate alternative treatment configurations; evaluate residuals disposal options; conduct bench and pilot tests as required

Year 2: Prepare Preliminary Engineering Report - based on Treatability Study define the facility improvements, facility layouts, construction cost estimate, construction schedule

Year 3: Prepare Construction Documents (plans and specifications)

Year 4: Bid and Begin Construction

Year 5: Complete Construction, Startup and Commission New Facility

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10), which will provide the timeframe suggested by the commenter. Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. Please see section 13 of the EPA response in this *Response to Comments* document with respect to costs.

Colorado Water Utility Council (CWUC) (Doc. #1622, SBC-044028)

In addition, there will likely be supply and labor issues for installing treatment, huge costs for ongoing maintenance, regeneration or disposal.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Aqua America, an Essential Utilities Company (Doc. #1623, SBC-043070)

Workforce Limitations will be Worsened

The water sector is currently working to overcome workforce challenges. EPA estimates that one-third of the sector's workforce is eligible to retire within the next 10 years and utilities are facing challenges in recruiting, training, and retaining employees.

These challenges are expected to be more severe as over 5,000 water systems are driven to more advanced technologies that require more specialized technical skills. To install and operate these facilities, water systems will need to hire or contract engineers, manufacturers and suppliers, construction crews, and skilled operators. These service providers are already in high demand and in short supply and this imbalance is impacting labor and material costs, lead times for materials, turnaround times for services (e.g., engineering, laboratory analysis, construction. The installation of new treatment facilities will surge following the rule's promulgation given the tight timeline for compliance, which will further worsen workforce challenges for utilities.

The demand for highly skilled water treatment operators will increase due to this rule. Systems currently not using filtration for water treatment may need to meet additional operator certification requirements. This change will have a significant impact on systems with less local or financial access to the skilled operators that will be needed to safely operate these advanced

treatment systems. Given existing workforce challenges, there is a chance that many systems will struggle to find water treatment plant operators to adequately operate their plant(s).

State Primacy Agency Capacity

The typical timeline for the construction of a new drinking water treatment facility for PFAS may take up to and exceed 5 years; thus, the standard compliance window of three years under SDWA will not be feasible. The compliance window is especially challenging given that implementation challenges will drive the timeline up as systems begin competing for the same limited workforce. Under SDWA, water systems may request a two-year extension for compliance with MCLs if it is determined that additional time is necessary for capital improvements.

It is anticipated that a vast majority of water systems will need to request this two-year extension, which is typically provided at the discretion of the state primacy agencies. State primacy agencies are currently working to review lead service line inventories, preparing to implement the corrosion control treatment requirements of the LCR, administering the DWSRF and additional projects accessing funds from the Bipartisan Infrastructure Law, and ensuring and improving water system compliance with existing rules. As the surge in water system requests for a two-year extension begins, these agencies will be inundated as they work to review and process these requests. Aqua anticipates that in one of our operating states we could potentially request over one hundred extensions alone if the current proposal is enacted with a three-year compliance deadline.

However, the Administrator also has the authority under SDWA to provide this extension and can do so as a part of the rule as opposed to being done so on a case-by-case basis. It is recommended that the Administrator leverage this authority to help ensure that all water systems can comply with the timeline of the rule and take adequate, effective steps towards mitigating PFAS levels in drinking water.

EPA Response: Based on this comment and many others, see section 12.1 of the *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10), which provides the timeframe suggested by the commenter. Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. Regarding concerns on operator certification licenses, please see the EPA response to comment Doc. #1567, SBC-042738 in section 12.1 in this *Response to Comments* document.

Aqua America, an Essential Utilities Company (Doc. #1623, SBC-043068)

Simultaneous Compliance will Slow Down Implementation

The installation of new water treatment facilities requires sufficient planning to ensure that bringing a plant into compliance with a new rule does not cause non-compliance with existing

regulations. For most water systems in the United States (U.S.), the installation of PFAS treatment facilities will create challenges for simultaneous compliance with the long-term revisions to the Lead and Copper Rule (LCR). If systems determine that mitigation is needed to comply with the final drinking water standards, either through new treatment or a change in the water supply source, the requirements of the LCR will initiate a lengthy review process with the State Primacy Agency prior to the system receiving approval to move forward.

Systems that need to initiate a review with their state through the LCR could be delayed as much as 18 months to get through the approval process. The state review process determines the impacts of treatment on the water system's ability to maintain compliant lead and copper levels, which may also require the installation of corrosion control treatment (CCT), re- optimization of CCT, and additional water quality monitoring. This will have a significant impact on the system's ability and cost to implement new treatment for PFAS within the compliance window of three years. To provide a case study example, Aqua spent 24 months working with the state agencies to pilot Ion Exchange (IX) for PFAS removal and simultaneous compliance with LCR in Pennsylvania. If every state requires 2 years just for this step alone, the time for a construction permit, combined with sewer discharge permits, zoning, and building permits can take up to 3 years, not including time for funding and design.

Most Systems will Need to Perform Pilot Testing

Finally, another key step in installing PFAS treatment facilities is pilot testing. While GAC, IX, and RO have been documented as being capable of removing PFAS effectively, they still require a sufficient level of pilot testing. Pilot testing typically takes at least six to nine months to complete and costs include equipment rental, engineering and other technical support, and appropriate monitoring and sample analysis. Bench scale testing can also be useful and less costly for some systems. Approval of pilot testing plans, conducting the testing, and getting approval of the pilot testing report can require up to 24 months based on our experience installing several PFAS treatment systems.

The goal of pilot and bench-scale testing is 3-fold: (i) demonstration of PFAS removal efficacy,

(ii) characterizing pre- and post-treatment needs, and (iii) optimal treatment technology selection. Subsequently, most of the water systems impacted by PFAS MCLs will need to perform pilot testing, especially given the permitting requirements to comply with the LCR, as discussed above. While pilot testing may not seem appropriate for smaller systems, it is similarly vital for these systems to ensure that the expense of capital for a new long-term treatment facility is both cost-effective and appropriately designed to protect public health from secondary water quality changes. In addition, it is possible or even likely that state public utility commissions may require private utilities to conduct pilot testing to prove that the best technology is selected for customers impacted by rate changes.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments*

document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. For the EPA's response to commenter concerns on simultaneous compliance challenges with the Lead and Copper Rule Improvements, please also see section 12.1 of the EPA response in this *Response to Comments* document. For additional discussion and considerations on available treatment technologies, please see section 10 of the EPA response in this *Response to Comments* document.

Aqua America, an Essential Utilities Company (Doc. #1623, SBC-043056)

Aqua appreciates EPA's interest in addressing PFAS in drinking water to protect public health and maintain public trust in the nation's drinking water supply. Aqua has been engaged on PFAS issues since 2016 and has been a leader in PFAS with testing capability, filing legal actions against polluters, installing treatment, and establishing its own PFAS standards in 2020, to support the Agency's efforts to address PFAS contamination. Aqua supports PFAS regulation and drinking water regulation when it can be implemented scientifically, feasibly, affordably, and holistically.

Based on costs and benefits, household affordability, supply chain concerns, and the challenges that are discussed in detail throughout this letter, our main recommendations include:

1. The standard implementation timeline is not appropriate for the current economic conditions. The need to plan, design, pilot, permit, and construct facilities will take much longer than the 3-year timeline given workforce and supply chain challenges. The burden for state primacy agencies to approve extensions for capital improvements will be overwhelming. The Administrator should exercise its authority under the Safe Drinking Water Act (SDWA) to extend the effective date of compliance two years for water systems installing capital improvements.

EPA Response: Consistent with this comment, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges, as well as simultaneous compliance challenges, that may affect the compliance timeline. Regarding rule costs and benefits, please see sections 13.3 and 13.4, respectively, of the EPA response in this *Response to Comments* document. Regarding affordability, please see section 13 of the EPA response in this *Response to Comments* document.

Aqua America, an Essential Utilities Company (Doc. #1623, SBC-043065)

Implementation Challenges

Public water systems subject to the Proposal will need to comply within three years unless a two-year extension is provided by state primacy agencies or the Administrator. An estimated 67,000 water systems will need to perform initial monitoring at nearly 90,000 entry points to the distribution system. Additionally, upwards of 5,000 water systems will need to take action to

address PFAS levels above the MCLs and continue to conduct quarterly sampling, according to the EPA's analysis. For water systems that need to install advanced treatment facilities for PFAS, a myriad of challenges will delay the implementation time for each system and impact cost to implement these facilities. Aqua's preliminary data indicates the potential for over 250 entry points in its systems may potentially need to install treatment. Roughly 75% of those 250 locations serve systems with less than 3,300 customers and demonstrates the potential impacts on smaller and less advantaged communities.

Aqua encourages EPA to consider how these challenges will impact not only the compliance cost of the rule, but also the feasibility of the rule to be implemented on the standard timeline provided by the SDWA.

EPA Response: The EPA has evaluated PWS compliance cost of the rule and considered costs in determining whether the MCL level in this rule is "feasible." Specifically, the EPA considers whether the costs associated with compliance and implementation of the MCLs are reasonable based on what may reasonably be afforded by large metropolitan or regional drinking water systems (*A Legislative History of the Safe Drinking Water Act*, Committee Print, 97th Cong., 2d Sess. (1982) at 550). For additional discussion on how the agency considers analytic feasibility when establishing the MCL, please see section 5.1.3 of the EPA response in this *Response to Comments* document. For additional information on the EPA's cost analysis, please see section 13.3 of the EPA response in this *Response to Comments* document. Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline as well as the extended compliance timeframes available for smaller systems under Section 1416 of SDWA (exemptions).

Aqua America, an Essential Utilities Company (Doc. #1623, SBC-043093)

As previously discussed, the regulation of PFAS in drinking water as proposed will create various implementation challenges and the Agency is encouraged to consider ways to alleviate these challenges while also protecting public health. Aqua recognizes that EPA is interested in an expeditious rulemaking to reduce PFAS exposure communities; it is nonetheless important that EPA advance this rulemaking effort in a way that is based on sound science, recognizing the importance of drinking water affordability, and the importance for regulations to be feasible to implement. As crafted, there are serious challenges with the EPA's proposed approach, which are coupled with flawed analyses.

First, implementation challenges may mean that systems will struggle to meet the compliance deadline set by the EPA. While EPA has a stated interest in advancing immediate protection of communities from PFAS exposure, water systems still need to perform the necessary work to implement these systems – regardless of the timeline. As proposed, water systems installing treatment will need a two-year extension for compliance. This will ease the burden on state

primacy agencies, which are currently significantly strained implementing other drinking water rules, the Administrator should provide a 2-year extension as part of the final rule.

EPA Response: Consistent with this comment, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

WaterPIO (Doc. #1624, SBC-043462)

3. The timeframe for the construction and implementation of these systems is impossibly short. Public water systems are guaranteed to get notices of violation before they will be able to develop and complete their compliance efforts.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

WaterPIO (Doc. #1624, SBC-043464)

5. There simply won't be enough personnel in the workforce to construct and operate the advanced treatment systems that will be required.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

WaterPIO (Doc. #1624, SBC-043476)

Next, let's talk about the drain on human resources. Like almost every other industry, there is a profound lack of people to fill necessary jobs. Water and wastewater providers were already fighting "brain drain" caused by the retirements of Baby Boomers. Now they are finding it tough to simply replace their numbers. Add in the need to take on high-pressure projects to construct and operate advanced treatment systems while being under attack from the EPA for producing "unsafe water" to their neighbors, and finding the employees needed to meet the proposed MCLs and HI will be damn near impossible.

WaterPIO regularly speaks at industry conferences across the country. When Mike McGill spoke at one such event on May 25, he received universal agreement from his audience when he talked

about the PFAS personnel issue. A few attendees threw in how happy they were to be close to retirement; they wanted out before they had to deal with the proposed MCLs and HI.

On top of being proud of the fact they were racing for the exits, they also lamented their inability to hire their replacements. The "bodies", as they put it, simply are not there.

Yes, water providers will be able to train current staff on advanced treatment, but those employees will need to be replaced as they move up the ladder. Those people simply aren't there right now, and it's entirely possible they will never be there if they believe they could be taking on a job where they'll be accused of poisoning their neighbors.

That is the environment the EPA is creating with these proposed MCLs and HI. It's an untenable situation.

EPA Response: The EPA's final rule represents data-driven drinking water standards that are based on the best available science and meet the requirements of SDWA; regulation of the PFAS covered by the NPDWR is vital toward protecting public health by removing these contaminants from our nation's drinking water. As discussed in the preamble to the final rule and elsewhere in this *Response to Comments* document, the health concerns posed by PFAS are serious and well-documented, and establishing a national PFAS NPDWR is a necessary step toward public health protection. Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

WaterPIO (Doc. #1624, SBC-043471)

Because of WaterPIO's work with utilities who have had to add advanced treatment to their water systems, we know firsthand what the impacts of the proposed MCLs and Hazard Index will be; they will create the need for thousands of water providers to augment their current treatment or construct completely new plants.

And all that work will have to happen at the same time. Because of the likely implementation timeline, thousands of water providers won't have a chance in Hell of meeting the new standards in time. They can't simply wave a wand and make the systems, media, and construction materials required to meet the unprecedented demand – on an accelerated timeframe to boot – magically appear. They will have to fight for whatever is available, and the prices for whatever is available will skyrocket.

Think about the supply chain issues we had with Covid where massive demand ran into dramatically inadequate supply. That is the situation the EPA is creating with the proposed MCLs and HI. Thousands of water providers will need reverse osmosis, granular activated carbon, or anion exchange systems, in addition to the billions of tons of media they will require, in little more than three to five years. Not only is this a recipe for disaster supply-wise, but costs

will also skyrocket because the systems, skids, and media that are available will be placed at such a premium.

In order to meet what is laid out as the current implementation schedule, water utilities that have found PFAS at any detectable level will have had to have started their processes to construct advanced treatment years ago. A responsible process for the selection of either advanced treatment or the construction of a new facility takes place over several months if not years.

WaterPIO has three clients in the pilot stages of their advanced treatment and plant construction choices. The implementation timeframe for the proposed MCLs and HI creates such an impossible schedule for compliance that even water providers like our clients who have already started on their path to meet the proposed regulations will likely be found in violation before they can make their solutions operational.

Imagine what that means for systems that haven't even begun to consider what kind of path they must take for future MCL and HI compliance. If you think about it, they already know now they're going to violate the new standards, even though they won't be in effect for three to five years.

That's the very definition of being put in a position to fail. That is what the EPA is guaranteeing with its proposed MCLs and HI; thousands of public water systems nationwide will receive notices of violation for failing to meet water quality standards. This circumstance even applies to water providers in states that have taken significant steps to protect public water by instituting their own MCLs as the EPA dawdled for decades.

Imagine being a water provider in Michigan that has gone through the state's steps – and millions of dollars in costs – to meet what are today the nation's toughest PFAS- related MCLs. Now, not only does the provider discover its state-MCL-focused work isn't good enough, but it will likely be in violation in the future because almost everyone else in the state – and now the entire country – will need to add more treatment to their systems at the same time. The Michigan system already knows it can't win, even though it's already done the job as far as its home state is concerned.

This is also the situation in several other states; all their work – completed while the EPA haphazardly addressed the subject over the years – has been cast aside by the proposed MCLs and HI. And it's not necessarily because four parts per trillion for PFOA and PFOS are the "must set" levels that need to be established to responsibly protect public health, or the fact that the first-ever "Hazard Index" for four other PFAS compounds is established science. Far from it, as the states have found through developing their science-based approaches to reach their individual MCLs.

EPA Response: The commenter provides no verifiable information on these claims that the EPA is putting PWSs in "a position to fail." The EPA's final rule represents data-driven drinking water standards that are based on the best available science and meet the requirements of SDWA; regulation of the PFAS covered by the NPDWR is vital toward protecting public

health by removing these contaminants from our nation's drinking water. For additional discussion on considerations for existing state standards, please see section 5.1.5 of the EPA response in this *Response to Comments* document. Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Water One - Water District No. 1 of Johnson County, Kansas (Doc. #1627, SBC-042325)

Additionally, it is unrealistic to suggest that implementation of the PFAS regulation could be completed within 5 years. Rather, it would take water utilities a minimum of 8-10 years to study, pilot test, design, and construct PFAS removal technology and methodologies. As the proposed regulation is currently written, there will be a substantial number of violations in a short time span. The EPA should be more pragmatic within the rule structure and provide realistic deadlines. Subsequently, if this is not modified, the public's confidence and trust in safe drinking water will subside and be tarnished.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10), which the maximum amount of time for compliance that the EPA can provide in an NPDWR; states can provide additional time for compliance through the 1416 exemption process. Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Water One - Water District No. 1 of Johnson County, Kansas (Doc. #1627, SBC-042330)

Additionally, we are concerned about the potential for escalating construction costs and project delays due to labor shortages and increase demand to meet the regulation.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Association of State Drinking Water Administrators (ASDWA) (Doc. #1628, SBC-044067)

7. ASDWA suggests that EPA allow flexibility in the compliance deadlines to ensure feasibility, similar to the flexibility offered as a part of the final arsenic regulation, allowing extended compliance deadlines depending on the system size and initial concentration. While systems with a population greater than 3,300 are currently sampling for PFAS under UCMR 5, only a small subset of small water systems are currently a part of that sampling pool. As many large and

medium-sized water systems will be taking advantage of the opportunity to use previously collected data from UCMR 5, many small systems will take their first PFAS samples when the final PFAS NPDWR is implemented. If these small systems exceed the MCL, the three-year compliance timeline will be challenging.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Association of State Drinking Water Administrators (ASDWA) (Doc. #1628, SBC-044077)

Primacy Agency Workforce and Workload

ASDWA recommends that EPA further acknowledge and support primacy agency efforts to address workforce issues to ensure continued public health protection.

Primacy agencies face increasing workloads with implementing existing rules and regulatory programs and starting new regulatory and non-regulatory efforts. Primacy agencies are assisting water systems with implementing the Lead and Copper Rule Revisions (LCRR) requirements for initial service line inventories and addressing cybersecurity. Additionally, primacy agencies are managing a significant increase in applications for Bipartisan Infrastructure Law (BIL) funding through the Drinking Water State Revolving Fund (DWSRF) programs. Primacy agencies are facing unique workforce issues in that the retirements of "Baby Boomers" are coinciding with the increased workload previously described. Hiring staff, especially engineers, is currently very difficult for primacy agencies. ASDWA recommends that EPA ensure that the Agency's water sector workforce initiative includes considerations for primacy agency staff.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges, as well as simultaneous compliance challenges, that may affect the compliance timeline. For additional discussion on the EPA's consideration of primacy agency costs, please see section 13.3.1 of the EPA response in this *Response to Comments* document.

Association of State Drinking Water Administrators (ASDWA) (Doc. #1628, SBC-044117)

Small Systems

ASDWA recommends that EPA continue to fund and dedicate resources to technical assistance programs, programs to advance small water systems' technical, managerial, and financial capability, and operator recruitment programs.

Small system compliance with the PFAS NPDWR, regardless of the final value of the MCLs, will be challenging. Most small ground water systems currently have minimal treatment installed. For those systems with no alternative water source, installation of one of the BAT may present a variety of challenges if the current treatment only consists of a chemical feed and a pressure tank. In order to install one of the BAT options, a small ground water system may need to construct an entirely new building to house the treatment—this could account for up to 50% of the project's cost. This increase in building size may trigger additional building code requirements that further increase the cost of the project.

In most cases, the advanced treatment needed for PFAS will require an increase in the level of certified operator needed to operate a PWS. The entire water sector is facing workforce shortages, especially for certified operators, and this issue is particularly prevalent in small and disadvantaged water systems. The challenges around hiring and retaining operators will continue to be exacerbated as systems install treatment to comply with the PFAS MCL.

EPA Response: For funding concerns, the agency notes that funds are also available through the passage of the BIL to assist many disadvantaged communities, small systems, and others with the costs of installation of treatment when it might otherwise be cost-challenging. Please see section 2.4 of the EPA response in this *Response to Comments* document for more discussion about currently available funding. Regarding concerns on operator certification licenses, please see the EPA response to comment Doc. #1567, SBC-042738 in section 12.1 in this *Response to Comments* document.

Association of State Drinking Water Administrators (ASDWA) (Doc. #1628, SBC-044103)

PFAS Treatment

Treatment Concerns

ASDWA recommends that EPA include guidance for extended compliance deadlines based on system size and level of contamination.

Complying with a drinking water regulation at a low MCL that is essentially equivalent to the laboratory detection limit, as would be the case for complying with the proposed PFAS MCLs, requires robust and reliable treatment technologies (more than one). ASDWA supports EPA's analysis that an MCL of 4.0 parts per trillion is generally technically feasible as defined by the SDWA. However, several factors compound the implementation and feasibility challenges associated with achieving and maintaining compliance with the MCL. The combination of factors will vary between water systems, and compliance with the MCL will be a challenge for many systems, especially those that are small and disadvantaged. These compounding factors include:

• Resource concerns, including supply chain issues, workforce shortages, and costs;

• Sampling challenges, including delays in receiving results, limited lab capacity, and costs;

• Small system technical, managerial, and financial (TMF) capacity;

• Treatment efficacy, including daily operation needs for advanced treatment and operator capability;

• Waste disposal methods and the potential demand and supply of available waste disposal means;

• Timelines for compliance, treatment piloting, review and approval, and installation; and

• Impacts on available certified operators where addition of treatment raises the level of the certified operator required at a water system.

ASDWA supports EPA's proposal to allow exemptions to compliance deadlines under certain circumstances. ASDWA recommends that EPA consider the above factors to appropriately evaluate extended initial compliance deadlines for water systems, similar to the flexibility for the compliance deadlines in the final arsenic regulation. Appendix B of this letter is an excerpt from Appendix G on exemptions within EPA's State Implementation Guidance for the Arsenic Rule. ASDWA recommends that EPA utilize a similar protocol to Table 1 (G-15), where the compliance timelines are based on population and contaminant concentration. This guidance will help ensure primacy agencies can efficiently provide exemptions when appropriate.

EPA Response: Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on exemptions under SDWA 1416(a). The EPA notes that the minimum reporting level (MRL) is not set at the laboratory detection limit, it is at the practical quantitation limit (PQL). For commenter concerns regarding practical quantitation limits, including implementation of the MCLs at the PQL, how the PQLs were set for the final NPDWR, or use of sample results below the PQLs to help operators manage their treatment operations, please see section 5.1.2 of the EPA response in this *Response to Comments* document. Regarding concerns on operator certification licenses, please see the EPA response to comment Doc. #1567, SBC-042738 in section 12.1 in this *Response to Comments* document.

Association of State Drinking Water Administrators (ASDWA) (Doc. #1628, SBC-044080)

ASDWA recommends that EPA better coordinate between its regions and headquarters to ensure the Agency is not creating any unnecessary burden on the primacy agencies.

Primacy agencies have reported frustrations with requests from EPA headquarters and regional staff for duplicative data beyond what is required. As co-regulators, primacy agencies want to work with EPA and be helpful, but these additional data collection and reporting efforts take significant staff time and increase implementation costs. ASDWA recommends that EPA improve coordination between its regions and headquarters to ensure the Agency is not creating any unnecessary burden on primacy agencies.

In summary, primacy agencies have a long list of resource feasibility concerns that need to be addressed for effective rule implementation. ASDWA recommends that EPA partner closely

with primacy agencies and dedicate the needed Agency resources to address these important concerns in the final rule.

EPA Response: The agency agrees with the commenter that successful partnerships between primacy agencies and the EPA remain critical to safeguard public health and drinking water resources. After finalization of the PFAS NPDWR, the EPA intends to work with stakeholders to provide support to utilities, primacy agencies, and other interested parties to ensure successful rule implementation.

Association of State Drinking Water Administrators (ASDWA) (Doc. #1628, SBC-044113)

Primacy agencies and EPA will need to continue partnering on addressing water sector workforce challenges through increased resources for operator certification and workforce development programs to ensure treatment is operated by qualified and experienced personnel.

In most states, the advanced treatment needed for PFAS will, in most cases, require an increase in the level of certified operator needed to operate a public water system (PWS). The entire water sector is facing workforce shortages, especially for certified operators, and this issue is particularly prevalent in small, rural, and disadvantaged water systems. The challenges around hiring and retaining operators will continue to be exacerbated as systems install treatment to comply with the PFAS NPDWR. As the demand for operators increases, the cost to hire operators will also increase.

EPA Response: Regarding concerns on operator certification licenses, please see the EPA response to comment Doc. #1567, SBC-042738 in section 12.1 in this *Response to Comments* document.

Association of State Drinking Water Administrators (ASDWA) (Doc. #1628, SBC-044115)

Compliance

Timelines

ASDWA recommends that EPA allow flexibility in the compliance deadlines to ensure feasibility, similar to the flexibility offered as a part of the final arsenic regulation, allowing staggered compliance deadlines depending on the system size and/or initial PFAS concentrations.

While systems with a population greater than 3,300 are currently sampling for PFAS under UCMR 5, only a very small subset of small water systems are currently a part of that sampling pool. As such, most small water systems will have a late start with their PFAS sampling. While many large and medium-sized water systems will be taking advantage of the opportunity to use previously collected data from UCMR 5, many small systems will take their first PFAS samples after the final PFAS NPDWR is promulgated. If these small systems exceed the MCL, the three-plus-two-year compliance timeline will be challenging to meet—systems will need time for

bench tests, approximately one year to pilot test, and approximately one year to design and obtain approval from the primacy agency. Additional time would be needed for bid preparation, obtaining financing, and for construction and start-up. ASDWA reiterates its recommendation that EPA consider the above factors to appropriately evaluate extended initial compliance deadlines for water systems, similar to the flexibility for the compliance deadlines in the final arsenic regulation.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Texas Commission on Environmental Quality (TCEQ) (Doc. #1632, SBC-044130)

If small systems exceed the MCL, the three-year compliance timeline will be challenging to meet. Texas systems will need time for bench tests, pilot testing, design, and obtaining approval from TCEQ. Systems should be given time to solicit bids, obtain financing, construct necessary infrastructure, and plan for potential delays due to supply chain issues and other unforeseen complications. For these reasons, TCEQ recommends a minimum four-year compliance timeline.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Rural Community Assistance Partnership Incorporated (RCAP) (Doc. #1633, SBC-044140)

Technical Assistance Needed for Testing Compliance

Overall, increased technical assistance and outreach about PFAS, risk communication strategies with communities, availability of possible treatment technologies, and availability of funding will be required to ensure small and disadvantaged systems are supported and able to comply with the new regulations and supply safe water.

Small systems may encounter issues with both sampling procedures and compliance. PFAS sampling is a highly sensitive process and susceptible to cross-contamination when done incorrectly. To avoid false results, the sampler must follow strict guidelines as PFAS chemicals are widely used in personal care products, clothing, food packaging, and other sampling equipment, all of which can lead to cross contamination. This will increase the need for training and technical assistance for small, rural, and tribal water systems.

Additionally, the pool of drinking water operators for small and very small public water systems will need significant training on this issue. When PFAS treatment is added to these small

systems' lists of regulatory requirements, their operators must get higher grade licenses or systems must find new operators. RCAP has provided operator training for many years and has seen firsthand a shrinking operator workforce due to aging and retirements, particularly with regards to small systems. Training this already diminishing workforce in an efficient manner will be a big priority in ensuring successful PFAS compliance for small systems.

EPA Response: For funding concerns, the agency notes that funds are also available through the passage of the BIL to assist many disadvantaged communities, small systems, and others with the costs of installation of treatment when it might otherwise be cost-challenging. Please see section 2.4 of the EPA response in this *Response to Comments* document for more discussion about currently available funding. After finalization of the PFAS NPDWR, the EPA also intends to work with stakeholders to provide support to utilities, primacy agencies, and other interested parties to ensure successful rule implementation and will consider the topics suggested by the commenter as the agency develops implementation materials for the final NPDWR. With respect to commenter concerns on operator training, please see the EPA response to comment Doc. #1567, SBC-042738 in section 12.1 in this *Response to Comments* document.

Rural Community Assistance Partnership Incorporated (RCAP) (Doc. #1633, SBC-044142)

Enforcement

As stated above, RCAP agrees with EPA that, when fully implemented, the PFAS Rule will prevent tens of thousands of PFAS-related illnesses or deaths. However, because PFAS are ubiquitous in our environment, there will be thousands of public water systems (PWSs) impacted by these new standards, and therefore EPA may be best served to bring systems into compliance in a phased manner, both in terms of resources needed for addressing compliance strategies as well as the treatment systems design and implementation, so that it doesn't cause significant supply chain issues and thereby increase costs.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Orange County Water District (OCWD), California (Doc. #1634, SBC-043236)

The EPA Administrator has authority under the SDWA to extend the effective date of compliance by two years (from three years to five years) for water systems installing capital improvements; OCWD recommends the Administrator exercise this authority, instead of leaving these decisions to the individual states on a case-by-case basis. This will avoid a deluge of extension applications to state primacy agencies, which are ill-equipped to handle this new burden alongside their existing responsibilities. Providing the two-year extension will also minimize otherwise unnecessarily burdensome consent agreements and/or orders for systems

inevitably unable to come into compliance within three years. Alternatively, EPA could determine eligibility for compliance extensions based on PFAS concentrations, analogous to its procedures under the Arsenic Rule whereby systems with greater relative public health risk are prioritized for compliance.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. Further extensions can be provided by primacy agencies through the Section 1416 exemption process, similar to the extensions provided for under the arsenic rule.

Orange County Water District (OCWD), California (Doc. #1634, SBC-043234)

Implementation Timeline

Achieving broad, nationwide compliance within the rule's proposed standard three-year compliance period under the SDWA is infeasible for a variety of reasons, including:

• The same current economic conditions cited above (significant inflation, labor shortages, global supply chain disruptions, and increased borrowing costs) for EPA's systematic underestimation of treatment costs also severely limit the ability of public water systems to achieve compliance with the proposed regulation within three years.

• The need to perform pilot testing, which is generally advisable and required in some states for consideration of system design and construction approvals.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Town of Tewksbury, Massachusetts (Doc. #1637, SBC-043248)

EPA's timeline for compliance with the rule is not reasonable, and likely not even achievable, given the work that goes into designing, constructing, and funding new treatment systems. The water sector, including operators, design engineers, and construction workers, is challenged with workforce issues like many other sectors of our society. More sophisticated treatment will likely cause a change in PWS classification and may require a higher-grade operator license. In Massachusetts, it takes time to get through the required training to be able to sit for a higher-grade exam. EPA does not appear to have given any thought to issues such as this when they crafted the rule and its three-year implementation timeframe. EPA must adjust the compliance timeframe to be more realistic.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Citizens Against Ruining the Environment (CARE) (Doc. #1638, SBC-043458)

Exemptions and Exceptions Must Be Strictly Limited

CARE opposes the exemptions in Section XII(D) of the Proposed Rule that would allow up to 14 years of exemptions from the MCL requirements for small systems. [FN35: PFAS National Primary Drinking Water Regulation Rulemaking, 80 Fed. Reg. at 18689.] As stated above regarding monitoring, MCLs do not protect human health if they are not monitored and enforced. Likewise, exemptions that would permit exceedances above MCL can not protect human health.

PFAS contamination is a public health emergency and urgent environmental justice concern. The potential for a PWS to receive an exemption that would allow for PFAS MCL exceedances for 14 years is unconscionable. In particular, making these exemptions available to small systems and those that can not afford capital improvements underscores the environmental justice and disproportionate burden this proposal would place on EJ communities.

CARE does not support granting an exemption from the PFAS MCLs due to a system's inability to afford capital improvements. If a water system is unable to afford treatment to bring the water quality to a safe level, then assistance must be provided to ensure that residents have access to safe drinking water. Merely exempting noncompliant water systems from the MCL requirements is not an acceptable solution to the problem of PFAS contamination.

CARE encourages EPA to define specific, limited conditions under which a State Primary Agency may issue an exemption under SDWA Section 1416. Those exemptions should be granted in only the rarest circumstances and when there is no other viable alternative. To ensure that Primary Agencies do not overuse exemptions, the US EPA could place a maximum cap on the number of exemptions permitted.

Additionally, CARE recommends that Primary Agency authority to issue an exemption trigger a requirement for the provision of emergency drinking water supplies or filtration equipment under 40 C.F.R. § 1412.11 or other statutory authority that EPA deems appropriate. [FN36: 40 C.F.R. § 1412.11 requires Primary Agencies to have a plan for the provision of drinking water when a PWS system is compromised by disaster, accident, or other reason. This requirement is discussed more fully in the U.S. EPA's State Emergency Drinking Water Supply Guidance document, available at https://www.epa.gov/system/files/documents/2023-04/StateEDWS_Guidance_508c.pdf.] Most importantly, CARE does not support providing an exemption to any system without a concomitant responsibility to provide safe drinking water to the community by alternative means while the PWS system PFAS levels are above MCLs.

EPA Response: Regarding the rule compliance timeframe, for the reasons discussed in this response to comment document, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. Additionally, section in 12.1 describes the availability of exemptions under SDWA section 1416(a): primacy agencies who have adopted the 1998 *Variance and Exemptions Regulation* (USEPA, 1998) may choose to grant exemptions where the water system meets the statutory requirements for an exemption. These requirements include the state finding that the water system is "unable to comply" with the MCL or "implement measures to develop an alternative source of water supply" and the granting of the exemption will not result in an unreasonable risk to health. In addition, at the time an exemption is granted, the state must prescribe schedules for compliance and implementation of control measures that the state may require for the contaminant. Such control measures could include the provision of alternative water and/or filters. See also 40 CFR 142.20(b). There is no authority in the statute for the EPA to put a cap on the number of systems with an exemption; however, historically, the use of exemptions issued by primacy agencies has been limited.

California Municipal Utilities Association (CMUA) (Doc. #1639, SBC-043255)

II. CMUA Requests Extra Time for MCL Compliance

The Regulation proposes to have public water agencies begin compliance, including installing treatment technologies, within three years after promulgation. Three years is insufficient time for public water agencies to overcome the financial implications to achieve compliance with the Regulation. Public agencies set budgets for infrastructure improvements and other costly operational projects several years in advance. It is highly unlikely that these agencies will be able to budget accordingly to include the high compliance costs within three years. Additionally, the loan or grant process may take longer than three years to get the funding needed. Public water agencies need time to plan and absorb the added costs of compliance.

CMUA urges the EPA to consider extending the time for compliance to give public water agencies an additional three years, for a total of six years after promulgation, to comply with the MCLs.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10), which is the maximum time allowed for compliance through the NPDWR; additional time can be provided in certain circumstances through the exemption process in SDWA Section 1416. Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Aidan Cecchetti (Doc. #1640, SBC-044376)

• EPA is seeking comment as to whether there are specific conditions that should be mandated for systems to be eligible for exemptions under 1416 to ensure that they are only used in rare circumstances where there are no other viable alternatives and what those conditions would be (pg. 18689 Federal Register Volume 88, Number 60).

o The commenters recommend that EPA provide additional clarification regarding how primacy agencies would use the criteria in 1416 to grant exemptions. It is unclear to the commenters how water systems would demonstrate eligibility for an exemption under the current criteria.

EPA Response: Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on exemptions under 1416, as well as the EPA response to comment Doc. #1638, SBC-043458 in section 12.1 in this *Response to Comments* document.

National Rural Water Association (NRWA) (Doc. #1641, SBC-043265)

Implementation Challenges

Three-year compliance implementation is not long enough to provide nearly 150,000 water systems nationwide with the time and opportunity needed to comply. The proposed rule states it will take 16 hours of training for systems smaller than 3,300 users. Additionally, the proposed rule estimates it will take primacy agencies 2,080 hours or 1 year to provide initial training and technical assistance to every water system in their state. These estimates are an oversimplification of the time and effort it will take just to conduct the outreach, training and technical assistance needed to start this process.

Water systems that need to install treatment equipment will need a minimum of five years to complete projects. The process for completing such projects is complex and time-consuming, involving various approvals, pilot studies, local land use or zoning processes, design and development, procurement, and construction. These steps require coordination with multiple entities, including boards, councils, other elected officials, and the public. Additionally, utilities are currently facing challenges, such as increased pricing, supply chain disruptions, and labor shortages, which further extend project timelines and increase costs.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. For funding concerns, the agency notes that funds are also available through the passage of the BIL to assist many disadvantaged communities, small systems, and others with the costs of installation of treatment when it might otherwise be cost-challenging. Please see section 2.4 of the EPA response in this *Response to Comments* document for more discussion about currently available funding.

National Rural Water Association (NRWA) (Doc. #1641, SBC-043267)

Small rural systems will be at a disadvantage when competing for engineers, equipment, construction, and laboratory availability.

NRWA strongly recommends that EPA use its authority to provide a nationwide two-year extension for the compliance timeline for systems installing capital improvements. A two-year extension will help address the concerns outlined above to alleviate burdens on water systems and allow for compliance by water systems addressing PFAS contamination. Additionally, EPA should ensure each state primacy agency has a streamlined approach for approving the nine additional years established in the proposed rule for small rural systems.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline, as well as the discussion of further extensions that may be available to certain systems under the Section 1416 exemption process.

American Farm Bureau Federation et al. (Doc. #1642, SBC-043492)

Additionally, access to contractors needed to install these technologies has already been identified as a concern by organizations representing the rural water communities. The contracts with large water systems will inevitably be far more lucrative, which will place smaller systems at the bottom of the priority list. Facilities will also need to bring in more employees to oversee the operations, maintenance and treatment of the equipment. This will require specific training, and trainer shortages have already presented challenges. Staff shortages even for the existing work required to safely operate and maintain drinking water systems are widespread: AWWA conducted a survey in 2021 on staffing and supply chain needs and found that 40% of drinking water utilities of all sizes are struggling to fill positions at their facilities, and employee turnover has doubled. Smaller communities will once again lose out because they have less available budget to hire additional staff and fewer available candidates to serve those roles. These systems will still have to meet the three-year implementation deadline but with many more hurdles and fewer resources. The agency must reevaluate the length of the implementation period or move towards a tiered roll out. It would be logical to allow the larger utilities to move ahead first to prevent a bottleneck on technologies and financial resources.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

American Farm Bureau Federation et al. (Doc. #1642, SBC-043499)

Given the costs and the challenges associated with obtaining the necessary technologies, availability of testing and the lack of disposal methods that we have already outlined, we recommend that the EPA consider extending the implementation period—particularly for small, rural water utilities. Simply put—these systems need more time and resources to ensure that they are in compliance with these new standards. At a minimum, the EPA should consider a tiered implementation timeline to alleviate the fallout from having every drinking water utility in the nation competing for technologies, testing and disposal.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Massachusetts Water Resources Authority (Doc. #1645, SBC-043284)

b. Impractical Implementation Timeline

EPA has provided an implementation timeline of three years for PWSs to conduct initial monitoring and take subsequent mitigation actions if PFAS levels exceed the MCL. The default SDWA implementation timeline is not practical given the number of systems impacted, inter-related regulatory requirements, and current economic conditions. As proposed, within three years a system must: (a) conduct at least one year of monitoring to characterize occurrence at all of their points of entry to the distribution system at a time when laboratory capacity is already strained; (b) select and design a compliance strategy; (c) obtain primacy agency approval from state programs already facing limited capacity to meet current demands; (d) address primacy agency requirements triggered under other rules (e.g., Lead and Copper Rule) -- requirements that themselves will require testing and potentially a year or more of pilot testing; and (e) construct necessary improvements in the midst of well-recognized supply chain delays and workforce shortages. MWRA requests that EPA grant an additional two year blanket extension (for a total of five years), at the minimum, for the implementation of a final PFAS NPDWR.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

SAVANNAH RIVER NUCLEAR SOLUTIONS, LLC (SRNS) COMMENTS TO U.S. ENVIRONMENTAL PROTECTION AGENCY (EPA) ON PROPOSED RULE; PER- and POLYFLUOROALKYL SUBTANCNES (PFAS) NATIONAL PRIMARY DRINKING WATER REGULATION May 30, 2023

SRNS GENERAL COMMENTS:

Comment 1

As written, in South Carolina, the treatment methods proposed for PFAS would all require daily operator visits by a grade C or higher drinking water treatment operator. Currently, many public water systems only require operation by E level (hypochlorite treatment) or D level (gaseous chlorine, corrosion control, sequestration) operators. The requirement to install systems such as Granulated Activated Carbon (GAC), Ion Exchange (AIX), or High-Pressure Membranes (Reverse Osmosis [RO] and Nanofiltration [NF]) will likely result in a shortfall of qualified operators of these systems as public water systems try to catch up with additional training and certification of the operators. This is especially true of RO and NF systems as they tend to be of a higher technical nature than GAC or AIX. Has EPA considered the potential additional burden on public drinking water systems to meet these new operator requirements, whether a sufficient number of schools exist to provide classroom and hands-on training, and the 6–12-month time period for providing adequate training on these technologies?

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. Regarding concerns on operator certification licenses, please see the EPA response to comment Doc. #1567, SBC-042738 in section 12.1 in this *Response to Comments* document.

Savannah River Nuclear Solutions LLC (Doc. #1647, SBC-043342)

Comment 7

Section XII.D, Rule Implementation and Enforcement (pg. 18688)

SRNS supports the ability of public water systems to obtain a two-year extension to comply with the proposed MCL's if a state or EPA determines additional time is needed for capital improvements. This provision is especially needed for federal facilities as funding from the federal government is lagged and any capital upgrades or improvements can only be accomplished if adequate funding is budgeted and approved generally years in advance of the project.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

New England Interstate Water Pollution Control Commission (NEIWPCC) (Doc. #1650, SBC-043158)

Personnel Capacity

Lastly, we are concerned that municipalities and states lack the personnel needed to effectively implement the rule. Engineers, scientists, and other necessary staff are all in high demand. Our member states are struggling to hire and retain sufficient personnel. Our member state's difficulty in competing with the private sector for trained personnel has left some state agencies short of capacity already, and they will need to significantly increase their staffing to implement the rule.

Moreover, contracting the implementation work out to consultants is not a viable solution. The extra burden associated with hiring consultants imposes other financial challenges. Such contracts would consume the available funding to implement the rule at an alarming rate.

We appreciate the opportunity to provide these comments, and we thank you for your consideration.

Sincerely,

Susan J. Sullivan

Executive Director

CC: NEIWPCC Executive Committee and Commissioners

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

North Carolina Division of Water Resources (NCDEQ) (Doc. #1652, SBC-044189)

H. PFAS Treatment

1. NCDEQ recommends that EPA include guidance for extended compliance deadlines based on system size and level of contamination.

Complying with a drinking water regulation at a low level, i.e., complying with the proposed PFAS MCLs and HI, will require robust and reliable treatment technologies (more than one). NCDEQ supports EPA's analysis that an MCL of 4.0 parts per trillion is generally technically feasible as defined by the SDWA. However, several factors compound the implementation challenges with achieving and maintaining compliance with the MCL. The combination of factors will vary between water systems, and compliance with the MCL will be a challenge for many systems, especially small and disadvantaged water systems. These compounding factors include:

• Resource concerns, including supply chain issues, workforce shortages, and costs

• Sampling challenges

• Small system capacity

• Treatment efficacy, including daily operation needs for advanced treatment and operator capability

• Waste disposal methods

• Timelines for compliance, treatment piloting, review and approval, and installation

• Adding treatment may raise the level of the certified operator required at a water system

NCDEQ recognizes that timely compliance with the proposed drinking water standards will be essential to reduce or eliminate PFAS contamination and to promote public health. However, NCDEQ supports EPA's proposal to allow exemptions to compliance deadlines under certain narrow circumstances. NCDEQ recommends that EPA consider the above factors to appropriately evaluate extended initial compliance deadlines for water systems, similar to the flexibility for the compliance deadlines in the final arsenic regulation. NCDEQ recommends that EPA utilize a similar protocol to Table 1 (G-15) [FN1: EPA State Implementation Guidance for the Arsenic Rule; Appendix G. https://www.epa.gov/sites/default/files/201509/documents/2005_11_10_arsenic_ars_final_app_g.pdf], where the compliance timelines are based on population and contaminant concentration.

This guidance will help ensure state agencies are able to efficiently provide exemptions when appropriate and necessary.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on exemptions under SDWA 1416 as well as supply chain and labor challenges that may affect the compliance timeline. For funding concerns, the agency notes that funds are also available through the passage of the BIL to assist many disadvantaged communities, small systems, and others with the costs of installation of treatment when it might otherwise be cost-challenging. Please see section 2.4 of the EPA response in this *Response to Comments* document for more discussion about currently available funding.

North Carolina Division of Water Resources (NCDEQ) (Doc. #1652, SBC-044198)

8. NCDEQ recommends that EPA continue to fund and dedicate resources to technical assistance programs, programs to advance small water systems' technical, managerial, and financial capability, and operator recruitment programs.

Small system compliance with the PFAS NPDWR, regardless of the final value of the MCLs, will be challenging. Most small ground water systems currently have minimal treatment installed. For those systems with no alternative water source, installation of one of the BAT may present a variety of challenges if the current treatment only consists of a chemical feed and a pressure tank. In order to install one of the BAT options, a small ground water system may need to construct an entirely new building to house the treatment—this could account for up to 50% of the cost of the project. This increase in building size may trigger additional building code requirements that further increase the cost of the project.

In most cases, the advanced treatment needed for PFAS will require an increase in the level of certified operator needed to operate a PWS. The entire water sector is facing workforce shortages, especially for certified operators, and this issue is particularly prevalent in small and disadvantaged water systems. The challenges around hiring and retaining operators will continue to be exacerbated as systems install treatment to comply with the PFAS MCL.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. Regarding concerns on operator certification licenses, please see the EPA response to comment Doc. #1567, SBC-042738 in section 12.1 in this *Response to Comments* document.

North Carolina Division of Water Resources (NCDEQ) (Doc. #1652, SBC-044195)

5. State agencies and EPA will need to continue partnering on addressing water sector workforce challenges through increased resources for operator certification and workforce development programs to ensure treatment is operated by qualified and experienced personnel.

In NC, the advanced treatment needed for PFAS will, in most cases, require an increase in the level of certified operator needed to operate a public water system (PWS). The entire water sector is facing workforce shortages, especially for certified operators. The challenges around hiring and retaining operators will continue to be exacerbated as systems install treatment to comply with the PFAS NPDWR. As the demand for operators increases, the cost to hire operators will also increase. NCDEQ is available to work with EPA to identify operator certification and training needs of the state.

For small, rural, and disadvantaged water systems, compliance with the PFAS NPDWR, regardless of the final value of the MCLs, will be challenging. Most small ground water systems currently have minimal treatment installed. For those systems with no alternative water source, installation of one of the BAT may present a variety of challenges if the current treatment only consists of a chemical feed and a pressure tank. In order to install one of the BAT options, a small ground water system may need to construct an entirely new building to house the treatment—this could account for up to 50% of the cost of the project. This increase in building size may trigger additional building code requirements that further increase the cost of the project.

In most cases, the advanced treatment needed for PFAS will require an increase in the level of certified operator needed to operate a PWS. The entire water sector is facing workforce shortages, especially for certified operators, and this issue is particularly prevalent in small and disadvantaged water systems. The challenges around hiring and retaining operators will continue to be exacerbated as systems install treatment to comply with the PFAS MCL.

NCDEQ recommends that EPA continue to fund and dedicate resources to technical assistance programs, programs to advance small water systems' technical, managerial, and financial capability, and operator recruitment programs.

EPA Response: For funding concerns, the agency notes that funds are also available through the passage of the BIL to assist many disadvantaged communities, small systems, and others with the costs of installation of treatment when it might otherwise be cost-challenging. Please see section 2.4 of the EPA response in this *Response to Comments* document for more discussion about currently available funding.

Virginia Municipal Drinking Water Association (VMDWA) (Doc. #1657, SBC-043168)

4. THE UNREALISTICALLY SHORT SCHEDULE FOR COMPLIANCE WILL CAUSE HARM TO THE NATION AND LOCAL COMMUNITIES AND SHOULD BE REPLACED

WITH A HEALTH-BASED PHASED APPROACH TO MCL ADOPTION AND IMPLEMENTATION

Undertaking all of EPA's estimated 3,400 to 6,300 water system PFAS upgrades over three to five years from MCL adoption will lead to many problems and should be reconsidered.

First, this schedule is neither workable nor prudent for a nationwide MCL proposal for the following reasons. Diligent efforts toward monitoring, design, construction simply are not generally feasible on EPA's compressed schedule considering the time required for the necessary steps:

• Lab expansions and certification for PFAS testing

• Monitoring to make compliance / noncompliance determinations

• Design and engineering procurement

• Preliminary engineering analysis

• Pilot and demonstration testing to support treatment technology selection

• Engineering design for treatment plant upgrades

• Spending authorization from governing body of the utility

• Financing arrangements and associated water rate increases

• Construction bids, selection, and contracts

• Equipment order lead times

• Construction process

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. For additional discussion on how the agency considers analytic feasibility when establishing the MCL, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

Virginia Municipal Drinking Water Association (VMDWA) (Doc. #1657, SBC-043173)

Seventh, the proposal's "all upgrades all at once" approach could lead to worse public health results as all projects concurrently compete for limited engineering, equipment, construction resources, and PFAS-removal material (e.g., granular activated carbon, ion exchange resins, novel absorbents), and facilities with the highest current PFAS levels are delayed in their upgrades. A better regulatory approach would enable primacy agencies to structure schedules such that limited engineering, state agency staff time, federal/state funding, equipment, and

contractors are available for and directed to water systems with the highest priority need (i.e., highest PFAS levels). The public interest would be better served by a regulatory approach that allows the worst situations to be fixed earlier than systems with only marginal needs for upgrades (e.g., those with PFAS levels only slightly above the proposed or final MCLs).

EPA Response: It is not clear what the basis is for the commenter's statement that the final NPDWR mandates an "all upgrades all at once" approach. The EPA's rule does not mandate that all upgrades happen at the same time. Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Virginia Municipal Drinking Water Association (VMDWA) (Doc. #1657, SBC-043171)

Fifth, in addition to the heightened prices this regulation would impose on the public, project delivery schedules are also a problem in a construction industry that is already overwhelmed with projects. The construction industry upon which water utilities depend will fall further behind when the MCL regulation adds thousands of water treatment plant upgrades.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Virginia Municipal Drinking Water Association (VMDWA) (Doc. #1657, SBC-043175)

5. RECOMMENDATION

VMDWA recommends and requests that EPA revise the proposed regulation to adopt a health-based phased approach, which could be established through use of the following existing EPA authorities and discretion:

• Adopt Regulations in a Manner to Create Multi-Phase Program – EPA should time its regulatory action(s) to achieve an orderly, feasible phased approach. EPA could also take multiple regulatory actions to reduce MCL concentrations over time, rather than the proposal's "all systems all at once" approach. In these ways, EPA has the ability to phase-in PFAS reductions to achieve appropriate levels in a much more prioritized, orderly, feasible, and cost-effective manner than would result from the currently proposed regulation. EPA should clearly communicate the phased approach to help affected water systems plan their implementation steps for each phase.

[VMDWA recommends and requests that EPA revise the proposed regulation to adopt a health-based phased approach, which could be established through use of the following existing EPA authorities and discretion:]

• Set Minimum 5-Year MCL Effective Date for Each Phase – For the initial phase and each phase adopted thereafter, EPA should establish in the final federal regulation an effective date five years (rather than three years) from the date of promulgation given the necessary capital improvements as allowed under 42 U.S.C. § 300g-1(b)(10).

EPA Response: Please see the EPA response to comment Doc. #1657, SBC-043173 in section 12.1 in this *Response to Comments* document on the assertion of this "all systems all at once" regulatory approach. Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline as well as discussion on a phased-in MCL approach. For additional discussion on how the agency considers analytic feasibility when establishing the MCL, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

Virginia Municipal Drinking Water Association (VMDWA) (Doc. #1657, SBC-043176)

[VMDWA recommends and requests that EPA revise the proposed regulation to adopt a health-based phased approach, which could be established through use of the following existing EPA authorities and discretion:]

• Acknowledge Need for Primacy Agency Use of 3-Year Exemption Extensions – EPA should acknowledge in the final regulation that many projects in each phase, especially larger more complex projects, will need to make use of the three year extension (beyond the 5-year minimum) for necessary capital improvements due to the compelling factors discussed in these comments, as allowed under 40 C.F.R. § 142.50).

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on exemptions under SDWA 1416 as well as supply chain and labor challenges that may affect the compliance timeline.

Virginia Municipal Drinking Water Association (VMDWA) (Doc. #1657, SBC-043177)

Using the above EPA authorities and discretion, EPA could establish the recommended health-based phased approach, avoid or mitigate the real world implementation problems associated with proposed regulation, and serve the public interest more effectively. The following example of the type of result that could be achieved in this manner is provided for illustration purposes assuming but not endorsing the proposed MCL levels (which warrant further review):

• Phase 1: All public water systems achieve 10 ppt for PFOA, 10 ppt for PFOS, and 5 for Hazard Index effective within 5 years.

• Phase 2: All public water systems achieve 7 ppt for PFOA, 7 ppt for PFOS, and 3 for Hazard Index effective within 10 years.

• Phase 3: All public water systems achieve 4 ppt for PFOA, 4 ppt for PFOS, and 1 for Hazard Index effective within 15 years.

To be clear, in outlining this three-phased approach, VMDWA is not recommending adoption specifically of MCLs at 4 ppt for PFOA and PFOS or of the proposed Hazard Index for the other four chemicals. The point is to illustrate a prioritized, health-based phase-in over time, regardless of whatever specific final MCL concentrations or index that may be adopted.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline as well as discussion on a phased-in MCL approach and the availability of additional extensions through the exemption process under Section 1416.

Maryland Association of Municipal Wastewater Agencies (MAMWA) (Doc. #1658, SBC-043406)

Fifth, in addition to the heightened prices this regulation would impose on the public, project delivery schedules are also a problem in a construction industry that is already overwhelmed with projects. The construction industry upon which water utilities depend will fall further behind when the MCL regulation adds thousands of water treatment plant upgrades.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Maryland Association of Municipal Wastewater Agencies (MAMWA) (Doc. #1658, SBC-043397)

A phased approach that prioritizes addressing a smaller set of water systems with higher PFAS concentrations first, and phases-in overtime whatever further reduced levels may be appropriate over the long-term for systems with lower PFAS concentrations, could be a better way to protect public health, avoid implementation and construction delays, and avoid wasted resources, especially when also considering the current construction market cost problems and price premiums and the schedule infeasibility problem discussed below.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline as well as discussion on a phased-in MCL approach.

Maryland Association of Municipal Wastewater Agencies (MAMWA) (Doc. #1658, SBC-043403)

THE UNREALISTICALLY SHORT SCHEDULE FOR COMPLIANCE WILL CAUSE HARM TO THE NATION AND LOCAL COMMUNITIES AND SHOULD BE REPLACED WITH A HEALTH-BASED PHASED APPROACH TO MCL ADOPTION AND IMPLEMENTATION

Undertaking all of EPA's estimated 3,400 to 6,300 water system PFAS upgrades over three to five years from MCL adoption will lead to many problems and should be reconsidered.

First, this schedule is neither workable nor prudent for a nationwide MCL proposal for the following reasons. Diligent efforts toward monitoring, design, construction simply are not generally feasible on EPA's compressed schedule considering the time required for the necessary steps:

• Lab expansions and certification for PFAS testing

• Monitoring to make compliance / noncompliance determinations

• Design and engineering procurement

• Preliminary engineering analysis

• Pilot and demonstration testing to support treatment technology selection

• Engineering design for treatment plant upgrades

• Spending authorization from governing body of the utility

• Financing arrangements and associated water rate increases

• Construction bids, selection, and contracts

• Equipment order lead times

• Construction process

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Maryland Association of Municipal Wastewater Agencies (MAMWA) (Doc. #1658, SBC-043407)

Sixth, the short schedule under the proposal effectively cuts off the ability of water treatment plants and their ratepayers (the public) to benefit from source reduction activities by others, such as a product substitutions and treatment installation at upstream PFAS-discharging industries, which would eliminate the need for ratepayers to bear the cost of water treatment plant upgrades. For water systems experiencing PFAS concentrations slightly above the proposed MCLs, this is an especially problematic aspect of the proposed regulation that should be revised. For example, for water systems with concentrations of 5 or 6 ppt for PFOA or PFOS, targeted reductions by one or more upstream industries could potentially achieve a 4 ppt MCL far more cost-effectively than adding treatment to the water system. In this sense, the proposed regulation also runs contrary to the generally-accepted public policy concept of "polluter pays" and transfers the burden to families and other innocent ratepayers, because there is no time allowed in this regulation for source water reductions to be accomplished. The proposal's tight schedule forces all affected water systems to jump immediately into design and construction on a compressed timeline.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Maryland Association of Municipal Wastewater Agencies (MAMWA) (Doc. #1658, SBC-043408)

Seventh, the proposal's "all upgrades all at once" approach could lead to worse public health results as all projects concurrently compete for limited engineering, equipment, construction resources, and PFAS-removal material (e.g., granular activated carbon, ion exchange resins, novel absorbents), and facilities with the highest current PFAS levels are delayed in their upgrades. A better regulatory approach would enable primacy agencies to structure schedules such that limited engineering, state agency staff time, federal/state funding, equipment, and contractors are available for and directed to water systems with the highest priority need (i.e., highest PFAS levels). The public interest would be better served by a regulatory approach that allows the worst situations to be fixed earlier than systems with only marginal needs for upgrades (e.g., those with PFAS levels only slightly above the proposed or final MCLs).

EPA Response: Please see the EPA response to comment Doc. #1657, SBC-043173 in section 12.1 in this *Response to Comments* document on the assertion of this "all systems all at once" regulatory approach. Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments*

document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Maryland Association of Municipal Wastewater Agencies (MAMWA) (Doc. #1658, SBC-043410)

5. RECOMMENDATION

MAMWA recommends and requests that EPA revise the proposed regulation to adopt a health-based phased approach, which could be established through use of the following existing EPA authorities and discretion:

• Adopt Regulations in a Manner to Create Multi-Phase Program – EPA should time its regulatory action(s) to achieve an orderly, feasible phased approach. EPA could also take multiple regulatory actions to reduce MCL concentrations over time, rather than the proposal's "all systems all at once" approach. In these ways, EPA has the ability to phase-in PFAS reductions to achieve appropriate levels in a much more prioritized, orderly, feasible, and cost-effective manner than would result from the currently proposed regulation. EPA should clearly communicate the phased approach to help affected water systems plan their implementation steps for each phase.

[MAMWA recommends and requests that EPA revise the proposed regulation to adopt a health-based phased approach, which could be established through use of the following existing EPA authorities and discretion:]

• Set Minimum 5-Year MCL Effective Date for Each Phase – For the initial phase and each phase adopted thereafter, EPA should establish in the final federal regulation an effective date five years (rather than three years) from the date of promulgation given the necessary capital improvements as allowed under 42 U.S.C. § 300g-1(b)(10).

EPA Response: Please see the EPA response to comment Doc. #1657, SBC-043173 in section 12.1 in this *Response to Comments* document on the assertion of this "all systems all at once" regulatory approach. Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Maryland Association of Municipal Wastewater Agencies (MAMWA) (Doc. #1658, SBC-043412)

Using the above EPA authorities and discretion, EPA could establish the recommended health-based phased approach, avoid or mitigate the real world implementation problems associated with proposed regulation, and serve the public interest more effectively. The following example

of the type of result that could be achieved in this manner is provided for illustration purposes assuming but not endorsing the proposed MCL levels (which warrant further review):

• Phase 1: All public water systems achieve 10 ppt for PFOA, 10 ppt for PFOS, and 5 for Hazard Index effective within 5 years.

• Phase 2: All public water systems achieve 7 ppt for PFOA, 7 ppt for PFOS, and 3 for Hazard Index effective within 10 years.

• Phase 3: All public water systems achieve 4 ppt for PFOA, 4 ppt for PFOS, and 1 for Hazard Index effective within 15 years.

To be clear, in outlining this three-phased approach, MAMWA is not recommending adoption specifically of MCLs at 4 ppt for PFOA and PFOS or of the proposed Hazard Index for the other four chemicals. The point is to illustrate a prioritized, health-based phase-in over time, regardless of whatever specific final MCL concentrations or index that may be adopted.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline as well as discussion on a phased-in MCL approach and the availability of addition extensions through the exemption process under SDWA Section 1416. For additional discussion on how the agency considers analytic feasibility when establishing the MCL, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

Maryland Association of Municipal Wastewater Agencies (MAMWA) (Doc. #1658, SBC-043411)

[MAMWA recommends and requests that EPA revise the proposed regulation to adopt a health-based phased approach, which could be established through use of the following existing EPA authorities and discretion:]

• Acknowledge Need for Primacy Agency Use of 3-Year Exemption Extensions – EPA should acknowledge in the final regulation that many projects in each phase, especially larger more complex projects, will need to make use of the three year extension (beyond the 5-year minimum) for necessary capital improvements due to

the compelling factors discussed in these comments, as allowed under 40 C.F.R. § 142.50).

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). The EPA discussed in the final rule preamble that SDWA § 1416(a) and (b)(2)(C) describe how the EPA or states may also grant an exemption for systems meeting specified criteria that provides an additional period for compliance. The EPA, therefore, has expressly acknowledged exemptions for states exercising primacy enforcement responsibility and have

adopted the 1998 Variance and Exemption Regulation. Further, please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

J.R. Simplot Company (Doc. #1661, SBC-044153)

Since the PFAS NPDWR effective date is anticipated for December 2026, there is a very short window for CWS to apply for grants, obtain funds, and install PFAS equipment. There also continues to be a nationwide shortage of contractors. Therefore, if EPA moves ahead with finalizing this proposal, it is imperative that the effective date of the proposed regulation be revised and extended from 3 years to 5 years after the date of publication of the final rule in the Federal Register.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Water Supply District of Acton (Doc. #1662, SBC-043664)

EPA's timeline for compliance with the rule is not reasonable, and likely not even achievable, given the work that goes into designing, constructing, and funding new treatment systems. Our experience has been that a permanent solution takes approximately 5 years to complete. A temporary PFAS treatment system underway in our system began with pilot testing in the fall of 2020 and is not anticipated to produce treated water until at least March 2024. This process was undertaken during a period when competition for similar services and equipment was not yet a national concern. The water sector, including operators, design engineers, and construction workers, is challenged with workforce issues like many other sectors of our society. More sophisticated treatment will likely cause a change in PWS classification and may require a higher-grade operator license. In Massachusetts, it can take years to complete the required training to be able to sit for a higher-grade exam. EPA does not appear to have given any thought to issues such as these when they crafted the rule and its three year implementation timeframe. EPA must adjust the compliance timeframe to be more realistic.

EPA Response: Consistent with the commenter's request regarding the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. Regarding concerns on operator certification licenses, please see the EPA response to comment Doc. #1567, SBC-042738 in section 12.1 in this *Response to Comments* document.

Washington State Department of Health (DOH) (Doc. #1665, SBC-044437)

• Drinking Water Operators with appropriate and adequate training and certification are challenging to locate and maintain for smaller water systems as there is a qualified labor shortage within the water industry. Therefore, the cost of keeping treatment in perpetuity represents a considerable cost to water delivery.

New treatment and source relocation are potential responses to the new PFAS rule, but the rule must consider cumulative impacts of multiple forms of drinking water contaminants. Cost and compliance with this rule must be structured to ensure compliance for PFAS without interfering with other contaminant treatment or compliance.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges, as well as simultaneous compliance challenges, that may affect the compliance timeline.

Inland Empire Utilities Agency (IEUA), California (Doc. #1666, SBC-043392)

Comment 2 – Compliance Deadline Extension – EPA's compliance deadline should be extended from three years to at least five years, as contemplated in SDWA.

The proposed rule would require compliance three years after the PFAS NPDWR promulgation; however, for water recycling utilities recharging recycled water, compliance is expected upon adoption. For instance, the existing Water Recycling Requirements, Order No. R8-2007-0039 for the Chino Basin Recycled Water Groundwater Recharge Program, issued by the California Regional Water Quality Control Board Santa Ana Region to Inland Empire Utilities Agency (IEUA), states that "recycled water used for recharge shall meet any new Federal and State maximum contaminant level upon adoption."

IEUA believes that this timeline is unreasonably short for installing PFAS treatment. Local permitting challenges, labor shortages, material and supply issues, funding constraints and inflation cost increases will hinder a construction project schedule. IEUA is also concerned with the lack of laboratory support that is currently available to provide reliable, accurate and consistent data to help track the treatment improvements for PFAS removal. When monitoring for PFAS in the recent years, IEUA faced several challenges with the limited capacity and the accuracy of data generated using unapproved methods for testing and inadequate quality checks. IEUA, since, developed inhouse capabilities for PFAS analysis to address some of the challenges and even though it is not an immediate concern to IEUA's operations, the availability of accurate, reliable and consistent laboratory support for PFAS analysis has been a challenge for most utilities and will continue to be a challenge. Therefore, IEUA recommends that EPA extend the compliance deadline. In accordance with SDWA § 1412(b)(10), we request that EPA extend the compliance deadline for PWSs, wastewater, and water recycling utilities by two years, for a total

of five years from the adoption of this regulation, to allow for additional time for necessary capital improvements and proper methods to be promulgated.

EPA Response: Consistent with the commenter's request regarding the compliance timeframe, and based on information provided in this and other comments, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. The EPA does not have authority under SDWA to restrict States from requiring shorter timeframes.

City of Allentown and Lehigh County Authority (LCA), Pennsylvania (Doc. #1667, SBC-043682)

3. Compounding compliance Financial Pressures -- The proposed PFAS requirements are coming at a time when water systems are already deeply engaged in a variety of other new regulatory compliance efforts, such as the efforts to meet new requirements laid out in the Lead & Copper Rule Revision (LCRR). The addition of these significant capital expenses will compound the cost of water for financially fragile rate payers, where in the City the percent of persons in poverty is equal to 23.3%

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges, as well as simultaneous compliance challenges, that may affect the compliance timeline.

City of Allentown and Lehigh County Authority (LCA), Pennsylvania (Doc. #1667, SBC-043684)

Based on these significant compliance and implementation challenges, the City believes the standard implementation timeline is not appropriate for the proposed PFAS rule. The need to plan, design, pilot, and construct facilities will take much longer than the three-year timeline given the challenges described above. We request that EPA extend the effective date of compliance by at least two years to ease the burden on water systems that must install capital improvements to achieve compliance.

EPA Response: Consistent with the commenter's request regarding the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

City of Hillsboro, Oregon (Doc. #1668, SBC-043120)

2. Implementation Timeline

As proposed, the NPDWR for PFAS has a three-year initial monitoring period that runs concurrently with the three-year window for utilities to implement mitigation strategies. This timeframe is unattainable for most utilities to plan, design, pilot, permit, procure, and complete construction or installation of necessary advanced treatment options. Although primacy agencies can extend this three-year implementation timeline to five, there is no guarantee that utilities will be granted this extension or that the five-year period would be enough to plan and complete a large capital project, such as installing and maintaining advanced treatment. Additionally, research and development of new treatment technologies is ongoing with PFAS, and the current timeline precludes water utilities from evaluating and potentially implementing some of these newer technologies and approaches that may address the utilities needs more efficiently and effectively. Hillsboro Water requests to leave the implementation timeline to the discretion of the primacy agency to approve based on factors specific to the utility including availability of funding, the mitigation method, evolving best practices, and other regulatory considerations.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline as well as further extensions that may be authorized by primacy agencies on a case-by-case basis under SDWA Section 1416.

Aurora Water, City of Aurora, Colorado (Doc. #1669, SBC-043734)

Compliance Schedule

In accordance with the Safe Drinking Water Act, systems have three years to comply with new rules with a possible two-year extension if capital improvements are needed. One of those years will be taken up by the initial monitoring period which leaves a timeline of 2-4 years for meeting compliance. Aurora Water has serious concerns about the ability to comply with this proposed regulation within three years of promulgation. It is likely Aurora will be forced to improve treatment processes to meet this proposed rule and a typical construction project would exceed this compliance period. Supply chain issues are already a concern in the city's day-to-day operations, but with these additional requirements causing nearly every system in the area to acquire the same technologies, there simply will not be enough manufacturing capacity to support a three-year or even five-year compliance timeline. The Safe Drinking Water Act allows for an extension of the compliance period when extensive capital expenses are required. The extensive and complex funding application process required to access BIL support is another reason for an extended compliance period. With the changes to processes and procedures, lengthy funding application processes, and technology limitations, meeting a three-year

compliance timeline will be extremely challenging for all water systems affected. Aurora Water recommends extending the compliance schedule with the proposed regulation.

EPA Response: Consistent with the commenter's request regarding the compliance timeframe, and the information provided by this and other commenters, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

National Association of Water Companies (NAWC) (Doc. #1670, SBC-044163)

5. The amount of time for implementation for public and private water systems to meet the final MCLs is insufficient.

As currently proposed, the water systems that will need to be upgraded to comply with the final MCLs will have three (3) years to from the date of the final rule to upgrade their systems. Due to the cost and complexity of upgrading water treatment systems, a deadline of three years to design, construct and begin operations of an upgraded treatment system to remove and dispose of PFOA and PFOS is not reasonable and may be almost impossible in some circumstances. Water systems are already balancing and burdened by many competing priorities for their time and financial resources due to increasing regulations, including mandates from the Lead and Copper rule. Complicating their efforts are increased worker shortages, the lack of qualified engineers, and shortages in the supply chain. These same challenges will make it difficult if not impossible in many cases to construct and begin operation of new treatment systems within the allowed three years. Before EPA can mandate dates for implementation, it must have a reasonable basis for assurance that those deadlines are achievable.

EPA Response: Consistent with the commenter's request regarding the compliance timeframe, and the information provided by this and other commenters, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is authorizing a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges, as well as simultaneous compliance challenges, that may affect the compliance timeline.

National Association of Water Companies (NAWC) (Doc. #1670, SBC-044165)

NAWC suggest that a more reasonable and achievable deadline for upgrading systems to meet the new MCLs is five (5) years. This is consistent with the compliance date for the in the National Primary Drinking Water Regulation for Arsenic (66 Fed. Reg. 6976, January 22, 2001) which followed the statutory authority set forth in section 1412(b)(10) of the Safe Drinking Water Act, 42 U.S.C. §§ 300f to 300j-26. After reviewing the complexity of the process to upgrade systems to achieve compliance, EPA stated the compliance date, "regardless of system

size, will be 5 years from the date of promulgation of the standard." (66 Fed. Reg. at 6993). EPA should follow the same approach here due to the complexity of the processes involved .

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Cleveland Water, City of Cleveland, Ohio (Doc. #1672, SBC-044919)

In the proposed rule preamble, the agency states, "EPA does not intend to provide a two-year extension nationwide." Cleveland Water urges EPA to reconsider this decision. While states may provide an extension on a case-by-case basis, there is no guarantee that the extension will be granted. There are many other social and political factors that may pressure a state to not grant any extensions even when it is warranted and justified. EPA could provide some relief to water systems by providing this blanket extension nationwide and could potentially ease the immediate impacts to labor markets and supply chains. Additionally, EPA could provide guidance to states on when is appropriate to provide a three-year exemption, particularly when a utility is acting diligently to implement treatment, but constraints out of its control have prevented completion in the five-year period.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on exemptions under SDWA 1416 as well as supply chain and labor challenges that may affect the compliance timeline.

Cleveland Water, City of Cleveland, Ohio (Doc. #1672, SBC-044918)

Section 5.4: Compliance timeline

EPA is proposing a three-year compliance time from the promulgation of the rule. A state or EPA may grant up to a two-year extension if it is determined that an individual system needs additional time for capital improvements, giving up to five years if the state or EPA grants the extension. Additionally, EPA or the primacy agency may grant an extension of three additional years beyond the five for systems meeting specific demands criteria explained in SDWA § 1416. Small systems have the option to apply for a series of three, two-year extensions beyond the eight years provided to medium and large systems. This is the compliance schedule laid out in the SDWA.

Cleveland Water cannot stress enough that the three-year compliance deadline will not be enough time for many water systems impacted by the proposal to complete capital improvement projects to address PFAS. If Cleveland Water is triggered into additional treatment under this

rule, it would take a minimum of six years if this project was the only priority and there were no delays or issues that arise from supply chain, labor, or the permitting and procurement processes.

The process for a PWS to complete a project of this magnitude is long and tedious. While each water system is different, there are similarities in the process that most must follow. Utilities like Cleveland Water are publicly owned and must go through certain channels for approvals on each step of the process. There are deeper considerations that some must address when it comes to rate increases, permitting, and general budgeting for improvement projects. Many of these steps must be approved by boards, councils, and/or elected officials. These steps take time, which in many cases is outside the control of the PWS.

Typically, approvals need to be granted for a project this size, which can take months based on scheduling and other priorities within a municipality. Water systems will then need to design and conduct pilot studies to determine the best approach to treatment, assess impacts on other aspects of treatment, determine the specific needs of the water system, and determine the efficacy of the chosen treatment. Design and building of these pilots can take 18 months to three years. These pilots would also need to capture seasonal variability in source waters, so this process can take about 12 months.

Public utilities are also subject to public procurement regulations. These processes add additional time to the design and the construction process. Development of a request for proposals for project design services, receipt and review of proposals, the consultant selection and negotiation process, and contract award typically takes six months or more. The process for receiving bids for construction and awarding those contracts will take another three to six months.

Construction of the treatment alternatives noted in the rule (GAC, IX, RO) would be additional treatment trains. Construction phasing to maintain plant operations and ensure an adequate supply of drinking water to the public is critical. Tie-ins to existing infrastructure will be necessary and must occur during low demand periods (often wintertime or other low use time based on location) to ensure sufficient water production capacity to meet community needs. These construction-staging intricacies will further lengthen the time to construct PFAS treatment improvements. Construction and commissioning timeframes will be project and site specific but could in some cases take three years.

PWSs and other sectors across the country are currently experiencing increased pricing of goods and services, supply chain disruptions, and labor shortages. The proposed compliance period would be impossible for many utilities to meet without extensions. EPA needs to include considerations for how the increased demand for contractors, materials, equipment, and other labor will prolong projects and drastically increase prices, costs that eventually must be passed on to ratepayers and impacts a utility's ability to provide affordable water to the public. Currently, even before this rule is finalized, some GAC suppliers have advised that the lead-time for GAC vessels for PFAS treatment is eighteen months. This is not a unique situation, and many utilities must prepare for the situation to worsen if this rule is finalized as is.

While Cleveland Water supports the proposal's overall goal of protecting public health by delivering safe, clean, and affordable drinking water to the public, a compliance period of three years will simply be impossible for many PWSs to meet. There are several options EPA could pursue to alleviate burdens on public systems while still implementing feasible actions that will ultimately be more protective of public health from the chronic conditions attributed to PFAS exposure.

EPA Response: Consistent with the commenter's request regarding the compliance timeframe, and the information provided by this and other commenters, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Association of California Water Agencies (ACWA) (Doc. #1675, SBC-044938)

COMMENT 6 – COMPLIANCE DEADLINE EXTENSION – EPA should extend the compliance deadline to five years from finalization of this regulation as contemplated in SDWA.

When finalized, water systems will have three years to comply with the regulation [FN32: 88 Fed. Reg. at 18,683.]. ACWA believes that this timeline is too short for the associated compliance requirements for monitoring and installing PFAS treatment.

The process for completing such projects is complex and time-consuming, involving various approvals, pilot studies, local land use or zoning processes, design and development, procurement, and construction. These steps require coordination with multiple entities, including boards, councils, other elected officials, and the public. Additionally, utilities are currently facing challenges, such as inflation, supply chain disruptions, and labor shortages, which further extend project timelines and increase costs.

In accordance with SDWA, [FN33: 88 Fed. Reg. at 18,689.] EPA should extend the compliance deadline by two years to allow for additional time for capital improvements that will be necessary as a part of implementation of this regulation. As a result, we ask EPA to extend the compliance deadline to five years from finalization of this regulation.

EPA Response: Consistent with the commenter's request regarding the compliance timeframe, and the information provided by this and other commenters, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

California Association of Mutual Water Companies (Doc. #1676, SBC-043778)

4. Treatment Facilities – Supply Chain – Costs – Increased Compliance Period

Where new treatment facilities are required to meet the PFAS MCL, small systems will find competing for necessary engineering and construction services impossible. Supply chain limitations, such as for Granular Activated Carbon and treatment equipment, coupled with the Build American, Buy American (BABA) requirements, further exacerbate the difficulty for small systems. We recommend that the EPA extend the compliance period to a minimum of five years for systems with fewer than 3,300 service connections, as the proposed three-year period is not enough to meet the requirements of this highly complex rule.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. Requirements under Build America, Buy America Act (BABA) will not prevent regulated PWSs from installing treatment. .

New York State Department of Health (NYS DOH) (Doc. #1677, SBC-044945)

7. Should the EPA proceed with MCLs of 4 ppt, the Department suggests that EPA evaluate a bin approach similar in structure to the Stage 2 Disinfectants and Disinfection Byproducts Rule or Long-Term Surface Water Treatment Rule. This approach could allow for staggered compliance with additional time for compliance provided to smaller systems. This approach will ease the workload on primacy agencies, ensuring appropriate and timely enforcement as well as equitable distribution of technical assistance resources. In addition, this approach may alleviate some of the competition between small systems and large systems for analytical services, engineering, construction materials and labor that may negatively impact disadvantaged communities.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline as well as discussion on a phased-in MCL approach.

City of Vancouver Water Utility, Vancouver, WA (Doc. #1684, SBC-044315)

Compliance Extensions:

Given the prevalence of PFAS in water supplies, the number of utilities that will be impacted, current supply chain issues and the overall complexity of this issue, it is imperative that the EPA provide the opportunity for a compliance extension. Even with a two-year extension, there are many utilities that will have trouble complying with the regulation within five years. Treatment systems take time to design, publicly bid and construct and given that many utilities will have multiple systems to install in a short period, a compliance extension period of up to 4 years should be included for extreme situations, therefore giving utilities up to seven years to comply.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline, as well as the opportunity for further extensions based on the authority of SDWA Section 1416.

Horsham Water & Sewer Authority (HWSA) (Doc. #1686, SBC-043808)

Regarding the compliance timetables, EPA is applying the standard timetable for compliance established in the 1996 Amendments to the Safe Drinking Water Act. This might be acceptable under normal times. But ever since the COVID-19 Pandemic emergency declaration in 2020, we have not been living in normal times. Supply chain issues have created extended timelines for water treatment equipment and appurtenances and costs for these and labor costs have risen dramatically. Having installed PFAS treatment both before the pandemic and during the pandemic, we can clearly see the impacts and can attest to the extended timelines and exaggerated costs. As mentioned earlier, we have three PFAS treatment systems that were bid and awarded in 2021 and the treatment units are still not on site as of the time of this letter (original 330 day construction timeline for the contract has now been extended to 530 days), and this is well before one would expect a multitude of equipment orders from water utilities across the country once this rule is promulgated. The now 530-day construction timeline (which may yet have to be extended even further) is in addition to the initial four quarters of monitoring, piloting, design, permitting and bidding timelines utilities will have to meet. Clearly as utilities across the country complete their required PFAS monitoring and the number of utilities that realize they need to install treatment is anything close to EPA's own estimates, the supply chain issues are going to become even much more exasperated than they already are. The normal three-year compliance timeframe for a rule impacting the magnitude of utilities projected, and under the existing supply chain conditions, is simply not realistic and it would be disingenuous of EPA to rely on the discretionary two-year extensions that state primacy agencies can give under the SDWA, knowing full well that some states do not grant these extensions at all. As a minimum, EPA must acknowledge the realities of today's construction constraints and take the "discretion" out of the "discretionary two-year extension" and grant a blanket extension for the extra two years applicable to all utilities to meet the rule regardless of which state they reside. Even with a five-year implementation window it is highly unlikely the estimated 4,000 to 5,000 systems nationwide that will need to install PFAS treatment will be able to complete initial compliance monitoring, pilot, design, permit, procure, construct, and start up PFAS treatment before being in violation.

EPA Response: Consistent with the commenter's request regarding the compliance timeframe, and the information provided by this and other commenters, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's

discussion on supply chain and labor challenges that may affect the compliance timeline and the opportunity for additional extensions pursuant to Section 1416 of SDWA.

Massachusetts Coalition for Water Resources Stewardship (MCWRS) (Doc. #1691, SBC-044332)

[Alternative Approach-While MCWRS does not agree with the proposed MCLs, an alternative implementation plan is offered regardless of what the final MCLs may be. That plan would include:]

h. Break the UCMR 5 results into quartiles and target the highest quartile (top 25% of results) for PFAS remediation, using federal monies, during the first 5 years. Federal dollars would thus be applied to the water systems with the highest PFAS levels and assumed highest health risk. The second highest quartile would be targeted for remediation in years 6-10, the third highest in years 11-15 and the lowest in years 16-20. Federal grant funding would be applied to all so if the funding runs out at least the systems with the highest levels would be addressed earliest and those that may go unaddressed would have the lowest concentrations.

[Alternative Approach-While MCWRS does not agree with the proposed MCLs, an alternative implementation plan is offered regardless of what the final MCLs may be. That plan would include:]

i. The quartiles could be established based on UCMR5 results but mandatory testing could be required for all other (non-UCMR) water systems with their respective results used to place them within the appropriate quartile.

[Alternative Approach-While MCWRS does not agree with the proposed MCLs, an alternative implementation plan is offered regardless of what the final MCLs may be. That plan would include:]

j. This approach relieves some of the burden imposed by having 6,000 or more water systems trying to simultaneously come into compliance. It may also lessen impacts on equipment and material suppliers. Stretching the compliance period based on detected levels of PFAS also provides more time to develop new treatment technology, to further research health impacts and to make significant inroads in source reduction, which is the true key to address PFAS presence in all environmental media.

MCWRS believes that EPA is selecting a risky and potentially dangerous approach in regulating certain PFAS with MCLs at the laboratory detection levels. The potential unintended consequences of this initiative are of great concern and must be further investigated and addressed before finalizing MCLs. Taking a measured approach to PFAS regulation in drinking water rather than a reactionary response to political, public and media pressure is in the best interests of public health protection.

Sincerely,

Philip D. Guerin President

EPA Response: The commenter suggested a monitoring framework where "highest-risk" systems are required to implement the NPDWR sooner than systems with lower levels of risk. The agency disagrees with the commenter that this approach is more public health protective as PFAS levels could fluctuate such that presumably "lower-risk" systems could experience elevated levels that may necessitate treatment or other actions to ensure compliance with the MCLs. The monitoring and compliance requirements finalized in the PFAS NPDWR address these issues (i.e., systems with elevated concentrations will require more frequent monitoring whereas systems without contamination or low levels of contamination will monitor less frequently). Based on these monitoring results, water systems may then be required to change their monitoring frequency if the results suggest increasing or decreasing concentrations. For additional discussion on monitoring and compliance requirements for the rule, please see section 8 of the EPA's *Response to Comments* document. In addition, contrary to the commenter's suggestion, the MCLs are not set the laboratory detection levels, but rather for PFOA and PFOS they are set at the PQLs which are distinctly different than levels of detection. For additional discussion on PQLs, please see section V and VII of the final rule preamble. Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Massachusetts Coalition for Water Resources Stewardship (MCWRS) (Doc. #1691, SBC-044327)

[The proposed MCLs raise the specter of serious unintended consequences that could pose public health risks for water consumers. Some of these are:]

b. Current shortages in certified drinking water operators will be worsened as thousands of new PFAS treatment plants may require treatment operators. Current operators may be enticed to relocate to run these new facilities if the system is in a community with the ability to pay higher salaries. Systems losing these operators are more likely to be in less wealthy communities with significant Environmental Justice populations who may then be harmed by a lack of experienced water operators.

[The proposed MCLs raise the specter of serious unintended consequences that could pose public health risks for water consumers. Some of these are:]

c. With the expectation that water systems exceeding the proposed MCLs will come into compliance (i.e., construct and operate treatment facilities or find new sources) within two years, there will be a significant issue obtaining equipment for these new facilities. EPA's own low estimate of some 6,000 water systems exceeding the MCLs and designing, bidding and building new treatment facilities all at the same time will create a massive supply chain log-jam.

Achieving a two year compliance schedule is not realistic and it will bring any progress on treatment to a quick halt.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Water Quality Association (WQA) (Doc. #1694, SBC-044990)

Furthermore, this regulation will lead to an increase in water testing and sampling for PFAS chemicals to ensure compliance. WQA has heard concerns regarding cost, laboratory capacity, and delayed results, and the association encourages the EPA to review comments from stakeholder groups that represent that industry.

EPA Response: The EPA agrees that the final NPDWR will have associated costs for compliance but also significant public health benefits realized upon implementation. A discussion of the costs and benefits of the regulation can be found in the final rule preamble (section XII) and section 13 of the EPA's *Response to Comments* document. Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

City of Scottsdale, Water Quality (Doc. #1698, SBC-043506)

May 30, 2023

Comments from the City of Scottsdale, Arizona

U.S. EPA's March14, 2023, Proposed National Primary Drinking Water Regulation (NPDWR) For Per-and Polyfluoroalkyl Substances (PFAS) [PFOA, PFOS, HFPO-DA (GenX), PFHxS, and PFBS]

Public Docket ID: EPA-HQ-OW-2022-0114

SUBMITTED ELECTRONICALLY (www.regulations.gov)

The City of Scottsdale submits the following comments on the above referenced proposed NPDWR:

Scottsdale is requesting that Public Water Systems (PWSs) be given sufficient time to comply with the final Maximum Contaminant Levels proposed in the NPDWR. Scottsdale has three groundwater wells slightly above the proposed MCLs of 4 parts per trillion (ppt) for PFOS and PFOA. These groundwater wells also have detections for PFBS, HFPO-DA, and PFHxS.

The EPA is proposing a three-year compliance time for the promulgation of the rule. Scottsdale does not believe that the three-year compliance deadline will be enough time to complete a capital improvement project to address PFAS issues. Scottsdale supports the proposal's overall goal of protecting public health, but a compliance period of three years will be extremely difficult for most PWSs to meet. There are other options the EPA could pursue to alleviate the compliance timeline burden to PWSs. The proposed preamble states, "EPA does not intend to provide a two-year extension nationwide." Scottsdale respectfully requests that EPA reconsider this position. EPA could provide guidance to states on when it is appropriate to provide a three-year extension, especially if a utility is pursuing treatment. EPA could also provide an exemption based on PFAS concentrations in the water system. This is the approach EPA used for the Arsenic Rule. Water systems would get five years for compliance but would be eligible for a three-year extension based on PFAS levels. Another benefit to this approach would be a system like Scottsdale with PFOA and PFOS close to the MCL would have more time to consider less costly options.

Scottsdale recently completed a $26,000,000 construction project adding reverse osmosis treatment to treat other pollutants in the three groundwater wells with PFOA and PFOS. Based on the treatment capacity of this new facility, Scottsdale will not be able to reduce PFAS concentrations in the treated water to the city's internal goal of 80% of the MCL. It is imperative that PWSs be given sufficient time to study and look at alternative treatment options to comply with the proposed NPDWR.

Sincerely,

Carie Wilson

Water Quality Regulatory Manager City of Scottsdale, Arizona

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on exemptions under SDWA 1416 as well as supply chain and labor challenges that may affect the compliance timeline.

New Jersey Department of Environmental Protection (NJDEP) (Doc. #1699, SBC-045046)

Under Exemptions and Extensions, a state or EPA may grant an extension to comply with an NPDWR's MCL(s) if the state or EPA determines an individual system needs additional time for capital improvements or the system is small and needs financial assistance. If the EPA will allow for extensions to comply with the MCL, EPA must provide specific criteria and not allow room for interpretation. In addition, the potential for a system to have 14 years to comply is too long with the known health impacts of PFAS contaminants.

EPA Response: States are not required to provide exemptions; under SDWA Section 1416, exemptions are at the discretion of the primacy agency. In addition, Section 1416 provides specific criteria and processes for exemptions.

Alabama Water and Wastewater Institute (AWWI) (Doc. #1700, SBC-043508)

AWWI believes that the 3-year compliance timeline included with the proposed regulation is not realistic given the current state of the water construction industry . Supply chain issues, the availability of the construction workforce, and engineering design resource capacity have become critical issues in the water and wastewater industry due to the lingering impacts of the COVID-19 pandemic and the war between Ukraine and Russia. As an example, many water industry construction projects are now being delayed due to electrical equipment lead times in excess of 52 weeks. These types of equipment delays are impacting water and sewer system capital projects for rehabilitation and replacement, and these delays will be further impacted by the significant number of capital projects resulting from the proposed PFAS regulation. It is not realistic to expect water and sewer systems impacted by these new PFAS regulations to be able to design and construct improvements to achieve compliance within three years. AWWI believes that it is more reasonable to provide utilities with no less than five years at a minimum to comply with the proposed PFAS regulation.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Association of California Water Agencies et al. (Doc. #1701, SBC-043835)

May 30, 3023

Michael S. Regan Administrator

US Environmental Protection Agency 1200 Pennsylvania Avenue, NW Washington, DC 20460

Via electronic submission

Re: Docket ID #: EPA-HQ-OW-2022-0114; PFAS National Primary Drinking Water Regulation Rulemaking

Dear Administrator Regan,

The undersigned organizations appreciate the opportunity to comment on the Environmental Protection Agency's (EPA) proposed Per- and Polyfluoroalkyl Substances (PFAS) National Primary Drinking Water Regulation (NPDWR). Our respective organizations have a vested interest in protecting public health from PFAS and therefore have examined the details of this

rulemaking. Individual comments have been submitted by these organizations representing each organization's perspective; however, we collectively would like to raise certain issues that EPA must address as it works to address PFAS.

Feasibility of Implementation

EPA's proposed three-year compliance timeline is insufficient and infeasible for compliance. EPA has proposed a three-year compliance time for water systems to address the presence of PFAS in their water supply above the proposed maximum contaminant level (MCL). The proposed NPDWR rulemaking indicates that EPA does not plan to issue a waiver for a two-year extension for systems that need to install PFAS treatment technologies or facilities. Water systems that need to install treatment facilities will need a minimum of five years to complete projects. The process for completing such projects is complex and time-consuming, involving various approvals, pilot studies, local land use or zoning processes, design and development, procurement, and construction. These steps require coordination with multiple entities, including boards, councils, other elected officials, and the public. Additionally, utilities are currently facing challenges, such as increased pricing, supply chain disruptions, and labor shortages, which further extend project timelines and increase costs. For these reasons, many utilities that must install treatment facilities to address PFAS will not be able to reasonably meet a three-year compliance timeline.

We recommend that EPA use its authority to provide a nationwide two-year extension for the compliance timeline for systems installing capital improvements. A two-year extension will address the concerns outlined above to alleviate burdens on water systems and allow for feasible compliance by water systems addressing PFAS contamination.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

<u>The City of Columbus, Department of Public Utilities (Doc. #1703, SBC-045058)</u>

Public water utilities will need more time to comply, especially if the MCL is 4 ppt.

Even if EPA believes that the 4 ppt MCL is generally feasible, EPA's proposed timeline to meet it is not. Meeting an MCL of 4 ppt will require the commitment of an extremely large amount of public money to accomplish these significant construction projects. Public water utilities across the nation, like CDPU, must navigate their budgeting, funding, and procurement processes before a shovel strikes the ground to add a treatment process. It will take time to do enough sampling to ensure that the expenditure of hundreds of millions of dollars is warranted, and then to design and plan the project. Then comes the long haul of actually constructing the treatment.

Added to these considerations is the requirement that the public water utility must maintain 100% of their operations while building out the treatment. In short, public projects of this magnitude take time.

On top of the typical lengthy project timeline, if 3,500 water utilities enter the market for the same few treatment techniques, there will be massive supply/demand issues. There are already limited resources for granular activated carbon equipment, media, and regeneration services. The same can be said for lab services for sampling. Even though EPA received dozens of applications for certification, on a recent call NACWA members from around the country only identified two labs that the entirety of utilities present were using for PFAS analysis. Compounding this difficulty are the general supply chain issues and labor shortages that linger across the United States. Build America, Buy America and other federal requirements add more hurdles. Three years is not enough time to get us to the finish line, especially when compliance and the corresponding consumer confidence are hanging in the balance.

Allowing more time for compliance will also enable EPA to tackle the data gap issues that are currently plaguing water utilities and PFAS science. UCMR 5 data will be instrumental in the nation's understanding of its PFAS problem. This crucial information will come too late with the current compliance timeline to allow EPA and water utilities to respond accordingly.

One option to solve the timing issues would be to extend the compliance timeline. Another option is a phased approach to the MCL (starting with a higher initial MCL) that would address these problems by reducing the competition for limited resources for installing treatment and allowing the science to catch up to policy. It would tackle the bulk of, and most significant, human health risks by targeting systems with the highest PFAS concentrations first.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

California Farm Bureau Federation (Doc. #1704, SBC-045080)

Given the costs and the challenges associated with obtaining the necessary technologies, availability of testing, and the lack of disposal methods that we have already outlined, we recommend that the EPA consider extending the implementation period, particularly for small, rural water utilities. We strongly believe these systems need additional implementation time and resources to ensure that they are in compliance with any new standard adopted in a final rule. As previously mentioned, at minimum, the EPA should consider a tiered roll out on implementation.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments*

document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

California Farm Bureau Federation (Doc. #1704, SBC-045075)

Access to contractors needed to install these technologies has additionally been identified as a concern by organizations representing rural water communities. Because contracts with large water systems are more lucrative, smaller systems inevitably fall to the bottom of the priority list. Facilities will also need to bring in more employees to oversee the operations, maintenance, and treatment of the equipment. This will require specific training and trainer shortages have already presented challenges. Staff shortages, even for the existing work required to safely operate and maintain drinking water systems, are widespread. For example, a 2021 AWWA survey on staffing and supply chain needs, found that 40 percent of drinking water utilities of all sizes are struggling to fill positions at their facilities, and employee turnover has doubled. For these reasons, we urge the agency to reevaluate the implementation period and consider the option of a tiered roll out with larger utilities moving ahead first to prevent a bottleneck on technologies and financial resources.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. For additional discussion on treatment technology availability and capacity, please see section 10.6 of the EPA response in this *Response to Comments* document.

State of Vermont Agency of Natural Resources and Department of Health (Doc. #1708, SBC-045094)

d. Enforcement/Compliance/Health-based violations:

Another concern is about how violations are logged, accrued, and reported given the focus on health-based violations. Given the current framework under management of the Enforcement Targeting Tool, systems would become a priority for enforcement before they are able to adequately address the PFAS contamination. In our experience in Vermont, enforcing against a system that is actively working to install treatment only serves as a distraction and delay to get to the end result of compliance. Therefore, information about expectations on how to enforce against systems with PFAS MCL exceedances is required and/or data management instructions are critical for us to know how to log, "count", and follow-up on respective violations. It is presumed that if a system has results for PFOA, PFOS, PFNA, PFBS and/or PFHxS that they

could exceed the PFOA MCL, the PFOS MCL, and the Hazard Index MCL. This would be 3 MCL exceedances.

In Vermont, even with our existing Do Not Drink notice requirement following our State MCL exceedance and provision of some state grant money created to address PFAS upon implementation of our MCL, the average number of days to reach completion of design, permitting, installation, and sampling to confirm treatment/well modification/new well efficacy is 613 days. While this has largely been due to many systems waiting to conduct a site investigation for the source of contamination before implementing a final remedy, it also is dictated by consulting engineer availability and to a lesser extent to State staff time and capacity. Additionally, being in a northern climate, work to install treatment or build associated buildings, where needed, cannot occur year-round. In Vermont we have had 16 systems exceed our MCL in the last 4 years, which has led to considerable reprioritization and workload changes; having 20-30+ systems immediately exceed the new MCL upon promulgation will create incredible demands on consulting engineers and state resources. In a framework under which we are regulating to the reporting level, we cannot rush the process to assess site information and characterization since installing a new well has far lower on-going operation and maintenance costs.

EPA Response: The Enforcement Targeting Tool (ETT) is outside the scope of this rulemaking. The EPA's SDWA Enforcement Response Policy, which discusses the ETT, explains how the EPA typically pursues enforcement cases involving a water system's violations of the SDWA. In this *Response to Comments* document, see also section 8.2 for more information on PWS compliance and violations and section 11.3 for a discussion of data management instructions. Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. Additionally, for PN with respect to MCL violations, the agency notes that the final NPDWR promulgates additional individual MCLs for PFHxS, HFPO-DA and PFNA. With respect to violations and reporting associated with the individual MCLs and Hazard Index (HI) MCL, the EPA recognizes that a utility may have two or more of these PFAS present that, over the course of four quarterly samples, may result in violation of multiple MCLs. For example, if, following four quarterly samples, a utility has PFHxS and HFPO-DA present and the running annual average (RAA) is above their respective MCLs and HBWCs of 10 ng/L, the system would be in violation of both the individual MCLs for PFHxS and HFPO-DA, as well as the Hazard Index MCL. Issuing multiple notifications (three in this example) for these violations may cause public confusion as the adverse health effects and exposure concern in this instance is not meaningfully different from either a Hazard Index or individual MCL perspective. To simplify implementation of PN in this scenario, the EPA is finalizing requirements in Appendix A to Subpart Q of Part 141 such that utilities who violate the Hazard Index MCL and one or

more individual MCLs because of the same compounds can issue one notification to satisfy the PN requirements for the multiple violations.

Philadelphia Water Department (PWD) (Doc. #1709, SBC-045734)

EPA must utilize a holistic regulatory approach to rulemaking that includes considerations for PFAS generators, implementation time, and cost of capital improvements associated with proposed BATs, and competing regulatory requirements when determining implementation of MCLs for PFOA and PFOS.

3. Many public water systems impacted by PFAS contamination, including PWD, have limited options for affordable and timely remediation.

PWD is the single largest public water system in the Commonwealth of Pennsylvania. PWD's three water treatment plants treat approximately 250 million gallons of drinking water per day sourced from the Delaware and Schuylkill Rivers, PWD does not own its watershed area above our WTPs and these rivers are the only viable source of water for the City of Philadelphia. Similarly, Philadelphia's 3,180 miles of water system mains do not have the interconnections that would allow for the distribution of purchased water from a neighboring system with PFAS treatment. While PWD does have a resilient system, with the ability to draw water from two rivers, both sources will be impacted by the proposed PFAS rule.

In a likely scenario, should PWD's average PFOA and PFOS results from the proposed rule's monitoring period exceed the MCLs, PWD will have to reevaluate the use of advanced water treatment technologies and consider other potential operational modifications to achieve compliance. Treatment modifications are expensive, and the scale of PWD's treatment operations further magnifies capital and operating costs. PWD expects that PWSs across the country will experience similar issues. Given that PFAS is widespread and persistent in the environment, the proposed regulation may be a catalyst for the most significant modifications to the nation's water treatment infrastructure to date.

Stakeholders must understand that modifications to water treatment systems cannot happen overnight. Philadelphia, as a large system serving 1.6 million residents, would need substantial time to complete a thorough evaluation of system improvement options, procure resources to pilot new or established technologies, complete those piloting efforts to determine design conditions, acquire regulatory approval for implementation, design full- scale infrastructure, acquire funding, procure construction services, and implement any necessary capital improvements. Considering the scale at which the proposed regulations will impact PWSs, it is reasonable to estimate lengthened capital improvement timelines due to extended review/approval times by regional and state regulatory agencies, which will face resource constraints, and widespread competition for a limited pool of construction contractors and equipment vendors. PWD is requesting that clear and consistent guidance for extensions for treatment upgrades, either from the compliance date or following an MCL exceedance, be provided to primacy agencies to communicate to the regulated community. Given the magnitude

of systems that EPA expects to exceed an MCL during initial monitoring, PWD is also requesting that a blanket extension to the compliance period for this regulation be granted for all PWSs by an additional two years to provide PWSs with adequate time to implement the required remedial actions, which in most cases will require significant capital improvements. This action of extending the compliance timeline up to two years is applicable to instances where significant capital improvements are required as detailed in SDWA §1412(b)(10).

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Protecting Our Water, Environment, and Ratepayers (POWER) (Doc. #1714, SBC-045937)

COMMENT 4 — IMPLEMENTATION OF THE PROPOSED RULE IS NOT FEASIBLE BECAUSE IT DOES NOT ALLOW SUFFICIENT TIME TO BRING NEW TREATMENT ONLINE OR EXPAND WATER QUALITY LABORATORY CAPACITIES FOR THE MONITORING IT REQUIRES.

Complying with the rule as proposed is not feasible because the three-year timeframe is too short a window to plan, finance, procure, and construct the additional treatment infrastructure required to comply with the proposed MCL. EPA also needs to complete more analysis of whether it has approved a sufficient number water quality testing laboratories with accreditation for promulgated PFAS methods to perform the volume of sampling that the rule would require.

Three years is too short to implement the new NPDWR standards.

EPA has proposed three years from the date the proposed MCL is finalized to meet the new standards. [FN19: Proposed Rule, 88 Fed. Reg. at 18733.] This time span is not feasible to implement the requisite changes to satisfy the new standards because the EPA has not determined if PFAS is considered hazardous waste, the approved standards and methods for by-product disposal have not been finalized, and the requisite infrastructure changes are costly and will take a substantial amount of time to plan, finance, procure, and construct.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. Whether the EPA takes a future potential action to designate PFAS as hazardous waste is beyond the scope of this action. The agency notes that a possible future hazardous waste designation has no bearing on the EPA's decision to authorize this capital

improvement extension. For additional discussion on disposal of spent treatment materials under possible future regulatory actions and costs, please see section 10.4.2 of the EPA response in this *Response to Comments* document.

Monterey One Water (Doc. #1715, SBC-043827)

Compliance Timeline

Monterey One Water contracts out the analysis of PFOA and PFOS in its purified recycled water effluent to a certified laboratory for environmental testing that uses EPA Method 537.1. With method detection limits of 0.44 parts per trillion and 0.55 parts per trillion respectively, additional or enhanced testing will be required to determine compliance with the proposed federal MCLs. Compliance within the proposed three-year window is not feasible.

As currently written, compliance will be based on a running annual average. Therefore, regulated entities, like Monterey One Water, will not become aware of noncompliance until a minimum of one year into the three-year compliance window, resulting in only two years to identify, finance, and implement a solution. This does not take into account developing and obtaining approval of a quality assurance project plan, setting up the sampling program, and contracting with a certified lab, all of which must occur before sampling can be conducted and results utilized to determine compliance. Further, if after initial monitoring an entity determines it needs to implement new treatment technology to obtain compliance with the proposed MCLs, this would require conducting feasibility studies, designing, bidding, permitting, and constructing these new components. EPA has stated that funding provided by the Bipartisan Infrastructure Law can help entities build new systems to comply with the rule. Many entities, however, will be unable to secure such funding within the three-year compliance window. Without funding, the cost burden will fall to our community members.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Wyoming Department of Environmental Quality (WDEQ) (Doc. #1716, SBC-044760)

10. EPA Should Consider Variable Source Water Quality When Estimating Annual Cost Per Household for Small System Candidate Technologies

EPA has provided assurances that the proposed BATs can treat PFAS-impacted water to the proposed MCLs at an affordable cost based on EPA's estimated total annual cost per household. However, the specific source water quality at each PWS will significantly impact the life span and operating costs of all four proposed BATs. Prior to installation, a proposed BAT will require

pilot testing to determine treatment efficacy before the permanent solution could be permitted through WDEQ. This process will significantly extend the timeline required for compliance with the proposed rule.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. The EPA agrees that specific source water quality may impact the operating life of the BATs for the final NPDWR and that utilities closely evaluate all specific factors when deciding when implementing treatment options to meet the final MCLs. For additional discussion on Small System Compliance Technologies (SSCTs), including the EPA's analysis and identification of SSCTs, please see section 10.5 of the EPA response in this *Response to Comments* document.

Wyoming Department of Environmental Quality (WDEQ) (Doc. #1716, SBC-044758)

WDEQ recommends EPA provide analysis on whether increased demand of PFAS treatment technology and infrastructure, including disposal of treatment media, can be met by the current PFAS technology and infrastructure supply chain for regulated PWSs affected by the proposed PFAS NPDW rule, and whether a three-year time frame for PWSs achieving compliance is reasonable.

Additionally, WDEQ recommends EPA implement a phased approach for PWSs, specifically for small and rural systems, to implement Best Available Technologies (BAT), allowing industrial equipment and materials suppliers to accommodate the increased demand for PFAS treatment technologies and infrastructure over a longer timeframe and to attempt to avoid supply chain issues and associated cost increases.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Loudoun Water (Doc. #1717, SBC-043523)

Loudoun Water is a member of the VMDWA, a non-profit membership association comprised of 42 local governments and local water authorities in the Commonwealth of Virginia. The VMDWA advocates sustainable laws and policies to help ensure safe and affordable water in support of vibrant and healthy communities. The VMDWA has prepared a detailed letter of comments with numerous references that Loudoun Water supports.

In conclusion, Loudoun Water supports the development of primary drinking water standards for PFAS compounds, and we strongly encourage a phased approach for implementation that allows for a focus on the systems with higher PFAS concentrations first and that allows for more time for compliance. We desire a regulation that protects public health while prioritizing limited public resources and without causing unnecessary financial burdens on the greater public.

Sincerely,

Mark E. Peterson

Deputy General Manager, Administration Loudoun Water

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Loudoun Water (Doc. #1717, SBC-043518)

May 30, 2023

By Electronic Submission: Docket EPA–HQ–OW–2022–0114

U.S. Environmental Protection Agency EPA Docket Center

PFAS: PFOA and PFOS National Primary Drinking Water Regulation Rulemaking, Mail Code 28221T

1200 Pennsylvania Avenue NW Washington, DC 20460

Dear Sir/Madam:

Loudoun Water is a not-for-profit utility that provides drinking water, wastewater, and reclaimed water service to over 330,000 residents and commercial enterprises in Loudoun County. Loudoun Water provides potable water service to 76 percent of the population of Loudoun County. We operate one surface water treatment plant, five community groundwater systems and are a wholesale customer of neighboring Fairfax Water. Our customers used an average of 28.5 million gallons per day in 2022, with a recent peak demand of 47 million gallons per day. Our long-range planning will provide for a 90 million gallon per day water supply system.

Loudoun Water supports the development of primary drinking water standards for PFAS compounds, and we strongly encourage a phased approach for implementation that allows for priority focus on the systems with higher PFAS concentrations. Loudoun Water has experienced increased costs and schedule delays due to the cumulative impacts of ongoing supply chain challenges, worker shortages, and a national inflation problem. We anticipate adverse cost

impacts due to extremely high numbers of public utility and other infrastructure projects being attempted over the next five-to-ten years. EPA should consider the benefits to phasing implementation of the rule to avoid unintended consequences of driving up costs, as well as to ensure that the water systems with higher PFAS concentrations are prioritized while protecting public health, avoiding delays, and without creating pricing premiums.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on a phased-in MCL as well as supply chain and labor challenges that may affect the compliance timeline.

Monte Vista Water District (MVWD) (Doc. #1718, SBC-043536)

Compliance Deadline

The proposed rule would require compliance three years after the PFAS NPDWR promulgation. MVWD believes this timeline is unreasonably short for installing PFAS treatment. Local permitting challenges, labor and material shortages, funding constraints, and inflation cost increases make it difficult to meet such a short timeframe. In accordance with Safe Drinking Water Act 1412(b)(10), MVWD requests the EPA extend the compliance deadline for public water systems by two years, for a total of five years from the adoption of this regulation, to allow for additional time for necessary capital improvements.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Monte Vista Water District (MVWD) (Doc. #1718, SBC-043530)

Compliance Deadline

The proposed rule would require compliance three years after the PFAS NPDWR promulgation. MVWD believes this timeline is unreasonably short for installing PFAS treatment. Local permitting challenges, labor and material shortages, funding constraints, and inflation cost increases make it difficult to meet such a short timeframe. In accordance with Safe Drinking Water Act 1412(b)(10), MVWD requests the EPA extend the compliance deadline for public water systems by two years, for a total of five years from the adoption of this regulation, to allow for additional time for necessary capital improvements.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

HRSD (Doc. #1719, SBC-043543)

[We see the following recommendations as productive and protective strategies that EPA can utilize:]

Set the stage for phased implementation, allowing prioritization of resources for those water systems most impacted

In questioning the application of the alternate MCLs, 4 ng/L, 5 ng/L and 10 ng/L, EPA is already setting the stage for a potential phased implementation that prioritizes the drinking water systems posing the most risk to public health. A strategy in which all drinking water systems are required to come into compliance with the most stringent of the aforementioned MCLs will necessarily mean that all impacted drinking water utilities are competing for the same funding, the same engineering consultants, the same laboratory capacity, and the same contractors. Resources for large infrastructure projects are already strained as a result of the recent beneficial influx in infrastructure spending. HRSD has experienced a reduction in the number of responsive bidders for its large infrastructure projects, a symptom of limited capacity in the industry. The bid price for three of its most recent large projects has also exceeded our engineering estimates by more than 20%.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on a phased-in MCL as well as supply chain and labor challenges that may affect the compliance timeline.

HRSD (Doc. #1719, SBC-043545)

In order to effectively meet the public health protection objectives of this proposed regulation, EPA needs to support a phased implementation effort such that the utilities that have the highest PFAS concentrations can receive the necessary support and resources as rapidly as possible.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments*

document for the EPA's discussion on a phased-in MCL as well as supply chain and labor challenges that may affect the compliance timeline.

Louisville Water Company (Doc. #1720, SBC-043558)

[In that regard, we are providing the following comments on key issues that we think require consideration.]

8. Louisville Water recommends that EPA reconsider the timeframe for compliance. The industry is seeing unprecedented material products shortages and extended delivery timeframes as well as unprecedent labor shortages. In addition to the availability of labor and equipment, the agency should consider whether treatment chemicals (e.g., PAC, GAC, IX resins, etc.) will be available given the new demand created by this rule. The agency has stated that it "does not intend to provide a two-year extension nationwide." Louisville urges EPA to reconsider this position. In fact, we cannot imagine a more appropriate situation for EPA to employ its authority to grant a nationwide extension. The agency is promulgating a rule concurrent with the collection of occurrence data (UCMR5). As such, many utilities will only now have access to data that can inform them of their anticipated compliance status, thereby shortening the planning, design, and construction timeframe. While states may provide an extension on a case-by-case basis, there is no guarantee that the extension will be granted, especially given other social and political factors that may be considered by a state to not grant any extensions even when it is warranted and justified. The extension process with a state could be drawn out and if not the utilities favor, may be time wasted. EPA could provide relief to water systems by providing a nationwide extension and may ease the impacts to labor markets and supply chains. Otherwise, EPA should provide guidance to states regarding under what circumstances it is appropriate to provide a utility an extension.

Louisville Water respects that EPA has a difficult job to do with regard to PFAS, and we encourage the agency to remain engaged with utilities as it moves to finalize this and other regulations. Thank you for your consideration of these comments. If you have any questions, please contact Peter Goodmann at pgoodmann@louisvillewater.com or at (502) 569-0849.

Sincerely,

Peter T. Goodmann, Director

Water Quality and Research

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Thurston Public Utility District (PUD), WA (Doc. #1729, SBC-043582)

This is especially pertinent at a time when water utilities are still overcoming the compounding difficulties caused by workforce shortages, lingering supply chain issues, and inflation. Drinking water professionals balance public health and environmental concerns with doing what is best in the communities where we live and serve.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

U.S Conference of Mayors, National League of Cities and National Association of Counties (Doc. #1733, SBC-043898)

Additionally, many local governments and water systems are experiencing workforce shortages that will impact the timeline and cost to comply with this regulation. These challenges not only include trained water utility personnel, but also limited staff capacity at testing labs, in the transportation sector needed for shipping and handling equipment and lab tests, and at the state agency level for review and approval of monitoring and compliance data.

Due to the challenges outlined above, attempting to implement this regulation in such a constrained time frame would only exacerbate current issues relating to skyrocketing supply prices, labor shortages, laboratory capacity, and surging market demands. Although EPA's proposal includes providing extensions on a case-by-case basis granted either from states or by EPA, this is not a guarantee. We strongly urge the Agency to clearly and definitively extend the current proposed three-year timeline for all public water systems.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Michigan Section American Water Works Association (MI-AWWA) (Doc. #1734, SBC-044477)

In addition, the implementation timeline of 3 years set forth by EPA, would vary depending on the number of systems impacted, inter-related regulatory requirements, and current economic conditions. The time to implement and fund a project along with the lack of available, qualified construction companies in remote areas of northern Michigan has not been considered.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Arizona Corporation Commission (ACC) (Doc. #1735, SBC-045183)

Additionally, the ACC believes that the EPA should consider the following cost effects associated with the proposed rule:

• increased demand for remediation technology

• additional infrastructure needed to operate remediation technology within its design parameters

• the availability of qualified contractors for constructing and installing remediation facilities

• complying with the three-year compliance window.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Arizona Corporation Commission (ACC) (Doc. #1735, SBC-045185)

TIME TO COMPLY

The proposed compliance schedule raises concerns for the ACC. The EPA has stated the rule will be implemented by the end of 2023, giving utilities a three-year timeframe to achieve compliance. However, projects of this magnitude typically span multiple years, involving activities such as piloting, design, regulatory approval, procurement, permitting and construction. These processes can easily extend the timeline beyond three years. Construction alone can take in excess of 24 months based on feedback from a Class A utility. Furthermore, Arizona is currently experiencing substantial growth, and the ACC worries that this mandate, coupled with the demand for specialized treatment equipment to meet PFAS regulations and mandates from the lead and copper rule, will make it challenging to meet the 2026 compliance deadline. Considering the complexity involved, the ACC requests a significant extension of the compliance period for utilities that require capital improvements, or barring that, a waiver provision process to allow a longer window, especially for smaller utilities who do not have the capital in place to build and install treatment. This will allow sufficient time for careful planning of treatment processes.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Florida Section American Water Works Association - Water Utility Council (FSAWWA WUC) (Doc. #1737, SBC-044488)

• Funding, Design, and Construction Costs Timelines:

The Florida Water Sector recommends EPA work with our national water sector leaders, such as American Water Works Association, to determine a more appropriate timeline than three years. The FSAWWA estimates Florida's drinking water facilities produce 1.6 billion gallons of water a day with over 300 utilities being classified as medium (3,300 population served) size or higher . While the technology type can vary dependent on source water, it is expected a large number of Florida PWS who currently use traditional treatment methodologies (e.g., lime softening) will need to develop new PFAS specific treatment techniques to reach 4 ppt. The competition for funding, people and supplies will increase the numerous construction projects' timelines and costs. In addition, local governmental purchasing requirements can extend project timelines to assure legal and appropriate expenditures of public dollars. Finally, some large urban water suppliers believe land purchases will be required to construct new facilities.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-045977)

Section 7: Treatment Technologies

EPA has identified three readily available treatment technologies that are successful in removing PFAS from drinking water. These three treatment techniques, identified as the BATs, are granular activated carbon (GAC), anion exchange (AIX), or high-pressure membranes, such as reverse osmosis (RO) and nanofiltration (NF). AMWA agrees with EPA's assessment that the proposed MCLs are technologically feasible, but also would like to urge EPA to further explore the economic feasibility of these treatment techniques.

Because PWSs must individually weigh a number of factors before deciding which treatment technology to employ, it is essential that utilities have an adequate amount of time to comply

with the proposed NPDWR. PWSs have significant differences in the composition of their source waters, as well as different environmental factors, which can influence a system's water quality. For example, source water composition is different depending on climate, region of the country, and type of water source. Utilities must consider these factors when new treatment techniques are required. The decision on which treatment technologies to use require extensive time and research to make the best choice with minimal negative effects, highlighting the need for an extended compliance timeline.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10).

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-045973)

Section 5.6: Compliance timeline

EPA is proposing a three-year compliance time from the promulgation of the rule. A state or EPA may grant up to a two-year extension if it is determined that an individual system needs additional time for capital improvements, giving up to five years if the state or EPA grants the extension. Additionally, EPA or the primacy agency may grant an extension of three additional years beyond the five for systems meeting specific demands criteria explained in SDWA § 1416. Small systems have the option to apply for a series of three, two-year extensions beyond this total of eight provided to medium and large systems. This is the compliance schedule laid out in the SDWA.

AMWA cannot stress enough that the three-year compliance deadline will not be enough time for many water systems impacted by the proposal to complete capital improvement projects to address PFAS. AMWA members have indicated that a project of this magnitude would take a minimum of five years if this project was the only utility priority and there were no delays or issues that arise from the supply chain, labor, or permitting and procurement processes. Others have estimated 10+ years. While SDWA does allow for a two-year extension and potentially a three-year exemption, these are not guaranteed and are at the discretion of the primacy agency or EPA.

The process for a PWS to complete a project of this magnitude is long and tedious. While each water system is different, there are similarities in the process that most must follow, and some unique pieces that are worth consideration. AMWA members are publicly owned and must go through certain channels for approvals at each step of the process. There are deeper considerations that some must address when it comes to rate increases, permitting, and general budgeting for improvement projects. Many of these steps must be approved by boards, councils, and/or elected officials.

Some examples of PWS timelines for specific utilities are included in Attachments 2, 3, and 4. Typically, approvals need to be granted for a project this size, which can take months based on scheduling and other priorities within a municipality. Water systems will then need to design and conduct pilot studies to determine the best approach to treatment, assess impacts on other aspects of treatment, determine the specific needs of the water system, and determine the efficacy of the chosen treatment. Design and building of these pilots can take 18 months to three years. These pilots would also need to capture seasonal variability in source waters, so this process can take about 12 months.

Many utilities must go through local land use or zoning processes to obtain approval to construct any facilities. This process can take six to eighteen months, preceded by at least six months of preliminary engineering and development of other application materials including an alternatives analysis. The zoning process is separate from and a prerequisite to obtaining site plans and building permits, processes that can take another six to twelve months. In between zoning and site permitting, the detailed design and development of bid documents would occur, a process that can take twelve to eighteen months depending on the complexity of the selected treatment process.

Public utilities are also subject to public procurement regulations. These processes add additional time to the design and construction process. Development of a request for proposals for project design services, receipt and review of proposals, the consultant selection and negotiation process, and contract award typically take six months or more. The process for receiving bids for construction and awarding those contracts will take another three to six months. While some public utilities may be able to employ alternative procurement methods, not all are able to do so, and even alternative methods will only shorten timeframes associated with the design and construction phase.

Construction of the treatment alternatives noted in the rule (GAC, IX, RO) would be additional treatment trains. Construction phasing to maintain plant operations and ensure an adequate supply of drinking water to the public is critical. Tie-ins to existing infrastructure will be necessary and must occur during low-demand periods (often wintertime or other low-use time based on location) to ensure sufficient water production capacity to meet community needs. These construction staging intricacies will further lengthen the time to construct PFAS treatment improvements. Construction and commissioning timeframes will be project and site-specific but could in some cases take three years.

PWSs and other sectors across the country are currently experiencing increased pricing of goods and services, supply chain disruptions, and labor shortages. The proposed compliance period would be impossible for many utilities to meet without extensions. EPA needs to include considerations for how the increased demand for contractors, materials, equipment, and other labor will prolong projects and drastically increase prices, costs that eventually must be passed on to ratepayers and impact a utility's ability to provide affordable water to the public. Currently, even before this rule is finalized, some GAC suppliers have advised that the lead time for GAC

vessels for PFAS treatment is eighteen months. This is not a unique situation, and many utilities must prepare for the situation to worsen if this rule is finalized as is.

While AMWA supports the proposal's overall goal of protecting public health by delivering safe, clean, and affordable drinking water to the public, a compliance period of three years will simply be impossible for many PWSs to meet. There are several options EPA could pursue to alleviate burdens on public systems while still implementing feasible actions that will ultimately be more protective of public health from the chronic conditions attributed to PFAS exposure.

In the proposed rule preamble, the agency states "EPA does not intend to provide a two-year extension nationwide." AMWA urges EPA to reconsider this decision. While states may provide an extension on a case-by-case basis, there is no guarantee that the extension will be granted. Many other social and political factors may pressure a state's primacy agency to not grant any extensions even when it is warranted and justified. EPA could provide some relief to water systems by providing this blanket extension nationwide and could potentially ease the immediate impacts on labor markets and supply chains. Additionally, EPA could provide guidance to states on when is appropriate to provide a three-year exemption, particularly when a utility is acting diligently to implement treatment, but constraints out of its control have prevented completion in the five-year period.

EPA could also take a similar approach it did with the arsenic rule (see table below), where systems were eligible for an exemption based on contaminant concentrations [FN17: EPA. (2002, August). Implementation Guidance for the Arsenic Rule. https://www.epa.gov/sites/default/files/2015-09/documents/2005_11_10_arsenic_ars_final_app_g.pdf]. Water systems would still get five years for compliance but would be eligible for the three-year exemption based on the concentrations of PFAS in their system. A potential option would be using over or under 10.0 ppt, as EPA already explored the option of a 10.0 ppt MCL and approximates 1,300 systems would be impacted. These 1,300 systems would need to be in compliance in the 5 years, but those under 10.0 ppt would have a little more time to explore other options or to spread out the demand for materials and labor [Table 1: see docket ID EPA-HQ-OW-2022-0114-1738].

This would allow for systems with the highest concentrations of PFAS, and therefore the highest risk to public health, to address the issue first and have first access to all the materials and labor needed for treatment, like a "worst-first" approach. Water systems that are closer to the MCL would have a little longer to comply to alleviate strains in the supply chain and labor and would not provide an unreasonable risk.

Another benefit to this approach would be that water systems close to the proposed MCL would have time to consider less costly and invasive approaches to compliance. As stated earlier, AMWA believes source water protection should be EPA's highest priority when it comes to preventing contamination of drinking water supplies. If water systems that are close to the MCL have time to identify the sources of PFAS in their watersheds, they can try to address the issue there instead of spending millions on treatment that may not be necessary.

A feasible compliance timeline is paramount to the success of this rulemaking. Rampant noncompliance places an unnecessary burden on primacy agencies and EPA and undermines public trust in drinking water. The public would be better served by knowing the path to compliance is achievable than by being routinely notified that their drinking water fails to meet newly implemented standards. Repeated notices of noncompliance will only drive more people to drink bottled water, which, ironically, does not have to comply with the same PFAS monitoring and treatment standards. EPA and AMWA must work together to build and maintain trust in drinking water. Unfortunately, distrust of drinking water leads to individuals, including those in low-income and underserved communities, spending money needlessly on less-regulated bottled water.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline as well as discussion on exemptions under SDWA 1416 and a phased-in MCL approach.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-045996)

High sample costs and limitations only reinforce the need for a longer compliance period and a focused approach on water systems with the highest concentrations of PFAS. More time will give labs time to adjust to the increased demand and will keep costs down for those systems that need to implement treatment. AMWA suggests EPA refine the rule before promulgation to better account for the significant increase in demand for lab capacity and analysis.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. For additional discussion on laboratory capacity, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-046035)

Time Required to Implement PFAS Treatment

The proposed rule provides only three years for compliance from final rulemaking. While utilities can apply for a two-year extension from their primacy agency, extensions are not guaranteed. Fairfax Water, like many utilities, must go through several local government approval processes and permitting by our primacy agency before construction can proceed.

Fairfax Water, like most public utilities, must also comply with public procurement laws that add time to the process to secure design and construction services. PFAS treatment will be a new train to an existing treatment plant. Properly sequenced construction that maintains plant operations and ensures an adequate supply of drinking water to the public will be critical and take longer than a "greenfield" construction project. Realistically, 7 to 10 years is required to implement PFAS treatment.

[Table: see docket ID EPA-HQ-OW-2022-0114-1738]

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-046036)

Schedule

Delivering water treatment-related infrastructure projects requires extensive testing and design to ensure the full spectrum of variations in source waters and treatment processes are fully considered and tested prior to bidding and construction. For many utilities in the South, this includes the variation of dissolved organic carbon (DOC) and a possible mix of potentially hundreds of PFAS compounds. Equipment installation must be staggered and scheduled during low demand seasons to reduce overall risks and maintain continuity of operations of water treatment plants.

Another challenge to delivery of treatment-related projects includes coordination with Virginia Department of Health (VDH) who are considered project partners during the testing, design, permitting, and construction phases. Delays during the review and approval process are normal, and with multiple water (and wastewater) utilities undergoing PFAS projects simultaneously, delays in VDH review and approval could be substantial.

The chart below provides a general estimate for a medium-sized municipal water utility with 2 treatment facilities, limited staff, and a fully engaged primacy agency (VDH). Testing, design, bidding, construction, start up, and permitted operations of the new facilities will take at least 4 years and likely closer to 5 years from the establishment of the final MCLs.

[Figure: see docket ID EPA-HQ-OW-2022-0114-1738]

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments*

document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Association of Metropolitan Water Agencies (AMWA) (Doc. #1738, SBC-045957)

The greatest health risks from PFAS in drinking water will come from systems with the highest concentrations, not those at the margins of compliance with EPA's proposal. EPA should work to address these systems first to protect individuals in those service areas. EPA's proposal estimates approximately 4,300 PWSs will be impacted by this rule [FN7: EPA Economic Analysis, (USEPA, 2023j)]. AMWA emphasizes that the upcoming implementation of UCMR 5 will provide more accurate estimations of the impacted systems' PFAS levels. Any system with levels above the proposed MCLs must promptly initiate planning and execute interventions to address PFAS contamination once this rule is finalized. It is important to anticipate that this substantial demand will exert significant pressure on supply chains and the labor market. Meanwhile, EPA estimates around 3,300 PWSs would be impacted if MCLs were implemented at 5.0 ppt and about 1,300 PWSs with MCLs set to 10.0 ppt. These 1,300 PWSs with PFOA and/or PFOS above 10.0 ppt should be prioritized, as greater demands in GAC, materials, and labor could prevent these systems from quickly remediating the issue, potentially exposing the public in these service areas to higher concentrations of PFAS for a longer period.

If EPA chooses to rush through finalizing this rulemaking before the September 2024 statutory deadline, it would be advantageous to finalize an MCL that is both feasible for PWSs to achieve and meaningfully protects public health. EPA should initially require PWSs with high levels of PFAS – those greater than 10 ppt – to implement actions to reduce PFAS exposure at these PWSs first. Then, EPA can use UCMR 5 and other up-to-date research to further explore lowering that threshold. The agency would still be protecting public health and would simultaneously be alleviating the strains, demands, and increased costs for labor, materials, and construction. This would also allow PWSs with lower concentrations to explore other, less costly, measures to reduce exposures to PFAS, yielding both fiscal and health-related advantages for the public.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline as well as a phase-in of the MCL. The EPA does not believe that issuing a final rule prior to September 2024 is "rushing through" but simply reflects the priority EPA is providing to this important health-protective regulation.

Liberty (Doc. #1747, SBC-043624)

Given the limited availability of laboratory resources, Liberty respectfully recommends that the EPA consider a five-year compliance period to allow utilities to stagger initial monitoring activities, which would allow laboratories to better manage incoming samples. Alternately, the EPA could impose staggered initial monitoring requirements across states, considering demonstrated need for those with significant disadvantaged communities, or those with communities whose water sources are seriously impacted by these contaminants. Both options also permit a greater number of laboratories to meet certification requirements over time, further enabling a successful initial monitoring effort.

Second, should a utility determine through initial monitoring (or other acceptable means as provided by the proposed regulation) that they must install treatment, the time allowed for meeting compliance is not adequate. The development of plans and specifications, permit approvals, construction, and start-up of any treatment facility takes significant time under the best of circumstances. Current supply chain limitations negatively impact even the most basic, and sometimes critical, materials needed to manage and maintain water and wastewater infrastructure. Meters that used to arrive in a week are now back-ordered six months to a year. Brass components require up to an eight-month lead time, and ductile iron piping can take three to 12 months to arrive.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Liberty (Doc. #1747, SBC-043626)

Liberty respectfully recommends the EPA consider a five-year compliance period to allow utilities to accommodate the regulatory requirements without risk of non-compliance due to time and materials elements outside of their control.

Thank you for the opportunity to provide our perspective and recommendations on this important rule proposal.

Sincerely,

Stacey Roberts

Sr. Manager, Water Quality

Liberty

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

City of Thornton, Colorado (Doc. #1748, SBC-044798)

Thornton believes that the NPDWR implementation timeframe of three years with waiver opportunities of up to two years is vastly insufficient for the study/piloting, design, construction, and commissioning of new treatment processes given supply chain constraints, lab capacity, and demand for engineering and construction services. While Thornton already has a decent understanding of PFAS loading in its source waters and has already begun preliminary engineering designs, the City is still concerned about being able to meet the regulatory compliance deadline for the rule due to the aforementioned factors. Thornton is also concerned about smaller utilities' ability to meet those deadlines considering they may not yet have sampled for PFAS or know whether they need treatment. These systems likely do not have the resources and finances for rapidly meeting the proposed rule. Thornton suggests extending the compliance timeline to four years with an additional two-year waiver period for utilities that are actively constructing treatment processes but struggling with supply chain or funding issues. As mentioned above, simplification of EPA funding is also needed as the requirements for receiving those funds could considerably slow utilities' treatment process implementation. Likewise, implementing a PFAS NPDWR prior to implementation of strict limits on PFAS discharges by polluters will challenge utilities' ability to meet the proposed rule. By providing additional timeframe for implementation of the rule while simultaneously prioritizing discharge limits, EPA will provide the best protection of public health.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Harris County Attorney's Office (HCA) (Doc. #1751, SBC-045265)

HCA raises several concerns regarding the feasibility of implementation and compliance, especially for small and rural water systems.

HCA is concerned that small and rural public water systems in Harris County will struggle to meet a three-year timeline to research, raise funds, purchase, install, and operate new PFAS removal technology. EPA is currently promoting expansion of the number of laboratories that

can process PFAS samples by soliciting proposals and awarding contracts to laboratories across the nation in order to expand the capacity for monitoring. However, HCA is concerned that EPA is soliciting contracts to expand laboratory capacity while the proposed rule simultaneously calls on currently un-regulated PWS to implement monitoring data for PFAS. HCA is concerned that even with expanded laboratory capacity the additional monitoring requirements will drive increased costs resulting in very expensive PFAS montioring, resuling in exorbitant waster bills for consumers.

HCA recommends robust guidelines regarding exemptions

HCA supports EPA's proposed rule requiring stringent standards for the processes and laboratories that will be considered for an exemption. More specifically, HCA supports EPA's proposed use of vulnerability assessments to determine if a small public water system is low risk and warrants a monitoring waiver. However, EPA's standards should be meticulously applied to provide community confidence in the monitoring data and ensure the exemptions are not used as a tool to circumvent investment in new PFAS removal technologies.

HCA asks that a notice and comment period is required for SDWA § 1416(b)(2)(C), which allows certain small systems to receive additional exemptions, and for State exemptions to ensure communities are aware of an exemption request and can participate in decisions regarding their PFAS exposure. HCA is concerned exemptions given too leniently or without community input could create a disparity between rural and urban PFAS exposure. HCA believes that community members should be informed of the potential approval for a small facility exemption, and they should be provided the opportunity to comment on such an exemption.

***

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on the strict criteria and process requirements for exemptions under SDWA 1416 as well as supply chain and labor challenges that may affect the compliance timeline.

Las Cruces Utilities (LCU) (Doc. #1753, SBC-043904)

In the case that no extension is granted, LCU is providing the following comments:

• In response to EPA's projected implementation timeline for the proposed regulations, LCU is planning further investigation beyond past and recent Unregulated Contaminant Monitoring Rule (UCMR) studies to assess the extent of potential groundwater contamination for the constituents of concern in our cities drinking water system. Given the lack of comprehensive data, there is uncertainty regarding the extent of increases in capital and annual operating costs associated with

achieving compliance. It is also difficult to assess our timeline to obtain compliance if conditions warrant.

EPA's goals of finalizing the rule by the end of 2023 and implementing three years to obtain compliance will be difficult to accomplish given the time required to attain funding, plan/ design, procure contracts, construct, hire and train specialized staff, etc. LCU has continued to experience ongoing delays in project completion in water and wastewater projects due to supply chain delays and logistical issues that will be further exacerbated. Any potential projects for treatment alone can take multiple years just to plan and coordinate. LCU requests EPA to extend the proposed compliance timeframe substantially beyond three years for water providers to attain compliance.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Los Angeles County Sanitation Districts (Doc. #1756, SBC-044516)

Feasibility of Implementation. EPA has proposed a three-year compliance time for water systems to address the presence of PFAS in their water supply above the proposed MCLs; however, this timeline is unrealistic and infeasible for compliance. The proposed NPDWR rulemaking indicates that EPA does not plan to issue a waiver for a two-year extension for systems that need to install PFAS treatment technologies, including facilities that supply recycled water and are required to meet MCLs. Most water systems and recycled water suppliers that need to install treatment facilities will need a minimum of five years to complete projects. The process for completing such projects is complex and time-consuming, involving various approvals, California Environmental Quality Act (CEQA) compliance, pilot studies, local land use or zoning processes, design and development, procurement, financing, and construction. These steps require coordination with multiple entities, including boards, other jurisdictions (such as cities or counties), and the public. Additionally, utilities are currently facing many challenges, such as inflation-driven increased costs, supply chain disruptions, and labor shortages, which further extend project timelines and may increase costs. Additionally, requiring utilities all across the nation to comply at the same time will cause not only a shortage of laboratory capacity for the required monitoring, but also is likely to create equipment and contractor shortages since the types of technologies used to remove PFAS are limited and very specialized. For those agencies able to apply for and receive funding under the State Revolving Fund loan programs or from the Bipartisan Infrastructure Law's Contaminants of Emerging Concern/PFAS funding program, Buy America/Build America (BABA) requirements will apply, and the ability to procure specialized technologies domestically (or obtain the necessary waivers) within a three-year timeframe is extremely questionable. For these reasons, many of the utilities that must install

treatment facilities to address PFAS will not be able to reasonably meet a three-year compliance timeline. We recommend that EPA use its authority to provide a nationwide extension for a minimum of two years for systems installing capital improvements, although an extension of up to three to five years would be preferable.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. Please also see the EPA response to comment Doc. #1676, SBC-043778 in section 12.1 in this *Response to Comments* document for the agency's response on concerns regarding BABA.

El Paso Water (Doc. #1757, SBC-044526)

Should the EPA adopt a lower MCL, the agency should allow adequate time for a PWS to be able to plan, design and construct the necessary new treatment facilities to treat PFAS contamination.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Arizona Water Company (Doc. #1758, SBC-044535)

PFAS Removal Technology and Hazardous Waste

Construction timelines for PFAS treatment facilities are unrealistic. The Company has extensive experience designing, permitting, and constructing arsenic removal facilities. In the Company's experience, the design, permitting, and construction timelines for such facilities often extends several years beyond estimated completion deadlines. This is due to a variety of factors, but especially lead times and delays to acquire required materials, such as raw metal, fabricated vessels, concrete, and treatment media. Labor shortages are already a cause of many construction delays. Under the proposed PFAS MCL, water utilities all around the country will be required to build PFAS removal facilities for these chemicals at once. Under these circumstances, the Company anticipates that material and labor delays will be severely exacerbated. The Company recommends the EPA provide an additional three years for compliance with the PFAS MCL. Such considerations were taken into account when the EPA implemented its current arsenic MCL and utilities faced similar challenges.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline as well as the availability of additional time under Section 1416 of SDWA.

American Water Works Association (AWWA) (Doc. #1759, SBC-045571)

Simultaneous Compliance will Slow Down Implementation

The installation of new water treatment facilities requires sufficient planning to ensure that bringing a plant into compliance with a new rule does not cause non-compliance with existing regulations. For most water systems in the U.S., the installation of PFAS treatment facilities will create challenges for simultaneous compliance with existing drinking water rules. Each of the best available technologies for PFAS will have impacts on the finished drinking water and may require post-treatment to avoid negative impacts. For example, the use of reverse osmosis (RO) and anion exchange (IX) treatment can increase the corrosivity of water impacting the potential for lead release into drinking water at homes. Granular activated carbon (GAC) has been known to contribute to distribution system nitrification. These impacts can be mitigated, but mitigation requires adequate evaluation.

One such example where simultaneous compliance concerns will delay the implementation of new drinking water treatment is the requirements Lead and Copper Rule Revisions (LCRR) (EPA, 2021d). When systems determine that mitigation is needed to comply with any new PFAS standards – either through new treatment or a change in the water supply source – they will need to comply with the LCRR requirements, which could include a lengthy process of analysis and subsequent studies to obtain approval from their primacy agency. The LCRR corrosion control studies and subsequent actions could take years to achieve. When complying with the LCRR leads to significant changes in corrosion control treatment (CCT) after the rule's administrative procedures are following, a system must have time to: (i) prepare the distribution system and customers for the transition, (ii) shift corrosion control practice at a pace that does not lead to water quality concerns, and (iii) simultaneously install the required PFAS treatment or water supply option. This will have a significant impact on the system's ability to install PFAS treatment within three to five years of any final PFAS rule and impact the cost of implementing new treatment for PFAS.

Most Systems will Need to Perform Pilot Testing

Finally, another important step in installing PFAS treatment facilities is pilot testing. While GAC, IX, and RO have been documented as being capable of removing PFAS effectively, they still require a sufficient level of pilot testing. Pilot testing typically takes at least six to nine months to complete, and costs vary but include the rental cost of equipment, engineering and

other technical support, and appropriate monitoring and sample analysis costs. Bench scale testing can also be useful and is less costly for some systems.

The are a number of important goals associated with pilot and bench-scale testing are 3-fold: (i) demonstration of PFAS removal efficacy, (ii) characterizing pre- and post-treatment needs, and (iii) optimal treatment technology selection, (iv) confirmation of design and operational parameters, and (v) estimation of capital, operations and lifecycle costs (AWWA, 2020a). It is anticipated that most of the water systems that must install treatment to meet PFAS MCLs will need to perform pilot testing, especially given the perming requirements to comply with the LCRR, as discussed above. While pilot testing may not seem appropriate for smaller systems, it is similarly vital for these systems to ensure that the expense of capital for a new long-term treatment facility is both cost-effective and appropriately designed to protect public health from secondary water quality changes. The potential cost to small systems if new treatment facilities fail to operate as intended can be severe, given the cost of identifying and implementing solutions cannot be distributed across a large number of households, particularly after water rates are already rising to take on debt of the initial PFAS rule compliance solution.

Implementation will Further Strain the Supply Chain

When considering the costs and feasibility of the timeline and proposed rule, EPA must also take into account current supply chain issues. Water systems have been faced with a strained supply chain, which were worsened following the start of the COVID-19 Pandemic. This strain has led to increased purchasing costs, longer lead times for equipment or materials, and limitations on the products that are available. Lead times for key equipment (e.g., vessels, carbon or resin media, electrical components, etc.) have already increased to beyond twelve months, depending on the equipment and the degree of specialization it requires. Vessels, GAC media, and IX resin are not widely available from more than a few suppliers. Lead times for replacement GAC media are currently six months or more and for new customers the lead time is in the range of twelve to eighteen months. The lead time for GAC media will increase as a surge of new systems begin ordering GAC and suppliers will need to acquire media internationally (e.g., China and India) as the domestic market becomes more strained. China and India) as the domestic market becomes more strained. Manufacturing of IX resin is currently not domestic given the safety concerns regarding the chemicals used in its production as demand for IX resin increases the supply chain is anticipated to strain as well. These issues are also impacting major ancillary equipment like electrical panels, motor control centers, etc.

Workforce Limitations will be Worsened

The water sector is currently working to overcome workforce challenges, which EPA must also recognize when considering the feasibility of the timeline and proposed approach. EPA estimates that one-third of the sector's workforce is eligible to retire within the next 10 years and water systems are facing challenges in recruiting, training, and retaining employees (EPA, 2023a).

These challenges are expected to be more severe as more than 4,300 water systems are driven to advanced technologies that require more specialized technical skills. To install and operate these

facilities, water systems will need to hire or contract engineers, manufacturers and suppliers, construction crews, and skilled operators. These service providers are already in high demand and in short supply. The resulting imbalance is impacting labor and material costs, lead times for materials, turnaround times for services (e.g., engineering, laboratory analysis, construction). The installation of new treatment facilities will surge following rule's promulgation, which will further worsen workforce challenges for water systems.

The demand for highly skilled water treatment operators will increase due to this rule. Systems currently not using filtration for water treatment may need to meet additional operator certification requirements. Systems currently not using filtration for water treatment may need to meet additional operator certification requirements. While each state independently sets certification requirements for water treatment plant operators, it is anticipated that systems requiring to install GAC, IX, or RO will need to staff operators with more advanced certification. Water systems in the states of Virginia [FN4: 18 Virginia Administrative Code 160-30-370 – Waterworks.], California [FN5: California Code Regs. Tit. 22, § 64412.1. - Classification of Water Treatment Facilities.], Colorado [FN6: 5 Code of Colorado Regulations 1003-2 Regulation 100 - Water And Wastewater Facility Operators Certification Requirements: Sections 100.4 to 100.9.], and Massachusetts [FN7: 310 Massachusetts Register 22.11B.], for example, will all see impacts to operator certification requirements as a result of new treatment systems for PFAS. This change will have a significant impact on systems with a limited local labor pool or limited financial capacity to attract skilled operators that will be needed to safely operate these advanced treatment systems. As EPA recognizes, systems must have staffing with appropriate qualifications to operate 24 hours a day, 365 days a year. Many systems will struggle to find qualified operators for adequate staffing.

State Primacy Agency Capacity

Because the typical timeline for the planning, design, perming, and construction of a new drinking water treatment facility for PFAS may take up to and exceed 5 years, the standard compliance window of three years under SDWA will not be feasible. This is especially important given that these implementation challenges will drive the timeline up as systems begin competing for the same limited supply of sector resources. Under SDWA, water systems may request a two-year extension for compliance with MCLs if it is determined that additional time is necessary for capital improvements.

It is anticipated that the vast majority of water systems that need to install treatment for PFAS will need to request this two-year extension, which is typically provided at the discretion of the state primacy agencies. State primacy agencies are currently working to review lead service line inventories, preparing to implement the corrosion control treatment requirements of the LCRR, administering the DWSRF and additional projects accessing funds from the Bipartisan Infrastructure Law, and working to ensure and improve water system compliance with existing rules. State primacy agencies are currently working to review lead service line inventories, preparing to implement the corrosion control treatment requirements of the LCRR, administering the DWSRF and additional projects accessing funds from the Bipartisan Infrastructure Law, and

working to ensure and improve water system compliance with existing rules. As the surge in water system requests for a two year extension begins, these agencies will be strained as they work to review and process these requests.

However, the Administrator also has the authority under SDWA to provide this extension and can do so as a part of the rule as opposed to being done so on a case-by-case basis. In order to prevent issuing a final rule that is infeasible due to the implementation timeline or otherwise violates the APA as arbitrary and capricious, AWWA recommends that the Administrator leverage this authority to increase the likelihood that all water systems can comply with the timeline of the rule and take adequate, effective steps towards mitigating PFAS levels in drinking water.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges, as well as simultaneous compliance challenges, that may affect the compliance timeline. Regarding concerns on operator certification licenses, please see the EPA response to comment Doc. #1567, SBC-042738 in section 12.1 in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-045562)

2. The standard implementation timeline is not appropriate for the current economic conditions. The process to monitor, plan, design, pilot, permit, and construct facilities will take much longer than the standard 3-year timeline given workforce and supply chain challenges. While states may be able to grant 2-year extensions, on a case-by-case basis the burden for state primacy agencies to process these requests will be significant. To avoid a final rule that is infeasible for water systems to comply with, the Administrator should exercise its authority under the SDWA to extend the effective date of compliance by two years for water systems installing capital improvements [FN1: Under 42 U.S.C. 300g–1(b)(10), the Administrator "may allow up to 2 additional years to comply with a maximum contaminant level if…additional time is necessary for capital improvements" (104th Congress, 1996).].

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

American Water Works Association (AWWA) (Doc. #1759, SBC-045568)

3. Implementation Challenges

Public water systems subject to the proposal will need to comply within three years unless a two-year extension is provided by state primacy agencies or the Administrator. An estimated 67,000 water systems will need to perform initial monitoring at nearly 90,000 entry points used by water systems. Additionally, upwards of 4,300 water systems will need to take action to address PFAS levels above the maximum contaminant levels (MCLs) and continue to conduct quarterly sampling, according to the EPA's analysis. For water systems that need to install advanced treatment facilities for PFAS, a myriad of challenges will delay the implementation timeline for each system and will impact costs to implement these facilities.

Simply put, the current implementation timeline will cause the final rule to be infeasible, and therefore conflicts with the SDWA. When EPA establishes an MCL, the combination of technology, treatment techniques, or other means required to meet the level must not be more stringent than feasible [FN2: 42 U.S.C. 300g-1(b)(B)(5)(B)(ii).]. The SDWA defines "feasible" to mean "feasible with the use of the best technology, treatment techniques and other means which . . . are available (taking cost into consideration)." [FN 3: 42 U.S.C. 300g-1(b)(B)(4)(D).] The tight timeline for implementation here would render the "the combination of technology, treatment techniques, or other means" infeasible because of the additional costs and implementation considerations.

As required by the SDWA, AWWA encourages EPA to consider how these implementation challenges will impact not only the compliance cost of the rule, but the feasibility of the rule to be implemented on the standard timeline provided by the SDWA. These challenges are further detailed below.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. For additional discussion on how the agency considers analytic feasibility when establishing the MCL, please see section 5.1.2 of the EPA response in this *Response to Comments* document.

American Water Works Association (AWWA) (Doc. #1759, SBC-045637)

14. Summary of Key Recommendations

Advancing public health is a shared goal between drinking water systems and EPA and AWWA has evaluated the rule to support EPA's actions moving forward meaningfully and legally, using sound science. AWWA appreciates the agency's interest in preparing a thoughtful, thoroughly crafted proposal to establish NPWDRs for PFOA, PFOS, and additional PFAS.

As previously discussed, the regulation of PFAS in drinking water as proposed will create numerous implementation challenges. Although EPA is interested in an expeditious rulemaking

to reduce PFAS exposure, it is nonetheless important that EPA finalize a rule that is based on sound science, recognizes the importance of drinking water affordability, and be feasible to implement.

While EPA has a stated interest in advancing immediate protection of communities from PFAS exposure, water systems still need to perform the necessary work to implement any rule requirements – regardless of the timeline. Three years is insufficient time for water systems to comply with EPA's proposed rule option. The Administrator should provide a 2-year extension as part of the final rule per authority provided by SDWA, instead of relying on already overextended state primacy agencies.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

California State Water Resources Control Board (Doc. #1760, SBC-044225)

[The State Water Board offers the following specific comments and recommendations for consideration regarding implementation of the rule:]

Suggests that EPA allow flexibility in the compliance deadlines to ensure feasibility, similar to the flexibility offered as a part of the final arsenic regulation, allowing extended compliance deadlines depending on the system size and initial concentration. California's monitoring data so far, while only done at wells near sites expected to be contaminated, shows a large number of water systems will ultimately have to seek treatment. California is also preparing to sample a large number of small disadvantaged public water systems and expects to find many of these contaminated with PFAS. Because PFAS has been shown to be so widely spread throughout the country, implementation of the PFAS rule will undoubtedly cause a large demand for treatment equipment. The State Water Board is presently proposing a similar approach for its hexavalent chromium MCL and cites another advantage in that small systems can benefit from reduced costs as treatment equipment matures with larger systems making the initial investments.

Thank you for the opportunity to comment on this rule making. We believe our comments above derived from our experience implementing PFAS monitoring and treatment will improve implementation of the rule, making it more effective and thus better protect the public.

Sincerely,

Darrin Polhemus, P.E.

Deputy Director, Division of Drinking Water

State Water Resources Control Board

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline as well as exemptions under Section 1416 of SDWA.

Riverside Public Utilities, Riverside, CA (Doc. #1762, SBC-044228)

[The following comments are submitted for consideration in the proposed EPA rulemaking:]

EPA should extend the compliance deadline to at least five years:

City staff believes that the three-year compliance timeline is not adequate to meet the associated requirements for additional PFAS monitoring and installation of treatment. Below is a timeline City staff has developed of the many steps necessary to design and install the PFAS treatment infrastructure which it anticipates will be required under the new regulations. Also, we would like the EPA to consider that this rulemaking will increase the nationwide demand for resources required to install treatment facilities, which will impact the availability of consultants, design firms, construction companies, and material (i.e. vessels), creating further challenges for agencies to meet the proposed deadlines.

PFAS Project Planning, Design and Construction anticipated Schedule

[Table 1: See Docket ID EPA-HQ-OW-2022-0114-1762]

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Connecticut Section of the AWWA (CTAWWA) and Connecticut Water Works Association (CWWA) (Doc. #1763, SBC-044232)

Timeline for PFAS Rule Implementation

The proposed PFAS Rule does not adequately account for the implementation time required for utilities to expediently work towards compliance. Utilities with concentrations of PFAS in their source water above the proposed maximum contaminant levels (MCLs) must consider treatment or alternative sources. Given the experience of our utility members who have or are currently pursuing a treatment alternative, it is evident that the project design, permitting, bidding, funding, and execution phases are lengthy and will exceed the proposed three-year

implementation timeline. Compounding this issue are the current and expected supply chain delays for materials including pressure vessels.

We encourage EPA to adopt a staggered compliance timeline based on multiple tiers of PFAS concentration, with the compliance deadline occurring first for systems that have the highest PFAS concentrations. The remaining systems would have compliance deadlines in subsequent years based on their respective PFAS concentrations. This approach would create an aggressive timeline for the systems with the highest PFAS concentrations while providing many benefits – a more reasonable timeframe for assessment, design, permitting and construction; relief in the supply chain; and additional time for new technology to be brought to market.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline as well as discussion on a phased-in MCL approach.

Connecticut Section of the AWWA (CTAWWA) and Connecticut Water Works Association (CWWA) (Doc. #1763, SBC-044234)

Federal funding sources are available to assist with PFAS mitigation for the next several years. These funds are critical in enabling utilities to limit the impact to ratepayers and preserving the affordability of drinking water. Therefore, we recommend extending the implementation time to ensure that funding sources can be fully utilized by utilities prior to the compliance deadline. This extension will also preserve public trust by ensuring that diligent utilities have sufficient time to execute a PFAS mitigation strategy prior to the compliance date. Supply chain pressure for PFAS treatment equipment and materials, in addition to workforce pressures, will also be reduced through this extension.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. For funding concerns, the agency notes that funds are also available through the passage of the BIL to assist many disadvantaged communities, small systems, and others with the costs of installation of treatment when it might otherwise be cost-challenging. Please see section 2.4 of the EPA response in this *Response to Comments* document for more discussion about currently available funding.

New Mexico Environment Department (NMED) (Doc. #1766, SBC-044252)

Small Systems

Approximately 80% of public water systems in New Mexico are small, serving populations of under 1,000 people and often operate with volunteer boards, administrators, and in some cases, operators. Small system compliance with the proposed PFAS MCL, regardless of the final value of the MCLs, will be challenging. Most small groundwater systems currently have minimal treatment installed. For those systems with no alternative source water, installation of one of the best available technologies may present a variety of challenges if the current treatment only consists of a chemical feed and a pressure tank. The entire water sector is facing workforce shortages, especially for certified operators, and this issue is particularly prevalent at small and disadvantaged water systems. The challenges around hiring and retaining operators will continue to be exacerbated as systems install treatment to comply with the PFAS MCL.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. For funding concerns, the agency notes that funds are also available through the passage of the BIL to assist many disadvantaged communities, small systems, and others with the costs of installation of treatment when it might otherwise be cost-challenging. Please see section 2.4 of the EPA response in this *Response to Comments* document for more discussion about currently available funding. Regarding concerns on operator certification licenses, please see the EPA response to comment Doc. #1567, SBC-042738 in section 12.1 in this *Response to Comments* document.

Bowling Green Municipal Utilities (Doc. #1767, SBC-043929)

• Impractical Implementation Timeline: EPA has provided an implementation timeline of 3 years for water systems to conduct initial monitoring and take subsequent mitigation actions if PFAS levels exceed the MCL. The default SDWA implementation timeline is not practical given the number of systems impacted, inter-related regulatory requirements, and current economic conditions. As proposed, within 3 years a system must:

o Conduct at least one year of monitoring to characterize occurrence at all of their points of entry to the distribution system at a time when laboratory capacity is already strained,

o Select and design a compliance strategy,

o Obtain primacy agency approval from state programs already facing limited capacity to meet current demands,

o Address primacy agency requirements triggered under other rules (e.g., Lead and Copper Rule) -- requirements that themselves will require testing and potentially a year or more of pilot testing, and

o Construct necessary improvements in the midst of well-recognized supply chain delays and workforce shortages.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Western Urban Water Coalition (WUWC) (Doc. #1768, SBC-043952)

Allowing public water systems to forego one initial sampling round also will not ensure that water utilities have sufficient time to ensure compliance within the proposed three-year rollout. Our members report that treatment plant upgrades typically take longer than three years from planning to completion, partly because of water utilities' capital planning obligations to their ratepayers. WUWC members anticipate needing to gather baseline data, conduct alternatives analysis, complete preliminary and final designs, obtain permits and complete environmental review where necessary, obtain budget approvals, and complete procurement processes before constructing and commencing operation of upgraded treatment plants capable of treating PFAS to proposed national drinking water standards. The three-year rollout also does not account for the potential cumulative effect of EPA's PFAS Strategic Action Plan and concurrent Advance Notice of Proposed Rulemaking, which envision future regulation of additional PFAS, their precursors, or groups of PFAS. The short timeline could force water utilities to invest large amounts of capital to quickly install treatment technologies to meet the standards in the Proposed Rule, only to find that additional treatment systems are required to remove additional types or precursors of PFAS. Accordingly, while allowing utilities to leverage existing data is helpful in the short-term, a longer implementation timeframe would be appropriate.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Council of State and Territorial Epidemiologists (CSTE) (Doc. #1770, SBC-044263)

5. Workforce Development and Training Needs: The new MCLs will result in the need for more public health staff especially in the areas of environmental health assessments and applied public health epidemiologists, as well as training for existing staff. An expanded applied public health epidemiologists and toxicologist workforce is needed to support biomonitoring studies, data collection, and sampling analysis. Some public health agencies do not have a state toxicologist at

the health department or are adequately training to support environmental health assessments which often take months or even years to complete due to the complexities. Furthermore, the existing public health workforce will require additional training and upskilling to fully respond, interpret and consult on the changes. Water operators will also need additional training on calculating compliance.

CSTE thanks the Environmental Protection Agency for its work towards promoting public health and delivering safe drinking water to communities across the United States. CSTE urges the EPA to consider the above resource needs and considerations to support epidemiologic needs within Public Health Agencies across the United States to support implementation of the regulation.

Sincerely,

Janet Hamilton, MPH

Executive Director

Council of State and Territorial Epidemiologists

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. In regard to commenter's statement that the final NPDWR will require "environmental health assessments" and other specialized roles (such as toxicologists and epidemiologists), the agency notes that the purpose of the NPDWR is to provide a national standard and regulation for six PFAS commonly found in drinking water based on the best available science. While public health epidemiologists and toxicologists serve important roles in protecting public health and the environment, these capacities do not play a direct role toward implementing the final rule (such as operating and maintaining treatment operators or monitoring for compliance). Regarding concerns on operator certification licenses, please see the EPA response to comment Doc. #1567, SBC-042738 in section 12.1 in this *Response to Comments* document.

Southwest Regional Water District (Doc. #1772, SBC-044727)

The District is very concerned with the compliance timeline that has been proposed for this regulatory rule. With the number of PWSs that could potentially be needing to make treatment changes, these projects will likely go to bid at similar times causing delays in construction and supply shortages. We request that flexibility is built into the compliance schedule and the USEPA work closely with those PWSs that are in violation of the MCLs.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to

SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Environmental Protection Network (EPN) (Doc. #1773, SBC-043876)

Compliance Requirements

EPA proposes allowing states to provide extended compliance dates to PWS needing additional time for capital improvements. For small systems serving at or below 3,300 people, the extension can be 14 years after this rule is promulgated. Fourteen years is unjustifiably too long given the availability of effective treatment technologies. EPA asks for public comment on whether there should be specific conditions mandated for PWS to be eligible for these extensions so that they are used only when no other viable alternatives exist. EPN agrees that there should be specific conditions mandated for PWS to be eligible for these extensions and recommends that state consideration of extending compliance dates for PWS with violations be a negotiated compliance agreement under a formal enforcement response to the violation. The specific conditions for extended compliance dates for a PWS should be set as a condition of state primacy for the new regulation. PWS in violation should continue to be reported in violation until they return to compliance under the negotiated compliance agreement.

EPA Response: The agency agrees with the commenter on the health concerns posed by PFAS and that establishing a national PFAS NPDWR as expeditiously as possible needed to protect public health and the environment. While individual state primacy agencies could require action sooner, the agency cannot do so for all PWSs regulated through this NPDWR. SDWA § 1412(b)(10) requires that a "NPDWR shall take effect "3 years after the date on which the regulation is promulgated unless the administrator determines that an earlier date is practicable." For all of the reasons provided in section 12.1 of the EPA response in this *Response to Comments* document, the EPA has determined that it is not practicable to require treatment earlier than 3 years after the date this regulation has been promulgated. Additionally, section 1412(b)(2) also authorizes "the Administrator, or a State (in the case of an individual system), may allow up 2 additional years to comply with a maximum contaminant level…if the Administrator or the State…determines that additional time is necessary for capital improvements. The agency has determined two additional years are necessary for capital improvements, and therefore, the agency is authorizing a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Whether to provide for additional extensions beyond the 5 years provided by this rule is at the discretion of the primacy agency; the strict criteria and process requirements for exemptions are discussed in section 12.1 of the EPA response in this *Response to Comments* document and are found in SDWA Section 1416. Due to the stringency of the existing criteria, EPA has not provided any further criteria as part of this rule but primacy agencies may adopt more stringent criteria than provided in Section 1416.

California-Nevada Section American Water Works Association (CA-NV AWWA) (Doc. #1775, SBC-045280)

9. EPA should extend the timeline for compliance to a more realistic period that will be achievable, at a minimum of six years, with options to extend the compliance deadline as warranted.

The proposed regulation will be difficult for water systems to achieve for several reasons, including planning for treatment systems capable of meeting the MCLs, capital project financing and construction, and in some cases, hiring or training operations staff. However, the proposed regulation would require all systems to comply within three years after final approval and promulgation.

Systems that encounter unavoidable obstacles or need extra time to comply with the MCLs should have options for compliance, particularly if the systems serve disadvantaged communities or are small systems with limited resources. Circumstances that may justify compliance extensions include unforeseen barriers for systems to develop alternative water sources, secure financing, complete design and construction of treatment facilities, or other factors.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline, as well as the criteria and process for further extensions allowed under SDWA Section 1416.

Eastern Municipal Water District (EMWD) (Doc. #1780, SBC-043824)

Lastly, EMWD would like to respectfully request EPA to extend the compliance deadline to five years from finalization of this regulation as contemplated in the Safe Drinking Water Act, instead of three years as proposed. Water agencies like EMWD will need to make a number of necessary infrastructure upgrades, which are time consuming and expensive. Water utilities are currently struggling to overcome the pressure of inflation, supply chain disruptions, and labor shortages, all of which further delay project delivery timelines and increase costs. EPA should extend the compliance deadline by two years to allow for additional time for capital improvements that will be necessary as part of the implementation of this regulation.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Ohio Water Utility Council (OWUC), Ohio American Water Works Association (OAWWA) (Doc. #1782, SBC-044724)

OWUC has great concern regarding the compliance schedule being proposed in this regulatory rule. As mentioned above, these proposed rules are just one of many important regulatory statues that PWSs are required to follow, including the Lead & Copper Rule Revisions with additional changes coming in the Lead & Copper Rule Improvements. Ohio water utilities are stretched thin already, economically and the available personnel. The parallel timeframe for the initial monitoring and ongoing compliance monitoring for the PFAS substances identified in the proposed rule and LCRR/LCRI will create an extreme burden on Ohio's PWSs and the rate payers. We are requesting that flexibility or significant extensions be built into the compliance schedule and the USEPA work closely with those PWSs that are in violation of the MCLs.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges, as well as simultaneous compliance challenges, that may affect the compliance timeline.

City of Tulsa Water and Sewer Department (CoT WSD) (Doc. #1785, SBC-043785)

7. 88 FR 18684. Statement in preamble that, "Water systems with PFAS levels that exceed the MCLs proposed would need to take action to provide drinking water which meets the NPDWR by the compliance dates established in the rule when final."

8. 88 FR 18684. Statement in preamble that, "EPA estimates GAC treatment will be sufficiently available to support cost-effective compliance with this proposed regulation…"

CoT WSD has concerns that there was little discussion in the preamble regarding timeline for compliance if initial monitoring data showed non-compliance with the MCL, and installation of new treatment is required to achieve compliance with the NPDWR. EPA's expects to finalize this rule at the end of 2023, with proposed compliance date three years after promulgation of rule, i.e. the end of 2026. UCMR5 monitoring continues through the end of 2025, so some systems may only have less than a year before compliance date. EPA states (88 FR 18689) that it will not provide a two-year extension allowed by SDWA, but States can issue extensions on an individual basis. This will increase the burden on states in the implementation of this rule. Given a conservative estimate of 3.5-4 years for a capital project to reach completion, a two-year extension would not be sufficient.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments*

document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

PFAS Project Lab (Doc. #1786, SBC-044710)

May 30, 2023

Public comments on the U.S. EPA PFAS National Primary Drinking Water Regulation Rulemaking, 40 CFR Parts 141 and 142.

We are writing in support of the U.S. Environmental Protection Agency's proposed PFAS National Primary Drinking Water Regulations for six PFAS compounds. The PFAS Project Lab (www.pfasproject.com) is an interdisciplinary academic research group that studies the scientific, social, and political factors related to PFAS. We produce accessible research and information about PFAS contamination and work in collaboration with impacted communities to address this significant health and environmental crisis. We also collaborate with state and federal agencies and have provided testimony on state regulation. We were involved in the 2022 NASEM Guidance on PFAS Testing and Health Outcomes. Since organizing the inaugural National PFAS Conference in 2017, we have played a major role in this biennial conference, which is a highly visible venue. Indeed, EPA announced its revised Health Advisory for certain PFAS at our June 2022 conference. Our map of known and presumptive PFAS contamination sites (PFAS Project Lab 2023), jointly produced with our collaborators at Silent Spring Institute, is widely used across the US and was the prompt to European investigative journalists to prepare a similar map for Europe (Dagorn et al. 2023).

EPA must act quickly to implement long overdue drinking water regulations for this class of chemicals with serious environmental and human health impacts.

EPA Response: The agency agrees with the commenter on the health concerns posed by PFAS and that establishing a national PFAS NPDWR as expeditiously as possible is needed to protect public health and the environment.

Fairfax Water (Doc. #1789, SBC-045314)

4. The underestimation of utilities impacted by the proposed rule and the unrealistic compliance deadline will place significant demand on limited resources for consulting engineers, contractors, suppliers, and primacy agency support to achieve compliance. This will lead to further cost increases and rampant noncompliance which would be contrary to the objective of the regulation.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. After considering public comment, the EPA has made a number of

adjustments to the cost model and collectively these changes have increased the agency's estimated annualized costs. The EPA has used the best available peer reviewed science to inform the cost estimates, including treatment costs of the final PFAS NPDWR. For additional discussion on cost considerations when establishing the final MCLs, please see section 5.1.3 of the EPA response in this *Response to Comments* document.

Fairfax Water (Doc. #1789, SBC-045310)

Summary

While Fairfax Water supports the goal of the proposed PFAS rule, a compliance deadline that is not founded in reality could ultimately lead to thousands of utilities being out of compliance. Rampant noncompliance places an unnecessary burden on primacy agencies and EPA and undermines the confidence of the public in its drinking water. The public would be better served by knowing the path to compliance is achievable rather than by being routinely notified that their drinking water fails to meet standards. Repeated notices of noncompliance will only drive more people to drink bottled water under the false impression that it is safer when it is not regulated by the same EPA PFAS standard. Many who choose bottled water may be those who can least afford to do so.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Fairfax Water (Doc. #1789, SBC-045299)

At the proposed MCL and HI levels, the rule will place significant demand on a limited pool of resources to achieve compliance. Too many utilities will be competing for the same consulting engineers, construction contractors, and suppliers at the same time. These limitations will invariably lead to cost escalations beyond what EPA currently estimates. The pool for construction contractors for water infrastructure projects is already stressed. Utilities are seeing fewer bidders, sometimes only one bidder, and bids are consistently higher than engineers' estimates. Utilities, consulting engineers, and contractors are all facing workforce challenges. Cost increases due to competition for limited resources will further strain the ratepaying public and drinking water affordability.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments*

document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Fairfax Water (Doc. #1789, SBC-045304)

Unrealistic Timeframe for Compliance

The proposed rule provides only three years for compliance from final rulemaking. While utilities can apply for a two-year extension from their primacy agency, extensions are not guaranteed. Even a five-year period to comply ignores the realities of implementing capital projects such as the addition of GAC, ion exchange (IX), or reverse osmosis (RO) treatment trains to existing plants. Any of these treatment alternatives would need to be piloted for at least one year to capture seasonal variations in source water quality. Depending on the alternative being studied, pipe loop studies may also be required to ensure that multiple competing regulations do not result in non-compliance. Certainly, any utility contemplating a change in source water to achieve PFAS compliance would need to undertake pilot plant and pipe loop studies to avoid unintended consequences in the distribution system. Additionally, utilities will have to develop the financial capacity to implement these capital projects. Utilities will have to increase rates, issue bonds, secure grants and/or loans, or a combination of these. All of these efforts take time, but funds have to be in hand before design and construction can proceed.

Fairfax Water, like many utilities, must go through local land use or zoning processes to obtain approval to construct any of our facilities. In our case, the zoning approval process can take six to eighteen months, preceded by at least six months of preliminary engineering, development of other application materials including an alternatives analysis, and public outreach. The zoning process is separate from and a prerequisite to obtaining site plans and building permits, processes that will take another six to twelve months. In between zoning and site permitting, the detailed design and development of bid documents would occur, a process that would easily take twelve to eighteen months depending on the complexity of the selected treatment process.

Public utilities are subject to public procurement regulations. These processes add additional time to the design and construction process. Development of a request for proposals for project design services, receipt and review of proposals, consultant selection, fee negotiation, and contract award will take a minimum of six months. The process for receiving bids for construction and awarding those contracts will take another three to six months. While some public utilities may be able to employ alternative procurement methods, not all are able to do so, and alternative methods will only shorten timeframes associated with design and construction.

The treatment alternatives identified in the rule (GAC, IX, RO) would be additions to existing treatment trains. Construction phasing to maintain plant operations and ensure an adequate supply of drinking water to the public at all times will be critical. Tie-ins to existing infrastructure must occur during low demand periods (wintertime) to ensure sufficient water production capacity to meet community needs. These construction staging intricacies will further lengthen the time to construct PFAS treatment improvements. Construction and commissioning

timeframes will be project and site specific but could easily take three years (see attached illustrative project schedule).

Fairfax Water, like other utilities, continues to experience significant delays for equipment and materials that were readily obtained prior to the pandemic. In addition to more realistic timeframes noted above for capital project execution, the proposed compliance period does not account for the supply chain challenges we continue to face. Our GAC supplier has advised that the lead time for GAC vessels for PFAS treatment is eighteen months. This is the lead time before a PFAS rule is finalized. Fairfax Water was paying $1.37/lb. for GAC just last year; now we are paying $1.60/lb. - a 17% increase. Without EPA knowing with certainty how many utilities need to implement treatment for PFAS, it is impossible to know what the supply chain challenges will be, to accurately evaluate the capacity of vendors to meet demand or to forecast the impact on pricing in a supply restricted environment. Fairfax Water recommends that EPA provide at least seven years for compliance from the adoption of the final rule to reflect the realities of capital project delivery and supply chain constraints. Otherwise, taken together, these time constraints are very likely to make the regulation's timeframe aspirational rather than practicable.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline and additional extensions that can be provided on a case-by-case basis under SDWA Section 1416.

Massachusetts Municipal Association (MMA) (Doc. #1800, SBC-043768)

As communities have learned throughout implementation of the Massachusetts PFAS6 MCL of 20 ppt, the process to get treatment facilities up and running is a lengthy one. Local land use or zoning processes, thoughtful design, procurement, development and construction has taken longer than anticipated in Massachusetts, and many communities are still in the process of installing treatment 3 years into our enforceable state maximum contaminant level. The cities and towns of Massachusetts have devoted local resources to build public awareness campaigns necessary to ensure trust and confidence in public water across the state, and assistance will be needed on a federal level to fill gaps in understanding. Thus, we also urge the EPA to provide a longer implementation timeline to make this more practical for cities and towns across the country.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments*

document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Massachusetts Municipal Association (MMA) (Doc. #1800, SBC-043765)

In addition to capital expenditures, municipalities bear the ongoing costs to provide PFAS-free drinking water during the construction period for the treatment plants and future costs to dispose of PFAS-laden filters and media. The true costs to build, staff, and run treatment plants to comply with a more stringent MCL will likely be much higher, especially when supply chain issues and increased demand to comply with a national standard are factored into the equation.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline and responses regarding cost issues topic 13.

Safe Drinking Water Branch, Hawaii Department of Hawaii (Doc. #1801, SBC-043751)

Workforce

The treatment technology such as GAC, IX and RO, requires the operators to have another higher-level certification. Achieving these certifications will require staff time and resources that will challenge the sustainability of many smaller water systems.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. Regarding concerns on operator certification licenses, please see the EPA response to comment Doc. #1567, SBC-042738 in section 12.1 in this *Response to Comments* document.

Palm Beach County Water Utilities Department (Doc. #1802, SBC-045337)

Page 18683, IX.F. Third column first full paragraph, " this proposed rule would require compliance three years after promulgation. To satisfy initial monitoring requirements and demonstrate rule compliance, within the three years following rule promulgation, groundwater systems serving a population greater than 10,000 and all surface water systems will be required to demonstrate their baseline concentrations using data from four quarterly samples collected over a one- year period.":

PBCWUD Comment: PBCWUD will be required to replace two lime softening plants with membrane filtration plants. The costs for this work is expected to be $S00M (2023 dollars) and will take 6 years to complete. Considering we will not be the only utility required to construct new facilities 6 years should be considered an optimistic estimate considering current labor, and worldwide equipment and material shortages. PBCWUD recommends changing the proposed rule to allow compliance within six years after promulgation. Allowances taking into account the availability of funding should also be considered.

Page 18684,X.A. First column entire section, " A. What are the Consumer Confidence Report requirements?":

PBCWUD Comment: Compliance with and public reporting via the Consumer Confidence Report (CCR) is another reason to set compliance to no earlier than 6 years after promulgation. It will not be possible for our utility to come into compliance within three years considering new water plants must be constructed.

Page 18694, XIII.C.1.c. First column first paragraph," on the range of component levels assumed and the range of estimated PFAS treatment costs.":

PBCWUD Comment: PBCWUD has already planned to replace two lime softening plants with membrane filtration plants and are part of this utility's long term planning and financing program. Installing granular activated carbon (GAC) as a stop-gap is not cost effective since the future membrane filtration plants will treat the drinking water to a greater standard than GAC. Therefore, the GAC systems will be replaced before the end of their useful life span.

The costs for this work is expected to be $S00M (2023 dollars) and take 6 years to complete. Considering we will not be the only utility required to construct new facilities 6 years should be considered an optimistic estimate considering current labor, and worldwide equipment and material shortages. PBCWUD recommends changing the proposed rule to allow compliance within six years after promulgation. Allowances taking into account the availability of funding should also be considered.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10).. Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline as well as exemptions under SDWA Section 1416.

National Ground Water Association (NGWA) (Doc. #1804, SBC-045459)

Small System Exemptions to Achieve Compliance – EPA asked for comments on this topic. While small systems exemptions may be useful to limit investment until adequate treatment technology may be available, this approach seems counter to being health protective for the people affected.

EPA Response: Regarding the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on exemptions under SDWA 1416 as well as supply chain and labor challenges that may affect the compliance timeline.

Laurens County Water and Sewer Commission (LCWSC) (Doc. #1805, SBC-043745)

Advanced technologies needed for PFAS treatment may require advanced licensing of water plant operators, an already depleting resource in many areas of the country. Additionally, water treatment plant design can be a complex and expensive exercise.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. Regarding concerns on operator certification licenses, please see the EPA response to comment Doc. #1567, SBC-042738 in section 12.1 in this *Response to Comments* document.

Laurens County Water and Sewer Commission (LCWSC) (Doc. #1805, SBC-043746)

The engineering Community struggles with the recent influx of water, sewer, stormwater, highway, and other projects that are being completed in the next 3-5 years due to ARPA. Adding more construction projects over the next 3-5 years is completely unrealistic.

We will have to pay design premiums and may not get the quality of work we normally would, due to the unprecedented volume of work. Even if the projects can be designed and bid on, the construction industry is already overburdened and will fall further behind when we add these drinking water plant upgrades to the already enormous number of projects. I am not sure what the market can withstand financially, but feel confident it will not be in our best interest.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Laurens County Water and Sewer Commission (LCWSC) (Doc. #1805, SBC-043748)

We think EPA needs to provide significant schedule flexibility in light of the thousands of facilities which EPA expects will be affected, the enormous cost, and the historically thin engineering and construction industry capacities. Three years is nowhere near enough time for so many water systems to plan, design, fund, and construct significant upgrades to their water

systems. This truncated and rushed schedule also increases the associated cost estimates, making the rule as proposed completely infeasible.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. The agency has evaluated the feasibility of the final standards; please see section 5 of the EPA response in this *Response to Comments* document for additional discussion. Additionally, the agency disagrees with commenter claims that the EPA did not consider the impacts of operation and residuals disposal; please see sections 5.1.3 (cost considerations and alternative MCLs), 10.4 (management of treatment residuals), and 13.3 (methods for estimating cost) of the EPA response in this *Response to Comments* document for additional discussion. With respect to operator training, please see the EPA response to comment Doc. #1567, SBC-042738 in section 12.1 in this *Response to Comments* document.

Laurens County Water and Sewer Commission (LCWSC) (Doc. #1805, SBC-043749)

We believe the EPA should republish the proposed rule with a phased/tiered step-down MCL and Hazard Index approach that might look like the following:

50 ppt for PFOA/PFOS and a Hazard Index of "5.0" effective December 31 , 2024

15 ppt for PFOA/PFOS and a Hazard Index of "3.0" effective December 31, 2034

4 ppt for PFOA/PFOS and a Hazard Index of "1.0" effective December 31, 2044

Others in our industry have shown significant concern that EPA has not used the available human health PFAS-related data both from the Federal Drug Administration and its own information from PFAS hotspots around the country. Unfortunately, with the level of expertise we have on staff, and the short time that was given to read thousands of pages of material, we cannot offer appropriate comments, as there has not been a reasonable opportunity to develop the knowledge and understanding to make them. We do have concerns that this abbreviated effort has been unfair to not allow smaller utilities to become educated and make thoughtful arguments either for or in opposition to the proposed regulation.

Again, we appreciate the opportunity to comment and want to reiterate that we do not oppose any necessary and appropriate public health-related requirements. However, we believe that EPA must reconsider a number of material aspects relating to its development of the proposed rule, the MCL levels, how the MCLs might be better structured to ensure that water systems are updated using in an orderly manner following an appropriate priority matrix.

Jeff Field

Executive Director

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline as well as discussion on a phased-in MCL approach. The commenter didn't provide supporting information for the agency to evaluate on the "significant concerns that EPA has not used the available human health PFAS-related data both from the Federal Drug Administration and its own information from PFAS hotspots around the country." The EPA's final rule represents data-driven drinking water standards that are based on the best available science and meet the requirements of SDWA; regulation of the PFAS covered by the NPDWR is vital toward protecting public health by removing these contaminants from our nation's drinking water.

Office of Advocacy at the U.S. Small Business Administration (Doc. #1807, SBC-045490)

b. EPA should provide additional time for compliance based on funding availability and to address any anticipated capacity issues.

The challenges associated with obtaining and using federal or state funding for compliance will likely not allow timely compliance with EPA's proposed requirements. During EPA's public hearing, several stakeholders including those representing small water systems expressed concerns about the three-year timeframe. Specifically, a Colorado stakeholder shared that a recent implementation of a treatment technology spanned a five-year period. Advocacy is concerned that EPA neglected to adequately consider the regulatory flexibility to provide an extended compliance timeline for small entities. In the Initial Regulatory Flexibility Analysis [FN16: Economic Analysis at pgs. 9-7-9-8.], EPA declined to extend compliance timelines in response to the panel recommendation to consider rule implementation delays for potential laboratory capacity-related challenges. Capacity-related challenges could potentially impact the ability of water systems to monitor for PFAS and reasonably comply with the proposed requirements. Instead, the agency referred to a state's ability to provide extensions under SDWA [FN17: The agency cites to 42 U.S.C. §300g–1(b)(10) (a state or EPA may grant an extension of up to two additional years to comply with an NPDWR's MCL if the state or EPA determines a system needs additional time for capital improvements) and to 42 U.S.C. § 300g-4 (states may provide such as extension on an individual system basis which may address compliance issues associated with treatment, laboratory, and disposal capacity).]. Obtaining an extension from a state for capital improvements or for other compliance issues will likely deplete the limited resources of the small water systems. Advocacy recommends that EPA conduct extensive outreach with small entities to better understand their ability to comply, including access to funding, availability of resources such as training staff, any potential supply chain issues or construction delays and lab and disposal capacity issues. To address these concerns, Advocacy encourages the agency to take predevelopment timelines and the availability of resources into account when reconsidering the compliance timeframe. Therefore, to ensure compliance,

Advocacy recommends that the EPA extend the compliance timeframe for small entities beyond the three years proposed.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. After finalization of the PFAS NPDWR, the EPA also intends to work with stakeholders to provide support to utilities, primacy agencies, and other interested parties to ensure successful rule implementation and will consider the topics suggested by the commenter as the agency develops implementation materials for the final NPDWR. For more on the EPA's evaluation of small entity impacts under the Regulatory Flexibility Act (RFA), including the initial and final regulatory flexibility analysis, please see section XIII.C. of the final rule preamble.

Office of Advocacy at the U.S. Small Business Administration (Doc. #1807, SBC-045485)

c. EPA does not account for other factors that will further deter timely compliance.

Even if small water systems somehow obtained the necessary funding to comply with the rule, significant challenges will complicate timely compliance. These challenges include personnel shortage, supply chain disruptions, limited lab capacity, limited disposal capacity and availability of affordable treatment technologies. A small entity representative to the SBREFA panel noted that PFAS treatment technologies require specialized training for sampling and a likely shortage of operators is imminent and will contribute to challenges associated with timely compliance.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. Regarding concerns on operator certification licenses, please see the EPA response to comment Doc. #1567, SBC-042738 in section 12.1 in this *Response to Comments* document.

Office of Advocacy at the U.S. Small Business Administration (Doc. #1807, SBC-045487)

Small entity representatives have also shared that given the low levels proposed, compliance will likely require treatment, which will lead to supply chain issues since most water systems will need to implement treatment technologies.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments*

document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

West Virginia Municipal Water Quality Association (Doc. #1816, SBC-044666)

The enormous costs experienced so far are likely to increase even further due to supply chain, worker shortage, inflation, and the unprecedented number of public utility/highway infrastructure projects being attempted over the next five-to-ten years. Adding PFAS barrier technology at thousands (according to US EPA) of drinking water plants nationwide can only further increase national engineering and construction prices.

There are simply not enough engineers, contractors, or workers to implement all these projects. Forcing PFAS barrier technology to the head of the line will trigger unprecedented cost premiums. It will also force utilities to delay needed infrastructure projects that protect human health, such as water main replacements and other projects to replace aging infrastructure. Infrastructure replacement delays will equate to more risk, less redundancy, less resiliency, and ultimately higher costs for utilities.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

West Virginia Municipal Water Quality Association (Doc. #1816, SBC-044671)

The sheer number of facilities that will have to install PFAS barrier technologies – 3-6,000 facilities by EPA's own estimate – demonstrates the impracticability of the 3-year (up to five for very small systems serving fewer than 10,000 population) implementation schedule. The treatment technology needed to comply with the proposed rule is simply not in place at this time, nor will it be to the extent needed to meet a 3-5-year national compliance schedule.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. For additional discussion on treatment availability and capacity, please see section 10.6 of the EPA response in this *Response to Comments* document.

West Virginia Municipal Water Quality Association (Doc. #1816, SBC-044677)

EPA must provide unprecedented implementation schedule flexibility for this unprecedented rule. This is warranted particularly in light of the thousands of facilities which EPA expects will be affected, the enormous cost, and the historically thin capacities of the engineering and construction industries (including the manufacturers of the supplies and equipment needed for PFAS barrier projects). Three years is nowhere near enough time for so many water systems to plan, design, permit, fund, and construct significant upgrades to their water systems. This truncated and rushed schedule also increases the associated cost estimates, making the rule as proposed completely infeasible. Additionally, the full impacts of operation and residuals disposal have not been fully considered. Not only will O&M costs significantly increase, but many utilities lack the ability to draw additional staff with the expertise to run these types of advanced water treatment systems.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. The agency has evaluated the feasibility of the final standards; please see section 5 of the EPA response in this *Response to Comments* document for additional discussion. Additionally, the agency disagrees with commenter claims that the EPA did not consider the impacts of operation and residuals disposal; please see sections 5.1.3 (cost considerations and alternative MCLs), 10.4 (management of treatment residuals), and 13.3 (methods for estimating cost) of the EPA response in this *Response to Comments* document for additional discussion. With respect to operator training, please see the EPA response to comment Doc. #1567, SBC-042738 in section 12.1 in this *Response to Comments* document.

West Virginia Municipal Water Quality Association (Doc. #1816, SBC-044675)

IV. A Decade-Plus Implementation Schedule is Needed or a Phased/Tiered Step-Down MCL Approach.

Water treatment plant design is a very complex and challenging exercise. Extensive facility-specific pilot studies will be needed to ensure we install the proper treatment for the PFAS chemicals present in each facility's raw water supply. We are in a period of unprecedented shortage of design engineers as the engineering community struggles with the gusher of water, sewer, stormwater, highway, and other projects that are being crammed into the next 3-5 years due to ARPA, BIL, and State budget surplus infrastructure investments. Adding even (EPA's estimated) 3-6 thousand water plant PFAS barrier projects on top of this over the next 3-5 years is completely unrealistic. We will have to pay design premiums and may not get the quality of work we need due to the unprecedented volume of work the engineering community faces. Even if the projects can be piloted, planned, designed, permitted, funded, and bids received, the

construction industry is already overburdened and will fall further behind when we add these drinking water plant upgrades to the already enormous number of projects. For the past year we have already seen no bids on projects that normally would get several bids. Where there have been bids, they have almost universally been higher than the engineer's (updated) estimate, if not shockingly higher. This fact is compounded by construction material supply chain delays, which lead to longer project schedules that contribute to higher bids.

Small systems will struggle the most because engineering and construction firms will want to prioritize work for their larger clients because they will comprise the bulk of their future work. Small systems will be more one-and-done-type projects. Moreover, smaller systems may lack the sophistication and middle management to oversee and interact with contractors on such projects. As such smaller systems should have additional compliance flexibility.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline as well as discussion on a phased-in MCL approach. For funding concerns, the agency notes that funds are also available through the passage of the BIL to assist many disadvantaged communities, small systems, and others with the costs of installation of treatment when it might otherwise be cost-challenging. Please see section 2.4 of the EPA response in this *Response to Comments* document for more discussion about currently available funding.

West Virginia Municipal Water Quality Association (Doc. #1816, SBC-044678)

EPA should defer rule adoption while it takes into account the appropriate levels of PFOA/PFOS (as well as the hazard index four chemicals), environmental updated costs and benefits, and other significant factors such as environmental justice.

As part of that re-evaluation, EPA should republish the proposed rule and seek public comment on a phased/tiered step-down MCL and Hazard Index approach that might look like the following:

• 10 ppt for PFOA/PFOS and 5 Hazard Index effective 12 months from the date of publication with a compliance schedule of up to 10 years from the effective date.

• 8 ppt for PFOA/PFOS and a 3 Hazard Index with an effective date of 2029 and a compliance deadline of no more than 10 years from the effective date.

• 4 ppt for PFOA/PFOS and a 1 Hazard Index with an effective date of 2034 and a compliance deadline of no more than 10 years from the effective date.

While the deadlines for MCLs are statutory in nature, we believe the phased effective date approach above would serve to provide EPA, the States, and affected water systems with the time necessary to implement PFAS barrier technologies.

EPA Response: The EPA disagrees with commenter assertions that the agency did not "account the appropriate levels of PFOA/PFOS (as well as the Hazard Index four chemicals), environmental updated costs and benefits, and other significant factors such as environmental justice." Analytic feasibility was evaluated when establishing the final MCLs (see section 5 of the EPA response in this *Response to Comments* document for more information). The EPA conducted robust occurrence analyses, as described in sections III and VI of the preamble and sections 3 and 7 of this *Response to Comments* document. The agency also conducted a robust environmental justice analysis discussed in the final rule preamble (section XII) and within section 14.10 of the EPA's *Response to Comments* document. The EPA's final rule represents data-driven drinking water standards that are based on the best available science and meet the requirements of SDWA; regulation of the PFAS covered by the NPDWR is vital toward protecting public health by removing these contaminants from our nation's drinking water. Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline as well as discussion on a phased-in MCL approach.

West Virginia Municipal Water Quality Association (Doc. #1816, SBC-044679)

Only if such a phased approach is unworkable should EPA resort to an advance exercise of its enforcement discretion to provide additional implementation time. Such an approach would be advisory to delegated states and would provide, in general, federally pre-approved compliance schedule parameters for the States to work within.

While many systems will need more time, EPA and the states will also want to ensure that limited engineering, agency, funding, and contractor resources are directed to systems with the highest priority (highest PFAS levels, significant environmental justice considerations, etc.). It is strongly in the public interest for EPA to issue the MCLs in a way that ensures the most impacted systems are able to upgrade earlier than systems that may be only marginally impacted or upgrading out of convenience or an abundance of caution.

EPA and the states could also allow compliance schedule flexibility up front for utilities that need it through EPA and/or state administrative orders giving systems with lower priority more time to meet the MCLs. This is a formalized variant of the agency enforcement discretion approach. This could be done on a case- by-case basis.

Again, we believe the best course is for EPA to adopt phased MCLs as follows:

10 ppt for PFOA/PFOS and a Hazard Index of "5.0" effective December 31, 2024 8 ppt for PFOA/PFOS and a Hazard Index of "3.0" effective December 31, 2029 4 ppt for PFOA/PFOS and a Hazard Index of "1.0" effective December 31, 2034

A compliance schedule of up to ten years would apply to each effective date. Even with this approach, enforcement discretion will be necessary to ensure that water system PFAS barrier installations are appropriately scheduled.

In support of this approach, we note that in 1979, EPA issued a final rule setting a MCL and associated monitoring and reporting requirements for total trihalomethanes (TIHMs). 44 Fed. Reg. 68,824 (Nov. 29, 1979). The MCL had phased implementation for facilities of different sizes written within the MCL:

For community water systems serving 75,000 or more persons, monitoring must begin 1 year following promulgation and the effective date of the MCL is 2 years following promulgation. For community water systems serving 10,000 to 75,000 persons, monitoring must begin within 3 years from the date of promulgation and the effective date of the MCL is 4 years from the date of promulgation.

Id. at 68,824. [FN3: We would note many of the relevant issues for that rulemaking are the same for this proposed rule: "EPA specifically solicited and received comments on the following major issues: The rationale for setting an MCL for TTHMs and the magnitude of the MCL; the feasibility of and timing for phased reduction of the MCL; the concept of phasing the application of the MCL based upon system size; an alternative of making the MCL applicable to all public water systems and to phase the implementation by a deferred monitoring schedule linked to population size … the availability of technology to achieve compliance …and the costs incurred by public water systems to achieve compliance with the MCL." Id. (emphasis added).] Several components went into this decision to implement phases, including inadequate lab capacity with an increased lab demand. Id. at 68,629. EPA characterized this type of delay as extending the time frame for the initiation of requirements. Id. at 68,630 (emphasis added). Thus, there is precedent for the phasing/tiered approach we suggest – which can also be viewed as a phased timeframe for initiating the requirements of the proposed PFAS MCLs to community water systems based upon the PFAS levels in their finished drinking water.

Another approach would be for EPA to provide a phase-in schedule by means of a group or class "exemption" adopted as part of, or concurrently with, the PFAS MCL regulations. See Safe Drinking Water Act §§ 1415, 1416. The exemption might have multiple tiers based on PFAS concentrations – the lower the concentration the longer the phase-in period – and be temporary, and expire in phases, e.g., 10 / 8 / 4 ppt, over 5 / 10 / 15 years, respectively. If exemptions cannot be issued on a group/class basis, EPA could announce a general expectation that States may approve exemptions for defined groups for defined periods, and the States then develop implementation schedules on an individual (but pre-determined) basis.

It is clear that EPA must phase water plant upgrades over at least the next 10-20 years. It is patently obvious that we can't install PFAS barrier technology at 3-6,000 water plants nationwide in a shorter period.

Finally, phasing the MCL in over time will reinforce for the public that the PFAS levels they will experience over the next 10-20 years are not the end of the world. The reality is that the vast majority of Americans have experienced significantly higher PFAS levels for decades than they do now. We understand that the federal government has been assessing both PFOA and PFOS blood lead levels in thousands of Americans for several decades and that the levels have plummeted. We expect those levels to plummet further with the intense governmental, legislative, and litigation focus on eliminating the use of PFAS chemicals.

We believe the health monitoring testing that has been done in PFAS hot spot areas such as Parkersburg and Vienna, West Virginia reinforce the fact that levels nationwide are dropping and that means that some necessary prioritization and phasing of water plant PFAS barrier installations is both warranted and appropriate.

V. State Permitting/Funding Agency Capacity to Permit and Fund PFAS Barrier Technology Projects is at an All Time Low.

State public health agencies are facing the same historic worker retirement and shortage phenomenon as everyone else. The tiered/phased MCL adoption and implementation approach that we suggest above is also necessary given the reality that State health agencies are simply unable to handle 3-6,000 PFAS barrier installation projects over the next few years on top of all the other projects they are being asked to manage. Even when funding is available for additional staff, the States have struggled to attract (and retain) staff given the competition from the private sector (which is woefully understaffed, and which pays better).

EPA must address this significant potential bottleneck in any MCL implementation schedule it adopts as part of the final rule.

EPA Response: With respect to health monitoring testing, the EPA believes that this type of biomonitoring can be an important tool to identify changes in population exposure over time. However, as discussed in section III of the final rule preamble and section III of the EPA's *Response to Comments* document (see final regulatory determinations), the agency has sufficient information now to regulate the six PFAS included in the final NPDWR. The EPA's final rule represents data-driven drinking water standards that are based on the best available science and meet the requirements of SDWA; regulation of the PFAS covered by the NPDWR is vital toward protecting public health by removing these contaminants from our nation's drinking water. Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10) which is the maximum that can be provided in an NPDWR. However, as discussed further in section 12.1 of the EPA response in this *Response to Comments* document, primacy agencies can provide additional time through case-by-case exemptions under SDWA Section 1416. Under SDWA EPA cannot mandate exemptions; these are solely at the discretion of the primacy agency and must be issued

pursuant to the criteria and processes set out in SDWA Section 1416. Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline as well as discussion on a phased-in MCL approach.

Association of Missouri Cleanwater Agencies (Doc. #1817, SBC-044644)

The enormous costs experienced so far are likely to increase even further due to supply chain, worker shortage, inflation, and the unprecedented number of public utility/highway infrastructure projects being attempted over the next five-to-ten years. Adding PFAS barrier technology at thousands (according to US EPA) of drinking water plants nationwide can only further increase national engineering and construction prices.

There are simply not enough engineers, contractors, or workers to implement all these projects. Forcing PFAS barrier technology to the head of the line will trigger unprecedented cost premiums. It will also force utilities to delay needed infrastructure projects that protect human health, such as water main replacements and other projects to replace aging infrastructure. Infrastructure replacement delays will equate to more risk, less redundancy, less resiliency, and ultimately higher costs for utilities.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Association of Missouri Cleanwater Agencies (Doc. #1817, SBC-044656)

EPA should defer rule adoption while it takes into account the appropriate levels of PFOA/PFOS (as well as the hazard index four chemicals), environmental updated costs and benefits, and other significant factors such as environmental justice.

As part of that re-evaluation, EPA should republish the proposed rule and seek public comment on a phased/tiered step-down MCL and Hazard Index approach that might look like the following:

• 10 ppt for PFOA/PFOS and 5 Hazard Index effective 12 months from the date of publication with a compliance schedule of up to 10 years from the effective date.

• 8 ppt for PFOA/PFOS and a 3 Hazard Index with an effective date of 2029 and a compliance deadline of no more than 10 years from the effective date.

• 4 ppt for PFOA/PFOS and a 1 Hazard Index with an effective date of 2034 and a compliance deadline of no more than 10 years from the effective date.

While the deadlines for MCLs are statutory in nature, we believe the phased effective date approach above would serve to provide EPA, the States, and affected water systems with the time necessary to implement PFAS barrier technologies.

EPA Response: The EPA disagrees with commenter assertions that the agency did not "account the appropriate levels of PFOA/PFOS (as well as the Hazard Index four chemicals), environmental updated costs and benefits, and other significant factors such as environmental justice." Analytic feasibility was evaluated when establishing the final MCLs (see section 5 of the EPA response in this *Response to Comments* document for more information). The EPA conducted robust occurrence analyses, as described in sections III and VI of the preamble and sections 3 and 7 of this *Response to Comments* document. The agency also conducted a robust environmental justice analysis discussed in the final rule preamble (section XII) and within section 14.10 of the EPA's *Response to Comments* document. The EPA's final rule represents data-driven drinking water standards that are based on the best available science and meet the requirements of SDWA; regulation of the PFAS covered by the NPDWR is vital toward protecting public health by removing these contaminants from our nation's drinking water. Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline as well as discussion on a phased-in MCL approach.

Association of Missouri Cleanwater Agencies (Doc. #1817, SBC-044657)

Only if such a phased approach is unworkable should EPA resort to an advance exercise of its enforcement discretion to provide additional implementation time. Such an approach would be advisory to delegated states and would provide, in general, federally pre-approved compliance schedule parameters for the States to work within.

While many systems will need more time, EPA and the states will also want to ensure that limited engineering, agency, funding, and contractor resources are directed to systems with the highest priority (highest PFAS levels, significant environmental justice considerations, etc.). It is strongly in the public interest for EPA to issue the MCLs in a way that ensures the most impacted systems are able to upgrade earlier than systems that may be only marginally impacted or upgrading out of convenience or an abundance of caution.

EPA and the states could also allow compliance schedule flexibility up front for utilities that need it through EPA and/or state administrative orders giving systems with lower priority more time to meet the MCLs. This is a formalized variant of the agency enforcement discretion approach. This could be done on a case-by-case basis.

Again, we believe the best course is for EPA to adopt phased MCLs as follows:

10 ppt for PFOA/PFOS and a Hazard Index of "5.0" effective December 31, 2024

8 ppt for PFOA/PFOS and a Hazard Index of "3.0" effective December 31, 2029

4 ppt for PFOA/PFOS and a Hazard Index of "1.0" effective December 31, 2034

A compliance schedule of up to ten years would apply to each effective date. Even with this approach, enforcement discretion will be necessary to ensure that water system PFAS barrier installations are appropriately scheduled.

In support of this approach, we note that in 1979, EPA issued a final rule setting a MCL and associated monitoring and reporting requirements for total trihalomethanes (TIHMs). 44 Fed. Reg. 68,824 (Nov. 29, 1979). The MCL had phased implementation for facilities of different sizes written within the MCL:

For community water systems serving 75,000 or more persons, monitoring must begin 1 year following promulgation and the effective date of the MCL is 2 years following promulgation. For community water systems serving 10,000 to 75,000 persons, monitoring must begin within 3 years from the date of promulgation and the effective date of the MCL is 4 years from the date of promulgation.

Id. at 68,824 [FN3: We would note many of the relevant issues for that rulemaking are the same for this proposed rule: "EPA specifically solicited and received comments on the following major issues: The rationale for setting an MCL for TTHMs and the magnitude of the MCL; the feasibility of and timing for phased reduction of the MCL; the concept of phasing the application of the MCL based upon system size; an alternative of making the MCL applicable to all public water systems and to phase the implementation by a deferred monitoring schedule linked to population size … the availability of technology to achieve compliance …and the costs incurred by public water systems to achieve compliance with the MCL." Id. (emphasis added).]. Several components went into this decision to implement phases, including inadequate lab capacity with an increased lab demand. Id. at 68,629. EPA characterized this type of delay as extending the time frame for the initiation of requirements. Id. at 68,630 (emphasis added). Thus, there is precedent for the phasing/tiered approach we suggest – which can also be viewed as a phased timeframe for initiating the requirements of the proposed PFAS MCLs to community water systems based upon the PFAS levels in their finished drinking water.

Another approach would be for EPA to provide a phase-in schedule by means of a group or class "exemption" adopted as part of, or concurrently with, the PFAS MCL regulations. See Safe Drinking Water Act §§ 1415, 1416. The exemption might have multiple tiers based on PFAS concentrations – the lower the concentration the longer the phase-in period – and be temporary, and expire in phases, e.g., 10 / 8 / 4 ppt, over 5 / 10 / 15 years, respectively. If exemptions cannot be issued on a group/class basis, EPA could announce a general expectation that States may approve exemptions for defined groups for defined periods, and the States then develop implementation schedules on an individual (but pre-determined) basis.

It is clear that EPA must phase water plant upgrades over at least the next 10-20 years. It is patently obvious that we can't install PFAS barrier technology at 3-6,000 water plants nationwide in a shorter period.

Finally, phasing the MCL in over time will reinforce for the public that the PFAS levels they will experience over the next 10-20 years are not the end of the world. The reality is that the vast majority of Americans have experienced significantly higher PFAS levels for decades than they do now. We understand that the federal government has been assessing both PFOA and PFOS blood lead levels in thousands of Americans for several decades and that the levels have plummeted. We expect those levels to plummet further with the intense governmental, legislative, and litigation focus on eliminating the use of PFAS chemicals.

We believe the health monitoring testing that has been done in PFAS hot spot areas such as Parkersburg and Vienna, West Virginia reinforce the fact that levels nationwide are dropping and that means that some necessary prioritization and phasing of water plant PFAS barrier installations is both warranted and appropriate.

V. State Permitting/Funding Agency Capacity to Permit and Fund PFAS Barrier Technology Projects is at an All Time Low.

State public health agencies are facing the same historic worker retirement and shortage phenomenon as everyone else. The tiered/phased MCL adoption and implementation approach that we suggest above is also necessary given the reality that State health agencies are simply unable to handle 3-6,000 PFAS barrier installation projects over the next few years on top of all the other projects they are being asked to manage. Even when funding is available for additional staff, the States have struggled to attract (and retain) staff given the competition from the private sector (which is woefully understaffed, and which pays better).

EPA must address this significant potential bottleneck in any MCL implementation schedule it adopts as part of the final rule.

EPA Response: With respect to health monitoring testing, the EPA believes that this type of biomonitoring can be an important tool to identify changes in population exposure over time. However, as discussed in section III of the final rule preamble and section III of the EPA's *Response to Comments* document (see final regulatory determinations), the agency has sufficient information now to regulate the six PFAS included in the final NPDWR. The EPA's final rule represents data-driven drinking water standards that are based on the best available science and meet the requirements of SDWA; regulation of the PFAS covered by the NPDWR is vital toward protecting public health by removing these contaminants from our nation's drinking water. See the EPA response to comment Doc. #1816, SBC-044679 in section 12.1 in this *Response to Comments* document with respect to exemptions. Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline as well as discussion on a phased-in MCL approach.

Association of Missouri Cleanwater Agencies (Doc. #1817, SBC-044649)

The sheer number of facilities that will have to install PFAS barrier technologies – 3-6,000 facilities by EPA's own estimate – demonstrates the impracticability of the 3-year (up to five for very small systems serving fewer than 10,000 population) implementation schedule. The treatment technology needed to comply with the proposed rule is simply not in place at this time, nor will it be to the extent needed to meet a 3-5-year national compliance schedule.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. For additional discussion on treatment availability and capacity, please see section 10.6 of the EPA response in this *Response to Comments* document.

Association of Missouri Cleanwater Agencies (Doc. #1817, SBC-044653)

IV. A Decade-Plus Implementation Schedule is Needed or a Phased/Tiered Step-Down MCL Approach.

Water treatment plant design is a very complex and challenging exercise. Extensive facility-specific pilot studies will be needed to ensure we install the proper treatment for the PFAS chemicals present in each facility's raw water supply. We are in a period of unprecedented shortage of design engineers as the engineering community struggles with the gusher of water, sewer, stormwater, highway, and other projects that are being crammed into the next 3-5 years due to ARPA, BIL, and State budget surplus infrastructure investments. Adding even (EPA's estimated) 3-6 thousand water plant PFAS barrier projects on top of this over the next 3-5 years is completely unrealistic. We will have to pay design premiums and may not get the quality of work we need due to the unprecedented volume of work the engineering community faces. Even if the projects can be piloted, planned, designed, permitted, funded, and bids received, the construction industry is already overburdened and will fall further behind when we add these drinking water plant upgrades to the already enormous number of projects. For the past year we have already seen no bids on projects that normally would get several bids. Where there have been bids, they have almost universally been higher than the engineer's (updated) estimate, if not shockingly higher. This fact is compounded by construction material supply chain delays, which lead to longer project schedules that contribute to higher bids.

Small systems will struggle the most because engineering and construction firms will want to prioritize work for their larger clients because they will comprise the bulk of their future work. Small systems will be more one-and-done-type projects. Moreover, smaller systems may lack the sophistication and middle management to oversee and interact with contractors on such projects. As such smaller systems should have additional compliance flexibility.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline as well as discussion on a phased-in MCL approach. For funding concerns, the agency notes that funds are also available through the passage of the BIL to assist many disadvantaged communities, small systems, and others with the costs of installation of treatment when it might otherwise be cost-challenging. Please see section 2.4 of the EPA response in this *Response to Comments* document for more discussion about currently available funding.

Association of Missouri Cleanwater Agencies (Doc. #1817, SBC-044655)

EPA must provide unprecedented implementation schedule flexibility for this unprecedented rule. This is warranted particularly in light of the thousands of facilities which EPA expects will be affected, the enormous cost, and the historically thin capacities of the engineering and construction industries (including the manufacturers of the supplies and equipment needed for PFAS barrier projects). Three years is nowhere near enough time for so many water systems to plan, design, permit, fund, and construct significant upgrades to their water systems. This truncated and rushed schedule also increases the associated cost estimates, making the rule as proposed completely infeasible. Additionally, the full impacts of operation and residuals disposal have not been fully considered. Not only will O&M costs significantly increase, but many utilities lack the ability to draw additional staff with the expertise to run these types of advanced water treatment systems.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. The agency has evaluated the feasibility of the final standards; please see section 5 of the EPA response in this *Response to Comments* document for additional discussion. Additionally, the agency disagrees with commenter claims that the EPA did not consider the impacts of operation and residuals disposal; please see sections 5.1.3 (cost considerations and alternative MCLs), 10.4 (management of treatment residuals), and 13.3 (methods for estimating cost) of the EPA response in this *Response to Comments* document for additional discussion. With respect to operator training, please see the EPA response to comment Doc. #1567, SBC-042738 in section 12.1 in this *Response to Comments* document.

NORTH CAROLINA WATER QUALITY ASSOCIATION (Doc. #1818, SBC-044633)

EPA must provide unprecedented implementation schedule flexibility for this unprecedented rule. This is warranted particularly in light of the thousands of facilities which EPA expects will

be affected, the enormous cost, and the historically thin capacities of the engineering and construction industries (including the manufacturers of the supplies and equipment needed for PFAS barrier projects). Three years is nowhere near enough time for so many water systems to plan, design, permit, fund, and construct significant upgrades to their water systems. This truncated and rushed schedule also increases the associated cost estimates, making the rule as proposed completely infeasible. Additionally, the full impacts of operation and residuals disposal have not been fully considered. Not only will O&M costs significantly increase, but many utilities lack the ability to draw additional staff with the expertise to run these types of advanced water treatment systems.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. The agency has evaluated the feasibility of the final standards; please see section 5 of the EPA response in this *Response to Comments* document for additional discussion. NORTH CAROLINA WATER QUALITY ASSOCIATION (Doc. #1818, SBC-044634)

EPA should defer rule adoption while it takes into account the appropriate levels of PFOA/PFOS (as well as the hazard index four chemicals), environmental updated costs and benefits, and other significant factors such as environmental justice.

As part of that re-evaluation, EPA should republish the proposed rule and seek public comment on a phased/tiered step-down MCL and Hazard Index approach that might look like the following:

• 10 ppt for PFOA/PFOS and 5 Hazard Index effective 12 months from the date of publication with a compliance schedule of up to 10 years from the effective date.

• 8 ppt for PFOA/PFOS and a 3 Hazard Index with an effective date of 2029 and a compliance deadline of no more than 10 years from the effective date.

• 4 ppt for PFOA/PFOS and a 1 Hazard Index with an effective date of 2034 and a compliance deadline of no more than 10 years from the effective date.

While the deadlines for MCLs are statutory in nature, we believe the phased effective date approach above would serve to provide EPA, the States, and affected water systems with the time necessary to implement PFAS barrier technologies.

EPA Response: The EPA disagrees with commenter assertions that the agency did not "account the appropriate levels of PFOA/PFOS (as well as the Hazard Index four chemicals), environmental updated costs and benefits, and other significant factors such as environmental justice." Analytic feasibility was evaluated when establishing the final MCLs (see section 5 of the EPA response in this *Response to Comments* document for more information). The EPA conducted robust occurrence analyses, as described in sections III and VI of the preamble and sections 3 and 7 of this *Response to Comments* document. The agency also conducted a robust environmental justice analysis discussed in the final rule preamble (section XII) and within section 14.10 of the EPA's *Response to Comments* document. The EPA's final rule represents data-driven drinking water standards that are based on the best available science and meet the requirements of SDWA; regulation of the PFAS covered by the NPDWR is vital toward protecting public health by removing these contaminants from our nation's drinking water. Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline as well as discussion on a phased-in MCL approach.

NORTH CAROLINA WATER QUALITY ASSOCIATION (Doc. #1818, SBC-044635)

Only if such a phased approach is unworkable should EPA resort to an advance exercise of its enforcement discretion to provide additional implementation time. Such an approach would be advisory to delegated states and would provide, in general, federally pre-approved compliance schedule parameters for the States to work within.

While many systems will need more time, EPA and the states will also want to ensure that limited engineering, agency, funding, and contractor resources are directed to systems with the highest priority (highest PFAS levels, significant environmental justice considerations, etc.). It is strongly in the public interest for EPA to issue the MCLs in a way that ensures the most impacted systems are able to upgrade earlier than systems that may be only marginally impacted or upgrading out of convenience or an abundance of caution.

EPA and the states could also allow compliance schedule flexibility up front for utilities that need it through EPA and/or state administrative orders giving systems with lower priority more time to meet the MCLs. This is a formalized variant of the agency enforcement discretion approach. This could be done on a case-by-case basis.

Again, we believe the best course is for EPA to adopt phased MCLs as follows:

10 ppt for PFOA/PFOS and a Hazard Index of "5.0" effective December 31, 2024

8 ppt for PFOA/PFOS and a Hazard Index of "3.0" effective December 31, 2029

4 ppt for PFOA/PFOS and a Hazard Index of "1.0" effective December 31, 2034

A compliance schedule of up to ten years would apply to each effective date. Even with this approach, enforcement discretion will be necessary to ensure that water system PFAS barrier installations are appropriately scheduled.

In support of this approach, we note that in 1979, EPA issued a final rule setting a MCL and associated monitoring and reporting requirements for total trihalomethanes (TIHMs). 44 Fed. Reg. 68,824 (Nov. 29, 1979). The MCL had phased implementation for facilities of different sizes written within the MCL:

For community water systems serving 75,000 or more persons, monitoring must begin 1 year following promulgation and the effective date of the MCL is 2 years following promulgation. For community water systems serving 10,000 to 75,000 persons, monitoring must begin within 3 years from the date of promulgation and the effective date of the MCL is 4 years from the date of promulgation.

Id. at 68,824 [FN3: We would note many of the relevant issues for that rulemaking are the same for this proposed rule: "EPA specifically solicited and received comments on the following major issues: The rationale for setting an MCL for TTHMs and the magnitude of the MCL; the feasibility of and timing for phased reduction of the MCL; the concept of phasing the application of the MCL based upon system size; an alternative of making the MCL applicable to all public water systems and to phase the implementation by a deferred monitoring schedule linked to population size … the availability of technology to achieve compliance …and the costs incurred by public water systems to achieve compliance with the MCL." Id. (emphasis added).]. Several components went into this decision to implement phases, including inadequate lab capacity with an increased lab demand. Id. at 68,629. EPA characterized this type of delay as extending the time frame for the initiation of requirements. Id. at 68,630 (emphasis added). Thus, there is precedent for the phasing/tiered approach we suggest – which can also be viewed as a phased timeframe for initiating the requirements of the proposed PFAS MCLs to community water systems based upon the PFAS levels in their finished drinking water.

Another approach would be for EPA to provide a phase-in schedule by means of a group or class "exemption" adopted as part of, or concurrently with, the PFAS MCL regulations. See Safe Drinking Water Act §§ 1415, 1416. The exemption might have multiple tiers based on PFAS concentrations – the lower the concentration the longer the phase-in period – and be temporary, and expire in phases, e.g., 10 / 8 / 4 ppt, over 5 / 10 / 15 years, respectively. If exemptions cannot be issued on a group/class basis, EPA could announce a general expectation that States may approve exemptions for defined groups for defined periods, and the States then develop implementation schedules on an individual (but pre-determined) basis.

It is clear that EPA must phase water plant upgrades over at least the next 10-20 years. It is patently obvious that we can't install PFAS barrier technology at 3-6,000 water plants nationwide in a shorter period.

Finally, phasing the MCL in over time will reinforce for the public that the PFAS levels they will experience over the next 10-20 years are not the end of the world. The reality is that the vast majority of Americans have experienced significantly higher PFAS levels for decades than they do now. We understand that the federal government has been assessing both PFOA and PFOS blood lead levels in thousands of Americans for several decades and that the levels have plummeted. We expect those levels to plummet further with the intense governmental, legislative, and litigation focus on eliminating the use of PFAS chemicals.

We believe the health monitoring testing that has been done in PFAS hot spot areas such as Parkersburg and Vienna, West Virginia reinforce the fact that levels nationwide are dropping and that means that some necessary prioritization and phasing of water plant PFAS barrier installations is both warranted and appropriate.

V. State Permitting/Funding Agency Capacity to Permit and Fund PFAS Barrier Technology Projects is at an All Time Low.

State public health agencies are facing the same historic worker retirement and shortage phenomenon as everyone else. The tiered/phased MCL adoption and implementation approach that we suggest above is also necessary given the reality that State health agencies are simply unable to handle 3-6,000 PFAS barrier installation projects over the next few years on top of all the other projects they are being asked to manage. Even when funding is available for additional staff, the States have struggled to attract (and retain) staff given the competition from the private sector (which is woefully understaffed, and which pays better).

EPA must address this significant potential bottleneck in any MCL implementation schedule it adopts as part of the final rule.

EPA Response: With respect to health monitoring testing, the EPA believes that this type of biomonitoring can be an important tool to identify changes in population exposure over time. However, as discussed in section III of the final rule preamble and section III of the EPA's *Response to Comments* document (see final regulatory determinations), the agency has sufficient information now to regulate the six PFAS included in the final NPDWR. The EPA's final rule represents data-driven drinking water standards that are based on the best available science and meet the requirements of SDWA; regulation of the PFAS covered by the NPDWR is vital toward protecting public health by removing these contaminants from our nation's drinking water. Please see the EPA response to comment Doc. #1816, SBC-044679 in section 12.1 in this *Response to Comments* document and the EPA response to topic 12.1 with respect to case-by-case exemptions. Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's

discussion on supply chain and labor challenges that may affect the compliance timeline as well as discussion on a phased-in MCL approach.

NORTH CAROLINA WATER QUALITY ASSOCIATION (Doc. #1818, SBC-044622)

The enormous costs experienced so far are likely to increase even further due to supply chain, worker shortage, inflation, and the unprecedented number of public utility/highway infrastructure projects being attempted over the next five-to-ten years. Adding PFAS barrier technology at thousands (according to US EPA) of drinking water plants nationwide can only further increase national engineering and construction prices.

There are simply not enough engineers, contractors, or workers to implement all these projects. Forcing PFAS barrier technology to the head of the line will trigger unprecedented cost premiums. It will also force utilities to delay needed infrastructure projects that protect human health, such as water main replacements and other projects to replace aging infrastructure. Infrastructure replacement delays will equate to more risk, less redundancy, less resiliency, and ultimately higher costs for utilities.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

NORTH CAROLINA WATER QUALITY ASSOCIATION (Doc. #1818, SBC-044631)

IV. A Decade-Plus Implementation Schedule is Needed or a Phased/Tiered Step- Down MCL Approach.

Water treatment plant design is a very complex and challenging exercise. Extensive facility-specific pilot studies will be needed to ensure we install the proper treatment for the PFAS chemicals present in each facility's raw water supply. We are in a period of unprecedented shortage of design engineers as the engineering community struggles with the gusher of water, sewer, stormwater, highway, and other projects that are being crammed into the next 3-5 years due to ARPA, BIL, and State budget surplus infrastructure investments. Adding even (EPA's estimated) 3-6 thousand water plant PFAS barrier projects on top of this over the next 3-5 years is completely unrealistic. We will have to pay design premiums and may not get the quality of work we need due to the unprecedented volume of work the engineering community faces. Even if the projects can be piloted, planned, designed, permitted, funded, and bids received, the construction industry is already overburdened and will fall further behind when we add these drinking water plant upgrades to the already enormous number of projects. For the past year we have already seen no bids on projects that normally would get several bids. Where there have been bids, they have almost universally been higher than the engineer's (updated) estimate, if not

shockingly higher. This fact is compounded by construction material supply chain delays, which lead to longer project schedules that contribute to higher bids.

Small systems will struggle the most because engineering and construction firms will want to prioritize work for their larger clients because they will comprise the bulk of their future work. Small systems will be more one-and-done-type projects. Moreover, smaller systems may lack the sophistication and middle management to oversee and interact with contractors on such projects. As such smaller systems should have additional compliance flexibility.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline as well as discussion on a phased-in MCL approach and exemptions that may be provided under Section 1416. For funding concerns, the agency notes that funds are also available through the passage of the BIL to assist many disadvantaged communities, small systems, and others with the costs of installation of treatment when it might otherwise be cost-challenging. Please see section 2.4 of the EPA response in this *Response to Comments* document for more discussion about currently available funding.

NORTH CAROLINA WATER QUALITY ASSOCIATION (Doc. #1818, SBC-044627)

The sheer number of facilities that will have to install PFAS barrier technologies – 3-6,000 facilities by EPA's own estimate – demonstrates the impracticability of the 3-year (up to five for very small systems serving fewer than 10,000 population) implementation schedule. The treatment technology needed to comply with the proposed rule is simply not in place at this time, nor will it be to the extent needed to meet a 3-5-year national compliance schedule.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10), which is the maximum that can be provided in a NPDWR, although further extensions can be provided under SDWA Section 1416. Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. For additional discussion on treatment availability and capacity, please see section 10.6 of the EPA response in this *Response to Comments* document.

South Carolina Water Quality Association (Doc. #1819, SBC-044611)

EPA must provide unprecedented implementation schedule flexibility for this unprecedented rule. This is warranted particularly in light of the thousands of facilities which EPA expects will be affected, the enormous cost, and the historically thin capacities of the engineering and

construction industries (including the manufacturers of the supplies and equipment needed for PFAS barrier projects). Three years is nowhere near enough time for so many water systems to plan, design, permit, fund, and construct significant upgrades to their water systems. This truncated and rushed schedule also increases the associated cost estimates, making the rule as proposed completely infeasible. Additionally, the full impacts of operation and residuals disposal have not been fully considered. Not only will O&M costs significantly increase, but many utilities lack the ability to draw additional staff with the expertise to run these types of advanced water treatment systems.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10), which is the maximum that can be provided in an NPDWR, although further extensions can be provided under SDWA Section 1416. Regarding commenter concerns on the compliance timeframe, the agency is authorizing a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. The agency has evaluated the feasibility of the final standards; please see section 5 of the EPA response in this *Response to Comments* document for additional discussion. Additionally, the agency disagrees with commenter claims that the EPA did not consider the impacts of operation and residuals disposal; please see sections 5.1.3 (cost considerations and alternative MCLs), 10.4 (management of treatment residuals), and 13.3 (methods for estimating cost) of the EPA response in this *Response to Comments* document for additional discussion. With respect to operator training, please see the EPA response to comment Doc. #1567, SBC-042738 in section 12.1 in this *Response to Comments* document.

South Carolina Water Quality Association (Doc. #1819, SBC-044612)

EPA should defer rule adoption while it takes into account the appropriate levels of PFOA/PFOS (as well as the hazard index four chemicals), environmental updated costs and benefits, and other significant factors such as environmental justice.

As part of that re-evaluation, EPA should republish the proposed rule and seek public comment on a phased/tiered step-down MCL and Hazard Index approach that might look like the following:

• 10 ppt for PFOA/PFOS and 5 Hazard Index effective 12 months from the date of publication with a compliance schedule of up to 10 years from the effective date.

• 8 ppt for PFOA/PFOS and a 3 Hazard Index with an effective date of 2029 and a compliance deadline of no more than 10 years from the effective date.

• 4 ppt for PFOA/PFOS and a 1 Hazard Index with an effective date of 2034 and a compliance deadline of no more than 10 years from the effective date.

While the deadlines for MCLs are statutory in nature, we believe the phased effective date approach above would serve to provide EPA, the States, and affected water systems with the time necessary to implement PFAS barrier technologies.

EPA Response: The EPA disagrees with commenter assertions that the agency did not take into "account the appropriate levels of PFOA/PFOS (as well as the Hazard Index four chemicals), environmental updated costs and benefits, and other significant factors such as environmental justice." Analytic feasibility was evaluated when establishing the final MCLs (see section 5 of the EPA response in this *Response to Comments* document for more information). The EPA conducted robust occurrence analyses, as described in sections III and VI of the preamble and sections 3 and 7 of this *Response to Comments* document. The agency also conducted a robust environmental justice analysis discussed in the final rule preamble (section XII) and within section 14.10 of the EPA's *Response to Comments* document. The EPA's final rule represents data-driven drinking water standards that are based on the best available science and meet the requirements of SDWA; regulation of the PFAS covered by the NPDWR is vital toward protecting public health by removing these contaminants from our nation's drinking water. Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline as well as discussion on a phased-in MCL approach.

South Carolina Water Quality Association (Doc. #1819, SBC-044600)

The enormous costs experienced so far are likely to increase even further due to supply chain, worker shortage, inflation, and the unprecedented number of public utility/highway infrastructure projects being attempted over the next five-to-ten years. Adding PFAS barrier technology at thousands (according to US EPA) of drinking water plants nationwide can only further increase national engineering and construction prices.

There are simply not enough engineers, contractors, or workers to implement all these projects. Forcing PFAS barrier technology to the head of the line will trigger unprecedented cost premiums. It will also force utilities to delay needed infrastructure projects that protect human health, such as water main replacements and other projects to replace aging infrastructure. Infrastructure replacement delays will equate to more risk, less redundancy, less resiliency, and ultimately higher costs for utilities.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Only if such a phased approach is unworkable should EPA resort to an advance exercise of its enforcement discretion to provide additional implementation time. Such an approach would be advisory to delegated states and would provide, in general, federally pre-approved compliance schedule parameters for the States to work within.

While many systems will need more time, EPA and the states will also want to ensure that limited engineering, agency, funding, and contractor resources are directed to systems with the highest priority (highest PFAS levels, significant environmental justice considerations, etc.). It is strongly in the public interest for EPA to issue the MCLs in a way that ensures the most impacted systems are able to upgrade earlier than systems that may be only marginally impacted or upgrading out of convenience or an abundance of caution.

EPA and the states could also allow compliance schedule flexibility up front for utilities that need it through EPA and/or state administrative orders giving systems with lower priority more time to meet the MCLs. This is a formalized variant of the agency enforcement discretion approach. This could be done on a case-by-case basis.

Again, we believe the best course is for EPA to adopt phased MCLs as follows:

10 ppt for PFOA/PFOS and a Hazard Index of "5.0" effective December 31, 2024

8 ppt for PFOA/PFOS and a Hazard Index of "3.0" effective December 31, 2029

4 ppt for PFOA/PFOS and a Hazard Index of "1.0" effective December 31, 2034

A compliance schedule of up to ten years would apply to each effective date. Even with this approach, enforcement discretion will be necessary to ensure that water system PFAS barrier installations are appropriately scheduled.

In support of this approach, we note that in 1979, EPA issued a final rule setting a MCL and associated monitoring and reporting requirements for total trihalomethanes (TIHMs). 44 Fed. Reg. 68,824 (Nov. 29, 1979). The MCL had phased implementation for facilities of different sizes written within the MCL:

For community water systems serving 75,000 or more persons, monitoring must begin 1 year following promulgation and the effective date of the MCL is 2 years following promulgation. For community water systems serving 10,000 to 75,000 persons, monitoring must begin within 3 years from the date of promulgation and the effective date of the MCL is 4 years from the date of promulgation.

Id. at 68,824 [FN3: We would note many of the relevant issues for that rulemaking are the same for this proposed rule: "EPA specifically solicited and received comments on the following major issues: The rationale for setting an MCL for TTHMs and the magnitude of the MCL; the feasibility of and timing for phased reduction of the MCL; the concept of phasing the application of the MCL based upon system size; an alternative of making the MCL applicable to all public

water systems and to phase the implementation by a deferred monitoring schedule linked to population size … the availability of technology to achieve compliance …and the costs incurred by public water systems to achieve compliance with the MCL." Id. (emphasis added).]. Several components went into this decision to implement phases, including inadequate lab capacity with an increased lab demand. Id. at 68,629. EPA characterized this type of delay as extending the time frame for the initiation of requirements. Id. at 68,630 (emphasis added). Thus, there is precedent for the phasing/tiered approach we suggest – which can also be viewed as a phased timeframe for initiating the requirements of the proposed PFAS MCLs to community water systems based upon the PFAS levels in their finished drinking water.

Another approach would be for EPA to provide a phase-in schedule by means of a group or class "exemption" adopted as part of, or concurrently with, the PFAS MCL regulations. See Safe Drinking Water Act §§ 1415, 1416. The exemption might have multiple tiers based on PFAS concentrations – the lower the concentration the longer the phase-in period – and be temporary, and expire in phases, e.g., 10 / 8 / 4 ppt, over 5 / 10 / 15 years, respectively. If exemptions cannot be issued on a group/class basis, EPA could announce a general expectation that States may approve exemptions for defined groups for defined periods, and the States then develop implementation schedules on an individual (but pre-determined) basis.

It is clear that EPA must phase water plant upgrades over at least the next 10-20 years. It is patently obvious that we can't install PFAS barrier technology at 3-6,000 water plants nationwide in a shorter period.

Finally, phasing the MCL in over time will reinforce for the public that the PFAS levels they will experience over the next 10-20 years are not the end of the world. The reality is that the vast majority of Americans have experienced significantly higher PFAS levels for decades than they do now. We understand that the federal government has been assessing both PFOA and PFOS blood lead levels in thousands of Americans for several decades and that the levels have plummeted. We expect those levels to plummet further with the intense governmental, legislative, and litigation focus on eliminating the use of PFAS chemicals.

We believe the health monitoring testing that has been done in PFAS hot spot areas such as Parkersburg and Vienna, West Virginia reinforce the fact that levels nationwide are dropping and that means that some necessary prioritization and phasing of water plant PFAS barrier installations is both warranted and appropriate.

V. State Permitting/Funding Agency Capacity to Permit and Fund PFAS Barrier Technology Projects is at an All Time Low.

State public health agencies are facing the same historic worker retirement and shortage phenomenon as everyone else. The tiered/phased MCL adoption and implementation approach that we suggest above is also necessary given the reality that State health agencies are simply unable to handle 3-6,000 PFAS barrier installation projects over the next few years on top of all the other projects they are being asked to manage. Even when funding is available for additional

staff, the States have struggled to attract (and retain) staff given the competition from the private sector (which is woefully understaffed, and which pays better).

EPA must address this significant potential bottleneck in any MCL implementation schedule it adopts as part of the final rule.

EPA Response: With respect to health monitoring testing, the EPA believes that this type of biomonitoring can be an important tool to identify changes in population exposure over time. However, as discussed in section III of the final rule preamble and section III of the EPA's *Response to Comments* document (see final regulatory determinations), the agency has sufficient information now to regulate the six PFAS included in the final NPDWR. The EPA's final rule represents data-driven drinking water standards that are based on the best available science and meet the requirements of SDWA; regulation of the PFAS covered by the NPDWR is vital toward protecting public health by removing these contaminants from our nation's drinking water. Please see the EPA response to comment Doc. #1816, SBC-044679 in section 12.1 in this *Response to Comments* document and the EPA response to topic 12.1 with respect to case-by-case exemptions. Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline as well as discussion on a phased-in MCL approach.

South Carolina Water Quality Association (Doc. #1819, SBC-044605)

The sheer number of facilities that will have to install PFAS barrier technologies – 3-6,000 facilities by EPA's own estimate – demonstrates the impracticability of the 3-year (up to five for very small systems serving fewer than 10,000 population) implementation schedule. The treatment technology needed to comply with the proposed rule is simply not in place at this time, nor will it be to the extent needed to meet a 3-5-year national compliance schedule.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. For additional discussion on treatment availability and capacity, please see section 10.6 of the EPA response in this *Response to Comments* document.

South Carolina Water Quality Association (Doc. #1819, SBC-044609)

IV. A Decade-Plus Implementation Schedule is Needed or a Phased/Tiered Step- Down MCL Approach.

Water treatment plant design is a very complex and challenging exercise. Extensive facility-specific pilot studies will be needed to ensure we install the proper treatment for the PFAS

chemicals present in each facility's raw water supply. We are in a period of unprecedented shortage of design engineers as the engineering community struggles with the gusher of water, sewer, stormwater, highway, and other projects that are being crammed into the next 3-5 years due to ARPA, BIL, and State budget surplus infrastructure investments. Adding even (EPA's estimated) 3- 6 thousand water plant PFAS barrier projects on top of this over the next 3-5 years is completely unrealistic. We will have to pay design premiums and may not get the quality of work we need due to the unprecedented volume of work the engineering community faces. Even if the projects can be piloted, planned, designed, permitted, funded, and bids received, the construction industry is already overburdened and will fall further behind when we add these drinking water plant upgrades to the already enormous number of projects. For the past year we have already seen no bids on projects that normally would get several bids. Where there have been bids, they have almost universally been higher than the engineer's (updated) estimate, if not shockingly higher. This fact is compounded by construction material supply chain delays, which lead to longer project schedules that contribute to higher bids.

Small systems will struggle the most because engineering and construction firms will want to prioritize work for their larger clients because they will comprise the bulk of their future work. Small systems will be more one-and-done-type projects. Moreover, smaller systems may lack the sophistication and middle management to oversee and interact with contractors on such projects. As such smaller systems should have additional compliance flexibility.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline as well as discussion on a phased-in MCL approach. For funding concerns, the agency notes that funds are also available through the passage of the BIL to assist many disadvantaged communities, small systems, and others with the costs of installation of treatment when it might otherwise be cost-challenging. Please see section 2.4 of the EPA response in this *Response to Comments* document for more discussion about currently available funding.

Wet Weather Partnership (Doc. #1820, SBC-044591)

Only if such a phased approach is unworkable should EPA resort to an advance exercise of its enforcement discretion to provide additional implementation time. Such an approach would be advisory to delegated states and would provide, in general, federally pre-approved compliance schedule parameters for the States to work within.

While many systems will need more time, EPA and the states will also want to ensure that limited engineering, agency, funding, and contractor resources are directed to systems with the highest priority (highest PFAS levels, significant environmental justice considerations, etc.). It is strongly in the public interest for EPA to issue the MCLs in a way that ensures the most

impacted systems are able to upgrade earlier than systems that may be only marginally impacted or upgrading out of convenience or an abundance of caution.

EPA and the states could also allow compliance schedule flexibility up front for utilities that need it through EPA and/or state administrative orders giving systems with lower priority more time to meet the MCLs. This is a formalized variant of the agency enforcement discretion approach. This could be done on a case-by-case basis.

Again, we believe the best course is for EPA to adopt phased MCLs as follows:

10 ppt for PFOA/PFOS and a Hazard Index of "5.0" effective December 31, 2024

8 ppt for PFOA/PFOS and a Hazard Index of "3.0" effective December 31, 2029

4 ppt for PFOA/PFOS and a Hazard Index of "1.0" effective December 31, 2034

A compliance schedule of up to ten years would apply to each effective date. Even with this approach, enforcement discretion will be necessary to ensure that water system PFAS barrier installations are appropriately scheduled.

In support of this approach, we note that in 1979, EPA issued a final rule setting a MCL and associated monitoring and reporting requirements for total trihalomethanes (TIHMs). 44 Fed. Reg. 68,824 (Nov. 29, 1979). The MCL had phased implementation for facilities of different sizes written within the MCL:

For community water systems serving 75,000 or more persons, monitoring must begin 1 year following promulgation and the effective date of the MCL is 2 years following promulgation. For community water systems serving 10,000 to 75,000 persons, monitoring must begin within 3 years from the date of promulgation and the effective date of the MCL is 4 years from the date of promulgation.

Id. at 68,824 [FN3: We would note many of the relevant issues for that rulemaking are the same for this proposed rule: "EPA specifically solicited and received comments on the following major issues: The rationale for setting an MCL for TTHMs and the magnitude of the MCL; the feasibility of and timing for phased reduction of the MCL; the concept of phasing the application of the MCL based upon system size; an alternative of making the MCL applicable to all public water systems and to phase the implementation by a deferred monitoring schedule linked to population size … the availability of technology to achieve compliance …and the costs incurred by public water systems to achieve compliance with the MCL." Id. (emphasis added).]. Several components went into this decision to implement phases, including inadequate lab capacity with an increased lab demand. Id. at 68,629. EPA characterized this type of delay as extending the time frame for the initiation of requirements. Id. at 68,630 (emphasis added). Thus, there is precedent for the phasing/tiered approach we suggest – which can also be viewed as a phased timeframe for initiating the requirements of the proposed PFAS MCLs to community water systems based upon the PFAS levels in their finished drinking water.

Another approach would be for EPA to provide a phase-in schedule by means of a group or class "exemption" adopted as part of, or concurrently with, the PFAS MCL regulations. See Safe Drinking Water Act §§ 1415, 1416. The exemption might have multiple tiers based on PFAS concentrations – the lower the concentration the longer the phase-in period – and be temporary, and expire in phases, e.g., 10 / 8 / 4 ppt, over 5 / 10 / 15 years, respectively. If exemptions cannot be issued on a group/class basis, EPA could announce a general expectation that States may approve exemptions for defined groups for defined periods, and the States then develop implementation schedules on an individual (but pre-determined) basis.

It is clear that EPA must phase water plant upgrades over at least the next 10-20 years. It is patently obvious that we can't install PFAS barrier technology at 3-6,000 water plants nationwide in a shorter period.

Finally, phasing the MCL in over time will reinforce for the public that the PFAS levels they will experience over the next 10-20 years are not the end of the world. The reality is that the vast majority of Americans have experienced significantly higher PFAS levels for decades than they do now. We understand that the federal government has been assessing both PFOA and PFOS blood lead levels in thousands of Americans for several decades and that the levels have plummeted. We believe the health monitoring testing that has been done in PFAS hot spot areas such as Parkersburg and Vienna, West Virginia reinforce the fact that levels nationwide are dropping and that means that some necessary prioritization and phasing of water plant PFAS barrier installations is both warranted and appropriate.

V. State Permitting/Funding Agency Capacity to Permit and Fund PFAS Barrier Technology Projects is at an All Time Low.

State public health agencies are facing the same historic worker retirement and shortage phenomenon as everyone else. The tiered/phased MCL adoption and implementation approach that we suggest above is also necessary given the reality that State health agencies are simply unable to handle 3-6,000 PFAS barrier installation projects over the next few years on top of all the other projects they are being asked to manage. Even when funding is available for additional staff, the States have struggled to attract (and retain) staff given the competition from the private sector (which is woefully understaffed, and which pays better).

EPA must address this significant potential bottleneck in any MCL implementation schedule it adopts as part of the final rule.

EPA Response: With respect to health monitoring testing, the EPA believes that this type of biomonitoring can be an important tool to identify changes in population exposure over time. However, as discussed in section III of the final rule preamble and section III of the EPA's *Response to Comments* document (see final regulatory determinations), the agency has sufficient information now to regulate the six PFAS included in the final NPDWR. The EPA's final rule

represents data-driven drinking water standards that are based on the best available science and meet the requirements of SDWA; regulation of the PFAS covered by the NPDWR is vital toward protecting public health by removing these contaminants from our nation's drinking water. Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline as well as discussion on a phased-in MCL approach and exemptions.

Wet Weather Partnership (Doc. #1820, SBC-044590)

EPA should defer rule adoption while it takes into account the appropriate levels of PFOA/PFOS (as well as the hazard index four chemicals), environmental updated costs and benefits, and other significant factors such as environmental justice.

As part of that re-evaluation, EPA should republish the proposed rule and seek public comment on a phased/tiered step-down MCL and Hazard Index approach that might look like the following:

• 10 ppt for PFOA/PFOS and 5 Hazard Index effective 12 months from the date of publication with a compliance schedule of up to 10 years from the effective date.

• 8 ppt for PFOA/PFOS and a 3 Hazard Index with an effective date of 2029 and a compliance deadline of no more than 10 years from the effective date.

• 4 ppt for PFOA/PFOS and a 1 Hazard Index with an effective date of 2034 and a compliance deadline of no more than 10 years from the effective date.

While the deadlines for MCLs are statutory in nature, we believe the phased effective date approach above would serve to provide EPA, the States, and affected water systems with the time necessary to implement PFAS barrier technologies.

EPA Response: The EPA disagrees with commenter assertions that the agency did not take into "account the appropriate levels of PFOA/PFOS (as well as the Hazard Index four chemicals), environmental updated costs and benefits, and other significant factors such as environmental justice." Analytic feasibility was evaluated when establishing the final MCLs (see section 5 of the EPA response in this *Response to Comments* document for more information). The EPA conducted robust occurrence analyses, as described in sections III and VI of the preamble and sections 3 and 7 of this *Response to Comments* document. The agency also conducted a robust environmental justice analysis discussed in the final rule preamble (section XII) and within section 14.10 of the EPA's *Response to Comments* document. The EPA's final rule represents data-driven drinking water standards that are based on the best available science and meet the requirements of SDWA; regulation of the PFAS covered by the NPDWR is vital toward protecting public health by removing these contaminants from our nation's drinking water. Regarding commenter concerns on the compliance timeframe, the agency is promulgating

a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline as well as discussion on a phased-in MCL approach.

Wet Weather Partnership (Doc. #1820, SBC-044583)

The sheer number of facilities that will have to install PFAS barrier technologies – 3-6,000 facilities by EPA's own estimate – demonstrates the impracticability of the 3-year (up to five for very small systems serving fewer than 10,000 population) implementation schedule. The treatment technology needed to comply with the proposed rule is simply not in place at this time, nor will it be to the extent needed to meet a 3-5-year national compliance schedule.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. For additional discussion on treatment availability and capacity, please see section 10.6 of the EPA response in this *Response to Comments* document.

Wet Weather Partnership (Doc. #1820, SBC-044587)

IV. A Decade-Plus Implementation Schedule is Needed or a Phased/Tiered Step-Down MCL Approach.

Water treatment plant design is a very complex and challenging exercise. Extensive facility-specific pilot studies will be needed to ensure we install the proper treatment for the PFAS chemicals present in each facility's raw water supply. We are in a period of unprecedented shortage of design engineers as the engineering community struggles with the gusher of water, sewer, stormwater, highway, and other projects that are being crammed into the next 3-5 years due to ARPA, BIL, and State budget surplus infrastructure investments. Adding even (EPA's estimated) 3-6 thousand water plant PFAS barrier projects on top of this over the next 3-5 years is completely unrealistic. We will have to pay design premiums and may not get the quality of work we need due to the unprecedented volume of work the engineering community faces. Even if the projects can be piloted, planned, designed, permitted, funded, and bids received, the construction industry is already overburdened and will fall further behind when we add these drinking water plant upgrades to the already enormous number of projects. For the past year we have already seen no bids on projects that normally would get several bids. Where there have been bids, they have almost universally been higher than the engineer's (updated) estimate, if not shockingly higher. This fact is compounded by construction material supply chain delays, which lead to longer project schedules that contribute to higher bids.

Small systems will struggle the most because engineering and construction firms will want to prioritize work for their larger clients because they will comprise the bulk of their future work.

Small systems will be more one-and-done-type projects. Moreover, smaller systems may lack the sophistication and middle management to oversee and interact with contractors on such projects. As such smaller systems should have additional compliance flexibility.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline as well as discussion on a phased-in MCL approach. For funding concerns, the agency notes that funds are also available through the passage of the BIL to assist many disadvantaged communities, small systems, and others with the costs of installation of treatment when it might otherwise be cost-challenging. Please see section 2.4 of the EPA response in this *Response to Comments* document for more discussion about currently available funding.

Wet Weather Partnership (Doc. #1820, SBC-044578)

The enormous costs experienced so far are likely to increase even further due to supply chain, worker shortage, inflation, and the unprecedented number of public utility/highway infrastructure projects being attempted over the next five-to-ten years. Adding PFAS barrier technology at thousands (according to US EPA) of drinking water plants nationwide can only further increase national engineering and construction prices.

There are simply not enough engineers, contractors, or workers to implement all these projects. Forcing PFAS barrier technology to the head of the line will trigger unprecedented cost premiums. It will also force utilities to delay needed infrastructure projects that protect human health, such as water main replacements and other projects to replace aging infrastructure. Infrastructure replacement delays will equate to more risk, less redundancy, less resiliency, and ultimately higher costs for utilities.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Wet Weather Partnership (Doc. #1820, SBC-044589)

EPA must provide unprecedented implementation schedule flexibility for this unprecedented rule. This is warranted particularly in light of the thousands of facilities which EPA expects will be affected, the enormous cost, and the historically thin capacities of the engineering and construction industries (including the manufacturers of the supplies and equipment needed for PFAS barrier projects). Three years is nowhere near enough time for so many water systems to plan, design, permit, fund, and construct significant upgrades to their water systems. This truncated and rushed schedule also increases the associated cost estimates, making the rule as

proposed completely infeasible. Additionally, the full impacts of operation and residuals disposal have not been fully considered. Not only will O&M costs significantly increase, but many utilities lack the ability to draw additional staff with the expertise to run these types of advanced water treatment systems.

EPA Response: Based on these and other significant comments regarding the compliance timeframe, see section 12.1 of the EPA response in this *Response to Comments* document. The agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. The agency has evaluated the feasibility of the final standards; please see section 5 of the EPA response in this *Response to Comments* document for additional discussion. Additionally, the agency disagrees with commenter claims that the EPA did not consider the impacts of operation and residuals disposal; please see sections 5.1.3 (cost considerations and alternative MCLs), 10.4 (management of treatment residuals), and 13.3 (methods for estimating cost) of the EPA response in this *Response to Comments* document for additional discussion. With respect to operator training, please see the EPA response to comment Doc. #1567, SBC-042738 in section 12.1 in this *Response to Comments* document.

Arkansas Department of Health (Doc. #1821, SBC-044574)

The treatment processes for PFAS are more complex than existing drinking water treatment processes and require additional training and certifications for drinking water operators. There is currently a shortage of qualified drinking water operators, especially with operators that have advanced training and certifications that PFAS treatment will require. This lack of qualified drinking water operators will create a significant risk to the operational capacity of these systems.

Sincerely,

Lance A Jones, P.E. Engineering Section Director

Arkansas Department of Health

cc: ASDWA, 1300 Wilson Blvd., Suite 875 Arlington, VA 22209

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. Regarding concerns on operator certification licenses, please see the EPA response to comment Doc. #1567, SBC-042738 in section 12.1 in this *Response to Comments* document.

Neuse Regional Water and Sewer Authority (Doc. #1822, SBC-044571)

3. EPA should delay the Proposed Rulemaking's effective date until EPA identifies all PFAS to be eliminated from drinking water.

NRWASA asks EPA to delay the Proposed Rulemaking until it identifies all PFAS chemicals and their respective acceptable risk levels. EPA acknowledges in its Proposed Rulemaking that the six PFAS proposed for regulation "co-occur with PFAS for which the Agency is not currently making a preliminary regulatory determination. Many of these other emergent co-occurring PFAS are likely to also pose hazards to public health and the environment." [FN5: Id. at 18651.] Presumably, EPA is working to further study other PFAS and identify which it may regulate and at what levels. The Proposed Rulemaking states the recommended treatment strategies are "anticipated to result in removing" the other PFAS but does not specify how or the likelihood of successfully removing additional PFAS. [FN6: Id.]

NRWASA's primary concern is that the significant labor and capital investments it will incur to remove PFOA, PFOS, PFHxS, HFPO-DA, PFNA, and PFBS to implement the Proposed Rulemaking may not be enough to address additional PFAS EPA identifies in the coming years. NRWASA could spend millions of dollars only to have to pay for additional equipment in the near future or re-engineer solutions that could have been implemented more efficiently at the beginning of the upgrade process.

The likelihood of additions to the list of regulated PFAS under a National Primary Drinking Water Standard are real. For example, in September 2022, EPA issued a proposed rule to designate two PFAS — PFOA, PFOS, and their salts and structural isomers — as hazardous substances under the Comprehensive Environmental Response, Compensation, and Liability Act ("CERCLA"). EPA currently is reviewing comments received on that proposed rule. However, on April 13, 2023, EPA released another Advance Notice of Proposed Rulemaking seeking input on whether to propose to designate seven additional PFAS, including GenX, as hazardous substances under CERCLA and whether some PFAS compounds can or should be designated as a group or category [FN7: EPA Advanced Notice of Proposed Rulemaking Addressing PFAS in the Environment, Federal Register Vol. 88, No. 71, April 13, 2023.]. The problem of additional, little-known PFAS is acute in North Carolina. In a 16-state study testing 41 PFAS not covered by EPA's test methods, "[s]amples collected in North Carolina contained the highest levels of unmonitored PFAS." [FN8: Coastal Review, Half of PFAS in drinking water not monitored by EPA: Study, https://coastalreview.org/2023/04/half-of-pfas-in-drinking-water-not-monitored-by-epa-study/.]. This suggests systems in North Carolina like NRWASA may face higher compliance costs in the event more PFAS are added to the six covered by the Proposed Rulemakings in the months and years ahead.

NRWASA requests EPA (a) delay the effective date of the final rule until EPA identifies how it will regulate other types of PFAS, and (b) address payment for additional upgrade costs of the addition of future PFAS.

EPA Response: The EPA disagrees with commenters that the agency should wait on regulation until "it will regulate other types of PFAS." As discussed in section III of the final rule preamble and section III of the EPA's *Response to Comments* document (see final regulatory determinations), the agency has sufficient information now to regulate the six PFAS included in the final NPDWR. The EPA's final rule represents data-driven drinking water standards that are based on the best available science and meet the requirements of SDWA; regulation of the PFAS covered by the NPDWR is vital toward protecting public health by removing these contaminants from our nation's drinking water. It would be contrary to SDWA's regulatory process to delay issuing drinking water standards for contaminants EPA has determined meet the criteria for regulation simply because there may be other similar contaminants regulated in the future. Indeed, the statute requires that EPA regulate contaminants that EPA has determined mee the statutory criteria for regulation within a specified period of time. SDWA Section 1412(b)(1)(E). EPA cannot speculate about which contaminants might be regulated in the future or what the upgrade costs for treatment of those might be. Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. The agency notes that a possible future hazardous waste or hazardous substance designation has no bearing on the EPA's decision to authorize this capital improvement extension. For additional discussion on disposal of spent treatment materials under possible future regulatory actions and costs, please see section 10.4.2 of the EPA response in this *Response to Comments* document. For funding concerns, the agency notes that funds are also available through the passage of the BIL to assist many disadvantaged communities, small systems, and others with the costs of installation of treatment when it might otherwise be cost-challenging. Please see section 2.4 of the EPA response in this *Response to Comments* document for more discussion about currently available funding.

Plymouth Village Water & Sewer District (Doc. #1827, SBC-044561)

[Please carefully consider the following points to help inform the pending rulemaking on this class of pervasive and persistent PFAS chemicals:]

• The three-year implementation timeline for PFAS detection and remediation is an unreasonable schedule to meet, given real constraints such as the number of impacted systems, manufacturing and supply chain constraints, analytical methods and laboratory capacity, widespread professional labor and certified water Operator shortages, residual disposal issues, and system owner liability concerns. Systemic failures to meet an unrealistic timeframe will result in numerous, unnecessary enforcement documents and actions that will consume regulatory time and erode public trust. These systemic constraints must be factored into a realistic implementation schedule.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA

1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

The District of Columbia Water and Sewer Authority (Doc. #1829, SBC-045775)

The typical timeline for the planning, design, permitting and construction of a new drinking water treatment facility for PFAS may take up to 5 years or more; the standard compliance window of three years under SOWA will not be feasible. It is recommended that the Administrator provide an automatic two-year extension of the compliance deadline to those water systems requiring capital improvements to effectively mitigate PFAS in drinking water.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

The District of Columbia Water and Sewer Authority (Doc. #1829, SBC-045769)

Proposed Compliance Timeline is Unreasonable

The Proposal requires compliance with the proposed PFAS standards within three years of issuance of the final rule. Public water systems may be eligible for an additional two years, at the discretion of the primacy agency, to comply with the standards, if capital improvements are required. These timelines are patently unreasonable and unattainable, and should be extended, particularly in the absence of any compelling evidence of immediate public health impacts from trace PFAS in drinking water.

The typical timeline for the planning, design, permitting and construction of a new drinking water treatment facility for PFAS may take up to 5 years or more, the standard compliance window of three years under SOWA will not be feasible. It is anticipated that most water systems will need to request this two-year extension, which is typically provided at the discretion of the state primacy agencies, or in our case, EPA Region 3. However, the Administrator also has the authority under SOWA to provide this extension and can do so as a part of the rule as opposed to being done so on a case-by-case basis. It is recommended that the Administrator consider extending these deadlines and at a minimum provide an automatic two-year extension of the compliance deadline to those water systems requiring capital improvements to effectively mitigate PFAS in drinking water.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments*

document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Corix Infrastructure Inc. (Doc. #1834, SBC-045364)

3. The amount of time for implementation for public and private water systems to meet the final MCLs is insufficient.

As currently proposed, the water systems that will need to be upgraded to comply with the final MCLs will have three years to from the date of the final rule to upgrade their systems. Due to the cost and complexity of upgrading water treatment systems, a deadline of three years to design, construct and begin operations of the treatment systems needed to remove and dispose of PFOA and PFOS is not reasonable and may be almost impossible in certain circumstances.

Water systems are already balancing and burdened by many competing priorities for their time and financial resources due to increasing regulations, including mandates from the EPA's recently promulgated Lead and Copper rule. Complicating their efforts are increased worker shortages, the lack of qualified engineers, and shortages in the supply chain. These same challenges will make it difficult if not impossible in many cases to construct and begin operation of new treatment systems within the allowed three years. Before EPA can mandate dates for implementation, it must have a reasonable basis for assurance that those deadlines are achievable.

With respect to the implementation timeline, the EPA also needs to consider logistical and liability considerations associated with residual management and disposal. The EPA has not provided the water industry and the communities served by the industry with a clear plan for managing water treatment residuals produced by compliance proposed rule. Without a residuals management plan that addresses disposal coordination and capacity, analytical methodology and standardized waste characterization, and CERCLA liability, residuals disposal poses a significant obstacle for all drinking water systems, and it raises the significant issue of potential liability for communities related to the transport and the final disposition of treatment residuals.

Accordingly, Corix suggests that a more reasonable and achievable deadline for upgrading systems to meet the new MCLs is five years. In addition, the ability to grant extensions by the state regulators will be key to implement the most expeditious solution while acknowledging the reality of all the logistical challenges noted above.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10) resulting in the 5 year timeframe suggested by the commenter. Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Little Hocking Water Association (Doc. #1835, SBC-045515)

An across-the-board three-year compliance timeframe is inappropriate for the proposed PFAS MCLs.

As stated above, the United States population has been dosed with PFAS for over 60 years. LHWA, upon learning of severe contamination in its wellfield, took legal and other measures to obtain treatment for its water. Other systems have also obtained treatment. For systems that already have treatment in place, compliance can, and should, be done as soon as practicable, but no longer than three years.

EPA's current proposal groups water systems into classes based on the number of people served. For the PFAS MCL rule, EPA needs to create two new classes: water supplies that are known to be highly contaminated with PFAS or are at a high risk of contamination; and water supplies that are not highly contaminated or are at low risk of contamination. Much work has been done by states to identify contaminated water supplies and sources of PFAS pollution. For water systems that are highly contaminated or at high risk, compliance with the new MCLs needs to be done as soon as practicable but no longer than three years. For non-highly contaminated or low risk systems, compliance should be done within three years.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline as well as an MCL phase-in. The EPA notes that the monitoring and compliance framework discussed in section 8 of the EPA's *Response to Comments* document has an approach where systems with elevated levels monitor more frequently relative to systems to lower levels of contamination. Please see section 8 of the EPA response in this *Response to Comments* document for additional discussion on monitoring and compliance requirements for the final NPDWR.

New England Water Works Association (Doc. #1836, SBC-045389)

While such testing provides critical design parameters and potentially cost-saving measures, it takes time. Designing and building permanent PFAS treatment facilities – assuming timely approval from primacy agencies and local permitting – can be a lengthy process. Renting temporary treatment equipment is not only very costly but also takes time. These challenges should be considered in EPA's timeframe for enforcing PFAS standards in drinking water. It is also recommended that EPA and primacy states streamline their new technology-review process to more quickly grant approvals.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments*

document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

New England Water Works Association (Doc. #1836, SBC-045377)

EPA needs to carefully consider implementation challenges for PWS caused by regulatory efforts related to PFAS. NEWWA is not sure that EPA has put enough time into this effort before moving forward with the proposed drinking water regulations. Without adequate consideration regarding these implementation challenges, public confidence in drinking water could be further jeopardized. EPA must address these challenges before finalizing the rule. NEWWA recommends that EPA delay the promulgation of the proposed regulations until the implementation challenges imposed on PWS are thoroughly evaluated and these findings are issued for public review and comment. We hope that EPA will strongly consider the information we are providing on behalf of New England PWS and will craft a final rule that is reasonable in its expectations of implementation and schedule and is adequately funded.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

New England Water Works Association (Doc. #1836, SBC-045390)

If a PWS must install treatment to address PFAS in their drinking water, it may cause the classification of their system to change, necessitating higher-grade licensed operators. In many states, operators sitting for higher-grade licenses have course requirements before they can even sit for the exams. EPA and primacy states must recognize that this will cause staffing issues and will need to provide compliance forbearance and flexibility for the operators to obtain the necessary licenses. As many PWS are already struggling to attract and retain appropriately licensed staff and the industry expects to lose many operators to retirement in the next 5 years, this is a significant concern.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline. Regarding concerns on operator certification licenses, please see the EPA response to comment Doc. #1567, SBC-042738 in section 12.1 in this *Response to Comments* document.

Washington Association of Sewer and Water Districts (Doc. #1842, SBC-044772)

Unrealistic Implementation Timeline

An implementation timeline of three years is inadequate. Even without supply chain issues, monitoring and analyzing results, hiring of consultants, permitting, bid process and hiring construction companies, ordering and obtaining equipment, installation and required pilot testing would typically take longer than the three year limit. Today, facilities will have to be implemented at a time when there is an increase in demand for engineering, equipment, and construction contractors, requiring goods and services from a limited pool of qualified engineers, manufacturers, and construction contractors. Add to this the timeline for securing federal support dollars. The prospect of federal dollars to mitigate the costs Is welcomed, but whether federal dollars come in the form of a grant, forgivable loan, or loan, securing federal dollars takes an exceptionally long time and almost always lengthens the duration of a project. A final burden on the implementation timeline is that utilities are also implementing the important Lead and Copper Rule. This is already straining the financial and staffing resources available to many utilities. For all these reasons, a timeline of at least five years would still be an aggressive schedule but at least somewhat more realistic.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10) consistent with the request of the commenter. Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Metropolitan Washington Council of Governments (Doc. #1843, SBC-044754)

Our second recommendation concerns the timeline for compliance with the proposed NPDWR, which provides only three years from the date of final rulemaking with a possible two-year extension that is not guaranteed. Experience at the local level indicates that a more realistic time frame needed to add infrastructure improvements such as a new water treatment train to an existing water treatment plant is seven to ten years. This considers things such as compliance with procurement laws, piloting, land use approvals, permit approvals, design and specifications, equipment acquisition, construction, commissioning, and more. Providing local governments and water utilities with maximum flexibility and longer compliance timeframes will be important to the successful implementation of the proposed NPDWR.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10). Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Zone 7 Water Agency and Association of California Water Agency's Water Quality Committee (Doc. #3072-66, SBC-046381)

Okay, thank you. I'm Sarah Palmer. I'm from Livermore, California. I'm a PhD biochemist and I'm on the board of directors of Zone 7 Water Agency. I'm also a member of the Association of California Water Agency's Water Quality Committee and part of the PFAS work group. I fully support EPA's findings and applaud your work. In California, we are faced with the realities of permitting timelines and along with everyone else here, there are and will be supply chain issues. In light of this, the three-year compliance period may be too short. So, while time is of the essence for all of these health conditions, I respectfully suggest a compliance period of five years. Thank you.

EPA Response: Regarding commenter concerns on the compliance timeframe, the agency is promulgating a two-year capital improvement extension pursuant to SDWA 1412(b)(10) consistent with the request of the commenter. Please see section 12.1 of the EPA response in this *Response to Comments* document for the EPA's discussion on supply chain and labor challenges that may affect the compliance timeline.

Oak Bluffs Water District (Doc. #3072-80, SBC-046389)
